CONTENTS

TABLE

Major stratigraphic and time divisions in use by the U.S. Geological Survey

Era	System or Period	Series or Epoch	Estimated ages of time boundaries in millions of years Holmes [1]	Kulp [2]
Cenozoic	Quaternary	Recent		
		Pleistocene	1	1
	Tertiary	Pliocene	11	13
		Miocene	25	25
		Oligocene	40	36
		Eocene	60	58
		Paleocene	70	63
Mesozoic	Cretaceous [3]	Upper (Late) Lower (Early)	135	135
	Jurassic	Upper (Late) Middle (Middle) Lower (Early)	180	181
	Triassic	Upper (Late) Middle (Middle) Lower (Early)	225	230
Paleozoic [3]	Permian [3]	Upper (Late) Lower (Early)	270	280
	Carboniferous Systems: Pennsylvanian [3]	Upper (Late) Middle (Middle) Lower (Early)		
	Carboniferous Systems: Mississippian [3]	Upper (Late) Lower (Early)	350	345
	Devonian	Upper (Late) Middle (Middle) Lower (Early)	400	405
	Silurian [3]	Upper (Late) Middle (Middle) Lower (Early)	440	425
	Ordovician [3]	Upper (Late) Middle (Middle) Lower (Early)	500	500
	Cambrian [3]	Upper (Late) Middle (Middle) Lower (Early)	600	600?
Precambrian [3]		Informal subdivisions such as upper, middle, and lower, or upper and lower, or younger and older may be used locally.	3, 000+	

Terms designating time are in parentheses. Informal time terms early, middle, and late may be used for the eras, and for periods where there is no formal subdivision into Early, Middle, and Late, and for epochs. Informal rock terms lower, middle, and upper may be used where there is no formal subdivision of a system or of a series.

[1] Age values given are the Holmes time scale (Holmes, A , 1960, A revised geological time scale: Edinburgh Geol. Soc., Trans. v. 17, pt. 3, p. 204).

[2] Ages given are the Kulp time scale (Kulp, J. Laurence, 1961, Geologic time scale: Science, v. 133, no. 3459, p. 1111).

[3] Includes provincial series accepted for use in U.S. Geological Survey reports.

LEXICON OF GEOLOGIC NAMES OF THE UNITED STATES FOR 1936–1960

By Grace C. Keroher and Others

INTRODUCTION

PREVIOUS COMPILATIONS OF GEOLOGIC NAMES

The U.S. Geological Survey has published six compilations treating the names of geologic formations and stratigraphic classification and nomenclature. The Survey publishes lexicons of geologic names at regular intervals as a means of keeping the geologic profession informed as to changes and current status of geologic names within the United States and its possessions.

The first compilation, "North American Geologic Formation Names," Bulletin 191, by F. B. Weeks, was published in 1902. This bulletin contains: (1) an alphabetical listing of 1,500 North American sedimentary formation names and 100 names applied to igneous rocks, together with their geologic age, geographic occurrence, and pertinent references, (2) a list of sedimentary formations arranged alphabetically by geographic provinces under the geologic periods to which they had been assigned, and (3) an index list of formation names.

The next compilation, "The Geologic Time Classification of the United States Geological Survey Compared with Other Classifications, Accompanied by the Original Definitions of Era, Period, and Epoch Terms," Bulletin 769 by M. Grace Wilmarth, was published in 1925 and is still invaluable for its quotations from original definitions and descriptions of standard and other stratigraphic and time divisions from widely scattered and sometimes unavailable sources.

In 1931, the Survey published the third compilation, "Names and Definitions of the Geological Units of California," Bulletin 826, by M. Grace Wilmarth. This work was actually an extract from a larger, more exhaustuve compilation on which Wilmarth was working; it was published to test the reactions of geologists to the material and the format of the forthcoming lexicon and at the same time to make available a useful reference for geologists who worked exclusively in California.

The first exhaustive compilation, M. Grace Wilmarth's "Lexicon of Geologic Names of the United States (including Alaska)," also called the Wilmarth Lexicon, was published in 1938 as Bulletin 896; it met a long-standing and continuing need and was reprinted in 1951 and again in 1957. The Wilmarth Lexicon contains 13,090 names. Of this number, 9,128 are stratigraphic units in the United States and its possessions.

After the publication of the Wilmarth Lexicon, the Survey planned to continue the compilation of geologic names as new names or revisions of old names appeared in the literature. This work was interrupted by World War II, but in 1952 a sustained effort was begun to review the pertinent geologic publications for preparation of a new lexicon. After the review had been brought up to date (through calendar year 1955), Bulletin 1056–A, "Geologic Names of North America Introduced in 1936–1955," by Druid Wilson, W. J. Sando, R. W. Kopf, and others, was published in 1957. A brief form of presentation made it possible to publish quickly some of the essential data concerning new names that had been published since 1935, the cutoff date of the Wilmarth Lexicon. Bulletin 1056–A listed about 5,000 new names introduced for use in North America, the Pacific Island possessions of the United States, and the Trust Territory of the Pacific Islands, as well as a few pre-1936 names not included in the Wilmarth Lexicon.

In the nonalphabetical "Index to the Geologic Names of North America," Bulletin 1056–B, by Druid Wilson, Grace C. Keroher, and Blanche E. Hansen, published in 1959, geologic names of North America, Greenland, the West Indies, the Pacific Island possessions of the United States, and the Trust Territory of the Pacific Islands, that were published before 1956 are arranged to form an index to both the Wilmarth Lexicon (1938) and the "Geologic Names of North America Introduced in 1936–1955" (1957). Grouping the geologic names by the age of the unit and by the politico-geographic divisions containing the type locality of the unit provided a valuable key to the literature not available elsewhere.

PRESENT LEXICON

Those who have collaborated in and contributed to the preparation of the present lexicon are Barbara Bedette, Jean L. Eggleton, Blanche E. Hansen, Rudolph W. Kopf, Carolyn Mann, William G. Melton, Jr., Helen L. Nace, Kay Dennison Palmer, William J. Sando, Jack E. Smedley, Sandra Whalen Stock, Carol S. Swift, Martha S. Toulmin, and Druid Wilson.

The geographic area covered includes the United States, its possessions, the Panama Canal Zone, and the Trust Territory of the Pacific Islands presently administered by the United States. This geographic area is much smaller than that for the Wilmarth Lexicon, which, in addition to U.S. geologic units, included the names and ages (but not the definitions) of geologic units of Canada, Mexico, the West Indies, and Central America. This smaller geographic area was selected primarily because the International Lexicon, compiled under sponsorship of the Stratigraphic Commission of the International Geological Congress, now treats the geologic nomenclature of the other countries.

The stratigraphic papers summarized and used in preparing this lexicon were published between January 1, 1936, and December 31, 1960. In order to clarify the history of some of the older names, however, several pre-1936 reports not summarized in the Wilmarth Lexicon were also included. In all, approximately 200,000 papers were evaluated in selecting the material to be summarized.

This lexicon contains 14,634 names, including cross references. Of this number, 9,128 names appeared previously in the Wilmarth Lexicon and 5,506 are post-1935 names or pre-1936 names not included in the Wilmarth Lexicon.

Names of subsurface units are included if they have been defined or distinguished as a part of formal stratigraphy.

Names listed in the Wilmarth Lexicon but omitted from the present lexicon include (1) all paleontologic and descriptive terms, (2) all names of economic units, such as miner's terms, trade names, and subsurface oil and gas sands, (3) names of moraines and other units of which physiography is an essential part of the definition, and (4) names of orogenies.

Research on the names from the Wilmarth Lexicon reveals that 3,589 of them have not been used since 1935, the cutoff date of that lexicon. These names are listed in the present lexicon, and the ages of the geologic units, the geographic areas, original references, and type localities or statements of derivation of the names are given verbatim as they appeared in the Wilmarth Lexicon.

The superscript (1) after a name in the present lexicon denotes entries taken from the Wilmarth Lexicon. Many pre-1936 names are still being used in the same way in which they are defined in the Wilmarth Lexicon. Other names are still being used as defined in the Wilmarth Lexicon but in addition have slightly modified usages that involve changes in rank and (or) lithology; the changes are noted in the present lexicon. For still another group of pre-1936 names, the usage given in the Wilmarth Lexicon has been replaced by a new usage, which is given in the present lexicon.

Thus, the superscript (1) indicates that additional annotated material can be found in the Wilmarth Lexicon; it also can be useful in tracing the history of the nomenclature of a particular formation. For example, the entry for the Ste. Genevieve Limestone is:

Ste. Genevieve Limestone
Ste. Genevieve Limestone (in Blue River Group)
Ste. Genveieve Limestone (in Meramec Group) [1]

The superscript (1) shows that the accepted name of the formation as of 1935 was the "Ste. Genevieve Limestone in the Meramec

Group." Since then the formation has been called "Ste. Genevieve Limestone in Blue River Group" in another area. Finally, the name in boldface indicates that the Survey now considers it a formation. The absence of the superscript, of course, means that the name has been introduced since 1935.

The term "original reference" refers to the original reference as cited in the Wilmarth Lexicon. As a general rule, these references were not rechecked.

In the interest of brevity, a semitelegraphic style of writing has been used in the summary material. Because this material has usually been gleaned from many pages of the report cited, not all pages from which the factual material was obtained are listed; only the page or pages containing the essential part of the data or the inclusive pages of the paper cited are given.

Various transliterations of many of the names of units described from the Trust Territory of the Pacific Islands have appeared in English, in the Romaji of Japanese publications, and in English translations of the Japanese. The published and unpublished recommendations of the U.S. Board on Geographic Names on the native geographic names from which the geologic names are derived have been followed, but there were no decisions on some names of obscure origin. Cross references are given if the recommended forms and published sources differ and if the transliterations are inconsistent.

The stratigraphic code proposed by the American Commission on Stratigraphic Nomenclature (1961, Am. Assoc. Petroleum Geologists Bull., v. 45, no. 5, p. 645–665) was adopted by the U.S. Geological Survey on June 6, 1961. Article 10 of this code recommends that the initial letters of all words used in forming the names of formal rock-stratigraphic units be capitalized. All the geologic names listed in this lexicon, however, were published before the 1961 code, and the bulk of the present lexicon had been compiled before the code became effective. Therefore, the Commission's recommendation on capitalization is followed in the entry listings but not in the summaries. Undoubtedly there will be differences of opinion about the capitalization (or noncapitalization) used for some of the names listed in this lexicon. Quotation marks are used around names if the author cited used them.

Geologic names currently adopted for use by the U.S. Geological Survey are printed in boldface type, as in the Wilmarth Lexicon. These names have been used in Survey reports, and they constitute a part of the official geologic nomenclature of the Survey. The Survey has had occasion to consider for acceptance or rejection considerably less than half of the names that have been applied to geologic units in the United States.

The rank, lithology, and (or) age designations of some units for which the Survey has approved names are shown as they are currently

(1964) carried in the files of the Survey, even if the reports for which such designations were adopted either were still in preparation or were published after 1960. These changes will be documented in future lexicons.

Ages of all the units are given in terms of the standard major divisions of geologic time, as used by the U.S. Geological Survey (p. iv). For the sake of consistency, the designation "early" or "late," if used by an author with the age of rock units, is changed to "lower" or "upper." The age given for a unit whose name is printed in boldface type is the age presently (1964) assigned by the U.S. Geological Survey. The age given for a unit not printed in boldface is the age given by the author of the report being cited.

ACKNOWLEDGMENTS

The cooperation and assistance of George V. Cohee, the late Roger G. Miller, Walter S. West, Rudolph W. Kopf, and Verda M. Dougherty, all of the staff of the Geologic Names Committee, is gratefully acknowledged. Information and suggestions generously furnished by many geologists with State universities and State geological surveys are greatly appreciated. Many helpful suggestions were given by U.S. Geological Survey colleagues. Special thanks are due Blanche E. Hansen for her accuracy and consistency in the compilation, Helen L. Nace for her invaluable assistance during the final stages of the preparation of the manuscript and, Dimitra J. Kalivas for her able help during the proofreading.

SYMBOLS

Names printed in boldface type have been adopted for use by the U.S. Geological Survey.

Names preceded by a dagger (†) have either been abandoned by their authors or rejected for use by the U.S. Geological Survey.

Names followed by the superscript (¹) are listed in the Wilmarth Lexicon (U.S. Geol. Survey Bull. 896).

Names in roman type without a dagger have not been considered by the Committee on Geologic Names of the U.S. Geological Survey for use in Survey reports.

LEXICON—PART 1, A–F

Aarde Shale[1] Member (of Howard Limestone)

Pennsylvanian (Virgil Series) : Eastern Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 94, 96.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 57 (fig. 22), 63, 70 (fig. 25). Bluish- to yellowish-gray clayey and sandy shale containing a persistent coal bed (Nodaway), ranging from about 1 inch to 2 feet in thickness, and a persistent black fissile shale in many outcrops. Thickness ranges from about 2 to 15 feet. Underlies Church limestone member; overlies Bachelor Creek limestone member.

M. R. Mudge, C. P. Walters, and R. E. Skoog, 1959, U.S. Geol. Survey Bull. 1060–D, p. 193, 252–253, pl. 7. In Nemaha County, Kans., member is basal unit of Howard limestone. Consists of silty slightly calcareous dark-gray to tan shale. Average thickness 4½ feet. Base of Nodaway coal designated as base of Aarde. Underlies Church limestone member.

Named for Aarde farm, sec. 4, T. 26 S., R. 11 E., Greenwood County.

Aaron Slate[1]

Precambrian or Paleozoic: Central northern North Carolina and central southern Virginia.

Original reference: F. B. Laney, 1917, Virginia Geol. Survey Bull. 14, p. 15, 19–27, map.

J. L. Calver, 1960, Virginia Div. Mineral Resources Bull. 75, p. 17. In Pittsylvania and Halifax Counties, overlies Hyco quartz porphyry. Varies from nearly pure greenstone to fairly pure argillaceous sandstone and slate; in some areas decidedly conglomeratic. Paleozoic or Precambrian.

Well exposed at many places along Aaron's Creek, Person and Granville Counties, N.C.

Abbott Formation (in McCormick Group)

Middle Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1), 28 (fig. 4), 30–31, 44 (table 1), pl. 1. geol. sections. Proposed for strata from top of Pounds sandstone member of Caseyville formation to top of Bernadotte sandstone member of western Illinois. Overlaps Caseyville formation, and throughout most of central, northern, and western Illinois is basal formation of Pennsylvanian. Overlapped by Spoon formation (new) of Kewanee group (new). Consists of strata that were included in lower part of sequence formerly called Tradewater group. Characterized by dominance of sandstone, sandy shale, and siltstone; coals rarely more than 24 inches thick and have much less continuity than higher coals. Maximum thickness 300 to 350 feet in southern Illinois; thins westward and northward. Members: southern Illinois—(ascending) Reynoldsburg coal, Grindstaff sandstone, Willis coal, Finnie sandstone (new), Delwood coal, and Murray Bluff sandstone; western Illinois—(ascending) Babylon sandstone, Manley coal, Tarter coal, Pope Creek coal, and Bernadotte sandstone. Report presents new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is independent of rock-stratigraphic classification.

Type locality: Along Illinois Central Railroad, secs. 5–7, T. 11 S., R. 5 E., Pope County. Named for Abbott Station.

Abbyville Gabbro[1]

Precambrian: Central southern Virginia.

Original reference: F. B. Laney, 1917, Virginia Geol. Survey Bull. 14, p. 37–38, map.

Occurs in vicinity of Abbyville, Mecklenburg County.

Abercrombie Formation[1]

Middle Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). Correlation chart of recommended revision of stratigraphic units pertaining to Great Basin shows Abercrombie formation below Young Peak dolomite and above Busby quartzite.

Underlies and named for Abercrombie Peak, on ridge south of Dry Canyon, in Gold Hill district.

Aberdeen Sandstone (in Pottsville Formation)[1]

Aberdeen Sandstone (in Tradewater Formation or Group)

Pennsylvanian: Western Kentucky, southern Illinois, and southern Indiana.

Original reference: A. F. Crider, 1915, Kentucky Geol. Survey, 4th ser., v. 3, pt. 1, p. 173–175.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 33. Noted as occurring in Illinois and Indiana.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart (column 26). Shown on correlation chart as sandstone in Tradewater formation. Underlies Mannington coal; overlies Ice House coal.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 14 (fig. 2). Shown on correlation chart as sandstone in Tradewater group. Below Rock Island coal and above Pope Creek coal.

Named for Aberdeen, Butler County, Ky., where it stands out in prominent cliffs along Green River. Typically exposed at Aberdeen Ferry.

Aberdeen Sandstone Member (of Blackhawk Formation)[1]

Upper Cretaceous: East-central Utah.

Original reference: F. R. Clark, 1928, U.S. Geol. Survey Bull. 793.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, 184, pl. 3. Stratigraphically extended to include overlying coal-bearing rocks and associated offshore bar deposits. Consists of basal white-capped sandstone with maximum thickness of 88 feet and an overlying series of shale, sandstone, and coal with a maximum thickness of about 100 feet at Kenilworth. Includes the Castlegate "A" or Aberdeen coal. Underlies Kenilworth member (new); overlies Spring Canyon member (new).

Exposed near Aberdeen mine, northeast of Kenilworth, Castlegate quadrangle, Carbon County.

Abilene Conglomerate[1]

Tertiary: Central Kansas.

Original reference: C. S. Prosser, 1895, Jour. Geology, v. 3, p. 786, 789, 797.

C. C. Williams and S. W. Lohman, 1949, Kansas Geol. Survey Bull. 79, p. 60. Locally conglomeratic bed occurs at base of McPherson formation. Material in conglomerate is similar to materials composing so-called Abilene conglomerate, a good exposure of which is near NW cor. sec. 30, T. 18 S., R. 2 E., just east of mapped area. Believed that, at various outcrops, beds called Abilene conglomerate may represent different ages; hence, term Abilene may not have much stratigraphic significance. Conglomerate at base of McPherson in this area [McPherson County, most of Harvey County, and parts of Sedgwick, Marion, and Reno Counties] may be equivalent to some exposures of the Abilene conglomerate in Dickinson County.

Named for Abilene, Dickinson County.

Abilene Formation[1]

Permian: Central and central northern Texas.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull., v. 1, p. 95–96.

Occurs around Abilene and perhaps southward beneath Callahan Divide.

Abilene Limestone[1]

Age not stated: Kansas.

Original reference: E. C. Parker, 1925, Am. Assoc. Petroleum Geologists Bull., v. 9, no. 6, p. 982.

Type section: Abilene, Dickinson County.

Abingdon Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), 62, pl. 1. Assigned member status in Spoon formation (new). Occurs above Isabel sandstone member and below Browning sandstone member. Very thin; represented by coaly streak in type section of Spoon. Coal named by Culver (1925, Illinois Geol. Survey Min. Inv. 29). Report presents new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Center sec. 6, T. 9 N., R. 2 E.

Abingdon cyclothem (in Carbondale Group)

Abingdon cyclothem (in Spoon Formation)

Pennsylvanian: Western Illinois and eastern Iowa.

J. M. Weller and H. R. Wanless *in* J. M. Weller and others, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1586 (fig. 1), 1589. Commonly embryonic and thin; characterized only by a dark streak or coal horizon separating underclay and gray shale; in most areas, identified and correlated solely on basis of its stratigraphic position. In area of Knox and Fulton Counties, Ill., includes basal sandstone, underclay, and a few inches of coal, and gray shale bearing a thin unpersistent layer of brownish- to purplish-gray fine-grained limestone. Neither a basal sandstone nor a marine limestone is characteristically present, and most distinctive member of cyclothem in Iowa is thin red platy almost fissile shale directly above coal horizon. In western Illinois and Iowa, persistently present between Greenbush cyclothem below and Liverpool cyclothem above. Formerly tentatively termed Lower Liverpool.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 83–85, geol. sections 6, 23, 25, 28–32, 34, 36, 37, 40, 42. Includes Isabel sandstone. Also includes a channel sandstone, called Browning by Searight (1929). It is possible Browning may be channel facies of Isabel sandstone. However, in this report Browning is included in Liverpool cyclothem. Cyclothem also present in western Indiana and western Kentucky, where it probably includes lowest beds of Carbondale formation as used in Kentucky.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. Included in Spoon formation, Kewanee group (both new). Occurs above Greenbush cyclothem and below Tonica cyclothem (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Well exposed in tributaries of Brush Creek, especially near the center of sec. 6, T. 9 N., R. 2 E., 4 miles east of Abingdon, Knox County, Ill.

Abiquiu Tuff

Abiquiu Tuff Member (of Santa Fe Formation)

Miocene: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103; 1938, Jour. Geology, v. 46, no. 7, p. 937 (fig. 4), 944–952, 958. Consists of stream-laid tuff and volcanic conglomerate, with a few small interbedded lava flows; maximum thickness more than 1,000 feet. Underlies Santa Fe formation; overlies El Rito formation (new). Miocene.

C. E. Stearns, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 467 (fig. 3), 469–472, pl. 1. Name Abiquiu(?) formation assigned to lower part of late Tertiary beds of Galisteo-Tonque area. Beds are chiefly nontuffaceous. Believed to be southward extension of water-laid volcanic debris named Abiquiu tuff by Smith (1938). Abiquiu(?) is as much as 1,500 feet thick. Occurs above Cienequilla limburgite and below Santa Fe formation.

A. J. Budding, C. W. Pitrat, and C. T. Smith, 1960, New Mexico Geol. Soc. Guidebook 11th Ann. Field Conf., p. 83, 84. Rank reduced to member status in Santa Fe formation. Unconformably overlies El Rito formation. Thickness at least 1,350 feet on west slope of Sierra Negra. Area of report is southeastern part of Chama basin.

Named for outcrops in Abiquiu quadrangle.

Abo Sandstone,[1] Redbeds,[1] or Formation

Lower Permian (Wolfcamp and Leonard): New Mexico.

Original reference: W. T. Lee, 1909, U.S. Geol. Survey Bull. 389.

G. F. Loughlin and A. H. Koschmann, 1942, U.S. Geol. Survey Prof. Paper 200, p. 20–22, pl. 2. In Magdalena district, Abo sandstone unconformably overlies Madera limestone of Magdalena group. Unconformable below Datil(?) formation. Maximum thickness about 175 feet.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 674–676. In some previous reports, Abo sandstone was considered to be approximately equivalent to Wolfcamp series, and supposed unconformity at its base was thought same as that at base of Wolfcamp. This correlation now seems to be incorrect. Herein suggested that Abo is mostly or wholly post-Wolfcamp and that equivalent of Wolfcamp series lies in upper part of Magdalena group as at present defined and mapped. Basal formation of Manzano group.

C. E. Needham and R. L. Bates, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1654–1657. Lee (1909) gave name Abo sandstone to succession of dark-red coarse-grained sandstones, in part conglomerate, exposed in Abo Canyon at south end of Manzano Mountains. He gave maximum thickness of 800 feet. Lee stated that Abo was underlain unconformably by Magdalena limestone (Pennsylvanian), but his definition of upper boundary is not clear. Abo was termed basal member of Manzano group, which contained (ascending) Abo sandstone, Yeso formation, and San Andres limestone. Several thin fossiliferous limestones that Lee described as lying near base of Abo are now known to belong to underlying Pennsylvanian. Lee's conclusion that shale in Abo is subordinate in amount to sandstone and conglomerate is in error. Lee did not designate type section. In type section herein designated and described, Abo consists of about 60 percent red shale and about 40 percent sandstone, arkose, and conglomerate. This ratio holds approximately true for most exposures in central New Mexico. It is incorrect to refer to formation as Abo sandstone. Thickness 915 feet at type section. Overlies unnamed basal Permian limestone; underlies Yeso (redefined).

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. In Sandoval and Rio Arriba Counties, Abo formation underlies and intertongues with Meseta Blanca sandstone member (new) of Yeso formation.

V. C. Kelley and G. H. Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. In Lucero uplift, Valencia, Socorro, and Bernalillo Counties, Abo formation overlies and intertongues with Red Tanks member (new) of Madera limestone and underlies and intertongues with Meseta Blanca sandstone member of Yeso formation.

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 61. Consists of dark-red shale, dark-red sandstone and arkose, conglomerate, and lime-pellet conglomerate. Thickness ranges from 300 feet in Joyita Hills to 910 feet in type section. Overlies Bursum formation (new). Age of formation is in question. Fossil plants indicate at least upper part should be correlated with strata of Leonard and not Wolfcamp age.

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1, p. 1155. In Los Pinos Mountains, Abo formation disconformably overlies Aqua Torres formation (new). Thickness exceeds 500 feet.

R. L. Bates and others, 1947, New Mexico Bur. Mines Mineral Resources Bull. 26, p. 26–28. As described by Needham and Bates, Abo in Abo Canyon, consists of 914 feet of continental red beds that overlie a thin "unnamed basal Permian limestone." Fieldwork for present report shows that this limestone is at top of Bursum formation. Uppermost unit of type Abo of Needham and Bates is a 6-foot white massive sandstone. Further work in Gran Quivira quadrangle has shown presence, just above this sandstone, of a thin limestone that is identical with lowest unit of Yeso as redefined by Needham and Bates. It has been pointed out by C. B. Read (personal commun.) that basal Yeso limestone cannot be found in Yeso sections in northern part of state—in Glorieta Mesa and Zuni Mountains, for example—and consequently cannot serve as universally recognizable base of Yeso. Read states that a 100- to 300-foot section of sandstones and shales, heretofore considered uppermost Abo, can be recognized and mapped regionally. Read and his workers have mapped Abo-Yeso contact some distance below basal Yeso limestone of Needham and Bates. Applied to Abo type section, this revision lowers Abo-Yeso contact 104 feet, to top of interval 32 of Needham and Bates section. Wood and Northrop (1946) have named this 104-foot section Meseta Blanca sandstone member of Yeso.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93 (columnar section), 101. Discussion of Sacramento Mountain escarpment. Abo formation was deposited over entire escarpment area. In basinal area east of Tularosa, Abo is about 1,100 feet thick and composed principally of dark-reddish-brown mudstone and arkose. Here it grades into underlying latest early Wolfcampian marine strata. Thins rapidly toward positive block in southeast and is about 400 feet thick in High Rolls area. Here it is composed of basal quartzite conglomerate cobbles and an overlying thicker sequence of dark-reddish-brown mudstones and arkose. Farther south, it is 200 to 550 feet thick and splits into an uppermost and a basal series of red beds and a middle sequence composed principally of thin-bedded limestone, dolomitic limestone, and nonred shales. Middle sequence thickens southward to Hueco Mountains, changes from brackish to marine facies, and forms most of Wolfcampian part of Hueco limestone. Upper tongue of Abo red beds (entire Abo of Darton, 1928, U.S. Geol. Survey Bull. 794) can be traced nearly to Texas border, and forms Deer Mountains red shale of Hueco limestone. Throughout area, overlies angular unconformity cut on folded and faulted pre-Permian strata. Columnar section shows Abo penetrated by Pendejo tongue (new) of Hueco formation.

M. L. Thompson, 1954, Kansas Univ. Paleont. Contr. 14, Protozoa, art. 5. p. 17. Mentioned as containing Powwow conglomerate member at base.

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 6, 7 (fig. 2), 10, pl. 1. In Socorro County, Abo formation conformably underlies Los Vallos member of Yeso formation.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 689–700. Discussion of Sand Canyon area, Otero County, N. Mex. Abo sandstone is divided into lower and upper tongues by interfingering with Hueco limestone. Lower tongue is herein named Danley Ranch and upper tongue Lee Ranch. About 15 miles north of area, Hueco wedges out between upper and lower parts of Abo. Rocks that previous workers have identified as Abo formation south of Culp Canyon are interpreted as distinct unit and herein named Otero Mesa member of Yeso formation. Contact with underlying Pennsylvanian rocks (Magdalena group) unconformable throughout area. Locally relief before deposition of Abo was so great that Danley Ranch tongue is absent because of nondeposition. Lee Ranch tongue is apparently early Leonard. Lower Permian.

Carel Otte, Jr., 1959, New Mexico Bur. Mines Mineral Resources Bull. 50, p. 58–71. In northern Sacramento Mountains, Abo formation overlies

Labrocita formation (new) and underlies Yeso formation; locally overlies Holder formation. Thickness as much as 1,400 feet. Basal formation of Manzano group. Wolfcampian and Leonardian.

U.S. Geological Survey has abandoned term Manzano Group.

Type section (Needham and Bates): From base of formation in sec. 32, T. 3 N., R. 5 E., Valencia County, just north of U.S. Highway 60, through sec. 33, into sec. 2, T. 2 N., R. 5 E., to upper limit of formation at top of hill just east of road to Abo Ruins in sec. 25, T. 3 N., R. 5 E., Torrance County. Base of section lies about 1 mile northwest of village of Scholle; top lies about 2 miles west-northwest of village of Abo. Named for Abo Canyon at south end of Manzano Range, Valencia and Torrance Counties.

Abrams Mica Schist[1]

Pre-Silurian: Northern California.

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 225–245.

Seymour Mack, 1958, U.S. Geol. Survey Water Supply Paper 1462, p. 16–18, pl. 1. Thick series of metasedimentary rocks, dominantly quartz-mica schist, which is overlain unconformably by Salmon hornblende schist. Hinds (1932) introduced term Siskiyou terrane to include Abrams and Salmon schists. Exact stratigraphic position of rocks composing Siskiyou terrane is not known. Abrams and Salmon are oldest formations in area of this report [Scott Valley]. In northern and western parts of area, they are overlain unconformably by several thousand feet of greenstone and greenstone schist possibly correlative with Devonian(?) Copley greenstone of southern Klamath Mountains. In southern part of mountains surrounding Scott Valley, Chanchelulla(?) formation of probable Silurian age lies unconformably on Abrams and Salmon schists. Present evidence indicates only that Abrams and Salmon schists can be adjudged with certainty to be of pre-Silurian age. Assignment to Precambrian or lower Paleozoic would be extremely tenuous.

W. P. Irwin, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B315–B316; 1960, California Div. Mines Bull. 179, p. 19–20. Geologic mapping in Weaverville quadrangle indicates that (1) structure of metamorphic rocks in that quadrangle is synclinorial and Abrams mica schist overlies Salmon hornblende schist, (2) Abrams is probably younger, rather than older, than Salmon, and (3) marble lenses are of stratigraphic significance in that they are chiefly in lower part of Abrams.

Named for Abrams post office, in upper Coffee Creek region, Trinity County.

Abrigo Limestone[1] or **Formation**

Middle and Upper Cambrian: Southeastern Arizona.

Original reference: F. L. Ransome, 1904, U.S. Geol. Survey Prof. Paper 21.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 9, 16–20, pl. 5. In Cochise County, described as limestone, limestone mottled with shale, shale, sandstone, edgewise conglomerate, and a little quartzite. Thickness varies but is 770 feet at type locality. Underlies Upper Devonian Martin limestone; overlies Bolsa quartzite.

Named for exposures in Abrigo Canyon, 3 miles southwest of Bisbee.

Absalona Formation

Precambrian(?): Rhode Island.

G. M. Richmond *in* G. M. Richmond and W. B. Allen, 1951, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 4, p. 10, 11–12, pl. 1. Predominantly porphyroblastic biotite gneiss; includes, locally, lenses of quartz-biotite schist at its base and mappable units of biotite gneiss and amphibolite in its upper part; small quartzite lenses occur throughout. Thickness 650 to 4,700 feet. Underlies Woonasquatucket formation (new); overlies Nipsachuck gneiss (new).

Named for exposures on southwest slope of Absalona Hill along U.S. Route 44, Georgiaville quadrangle.

Absaroka sequence

Mississippian (Chesterian) to Pennsylvanian (Des Moinesian): Central and Western United States.

L. L. Sloss, W. C. Krumbein, and E. C. Dapples *in* C. R. Longwell, chm., 1949, Geol. Soc. America Mem. 39, p. 110–111, 112 (table 2), 121. "Operational unit" for use in interregional facies analysis. Term derived from Absaroka Mountain Range in northwestern Wyoming and southern Montana. Outcrops along eastern flank of range at western border of Bighorn basin expose base of sequence at contact between Madison limestone and Amsden formation. Top of sequence not defined, but no regionally significant discontinuity is recognized short of base of Upper Jurassic Morrison formation.

Absher Limestone (in Carbondale Group)

Pennsylvanian (Des Moines): Southern Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 17 (fig. 3), 23 [1943]. Comparatively thin and somewhat impure bed. Overlies Harrisburg (No. 5) coal; in vicinity of Harrisburg, generally separated from coal by as much as 20 feet of shale (bed 6 of complete cyclothem). Included in St. David cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 54 (table 3). Replaced by St. David limestone member of Carbondale formation (redefined). Report presents new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Named from village in southeastern Williamson County.

†Accabee Gravels[1] or Phos-gravels[1]

Pleistocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published 1908 *in* South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 20, 21.

Named for exposures in pit at Corn Hill, near Accabee Flats, west of Charleston.

Accord Shale

Upper Silurian (Murderian): Southeastern New York.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser., no. 1. Suggested for unfossiliferous calcareous shale underlying Rosendale waterlime. Thickness at type section 18 feet.

Type section: Abandoned railroad cut, southern edge of Accord, Rosendale quadrangle.

Acebedo Formation

Acebedo Member (of Lodo Formation)

Eocene, middle: Southern California.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 46 (footnote), 50–51. Name Acebedo formation applied by Leo Herrera (1951, unpub. thesis) to siltstones underlying Avenal sandstone in Tent Hills area. Consists, at least locally, of a basal conglomerate containing a coarse orbitoidal sandstone and a siltstone sequence. Rests unconformably on Cretaceous. May represent a coarser clastic phase of Lodo formation deposition, about equivalent, at least in upper part, in age and stratigraphic position to Arroyo Hondo member of Lodo farther north at Cantua Creek. Falls within Ulatisian stage. Footnote, page 46, refers to unit as member of Lodo formation.

Well exposed in Tent Hills region, south of Reef Ridge area, about 18 miles southwest of Avenal, Kern County.

†Ackerman Formation (in Wilcox Group)[1]

Eocene, lower: Northeastern Mississippi, southwestern Alabama, southeastern Missouri, and western Tennessee.

Original reference: E. N. Lowe, 1913, Mississippi Geol. Survey Bull. 10, p. 23–35.

J. M. Weller and H. S. McQueen, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 159. Geographically extended into Scott County, Mo., where it underlies Holly Springs formation and overlies Porters Creek formation.

F. F. Mellen, 1939, Mississippi Geol. Survey Bull. 38, p. 30 (fig. 6), 33, 37–43. Restricted to exclude Midway-Wilcox "transitional beds" or "basal clays" of Lowe. As thus restricted, underlies Holly Springs formation and overlies Fearn Springs formation (new) and includes not only clays and lignites as exposed in type section but a persistent basal sand member.

G. I. Whitlatch and Benjamin Gildersleeve, 1946, Econ. Geology, v. 41, no. 8, p. 843 (fig. 2), 844–845. Geographically extended into western Tennessee where it underlies Holly Springs formation and overlies Porters Creek clay.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 17–18. In 1943, during work on Mississippi geologic map, it was found that type Holly Springs of northern Mississippi, formerly included in the Wilcox and correlated with Tuscahoma sand of Alabama, is nonmarine equivalent of Tallahatta formation to south. Name Holly Springs was abandoned in favor of Tallahatta for all of Mississippi. Removal of beds designated as Holly Springs from Wilcox group left Ackerman formation as only unit formerly recognized by U.S. Geological Survey in the Wilcox of Mississippi. Although usually correlated with Nanafalia formation of Alabama, Ackerman at its type locality in Mississippi was found to correlate with beds well up in Tuscahoma sand of Alabama. It was decided, rather than attempt to redefine Ackerman, to adopt Wilcox formation for all beds of Wilcox age in Mississippi. [Hence, Ackerman formation is abandoned.]

J. S. Attaya, 1951, Mississippi Geol. Survey Bull. 71, p. 10–19. Ackerman formation in its outcrop in Lafayette County is entirely nonmarine. On basis of data obtained from shallow exploratory holes and surface exposures, Ackerman is herein divided into four units (numbered 1 to 4 in ascending order), the composite of which forms a cyclothem. Third unit of Ackerman has probably been confused with Holly Springs formation. Herein proposed that name Holly Springs be dropped from literature. Overlies Fearn Springs formation; underlies Meridian formation.

James Turner, 1952, Mississippi Geol. Survey Bull. 76, p. 10–14. Described in Yalobusha County, Miss., as composed of sand, clay, shale, lignite, quartzite, and iron concretions. Basal sand not present at surface. Thickness 68 to 140 feet. Underlies Meridian formation.

T. W. Lusk, 1956, Mississippi Geol. Survey Bull. 80, p. 25–43, pl. 1. Entire Ackerman is present in Benton County. Thickness varies from featheredge on east to about 100 to 150 feet on west. Overlies Fearn Springs formation; underlies Meridian formation. Wilcox.

Typically exhibited in cut 1 mile east of town of Ackerman, Choctaw County, northeastern Mississippi.

Acme Dolomite Member (of Blaine Formation)[1]

Permian: Northwestern Texas and west-central Oklahoma.

Original reference: A. M. Lloyd and W. C. Thompson, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 948 (fig. 1), 951.

R. L. Clifton, 1942, Jour. Paleontology, v. 16, no. 6, p. 686 (table 1). Geographically extended into Oklahoma where it is shown as underlying shales below Shimer member and overlying shales above Cedartop member.

Named Acme from type exposure in Hardeman County, Tex.

Acton Granite

Late Paleozoic(?): Eastern Massachusetts.

W. R. Hansen, 1956, U.S. Survey Bull. 1038, p. 48–50, pl. 1. Fine-grained moderately foliated light-gray to light-olive-gray granite. Composed chiefly of quartz, orthoclase, microcline, and oligoclase. Occurs in small individual plutons, chiefly as intruded sheets or sill-like bodies, and as crosscutting dikes and irregular masses that range in thickness from a few inches to several hundred feet and in length from a few yards to more than a mile. All observed exposures lie within boundaries of Nashoba formation (new).

Named for town of Acton where it is well exposed. Also exposed in Boxborough, Bolton, Harvard, Hudson, and Stow.

Acworth Gneiss[1]

Precambrian: Northwestern Georgia.

Original reference: C. W. Hayes, 1901, Am. Inst. Mining Engineers Trans., v. 30, p. 408.

Named for development around Acworth, Cobb County.

Ada Formation[1]

Pennsylvanian (Virgil Series): South-central Oklahoma.

Original reference: G. D. Morgan, 1924, [Oklahoma] Bur. Geology Bull. 2. p. 128–132, pls. 3, 27, map.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 99–103. Formation in Seminole County consists of variegated pastel shales, sandstones, and siltstones, and limestones and limestone conglomerates. Includes Snomac limestone member (new). Thickness 150 to 250 feet; thickens and thins in no regular manner. Overlies Vamoosa formation; underlies Vanoss formation. Fieldwork across Okfuskee, Seminole, and Pontotoc Counties coupled with data taken from Morgan's map shows that Ada formation truncates in succession Pawhuska, Vamoosa, Hilltop, Belle City, Nellie Bly, Coffeyville, and Seminole formations.

Named for development within and to west of town of Ada, Pontotoc County.

Ada Limestone

Upper Ordovician: Central Oklahoma, western Illinois, and Missouri.

W. H. Shideler, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 367–368. The "Fernvale," extending from Glen Park, Mo., and Valmeyer, Ill., to south side of Arbuckles in Oklahoma, is massive, uniformly crystalline limestone with varied fauna of ostracods and trilobites; this limestone differs from the typical Fernvale. Name Ada is proposed for the crystalline limestone.

A. M. Gutstadt, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 3, pt. 1, p. 524. Templeton and Willman (1953, unpub.) reported that name Ada was preempted and proposed name Cape limestone for the Missouri "Fernvale."

Well exposed at Lawrence quarry, 7 miles southwest of Ada, Pontotoc County, Okla.

Ada Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia, eastern Tennessee(?), and southwestern Virginia.

Original reference: D. B. Reger. 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 421.

C. L. Cooper, 1941, Illinois Geol. Survey Rept. Inv. 77, p. 12. Mentioned in discussion of Chester ostracodes of Illinois. Overlies Reynolds limestone member; underlies Talcott shale member.

Type locality: On north side of East River, in public road between Ada and Stony Gap, and less than one-fourth mile west of Ada, Mercer County, W. Va.

Adamana shales[1]

Lower Triassic: Northeastern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 250, 335.

Exposed near railroad station of Adamana, Apache County.

Adamant Granite

Devonian: Central Vermont.

W. M. Cady, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–79. Mottled gray fine- to medium-grained granite, occurring as thick sills, thinner subsidiary sills, and sill-like dikes. Maximum thickness of individual sills several hundred feet. Enclosed in Waits River formation, except for one thin sill in Moretown formation.

Typically exposed at surface and in quarries within a mile north and northwest of village of Adamant in southwestern Calais Township, Montpelier quadrangle.

Ada Mayes facies[1]

See **Mayes Formation.**

Adams Branch Limestone Member (of Graford Formation)[1]

Adams Branch Formation (in Graford Group)

Upper Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 391.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Graford group (redefined). Expanded below to include shale and sandstone section about 50 feet thick above Wiles limestone.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 64–65. Middle member of Graford formation. Overlies Brownwood shale member; underlies Cedarton shale member. Commonly light-gray wavy-bedded slabby limestone. A few miles northeast of Brownwood, member grades laterally into shale, calcareous sandstone, and, in some places, a coquina of brachiopod, mollusk, and crinoid fragments. Thickness about 15 feet, just west of Brownwood; thickens downdip to about 40 feet in wells; 50 to 60 feet in McCulloch County, south of Colorado River.

Type locality: Adams Branch, Brown County, close to town of Brownwood.

Adaville Formation[1]

Upper Cretaceous: Southwestern Wyoming.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56.

R. H. Peterson, D. J. Gauger, and R. R. Lankford, 1953, Utah Geol. and Mineralog. Survey Bull. 47, p. 16 (fig. 4), 17–18. Consists of about 4,000 feet of yellow, gray, and black carbonaceous clays with irregularly bedded brown and yellow sandstones and numerous coal beds. Includes Lazeart member at base. Overlies Hilliard formation.

Well exposed at Adaville mine, 2 miles south of Hodges Pass Tunnel, on Oregon Short Line.

Addington Formation[1]

Permian: Central southern Oklahoma.

Original reference: J. R. Bunn, 1930, Oklahoma Geol. Survey Bull. 40PP, p. 8–9.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 106. Rejected by Oklahoma Geological Survey. Name preoccupied.

Exposed in Jefferson County.

Addington Sandstone Member (of Wise Formation)[1]

Pennsylvanian: Southwestern Virginia.

Original reference: J. B. Eby, 1923, Virginia Geol. Survey Bull. 24.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 72, 77 (table 5). In Wise formation about 180 feet above base, between Addington and Clintwood coals.

Named for Addington Station, 1½ miles south of Glamorgan, Wise County.

Addison Formation[1]

Middle Ordovician: Northwestern Vermont.

Original reference: E. J. Foyles, 1929, Vermont State Geologist 16th Rept., p. 275–279.

In central part of Ferrisburg Township, northwestern part of Addison County.

Addy Quartzite[1]

Lower Cambrian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 61, map.

H. E. Culver, 1939, Washington State Coll. Monthly Bull., v. 22, no. 7, pt. 1, p. 19. Mentioned as overlying Huckleberry greenstone (new).

W. A. G. Bennett, 1941, Washington Div. Geology Rept. Inv. 5, p. 9, pls. 1, 2. Restricted to exclude underlying greenstone and conglomerate. These units, now named Huckleberry greenstone and Huckleberry conglomerate, were included in Addy by Weaver (1920). Thickness at least 3,000 feet; may be as much as 5,000 feet. In most of area, Addy lies on greenstone, but in south, locally overlaps greenstone and lies on schistose conglomerate. Overlain by what are presumably extensions of Old Dominion limestone.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Unconformably overlies Huckleberry group. Probably Cambrian.

U.S. Geological Survey currently considers Addy Quartzite to be Lower Cambrian in age.

Near Addy, Stevens County.

Adel Mountain Volcanics

Upper Cretaceous: Northwestern Montana.

J. B. Lyons, 1944, Geol. Soc. America Bull., v. 55, no. 4, p. 449 (fig. 2), 455, 459–460, pl. 1. Trachybasalt and basalt agglomerates, coglomerates, and flows, with numerous intrusives, analcime and augite trachybasalts in upper measures. Contains plant fossils in upper conglomerates. Entire succession strongy zeolitized. Unconformably underlies Great Falls lake sands (new); unconformably overlies Two Medicine formation. Thickness 3,200 feet. In area of Lewis overthrust, Precambrian Spokane shale is thrust over Adel Mountain volcanics.

J. D. Barksdale, 1951, Am. Jour. Sci., v. 249, no. 6, p. 439–442. Mentioned in discussion of Cretaceous glassy welded tuffs of Lewis and Clark County, Mont.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 40. Adel Mountain volcanics are younger than Elkhorn Mountains volcanics (new) in southern Elkhorn Mountains.

Area of reports includes about 900 square miles of northern end of Big Belt Range and adjacent plains. Adel Mountain volcanics occupy approximately 330 square miles of northern Big Belts. Adel Mountain is in mapped area.

Aden Basalt Flow

Quaternary: Southwestern New Mexico.

F. E. Kottlowski, 1960, New Mexico Bur. Mines Mineral Resources Geol. Map 14. Named on map legend. Unit mapped in southwestern part of Las Cruces quadrangle.

Adirondack (Anorthosyte) Anorthosite[1]

Precambrian: Eastern New York.

Original reference: C. H. Chadwick, 1930, Geol. Soc. America Bull., v. 41, no. 1, p. 82.

W. J. Miller, 1943, Am. Geophys. Union Trans., v. 24, pt. 1, p. 257–264. Discussion of emplacement of Adirondack anorthosite. Terms Adirondack anorthosite body (or massif) and Adirondack syenite-granite series also used in text.

Anorthosite mass constitutes all high central peaks of true Adirondack Mountains.

Adirondack Gneiss[1]

Precambrian: Northeastern New York.

Original reference: C. H. Hitchcock, 1879, Macfarlane's Geol. Ry. Guide, p. 56.

David Gallagher, 1937, New York State Mus. Bull. 311, p. 15–16. Suggests that best term for the rock as a whole is granite.

In Adirondack region.

Adirondack-Border Series

Upper Cambrian: Northern New York.

R. R. Wheeler, 1946, Harvard Univ. Summ. of Theses, 1942, p. 143, 145. Term used for Upper Cambrian deposits which represent an on-lap and off-lap cycle of deposition. Comprises (descending) Whitehall formation, Little Falls dolomite, Theresa passage beds, and Potsdam sandstone. Physically and faunally distinct from overlying Beekmantown rocks.

Adirondack-Border region.

Adler Sedimentary Series (in Yavapai Group)

See **Alder Group** (in Yavapai Series).

Admiral Formation (in Wichita Group)[1]

Admiral Group

Lower Permian (Wolfcamp Series): West-central Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Texas Univ. Bull. 2132, p. 192–195, charts.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 93, 94–96. Rank raised to group. Restricted; redefined to include beds above Coleman Junction and below Jim Ned shale members (new) of Belle Plains formation. Comprises Fisk formation (new), above, and redefined Hords Creek formation.

R. C. Moore, 1947, *in* A. K. Miller and Walter Youngquist, Kansas Univ. Paleont. Contr. 2, Mollusca, art. 1, p. 1 (footnote). Mentioned as formation including two new members: Overall limestone and underlying Wildcat Creek shale.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80. Shown on composite columnar section as comprising (ascending) Lost

Creek shale, Hords Creek limestone, Wildcat Creek shale, and Overall limestone. Underlies Belle Plains formation; overlies Putnam formation.

Named for village of Admiral, Callahan County.

Admiralty Drift[1] or Clay

Pleistocene (pre-Wisconsin): Western Washington and British Columbia, Canada.

Original reference: B. Willis, 1898, Geol. Soc. America Bull., v. 9, p. 111.

R. C. Newcomb, 1952, U.S. Geol. Survey Water-Supply Paper 1135, p. 13–18, 38–39, pl. 1. Described in Snohomish County as firm finely bedded gray, green, and blue silt and clay with carbonized wood and a few dirty sand and gravel beds. Exposed thickness about 200 feet. In some areas underlies Pilchuck clay member (new) of Vashon drift, and in some areas Esperance sand member (new) of Vashon. In plateau blocks of the county, clay is overlain by several hundred feet of water-laid deposits.

J. E. Sceva, 1957, U.S. Geol. Survey Water-Supply Paper 1413, p. 14–15, 26, pl. 1. Drift described in Kitsap County where it consists principally of massive blue clay and silt; deformed in most places. Contains till, volcanic ash, peat, or lignite, sand, and some gravel. Top of formation commonly near or below sea level. Thickness as much as 400 feet. Underlies lower member of Orting gravel.

Principal exposures in bluffs along shores of Admiralty Inlet.

Admiralty glacial epoch[1]

Pleistocene (pre-Wisconsin): Western Washington.

Original reference: B. Willis, 1898, Geol. Soc. America Bull., v. 9, p. 111.

Admire Group[1]

Admire Formation

Admire Shale (in Wabaunsee Group)[1]

Permian: Eastern Kansas, southeastern Nebraska, and central Oklahoma.

Original reference: G. I. Adams, 1903, U.S. Geol. Survey Bull. 211, p. 53.

G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 8–9. Rank raised to group; age designated as Permian. Subdivided into (ascending) Towle shale, Aspinwall limestone, Hawxby shale, Falls City limestone, West Branch shale, Five Point limestone, and Hamlin shale. Underlies Council Grove group; overlies Wabaunsee group (Pennsylvanian).

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Group mapped in Oklahoma. Not subdivided.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1). Redefined. Subdivided into three formations (ascending): Onaga shale (new), Falls City limestone, and Janesville shale (new). Overlies Wood Siding formation of Wabaunsee group.

C. C. Branson, 1956, Oklahoma Geology Notes, v. 16, no. 11, p. 123, 124–125. Stratigraphic unit from top of Brownville limestone to base of Foraker limestone is indivisible in Lincoln, Payne, and Pawnee Counties. Corresponds to entire Admire group of Kansas and can be referred to as Admire formation.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 73–77. Group, as currently defined, is basal Permian (Wolfcampian) unit of midcontinent area and includes beds overlying Brownville limestone and underlying

Americus limestone. In Nebraska and Kansas, group is subdivided into seven limestone and shale units; Indian Cave channel sandstone occurs locally at base. Taylor (1953), Vosburg (1954), and Fisher (1956) in unpublished theses made tentative correlations with some Kansas units. In Pawnee County, exposures of group are poor, and no attempt at subdivision has been made. Branson (1956) proposed that, where subdivision of group is not possible, name Admire formation be applied to sedimentary sequence separating Brownville and Americus limestones. Formation in Pawnee County forms broad valley, averaging 3 miles in width, that trends north-south across county. Thickness 140 feet, representing abrupt increase in thickness southward from Osage County.

Probably named for Admire, Lyon County, Kans.

Adobe Formation (in Veredas Group)

Pennsylvanian (Missouri Series): New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 61–62. Name introduced for all rocks in northern part of Oscura Mountains between top of Coane formation (new) and base of Council Springs limestone (new). At type locality, composed of noncherty to highly cherty gray limestone, gray shale, and arkosic sandstones. In most areas of central New Mexico, basal part of formation is fossiliferous highly arkosic sandstone to granule conglomerate. Thickness ranges from about 47 feet at type locality to more than 200 feet in area of Ladron Mountains and Cadronito Hills.

Type locality: Northeast slope of Oscura Mountains (SE¼ sec. 36, T. 5 S., R. 5 E.) in Socorro County. Geographic term Adobe is derived from Adobe village, about 3 miles northeast of north end of Oscura Mountains.

Aeolian Buttes Glacial Stage

Aeolian Buttes Till

Pleistocene: East-central California.

W. C. Putnam, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1289, pl. 1. At least four ice advances occurred in Pleistocene; earliest stage, here named Aeolian Buttes, was followed by the Sherwin, Tahoe, and Tioga previously named by Blackwelder. Till may be equivalent in age to McGee stage, but Aeolian Buttes can be dated with respect to local volcanic and glacial succession and McGee at its type locality 25 miles southeast cannot; therefore new name is proposed. Rhyolitic ash and pumice, now Bishop welded tuff, were erupted in interval between Aeolian Buttes and Sherwin stages. Aeolian Buttes till rests on an abraded surface of quartz monzonite.

W. C. Putnam, 1960, California Univ. Pubs. Geol. Sci., v. 34, no. 5, p. 235. Sherwin till is pre- rather than post-Bishop tuff. Name Aeolian Buttes till should be considered invalid as representing an earlier Pleistocene, pre-Sherwin glacial till. If name is retained at all, it should be regarded as having significance only in Mono Basin as probable equivalent of more widely recognized Sherwin glacial stage.

Till crops out on crest of Aeolian Buttes, a low craggy ridge between U.S. Highway 395 and Mono Craters; till also exposed in Mono Craters tunnel.

Aetna[1]

Permian: Kansas and western Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 353.

Named from Aetna, Barber County, Kans.

Afono Trachyte

Pleistocene(?): Samoa Island (Tutuila).

R. A. Daly, 1924, Carnegie Inst. Washington Pub, 340, p. 108, 129–130. Trachyte plug and associated trachyte dike. Pioa rhyolite, Matafao, Papatele, Afono, and Vatia trachytes were erupted contemporaneously or nearly so.

H. T. Stearns, 1944, Geol. Soc. American Bull., v. 55, no. 11, p. 1285–1286 (table 1), 1305. Afono trachyte plug associated with Pago volcanics (new). Pliocene and early Pleistocene(?).

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 150. Pleistocene(?).

Forms 200-meter cliff on east side of Afono Bay.

Afton Beds

Middle Devonian: Northeastern Michigan.

[G. M. Ehlers], 1938, Michigan Acad. Sci., Arts and Letters Sec. Geology and Mineralogy [Guidebook] 8th Ann. Field Excursion, [fig. 2] after p. 8. Shown on columnar section as underlying Marvin Quarry bed (new) and overlying Black Killians bed [Killians limestone].

W. A. Kelly, 1940, Michigan Acad. Sci., Arts and Letters Sec. Geology and Mineralogy [Guidebook] 10th Ann. Field Excursion, [p. 1, figs. 3, 4, 6, and 7], maps 1 and 2. Shown on columnar section as limestone beds. Thickness about 29 feet. Upper half of section at Afton cannot be definitely correlated with section near Lake Huron, and provisional names Afton beds, Marvin beds, and Beebe beds are used in place of Alpena, Norway Point, Potter Farm, Partridge Point, and Squaw Bay, employment of which would imply stricter correlation than is justified.

Present in Black Lake-Afton area.

Afton Limestone Member (of Wellington Formation)

Permian: Southeastern Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 4, 10–11. Claystones, green and red shales and clays at top of formation. Claystones at the top of the member carry copper carbonate flakes and nodules. Underlies typical Harper red beds; overlies Slate Creek limestone member (new).

Type locality: Afton Township 28 S., R. 3 W., Sedgwick County.

Aftonian Interglaciation

Aftonian Age, Stage

Aftonian stage of deglaciation[1]

Pleistocene: Iowa, Illinois, Kansas, and Nebraska.

Original reference: T. C. Chamberlain, 1895, Jour. Geology, v. 3, no. 3, p. 272–277.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99. Discussion of Pleistocene of Kansas. Aftonian age (stage), second time unit in Pleistocene, is an interglacial interval. Follows Nebraskan age (stage) and precedes Kansan age (stage).

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 128–130. Aftonian stage represented in this area—Beardstown, Glasford, Havana, and Vermont quadrangles—by brown leached gravel, of early Aftonian or possibly Nebraskan age, and noncalcareous silt with wood, probably of early or middle Aftonian age.

Name amended to Aftonian Interglaciation to comply with Stratigraphic Code adopted 1961.

Name derived from exposures between Afton and Thayer, southwestern Iowa.

Agamenticus Complex[1]

Devonian (?) or Mississippian (?) : Southwestern Maine.

Original reference: Alfred Wandke, 1922, Am. Jour. Sci., 5th ser., v. 4, p. 149, 152–154.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 104. Age given as Mississippian (?).

Occurs on slopes of Mount Agamenticus, York County.

Agamok Sediments

Precambrian (Knife Lake Series) : Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1615. Name applied to beds that have not been correlated successfully with any of the other 19 units of Knife Lake series described in this report. It seems these sediments were among earlier ones to form. They could antedate Knife Lake series if it were not for fact that some pebbles of Saganaga granite are found in conglomerate layers which are interstratified with slates and graywackes in NE¼ sec. 30, T. 65 N., R. 5 W. Sediments form a synclinorium which strikes about S. 60° E. between Ogishkemuncie and Gabimichigami Lakes.

Report covers belt in eastern Vermilion district more or less parallel to international boundary.

Agate Bay Group[1]

Precambrian (Keweenawan) : Northeastern Minnesota.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 143–146, pl. 14.

Exposed on Agate Bay, northeast of Duluth, St. Louis County.

Agathla Sandstone[1]

Lower Triassic: Northeastern Arizona and southeastern Utah.

Original references: D. Hager, 1924, Min. and Oil Bull., v. 10, no. 2, p. 137; no. 4, p. 383–384, 423, 437.

Near Agathla Peak, northern part of Navajo County, northeastern Arizona.

Agathla Shale[1]

Lower Triassic: Northeastern Arizona and southeastern Utah.

Original references: D. Hager, 1924, Min. and Oil Bull., v. 10, no. 2, p. 137; no. 4, p. 383–384, 423, 437.

Near Agathla Peak, northern part of Navajo County, northeastern Arizona.

Agattu Beds

Cretaceous or Tertiary: Southwestern Alaska.

R. P. Sharp, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1197; 1946, Jour. Geology, v. 54, no. 3, p. 193–199. Name applied to well-bedded sedimentary strata occurring on Agattu Island. Consist chiefly of amorphous silica and fine detritus derived from a volcanic terrain. Beds are gently tilted, faulted, and possibly folded. Thickness at least 2,000 feet. Deposits may be as old as Cretaceous but are more probably Tertiary.

Exposed on Agattu, Aleutian Islands.

†Agawa Iron-Formation Member (of Knife Lake Slate)[1]

Precambrian (Knife Lake Series): Northeastern Minnesota, and western Ontario, Canada.

Original reference: J. M. Clements, 1903, U.S. Geol. Survey Mon. 45.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1616; F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1035–1036. Suggests that term Agawa formation be dropped. In area of this report [Knife Lake region to northwestern Minnesota], Knife Lake series consists of 10 to 20 recognizable members. Agawa iron formation as described by Clements (1903) may not exist as a formation at all. It does not occur at a definite horizon in the series, and except on Lake Agawa it is never more than a very few feet thick. Some of Agawa formation of older surveys is really a replacement.

Named for exposures on shores of Agawa Lake, Ontario, 1½ miles north of international boundary.

Agawan Gypsum Bed (in Marlow Formation)

Permian: Southwestern Oklahoma.

C. C. Branson, 1954, Shale Shaker, v. 4, no. 6, p. 7. A thin white gypsum bed in the Marlow.

Occurs only in Grady and Stephens Counties.

Agency Shale Member (of Pierre Shale)

Agency Shale zone (in Sully Member of Pierre Formation)

Upper Cretaceous: North-central South Dakota.

W. L. Russell, 1930, South Dakota Geol. and Nat. History Survey Rept. Inv. 7, p. 5. Hard fissile very light gray shale defined as basal member of Pierre shale. Exposed thickness about 120 feet.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 8, 18, 19, 22–23, pls. 2, 3. Rank reduced to zone in Sully member (new) of Pierre formation.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 10), 2341, 2343. Abandoned. Agency-Oacoma zone redefined and included in DeGrey member (new) of the Pierre shale.

Named from Cheyenne River Agency where it is well exposed. Unit extends up Missouri River to within a few miles of mouth of Moreau River, down the Missouri below mouth of Cheyenne River, and some distance up Cheyenne River.

Agua Sandstone Member (of Santos Shale)[1]

Agua Sandstone Member (of Temblor Formation)

Miocene, lower: California.

Original reference: L. M. Clark and A. Clark, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 1, p. 137.

H. H. Heikkila and G. M. MacLeod, 1951, California Div. Mines Spec. Rept. 6, p. 4 (table 1), 5 (table 2), 8, pl. 1. Described in Bitterwater Creek area, where it is treated as basal member of Temblor formation. Consists of gray to buff fine- to medium-grained friable sandstone with abundant fragments of pectens. Thickness as much as 48 feet. Unconformably overlies Point of Rocks sandstone; overlapped by upper Santos shale.

Traceable from vicinity of Carneros Creek to mouth of Cedar Canyon, several miles northwest, Temblor Range, Kern County.

Agua Caliente Gabbro

Precambrian (Keweenawan?): Northern New Mexico.

Evan Just, 1937, New Mexico Bur. Mines Mineral Resources Bull. 13, p. 11, 25. Gabbroic rocks; not schistose. Suggests that they may be intrusive and of Keweenawan age.

Exposed on one of southern tributaries of Agua Caliente Creek, Picuris area.

Aguada Formation or **Limestone**

Miocene, lower: Puerto Rico.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85, 2 sheets. Proposed for transitional beds, approximately 75 meters thick, between underlying Río Guatemala group (new) and overlying Aymamón limestone (new). Consists essentially of interbedded hard pure limestone and softer chalky to marly limestone; from 1 to 10 meters of basal gravel, sand, and shale present where unit rests directly on Cretaceous rocks.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 33–34, pl. 2. In San Juan metropolitan district, consists predominantly of noncarbonate rocks; hence termed formation to allow for lithologic variation. Estimated thickness 325 feet; 62½ feet exposed in quarry near Bayamón hospital. There is some question whether formational name Aguada is correctly applied to these beds. From lithologic standpoint, they resemble noncarbonate clastic subdivisions of late Oligocene Río Guatemala group which, according to Zapp and others (1948), does not occur in San Juan area. Because no paleontologic study was made of middle Tertiary section of San Juan area in preparation of this report, formational assignment cannot be examined in light of age criteria.

W. H. Monroe, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B356, B358 (fig. 164.2). Oligocene and Miocene sequence in north-central Puerto Rico is (ascending) San Sebastian formation, Lares limestone, Cibao formation, Aguada limestone, and Aymamón limestone. Aguada, about 90 meters thick, consists of somewhat earthy limestone interbedded with chalk and marl.

Named from prominent exposures in vicinity of town of Aguada, near west coast of Island.

Aguadilla Limestone (in Arecibo Formation)

Miocene, lower: Puerto Rico.

C. J. Maury, 1919, Am. Jour. Sci., v. 48, no. 285, p. 214 (chart). Shown on correlation chart as subdivision of Arecibo formation above Lares limestone and below Quebradillas limestone. Upper Oligocene.

C. J. Maury, 1919, Science, v. 70, no. 1825, p. 609. Lower Miocene.

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 315. Not distinguished in field and of doubtful stratigraphic value. Lower Miocene.

Aguadulce Formation

Pleistocene(?): Panama.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 258.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 322. Poorly defined name for surficial deposits. Pleistocene(?).

Occurs in Aguadulce Plain, Coclé Province.

Agua Fria[1] Formation (in Amador Group)

Middle or Upper Jurassic: East-central California.

Original reference: N. L. Taliaferro, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 149.

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 283, 284. In Merced River section Agua Fria is uppermost formation in Amador group. Thickness 3,500 feet. Overlies Penon Blanco volcanics. Age of Amador group believed to be upper Middle to lower Upper Jurassic.

Occurs on Merced River and southward into Indian Gulch quadrangle.

Aguagua [Formation in Tapaliza Group or Member of Tapaliza Formation]

Aquaqua formation

Miocene: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no. 29, p. 131–132, 134 (chart). Correlation chart shows Aquaqua formation above Arusa formation and below Tuira formation. Upper Oligocene and lower Miocene.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (chart), 241. Tapaliza can be divided into an upper or Miocene part and a lower or Oligocene part. These are known respectively as the Aguagua and the Arusa.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5 Amérique Latine, fasc. 2a, p. 322. Aguagua formation is undefined name for early Miocene fine-grained deposits. Age based on foraminifera.

In Darien area.

Aguanga Tonalite

Cretaceous: Southern California.

J. F. Mann, Jr., 1955, California Div. Mines Spec. Rept. 43, p. 9 (table), pl. 1. Named on map legend in list of Cretaceous plutonics. Occurs below Lake Mountain tonalite and above San Marcos gabbro.

1956, California Dept. Public Works, Div. Water Resources Bull. 57, v. 1, pl. 13B; v. 2, p. B–21 (table B–1), B–34. Mapped in Santa Margarita

River watershed. Described as a biotite-rich quartz diorite. In plutonic sequence, occurs below Bonsall tonalite and above San Marcos gabbro.

Well exposed on north and south sides of Aguanga Valley and north of Lancaster Valley, Riverside County.

Aguas Buenas Limestone Member (of Fajardo Formation)

Aguas Buenas Limestone[1]

Upper Cretaceous: Puerto Rico.

Original reference: D. R. Semmes, 1919, New York Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, v. 1, p. 64.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47, 48 (table 4). Heading on table 2 (stratigraphic table for Puerto Rico) reads Upper(?) Cretaceous; however, text and other table headings do not qualify Upper Cretaceous.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 143. Assigned to member status in Fajardo formation. Contains rudistids and crinoid remains. Lies at base of formation and unconformably overlies nonstratified rocks of volcanic complex.

Named for occurrences near town of Aguas Buenas, San Juan district.

Agua Verde Shale Member (of Fayette Formation)

Eocene: Southern Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 269–270. Proposed for marine shales overlying Sanchez sandstone tongue. Shales are 150 feet thick, mostly gray green, and bentonitic but contain some red nonmarine beds in upper part. Underlies Villa Nueva sandstone member. In southern Zapata County, the shales appear to be overlapped by the Frio, or may, in part, grade into nonmarine shales that resemble Frio. Area in which Agua Verde shale crops out is limited, and beds are poorly exposed because of heavy overburden.

Named from Agua Verde ranchhouse on north line of Escobares quadrangle [Zapata County].

Agua Zarca Sandstone Member (of Chinle Formation)

Agua Zarca Sandstone Member (of Moenkopi Formation)

Upper Triassic: Northwestern New Mexico.

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. Consists of conglomeratic sandstone with occasional siltstone and silty shale. Underlies Salitral shale tongue (new); overlies Glorieta sandstone member of San Andres formation. From latitude of San Miguel Canyon, unit thins rapidly; in Mesa Poleo it is thin but recognizable.

J. A. Momper and W. W. Tyrrell, Jr., 1957, Four Corners Guidebook 2d Field Conf., p. 17. Age given as Lower Triassic. Type locality indicated.

J. A. Momper, 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 91, 92. Interpreted as basal sand member of Moenkopi. Thickness ranges from less than 70 feet to 150 feet across San Juan basin; Salitral member thickens westward in main body of Moenkopi at expense of underlying Agua Zarca.

Type locality: Agua Zarca Creek, Rio Arriba County.

Aguigan (Aguijan) Limestone

Pliocene or Pleistocene: Mariana Islands (Aguigan).

Risaburo Tayama and Yasushi Ota, 1940, Geomorphology, geology, and coral reefs of Aguijan Island: Tropical Industry Inst., Palau, South Sea Islands Bull. 6 [English translation in library of U.S. Geol. Survey, p. 16–17, 19 (chart)]; Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 55, table 4 [English translation in library of U.S. Geol. Survey, p. 66]. Gray well-bedded limestone. Unconformably underlies Mariana limestone. Pliocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 14–16. Age given as Pleistocene.

Occupies base of sea cliff on southern coast of island.

Aguila Sandstone

Upper Cretaceous: Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 19–20, pls. 2, 3. Massive light-brown medium-grained graywacke with closely spaced concretionary ledges and local thin conglomerate at top. Thickness at type locality 2,035 feet. Rests with apparent conformity upon Johnson Peak formation (new); at most places conformably underlies Serpiente sandstone (new); along south limb of Stoker Canyon syncline, where perhaps as much as 8,000 feet of Upper Cretaceous strata have been removed by erosion, Aguila is unconformably overlain by middle Eocene Avenal sandstone; locally underlies lower Eocene(?) beds.

Type locality: Stoker Canyon syncline, Orchard Peak area, Tent Hills quadrangle, Kern County. Named for Aguila Canyon on north limb of Stoker Canyon syncline.

Aguja Formation[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 271, 505, 506.

C. G. Moon, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 153, 170–173, pl. 1. Described in Agua Fria quadrangle. Consists primarily of sandstone and shale. Standstone yellowish gray, gray, and brown, fine grained; shales light to dark gray or almost black and blackish red; lignite and lignitic shales. Thickness, partial section, 101 feet. Underlies Terlingua beds; contact gradational. Wherever Aguja is overlain by Tertiary rocks, contact is distinctly marked by an unconformity which is angular in some localities and apparently disconformable in others.

Type locality: Sierra Aguja (Needle Peak), in the flat in front of Santa Helena fault scarp, 6 miles south of Terlingua, Brewster County.

Aguja sandstone

Precambrian (Protozoic): Northern Arizona.

C. R. Keyes, 1939, Pan-Am. Geologist, v. 71, no. 1, p. 69. Substitute title for the Protozoic Chiquito sandstone of the Grand Canyon.

Named for "The Needle," or Aguja, hillock at mouth of Little Colorado River, near entrance to Grand Canyon.

Ahearn Member (of Chadron Formation)

Oligocene, lower: Southwestern South Dakota.

John Clark, 1954, Carnegie Mus. Annals, v. 33, art. 11, p. 197. Designated as basal member of formation. Underlies Crazy Johnson member (new). Author previously described unit as "Lower Member" of Chadron.

Type locality: At standard section of Chadron formation in Big Badlands on south fork of Indian Creek, Pennington County, from sec. 34, T. 3 S., R. 12 E. to sec. 10, T. 4 S., R. 12 E. Name is that of a ranch formerly at mouth of south fork of Indian Creek.

Ahern Quartzite

See **Ahorn Quartzite.**

Ahlosa Member (of Caney Shale)

See Ahloso Member (of Caney Shale).

Ahloso Member (of Caney Shale)

Mississippian (Meramecian): South-central Oklahoma.

M. K. Elias, 1956, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 60–62, 70 (table 2). Name Ahlosa introduced for basal unit of Caney shale; commonly referred to as "Mayes" or "Ada Mayes." Consists of dark-gray fine-grained coarsely laminated to nearly massive calcareous shale. Thickness 25 to 190 feet. Underlies Delaware Creek member (new); overlies Welden limestone.

M. K. Elias and C. C. Branson, 1959, Oklahoma Geol. Survey Circ. 52, p. 5, 7, 21. Name emended to Ahloso. Type section designated. Thickness 49.2 feet.

Type section: Beds 10 to 18, measured section D, sec. 14, T. 2 S., R. 7 E., Johnston County. Name derived from village at junction of Highways 99 and 3, in sec. 14, T. 3 N., R. 6 E., about 3 miles southeast of Ada, Pontotoc County.

Ahorn Quartzite

Precambrian (Belt Series): Northwestern Montana.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 211, 213 (table 1), 217–218. Composed of two sharply demarcated units, a lower pink quartzite about 1,700 feet thick and an upper green and red argillite 400 feet thick. Because upper part of formation has been greatly eroded, thickness varies considerably within relatively short distances. Unconformably underlies Flathead formation; overlies Hoadley formation (new). Miller Peak argillite, Cayuse formation (new), Hoadley formation, and Ahorn quartzite are equivalent in age to lower and middle part of Missoula group of Clapp and Deiss (1931) in Sapphire and Garnet Ranges.

Present in Saypo and Silvertip quadrangles. Named from Ahorn Creek in southeastern corner of Silvertip quadrangle where headward part of creek is incised in these rocks.

Ahtell Diorite[1]

Carboniferous: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 38, map.

Composes hills drained by west tributaries of Ahtell Creek.

Aibonito Conglomerate[1]

Cretaceous: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 61.

†Aiken Beds[1]

Upper Cretaceous and Pliocene(?): Western South Carolina.

Original reference: E. Sloan, 1904, South Carolina Geol. Survey, ser. 4, Bull. 1, p. 72.

Exposed at Aiken, Aiken County.

Aimeliik Formation

Aimiriiki Agglomerate

See Aimiliiki Agglomerate or Conglomerate.

Aimiliiki (Aimiriiki) Agglomerate or Formation

Eocene, upper: Caroline Islands (Babelthuap).

Risaburo Tayama and Misaburo Shimakura, 1937, On the coal of Babelthuap Island, Palau group. Geol Soc. Japan Jour., v. 44, no. 6, p. 526 [English translation in library of U.S. Geol. Survey, p. 1]. Aimiliiki listed in stratigraphic succession on Babelthuap. Below lignite-bearing beds and above Galdog beds.

Risaburo Tayama, 1939, Brief report on the geology and ore resources of Babelthuap Island (Palau Island proper): Tropical Industry Inst., Palau South Sea Islands Bull. 3 [English translation in library of U.S. Geol. Survey, p. 8–9]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 65, table 4 [English translation in library of U.S. Geol. Survey, p. 77]. Older than Almongui agglomerate and younger than Ngardok beds. Agglomeratelike tuff; contains fragments of amygdaloidal andesite, shale, and limestone in lower part.

S. Hanzawa *in* J. Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 16. Conformably and locally unconformably underlain by Ngardok (Galdog) formation and probably unconformably overlain by Ngaremlengui (Almonogui) agglomerate. Upper Eocene.

U.S. Army Corps of Engineers, 1956, Military geology of Palau Islands, Caroline Islands: U.S. Army Corps of Engineers, Far East, p. 40–45, pls. 4, 8, 9. Aimeliik formation consists of andesitic basaltic volcanic breccias, tuff breccias, and tuff. Divided into older Ngarsul member and younger Ngardok member. Thickness may be more than 2,000 feet. Overlies Babelthuap formation; underlies Ngeremlengui formation. Eocene.

Type locality: Aimelik, Babelthuap Island.

Ainoni Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 76. Nepheline basalt flow about 100 feet thick, and associated cinder cone. Eruption probably occurred simultaneously with that of Maunawili volcanics. Distribution noted.

Named for Ainoni Spring, which issues from east margin of flow. Flow is 0.75 mile long and 0.5 mile wide; lies on northeast side of Koolau Range about 8 miles northwest of Makapuu Head.

Ainsworth Formation[1]

Upper Cretaceous: Southwestern South Dakota and northwestern Nebraska.

Original reference: F. Ward, 1922, South Dakota Geol. and Nat. History Survey Bull. 11.

First described in southeastern part of Pennington County and southwestern part of Jackson County, S. Dak.

Airai Clay or Formation

Airai Lignite Bearing Beds

Miocene and Pliocene: Caroline Islands (Babelthuap).

Risaburo Tayama, 1939, Brief report on the geology and ore resources of Babelthuap (Palau Island proper): Tropical Industry Inst., Palau, South Sea Island Bull. 3 [English translation in library of U.S. Geol. Survey, p. 6–7, 17]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull. v. 11, p. 66, table 4 [English translation in library of U.S. Geol. Survey, p. 78–79]. Referred to as lignite-bearing beds containing carbonaceous clay, sand and gravel, and brown lignite. Thickness on Palau proper, less than 40 meters. Resembles Talofofo peat-bearing beds on Guam. Older than Palau limestone; younger than Alumongui agglomerate. Pliocene.

U.S. Army Corps of Engineers, 1956, Military geology of Palau Islands, Caroline Islands: U.S. Army Corps of Engineers, Far East, p. 39 (table 5), 52–55, pls. 4, 8, 9. Airai clay or formation probably has maximum thickness of 150 feet, but beds rest on irregular base. Assigned to Miocene and Pliocene, but exact age not certain. Probably equivalent to lower beds of Palau limestone at some localities, although not lowermost beds of Palau.

Named for deposits north of Goikul, in Airai municipality.

Air Point Granite[1]

Precambrian: Southwestern Virginia.

Original reference: A. I. Jonas, 1933, Geol. Soc. America Bull., v. 44, p. 29–30.

Edward Steidtmann, 1945, Virginia Geol. Survey Bull. 64, p. 26, 27–28. Mentioned in discussion of commercial granites in Virginia.

Named for Air Point on Bent Mountain, Roanoke County.

Aitkin Formation[1]

Precambrian (upper Huronian): Central Minnesota.

Original reference: C. Zapffe, 1930, Lake Superior Min. Inst. Proc., v. 28, p. 101–106.

Underlies large area in northern and eastern parts of Aitkin County and extends into Crow Wing and Cass Counties.

Ajax Dolomite

Ajax Limestone[1]

Upper Cambrian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 5 (fig. 2), 9, 11 (fig. 3). Limestone described in East Tintic Mountains. Subdivided into three members: lower, 90 to 100 feet thick, chiefly medium- to coarse-grained medium- to dark-blue-gray faintly mottled dolomite which encloses pods and short lenses of black and brown chert; Emerald dolomite member, about 30 feet; upper, averaging about 450 feet, chiefly dolomite with thin-bedded argillaceous dolomite at top. Conformably overlies Opex formation; conformably underlies Opohonga limestone.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 25–26, 28 (fig. 4). Limestone described in Stansbury Mountains where it is 750 to 900 feet thick. Overlies Dunderberg shale and underlies Garden City formation.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 57, pls. 1, 17. Described in Sheeprock Mountains where it is entirely dolomite. Thickness in West Lookout Hills 1,012 feet. Includes Emerald member, 150 feet thick, near middle. Underlies House limestone; overlies Opex formation.

Named for Ajax mine, one-fourth mile east of Mammoth, Tintic district.

†Ajax Quartzite[1]

Middle Cambrian: Southeastern Arizona.

Original reference: J. A. Church, 1903, Am. Inst. Mining Engineers Trans., v. 33, p. 3–37.

In Tombstone district.

Ajibik Quartzite[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 540.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1436 (table 1), 1461. Palmer gneiss, previously considered pre-Huronian, consists of metamorphic Mesnard quartzite, Koma dolomite, Wewe slate, and Ajibik quartzite. Table 1 shows middle Huronian sequence in Marquette area (ascending): Ajibik quartzite, Siamo slate, and Negaunee iron-formation.

W. T. Stuart, E. A. Brown, and E. C. Rhodehamel, 1954, Michigan Dept. Conserv., Geol. Survey Div. Tech. Rept. 3, p. 11 (table 3). Thickness 700 to 900 feet in Marquette district. Underlies Siamo slate. Overlies Wewe slate; unconformity. Middle Huronian.

Typical exposures on Ajibik Hills northeast of Palmer.

Ajo Volcanics

Tertiary, middle(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 15 (table 1), 43–45, pl. 1; 1946, U.S. Geol. Survey Prof. Paper 209, p. 39–40. Biotite and hornblende andesite tuffs and breccias, passing upward into flows. Unconformably underlies Sneed andesite (new); interfingers with underlying Locomotive fanglomerate (new). Thickness 3,500 to 5,000 feet.

Ajo quadrangle, Pima County. Caps Ajo Peaks; makes up hills west and southwest of Ajo Peaks and extends for about 3 miles in low range of hills southeastward from peaks.

†Akins Shale Member[1] (of Winslow Formation)

Pennsylvanian: Central eastern Oklahoma.

Original reference: J. A. Taff, 1905, U.S. Geol. Survey Geol. Atlas, Folio 122.

Named for Akins, Sequoyah County.

Akron Dolomite[1]

Upper Silurian: Western New York and Ontario, Canada.

Original reference: A. W. Grabau, 1909, Geol. Soc. America Bull., v. 19, p. 544, 550.

Winifred Goldring, 1946, New York State Mus. Bull. 332, p. 129. Dolomitic phase of Cobleskill limestone in Erie County.

D. W. Fisher, 1959, New York State Mus. Sci. Services Geol. Map and Chart Ser. 1. Shown on correlation chart above Williamsville waterlime of Bertie group.

Named for exposures in village of Akron, Erie County, N.Y.

†Alabama White Limestone[1]

Tertiary: Alabama.

Original reference: T. L. Casey, 1902, Philadelphia Acad. Nat. Sci. Proc., v. 53, p. 513.

Exposed on Tombigbee River near St. Stephens and on Alabama River near Claiborne, Monroe County.

Alabaster Gypsum Member (of Blaine Formation)

Permian: Oklahoma.

Sherwood Buckstaff, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4, p. 434–435. A fifth gypsum bed, called by field men the "alabaster" or "rock-crusher" gypsum, and lying between the Shimer and Medicine Lodge members of the Blaine as defined by Evans (1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4, p. 409–412), is present in Blaine County. Probably not present in area discussed by Evans, but should be considered in any complete revision of Blaine nomenclature.

D. A. Green, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1468. Name applied to gypsum bed in Blaine formation; occurs above Medicine Lodge member and below Shimer gypsum member. Thickness 3 feet.

Occurs northwest of El Reno in Canadian County.

Alachua Formation[1]

Pliocene: Northern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 127–130, 157, 320.

H. E. Wood, 2d, and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 13, pl. 1. Hemphillian.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 189–208. As described in Citrus and Levy Counties, Alachua includes terrestrial deposits of diverse lithology, but is composed largely of clays, fine sands, and a basal rubble of phosphate rock, silicified wood, clay beds, and silicified Suwannee and Ocala limestone residuum. Sediments rest on bedrock of limestone ranging in age from middle Eocene to Oligocene, except in Citrus County where they interfinger with, and, in part, lie upon

Hawthorn formation. Unconformably overlain by fine to medium quartz sand containing no phosphate and believed to be early Pleistocene in age. Undetermined phosphate clay mineral forms matrix for much of fine sand and phosphate rubble, and Alachua formation is characterized by presence of this mineral and by fairly numerous specimens of vertebrate remains contained in sinks and depressions. These vertebrates range in age from lower Miocene into Pleistocene, and sediments of formation may have accumulated not only throughout Miocene epoch but also during period extending into Pleistocene. No stratigraphic relationships were determined during identification of vertebrate fossils, and presence of Pliocene and Pleistocene fossils may represent contamination by entrapment of these animals during epochs following Miocene, Maximum thickness about 66 feet.

H. S. Puri and R. O. Vernon, 1956, (abs.) Jour. Paleontology, v. 30, no. 4, p. 1000. Facies in Hawthorn facies of Alum Bluff stage.

K. B. Ketner and L. J. McGreevy, 1960, U.S. Geol. Survey Bull. 1074–C, p. 59–62. Lower Miocene strata commonly included in Alachua formation of Sellards (1914, Florida Geol. Survey 6th Ann. Rept.) are included in Tampa limestone. Simpson (1930, Am. Mus. Nat. History Bull., v. 59), who considered type locality of Alachua to be in vicinity of Williston, reviewed evidence to determine age of formation. He studied vertebrate fossils, which were collected from clay of Alachua on Mixson farm and from largely unknown stratigraphic positions in several hardrock phosphate mines north of area. He concluded that Alachua is late Miocene or early Pliocene in age. Cooke (1945, Florida Geol. Survey Bull. 29), on basis of same fauna, designated age as middle Pliocene. Authors of present report believe that term Alachua should be used only in its original sense; that is, for clay deposits which Simpson designated to be of late Miocene or early Pliocene age, typified by those on Mixson farm.

Named for its many exposures in Alachua County.

Aladdin Sandstone

Middle Ordovician: Eastern Wyoming and western South Dakota.

M. R. McCoy, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 45 (chart), 46–47. Quartzose-type sandstone which is occasionally calcareous. Commonly 25 to 30 feet thick. Conformably underlies Ice Box shale (new); conformably overlies Deadwood formation.

Type section: Bear Lodge Mountains, Crook County, Wyo., in sec. 14, T. 52 N., R. 63 W. Formation crops out on southern flank of Sheep Mountain, where it is exposed by faulting. Name taken from town of Aladdin, Wyo.

Alajuela Formation

See **Alhajuela Sandstone Member** (of Caimito formation).

Alameda Formation[1]

Pleistocene: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, **Folio 193.**

D. H. Radbruch, 1957, U.S. Geol. Survey Misc. Inv. Map I–239. Overlain by Temescal formation, Merritt sand, or Bay mud. Maximum known thickness 1,050 feet (south of Oakland West quadrangle).

Named for fact that it is well developed at Alameda, San Francisco region.

Alamito shale[1]

Pennsylvanian: New Mexico.

Original reference: C. R. Keyes, 1906, Jour. Geology, v. 14, p. 147–154.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 22. Keyes proposed to divide Pennsylvanian into two (or possibly three) series which he called Ladronesian below and Manzanan above. He listed term Alamito under Ladronesian. He did not give source or definition of any of his terms. Terms introduced by Keyes are not considered established and are not used in present report.

Alamo Formation

Pliocene, lower: Northern California.

A. S. Huey, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 335. Incidental mention.

Carlton Condit, 1938, Carnegie Inst. Washington Pub. 476, p. 224, 228. Underlies Orinda formation; overlies Neroly formation. Southwest side of Mount Diablo.

B. L. Clark, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1957. Underlies newly defined Green Valley formation (previously referred to as Orinda).

B. L. Clark *in* C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 585, chart 11. Abandoned; formation renamed Diablo.

G. D. Louderback, 1951, California Div. Mines Bull. 154, p. 76. Mentioned as 1,000 feet of marine beds deposited above Neroly beds during lower Pliocene.

Occurs in Tesla quadrangle located about 40 miles southeast of Berkeley.

Alamogordo Member (of Lake Valley Formation)

Mississippian (Osage): Southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1941, (abs.) Tulsa Geol. Soc. Digest, v. 9, p. 73, 74 (strat.. column); 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 12, p. 2114–2116, 2118–2119 (figs. 5, 6), 2125–2133. Defined as basal member of Lake Valley formation. Consists normally of four distinct facies: siltstone at base, overlain by hard cherty limestone, overlain by soft blue-gray marl, and capped with gray thin-bedded crinoidal limestone. Member is complicated by large crinoidal bioherms; bioherm facies consists of rounded dome-shaped masses of black relatively unfossiliferous almost featureless limestone. Thickness 130 feet. Underlies Arcente member (new); unconformably overlies Caballero formation (new).

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 13, 26, 27 (fig. 13). As originally defined Alamogordo included beds here designated as Andrecito, Nunn, and Tierra Blanca. Alamogordo is here restricted to massive black very cherty poorly fossiliferous cliff-forming limestone beds above thin-bedded Andrecito member and below blue-gray crinoidal marls of Nunn member. Thickness averages from 30 to 50 feet and is fairly constant. Alamogordo (restricted) makes conspicuous scarp along front of Sacramento Mountains.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 74 (fig. 9), 83, 84 (fig. 10). Geographically extended to Caballo Mountain area where it is shown as overlying Percha shale.

Type area: Deadman Canyon, sec. 3, T. 17 S., R. 10 E., near Alamogordo, Otero County.

Alamosa Formation[1]

Pliocene, upper, or Pleistocene, lower: Central southern Colorado.

Original references: C. E. Siebenthal, 1910, Science, new ser., v. 31, p. 745; U.S. Geol. Survey Water-Supply Paper 240, p. 40.

W. J. Powell, 1958, U.S. Geol. Survey Water-Supply Paper 1379, p. 20–24. Underlies large part of San Luis Valley but is well exposed only in southern part, where Rio Grande and its tributaries have cut into upper part of formation. Thickness 41½ feet at Hansen Bluff on east bank of Rio Grande southeast of Alamosa. Recent deposits overlie Alamosa, but similarity of materials make it difficult to determine contact between the two; in this report, Recent materials are included in Alamosa except in some well logs. Most reliable data on formation comes from well logs.

Named for Alamosa, Conejos County, near center of San Luis Valley.

Alapah Limestone (in Lisburne Group)

Upper Mississippian: Northern Alaska.

A. L. Bowsher and J. T. Dutro, Jr., 1957, U.S. Geol. Prof. Paper 303–A, p. 4, 6, 25–34, figs. 2–4, pl. 2. Forms upper part of Lisburne group. Comprises nine unnamed members at type locality (ascending): shaly limestone, 85 feet thick; dark limestone, 175 feet; platy limestone, 187 feet; banded limestone, 210 feet; black chert-shale, 38 feet; light-gray limestone, 46 feet; fine-grained limestone, 80 feet; chert-nodule member, 80 feet; and upper limestone, 70 feet. Total thicknss 970 feet. Disconformably overlies Wachsmuth limestone (new).

Type locality: On northern part of Mount Wachsmuth, Shainin Lake area, central Brooks Range. Named from Alapah Creek, which flows into south end of Shainin Lake.

Alapah Mountain Glaciation

Pleistocene (late Wisconsin): Northern Alaska.

R. L. Detterman, A. L. Bowsher, and J. T. Dutro, Jr., 1958, Arctic, v. 11, no. 1, p. 45, 54–57, 60 (table 1), figs. 2, 3. Six glacial advances recognized in northern Brooks Range and on Arctic Slope. Alapah Mountain preceded by Echooka and Itkillik glaciations and succeeded by Fan Mountain glaciation (new). Deposits largely remnants of unsorted drift composed of limestone, sandstone, and shale fragments derived from nearby cirques. Morainal areas contain kettle lakes, and consequent drainage has undergone little or no modification.

Morainal remnants found in pass between Anaktuvuk River and Ernie Creek 16 miles south of Shainin Lake, these deposits having been formed at snouts of glaciers originating on slopes of Alapah Mountain, Arctic slope of Brooks Range.

Alaska Bench Limestone[1] (in Big Snowy Group)

Alaska Bench Limestone Member (of Amsden Formation)

Mississippian or Pennsylvanian: Central Montana.

Original reference: O. W. Freeman, 1922, Eng. and Min. Jour.-Press, v. 113, no. 19, p. 826–827.

P. A. Mundt, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1925–1929. Limestone is light to dark brown and gray, with dull purplish red mottlings. Where exposed, commonly weathers to shades of pink, red, and gray; weathered Alaska Bench limestone superficially resembles unweathered carbonate rocks of Amsden formation. Many workers have assigned both limestone and overlying dolomite to Amsden, and this is common usage among Montana geologists. Thickness along

Durfee Creek, Fergus County, 201 feet. Underlies Amsden formation; overlies and is gradational with Tyler formation.

H. D. Hadley and P. J. Lewis, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 142, 143. Overlies Cameron Creek formation and underlies Devils Pocket formation (both new).

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 332 (fig. 2), 334 (fig. 3), 338–339, 347. Included in Big Snowy group. Alaska Bench limestone, as used in this report, includes not only massive limestone sequence recognized by Freeman but also similar and closely related overlying beds of limestone and dolomite that are missing from type area but that are exposed on south flank of Big Snowy Mountains. Freeman gave no specific measured section for formation but implied that Beacon Hill, sec. 6, T. 12 N., R. 20 E., should be type locality. On Alaska Bench and throughout most of Fergus County, all overlying strata and much of Alaska Bench limestone itself have been removed by erosion; only known complete surface sections are in vicinity of Stonehouse Ranch on south slope of Big Snowy Mountains and at Durfee Creek. Overlies Cameron Creek formation; underlies Devils Pocket formation.

R. P. Willis, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1942 (fig. 2), 1963. Reallocated to member status in Amsden formation (restricted). Underlies unnamed dolomite member; overlies Cameron Creek member of Tyler formation.

Well exposed on top of Alaska Bench, east of the Snowies. Forms series of hogbacks and sloping benches around Big Snowy Mountains.

Alaskan Glaciation

Recent: Alaska.

T. N. V. Karlstrom, 1957, Sci., v. 125, no. 3237, p. 74. Named on correlation chart of Alaskan glacial sequences. Younger than Naptowne glaciation.

T. N. V. Karlstrom, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B331 (fig. 153.1). Table shows Alaskan glaciation as Recent. Includes Tustumena and Tunnel advances.

Report discusses Cook Inlet area.

Albanian series[1]

Permian: North-central Texas.

Original references: C. R. Keyes, Pan-Am. Geologist, 1933 v. 57, p. 350, 351; 1933, v. 59, p. 144, 146.

Albany Clay[1]

Pleistocene: Eastern New York and western Vermont.

Original reference: E. Emmons, 1846, New York Nat. History, Agric., v. 1, p. 202–204.

G. H. Chadwick, 1944, New York Mus. Bull. 336, p. 196 (fig. 72). Varved clays in part of Cats Kill delta in Lake Albany.

Well developed at Albany, N.Y.

Albany Conglomerate[1]

Lower Ordovician: Northeastern Vermont.

Original reference: C. H. Richardson, 1929, Vermont State Geologist 16th Rept., p. 107–110.

In Orleans County.

†Albany Formation[1]

Permian: Northern Texas and southwestern Oklahoma.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., pl. 3, p. lxvii.

J. E. Adams and others, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1677. Incidental mention in discussion of Wolfcamp series equivalents.

Well developed in vicinity of Albany, Shackelford County, Tex.

Albany Granite[1]

Upper Devonian or Upper Carboniferous: Northern New Hampshire.

Original references: C. H. Hitchcock, 1874, Geology of New Hampshire, pt. 1, p. 508–545; 1877, pt. 2, p. 143.

In northern part of Carroll County.

Albany Porphyritic Nordmarkite[1]

Devonian(?): New Hampshire.

Original reference: L. Kingsley, 1931, Am. Jour. Sci., 5th, v. 22, p. 143.

Albany Porphyritic Quartz Syenite (in White Mountain Plutonic-Volcanic Series)

Albany Quartz Syenite[1]

Mississippian(?): New Hampshire.

Original reference: C. R. Williams, 1934, Appalachia, v. 20, no. 4, Summer Mag. No., p. 73.

Alonzo Quinn, 1941, Geology of the Winnipesaukee quadrangle, New Hampshire: New Hampshire State Plan. and Devel. Comm., p. 14, geol. map. Albany porphyritic quartz syenite mapped in Winnipesaukee quadrangle. Included in White Mountain magma series. Probably Carboniferous.

Alonzo Quinn, 1953, Geology of the Wolfeboro quadrangle, New Hampshire: New Hampshire State Plan. and Devel. Comm., p. 13, geol. map. Mapped in northwestern part of Wolfeboro quadrangle. Intrudes Moat volcanics. Mississippian.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Included in the White Mountain plutonic-volcanic series of Mississippian(?) age.

Town of Albany is in Carroll County.

Albany and Boston Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 25–27, 80, 81, 85, chart.

Named for occurrence in Albany and Boston mine, Houghton County.

†Albany and Boston Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 53–57, 61, 81, 84, 85, chart.

Named for occurrence in Albany and Boston mine, Houghton County.

Albee Formation[1]

Ordovician: Northwestern New Hampshire and eastern Vermont.

Original reference: M. Billings, 1934, Science, v. 79, no. 2038, p. 55–56.

M. P. Billings, 1937, Geol Soc. America Bull., v. 48, no. 4, p. 472–475, pl. 1. Four belts of Albee formation cross area [Littleton-Moosilauke], one near Gardner Mountain (Littleton quadrangle), second near Towns Mountain (Littleton quadrangle), third near village of Littleton, and fourth near villages of Lisbon and Bath. Thickness about 4,000 feet. Base not exposed in area. Not everywhere possible to establish precise boundary between Albee and overlying Ammonoosuc volcanics. Probably Upper Devonian.

J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle (1:62,500): New Hampshire Highway Dept. In Grafton County, includes Piermont member (new). Thickness about 5,000 feet. Ordovician.

J. B. Hadley, 1950, Vermont Geol. Survey Bull. 1, p. 17. Geographically extended into Orange County, Vt. Two narrow tongues of formation extend on either side of Orfordville formation just south of village of Bradford.

D. J. Melton, 1960, New England Intercollegiate Geol. Assoc. Guidebook 52d Ann. Mtg., p. 25. Stratigraphic nomenclature developed by Billings and his coworkers in New Hampshire is, in general, valid in Speck Mountain quadrangle, Maine, but is used here only in an informal sense. Oldest formation is Albee considered to be of Ordovician age.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, pl. 3. Shown on correlation chart as Middle Ordovician.

Type locality: That part of Gardner Mountain which lies between Hunt Mountain (just southwest of Littleton quadrangle) and Albee Hill in Littleton quadrangle, New Hampshire.

Alberhill Clay[1]

Eocene: Southern California.

Original reference: P. H. Dudley, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 223.

P. H. Dudley, 1936, Geol. Soc. America Bull., v. 47, no. 3, p. 361. Clays include marine, lacustrine, and residual facies. Shown on table as underlying San Jacinto sediments and overlying late Jurassic(?) Cajalco quartz monzonite.

Occurs in area between towns of Riverside, San Jacinto, Corona, and Elsinore.

Albertan System

Middle Cambrian: Western North America.

A. W. Grabau, 1921, A text book of geology, pt. 2, Historical geology; New York, D. C. Heath & Co., p. 243 (footnote). Author states he proposed name Albertan for Middle Cambrian of Pacific Province in his "Geology of the Non-Metallic Mineral Deposits other than Silicates," v. 2, chapter 21, 1920. [Apparently this was never published.]

A. W. Grabau, 1936, Pan-Am. Geologist, v. 66, no. 1, p. 24. Restricted to western North America where Cambrian (old Middle Cambrian) has its greatest development.

Albin shale[1]

Upper Cambrian: Northeastern Iowa.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 319, 326.

Named for fine exposures at Albin, Allamakee County.

Albion Formation or Shale

Mississippian (Meramecian): Southeastern Oklahoma.

B. H. Harlton, 1947, Tulsa Geol. Soc. Guidebook Field Trip, May 8, 9, and 10, p. 41. Basal section of Stanley is well exposed on east side of Black Knob Ridge in T. 1 S., R. 12 E., and along outer periphery of Potato Hills, especially in T. 2 N., R. 19 E. Gray to dark-gray fossiliferous siliceous shale bed, about 20 feet thick, is present near base. T. A. Hendricks contemplates using name Albion for this shale.

R. M. Becker, chm., 1954, Ardmore Geol. Soc. [Guidebook] Field Trip, October 1954, chart facing p. 1. Shown on chart as underlying Ten Mile Creek formation.

Albion Glacial Stage

Pleistocene (Wisconsin): North-central Colorado.

R. L. Ives, 1953, Geog. Review, v. 43, no. 2, p. 237–243, 249 (table). Time covered by deposition of Albion moraines. Younger than Pretty Meadow glacial stage (new).

Area: Silver Lake Valley at head of North Boulder Creek in Boulder County.

Albion Gravel[1]

Pleistocene: Central northern Iowa.

Original reference: S. W. Beyer, 1897, Iowa Geol. Survey, v. 7, p. 210, 231.

Albion, Marshall County.

Albion Group

Albion Sandstone[1]

Albion Series

Lower Silurian: Western New York and Ontario, Canada.

Original reference: E. O. Ulrich, 1913, Int. Geol. Cong. 12th, Canada, p. 26, 27, 30, 36, 39.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 15–26. Term Albion group, Medinan series, used in this report [Clyde and Sodus Bay quadrangles] in preference to Alexandria group. Term used to include Whirlpool sandstone, Manitoulin sandstones and shales, Cabot Head shale, and Grimsby sandstones and shales. Grimsby sandstone is oldest rock cropping out in area of report. There may be an equivalent age relationship between Albion group and Alexandria group. Overlies Richmond group.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Term Albion group used to include (ascending) Whirlpool sandstone, Manitoulin shale, Cabot Head shale (restricted), Grimsby sandstone, and Thorold sandstone. Occurs below Clinton group. Term Albion series used for lower part of Silurian below Niagaran series.

R. E. Griswold, 1951, New York Water Power and Control Comm. Bull. GW–29, p. 10–12. Only upper beds of Albion sandstone are exposed in Wayne County. These consist mainly of thick red layers of sandstone interbedded with a few layers of red sandy shale; pebbly layer present locally. Thickness about 119 feet. Underlies Clinton formation of Niagara group.

J. J. Galloway, J. B. Patton, and T. G. Perry, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Term Albion series used on generalized stratigraphic column of Silurian rocks exposed in Jefferson and Switzerland Counties. Includes Medina group.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1983, 1984. Silurian of type section along Niagara Gorge is divided into three groups (ascending): Medinan, Clintonian, and Niagaran. Recommended that term Albion be suppressed.

Named for village of Albion, Orleans County, N.Y.

Albion Monzonite

Cretaceous(?): Eastern Colorado.

R. L. Ives, 1950, Sci. Monthly, v. 71, no. 2, p. 114. Albion monzonite of Colorado Front Range is substantially similar to Little Cottonwood monzonite in Little Cottonwood Canyon, Utah.

R. L. Ives, 1953, Geog. Rev., v. 43, p. 232 (fig. 3). Albion monzonite mapped in Silver Lake Valley.

Silver Lake Valley is at head of North Boulder Creek, Boulder County.

Albion Schist Member (of Westboro Quartzite)[1]

Precambrian(?): Eastern Rhode Island.

Original reference: B. K. Emerson and J. K. Perry, 1907, U.S. Geol. Survey Bull. 311, p. 8, 10–13, map.

A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Survey Quad. Map [GQ–1]. Lens of schist 4,500 feet long and 400 feet thick lying within Westboro quartzite. Includes conglomerate beds that contain boulders as much as 10 feet in diameter.

Extends northwestward from village of Albion that it underlies.

Albion Range Group[1]

Precambrian(?): South-central Idaho.

Original reference: A. L. Anderson, 1934, Jour. Geology, v. 42, no. 4, p. 377–379.

C. P. Ross and J. D. Forrester, 1947, Geologic map of the State of Idaho (1:500,000): U.S. Geol. Survey. Age given as Precambrian(?).

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 3–4. Postulated Precambrian(?) beds in Cassia County were first named Harrison series by Anderson (1931) and later changed to Albion group by Anderson (1934). Consists mainly of quartzite, with some schist and marble. Thickness more than 9,000 feet. Anderson suggests correlation between his Albion Range group and Hyndman and East Fork formations on basis of lithologic similarity. Not correlated with Belt series.

Type locality not stated, but Albion Range is in Cassia County.

Albirupean Black Marl[1]

Upper Cretaceous: Maryland.

Original reference: P. R. Uhler, 1901, Maryland Acad. Sci. Trans., new ser., v. 1, p. 185–201.

†Albirupean Formation[1]

Upper Cretaceous: Eastern Maryland and Virginia.

Original reference: P. R. Uhler, 1888, Am. Phil. Soc. Proc., v. 25, p. 42, map.

Excellent sections on the Severn River, Md.

Alboroto Rhyolite (in Potosi Volcanic Group)

Alboroto Quartz Latite[1] or Group

Tertiary, middle or upper: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13, p. 20, 36.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 93 (table 18), 132–143, pl. 1. Referred to as rhyolite. Described in detail in San Juan district. Lies between Sheep Mountain quartz latite (below) and Huerto quartz latite (above). Lower part chiefly tridymite rhyolite, 0 to 500 feet thick, which consists of widespread thin flows and associated tuff beds. Found chiefly near borders of mountains. Includes Campbell Mountain rhyolite, Willow Creek rhyolite, and probably Outlet Tunnel quartz latite [all included in Alboroto group] of Creede district. Upper part biotite-hornblende latitic rhyolite, 0 to 3,000 feet, makes up most of formation; includes Equity and Phoenix Park quartz latites [included in Alboroto group] in Creede district.

U.S. Geological Survey currently designates the age of the Alboroto Rhyolite or Group as middle or upper Tertiary on the basis of age change of Potosi Volcanics.

First described in Platoro-Summitville district.

Albright Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Northeastern West Virginia and western Maryland.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Preston County, p. 140.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 120. Bloomfield limestone member of the Conemaugh was named by Stout (1918) in Muskingum County, Ohio. According to Waagé (1950, Maryland Dept. Geology, Mines and Water Resources Bull. 9), Hennen and Reger (1914) named an equivalent limestone in Preston County, W. Va., the Albright. Thus, Albright has precedence over Bloomfield. Recommended that term Albright replace term Bloomfield if and when positive correlation is determined.

Occurs at Albright, Preston County, W. Va.

Albuquerquan series[1]

Precambrian: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geological formations of New Mexico, p. 4.

Exposed in the Tijeras Canyon, east of Albuquerque.

Albuquerque Marl[1]

Tertiary, upper: Central northern New Mexico.

Original reference: C. L. Herrick, 1898, Am. Geologist, v. 22, p. 26–43.

Kirk Bryan and F. T. McCann, 1937, Jour. Geology, v. 45, no. 8, p. 806. Mentioned in discussion of Santa Fe formation. Herrick recognized dissimilarities between valley fill at Albuquerque and Santa Fe marls of Hayden (1869) and Cope (1874, U.S. Geol. and Geog. Survey W. 100th Mer. (Wheeler report), p. 115–130), but his attention was largely directed to caliche on the upland surface, which he regarded as lake deposit. His term Albuquerque marl applies strictly to the caliche.

Named for occurrence in Albuquerque region.

Albuquerque series[1]

See Rio Grande series.

Alcalde Shale (in Panoche Formation or Group)

Upper Cretaceous: Central western California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2), 991. Panoche group (or formation) is subdivided into 10 units. Alcalde shale is seventh in sequence (ascending). Underlies Joaquin Ridge sandstone (new); overlies Los Gatos sandstone. Assigned to Cachenian stage (new). Name credited to J. Q. Anderson.

Occurs in Alcalde Hills, Coalinga-Ortigalito area, San Joaquin Valley.

Alcova Limestone Member (of Chugwater Formation)[1]

Alcova Dolomite (in Chugwater Group)

Triassic: Central Wyoming.

Original reference: W. T. Lee, 1927, U.S. Geol. Survey Prof. Paper 149, p. 14.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 135. In Wind River basin, referred to as Alcova dolomite in Chugwater group. Overlies Red Peak formation; underlies Crow Mountain formation.

J. D. Love and others, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 17. Underlies Popo Agie member; overlies Red Peak member. Crow Mountain member not present in area of this report [central Wyoming]. Thickness ranges from wedge-edge to 15 feet.

T. C. Woodward, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 230, 231. In Deadman Butte area, Alcova member overlies Red Peak member and underlies Crow Mountain sandstone member (restricted usage). Thickness 6 to 10 feet.

G. N. Pipiringos, 1957, Wyoming Geol. Survey Bull. 47, p. 2, 9 (table 1), 13–15, pl. 5. Described in Laramie basin where it consists of about 11 feet of limestone, separated into beds 1 to 4 feet thick, colored gray black, purple to green brown, green gray and gray white; upper and lower parts sandy. Overlies main body of Chugwater; under lies Jelm formation (restricted). Contains mollusks of probable Early Triassic; may be Middle Triassic, but unlikely to be of Late Triassic age.

E. D. McKee and others, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I-300, p. 12. In this report [paleotectonic map of Triassic], Alcova member is assigned to interval C, which is approximately correlative with Upper Triassic series and with Karnian, Norian, and Rhaetian of Europe.

Named for occurrence near Alcova, Natrona County.

Alcyone Trachyte[1]

Teritary, middle or upper: Northwestern Arizona.

Original references: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743; Carl Lausen, 1931, Arizona Bur. Mines Bull. 131, Geol. Ser. 6, p. 27, map.

Named for Alcyone mine.

Alden Limestone[1]

Mississippian: North-central Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 52, 92, 99.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 101, 150. Also called Gilmore City limestone.

Named for exposures in south bank of Iowa River, just below wagon bridge at town of Alden, Hardin County.

Alden Limestone[1] (in Arbuckle Group)

Ordovician: Southern Oklahoma.

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55, 56. Included in Arbuckle group. Shown in list of formations for Arbuckle and Wichita Mountains section as underlying West Spring Creek formation and overlying Cool Creek limestone.

C. E. Decker, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1313. Name Kindblade formation substituted for preoccupied name Alden.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 106. Abandoned by Oklahoma Geological Survey.

Alder Group

Alder Formation

Alder Sedimentary Series (in Yavapai Group)

Precambrian (Yavapai Series): Central Arizona.

E. D. Wilson, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 112; 1939, Geol. Soc. America Bull. v., 50, no. 7, p. 1118 (table 1), 1121–1123. Yavapai group is subdivided into Yaeger greenstone, Red Rock rhyolite, and Adler [Alder] sedimentary series (all new). Series consists of locally metamorphosed shale, grit, quartzite, and conglomerate; intensely folded and faulted. Exposed thickness unknown; appears to exceed 5,000 feet. All observed contacts with Yaeger greenstone (probably oldest in group) and Red Rock rhyolite are faults; hence relative age not definitely known, but character of rhyolite pebbles in its conglomerate suggests that Alder is younger than Red Rock.

Gordon Gastil, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1225; 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (tables 1 and 2), 1499–1500, pl. 1. Referred to as formation. Divided into three unnamed members (ascending): interbedded slate, wacke, quartzite, and conglomerate, thickness unknown, probably 4,000 feet or more; quartzite, 300 to 1,000 feet; slate, wacke, and conglomerate as much as 580 feet. In Diamond Butte quadrangle (this paper), conformably underlies Flying W formation (new); in fault contact with pre-Alder(?) rocks. Upper contact of formation, as here defined, is base of lowest cobble volcanic or volcanic strata. Wilson's Alder series includes up to 1,000 feet of cobble conglomerate. This portion of Alder series may be equivalent to part of Flying W formation. Correlation chart shows Wilson's Alder series stratigraphically above Yaeger greenstone and below Red Rock rhyolite.

C. A. Anderson and C. S. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 9, 20–32, pl. 1. Wilson's Alder series modified to Alder group. Rocks divided into six formations, which fall into two classes: those of probable known stratigraphic succession and those of unknown stratigraphic succession. Former comprises three volcanic sequences (ascending): Indian Hills, Spud Mountain, and Iron King (all new); latter divided into Green Gulch volcanics, Chaparral volcanics, and Texas Gulch formation (all new). Thickness not known; appears to be 20,000 feet or more, and may be as much as 30,000. Separated from Ash Creek group (new) by Shylock fault; hence relative ages not certain.

Named for typical occurrence in vicinity of Alder Creek in central segment of Mazatzal Range, Jerome area. Crops out extensively in Mazatzal Mountains, eastern Tonto basin, Black Hills, and to small extent in Del Rio area.

Alder Creek Basalt

Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 46–47. Contains conspicuous phenocrysts of augite. Has blocky to scoriaceous crust. Thickness 100 to 150 feet. Covers Butte Creek basalt (new).

Issued from fissure near top of precipitous north wall of Alder Creek Canyon and cascaded 1,700 feet to canyon floor, Macdoel quadrangle.

Alderson Limestone (in Greenbrier Limestone)[1]

Mississippian (Chesterian): Eastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 449, 462, 699.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 98, 99). Shown on correlation chart in Greenbrier series. Chesterian.

Type locality: On road toward Wolf Creek one-third mile south of Alderson, Monroe County, W. Va.

Alderton Formation or Interglaciation

Pleistocene: Northwestern Washington.

D. R. Crandell, D. R. Mullineaux, and H. H. Waldron, 1958, Am. Jour. Sci., v. 256, no. 6, p. 389–391. Consists of alluvial and lacustrine sediments, peat, volcanic ash, and mudflows from Mount Rainier. Alluvial sediments, composed chiefly of andesite fragments, range from sand to pebble and cobble gravel. Lacustrine sediments are mostly silt and fine to medium sand. Volcanic ash occurs both as distinct layers and disseminated throughout formation. Mudflows, which occur at several horizons, range from less than 10 feet to several tens of feet in thickness and are lenticular in cross section. Exposed thickness at type section 52 feet; probable total thickness more than 130 feet. Considered to have been deposited during a nonglacial interval that followed Orting glaciation and preceded Stuck glaciation. Separated from overlying Stuck drift (new) by erosional unconformity.

Typically exposed in west wall of Puyallup-Duwamish Valley in gullies under transmission line of Bonneville Power Administration in center sec. 1, T. 19 N., R. 4 E., about half a mile southwest of Alderton, Pierce County.

†Aldrich Limestone[1]

Middle or Upper Cambrian: Central Alabama.

Original reference: H. McCalley, 1897, Alabama Geol. Survey Rept. on Coosa Valley, p. 41–42.

Near Aldrich, Shelby County.

Aldrich Station Formation (in Wassuk Group)

Miocene, upper, and Pliocene, lower: Western Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 23–29, 63–64, figs. 2, 3, 4. Consists of six major lithologic units (ascending): sandstone, shale, conglomerate, and breccia—thickness 150 feet; siliceous shale—thickness 400 feet; sandstone and conglomerate—thickness 750 feet; siliceous shale—thickness 350 feet; diatomaceous shale—thickness 1,600 feet; and silt, sandstone, and pebble conglomerate—thickness 800 feet. Aggregate thickness 4,050 feet. Underlies Coal Valley formation with local unconformity; overlies older rocks with unconformity.

Type area named for Aldrich Station, an old stagecoach station which is now represented by a stone foundation on county road at north base of Aldrich Hill; this site lies near middle of formation. Crops out prominently near base of Wassuk Range 5 miles southeast of Morgan's ranch, where lower part forms conspicuous white knolls against base of the range, Hawthorne quadrangle.

Aldwell Formation

Eocene, middle to upper: Northwestern Washington.

R. D. Brown, Jr., H. D. Gower, and P. D. Snavely, Jr., 1960, U.S. Geol. Survey Oil and Gas Inv. Map OM–203. Named for a sequence of well-indurated greenish-gray to medium-olive-gray marine siltstone that overlies and interfingers with Crescent formation in south limb of Clallam syncline. At type locality, lentil of pillow lava and flow breccia about 350 feet thick occurs 1,000 feet above base of formation; similar lentils or tongues of lava present in formation in other parts of area. Thickness about 2,950 feet at type locality; less than 100 feet near western boundary of mapped area. Underlies and interfingers with Lyre formation. Foraminifera, together with stratigraphic position, establish age of formation as middle to early late Eocene.

Type section: Exposures along Lake Aldwell on Elwha River from point 700 feet south of NE cor. sec. 28, T. 30 N., R. 7 W., to point 1,600 feet east, 1,200 feet south of NW cor. sec. 22, T. 30 N., R. 7 W.

Alegria Formation

Oligocene (Refugian): Southern California.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 30–31, pls. 1, 2. Defined as marine facies of continental Sespe formation in Gaviota and Point Conception quadrangles. Consists of about 1,200 feet of sandstone and minor amount of siltstone lying conformably above Gaviota formation and disconformably below Vaqueros formation. Varies in lithology and thickness along strike. From Agua Caliente Canyon grades laterally eastward into nonmarine Sespe; red clays appear progressively lower until at Capitan Canyon they occur throughout section, which apparently is all nonmarine.

Type locality: Ridge east of Canada de Santa Anita, Santa Barbara County. Formation is developed only on south flank of Santa Ynez

Range between a point 4 miles north of Point Conception and Capitan Canyon.

Aleman Cherty Member (of Montoya Dolomite)

Aleman Formation (in Montoya Group)

Upper Ordovician: Southwestern New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 57, 60–62, figs. 2, 3; F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 25–26. Consists of alternating beds of chert and dolomite. Chert occurs as irregular bands 1 to 3 inches thick alternating with 1- to 6-inch bands of dolomite. Chert weathers white, brown, and black, and the dolomite light gray to medium gray. Thickness varies; about 200 feet in Organ Mountains. Thins to an edge northward owing to pre-Percha, pre-Lake Valley, and pre-Magdalena erosion. Underlies Cutter formation (new); overlies Upham dolomite (new).

U.S. Geological Survey currently classifies the Aleman as a member of Montoya Dolomite on basis of study now in progress.

Type locality: In Cable Canyon opposite Sierrite mine in NW¼ sec. 10, T. 16 S., R. 4 W. (Sierra County). Name taken from station along Santa Fe Railroad to east of the mountains in the Jornada del Muerto.

Aleuts Member (of Kialagvik Formation)

Lower Jurassic: Southwestern Alaska.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1), 205–206. Lower 650 feet consists of dark-gray to black shale grading upward into gray shaly sandstone; upper 450 feet consists of interbedded sandstone, shale, and conglomerate, increasing in coarseness upward with several beds of conglomerate in upper 200 feet. Underlies Kolosh member (new); overlies Bidarka formation (new).

Occurs in vicinity of Wide Bay, south of Katmai National Monument, Alaska Peninsula.

Alexandria Syenite[1]

Precambrian: Northeastern New York.

Original reference: H. P. Cushing and others, 1910, New York State Mus. Bull. 145, p. 10, 39, map.

Named for Alexandria Township, west and north of Redwood.

Alexandrian Series[1]

Alexandrian Group

Lower Silurian: Mississippi Valley.

Original reference: T. E. Savage, 1908, Illinois Geol. Survey Bull. 8, p. 110.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Alexandrian group comprises (ascending) Girardeau limestone (Orchard Creek shale), Edgewood limestone, and Brassfield limestone. In Albion series.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1984. Discussion of stratigraphy of Medinan group in New York and Ontario. Recommended that terms Albion, Alexandrian, Anticostian, Cataract, and Power Glen be suppressed and discontinued in type area of "Early" Silurian.

U.S. Geological Survey uses term Alexandrian as provincial series comprising Lower Silurian in Missouri, Illinois, and Michigan.

Named for Alexander County, Ill.

Alferitz Formation

Miocene, middle (Luisian): Central California.

Martin Van Couvering and H. B. Allen, 1943, California Div. Mines Bull. 118, pt. 3, p. 496–500. Whitish to yellowish siltstone containing orange concretionary layers and occasional thin poorly sorted sands. Maximum thickness 700 feet. Unconformably underlies McLure shale; overlies Escudo sandstone (new).

Occurs in Devils Den oil field district in northwestern Kern County adjacent to Kings County line, about 40 miles from Paso Robles and about 60 miles northwest of Bakersfield.

Alfred Shale[1]

Upper Devonian: Western New York.

Original reference: E. R. Eller, 1935, Carnegie Mus. Annals, v. 24, no. 164, art. 8, p. 263–264.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Listed on correlation chart. Stratigraphically above Dunkirk shale and below Rushford sandstone.

Occurs at Alfred Station, Allegany County.

Alger Formation[1]

Silurian (Niagaran): East-central Kentucky and southwestern Ohio.

Original reference: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145; 1906, Bull. 7, p. 27, 61.

Wilber Stout, 1941, Ohio Geol. Survey Bull. 42, p. 34–35. Subdivided in southwestern Ohio into three members (ascending): Osgood, Laurel, and Massie. Average thickness about 55 feet.

Named for Alger, a station on railroad between Panola and Irvine, about 1 mile east of Estill-Madison County line, Kentucky.

Algomah Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144.

Named for occurrence at Algomah mine, Ontonagon County.

Algomah Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for occurrence at Algomah mine, Ontonagon County.

Algoman granite or gneiss[1]

Precambrian: Lake Superior district.

[Original reference]: A. C. Lawson, 1914, *in* Internat. Geol. Cong., 12th, Canada, 1913, Comptes rendus, p. 349–370.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1038–1041, 1070 (table 4). Terms Algoman intrusives, Algoman granite, and Algoman time used in discussion of Precambrian stratigraphy in

Minnesota. As shown on table of possible correlations, Algoman granite is younger than Knife Lake group and older than Animikie group.

Name derived from Algoma, a district in western Ontario, Canada.

Alhajuela Sandstone Member (of Caimito Formation)

Alajuela Formation or Member (of Caimito Formation)

Miocene, lower: Panamá.

Charles Schuchert, 1935, Historical geology of the Antillean-Caribbean region: New York, John Wiley and Sons, p. 586. Alajuela formation consists principally of sandstones which become more calcareous below and have a barnacle limestone at their base. In part, marine equivalent of Caimito formation. Lower Miocene.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (chart). Correlation chart shows Alajuela as uppermost member of Caimito formation. Lower Miocene.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 235–236, 246 (fig. 2). Uppermost member of Caimito formation in Madden basin. Present only in type area. Consists of massive fine- to coarse-grained tuffaceous sandstone. Thickness 275 feet. Late early Miocene or possibly early middle Miocene. The Alhajuela is the Gatún(?) formation of Reeves and Ross (1930, U.S. Geol. Survey Bull. 821) and member 1 of sandstone formation of Kellogg (1931, Final report on field investigations of the Madden Dam and Reservoir site at Alhajuela, Panama Canal Zone, Panama Canal Rept.).

Type region: Small area at and near Madden Dam in central part of Madden Basin, including site of former village of Alhajuela.

Alhambra Formation

Eocene, upper: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 49, 50–53, pls. 2B, 4A. Proposed for a sequence of brown silty shale, coarse silty sandstone and thinly laminated light-gray to white brittle shale which unconformably underlies San Ramon formation and overlies Escobar sandstone (new) in both limbs of Pacheco syncline. Thickness about 834 feet. In area of type section, comprises (ascending) Castro shale, Roop sandstone, and Pereira shale members (all new). Alhambra was mapped as Tejon in Concord quadrangle of San Francisco folio.

Type section: West limb of Pacheco syncline in Santa Fe cuts east of east portal of Muir Tunnel near Martinez, Contra Costa County.

Aliamanu Basalt (in Honolulu Volcanic Series)

Pleistocene: Oahu Island, Hawaii (subsurface).

H. T. Stearns, 1940, Hawaii Div. Hydrography Bull. 5, p. 55; G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 76–77. Melilite nepheline basalt. Overlain by 47 feet of Salt Lake tuff; underlain by 17 feet of alluvium which rests on Koolau basalt. Occurs between 62 and 93 feet in well.

Named for Aliamanu Crater within which it occurs. Penetrated only in one well, hence extent not known.

Aliamanu Tuff[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, 77. Water-laid gray to black or grayish-brown tuff containing numerous olivine crystals and some augite and magnetite, and also rounded gravel and sand; partly deposited by mud flow. Distribution noted.

Named from Aliamanu Crater, from which it is believed to have been erupted. Exposed intermittently over area of about 3 square miles east of Pearl Harbor, southwest of Koolau Range about 17 miles west of Makapuu Head.

Ali Baba Member (of Moenkopi Formation)

Lower Triassic: Southwestern Colorado and southeastern Utah.

E. M. Shoemaker and W. L. Newman, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1840–1841, 1842–1843, 1845–1846. Consists mainly of red-brown to purplish ledge-forming beds of conglomeratic arkosic sandstone separated by interbedded red- and chocolate-brown silty shale and thin layers of fine- and coarse-grained sandstone. Exhibits marked facies change from northeast to southwest near Uncompahgre Plateau, to northeast, ledge-forming beds of sandstone are highly arkosic, heavily conglomeratic, and constitute dominant part of member. To southwest, sandstones become progressively finer grained, better sorted, and less abundant. Southwest of Moab Valley becomes lithologically indistinguishable from overlying Sewemup member (new). Thickness 0 to 290 feet. Over most of salt anticline region, Ali Baba unconformably overlies Tenderfoot member (new), and locally in Sinbad Valley, Paradox Valley, and around Fisher Valley unconformity is sharply angular. In Sinbad Valley, rests locally on Paradox member of Hermosa formation. In Paradox Valley, rests in places on Cutler formation. In Fisher Valley, rests locally on the Cutler and on Paradox member. Cut out toward Uncompahgre Plateau in vicinity of Gateway, Colo., by angular unconformity at base of Chinle. In Sinbad Valley, thins locally by internal angular uncomformities and is overlapped by Sewemup and Pariott (new) members toward axis of salt anticline.

Type section: East side Sinbad Valley, sec. 15, T. 49 N., R. 19 W., Mesa County, Colo. Named for Ali Baba Ridge in Sinbad Valley, hogback underlain by conglomeratic sandstone of member.

Alibates Dolomite Lentil (of Quartermaster Formation)[1]

Permian: Northern Texas.

Original reference: C. N. Gould, 1907, U.S. Geol. Survey Water-Supply Paper 191, p. 17–20.

L. E. Lincoln, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 259–264. Described as persistent dolomite occurring in upper portion of Rustler formation.

Named for Alibates Creek, Potter County.

Alkali Formation[1]

Recent: Central southern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Type locality: Alkali Lake and Alvord Basin, Lake County.

Alkali Creek[1] (red stratum in Wind River Formation)

Eocene, lower: Wyoming.

Original reference: W. Granger, 1910, Am. Mus. Nat. History Bull., v. 28, p. 244.

Along Alkali Creek near Lost Cabin, northeast corner of Fremont County, Wyo.

Allah Quartzite

Paleozoic: North-central Utah.

B. F. Stringham, 1942, Geol. Soc. America Bull., v. 53, no. 2, p. 271, pl. 1. A 50-foot bed of fine-grained quartzite with prominent bedding planes. Easily traceable across entire district.

Occurs in West Tintic Mining District [Juab County], approximately 21 miles southwest of Eureka, Utah. Named for Allah mine.

Allamakee dolomite[1]

Upper Cambrian: Northeastern Iowa.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 319–326.

Probably named for exposures in Allamakee County.

Allamoore Limestone or **Formation**

Precambrian: Western Texas.

P. B. King, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 144 (fig. 1), 145, 148–149. Proposed for lower part of Millican formation of Richardson. Limestone is characteristically thin bedded, of blue, gray, or brown color, with nearly all beds seamed at regular intervals by thin bands of chert. Associated with limestone are masses of volcanic rocks; these include diabasic flows, in part amygdaloidal, in part massive, and various pyroclastic rocks, such as breccias and fine-grained, well-bedded tuffs. Volcanics are interbedded with limestone in thin to thick members. Allamoore is exposed only in strongly folded belt north of overthrust mass of Carrizo Mountain schist. Over wide areas its beds stand nearly vertical, so that its thickness is perhaps to be measured in thousands of feet. Underlies Hazel sandstone; overlies Carrizo Mountain schist.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 1. Thickness given as 3,000 feet.

Type area: Van Horn region. Name derived from village of Allamoore, 11 miles west of Van Horn on the Texas and Pacific Railway and U.S. Highway 80. This name is spelled two ways, Allamoore for the post office, Allamore for the railroad station. Post office spelling is one adopted.

Allan Hollow Shale Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 138–140, 143 (fig. 2), 145 (fig. 3). Dark-gray marine shale with interbedded thin sandstone at base and top. Thickness 780 feet. This occurrence of marine shale represents parts of section by faulting. Only complete surface section found on northwest flank between crest of [Coalville] anticline in sec. 6, T. 2 N., R. 6 E., and Grass Creek Valley 3½ miles north-northwest. Formation, where it occupies northwest flank, partly covered by unconformable overlap of Knight formation and cut by several normal faults. Overlies Coalville member (new).

Named for typical exposures in Allan Hollow immediately northeast of Coalville, Summit County. Allan Hollow is a strike valley between northwest dip slope of Coalville member and overlying cliff of Oyster Ridge sandstone.

Allegany Drift[1]

Pleistocene: Pennsylvania.

Original reference: R. M. Deeley, 1913, Geol. Mag. London, new ser., Dec. 5, v. 10, table opposite p. 14.

Probably refers to drift west of Allegheny River in northwestern Pennsylvania.

Allegany Park parvafacies[1]

Devonian or Carboniferous: Southwestern New York.

Original reference: K. E. Caster, 1934, Bulls. Am. Pal., v. 21, no. 71, p. 28.

Named for development in New York State Park of this name, south of Salamanca, N.Y.

Allegheny Formation[1] or Group

Allegheny Series

Middle Pennsylvanian: Western Pennsylvania, eastern Kentucky, western Maryland, eastern Ohio, western Virginia, and western West Virginia.

Original reference: H. D. Rogers, 1840, Pennsylvania Geol. Survey 4th Ann. Rept., p. 150.

C. K. Graeber and R. M. Foose, 1942, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 54, p. 28–55, pls. Group described in Brookville quadrangle. Includes all rock between top of Upper Freeport coal and base of clay under Brookville coal. Contains seven coal beds or horizons (descending): Upper Freeport, Lower Freeport, Upper Kittanning, Middle Kittanning, Lower Kittanning, Clarion, and Brookville. Divided into three formations: Freeport, extending from top of Upper Freeport coal to top of Upper Kittanning coal; Kittanning, extending from top of Upper Kittanning coal to base of clay under Lower Kittanning coal: Clarion, extending from base of Kittanning formation to bottom of clay under Brookville coal. Thickness about 325 feet. Underlies Conemaugh group; overlies Pottsville series.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 665–666, 683, chart 6 (columns 8, 9, 10, 11, 12, 23). Boundary between Pottsville and Allegheny strata has been fixed only by correlations between anthracite and bituminous coal districts, and there are uncertainties in this correlation. Generally, base of Allegheny beds has been drawn at base of Brookville coal. The Allegheny beds, which are designated as a series on present chart, are treated as extending downward to base of Homewood sandstone (slightly below Brookville coal) and upward to top of Freeport coal, which has long been recognized as Allegheny-Conemaugh boundary. Some students believe Allegheny should be defined as extending up from base of Lower Kittanning coal, which corresponds to Buck Mountain coal, just above type Pottsville. In eastern Kentucky, Allegheny is treated as a formation and shown as overlying Breathitt formation.

G. H. Ashley, 1945, Jour. Geology, v. 53, no. 6, p. 374–389. Base of Brookville coal (or top of underlying Homewood sandstone) long accepted Pittsburgh-Pottsville (Upper-Lower Pennsylvanian) boundary in Appalachian bituminous coal fields. But increasingly, for last 45 years, detailed studies have shown that boundary has been drawn at many horizons, some over 500 feet apart in same section, owing to different correlations. Reasons for these diverse correlations cited. It is proposed to shift boundary to base of Lower Kittanning-No. 5 Block coal, believed to correlate with Buck Mountain bed, whose base forms boundary at type Pottsville locality, at Pottsville, Pa. If above proposal is accepted, it is further proposed that, until thoroughly established, the Allegheny group, down to base of Lower Kittanning coal, be called "Allegheny group, restricted," and that all Pottsville series, including all strata up to base of Lower Kittanning coal, be called "Pottsville series, extended."

M. N. Shaffner, 1946, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 55, p. 46–77, pls. Group described in Smicksburg quadrangle, where it is 340 to 370 feet thick. Overlies Pottsville series, base taken at base of clay underlying Brookville coal. Underlies Conemaugh group. Studies by Ashley showed that Lower Kittanning coal is, regionally, most persistent coal in lower Allegheny group. Ashley (unpub. manuscript) proposed reclassification of Pennsylvanian system into Pottsville and Pittsburgh series. Pittsburgh series contained (ascending) Allegheny, Conemaugh, and Monongahela groups. Allegheny group contained (ascending) Kittanning member (with base at base of Lower Kittanning clay) and Freeport member. Clarion member placed in Kanawha group of Pottsville series. Until Ashley's proposal is accepted, Brookville coal considered base of Allegheny group.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 40–57, pl. 1. Series described on cyclothemic basis. Nine cyclothems named. [For sequence see Brookville cyclothem.] In this report, Allegheny includes Homewood, lowest member of Brookville cyclothem. Area of report, Perry County.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 14–24. Considered series in this report. Strata included in Ohio extend from base of Brookville (No. 4) coal to top of Upper Freeport (No. 7) coal. In Morgan County, outcropping strata range from Middle Kittanning (No. 6) coal to top of series, or about top third of Allegheny strata present in Ohio. Total thickness in Morgan County 111 feet including covered interval of 23 feet. Cyclothemic classification not used in this report, but units are referred to as members.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 46–92. Series described on cyclothemic basis in report on Athens County. Thirteen cyclothems named. [For sequence see Brookville cyclothem.] Lower limit of series placed between base of Homewood sandstone and top of Tionesta coal, and top boundary between top of Uffington shale and base of Lower Mahoning shale and sandstone. This transfers Homewood sandstone and Brookville underclay from Pottsville to Allegheny series and Uffington shale from Conemaugh to Allegheny series.

E. G. Williams and R. P. Nickelsen, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 36–50. Allegheny series described in parts of Clearfield and Centre Counties. Boundary between Pottsville and Allegheny series placed at base of clay beneath Brookville coal, following Graeber and Foose (1942). Comprises (ascending) Clarion, Kittanning, and Freeport formations.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 68–71. Stratigraphic classification of parts of Pottsville-Allegheny rocks in western Pennsylvania still a matter of controversy. There is general agreement that Allegheny-Conemaugh boundary, drawn at top of Upper Freeport coal, is significant and useful one. However Pottsville-Allegheny boundary, drawn at base of so-called Brookville coal or clay, has not been generally satisfactory. Brookville coal not adequately defined in type area, and coal designated Brookville by later geologists is probably Mercer (Ashley, 1945). Investigations by Renick (1924, Jour. Geology, v. 32, no. 1), Ashley (1945), and Williams and Nickelsen (1958) showed that, throughout many areas of western Pennsylvania, either Mercer or Clarion coals have been mapped as Brookville, and there is some doubt that true Brookville was ever mapped. In present report, Lower Clarion clay is used as boundary between Allegheny and Pottsville groups. Use of this boundary requires the least modification of existing terminology. In southern counties of state, where marine fossils are not associated with lower Allegheny and Pottsville coals, correlation with type areas has not yet been established. Group in western Pennsylvania averages 280 feet thick. Consists of six mappable coals or coal zones separated by variable and locally cyclic sequences of shale, siltstone, sandstone, limestone, and clay. Group has been arbitrarily subdivided into three formations (ascending), Clarion, Kittanning, and Freeport, at horizon of certain economically important clay or coal horizons.

Named for exposures in valley of Allegheny River, western Pennsylvania.

†Allegheny Group[1]

Mississippian: Pennsylvania.

Original reference: A. Sherwood, 1878, Pennsylvania Geol. Survey Rept. G, p. 11–42.

Corresponds approximately to Pocono formation, and name is also preoccupied.

†Allegheny River coal series[1]

Mississippian and Pennsylvanian: Pennsylvania and northern West Virginia.

Original reference: J. P. Lesley, 1877, Pennsylvania 2d Geol. Survey Rept. H_3, p. XXIII.

Allegrippis Sandstone Member (of Chemung Formation)[1]

Upper Devonian: Central Pennsylvania.

Original reference: I. C. White, 1885, Pennsylvania 2d Geol. Survey Rept. T_3, p. 99–100.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart shows Allegrippus conglomerate underlying Middle Chemung (Wellsburg sandstone) and overlying Lower Chemung (Cayuta sandstone and shale).

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Member of Chemung formation. Generally, greenish-gray sandstone weathering white but locally coarse conglomerate; commonly has layers or pockets of conglomeratic sandstone. Thickness about 77 feet near Saxton. Occurs about 1,400 feet above Piney Ridge sandstone member. Occurs below Saxton conglomerate member.

Forms Allegrippus [Allegrippis] Ridge, Huntingdon County.

Allen Complex

Tertiary: Western Texas.

D. L. Amsbury, 1958, Texas Univ. Bur. Econ. Geology Quad. Map 22. Name given to an intrusive complex composed of rhyolite porphyries, vitrophyres, perlite, glassy breccias, and some sedimentary breccias.

Most rock types of complex crop out in belt of intrusions that trends west-southwest—east-northeast of old Allen place, Pinto Canyon area, Presidio County.

†Allen Limestone Member[1]

Pennsylvanian: Southeastern Kansas.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Bull. 238, p. 20.

Named for Allen, Lyon County.

Allenby Coal Member (of Carbondale Formation)

Pennsylvanian: Southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 48 (table 1), pl. 1. Proposed for coal formerly called Bankston so that name may be restricted to Bankston Fork limestone. Stratigraphically above Bankston Fork limestone member and below Galum limestone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: In roadside east of railroad crossing in NE¼NW¼ sec. 24, T. 9 S., R. 4 E., Williamson County. Name derived from village of Allenby in Saline County, about one-half mile southwest of type outcrop.

Allen Ridge Formation (in Mesaverde Group)

[Upper Cretaceous]: Southeastern Wyoming.

J. R. Bergstrom, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 114 (generalized composite strat. section). Comprises (ascending) about 550 feet of ripple-marked sandstones alternating with thicker carbonaceous shales and coaly beds; more than 550 feet of light-brown sandstones, generally 5 to 20 feet thick, separated by very poorly consolidated sandy shales and shaly sandstones which contain a few carbonaceous units; and 80 feet primarily of gray to gray-blue soft noncalcareous shale. Total thickness of formation 1,200 feet. Underlies Pine Ridge sandstone; overlies Steele formation.

Composite section from sec. 9, T. 22 N., R. 79 W., and sec. 18, T. 23 N., R. 79 W.

Allens Creek facies (of Edwardsville Formation)[1]

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 249.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 74. Listed as a facies in Edwardsville formation. Includes (ascending) Mount Ebel sandstone, Weed Patch, and Cutright sandstone members.

Occurs in Lawrence, Monroe, and Morgan Counties.

Allens Falls Fanglomerate

Precambrian: Northwestern New York.

P. D. Krynine, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1333–1334. Fluvial arkosic fanglomerate referred to as "basal breccia" filling ancient sinkholes in Grenville marble and covered unconformably by Potsdam quartzite.

Vicinity of Allens Falls and Canton, St. Lawrence County.

Allensville Conglomerate Member[1] (of Logan Formation)

Mississippian: Central and southern Ohio.

Original references: J. E. Hyde, 1912, History of Fairfield County, p. 211; 1915, Jour. Geology, v. 23, p. 656, 657, 764, 771, 775–778.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173. Included in Pretty Run sandstone facies of Logan formation.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 27, 67, 68. Moderately fine-grained to coarse conglomeratic sandstones interbedded with bluish-gray, argillaceous shale. Thickness commonly 15 to 25 feet. Underlies Vinton member; overlies Byer member.

Named for exposures at Allensville, Vinton County.

Allentown Dolomite

Allentown Limestone[1] or Formation.

Upper Cambrian: Eastern Pennsylvania and western New Jersey.

Original reference: E. T. Wherry, 1909, Science, new ser., v. 30, p. 416.

B. L. Miller, D. M. McCoy, and R. L. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–48, p. 229–241. Formation represented in Northampton County by broad band of magnesian limestones that extends from New Jersey west-southwestward to Lehigh County and underlies major portions of Easton and Bethlehem; also forms floor of larger part of Saucon Valley and occurs in extreme southeastern corner of county in vicinity of Coffeetown and Frya Run. Estimated thickness 1,500 to 1,600 feet; no exposure of entire thickness known in region. Overlies Tomstown with apparent conformity; underlies Beekmantown strata.

B. F. Howell, Henry Roberts, and Bradford Willard, 1950, Geol. Soc. America Bull., v. 61, no. 12, pt. 1, p. 1355–1368. Discussion of subdivision and dating of Cambrian of eastern Pennsylvania. Trempealeauian Late Cambrian age of highest limestones in Lehigh and Durham Valleys established, and formation name, Allentown, applied. Dresbachian Late Cambrian age of next underlying limestones established, and formation name Limesport proposed for them. Restricted Allentown 400 to 500 feet thick. In Lehigh Valley, underlies Beekmantown dolomite. Allentown pinches out and is absent in Buckingham Valley.

Bradford Willard, 1958, Pennsylvania Acad. Sci. Proc., v. 32, p. 178–179, 182. Correlation of magnesian limestone of Ordovician age in Lehigh Valley with Beekmantown questioned. Proposes to reinstate Wherry's Coplay formation for Lower and Middle Ordovician beds between Upper Cambrian Allentown and Middle Ordovician Jacksonburg formations.

Named for exposures along Lehigh and Jordan Creeks in vicinity of Allentown, Pa.

Allen Valley Shale (in Indianola Group)

Upper Cretaceous: Central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 127–128, 133 (fig. 17). Body of marine shale, 600 to 800 feet thick, underlying Funk Valley formation (new) and overlying Sanpete formation (new).

Consists largely of evenly bedded gray marine shale interbedded with thin layers of yellowish bentonite, siltstone, very fine grained sandstone, and gray limestone. No individual bed more than 1 foot thick. Thickness at type locality 620 feet.

Type locality: Base of Wasatch Plateau in Allen Valley about 3 miles southwest of Manti. Top and base are well exposed in Salina Canyon, about 5 miles east of Salina.

Allison Member (of Menefee Formation)

Allison Member or Barren Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1925, U.S. Geol. Survey Bull. 767.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2156, 2157. Nomenclature of Mesaverde in San Juan basin, revised. Allison reallocated to member status in Menefee formation. Overlies Cleary coal member (new).

Well exposed near village of Allison, McKinley County.

Alloa Rhyolite[1]

Precambrian: South-central Wisconsin.

Original reference: J. T. Stark, 1932, Jour. Geology, v. 40, no. 2, p. 120, 121, 126.

Exposed on both sides of elliptical mound on Shanks Farm, just northeast of United Presbyterian Church, Caledonia Township.

Allouez Conglomerate (in Portage Lake Lava Series)

Allouez Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 53–57, 60, chart.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

Named for occurrence in Allouez mine, Houghton County.

Alloway Clay[1]

Miocene, upper: Southwestern New Jersey.

Original reference: H. B. Kummel and G. M. Knapp, 1904, New Jersey Geol. Survey, v. 6, p. 142.

William Lodding, 1956, Rutgers Univ. Bur. Mineral Research Bull. 7, p. 19, 65, 78, pl. 2. Alloway clay (Kirkwood) mentioned in discussion of raw materials for lightweight aggregate production in New Jersey.

Near Woodstown and Ewan Mills. Continues from near Swans Mill, south of Mullica Hill, Gloucester County, to point 2 miles south of Alloway, Salem County.

Allsboro Sandstone (in Chester Group)[1]

Mississippian: Northwestern Alabama and northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Allsboro sandstone of Morse (1928) included in Tanyard Branch member of Pride Mountain formation (both new).

Named for small village in Alabama near Mississippi line.

Alma Glacial Substage

Pleistocene (Wisconsin): Central Colorado.

Q. D. Singewald, 1950, U.S. Geol. Survey Bull. 955-D, p. 120, pl. 9 [1951]. Times of maximum ice advance and of two principal ice stands during retreat are called Fairplay, Briscoe, and Alma substages, respectively, of Wisconsin stage of glaciation. Alma substage represents time covered by deposition of Alma moraine.

Area, northwestern Park County.

†Alma Limestone (in Council Grove Group)[1]

Permian: Northeastern Kansas.

Original reference: C. S. Prosser, 1894, Geol. Soc. America Bull., v. 6, p. 44-45.

Named for Alma, Wabaunsee County.

†Almagre Beds[1]

Eocene, lower: Northwestern New Mexico.

Original reference: Walter Granger, 1914, Am. Mus. Nat. History Bull., v. 33, p. 205-207.

C. H. Dane, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 24. Wasatch formation as described in this report [eastern side of San Juan Basin, N. Mex.] contains lower faunal division of the Wasatch as recognized by Granger (1914), the Almagre beds.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 6, p. 368, 369, 370-374. In type region of San Jose formation (new) are two distinguishable clay facies corresponding to Granger's (1914) Almagre and Largo beds. "Almagre" facies occurs in lower part of formation throughout type region, except northward of Arroyo Blanco where it is sandstone facies. Forms lower part of formation.

Named for Almagre watershed. Simpson measured section near where continental divide crosses pass between head of the Largo and southwest branch of "Almagre" Arroyo, mostly in NE¼ sec. 8, T. 23 N., R. 1 W., Rio Arriba County.

Almenan Sub-Age

Pleistocene: Midcontinent region.

J. C. Frye and A. B. Leonard, 1955, Am. Jour. Sci., v. 253, no. 6, p. 359 (fig. 1), 363. Provincial term used to designate third and youngest time-stratigraphic and time unit of post-Sangamonian time. Includes time from Bradyan to present.

Name derived from vicinity of Almena, Norton County, Kans., which is type area of Almena terrace of Prairie Dog Creek Valley.

Almond Formation (in Mesaverde Group)[1]

Upper Cretaceous: Southwestern Wyoming.

Original reference: A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Consists of white and brown soft sandstone, gray sandy shale, coal, and carbonaceous shale. Overlies Ericson sandstone and underlies Lewis shale.

Rock Springs uplift, Sweetwater County.

Almongui (Almonogui, Arumonogui) Agglomerate

Eocene(?): Caroline Islands (Babelthuap)

Risaburo Tayama, 1939, Brief report on the geology and ore resources of Babelthuap Island (Palau Island proper): Tropical Industry Inst., Palau, South Sea Islands Bull. 3 [English translation in library of U.S. Geol. Survey, p. 7–8, 17]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 65, table 4 [English translation in library of U.S. Geol. Survey, p. 78]. Composed chiefly of augite-andesite, with occasional layers of tuff. Bedding horizontal or dips less than 10°. Not in contact with Airai lignite-bearing bed, but considered older than those beds.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 17. Consists mostly of augite- and pyroxene-andesite with occasional interbedded tuff. Dip of formation is commonly less than 10°. Distinguished from Babelthuap and Aimelik [Aimiliiki] agglomerates by not being propylitized and by having no limestone lenses and metallic ore deposits. Although direct contact with Aimelik formation not found, latter is supposed to be unconformable below this formation. Eocene(?).

Covers more than half of Babelthuap Island. Along western coast of Almongui edge of formation forms hogback.

Almont Sandstone (in Tongue River Member of Fort Union Formation)

Paleocene: Southwestern North Dakota.

R. V. Hennen, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 12, p. 1573 (fig. 1), 1580. In a measured section, Almont lies approximately 35 feet above base of Tongue River member.

Section was measured along south margin of T. 138 N., Rs. 86 and 87 W. Sandstone forms high cliffs just above drainage, 1 mile south of Almont Railway Station [Morton County].

Almy Formation

Almy Conglomerate

Almy Formation (in Wasatch Group)[1]

Eocene, lower: Southwestern Wyoming.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 14, pl. 1. Formation included in Wasatch group. Tentatively considered Paleocene (Dragonian-Torrejonian).

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1), 842–844, pl. 1. Conglomerate, in north-central Wasatch Mountains, includes (ascending) Pulpit conglomerate and Saw Mill conglomerate divisions (both new). Thickness about 3,200 feet. Overlies Henefer formation (new); underlies Fowkes(?) formation. Paleocene; included in Wasatch group, which is here given as middle Paleocene(?) to lower Eocene (Wasatchian?).

A. J. Eardley, 1952, Utah Geol. Soc. Guidebook 8, p. 54–55. In Wasatch hinterland, Almy conglomerate probably rests unconformably on Wanship formation (new). Best exposed in cliffs at mouth of Echo Canyon and up canyon for about 5 miles to where it is covered unconformably by Knight conglomerate. In vicinity of Henefer in core of Henefer anticline, Almy is thousands of feet thick. Some beds were originally thought to underlie Almy unconformably and were named Henefer formation. They are now thought to make up lower part of the Almy. Locally underlies Fowkes formation.

B. E. Lofgren, 1955, Utah Geol. Soc. Guidebook 10, p. 75. Coarse red cliff-making conglomerate near headwaters of South Fork 8 miles above Huntsville has been mapped as Almy conglomerate by Eardley (1944), thus correlating it with Almy formation (Veatch, 1907) in southwestern Wyoming. Since Eardley's original mapping, he and students have remapped area and now regard Saw Mill conglomerate as Knight conglomerate.

J. I. Tracey, Jr., and S. S. Oriel, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 126–130. Veatch (1907) subdivided Wasatch group in Evanston area into Almy formation—basal unit of reddish-yellow sandy clays containing prominent conglomeratic beds in places; Fowkes formation—sequence of rhyolitic ash beds containing limestone lenses; and Knight formation—reddish-yellow sands and clays similar to Almy but separated from it and Fowkes by pronounced angular unconformity. Veatch noted that in places Almy seemed more closely related to underlying Evanston than to overlying Knight. In Kemmerer and Sage quadrangles, much of areas Veatch mapped as Almy are underlain by rocks more properly assigned to Evanston formation. Also, rhyolitic ash beds that Veatch defined as Fowkes formation, although apparently accordant with dipping beds of Almy at type locality, are, in fact considerably younger than nearby beds of Knight formation that Veatch interpreted as overlying the Fowkes. Fresh-water gastropods from type locality of Fowkes and from lithologically similar beds near Sage which Veatch called Fowkes are late Eocene or, possibly, earliest Oligocene. Massive light-gray conglomeratic cliffs northeast of Sage, called Almy by Veatch, are a part of this late Eocene unit. No vertebrate fossils have been collected from type locality of Almy. Knight and Almy formations were distinguished by Veatch partly on basis that lower peripheral conglomeratic beds of Wasatch are apparently more involved in structural deformation of basin than higher beds near center of basin. Lower, conglomeratic Almy of Veatch's type section may be as old as latest Paleocene despite absence of supporting evidence, whereas beds underlying Green River formation near Fossil Butte in center of basin are of early Eocene (Lysite) age. At present, use of names Almy and Knight seems inadvisable without explicit statements as to their meaning. Future mapping may clarify subdivisions of Wasatch in Fossil basin and perhaps relate them to subdivisions in Bridger basin.

A. J. Eardley, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 167. With recognition that Fowkes does not occupy a layered position between Knight and Almy, relation of Knight and Almy becomes a problem. In those localities where Veatch shows Knight resting directly on Almy, present writer [Eardley] has found it impossible to detect any real break. Apparently Almy is simply a basal unit of Knight and of no real stratigraphic significance. No means has been found of recognizing Almy outside of its type locality just north of Evanston.

U.S. Geological Survey currently designates the age of the Almy as earliest Eocene in Fossil basin (type area) on the basis of a study now in progress.

Named for Almy, a few miles north of Evanston, Uinta County, Wyo.

Alnwick Lake Beds[1]

Miocene, upper, or Pliocene: Eastern Colorado.

Original reference: W. Cross, 1894, U.S. Geol. Survey Geol. Atlas, Folio 7.

Occurs in valley of Oil Creek about Alnwick, Pikes Peak region.

Alofau Volcanics

Pliocene(?): Samoa Islands (Tutuila).

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1286 (table 1), 1289–1290, pl. 1. Include all thin-bedded, chiefly olivine-bearing aa and pahoehoe basalts and dikes, breccias, firefountain deposits, and trachyte forming Alofau Volcano. About 962 feet thick.

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 151–152. Appear to overlap Olomoana volcanics and to be overlapped by Pago volcanic series. Pliocene(?); no fossils; age designation on basis of weathering and erosion.

Named for village of Alofau in center of volcano. Cover about 1½ square miles on east side of Fagaitua Bay at east end of island.

Alpena Limestone[1] (in Traverse Group)

Devonian: Northeastern Michigan.

Original reference: A. W. Grabau, 1902, Michigan Geol. Survey Rept. 1901, p. 175.

A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 526. Restricted to exclude "black Alpena" zone which is separated below as Killians limestone (new). Dock Street clay of Grabau (1902) is considered local clay facies of upper Alpena horizon. Underlies Norway Point formation (new). Included in Traverse group.

G. A. Cooper and A. S. Warthin, 1941, Washington Acad. Sci. Jour., v. 31, no. 6, p. 260. Overlies Newton Creek limestone (new).

G. A. Cooper and A. S. Warthin, 1942, Geol. Soc. America Bull., v. 53, no. 6, p. 879; G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, p. 1743–1744, chart 4. Further restricted. Lower 15 feet, which contains a Genshaw fauna, placed in that formation. Next division, which consists of 25 feet of yellowish to brown crystalline limestone, to which the name Alpena is restricted, consists of 79 feet of light-gray to white limestone. Above Alpena (restricted) occur 8 feet of blue clay shale, Dock Street clay of Grabau (1902), a lens confined to east side of Alpena, and classified with Alpena limestone. Overlying Dock Street and Alpena is Four Mile Dam limestone.

G. V. Cohee, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 28. Michigan Geological Survey considers Newton Creek limestone a member of Alpena limestone.

Named for exposures at Alpena, Mich.

Alpine Formation (in Lake Bonneville Group)

Pleistocene: West-central Utah.

K. C. Bullock, 1951, Utah Geol. and Mineralog. Survey Bull. 41, p. 21. Oldest of Lake Bonneville deposits. Gilbert (1890, U.S. Geol. Survey Mon. 1) used term Intermediate to refer to Lake stage represented by these deposits. Consists of a high proportion of fine-textured sediment, mostly silt. Sorting excellent and bedding distinct. Underlies Bonneville formation (new). Name credited to H. J. Bissell (unpub. thesis).

C. B. Hunt, H. D. Varnes, and H. E. Thomas, 1953, U.S. Geol. Survey Prof. Paper 257-A, p. 17-20, pl. 1. Formation thickens southward from about 50 feet in vicinity of Lehi to about 100 feet near Provo. Underlies glacial outwash and in some places Provo formation; overlaps onto pre-Lake Bonneville alluvial fans.

Named for town of Alpine in northern Utah Valley.

Alpine Quartz Diorite[1]

Upper Jurassic or Lower Cretaceous: Southern California.

Original reference: W. J. Miller, 1935, California Jour. Mines and Geology, v. 31, no. 2, p. 115-141, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 486, table 4. Plutonic sequence in southern San Diego County comprises (ascending) Viejas gabbro-diorite, Alpine quartz diorite, Harbison quartz diorite, Descanso granodiorite, and La Posta quartz diorite. Late Mesozoic.

Typical occurrence in general vicinity of Alpine, southern Peninsular Range.

Alpreston Quartzite[1]

Middle Cambrian: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, 435, map.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 3. Mentioned in summary of work on Cambrian system in and near western Montana. Alpreston quartzite (Flathead quartzites) is oldest Cambrian in Elkhorn region. Succeeded by Starmount limestones.

Forms crest of hill west of Elkhorn, Jefferson County.

Alsate Shale[1]

Lower Ordovician: Southwestern Texas.

Original reference: P. B. King, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 9, p. 1066, 1069-1070.

W. B. N. Berry, 1960, Texas Univ. Bur. Econ. Geology Pub. 6005, p. 6, 13 (table 1), 19-20, 106-107, 110, 117. Black shale that forms distinct break between blue-gray-weathering Marathon limestone and tan-weathering limestones and sandstones of Fort Pena formation. In Alsate Creek exposure in Marathon anticlinorium, conglomerate underlies black shale and was included in Alsate by King. Conglomerate is merely a lens; it can be traced into limestone at top of Marathon and should not included in Alsate. Thickness about 100 feet in Alsate Creek and in exposures on ridge east of road to Roberts ranch; thins to 85 feet 3 miles to southwest. Thinner in Dagger Flat anticlinorium and commonly occupies covered interval. Here is greenish-weathering black shale. Granular limestone layers containing *Oncograptus*, which King (1937, U.S. Geol. Survey Prof. Paper 187) described as part of formation, belong to overlying Fort Pena formation.

Named for Alsate Creek, which joins Pena Colorada Creek from west at Fort Pena, Colo. Well exposed in cut on creek 2½ miles west southwest of Fort Pena, near road to Roberts ranch, Brewster County.

Alsen Limestone[1] (in Helderberg Group)

Lower Devonian: Eastern New York.

Original reference: A. W. Grabau, 1919, Geol. Soc. America Bull., v. 30, p. 468–470.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 184–190. Overlies Becraft and underlies Port Ewen, but Port Ewen is missing at Alsen (locality from which Alsen was named). Underlies Oriskany where Port Ewen is missing. Thickness 25 feet in quarry at Alsen. Has been considered basal part of Port Ewen.

Named for section at Alsen, Greene County, where it is well shown in the hills.

Alsobrook Member (of Pride Mountain Formation)

Alsobrook Formation (in Chester Group)[1]

Upper Mississippian: Northwestern Alabama and northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

W. C. Morse, 1936, Mississippi Geol. Survey Bull. 32, p. 11, 16, 21. Constitutes lowest formation in Chester series. Shown as comprising Cripple Deer sandstone or shale member above, Hargett sandstone or shale member, and unnamed limestone. Underlies Allsboro sandstone.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Basal member of Pride Mountain formation (new) in Colbert County, Ala., and Tishomingo County, Miss. Morse described sequence as consisting of limestone 1 to 10 feet thick, containing brachiopod *Productus inflatus* McChesney, and overlying green shale 70 to 80 feet thick, containing a sandstone bed of variable thickness in upper part. He named the sandstone Cripple Deer sandstone member of his Alsobrook. Name Alsobrook is herein reduced to member status and redefined to include only basal limestone and that part of shale below Morse's Cripple Deer sandstone. Thickness about 50 feet in type area; thins eastward to 3 feet or less in vicinity of Spring Valley in Colbert County. Underlies Tanyard Branch member (new); overlies Tuscumbia limestone. Upper Mississippian.

Named for Alsobrook Homestead and Alsobrook Bridge, located about 3 miles north of Allsboro, Ala., in sec. 10, T. 4 S., R. 15 W.

Alta Formation[1]

Permian: Southwestern Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Min. Survey Bull. 8, p. 10–25.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 673, 674, pl. 2 (column 2). Composed largely of clastics. Underlies Cibolo formation; overlies Cieneguita formation.

D. L. Amsbury, 1958, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 22. Oldest formation exposed in Pinto Canyon, Presidio County. Dark-gray thin-bedded mudstone forms about 80 percent of the 610 feet exposed in measured section. Underlies Pinto Canyon formation (new).

Named for Sierra Alta Hill, on side of Sierra Alta Creek, Presidio County.

Alta Formation

Alta Andesite or Andesite Series

Oligocene(?): Western Nevada.

V. P. Gianella, 1936, Nevada Univ. Bull., v. 30, no. 9, p. 33, 52–54, pl. 1. Referred to as Alta andesite series. Breccias predominate in lower part of series; toward top are lavas and lesser amounts of breccia. Thickness about 3,600 feet. Contains Sutro tuff member. Overlies Hartford Hill rhyolite. Miocene. Series was previously named Forman andesites [volcanics].

D. I. Axelrod, 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1935. Oligocene age indicated on basis of flora in Sutro tuff member.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 51–52. Formation consisting mainly of tuff-breccia, flow breccia, and lava flows. Contains sedimentary Sutro tuff member (present only in Comstock lode district), which ranges in texture from shale to conglomerate and forms discontinuous lenses at different stratigraphic horizons. Probably interfingers with overlying Kate Peak formation in some places, but rock types are not sufficiently distinctive to be absolutely sure of this relation; intruded by Davidson granodiorite. Oligocene(?).

Occurs in Silver City district, on eastern slope of Virginia Range, 12 miles north of Carson City. Named for exposures near Alta mine shaft [on Comstock lode].

†Alta Granodiorite[1]

Upper Cretaceous or Tertiary, lower: Utah.

Original reference: F. F. Hintze, 1913, New York Acad. Sci. Annals, v. 23, p. 85–143.

Crops out just east of Alta, in central Wasatch Mountains, Salt Lake County.

†Alta Shale[1]

Lower and Middle Cambrian: Central northern Utah.

Original reference: F. F. Hintze, Jr., 1913, New York Acad. Sci. Annals, v. 23, p. 104.

Named for its prominence at little town of Alta.

Alta Loma Sand

Pleistocene: Texas (subsurface).

N. A. Rose, 1943, Progress report on the ground-water resources of the Texas City area, Texas: Texas Board of Water Engineers, p. 3–5. Consists of massive sand bed ranging from about 100 to 350 feet in thickness. Composed principally of fine- to coarse-grained sand but contains lenses of clay and sandy clay. Sand dips southeastward at rate of 15 to 20 feet per mile. Underlies Beaumont clay; overlies Lissie sand.

Named for town of Alta Loma, Galveston County. Sand is well developed in all wells that have been drilled in this locality for city of Galveston water supply.

†Altamaha Formation[1] or Grit[1]

Miocene, lower: Southeastern Georgia, Alabama, and northern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 81–82, 157, 320.

Named for exposures in bluffs of Altamaha River, especially between Rocky Hammock and Doctortown, Wayne County, Ga.

Altamira Shale Member (of Monterey Formation)[1]

Miocene, middle and upper: Southern California.

Original reference: W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 2, p. 131.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 16–33, 39–40, pls. 3, 4, 6–7, 10–B, 28. Basal member of Monterey in Palos Verdes Hills area. Includes thick bentonitic tuff, Portuguese tuff bed, and a thin pumice tuff, Miraleste tuff bed. Thickness about 1,000 feet in type region; about 600 feet on north slope of hills owing to overlap on schist basement. Underlies Valmonte diatomite member. Division between middle and upper Miocene is between middle and upper parts of Altamira.

Type region: On south slope of hills along and adjoining Altamira Canyon, Palos Verdes Hills, Los Angeles County.

Altamont Limestone[1] (in Marmaton Group)

Altamont Limestone Member (of Oologah Limestone)

Pennsylvanian (Des Moines Series): Southeastern Kansas, southern Iowa, southwestern Missouri, and northeastern Oklahoma.

Original reference: G. I. Adams, 1896, Kansas Univ. Geol. Survey, v. 1, p. 22.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 29. Subdivided into two formations, Tina below and Worland. Occurrences in Iowa noted.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 325–334. Further subdivided to include a middle member, Lake Neosho shale. Type exposure designated; thickness at type exposure about 19 feet.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 7–8; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 96. Comprises (ascending) Amoret limestone (name Amoret limestone substituted for Tina limestone), Lake Neosho shale, and Worland limestone members. Overlies Bandera formation; underlies Nowata formation.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as upper member of Oologah limestone in Rogers, Nowata, and Craig Counties.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 30–31, fig. 5. Comprises (descending) Worland limestone, Lake Neosho shale, and Amoret limestone members. Unit not previously recognized as formation in Iowa, but as result of studies made in Madison County it now appears valid formation for this area. Underlies Nowata shale; overlies Bandera shale. Maximum thickness about 13 feet. Marmaton group.

Type locality: Near center of west line of sec. 5, T. 33 S., R. 19 E., about 3.5 miles west of Altamont, Labette County, Kans. No exposures in vicinity of Altamont show whole Altamont formation.

Alto coal group (in Pottsville Formation)[1]

Pennsylvanian: Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1880, Pennsylvania 2d Geol. Survey Rept. R.

In Alton Basin, Lafayette Township, McKean County.

Alto Formation[1]

Middle Devonian: Southwestern Illinois.

Original reference: T. E. Savage, 1920, Am. Jour. Sci., 4th ser., v. 49, p. 168–178.

J. M. Weller and G. E. Ekblaw, 1940, Illinois Geol. Survey Rept. Inv. 70, p. 16–19. Strata intervening between Grand Tower limestone (or Dutch Creek sandstone where that is absent) and Mountain Glen shale (or Springville shale where that is absent) have been referred by Savage (1920) to Misenheimer shale and Lingle and Alto limestones. Restudy of area suggests that recognition of these three formations may be neither stratigraphically logical nor practically feasible. Might be advisable to apply to them the name St. Laurent formation which is used for Devonian beds overlying Grand Tower limestone in southeastern Missouri.

A. S. Warthin, Jr., and G. A. Cooper, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 10, p. 1524–1525. At its type locality, contains at its top about 11 feet of hard brown irregularly bedded finely granular dolomitic sandy limestone with much brown chert. Below this is about 70 feet of dark-brown to dark-gray irregularly laminated silty to sandy shale, with a few 1-foot layers of sandstone and sandy limestone. Some of shales are dark enough to be confused with Mountain Glen black shale above, if it were not for intervening cherty limestone. Formation has been variously correlated with rocks of Hamilton age, but is here considered as entirely post-Hamilton. Subsurface data. Middle Devonian.

Named for exposure along a creek in NE¼ sec. 34, in Alto Township, Union County.

Altona Dolomite Member (of Blaine Gypsum)[1]

Permiam: Central Oklahoma.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 48.

Named for Altona, western part of Kingfisher County.

Altonian Substage

Pleistocene (Wisconsinan): Illinois.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 1, 2 (fig. 1), 5–6. Wisconsinan stage of Lake Michigan lobe is subdivided into (ascending) Altonian, Farmdalian, Woodfordian, Twocreekan, and Valderan substages. Radiocarbon dates suggest an age of 50,000 to 70,000 radiocarbon years B. P. as beginning of Altonian. Altonian is judged to include half or more of total duration of Wisconsinan age. Includes Roxana silt and Winnebago drift (both new).

Named for city of Alton, in southwestern Illinois, located on bluff of Mississippi River valley below mouth of Illinois River.

Altoona Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: E. Haworth and W. H. H. Piatt, 1894, Kansas Univ. Quart., v. 2, p. 115–117.

Named for Altoona, Wilson County.

Altuda Formation

Altuda Shaly Member (of Capitan Limestone)[1]

Permian (Guadalupe): Western Texas.

Original reference: P. B. King, 1927, Am. Jour. Sci., 5th ser., v. 14, p. 217.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 655. Rank raised to formation.

Named for exposures in vicinity of Altuda section house [Brewster County].

†Altuda Granite[1]

Age(?): Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, Sci. ser. No. 11, p. 70.

Covers an area of somewhat more than 1 square mile, 4 miles north of Mount Ord, southwest of Altuda, Brewster County.

Alturas Formation[1]

Pliocene, middle or upper: Northeastern California.

Original reference: Erling Dorf, 1933, Carnegie Inst. Washington Pub. 412, p. 6, 23.

D. I. Axelrod, 1944, Carnegie Inst. Washington Pub. 553, p. 264, 276 (table 25). Relatively horizontal strata; includes coarse, brownish tuffaceous sandstones and pebbly conglomerates, as well as lenses of white to gray tuffaceous shales and clays. Total thickness only a few hundred feet. Rests disconformably upon channeled and eroded surface of Upper Cedarville formation; overlain regularly by Warner basalt. Pliocene.

Flora collections made in vicinity of Rattlesnake Butte, about 4 miles east of Alturas, Modoc County.

Altyn Limestone[1] (in Ravalli Group)

Precambrian (Belt Series): Northwestern Montana, and southwestern Alberta and southeastern British Columbia, Canada.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 321.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1881–1884. Consists of dolomites, limestones, limy argillites, sandstones, and minor mud breccias, which form lower calcareo-magnesian division in Belt sediments in Glacier Park facies. Sediments show considerable variety in color, texture, and bedding; they contain mud cracks, ripple marks, and many beds of flat-pebble and edgewise conglomerates. Upper limit is base of Appekunny formation with which there is some intergradation; lower limit concealed beneath Lewis thrust. Thickness 2,180 to 2,480 feet. Includes (ascending) Waterton (Canada only), Hell Roaring (new), and Carthew (new) members. This definition includes Altyn of Willis (1902) and Daly's Waterton formation because no significant break exists between them.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 112. Included in Ravalli group. Underlies Appekunny argillite.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 18–21, pls. 1, 2. Not exposed in Flathead region, and base has nowhere been recognized. Does not appear to be exposed in any other part of Montana. Commonly regarded as part of Ravalli group—a convenient procedure which is herein adopted provisionally. No evidence exists as to stratigraphic relations of the Altyn of Glacier National Park to basal components of Ravalli group in other parts of Montana or to underlying Prichard formation. Fenton's members discussed, but formation not subdivided in present report. Limestone forms Range extending about as far south as lat 48°20′ N. and northward past Canadian border. Here it immediately overlies Lewis overthrust, and much of it has been cut out by that fault. Also exposed in outlying blocks such as those in Divide and Chief Mountains and on either side of Waterton Lake.

Type locality: In cliffs of Appekunny Mountain, due north of Altyn, in Swift Current Valley, Glacier National Park. Entire section exposed only in Waterton Lakes Park, where it is complicated by faults and folds.

Alum Phyllite

Precambrian: Southwestern Virginia.

R. V. Dietrich, 1959, Virginia Polytech. Inst. Bull., Eng. Expt. Sta. Ser. 134, p. 75–84, pl. 1. Chiefly sericitic slate-phyllite. Main mass appears to lie conformably within Lynchburg gneiss (Lynchburg as used here may not be correlative of type locality Lynchburg). The Alum grades both upward and downward, through a few feet, into Lynchburg gneiss, except locally along its northern contact where it appears to grade into Little River gneiss (new).

Named for Alum Ridge district. Underlies a nearly 2-mile-wide belt that extends from near northwestern corner of Floyd County northeastward to Route 8.

Alum Bluff Group[1]

Alum Bluff Stage

Miocene, lower and middle: Florida, southern Georgia and southeastern Alabama.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 112–113, 122–123, 157, 158, 320.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 16 (table 1), 18 (fig. 2), 21–27, fig. 3 facing p. 18. Stage embraces all sediments of post-Tampa and pre-Choctawhatchee age, the middle Miocene of most authors, in Florida panhandle and their equivalents in Central and Western Gulf states. In Florida panhandle, includes Chipola, Shoal River, Oak Grove, and Hawthorn facies.

C. W. Cooke, 1954, Florida Geol. Survey Bull. 29, p. 18 (table), 136–144. Formations now included in group are (descending) Shoal River, Chipola, and Hawthorn (east of Apalachicola River). Oak Grove sand included in Shoal River formation. Group consists predominantly of micaceous sand, sandy clay, fuller's earth, and limestone. Conformably overlies Tampa limestone, or, where Tampa is absent, Ocala limestone or Suwannee limestone forms the bedrock. Unconformably underlies Duplin marl or Pliocene or Pleistocene deposits.

Named for exposures at Alum Bluff on east side of Apalachicola River, Liberty County, Fla.

†Alum Bluff series[1]

Miocene, middle and upper: Northwestern Florida.

Original reference: D. W. Langdon, 1891, Georgia Geol. Survey 1st Rept. Prog., p. 91–97.

Alum Cave[1] Limestone Member (of Petersburg Formation)

Pennsylvanian: Western and southwestern Indiana.

Original reference: W. N. Logan, 1929, Indiana Dept. Conserv. 11th Ann. Rept., p. 30–34.

C. E. Wier, 1950, U.S. Geol. Survey Coal Inv. Map C–1. Allocated to member status in Petersburg formation. In Jasonville quadrangle, Clay, Greene, and Sullivan Counties, consists of gray impure hard limestone. Normally separated into two beds by 1 to 6 inches of calcareous shale; lower 1 or 2 inches of lower bed is shaly and fossiliferous. Thickness 4 to 6 feet. Underlies Dugger formation (new); overlies a black shale unit which overlies Coal V.

Derivation of name not stated.

Alumonogui Agglomerate

See Arumonogui (Almongui) Agglomerate.

Alum Rock Rhyolite

Post-Cretaceous: Northwestern California.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 47–48, pls. 1, 3. Pale-colored aphanitic rock; strongly jointed; more or less silicified. Fresh surfaces range in color from nearly white to brownish red or purple. Intruded into Cretaceous Oakland conglomerate and Berryessa formation (new). Known only to be post-Cretaceous, but by analogy with Leona rhyolite of the Oakland, it is more likely post-Orinda and possibly Quaternary.

Area: San Jose-Mount Hamilton area in Coast Ranges about 50 miles southeast of San Francisco. Mapped area is on west slope of Diablo Range. Rhyolite is intrusive body about 1,000 feet wide and 400 feet long which crops out in lower Alum Rock Canyon.

Alverson Andesite Lava

Miocene: Southeastern California.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 22. Dark-brown basic andesite. About 400 feet thick in Alverson Canyon and about 700 feet thick at east end of Coyote Mountains where it is associated with tuff and breccia. Overlies Split Mountain conglomerate and older basement rocks in western foothills of Coyote Wells Valley, in Coyote Mountains, and in Fish Creek Mountains; in some areas underlies the Fish Creek gypsum (new) and (or) Imperial formation.

Type locality: Alverson Canyon, Imperial Valley region.

Alverson Canyon Formation

Miocene(?): Southeastern California.

L. A. Tarbet and W. H. Holman, 1944, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1781–1782. Nonmarine unassorted sediments and associated basic igneous flows and tuffaceous sediments unconformably overlying all older rocks. Unfossiliferous. Thickness as much as 700 feet. Overlies Split Mountain formation (new); underlies Imperial formation.

L. A. Tarbet, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 260, 261 (fig. 40). Because Alverson Canyon formation rests directly on basement complex, it may be equivalent in age to Split Mountain formation. However, Split Mountain probably predates volcanic activity prevalent in Alverson Canyon formation because no volcanic debris was observed in Split Mountain.

Imperial Valley area.

Alvord Formation[1]

Miocene, lower: Southeastern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Typically exposed on east side of Alvord Valley, southern part of Harney County.

Alvord Creek Formation

Alvord Creek Beds[1]

Pliocene: Southeastern Oregon.

Original reference: R. E. Fuller, 1931, Washington Univ. Pubs. in Geology, v. 3, no. 1, p. 7–130.

D. I. Axelrod, 1944, Carnegie Inst. Washington Pub. 553, p. 225. Alvord Creek beds described by Fuller are here designated Alvord Creek formation. Lower Pliocene.

Howel Williams and R. R. Compton, 1953, U.S. Geol. Survey Bull. 995–B, p. 24–25. In mapped area (Steens and Pueblo Mountains), formation is restricted to narrow belt along foot of High Steens scarp bordering Pike and Little Alvord Creeks. Consists predominantly of well-stratified flat-lying white and pastel-tinted tuff, tuffaceous clay, and silt, with occasional interbeds of chert, opaline shale, and conglomerate; near mouth of Pike Creek includes a rhyolite flow. Thickness 500 feet; base not exposed. Unconformably underlies Pike Creek volcanic series; unconformably overlies pre-Tertiary rocks.

Probably named for occurrences near base of Steens Mountain scarp between Cottonwood Creek and Little Alvord Creek, Harney County.

Alvord Peak Basalt

Miocene: Southern California.

F. M. Byers, Jr., 1960, U.S. Geol. Survey Bull. 1089–A, p. 18–21, pls. 1, 2. Nonporphyritic basalt flow sequence. Thickness 300 to 400 feet at Alvord Peak. Conformably overlies Clews fanglomerate (new); northwestward, overlaps Clews as fanglomerate wedges out, and rests on plutonic rocks and granodiorite porphyry dikes of basement complex. Underlies Spanish Canyon formation (new) or Barstow formation where Spanish Canyon is missing. Assigned to middle Miocene or older on basis of middle Miocene vertebrate fossils in lower part of overlying Barstow.

Named for Alvord Peak, Alvord Mountain quadrangle, San Bernardino County.

Amador Group

Middle and Upper Jurassic: East-central California.

N. L. Taliaferro, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 89–90. Amador group substituted for preoccupied name Tuolumne. Consists of clastic sediments and volcanics which are strongly folded and frequently faulted. Thickness less than 5,000 to more than 15,000 feet. Underlies Mariposa [slates].

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 282–284, 303, 306 (fig. 2), 307 (fig. 3). On Cosumnes and Calaveras Rivers, divisible into two formations: Cosumnes below and Logtown Ridge agglomerates (both new). Thickness on Cosumnes River immediately west of Mother Lode Highway 7,100 feet; thicker to west and acutely folded. On Merced River, divisible into five formations: lower volcanics (thickness unknown, and base not exposed), pillow basalts (1,200 feet), Hunter Valley cherts (950 feet), Penon Blanco volcanics (about 9,000 feet), and Agua Fria (3,500 feet). Complete correlation of sections not established, but Logtown Ridge and Penon Blanco are correlated and pillow basalts and Hunter Valley cherts are equivalent to part of Cosumnes formation. Batholithic intrusions of granodiorite and diorite common, as are plugs, sills, and dikes of basic and ultrabasic rocks. Younger than Calaveras and older than Mariposa. Nearly everywhere Amador grades upward into Mariposa; north of Middle Fork of American River, Mariposa overlaps Amador. Occurs as long narrow belts, either flanking western Calaveras or rising as overturned anticlines from beneath Mariposa; overturning is commonly toward west, axial planes of folds dipping eastward at angles of 60° to 70°. Exact age of Amador not known but believed to be from upper Middle to lower Upper Jurassic. Type sections designated. On various geologic folios, group of rocks here called Amador has been mapped as Calaveras, Mariposa, "diabase and porphyrite," amphibolite schist, and quartz amphibolite.

G. R. Heyl and J. H. Eric, 1948, California Div. Mines Bull. 144, pt. 1, p. 51–53, pl. 7. Series of schists and greenstone in Newton mine area (near Jackson, Amador County), tentatively correlated with Jurassic Amador group described by Taliaferro (1942), subdivided into four formations (descending): Mountain Spring volcanics, Dufrene slate, Newton Mine volcanics, and Sunnybrook volcanics. Section described exposed in western part of area from Mariposa slate eastward along Mountain Spring Creek to Newton mine. In general rocks dip steeply eastward; in some places beds are vertical; graded bedding suggests that rocks lie on western, overturned limb of major anticline and become progressively older toward east. Approximate thickness of section 2,057 feet.

J. H. Eric, A. A. Stromquist, and C. M. Swinney, 1955, California Div. Mines Spec. Rept. 41, p. 10–11, pls. 1, 2. Described in Angels Camp and Sonora quadrangles, Calaveras and Tuolumne Counties, where it includes Cosumnes and Logtown Ridge formations. Middle or Upper Jurassic.

Type section for northern end of group is on Cosumnes River, Eldorado and Amador Counties; for southern end, on Merced River. Named for exposures along Cosumnes River, Amador County.

Amalia Formation

Tertiary, middle or upper: Northern New Mexico and southern Colorado.

P. F. McKinlay, [1955], New Mexico Bur. Mines Mineral Resources Bull. 42, p. 16–18, pl. 1. Includes interbedded arkosic sedimentary rocks, basalt flows, and rhyolite tuffs. Beds and flows are often lenticular and irregular. Thick flows of olivine basalt occur near base. These are overlain by beds of siltstone, tuff, and pumice, 50 to 200 feet thick. A 50- to 150-foot layer of welded tuff lies above the siltstones. This unit is silicified and forms conspicuous outcrops for more than 7 miles along strike. Welded tuff is overlain by 200 to 600 feet of semiconsolidated sandstones and conglomerates. The total exposed thickness approximately 2,000 feet.

Upper beds of formation grade into, or are overlain by, thick Tertiary gravels. South and east of Costilla, Amalia overlain unconformably by Quaternary-Tertiary basalt flows. Amalia lies above andesite and andesite tuffs. South of Rito de los Cedros, appears to overlap onto Precambrian granite and metamorphic rocks.

Named for Amalia [N. Mex.] post office which lies on west side of Costilla Valley, 5 miles southeast of town of Costilla. Unit is best exposed east of the Rio Costilla, 4 or 5 miles south of Costilla, N. Mex., and on north side of canyon formed by Rito de los Cedros.

Amana Beds

Devonian: East-central Iowa.

S. W. Stockey, 1933, (abs.) Pan-Am. Geologist, v. 60, no. 1, p. 78. Incidental usage.

M. A. Stainbrook, 1945, Geol. Soc. America Mem. 14, p. 7–8. Described as a thick body of shales overlying Cedar Valley limestone. Encountered in wells.

Apparently occur at surface only between Middle and High Amana communities in Iowa County.

Amargo Formation

Jurassic: Southern California.

H. S. Gale, 1946, California Jour. Mines and Geology, v. 42, no. 4, p. 358. Group of altered volcanic rocks and minor intrusive bodies. Evidently unmelted remnants of rocks that were intruded by quartz monzonite, apparently portions that floated on the upper surface of the granitoid batholithic magma during its intrusion.

Occurs in low hills beginning less than 1 mile southeast of the Baker and Western mines. Lies on both sides of paved road that connects the mines with the settlement, formerly called Amargo, but now called Boron [Mohave Desert region, Kern County].

Amargosa chaos

Post-Miocene(?): Southeastern California.

L. F. Noble, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1936; 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 963–978, pl. 3. Name applied to rocks of overthrust plate of Amargosa thrust. These rocks are broken into innumerable blocks and slices, which are thrust over one another to form an extremely complex mosaic. Chaos is divided into Virgin Spring, Calico, and Jubilee facies, each characterized by certain kinds of rock. The thrust and chaos are folded into several plunging anticlines of northwesterly trend, along whose crests earlier Precambrian rocks below the thrust are exposed. Unconformably underlies Funeral fanglomerate.

Virgin Spring area, in Black Mountains east of Death Valley. Features similar to Amargosa thrust and chaos occur throughout an area of at least 8,000 square miles that borders and includes Death Valley trough.

Amargosan series[1]

Early Tertiary: California.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 78.

Best exposed in Amargosa Desert and in Furnace Canyon near Death Valley.

Amarillo sandstone[1]

Jurassic(?): Northeastern New Mexico.

Original reference: C. R. Keyes, 1905, Am. Jour. Sci., 4th, v. 20, p. 424.

Derivation of name not given.

Amasa Formation (in Baraga Group)

Precambrian (Animikie Series): Northwestern Michigan.

Stephen Royce, 1936, Lake Superior Min. Inst. Proc. 29th Ann. Mtg., p. 78, 81, 86, 97. One of the iron-bearing formations of Lake Superior region. Separated by conglomerate from overlying Upper Huronian slates; associated with contemporaneous volcanics, called Hemlock greenstone, at its base.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 36–37. Included in Baraga group (new); Animikie series. Lies stratigraphically between Hemlock formation and Michigamme slate. Occupies same stratigraphic position as Fence River formation (new), but direct equivalence not yet proved. Contains wide variety of rocks—pyritic slate, ferruginous slate and quartzite, chert, and cherty hemotitic iron-formation. Aggregate thickness about 1,500 feet.

Occurs in Iron County on western Menominee Range.

Amawalk Granite

Upper Ordovician(?): Southeastern New York.

T. W. Fluhr, 1948, Rocks and Minerals Mag., v. 23, no. 8, p. 699. Shown on map legend as underlying Croton Falls diorite and overlying Thomaston granite.

Vicinity of New York City.

Amazonia Limestone Member (of Lawrence Shale)

Amazonia Limestone Bed (in Lawrence Shale)[1]

Pennsylvanian (Virgil Series): Northwestern Missouri and eastern Kansas.

Original reference: H. Hinds and F. C. Greene, 1915, Missouri Bur. Geology and Mines, v. 13, 2d ser., p. 31, 170, 179.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 158–159. Amazonia limestone member occurs about 24 feet below top of Lawrence shale at Amazonia, at Heumader quarry, 1½ miles northwest of St. Joseph, Mo., and near Wathena, Kans. Thickness 9 feet at type locality; 13 feet near St. Joseph and Wathena; thins southward.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 68 (fig. 24), 72. Typically light-gray dense hard limestone occurring about 25 or 30 feet below top of Lawrence shale. Separated from underlying Ireland sandstone member by unnamed shale and sandstone interval. Thickness ranges from featheredge to about 13 feet. In southern outcrop area, it averages about 1.5 feet.

Type locality: Amazonia, Andrew County, Mo.

Amboy stoneware clay[1] (in Raritan Formation)

Cretaceous: Northeastern New Jersey.

Original reference: Heinrich Ries, H. B. Kümmel, and G. N. Knapp, 1904, New Jersey Geol. Survey, v. 6, p. 168–172.

H. C. Barksdale and others, 1943, The ground-water supplies of Middlesex County, New Jersey: New Jersey State Water Policy Comm. [Spec.

Rept. 8], p. 66, 67. Varies in color from light gray through darker grays to nearly black with considerable amount of carbonaceous material. Thickness 0 to 30 feet. Where present, forms impermeable layer between Old Bridge sand member (new) of Raritan and Magothy formation.

Named for occurrence at South Amboy, Middlesex County.

Amchitka Formation

Tertiary or older: Alaska.

H. A. Powers, R. R. Coats, and W. H. Nelson, 1960, U.S. Geol. Survey Bull. 1028–P, p. 533–536, pl. 69. Water-laid beds of volcanic breccia and some thin-bedded fine-grained tuff, all interbedded with pillow flows of lava. Andesitic to latitic in composition. Tilted, jointed, and slightly metamorphosed in many areas. Thickness several thousand feet. Overlain with angular unconformity by tuff and conglomerate of Banjo Point formation (new) and lava and conglomerate of Chitka Point formation (new). Oldest recognized rocks on island. Geologic age unknown but must be at least as old as early Tertiary inasmuch as overlying Banjo Point rocks are of early middle Tertiary age.

Type section: Exposed along south coast from South Bight westward to long 179°18′ E., Amchitka Island (Aleutian Islands). Makes up northern part of western third, and most of eastern fourth of island; small isolated exposures at and west of Cyril Cove.

Amelia-Goochland Quartz Monzonite Gneiss[1]

Precambrian: Central Virginia.

Original reference: A. A. Pegau, 1932, Virginia Geol. Survey Bull. 33, p. 15, 20–22, pl. 1.

Occurs in Amelia, Goochland, Powhatan, and southern Louisa Counties.

American Falls Lake Beds[1]

Pleistocene, upper: Southeastern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 30 (table), 69–72, pl. 6. Report discusses ground-water resources of Snake River Plain. American Falls lake beds are younger than Cedar Butte basalt and older than Madson basalt. Consist of a sedimentary member and a basalt member. Thickness about 150 feet.

Type locality: Bluffs along Snake River from American Falls Dam, Power County, to narrows, a distance of about 5 miles.

American Flat Basalt

Quaternary: Western Nevada.

V. P. Gianella, 1936, Nevada Univ. Bull. 30, no. 9, Geology and Mining Ser. no. 28, p. 33, 76–77, pl. 1. Flow of dark-gray to almost black-olivine basalt about 25 feet thick. Underlies alluvium. Stratigraphically above Knickerbocker andesite (new).

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 59–60. Replaced by McClellan Peak olivine basalt. Name American Flat preoccupied.

Occurs in Silver City district in Virginia Range, 12 miles north of Carson City. Largest body of basalt is in extreme southeastern part of American Flat.

American Flat Latite[1]

Miocene: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1907, U.S. Geol. Survey Geol. Atlas, Folio 153.

F. D. Spencer and M. I. Erwin, 1953, U.S. Geol. Survey Circ. 258, p. 8 (fig. 1). Chart shows American Flat latite in sequence above Silverton volcanic series and below Potosi volcanic series.

Occurs in vicinity of Ouray.

American Fork Formation[1]

Lower(?) Cretaceous: Central southern Montana.

Original reference: E. Douglass, 1909, Carnegie Mus. Annals, v. 5, p. 269–288.

Occurs near American Fork of Musselshell River, Sweetgrass County.

American Lakes Glacial Substage

American Lakes Till

Pleistocene (Wisconsin): Central Colorado.

D. F. Eschman, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1380. Time of latest of four glacial advances in area. Minor advance resulting in deposition of formless deposits of fresh drift. Followed Silver Creek advance (new).

D. F. Eschman, 1955, Jour. Geology, v. 63, p. 201 (fig. 2), 206–207, pl. 2. Deposits of substage mapped as American Lakes till. Pebbles in till are fresh, and no weathered profile evident. Surface of drift area sparsely strewn with large boulders of rock types present in cirque head wall. Deposits are more recent than those of Silver Creek substage but not so recent as some deposits not definitely connected with a glacial advance and referred to as post-American Lakes in age.

Named for American Lakes, at head of Middle Fork Michigan River, North Park. Two rock steps immediately below lakes are covered with deposits of substage. Deposits also present in hanging valley below Lake Agnes and near head of Silver Creek.

American Nettie Quartzite[1]

Upper Cretaceous: Southwestern Colorado.

Original reference: J. D. Irving, 1905, U.S. Geol. Survey Bull. 260, p. 56.

Probably named for a mine.

American Ravine Andesite Porphyry

Miocene(?): Western Nevada.

V. P. Gianella, 1936, Mining and Metallurgy, v. 15, no. 331, p. 299 (table 1). Incidental usage.

V. P. Gianella, 1936, Nevada Univ. Bull., v. 30, no. 9, p. 33, 44–45, 50–52, pl. 1. Light-gray felsitic hornblende andesite about 500 feet thick. Underlies Hartford Hill rhyolite; overlies fanglomerate, monzonite, or metamorphic rocks. Eocene.

F. C. Calkins, 1944, Outline of the geology of the Comstock lode district, Nevada: U.S. Geol. Survey, p. 16–17; F. C. Calkins and T. P. Thayer, 1945, Geologic map of the Comstock lode district (1:24,000): U.S. Geol. Survey. Intrusive into Hartford Hill rhyolite and probably into Alta andesite. Miocene(?).

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042-C, p. 52, pl. 3. Distinguished only in Comstock lode district.

Occurs on eastern side of Virginia Range, near Virginia City.

†Americus Beds[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Named for Americus, Lyon County.

Americus Limestone Member (of Foraker Limestone)[1]

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: M. Z. Kirk, 1896, Kansas Univ. Geol. Survey, v. 1, p. 80.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 43 (fig. 17), 49, 51 (fig. 19). Basal member of Foraker limestone. Underlies Hughes Creek shale member; overlies Oaks shale member of Hamlin shale. Commonly two limestone beds separated by shale. Thickness ranges from 6 to 22 feet. Wolfcampian.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 14 (table 2), 53-56. Described in Wabaunsee County, Kans. Limestone formerly called Houchen Creek south of Pottawatomie County does not correlate with type section in Nebraska, but coalesces with Americus limestone member in Wabaunsee County. This limestone has distinctive type of algae in lower part of Americus that can be traced north into Pottawatomie and Jackson Counties. Americus formerly consisted of one or two beds of limestone 12 or more inches thick in lower part, 4 to 8 feet of gray fossiliferous shale in middle part, and bed of gray limestone 18 or more inches thick in upper part. In this report, upper contact of Americus is restricted to top of lower one or two beds of limestone. This places upper bed of limestone, which is absent in some places, and beds of shale in Hughes Creek shale member. Lower part of Americus is redefined to include algal bed heretofore referred to as Houchen Creek limestone in Chase County (Moore, Jewett, and O'Connor, 1951, Kansas Geol. Survey, v. 11, pt. 1) and in Lyon County (O'Connor, 1953, Kansas Geol. Survey, v. 12, pt. 1). In southern part of Wabaunsee County, Americus now consists of three beds of limestone separated by two beds of shale, but northward lower shale bed pinches out and lower bed of limestone coalesces with, and becomes part of, middle bed of limestone in northern part of county. Shale that lies above algal limestone was called Oaks shale member in Chase County (Moore, Jewett, and O'Connor, 1951) and in Lyon County (O'Connor, 1953). In Wabaunsee County, this is lower shale bed of Americus. Underlies Hughes Creek shale member; overlies Hamlin shale member of Janesville shale.

Named for exposures near Americus, Lyon County, Kans.

Ames cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 134-140. Embraces interval between Harlem cyclothem, below, and Gaysport cyclothem (new) above. Thickness about 17 feet. Includes (ascending) Ames shale and (or) sandstone, Ames underclay, Ames coal, and Ames limestone members. In area of this report, Conemaugh series is discussed on a cyclothemic basis; 15 cyclothems are named. [For sequence, see Mahoning cyclothem.]

Type section: About center of Ames Township, Athens County (locality 8984, map 16).

Ames Limestone Member (of Conemaugh Formation)[1]

Ames Limestone (in Conemaugh Group)

Upper Pennsylvanian: Eastern Ohio, eastern Kentucky, southwestern Maryland, southwestern Pennsylvania, and northern West Virginia.

Original reference: E. B. Andrews, 1873, Ohio Geol. Survey, v. 1, p. 235, 271, 296.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 43, pl. 9. Correlation chart shows occurrence in eastern Kentucky.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 31–32. Described in eastern Ohio as a dark bluish- to greenish-gray limestone. Thickness varies from a few inches to a maximum of about 15 feet. Lies below Gaysport limestone in some areas. In this report, the Conemaugh is treated as a series.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 71–72, table 1. Top member of Harlem cyclothem.

J. J. Burke, 1958, Science, v. 128, no. 3319, p. 302. Occurs 172 feet above Nadine limestone (new) and 126 feet above Carnahan Run shale (new) in Armstrong County, Pa.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 54–55. Described in Morgan County as member in Conemaugh series. Thickness 10 inches to 3½ feet. Occurs about middle of series and about 140 to 160 feet below Pittsburgh (No. 8) coal. Above Harlem coal and Harlem shale member; separated from Gaysport limestone member by unnamed shale and sandstone members.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94, 138–140. In this report [Athens County], Conemaugh is described on a cyclothemic basis. Ames limestone, Ames coal, Ames underclay, and Ames shale and (or) sandstone are classified as members of Ames cyclothem (new). Ames limestone is about 200 feet above Upper Freeport (No. 7) coal and 180 feet above Pittsburgh (No. 8) coal.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 69, 71, 77. Referred to as Ames limestone in Conemaugh group.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Conemaugh formation as mapped includes Mahoning sandstone near base, Ames limestone in middle of sections, and Brush Creek limestone in lower part of section.

Named for exposures near Amesville, Ames Township, Athens County, Ohio.

Ames Monzodiorite[1]

Mississippian(?): Central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1895, 1901–1902, pl. 1. Listed in chronology of White Mountain Magma series as older than Endicott diorite (new) and younger than Gilmanton monzodiorite (new). Described as gray medium-grained monzodiorite composed primarily of feldspar and hornblende, with some biotite.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 73. Included in a discussion of White Mountain plutonic-volcanic series of Mississippian(?) age.

On shore of Lake Winnipesaukee, northwest of Ames Station, in Belknap Mountains.

Ames Red Bed (in Conemaugh Formation)[1]

Pennsylvanian: Northern West Virginia and western Pennsylvania.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, pl. 6.

Occurs at Morgantown, W. Va., and at Latrobe, Pa.

Ames Shale (in Conemaugh Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 289.

Probably named for occurrence in limestone identified as Ames limestone.

Ames shale and (or) standstone

See Ames cyclothem.

Ames Knob Formation[1]

Silurian: Central southern Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 4.

W. T. Forsyth, 1953, Report of the State Geologist 1951–1952, p. 45. Incidental mention in discussion of Ellsworth schist in Blue Hill. Contains Niagaran fossils.

Named for exposures on shore of Southern Harbor, northwest of Ames Knob, which lies one-half mile west of village of North Haven, Knox County.

Amherst Schist[1]

Pre-Triassic: Central Massachusetts, northern Connecticut, and southwestern New Hampshire.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 218, 219, 222, 224–225.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. In Mount Toby quadrangle, Amherst is quartz-muscovite-biotite schist that locally has been so silicified and pegmatized as to change it into a massive gneissic granitelike rock. Extensive area north of Amherst that was mapped earlier by Emerson as Williamsburg granodiorite and interpreted by him as an intrusive igneous body is altered Amherst schist. Pre-Triassic.

Exposed in Mount Warner and across Amherst, Mass.

Amherstburg Formation (in Detroit River Group)

Amherstburg Dolomite Member (of Detroit River Dolomite)[1]

Middle Devonian: Western Ontario, Canada, southeastern Michigan, and northern Ohio.

Original reference: W. H. Sherzer and A. W. Grabau, 1909, Geol. Soc. America Bull., v. 19, p. 542.

Wilber Stout, 1941, Ohio Geol. Survey, 4th ser., Bull. 42, p. 41–42. Referred to Detroit River group in Ohio where it is basal unit of group and underlies Lucas formation.

G. M. Ehlers, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1455–1466. In revised classification of Detroit River group, Amherstburg dolomite is noted as overlying Sylvania sandstone and underlying Lucas dolomite.

K. K. Landes, 1951, U.S. Geol. Survey Circ. 133, p. 2 (fig. 2), 7–14. Redefined to include Sylvania sandstone, where present, as basal sandstone member of formation. Includes Filer sandstone lentil (new). Except for Sylvania and Filer sandstones, Amherstburg is limestone or dolomite. The only evaporites within the formation are occasional nodules of anhydrite observed in cores from wells drilled in the basin. Beds assigned to Amherstburg in central part of basin agree with fauna, stratigraphic position, and lithologic character of Amherstburg at its type locality. Noncherty limestone or dolomite beneath evaporites and above the Bois Blanc formation on north flank of Michigan basin, and heretofore described by the writer [Landes, 1945] as upper part of the Bois Blanc, is now considered to be Amherstburg. Basal formation of Detroit River group. Underlies Lucas formation. Overlies Bois Blanc formation.

Named for fact that it forms bottom of eastern channel of Detroit River opposite Amherstburg, Ontario.

Amicalola Gneiss

Precambrian: North-central Georgia.

A. S. Furcon and K. H. Teague, 1945, Georgia Geol. Survey Bull. 51, p. 31–34, pl. 3. Term Amicalola gneiss is used to define that part of Precambrian basal complex [of this area] which contains much altered sedimentary rocks and which is characterized by deposits of massive kyanite. Locally replaces term Carolina gneiss. On north, underlies beds of Oglethorpe formation (new); on south and east, terminated by Dawsonville shear zone; western boundary marked by Marble Hill overthrust.

Mapped in parts of Cherokee, Pickens, Gilmer, and Dawson Counties. Lies between Tate and Dawsonville so that a line connecting these towns divides area into about equal parts.

Amity limestone (deposit)

Age not stated: Eastern Oregon.

J. E. Allen, 1946, Oregon Dept. Geology and Mineral Industries G.M.I. Short Paper 15, p. 11. Mentioned in report on limestone deposits in Willamette Valley. One and possibly two limestone lenses that strike north and dip a few degrees west. Only a few feet thick. Lower contact covered. Limestone is interbedded with fine-grained white fossiliferous tuff which is in turn overlain by light-colored tuffaceous sandstone. Fossils indicate marine origin.

Occurs 3 miles south of Amity, Polk County, in foothills of Eola Hills about 1 mile east of Pacific Highway (U.S. 99W) in NE¼ sec. 9, T. 6 S., R. 4 W., W. M., at elevation of about 225 feet.

Amity Member (of Cattaraugus Formation)

Amity Shale[1]

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

Original reference: G. H. Chadwick, 1925, Geol. Soc. America Bull., v. 36, p. 457–464.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1744, chart 4. Upper Devonian. In column occurs above Panama conglomerate and below Salamanca. Geographically extended to southwestern New York.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 33. Member of Cattaraugus formation in southwestern New York where it overlies Panama conglomerate member and underlies Saegerstown member. Derivation of name given.

Name derived from Amity Township, located in Erie County, Pa.

Ammonoosuc Volcanics[1]

Middle Ordovician: Northwestern New Hampshire, north-central Massachusetts, and Vermont.

Original reference: M. P. Billings, 1934, Science, v. 79, no. 2038, p. 55–56.

J. B. Hadley, 1949, Bedrock geology of the Mount Grace quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map. Geographically extended into Massachusetts, where it underlies Clough formation.

M. P. Billings, 1956, The geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 7 (fig. 3), 17–19, 94–98, geol. map. Ammonoosuc volcanics present in four zones, chiefly in western part of state. Belt that extends northeast from Woodsville includes type locality. Second belt northeast of Monroe correlated with Ammonoosuc volcanics because of its lithology and stratigraphic position above Albee formation. Third belt, extending northeast from 3 miles east of Haverhill, correlated because of its lithology and repetition of entire stratigraphic sequence from Albee to Littleton. Fourth belt extending whole length of the state, correlated because of its lithology and repetition of startigraphic sequence, from Ammonoosuc formation through Littleton. In area southwest of Littleton, where both top and bottom of formation are present. Ammonoosuc volcanics are about 2,000 feet thick, but extensive folding makes precise determination difficult. In belt that extends north from Massachusetts to Maine, formation is thinner because only top is exposed above Oliverian plutonic series. Four miles southwest of Randolph thickness is about 5,000 feet. Summary of arguments for and against correlations with other units. Assigned to Upper Ordovician(?) on geologic map, but formation may be Middle Ordovician.

L. M. Hall, 1959, Vermont Geol. Survey Bull. 13, p. 15 (fig. 4), 17–19. Described in southeast corner of St. Johnsbury quadrangle, Vermont and New Hampshire. Overlies Albee formation. Older than Waits River formation. Middle or Upper Ordovician.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, p. 544–545, 551, 554, pl. 1. Discussion of stratigraphic and geotectonic relationships in northern Vermont and southern Quebec. Ammonoosuc volcanics assigned to Middle Ordovician.

Type locality: In district bounded on north by Slate Ledge School and Partridge Lake and on south by Youngs Pond (Ogontz Lake) and Tinkerville, N.H. Locality name taken from old Ammonoosuc mining district, northwest of Ammonoosuc River between Woodsville and Littleton.

Amnicon Formation (in Oronto Group)[1]

Precambrian: Northwestern Wisconsin.

Original reference: F. T. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 50, 54.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1474–1479. Thwaites assumed that Eileen sandstone (in Oronto group) lay below Amnicon sandstone on basis of distribution of outcrops and strike and dip. Eileen at type locality is not in contact with any other formation of Oronto series but is separated by unexposed interval of almost 1½ miles from Amnicon formation. Therefore relation of Eileen and Amnicon is not definitely known at type locality, and sequence postulated by Thwaites is only one of several possible explanations of relation of these two sandstones. Lithological and heavy-mineral evidence suggest that Eileen sandstone belongs above the Amnicon and includes beds on Middle River and Fish Creek sections that Thwaites classes as lower Orienta (in Bayfield group). The Eileen, which resembles Bayfield group of sandstones, is probably basal Orienta, and Amnicon arkose is upper Freda. Thickness of Amnicon as given by Thwaites—5,000 feet—included in his estimate of thickness of Freda. Hence, Oronto group revised to exclude Eileen and Amnicon sandstones.

Exposed on Fish Creek, near Ashland, and on Middle and St. Louis Rivers in Douglas County.

Amoeba Lake Graywackes, Slates, and Tuff

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1603–1605. Differs only slightly from "well-banded Knife Lake" slates and graywackes (unit 5 of series) in that they contain more graywacke and considerable tuffaceous material. Gradational bedding common; interstratified lenses of conglomerate. Highly folded. Thickest sediments, 4,000 to 5,000 feet, occur in segment of Knife Lake snyclinorium whose axis passes through Amoeba Lake. Overlie massive arkosites; underlie Kekekabic Lake tuffs, agglomerates, and slates (new). In this report, Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Amoeba Lake graywackes as unit 9 occurring above pink andesite conglomerates and agglomerates and below Ensign Lake green slates, tuffs, and graywackes (new).

Sediments named after Amoeba Lake where they are best exposed. Report covers a belt in eastern Vermilion district more or less parallel to international boundary.

Amole Arkose or Group

Lower Cretaceous and (or) Upper Cretaceous: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 710 (fig. 2), 713, 716–720, pl. 1. Series of gray to pink coarse-grained arkose, interbedded with shales and a few limestone beds; characterized by rapid and repeated changes in rock type; interbedded shales are usually silvery gray. Few of the limestone units are more than 2 feet thick, and most of them are very thin bedded and range in color from blue gray to black. Unconformably underlies Cat Mountain rhyolite (new); conformably overlies Recreation redbeds (new) into which it grades through a zone about 75 feet thick. Thickness of formation about 2,275 feet [measured near the Ranger Station]. Similarity in some limestone beds suggests repetition in the section, but this could not be proved. Top of Cretaceous is apparently not exposed in range but is cut off either by erosion, as in measured section, or by overthrust sheet.

W. B. Fergusson, 1959, Arizona Geol. Soc. Guidebook 2, p. 44 (fig. 4), 46–47. In southern parts of Tucson Mountains, Kinnison (1958, unpub. thesis) estimated that clastic sediments similar to Amole arkose are more than 5,000 feet thick. At least part of this section was mapped by Brown (1939) with his volcanic unit. Kinnison divided southern section into four formations and suggested that term Amole be elevated to group status. Base of group rests on Permian limestone with a limestone conglomerate. Because there is an angular unconformity within Amole group, Kinnison suggests that group may include two sequences of lithologically similar clastic rocks separated by andesite-pebble conglomerate and the Recreation red beds.

J. E. Kinnison, 1959, Arizona Geol. Soc. Guidebook 2, p. 48 (fig. 5A), 49, 50, 51 (fig. 5B), 54, 55, 149 (fig. 28). Group includes Recreation red beds of Brown (1939) and, possibly andesitic volcanic rocks (Kinnison, 1958) whose exact stratigraphic positions are unknown. Age of group probably Lower and Upper Cretaceous, and some strata may be as young as early Tertiary. Group underlies Tucson Mountain chaos.

D. L. Bryant and J. E. Kinnison, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1235. Paleontological evidence suggests that Amole arkose and underlying Recreation redbeds are most probably Lower Cretaceous and are not wholly Upper Cretaceous as previously designated.

Area: Tucson Mountains, southeastern Arizona. Amole arkose crops out chiefly on western side of southern part of range and extends north to Amole Peak, where it is cut off by granitoid intrusives. Northeastern part of belt extends across and around eastern side of peak.

Amole Granite

[Upper Cretaceous and (or) Tertiary] (Laramide): Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 710 (fig. 2), 721–722. Granite occupies western side of exposed part of a stock west of Amole Peak. Occurs in three different topographic positions which govern its appearance on weathered outcrops. On fresh surfaces, rock is pink speckled with black. On weathered surfaces, it is light tan to drab. Along its southern margin, granite is clearly intrusive into Cretaceous sedimentary rocks. It is not in contact with Tertiary volcanic rocks, but metamorphosed Cretaceous adinoles and hornfels occur in conglomerate at base of Tertiary volcanic rocks on cliff south of Safford Peak. This seems to indicate that granite is Laramide in age.

Area: Tucson Mountains, southeastern Arizona. City of Tucson is located at east base of central part of range.

Amole Latite

[Upper Cretaceous and (or) Tertiary] (Laramide): Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 710 (fig. 2), 725–726, pl. 1. An intrusive on top of Amole Peak. Occurs in series of roughly east-west fingers extending eastward from [Amole] quartz monzonite. Latite is intrusive as sills into Cretaceous sedimentary rocks. It shows extreme variety. Commonest is dense felsitic rock with inconspicuous phenocrysts of quartz and feldspar and abundant xenoliths of arkose and other Cretaceous sedimentary rocks. Elsewhere, rock is coarsely felsitic and so full of fine-grained inclusions that it closely resembles invaded arkoses. No gradational contacts with [Amole] quartz monzonite have been found.

Area: Tucson Mountains, southeastern Arizona. City of Tucson is located at east base of central part of range.

Amole Quartz Monzonite

[Upper Cretaceous and (or) Tertiary] (Laramide): Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 710 (fig. 2), 723–725. Belt of gray quartz monzonite about 1 mile wide and 4 miles long. Occurs to west and northwest of Amole Peak and circles northeasterly part of Amole granite (new). Best exposure is in steep arroyo heading about 1,000 feet west of Amole Peak and extending northward.

Area: Tucson Mountains, southeastern Arizona. City of Tucson is located at base of central part of range.

Amoret Limestone Member (of Altamont Formation)

Pennsylvanian (Des Moines Series): Western Missouri, south-central Iowa, eastern Kansas, and northeastern Oklahoma.

J. G. Grohskopf and Earl McCracken, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 10, p. 17. Mentioned as basal member of Altamont formation. Underlies Lake Neosho shale member. Name credited to L. M. Cline and F. C. Greene.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 7–8. Name Amoret suggested as substitute for Tina, which is abandoned because type Tina proved not to be Altamont. Type locality designated.

L. M. Cline and F. C. Greene, 1950, Missouri Geol. Survey and Water Resources Rept. Inv. 12, p. 18–21. At type locality, consists of three gray limestone beds and a thin greenish-gray shale bed; thickness about 5 feet. Varies in thickness and lithology in short distances. Overlies Bandera shale. Reference is made to an underclay as part of Amoret cyclothem. Occurrence in Madison County, Iowa, noted.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 15, 16 (fig. 2). Occurs in Oklahoma where it is shown as a limestone [bed] within Altamont member of Oologah formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 31, fig. 5. Represented in Madison County by thin layer of fresh-water limestone nodules in matrix or red underclay that is continuous with Neosho Lake shale member above. Amoret is not present farther south in Iowa. Maximum thickness exposed in Madison County 10 inches.

Type locality: Two miles south of Amoret, Bates County, Mo., in sec. 33, T. 40 N., R. 33 W.

Amos Wash Member (of Supai Formation)

[Permian]: Central Arizona.

R. L. Jackson, 1951, Plateau, v. 24, no. 2, p. 86–88. Shown on stratigraphic section as overlying Naco formation and underlying Big "A" sand facies of Supai. Name credited to S. S. Winters.

Type locality and derivation of name not stated. Winters (1951, Plateau, v. 24, no. 1) described, but did not name, members of the Supai along Amos Wash, 15 miles west of White River, Fort Apache Reservation.

Amsden Formation[1]

Amsden Formation (in Montchauve Group)

Mississippian and Pennsylvanian: Wyoming and Montana.

Original reference: N. H. Darton, 1904, Geol. Soc. America Bull., v. 15, p. 394–401.

H. W. Scott, 1935, Jour. Geology, v. 43, no. 8, pt. 2, p. 1017 (table 3), 1020–1023. In its type locality, consists of those beds that occur between top of Madison limestone and base of Tensleep formation. Originally considered Pennsylvanian in age; Branson and Greger (1918, Geol. Soc. America Bull., v. 29, no. 2) have shown Amsden of Wind River Mountains to be Mississippian. In south-central Montana, Amsden rests upon erosional surface developed on Madison limestone. In area between Three Forks and Townsend, Amsden is separated from Madison by series of fossiliferous sandstones, shales, and limestones that attain thickness as great as 1,200 feet in central Montana. Group of strata between Amsden and Madison in central Montana has been designated Big Snowy group (new). In central Montana, Amsden underlies Ellis formation (Upper Jurassic). Section measured on southeast corner of Quadrant Mountain (type section of Quadrant) shows Amsden formation (beds 1–7) 109 feet thick; underlies Quadrant formation (beds 8–21); overlies Madison limestone.

C. C. Branson, 1937, Jour. Paleontology, v. 11, no. 8, p. 650–660. Restricted at base to exclude unit herein named Sacajawea formation. At measured section on Bull Lake Creek, Wyo., Lower Amsden consists of 21 feet of unfossiliferous laminated limestone possibly of Chester age; Upper Amsden consists of 80 feet of sandstone overlain by 96 feet of limestone, sandstone, and shale. Underlies Tensleep sandstone.

C. C. Branson, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1201, 1223. Discussion of Pennsylvanian of central Wyoming. Tensleep sandstone of Darton is only locally recognizable as lithologic unit and is not a true stratigraphic unit. No boundary can be drawn to separate it from Amsden formation, and fauna of upper part of Amsden is indistiguishable from that of Tensleep sandstone. Name Tensleep is herein retained as name of a formation which includes entire Pennsylvanian sequence in central Wyoming; that is, Tensleep sandstone of Darton, upper part of Amsden, and some unnamed beds above Tensleep. Measured sections show that the Tensleep overlies Sacajawea formation, or Sacajawea(?), or unnamed beds of Chester(?) age.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 132. Discussion of Wind River Mountains area. Tensleep as herein defined includes upper part of Amsden of Darton and name Amsden is dropped.

M. L. Thompson and H. W. Scott, 1941, Jour. Paleontology, v. 15, no. 4, p. 350. Scott's (1935) section on Quadrant Mountain revised. Beds 3–21 are Pennsylvanian and are included in Quadrant formation; beds 1–2 are Mississippian and are referred to Sacajawea(?) formation. Name Amsden deleted from section.

G. W. Berry, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 18–19, 21 (fig. 5). Amsden, in Three Forks area, overlies Madison formation and underlies Quadrant formation. Lower part, which is probably equivalent to Sacajawea, contains an upper Mississippian fauna comparable to that of Brazer limestone; beds in upper 100 feet contain fossils generally considered Pennsylvanian.

E. S. Perry and L. L. Sloss, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1293–1295. Branson (1937, 1939) and Thompson and Scott (1941) recognized that the Amsden, as defined by Darton, included strata of both Pennsylvanian and Mississippian age. They placed all Pennsylvanian strata in the Tensleep (Quadrant) and established Sacajawea formation to include lower beds bearing a Ste. Genevieve fauna. Between redefined Tensleep and Sacajawea are unnamed strata bearing a Chester fauna. These latter beds may be traced throughout central Montana and much of Williston basin, overlapping truncated edges of Big Snowy strata and transgressing peninsula area devoid of both Big Snowy and Sacajawea sediments along Montana-Wyoming border. Name Amsden should be retained for these strata in Montana and Williston basin; if name Amsden is not retained, then new term must be coined for these strata.

H. W. Scott, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1195. *Millerella* zone occurs about middle of formation.

P. T. Walton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, p. 1296, 1301–1302. Amsden, in Judith basin area, consists of two members: lower sequence of red and pink shales and mudstone, red coarse poorly sorted ferruginous sandstones, and locally thin beds of grayish-green and buff fine-grained limestone; upper sequence of marine fossiliferous limestone contining interbedded red, maroon, and purple shale. In places, where pre-Ellis erosin has not cut too deep, a thin sequence of yellow, pink, and purple clay shale lies above the marine limestone section. Overlies erosional surface truncating Heath and Otter shales; underlies Ellis formation. Mississippian and Pennsylvanian (Morrow).

J. D. Vine and W. J. Hail, Jr., 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 108. Where exposed along northern flank of Little Belt Mountains, the Amsden ranges in thickness from about 500 feet to more than 900 and rests with apparent conformity on Otter formation. Unconformably underlies Ellis group which in this area commonly consists only of Swift formation.

L. R. Laudon and J. L. Severson, 1953, Jour. Paleontology, v. 27, no. 4, 512 (fig. 2d). Discussion of crinoid fauna from Mississippian Lodgepole formation. Columnar section shows Amsden formation overlying Mission Canyon formation. Pennsylvanian.

W. F. Scott and P. C. Wilson, 1953, (abs.) Geol. Soc. America Bull., v. 64, no. 12, pt. 2, p. 1554. Sacajawea formation restricted vertically to include only red-bed sequence at base of Amsden and extended laterally throughout area where red beds are recognizable. Term Amsden should be retained for limestones and dolomites between Sacajawea (restricted) and typical sandstone of Tensleep or its equivalents.

C. A. Burk, 1954, Jour. Paleontology, v. 28, no. 1, p. 1–16. Review of fossils identified from Amsden formation indicates a Pennsylvanian rather than Mississippian age for the Amsden in Wyoming.

J. D. Love, 1954, Tentative diagrammatic correlation of Tensleep, Amsden, Casper, and Hartville formations in Wyoming: Wyoming Geol. Assoc.

Guidebook 9th Ann. Field Conf. Chart shows that Darwin sandstone member of Amsden overlies type Sacajawea formation at Bull Lake.

A. B. Shaw and W. G. Bell, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 3, p. 333–337. Discussion of age of Amsden formation at Cherry Creek, Wind River Mountains. Six new collections of fossils from lower part of Amsden place Mississippian-Pennsylvanian boundary more than 48 feet and less than 63 feet above Madison limestone. Lower faunas are Chesteran in age, and upper faunas are tentatively dated Atokan. Name Sacajawea formation is rejected for Mississippian beds at Cherry Creek. Presence of two sandstones in Amsden, both of which have been called "Darwin sandstone" is inferred. Amsden at Cherry Creek contains beds that are specifically excluded farther north in Wind River Mountains. Thus, there is dual usage of name Amsden. Solution of problem lies in type area of formation. If typical Amsden contains both Mississippian and Pennsylvanian faunas, Cherry Creek section is also typical Amsden, and Love's (1954) restricted Amsden should be renamed. Conversely, if type Amsden lacks Sacajawea fauna, restricted Amsden is proper, and Cherry Creek section should be renamed.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 49, pl. 6. Formation, in Crazy Creek area, Johnson County, Wyo., overlies Madison limestone and underlies Tensleep sandstone. Thickness about 250 feet. Corals in lower part of formation range from late Mississippian to early Pennsylvanian.

P. A. Mundt, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1918–1919, 1928–1929. In central Montana, so-called "Amsden" formation consists of three lithologic divisions: an upper dolomite unit, a middle brownish limestone unit, and a lower sequence of red shale and sandstone beds. Dolomite unit is lithologically, stratigraphically, and paleontologically equivalent to carbonate part of Amsden at its type locality in Wyoming. Amsden dolomite overlaps toward the south the underlying brown limestone and red shale beds and also formations of Big Snowy group. Unconformably(?) underlying Amsden dolomite of Atokan age is brown ostracodal limestone unit which is probably of Chester age but may be all or in part early Pennsylvanian. This brown limestone was named Alaska Bench formation by Freeman (1922), and his terminology is recommended herein. Thickness 33 feet along Durfee Creek, Fergus County; top of section eroded.

V. L. Freeman, E. T. Ruppel, and M. R. Klepper, 1958, U.S. Geol. Survey Bull. 1042–N, p. 498–499, 550, pl. 42. In Townsend Valley, Broadwater and Jefferson Counties, Mont., Amsden formation, which is probably separated from Mission Canyon limestone by erosional unconformity, includes rocks of both Mississippian and Pennsylvanian age. Consists of red calcareous siltstone with medial unit of gray carbonate rock and grades into Quadrant formation. Thickness 259 feet in Limestone Hills.

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 344–346. Big Snowy group revised to include (ascending) Kibby sandstone, Otter, Heath, Cameron Creek, and Devils Pocket formations. Various parts of Big Snowy group (revised) have been correlated with Amsden formation of northern Wyoming and southern Montana. The two sequences represent same general interval of geologic time, from end of Madison to beginning of Tensleep. They occupy distinct basins separated by a divide, toward which Amsden rocks thin and vanish from the south and Big Snowy rocks thin and vanish from the north. Scott (1935) used Amsden formation in central Montana for rocks (Cameron Creek formation and Alaska Bench limestone) lying above Heath formation. Very few dependable correlative ties have been found between Big Snowy rocks of central Montana and Amsden rocks less than 50 miles away in southern Montana. Mundt (1956) shifted name Amsden from rocks to which it was assigned by Scott and applied it to entirely different rocks of Atokan age. In present report, it is preferred to give these rocks separate formational names and discontinue term Amsden in central Montana.

R. P. Willis, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1942 (fig. 2), 1962–1963. This paper concurs with Scott and Wilson's (1953) proposals of applying name Sacajawea to persistent predominantly red shale unit (including Darwin sand) formerly referred to as "lower Amsden." Term Amsden then is restricted to the overlying predominantly cherty carbonate sequence. Term Amsden (restricted) is used in central Montana area to refer to carbonate sequence underlain by Tyler formation, or older rocks where Tyler is absent. Unit is overlain either by Tensleep sandstone, Minnelusa formation of Williston basin, or strata of Ellis group. Maximum thickness 400 feet (south end of Judith basin). Divisible into two units: lower, predominantly Alaska Bench limestone member, and unnamed upper part referred to as dolomite member. Pennsylvanian (Morrowan-Atokan). Name Amsden (restricted) could possibly be extended into Williston basin region.

T. W. Todd, 1959, Dissert. Abs., v. 20, no. 6, p. 2230–2231. Sacajawea formation, Amsden formation, and Tensleep sandstone are products of marine transgressive-regressive cycle that took place on Wyoming cratonic shelf during Pennsylvanian period as one phase in development of eastern Cordilleran geosyncline. Name Montchauve group is suggested for these formations.

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Discussion of stratigraphy of Pennsylvanian in northern Utah, western Wyoming, northwestern Colorado, and southeastern Idaho. Suggested that Quadrant and Casper formational names be abandoned and Tensleep-Amsden-Sacajawea terminology extended to include strata formerly referred to by these names and that term Sacajawea be accepted as formational name applicable to red clastic sequence between Madison limestone, or equivalent, and Amsden carbonates.

Named for Amsden Branch of Tongue River, west of Dayton, Sheridan County, Wyo.

Amsterdam Limestone (in Black River Group)[1]

Amsterdam Limestone (in Trenton Group)

Middle Ordovician: Eastern New York and western Vermont.

Original reference: R. Ruedemann, 1910, New York State Mus. Bull. 138, p. 72.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 259–260, pl. 2. Included in lower part of Trenton group and discussed under formations of Rockland age. At Manny Corners, underlies Larrabee member (new) of Glens Falls formation and overlies Lowville formation. Dark-gray medium-textured limestone. Thickness about 11 feet. At Crown Point, 16 feet of Amsterdam beds overlie 27 feet of Chaumont and underlie 16 feet of Isle la Motte. Typical section given.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 795–814. Evidence presented to substantiate radical change in interpretation of Paleozoic stratigraphy of Saratoga Springs region. Previously accepted sequence of beds (Potsdam sandstone, Theresa formation, Hoyt limestone, Little Falls dolomite, Amsterdam sandstone, Trenton limestone, Canajoharie shale) is revised to read Potsdam sandstone, Galway formation (new), Hoyt limestone, Ritchie limestone (new), Mosherville sandstone (new), Gailor dolomite (new), Lowville limestone, Amsterdam limestone, Trenton limestone (Rockland? Hull, Sherman Fall representatives), and Canajoharie shale. Amsterdam is 3 feet thick in area instead of 50 feet as previously indicated. Where Lowville is absent, the Amsterdam overlies Gailor dolomite.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 15). Shown on correlation chart as underlying Isle la Motte limestone in western Vermont and Lake Champlain area.

Typical section in quarry one-half mile east of Manny Corners, 3 miles east-northeast of Amsterdam, Montgomery County, N.Y.

Anacacho Limestone[1]

Anacacho Limestone (in Taylor Group)

Upper Cretaceous (Gulf Series): Southwestern Texas.

Original reference: R. T. Hill and T. W. Vaughan, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 240.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 46–47. Foraminifera described. Anacacho limestone listed in Taylor group.

Named for Anacacho Mountains, Kinney County, which are capped by the formation.

Anadarche Conglomerate (in Hoxbar Formation)[1]

See Anadarche Member (of Hoxbar Formation).

Anadarche Limestone (in Hoxbar Formation)[1]

See Anadarche Member (of Hoxbar Formation).

Anadarche Member (of Hoxbar Formation)[1]

Anadarche Member, Beds, or Limestone (in Hoxbar Group)

Pennsylvanian (Missouri Series): Southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 15–16.

C. W. Tomlinson, 1929, Oklahoma Geol. Survey Bull. 46, p. 43–44. Described as Anadarche member of Hoxbar formation. Includes Anadarche conglomerate and Anadarche limestone of Tomlinson (1928). Consists of dense hard bluish-gray limestone as much as 20 feet thick at top and limestone conglomerate as much as 10 feet thick at base. Thickness 100 to 200 feet. Lies 500 to 800 feet above Crinerville member and 400 to 600 feet below Daube limestone member. Type locality designated.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 697, chart 6 (column 37). Correlation chart shows Anadarche limestone in Hoxbar group.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 42–43. Anadarche referred to as Anadarche beds or member of Hoxbar group. Thickness 100 to 200 feet. Lies 400 to 500 feet above Crinerville beds or member and some 400 feet below Daube limestone member. Includes basal sandstone or conglomerate, medium shale, and capping limestone.

Type locality: On Anadarche Creek one-eighth mile south of NW cor. sec. 35, T. 5 S., R. 2 E. [Carter County].

Anahuac Formation

Anahuac Stage

Oligocene, upper, or Miocene, lower: Subsurface in Louisiana and Texas.

J. B. Eby, 1943, Oil Weekly, v. 111, no. 4, p. 22–23. Wedge of dark-greenish shale. Ranges in thickness from about 1,600 feet in southeast corner of [Jackson] county to featheredge in northwest section of county.

A. C. Ellisor, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1355–1368. Includes *Discorbis*, *Heterostegina*, and *Marginulina* zones. Lies between basal sands of Fleming above and subsurface Frio below. Type well and locality designated.

A. D. Warren, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 223 (fig. 1), 225–227. In southwestern Louisiana, sediments of Anahuac stage are almost identical to type section in Texas. Stage consists, for most part, of shales with some sand in west and central parts of south Louisiana and of limestone and calcareous clastics in eastern part of State. Younger than Frio stage. Either upper Oligocene or lower Miocene; age is controversial. In reference well for stage, Anahuac sequence is about 3,500 feet thick.

H. C. Goheen, 1959, Gulf Coast Assoc. Geol. Soc. Trans., v. 9, p. 91–103. Formation in southern Louisiana subdivided to include Erath member (new). Upper Oligocene or lower Miocene.

Type locality: Anahuac oil field, 5 miles east of town of Anahuac, Chambers County, Tex. Type well: Humble Oil and Refining Co. Middleton No. 1. Formation present in well from 5,890 to 6,984 feet. Reference well: Humble Oil and Refining Co. E. E. Wild No. 1, Jefferson Davis Parish, La.

Anakeesta Formation (in Great Smoky Group)

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 959–960. Consists mainly of dark-gray or black silty argillaceous rocks, variously metamorphosed. Interbedded are thick beds of lighter gray coarser feldspathic sandstone. Many of the lighter beds form single layers in the darker rocks, but some form units of considerable thickness that are classed as tongues of Thunderhead sandstone. Overlies and intertongues extensively with the Thunderhead; individual tongues do not exceed 2,000 feet in thickness but range through a stratigraphic interval of nearly 5,000 feet. East of Thunderhead Mountain where there is no intertonguing, the Anakeesta forms unbroken unit about 4,500 feet thick, underlain by Thunderhead sandstone and overlain by a similar but unnamed sandstone.

Named for Anakeesta Ridge, a high spur between Mount Le Conte and Newfound Gap, Sevier County. Typically exposed along U.S. Highway

441 from base of the ridge up to the gap. Occurs well back in Great Smoky Mountains where it crops out in narrow steep-sided ridges and craggy pinnacles. A synclinal belt extends westward from Mount Sequoyah to meridian of Gatlinburg, most of belt being north of State-Line divide. Farther west, formation appears in homoclinal sequence in head drainages of the prongs of Little River.

Anaktuvuk Group[1]

Lower Cretaceous: Northern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 245.

P. S. Smith, 1913, U.S. Geol. Survey Bull. 536, p. 55 (table), 82–84. Discussion of Noatak-Kobuk region. Anaktuvuk group consists of sandstones with subordinate shales and conglomerates. Estimated thickness 2,000 feet. Probably contemporaneous with Koyukuk group. Probably Lower Cretaceous.

Named for Anaktuvuk River on which it occurs.

Anaktuvuk River Glaciation

Pleistocene (pre-Wisconsin): Central northern Alaska.

R. L. Detterman, 1953, *in* T. L. Pewe and others, U.S. Geol. Survey Circ. 289, p. 11, 13 (table 1). Four Quaternary glacial advances recognized in Sagavanirktok-Anaktuvuk district. Anaktuvuk, the oldest, succeeded by Sagavanirktok glaciation (new). Evidence for glaciation consists of quartzitic conglomerate boulders on hills 500 to 600 feet above Anaktuvuk River and drift preserved as low subdued tundra-covered morainal hills that occupy area of 100 square miles along the river.

Renamed Anaktuvuk River Glaciation in order to retain name Anaktuvuk for group.

In Sagavanirktok-Anaktuvuk region.

Analomink Red Shale[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: Bradford Willard, 1935, Geol. Soc. America Bull., v. 46, no. 8, p. 1206.

Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 5, p. 588. Local unit of 100 feet of red beds at its type locality. White (1881) mistook it for his much younger New Milford red shale, from which it is separated by beds probably equal to lower Chemung and upper Portage. Valuable only for recognizing base of Delaware River formation.

Type locality: Analomink, Monroe County.

Anamosa Dolomite[1]

Silurian (Niagaran?): Central eastern Iowa.

Original reference: S. Calvin, 1895, Iowa State Univ. Bull. Lab. Nat. History, v. 3, no. 3, p. 186, 189.

Named for Anamosa, Jones County.

Anarchist Series[1]

Late Paleozoic: Southern British Columbia, Canada, and north-central Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 10, 11, 12.

A. C. Waters and Konrad Krauskopf, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1358–1364, pl. 1. Heterogeneous group of greenstones, phyllites, quartzites, chlorite schists, crystalline limestone, and partially metamorphosed conglomerates. Subdivided into three units termed Lower, Middle, and Upper Anarchist series. Total thickness unknown; sections over 5,000 feet thick, apparently without duplication, include only a part of 1 of the 3 divisions. Older than Colville batholith. Shown on map legend as unconformably underlying Triassic limestone.

Daly mapped Anarchist series around Anarchist Mountain, British Columbia.

Anastasia Formation[1]

Pleistocene: Florida.

Original reference: E. H. Sellards, 1912, Florida Geol. Survey 4th Ann. Rept., p. 18.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 65–67. Formation as herein defined includes coquina, sand, sandy limestone and shelly marl of pre-Pamlico Pleistocene age that lies along both Florida east and west coasts. This excludes surficial sand of Pamlico age. Upper part of formation is contemporaneous with Miami oolite, upper part of Key Largo limestone, and Coffee Mill Hammock marl member of Fort Thompson formation, all of which might be considered as facies of Anastasia. Formation is wedge shaped, thin toward the interior and thick toward coast, where it may be as much as 60 feet thick. On west coast is a thin irregular deposit extending from Marco Island as far north as Tampa Bay; greatest thickness probably not more than 10 feet. Merges with upper marine members of Fort Thompson in Caloosahatchee River valley.

Typically exposed on Anastasia Island; also in cut made by Florida East Coast Railway on Tomora Creek, near Ormon, and along coast at Rockledge.

Anaverde Beds

Miocene: Southern California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on geologic map legend as nonmarine sediments. No text.

This may or may not be same unit later defined as Anaverde Formation.

Anaverde Formation

Pliocene, lower to middle: Southern California.

R. E. Wallace, 1946, (abs.) Am. Geophys. Union Trans., v. 27, no. 4, p. 552. Mentioned as part of sediments occurring in trough of San Andreas rift between Palmdale and Elizabeth Lake.

R. E. Wallace, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 785, 790–792. Consists of pink to reddish conglomerate and arkose (at base), white to buff conglomerate and arkose, and about 1,000 feet gypsiferous shale at top. Thickness about 2,000 feet. Unconformably underlies Quaternary deposits; rests with depositional contact on granite. Derivation of name given. Name credited to C. L. Gazin (unpub. ms.).

L. F. Noble, 1953, Geology of the Pearland quadrangle, California: U.S. Geol. Survey Geol. Quad. Map [GQ–24]. Further described and noted as occurring only north of San Andreas fault.

This may or may not be same unit as Anaverde Beds (Jenkins, 1938).

Named from Anaverde Valley [Palmdale quadrangle].

Anawalt Sandstone[1]

Mississippian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 245.

Exposed at southwest edge of town of Anawalt, McDowell County.

Ancell Group

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 11. Shown on columnar section as comprising (ascending) Kingdom, Daysville, Loughridge, and Harmony Hill formations. Underlies Platteville group; overlies Prairie du Chien group. Includes Glenwood subgroup.

Occurs in Dixon-Oregon area.

Ancha Formation (in Santa Fe Group)

Pliocene, upper, or Pleistocene: North-central New Mexico.

E. H. Baltz, Jr., and others, 1952, New Mexico Geol. Soc. Guidebook 3d Field Conf., p. 12, 15, 16, 17. Consists of poorly consolidated sandstone, siltstone, and conglomerate. Thickness 0 to 200 feet. Unconformably overlies Galisteo sandstone. Considered eastward extension of Puye gravel.

Brewster Baldwin and F. E. Kottlowski, 1955, New Mexico Bur. Mines Mineral Resources Scenic Trips to the Geologic Past, no. 1, p. 8, 21, 24, geol. map. Formation rests on westward-sloping surface that cuts across tilted Tesuque formation. Mapped near Canada Ancha west of city of Santa Fe.

Brewster Baldwin, 1957, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 115–121. Included in upper unit of Santa Fe group. Puye gravel, Ancha formation, and Tuerto gravel all rest with angular unconformity on deformed beds of Tesuque formation. These units of gravel are 500, 300, and 150 feet in maximum thickness respectively. Distinction between Tesuque and Ancha formations in Santa Fe area is based largely on westward dip and somewhat better consolidation of the former. In Buckman area, Ancha appears to intertongue with Puye gravel and with river gravel that has been assigned by some workers to the ancestral Rio Grande.

A. E. Disbrow and W. C. Stoll, 1957, New Mexico Bur. Mines Mineral Resources Bull. 48, p. 5 (table 1), 28–29. In Cerrillos area, underlies Cuerbio basalt. Thickness 0 to 350 feet. Early Pleistocene(?).

Ming-Shan Sun and Brewster Baldwin, 1958, New Mexico Bur. Mines Mineral Resources Bull. 54, p. 7 (table 1), 18, 22–23, pl. 1. Discussion of Cienga area, Santa Fe County. Formation forms blanket of silt, sand, and gravel that is now being eroded from Cienguilla limburgite and earlier rock units in area. Thickness commonly less than 100 feet. On west side of area, covered by and interbedded with flows of olivine-bearing basalt; locally gravel rests on top of flows. Basalt tuff present about 20 feet below lowest flow, and, though tuff mapped separately in Santa Fe area, it is not distinguished from Ancha formation in area of this report. Formation and basalt flows tentatively dated as early Pleistocene, but they might be Pliocene in age.

Named in vicinity of Santa Fe. Derivation of name not stated. Canada Ancha is shown on topographic map of Agua Fria quadrangle, west of Santa Fe.

Anchor Limestone Member (of Monte Cristo Limestone)[1]

Anchor Member (of Monte Cristo Dolomite)

Lower Mississippian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 17.

J. C. Hazzard, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1503; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 880, 881, 883 (fig. 2). Geographically extended into Nopah Range, Inyo County, Calif., where it consists essentially of limestone with minor amounts of shale and chert. Thickness 622 feet. Underlies Bullion limestone member; overlies Dawn limestone member.

Charles Deiss, 1952, U.S. Geol. Survey Bull. 973–C, p. 115–116, pl. 13. Described in Sloan district, Nevada, where it is 65 to 75 feet thick and consists of thin-bedded (2 to 18 inches) buff and pale-gray dolomite with nodules of gray and tan chert in irregular layers. Overlies Dawn member; underlies Bullion member.

D. F. Hewett, 1956. U.S. Geol. Survey Prof. Paper 275, p. 42. Described in Ivanpah quadrangle (California-Nevada) where it commonly consists of several thick layers of light-bluish-gray limestone that contains layers of chert nodules. Overlies Dawn limestone member; underlies Bullion dolomite member.

Named for exposures in region of Anchor mine, Goodsprings quadrangle, Nevada.

Anchor Silt

Pleistocene, lower: Southern California.

P. U. Rodda, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 11, p. 2478–2481, 2489–2490. Consists largely of massive buff-colored fine sands and silts with thin irregular beds of cobble gravel. Maximum thickness 60 feet; base not exposed. In disconformable contact with overlying Medill sand (new).

Area is near hilltop on Overland Avenue, about 1,000 feet south of National Boulevard, and 1 mile southwest of Castle Heights area, in Cheviot Hills, Los Angeles. Named for exposures on Anchor Avenue.

Anchor Mine Tongue (of Mancos Shale)[1]

Upper Cretaceous: Eastern Utah.

Original reference: C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851, p. 36–38.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 180 (fig. 2), 190. Figure 2 shows Anchor Mine tongue of Mancos intertonguing with Sego member of Price River formation. Erdmann reported series of coal-bearing rocks in Anchor Mine tongue and named most conspicuous unit Anchor Mine coal. In present study, coal-bearing bed in Anchor Mine tongue was not noted. These beds lie above upper sandstone tongue of Sego member. Proposed herein to use Erdmann's name Anchor Mine coal for the main coal bed in Sego member of Price River.

Exposed at Anchor mines, Book Cliffs coal field.

Ancon Hill Rhyolite or Dacite

Miocene: Panama.

[T. F. Thompson], 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 25. Dense porphyritic much-jointed hard light-gray material. Pre-Pliocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 323. Rock is dacite. Miocene.

Forms rocks at Ancon Hill, located between towns of Panama and Balboa.

Anderdon Limestone Member (of Lucas Formation)

Anderdon Limestone Member (of Detroit River Dolomite)[1]

Middle Devonian: Western Ontario, Canada, southeastern Michigan, and northwestern Ohio.

Original reference: W. H. Sherzer and A. W. Grabau, 1908, Science, new ser., v. 27, p. 408.

G. M. Ehlers, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1455–1466. Considered an uppermost formation in Detroit River group. Overlies Lucas dolomite. Middle Devonian.

G. M. Ehlers, E. C. Stumm, and R. V. Kesling, 1951, Devonian rocks of southeastern Michigan and northwestern Ohio, p. 5, 8 (fig. 2), 11, 12. Geographically extended into Ohio where it is shown as underlying Dundee limestone. Thickness about 24 feet. Type locality stated.

U.S. Geological Survey classifies the Anderdon as member of Lucas Formation.

Named for exposure in Anderdon (Brunner, Mond Canada, Ltd.) quarry about 1¼ miles north of Amherstburg, Ontario.

Anderson Clay[1] (in Conemaugh Formation)

Pennsylvanian: Ohio.

[Original reference]: Wilber Stout and others, 1923, Ohio Geol. Survey, 4th ser., Bull. 26, p. 452–456.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 40. Member of Conemaugh series. In Morgan County, Anderson clay is developed subjacent to Anderson coal in some exposures. Beds range in thickness from 2 inches to maximum of 1½ feet and consist of gray to tan, subplastic to plastic clays and clay shales.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 121. Anderson underclay member of Anderson cyclothem. Average thickness 2⅔ feet in Athens County. Normally lies directly below Anderson coal, although the coal may be reduced to paper thinness. In northern Appalachian region, the clay is known as (Lower) Bakerstown or Thomas clay. Overlies Bloomfield limestone member. Conemaugh series.

Takes its name from overlying Anderson coal.

Anderson cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 16. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 66–68, table 1, geol. map. Includes (ascending) Anderson shale, 15 feet; Bloomfield limestone (absent in Perry County); Anderson coal; and Portersville shale and limestone, 3 to 8 feet. Occurs below Barton cyclothem and above Wilgus cyclothem. In area of this report Conemaugh series is described on cyclothemic basis; seven cyclothems are named. [For sequence see Mahoning cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 118–123. In Athens County, includes (ascending) Bakerstown shale and (or) sandstone, Bloomfield limestone, Anderson underclay, Anderson coal, and Portersville shale and limestone. In this report [Athens County], Conemaugh series is described on cyclothemic basis; fifteen cyclothems are named. [For sequence see Mahoning cyclothem.]

Exposed in Perry County.

Anderson Phyllite[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 622, 641.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included in Snowy Range series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consists of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

In Medicine Bow Mountains. Named for old Anderson mining prospect on Libby Creek, near contact of this formation with Nash marble series.

Anderson Sandstone

Anderson Sandstone (in Pottsville Group)[1]

Pennsylvanian: Eastern Tennessee.

Original reference: A. Keith, 1896, U.S. Geol. Survey Geol. Atlas, Folio 33.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 18). Shown on correlation chart as overlying Scott formation and including strata from Pilot Knob sandstone up to top of Pennsylvanian.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [Folio], p. 1. Name Anderson formation discontinued. In new classification presented, sediments formerly described as Anderson are redefined and included in Cross Mountain and Vowell Mountain groups (both new).

J. K. Englund, 1957, U.S. Geol. Survey Coal Inv. Map C–39. Youngest Pennsylvanian in mapped area [Scott and Campbell Counties, Tenn.]. Overlies Scott shale. [Pottsville group not used in this report.]

U.S. Geological Survey has discontinued use of Pottsville Group in Tennessee.

Named because of its frequent occurrences in Anderson County.

Andorno Formation

Upper Triassic: North-central Nevada.

R. R. Compton, 1960, Geol. Soc. America Bull., v. 71, no. 9, p. 1388, pl. 1. Phyllite interbedded with persistent thin beds of quartzite, dolomitic quartzite, dolomite, and limestone. Thickness 7,000 to 8,000 feet. Overlies Singas formation (new) with contact gradational; underlies Mullinix formation (new) with contact gradational.

Type area: On high ridges that separate drainage of Andorno, Buffalo, Stone House, and Wash O'Neill Creeks, Santa Rosa Ranges, Winnemucca region.

Andover Granite[1]

Carboniferous: Northeastern Massachusetts.

Original reference: C. H. Clapp, 1910, Igneous rocks of Essex County, Massachusetts.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 39–40. Term Gospel Hill gneiss proposed for mass of granitic rocks that Emerson (1917) mapped as variant of Andover granite but that is considered in this report [Hudson and Maynard quadrangles] as granitized product of Nashoba (new) and Marlboro formations.

Occupies large area around Andover.

Andrada Formation

Permian: Southeastern Arizona.

E. D. Wilson, 1951, Arizona Bur. Mines Bull. 158, Geol. Ser. 19, p. 50. Listed in stratigraphic sequence in Empire Mountains. Consists of shale, marl, limestone, and gypsum, 300 to 1,500 feet thick. Underlies Snyder Hill formation; overlies Naco limestone. Permian.

R. E. Thurmond, W. E. Heinrichs, Jr., and E. D. Spaulding, 1954, Mining Eng., v. 6, no. 2, p. 198 (fig. 1). Shown on generalized columnar section of Mineral Hill area as Andrada (Manzano) formation. Thickness about 400 feet. Underlies Snyder Hill formation; overlies Naco limestone. Permian.

D. L. Bryant, 1955, Dissert. Abs., v. 15, no. 7, p. 1224. Defined to include rocks between Horquilla (Pennsylvanian) and Scherrer (Permian) formations in western part of area where distinctive characters of Earp, Colina, and Epitaph formations are lost.

First described in Empire mining district, Empire Mountains, southeast of Tucson. Derivation of name not given.

Andrecito Member (of Lake Valley Formation)

Mississippian (Osage): Southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 11 (fig. 4), 12–13, passim. Proposed for basal member of Lake Valley formation (redefined). At type section, consists of approximately 35 feet of thin-bedded gray fossiliferous limestone grading upward into thin-bedded dark-gray somewhat cherty limestone. Varies in thickness and lithology throughout area of exposure; thickens northward from type section to over 75 feet in Rich Rim and thins again toward north end of range; maximum thickness approximately 270 feet in Cooks Mountains. At type section, underlies Alamogordo member and unconformably overlies Caballero formation; overlies various units of the

Devonian in areas where Caballero is missing—either Contadero formation or Box member of Percha shale.

Type section: Along south wall of Andrecito Canyon in San Andres Mountains in NW¼ sec. 8, T. 18 S., R. 4 E.

†Andrew shale (in Douglas Formation)[1]

Pennsylvanian: Northwestern Missouri, southwestern Iowa, and eastern Kansas.

Original reference: C. R. Keyes, 1899, Am. Geologist, v. 23, p. 306.

Named for Andrew County, Mo.

Andrew Bay Volcanics

Tertiary: Southwestern Alaska.

R. R. Coats, 1947, U.S. Geol. Survey Alaska Volcano Inv. Rept. 2, pt. 5, p. 77, 78, pl. 6. Thick accumulation of breccia, tuff-breccia, and lava flows; these rocks are products of an ancient volcano, herein called Andrew Bay Volcano. Maximum thickness about 1,000 feet; original thickness much greater. Considered younger than newly defined Zeto Point basalt porphyry (Mesozoic?): oldest volcanic rocks of "Mount Adagak" are banked against a sea cliff cut in Andrew Bay volcanics.

Andrew Bay volcanics make up ridge rising steeply from water's edge on east shore of Andrew Bay, northern Adak Island.

Andrews Schist[1]

Andrews Formation

Lower Cambrian: Western North Carolina, north-central Georgia, and eastern Tennessee.

Original reference: A. Keith, 1907, U.S. Geol. Survey Geol. Atlas, Folio 143.

G. W. Stose and A. J. Stose, 1944, Am. Jour. Sci., v. 242, no. 7, p. 377. Suggested stratigraphic sequence (descending): Murphy marble, Andrews schist, Nottely quartzite. Calcareous and ferruginous Andrews schist may be transitional beds between the quartzite and the marble.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27. Included in Talladega series considered to be Precambrian.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 53–54, pl. 1, geol. map. Redefined as formation. Metasedimentary sequence, 1,400 to 1,800 feet thick, that lies between Murphy marble [below] and Nottely quartzite. Base of sequence is a calcareous schist which corresponds to Keith's Andrews schist in Nantahala quadrangle but were mapped by Keith as part of Valleytown formation. Although formation contains rocks which were mapped by Keith (1907) and LaForge and Phalen (1913, Folio 187) as parts of other formations, its stratigraphic limits are same as those specified by Keith for Andrews schist.

Named for exposures in vicinity of Andrews, Cherokee County, N.C.

Androscoggin Formation

Androscoggin Gneiss and Schist

Androscoggin Series

Ordovician(?): Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Listed as Androscoggin gneiss and schist. Underlies Bates limestone (new); overlies Precambrian orthogneisses. Cambro-Ordovician(?).

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. Seven formations in Lewiston area (ascending): Danville injection gneiss (new), Androscoggin gneiss, Bates crystalline limestone, Deer Rips lime-silicate-gneiss (new), Thorncrag biotite-sillimanite gneiss, Tacoma lime-silicate series, and Sabbatus quartz-sillimanite biotite schist. Middle Silurian.

L. W. Fisher, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 81. Five mappable units have been established in area formerly mapped as Precambrian in southwestern Maine. Sequence (ascending): Danville-Pejepscot (new) series, Taylor Brook injection gneiss (new), Androscoggin series, including Bates limestone and Deer Rips lime silicate gneiss, and Thorncrag-Sabbatus series.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 117–124, pl. 1, table 1 (facing p. 112). Formation includes four phases: highly injected biotite-garnet gneiss, lime-silicate gneiss, marble, and quartz-biotite schist. Thickness about 3,500 feet. Underlies Sabattus formation; overlies Taylor Brook formation. Quartz-biotite facies traced into Vassalboro formation between Litchfield and South Litchfield. Ordovician(?). Type locality designated.

Type locality: At City Rapids between Lewiston and Auburn [Androscoggin County].

Aneth Formation

Upper Devonian: Subsurface in Utah, Arizona, Colorado, and New Mexico.

R. L. Knight and J. C. Cooper, 1955, Four Corners Geol. Soc. Guidebook [1st] Field Conf., p. 56, 57, 58; J. C. Cooper, 1955, Four Corners Geol. Soc. Guidebook [1st] Field Conf., p. 61–63. Dark dolomite interval interbedded with varying amounts of gray, brown, and black shale, gray siltstone, and lighter dolomites. Thickness 170 feet in type well; occurs between depths of 8,161 and 8,331 feet. Thins gradually in all directions from a center just southwest of type well. Underlies McCracken sandstone (new); unconformity inferred. Overlies Ophir formation, contact unconformable.

Type section: Described from well core Shell Oil Company Bluff Unit No. 1 located in sec. 32, T. 39 S., R. 22 E., near the town of Blanding, Utah.

Angaur (older and younger) Limestone

Pleistocene or early Holocene: Caroline Islands (Angaur).

Risaburo Tayama, 1951, Tohoku Univ. Inst. Geology and Paleontology Short Papers no. 3, p. 102 (geol. map), 103, 105; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 67, table 4 [English translation in library of U.S. Geol. Survey, p. 80]. Consists of two units referred to as Older Angaur and Younger Angaur limestone. Older limestone constitutes major part of Angaur terraces referred to as C_1 and C_2; white and porous, composed mainly of *Halimeda* limestone with some coral limestone. Younger limestone constitues lowest terrace C_3 and is exposed at altitude of 5 feet in limited areas along shore; hard limestone principally of *Halimeda* and corals. Younger than Palau limestone. Pleistocene and Recent.

Angaur Island, Palau group.

†Angelina series[1]

Tertiary: Eastern Texas.

Original reference: R. T. Hill, 1902, Franklin Inst. Jour., v. 154, no. 2, p. 153–154.

Probably named for Angelina County or Angelina River.

Angell Member (of Ballard Formation)

Pleistocene (Nebraskan): Southwestern Kansas.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1), 57–58. Name applied to sand, gravel, and cobble member at base of Ballard formation. Thickness about 7 feet. Underlies Missler member; overlies Rexroad formation.

Type section: Sanders gravel pit, SE¼NW¼ sec. 7, T. 32 S., R. 28 W., Meade County. Name derived from old Angell Schoolhouse which was located in SE cor. NE¼ sec. 31, T. 32 S., R. 29 W.

Angel Lake Glacial Stage[1]

Pleistocene: Northeastern Nevada.

Original reference: E. Blackwelder, 1931, Geol. Soc. America Bull., v. 42, p. 918.

Ernst Antevs, 1945, Am. Jour. Sci., v. 243A, table 2 facing p. 24. Mentioned in discussion of Wisconsin glaciation.

Well displayed at Angel Lake, southwest of Wells, Elko County.

Angola Shale Member (of West Falls Formation)

Angola Shale[1]

Upper Devonian: Western New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 24, chart.

Wallace de Witt, Jr., and G. W. Colton, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–30. Conformably underlies Pipe Creek member of Hanover shale. Gradational contact with underlying Rhinestreet shale. About 235 feet thick in Silver Creek quadrangle. Composed largely of medium- to light-gray even- to lumpy-bedded shale and blocky- to irregular-bedded mudstone. Interbedded are small amounts of fissile grayish-black and dark-brown shale; a few medium-light-gray muddy siltstones; some thin beds of medium-gray argillaceous limestone; many calcareous nodules and concretions.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Chart OC–55. Reallocated to member status in West Falls formation (new). Overlies Rhinestreet member; in some areas, intertongues with Gardeau shale member; in some areas, overlies Nunda sandstone member; locally underlies Pipe Creek member of Hanover shale.

Named for Angola, Erie County, where it is exposed along Big Sister Creek.

Animas Formation[1]

Upper Cretaceous and Paleocene: Southwestern Colorado and northwestern New Mexico.

Original references: C. W. Cross, 1896, U.S. Geol. Survey Mon. 27, p. 217–219; J. H. Gardner, 1917, U.S. Geol. Survey Prof. Paper 101, p. 185–186.

C. H. Dane, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 24. Described on eastern side of San Juan Basin, N. Mex. Estimated thickness, 3,000 feet near New Mexico-Colorado line. Thins southward to about 1,200 feet in northwestern part of T. 25 N., R. 1 E. Divisible into lower part consisting chiefly of sandstone and conglomerate and an upper part consisting chiefly of soft sandstone and clay. Toward south, formation includes larger percentages of clays and sandy clays and grades laterally into lithologic unit consisting chiefly of softer beds which has been traced to south into sequence that has been mapped as undivided Puerco and Torrejon formations (Dane, 1936, U.S. Geol. Survey Bull. 860–C) in vicinity of Cuba. This lateral transition takes place gradually over distance of many miles, but some arbitrary division of nomenclature is necessary. Name Animas is extended only southward to Canyoncito de las Lleguas in T. 25 N., R. 1 E. Conformably overlies Fruitland formation in northern and northwestern part of basin; underlies Wasatch formation. Separation on lithologic grounds of the part of the Animas that is Cretaceous and the part that is Paleocene has not yet been made.

Harley Barnes, E. H. Baltz, Jr., and P. T. Hayes, 1954, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map OM–149. Described in La Plata and Montezuma Counties, Colo. Above Kirtland shale a sequence of purple and olive-drab rocks containing much volcanic debris was named, "Animas River beds" by Cross and Animas formation by Gardner (1917). Reeside (1924) divided sequence into McDermott formation and Animas formation. Reeside's typical section of the McDermott is herein subdivided as follows: lowest 95 feet of pebble-bearing sandstone and sandy shale is part of Kirtland shale, the overlying 127 feet of purplish beds is McDermott member, and top 106 feet is included in upper member (unnamed) of Animas. The two members are gradational, and aside from contrast in color, show no consistent lithologic distinction. The dominantly purple McDermott strata are best exposed on Animas River, where they intertongue with overlying greenish-gray olive-drab, and tan Animas strata. Northeastward from Animas River, the McDermott thins by intertonguing with upper member so that in area of Florida-Los Pinos divide the purple sediments are replaced by greenish beds. Where maroon and purple sequence is present in Colorado the formation consists of basal McDermott member and an upper member; elsewhere in Colorado the formation is not subdivided. Above Animas formation is sequence of tuffaceous shale and lenticular sandstone mapped by Reeside as Torrejon formation but herein called Nacimiento formation.

Typical exposures on Animas River below Durango, Colo.

†Animas interglacial epoch[1]

Pleistocene: Southwestern Colorado.

Original reference: W. W. Atwood and K. F. Mather, 1912, Jour. Geology, v. 20, p. 392–409.

Animas Valley Basalt

Pleistocene, upper, or Recent: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 77–78, table 1, pl. 1. Dark-gray to dull-black fine-grained vesicular olivine basalt. Thickness estimated to be about 60 feet, undoubtedly not uniform. Part of flow covered by valley sediments.

Exposures confined to floor of western side of Animas Valley, along southeastern side of Peloncillo Mountains, Hidalgo County.

Animikie Group[1]

Animikie Series[1]

Precambrian: Ontario, Canada, and northern Michigan, northeastern Minnesota, and northern Wisconsin.

Original reference: T. S. Hunt, 1873, Am. Inst. Mining Engrs. Trans., v. 1, p. 331–395.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1041–1051. Retained as group name in Minnesota because outcrops are well correlated with original Animikie locality and not well correlated with type locality of Huronian. Includes (ascending) Pokegama quartzite, Biwabik iron formation series, and Virginia slate. Unconformable above Algoman batholithic intrusives; unconformable below Keweenawan group.

D. A. White, 1954, Minnesota Geol. Survey Bull. 38, p. 3 (table 1), 4. In Gunflint district, the three units of Animikie group corresponding to Pokegama, Biwabik, and Virginia formations of Mesabi district are called, respectively, Kakabeka, Gunflint, and Rove formations.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 33–35. Reinstated and given series rank in application to Michigan strata. Term Huronian, used in area for nearly 60 years, is not used here because of uncertainty of correlation with type Huronian of Canada; strata previously correlated with Huronian are now referred to Animikie on basis of accepted correlations with strata of Mesabi district of Minnesota, which have been traced into type Animikie of Thunder Bay area of Canada. Series divided into four groups (ascending): Chocolay, Menominee, Baraga, and Paint River. Series rests unconformably on eroded surface of lower Precambrian (post-Dickinson) granitic rocks; Animikie strata were deformed, metamorphosed, and intruded by dikes, stocks, and sills of gabbroic to granitic composition in a pre-Keweenawan orogenic interval.

F. F. Grout, R. P. Sharp, and G. M. Schwartz, 1959, Minnesota Geol. Survey Bull. 39, p. 20–29. In Cook County, group consists of Pokegama quartzite, Gunflint iron formation, and Rove formation. These units are correlated with Pokegama quartzite, Biwabik iron formation, and Virginia formation of Mesabi Range. Lies between Knife Lake group below, and Keweenawan group above.

Named for occurrence along Thunder Bay, north shore of Lake Superior, Ontario, Canada. Animikie is Indian same for Thunder Bay.

Anita Shale

Eocene, middle: Southwestern California.

F. R. Kelley, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 1, p. 3, 4, 5, 6–7. Thick unit of Eocene shales with subordinate beds of sandstone and some limestone nodules. At one or more horizons, includes red foraminiferal shale. Disconformably underlies Matilija sandstone; disconformably overlies Upper Cretaceous sandstone. Thickness about 600 feet.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 26, pls. 1, 2, 5, 6. Consists of about 1,000 feet of clay shale lying above Jalama formation (new). Relationship to the Jalama appears to be conformable, but in northerly exposures [Santa Ynez Range] the Anita rests unconformably on Jalama or older formations.

Type locality: On south side of Santa Anita Canyon 1 mile west of Big Bend [Santa Barbara County].

Ankareh Shale,[1] Formation, or Redbeds

Lower and Upper Triassic: Northeastern Utah. southeastern Idaho, and southwestern Wyoming.

Original reference: J. M. Boutwell, 1907, Jour. Geology, v. 15, p. 439–458.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 474, 476, 477 (fig. 2). Name Ankareh shale restricted to those red beds between Thaynes limestone and unconformity below Higham grit in northeastern Utah. Name Red Wash formation proposed for red beds at eastern end of Uinta Mountains that are equivalent to Woodside, Thaynes, and Ankareh (restricted).

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, pt. 1, p. 1260 (fig. 2), 1266 (fig. 5), 1270, strat. sections. In western Uinta and central Wasatch Ranges, overlies Thaynes limestone and unconformably underlies Gartra member of Stanaker formation (both new). Thickness 862 to 1,400 feet. Summary of stratigraphic nomenclature in area.

Bernhard Kummel, 1953, Intermountain Assoc. Petroleum Geologists Guidebook 4th Ann. Field Conf., fig. 1 facing p. 48. In central Wasatch Mountains and western Uinta Mountains, subdivided into (ascending) Mahogany (new), Gartra grit. and Stanaker members.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 166 (fig. 18), 178 (fig. 21), 179–180. As now used, name Ankareh is applied to different parts of post-Thaynes sequence in middle Rocky Mountains. In western Wyoming, applied to all strata between Thaynes formation and Nugget sandstone. In Utah, applied only to beds from Thaynes to Gartra grit. In Idaho, name Ankareh was abandoned by Mansfield (1927) although Gartra grit is probably equivalent to Higham grit and Higham grit is present in Ankareh in Wyoming. It is here proposed that Ankareh formation, as originally defined by Boutwell to include all strata between Thaynes and Nugget formations, be applied in northern Utah and western Wyoming and all formations that have been proposed for parts of this sequence be reduced to member rank. In eastern Uinta Mountains, Colorado Plateau nomenclature is used following Kinney and Rominger (1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 82). Wood shale is considered westward tongue of Ankareh formation as used in Wyoming. Stanaker formation and Gartra grit (Thomas and Krueger, 1946) are reduced to member status in Ankareh. Unit referred to Ankareh by Thomas and Krueger (1946) and Williams (1945) must be renamed. Name Mahogany member is here proposed for unit between top of Thaynes and base of Gartra member. Name Lanes tongue of Ankareh proposed for Sheep Creek section in Idaho. Main areas of outcrop and units present in each discussed briefly.

W. W. Rubey, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–109. Ankareh redbeds mapped in Bedford quadrangle, Wyoming.

U.S. Geological Survey currently designates the age of Ankareh as Lower and Upper Triassic on the basis of a study now in progress.

Named for Ankareh Ridge, Park City district, Utah.

Anna Shale Bed (in Pawnee Limestone Member of Oologah Formation)

Anna Shale Member (of Pawnee Limestone)

Pennsylvanian (Des Moines Series): Eastern Kansas, southwestern Iowa, western Missouri, and northeastern Oklahoma.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 316–317, pl. 1. Lowermost member of Pawnee limestone. Includes a thin dark slabby limestone (at base) and a black platy and locally fissile shale. Thickness 3 to 11 feet. Underlies Myrick Station member; overlies Labette shale.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 6–7, fig. 1. Geographically extended into Missouri and reallocated to Pawnee formation. Unit now termed Anna shale had been included in Labette formation.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 15, 16 (fig. 2). Occurs in Oklahoma where it is shown as a shale [bed] at base of Pawnee member of Oologah formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 32, fig. 5. Geographically extended into southwestern Iowa. As exposed in Madison County, upper bed is olive shale that weathers buff and contains fossil fragments; below this is dark-gray platy shale with light-gray fucoidal markings; lower shales are dark gray to black, hard, and slaty with thin gray lime concretions and bands in the upper part and are soft and clayey in lower part. Thickness 2.2 feet. Lowermost member of formation. Underlies Myrick Station limestone member; overlies Labette shale.

Type locality: North of center sec. 7, T. 27 S., R. 24 E., in Bourbon County, Kans., on Kansas Highway 7.

Annabelle Shale (in Monongahela Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 250.

At Annabelle, Marion County.

Annelly Gypsum Member (of Wellington Formation)

Permian: Southeastern Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 5, 12. Consists of gypsum interbedded with lesser amounts of drab clays; both selenite and alabaster varieties of gypsum are present. Three prominent beds of gypsum commonly present, but locally, only two are present; in some places additional thin gypsum beds are interbedded with the clays. Thickness about 13 feet; at type locality, three beds of gypsum are exposed, each about 3 feet thick. Underlies Chisholm Creek shale member (new); overlies Geuda Springs shale member (new).

Type locality: High cliff on west branch of Whitewater River one-fourth mile south of Annelly, sec. 15, T. 24 S., R. 2 E., Harvey County.

Annie Creek Flows, Pumice Flows

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 87–89, pl. 5 (fig. 2). Annie Creek flows (pumice flows) were products of glowing avalanches that swept down Munson Valley from Mount Mazama into Annie Creek. Glowing avalanches of pumice and scoria were part of final activity of Mount Mazama and followed what is termed main pumice fall.

Annie Creek flows southward from Crater Lake.

Annona Chalk[1]

Annona Chalk (in Taylor Group)

Upper Cretaceous: Northeastern Texas, southwestern Arkansas, Louisiana, and southeastern Oklahoma.

Original reference: R. T. Hill, 1894, Geol. Soc. America Bull., v. 5, p. 308.

L. W. Stephenson, 1937, U.S. Geol. Survey Prof. Paper 186–G, p. 133–146. Annona chalk, which in eastern Red River County is estimated to be 300 or 400 feet thick, is time equivalent of combined lower part of Taylor marl, Wolf City sand member, and Pecan Gap member of Lamar, Delta, and Fannin Counties. Phosphatic bed that forms base of Annona chalk north of White Rock, in Red River County, has been traced westward and found to be continuous with phosphatic bed at base of Taylor marl just above Gober tongue of Austin chalk in Lamar County. In southwestern Arkansas, Annona chalk and underlying Ozan formation are together the approximate time equivalent of Annona chalk in Red River County, Tex.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 43–45. Annona chalk included in Taylor group. Pecan Gap chalk has been considered to be tongue of Annona chalk, with lower marl [east of Taylor group] and Wolfe City sand being lateral equivalents of lower part of Annona chalk (interpretation accepted here). Foraminifera described.

F. F. Mellen, 1958, Mississippi Geol. Survey Bull. 85, p. 29–40. Name Annona first projected into Mississippi into a part of Selma chalk by Shreveport Geological Society. In stratigraphic cross sections, projection was from Desha basin on north side of Monroe-Sharkey uplift and also within salt basin province south of Monroe-Sharkey uplift. Nomenclature and usage are set out in Gulf Cretaceous correlation chart (Shreveport Geol. Soc., 1945, v. 2, p. 480–481). In present study, it was assumed that stratigraphic studies and correlations of Annona section by Shreveport stratigraphers were essentially correct. It was upon this premise, that name Annona chalk was adopted to apply to a portion of lower part of Demopolis chalk. A 2-foot bed in upper part of Annona chalk as used herein has been traced over an area of all or part of more than 40 counties in Mississippi. This bed is herein named Coonewah, for outcrops in Coonewah Creek valley. Most data subsurface.

Named for outcrops about 2 miles northwest of Annona, Red River County, Tex.

Annsville Phyllite

Cambro-Ordovician: Eastern New York.

K. E. Lowe, 1947, Geol. Rev., v. 7, no. 1, p. 10. Near Tomkins Cove, both Wappinger limestone and associated Annsville phyllite (Hudson River series) trend southwest representing continuation of Cambro-Ordovician belt of sediments in Sprouts Brook (Peekskill) across Hudson River to northeast.

S. Schaffel, 1958, New York Geol. Assoc. Guidebook 30th Ann. Mtg., p. 2. Commonly dark bluish gray but may be black. Thickness uncertain because extent of isoclinal folding is not known. Conformably overlies Wappinger limestone. Youngest rock unit of Paleozoic age preserved in Peekskill Valley.

Probably named for occurrence in vicinity of village of Annsville, near Peekskill, Westchester County.

Annville Limestone[1]

Annville Formation (in St. Paul Group)

Middle Ordovician: Eastern Pennsylvania.

Original reference: B. L. Miller, 1925, Pennsylvania Geol. Survey, 4th ser., Bull. M–7, p. 124, 125, 133.

Carlyle Gray, April 1951, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 136, p. 12–15. Composed of two members: lower, thick-bedded high-calcium limestone; and upper, thin-bedded impure limestone. Total thickness more than 250 feet at western boundary of Berks County. Overlies Beekmantown limestone; underlies Jacksonburg formation. Formerly considered to be of Stones River age, but now correlated with "cement limestone" member of Jacksonburg. This correlation implies that Annville is in part Trenton and possibly in part Black River in age. Name Annville has been used as trade name.

C. E. Prouty, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1471. Annville limestone, heretofore a commercial term for cement limestone in Lebanon and adjacent counties, is defined and given formational status. Overlying "Leesport" will be renamed.

Carlyle Gray, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 140, p. 1, 3. Predominantly thick-bedded to massive crystalline high-calcium limestone. In eastern part of area, beds are blue, with some light-gray colors and pinkish gray. Light-gray and pinkish-gray colors dominant in west. Normal stratigraphic thickness about 240 feet; thins east of Myerstown to 20 feet at Womelsdorf. Underlies Myerstown limestone (new). Directly overlies Beekmantown group.

J. P. Hobson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 12, p. 2720. Overlies Ontelaunee formation (new).

C. E. Prouty, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G–31, p. 6–12. Though Miller (1925) used name in formational sense (Annville limestone), it was apparently proposed as trade name. Overlies Beekmantown group throughout most of its extent, but, in Harrisburg area, overlies rocks similar to middle member of "Stones River." Underlies Myerstown limestone in all observed sections. Type section designated.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped in St. Paul group.

Type section: Quarry at old Palmyra plant of H. E. Millard Limestone Company about 1½ miles northwest of Palmyra. Named for town of Annville, Lebanon County.

Anón Andesite-Diorite

Eocene, postearly middle: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 113–115, geol. map. At type locality, shows needlelike phenocrysts of hornblende and square phenocrysts of plagioclase feldspar. Intrudes lower middle Eocene rocks of Jacaguas group. Postearly middle Eocene and probably premiddle Oligocene.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 85. Commonly light to medium gray in color with phenocrysts of plagioclase feldspar. Andesitic rather than dioritic in texture. Intrudes rocks of Guayabal group (new). Footnote states that Guayabal group is currently called Jacaguas.

Type locality: On Camino Anón at kilometer post K9HO and below in bed of Río Inabon. Name derived from Hacienda Anón, 1.65 kilometers northeast of Cerro Santo Domingo. Occurs in series of stocks extending from Barrio Guayahal in northwestern part of Río Descalabrado quadrangle to Barrio San Patricio in northwestern Ponce quadrangle.

Anson Formation

[Silurian]: West-central Maine.

A. R. Cariani, 1959, Dissert. Abs., v. 19, no. 10, p. 2577. Brown-mottled grits and arenaceous phyllites. Brown spots caused by oxidation of siderite. Position and formational status of Anson still in doubt. Correlates on basis of similar lithology with Vassalboro formation which is Clinton [Silurian] in age.

In Anson quadrangle.

Ansonia Granite

Pre-Triassic(?): Southwestern Connecticut.

M. H. Carr, 1960, Connecticut Geol. Nat. History Survey Quad. Rept. 9, p. 18–19, pl. 1. Light-gray biotite-muscovite granite gneiss. Cuts Hartland formation and Prospect gneiss.

Named for town of Ansonia, Naugatuck quadrangle.

Antelope Rhyolite[1]

Tertiary(?): Northwestern Arizona.

Original reference: C. Lausen, 1931, Arizona Bur. Mines Bull. 131, map.

Oatman district, Mohave County.

Antelope Shale

Upper Cretaceous: North-central California.

N. L. Taliaferro, 1954, *in* Northern California Geol. Soc. Spring Field Trip, [p. 6, 7], correlation chart, structure sections A, B, and C. Shown on correlation chart and structure sections as underlying Venado sandstone and overlying Salt Creek conglomerate (new). Beds vertical to overturned. Thickness 4,200 to 5,200 feet.

Klaus Kupper, 1956, Cushman Foundation Foram. Research Contr., v. 7, pt. 2, no. 152, p. 40–47. Description of Upper Cretaceous pelagic Foraminifera from "Antelope shale" of Taliaferro (1954). Kirby (1943, California Div. Mines Bull. 118) referred to these strata as Horsetown formation of Shasta group. J. Lawton (unpub. thesis) has proposed term Fiske Creek formation for "Antelope shale" which is junior homonym of Antelope formation (Miocene) of Kern County, described by Noble (1940 Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3).

W. P. Irwin, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2287. If it is desirable that Shasta series be restricted to Early Cretaceous, base of conglomerate below so-called Antelope shale of

Taliaferro appears to be good choice for its upper limit and is so considered in this report.

Occurs in Rumsey Hills-Capay Valley-Wilbur Springs area on west side of Sacramento Valley.

Antelope Shale Member (of Monterey Formation)

Miocene, upper: Central California.

E. B. Noble, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 7, p. 1332 (fig. 1). Initially used as local name for a productive oil zone in Kern County.

R. R. Simonson and M. L. Krueger, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1611 (fig. 2), 1617, 1621 (fig. 4), 1627 (fig. 8). At surface, consists of siliceous well-bedded light-brown shale containing minor lenses of sandstone and limestone. Thickness about 2,400 feet. Unconformably underlies Santa Margarita formation; conformably overlies McDonald shale member of Monterey formation.

L. B. McMichael, chm., 1959, San Joaquin Geol. Soc. Guidebook Field Trip, May 9, road log, strat. profile, chart, map. Underlies Chico Martinez chert member (new) and overlies McDonald shale member in Chico Martinez Creek area. Thickness about 2,750 feet. McDonald shale, Antelope shale, and Chico Martinez chert members are equivalent to McLure shale member of Monterey.

Type locality not stated. Area under study was Crocker Flat landslide in central Temblor Range.

Antelope Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 385, 386.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 70. Variable sandstone, friable to hard, pure to clayey, with conglomerate and some clay. Underlies Indian Creek bed; overlies Comanche Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, Ricker, is in common use today, and that name has been restricted to base of Drake's Ricker bed.

Named for Antelope Creek, San Saba County.

Antelope Flats Member (of Wellington Formation)

Permian: North-central Oklahoma.

G. O. Raasch, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1928. Uppermost member of formation. Thickness 195 feet. Overlies Billings member (new).

Type locality and derivation of name not stated.

Antelope Valley Limestone (in Pogonip Group)

Lower and Middle Ordovician: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 28–29. Name applied to uppermost formation in

Pogonip group. Dominantly thick-bedded or massive medium-gray or light-bluish-gray fine-grained limestone. Very little chert present. Cliff-forming units not uncommon. Locally contains thinner bedded zones, as at base of formation on Martins Ridge, where there is about 150 feet of rather thinly bedded argillaceous limestone. Here, formation not separable from underlying Ninemile formation (new) on basis of change from thinner bedded to thicker bedded limestone, but color change in thin-bedded rocks is distinctive. Thinner bedded limestones present near top of formation both in Antelope Valley and at Eureka. In this part of section, limestone tends to be flaggy or platy with tan argillaceous partings and mottlings, although limestone still retains medium-gray to light-bluish-gray color in bulk of unit. Thickness about 400 feet near Eureka; about 1,100 feet at Martins Ridge. In type area, underlies Copenhagen formation (new); in Eureka district proper, underlies Eureka quartzite.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). In Toquima Range, overlies Stoneberger shale (new); underlies Caesar Canyon formation or Diana formation (both new).

U.S. Geological Survey currently designates the age of the Antelope Valley Limestone as Lower and Middle Ordovician on the basis of studies now in progress.

Named for occurrence in Antelope Valley region. Well exposed on Martins Ridge, linear northward-trending ridge that separates Copenhagen Canyon from Antelope Valley and is about 25 miles southwest of Eureka.

Antero Formation

Oligocene: Central Colorado.

J. H. Johnson, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 77; J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 34 (table 7), 63–67, 170–171, pl. 1. Lacustrine sediments with some associated delta and flood plain deposits and beds of volcanic ash and agglomerate. Beds contain layers and reefs of algal limestones. Thickness about 2,010 feet. Underlies Wagontongue formation (new); overlies Balfour formation (new).

Area: South and west of Hartsel in Tps. 12–15 S., Rs. 75–76 W.; occupies several long, narrow, and partly connected basins in the Precambrian north-northeast of Hartsel, in Tps. 10–11 S., Rs. 74–75 W., Park County.

Antes Shale (in Trenton Group)

Middle Ordovician (Mohawkian): Central Pennsylvania.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 3 (fig. 2); no. 2, p. 114. Comprises about 400 feet of dark, brownish-weathering shale lying between Coburn limestone and silty and arenaceous Reedsville shale. *Dicranograptus nicholsoni* (Hall) abundant near top of formation; *Tiarthrus eatoni* Hall common in underlying shales. Antes has been included in Reedsville in reports and maps of region.

Exposed along Antes Creek above Antes Gap, Clinton County.

Antes Gap Shale

See Antes Shale.

Anthony cyclothem

Pennsylvanian (Pottsville Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann Field Conf., p. 18. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 21–22, table 1, geol. map. Includes (ascending) Anthony shale and (or) sandstone, 7 feet thick; Sciotoville clay, 4 feet; and Anthony coal. Occurs below Huckleberry cyclothem and above Harrison formation. In area of this report, Pottsville series is described on a cyclothemic basis; 10 cyclothems are named (ascending): Anthony, Huckleberry, Quakertown, Bear Run, Vandusen, Lower Mercer, Flint Ridge, Middle Mercer, Bedford, and Tionesta.

Well exposed in Monday Creek Township along Little Monday Creek valley, in Temperance Hollow, and in headwater region of Turkey Run, Perry County.

Anthony Sandstone (in Hennessey Formation)

Permian: Western Oklahoma.

Henry Schweer *in* O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1553 (fig. 9). Shown on a projected cross section of upper Permian.

Anthony Shale or Sandstone

Pennsylvanian (Pottsville Series): Eastern Ohio.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 70–80. Defined as shale which occupies interval extending upward from Anthony coal to base of Quakertown clay. Locally contains an iron ore above Anthony coal. Shale horizon has rather limited extent. Average thickness about 22 feet. Underlies Massillon shale; overlies Sciotoville clay.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 21–22. Anthony shale and (or) sandstone included in Anthony cyclothem.

Generally present on outcrop through Scioto, Jackson, Vinton, Hocking, Perry, Licking, and Muskingum Counties. Present in parts of Wayne, Summit, Trumbull, and Mahoning Counties.

Anthony Lake granodiorite

Lower Cretaceous(?): Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 205–206, 235. Potash-poor granodiortie. Contemporaneous with Bald Mountain tonalite (new).

Occurs near Anthony Lake, Elkhorn Mountains [Grant County]. Granodiorite commences in zone approximately 2½ miles inward from contacts of Bald Mountain batholith and covers area of about 36 square miles.

Antietam Sandstone,[1] **Quartzite,** or **Schist** (in Chilhowee Group)

Antietam Formation

Lower Cambrian: Maryland, southeastern Pennsylvania, Virginia, and West Virginia.

Original reference: A. Keith, 1893, as reported by G. H. Williams and W. B. Clark, *in* Maryland, its resources. industries, and institutions, chap. 3, p. 68.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties [Rept. 12], p. 41–42. Antietam quartzite described in Carroll and Frederick Counties. Occurs in foothills east side of Catoctin Mountain west of Frederick Valley, and in series of linear hills in eastern part of valley. In foothills of Catoctin Mountain, crops out in narrow belt about one-fourth mile wide which extends from Point of Rocks at Potomac River to Little Tuscarora Creek northwest of Frederick, where it is cut out by Triassic border fault. Quartzite throughout this belt is underlain by Harpers phyllite and overlain by Tomstown dolomite, in normal sequence. On east side of Frederick Valley, Antietam forms discontinuous line of low wooded hills from New Midway, where quartzite is overlapped by Triassic sedimentary rocks, southwestward to Potomac River. Quartzite here is unconformably overlain by Frederick limestone. Total thickness in belt west of Frederick Valley estimated about 300 feet. Lower Cambrian.

H. P. Woodward, 1949, West Virginia Geol. Survey, v. 20, p. 115–124. Referred to as sandstone or quartzite in West Virginia. Only outcrop is in Jefferson County where its length is about 14 miles and its width ¾ mile. Underlies Tomstown dolomite. Oldest fossiliferous formation in state. Estimated thickness 500 to 600 feet.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 15 (fig. 5), 20–24, pl. 1. Described in Elkton area, Virginia, where it is assigned to Chilhowee group. Uniform thickness of about 800 feet. Divided into two members of about equal thickness. Lower member composed of white vitreous quartzite and contains worm tubes, or *Scolithus*. Forms prominent ledges up to 100 feet thick; between ledges are thinner bedded sandstone or quartzite, but greater part is formed by relatively less resistant buff or brown sandstone. Overlies Harpers formation; underlies Tomstown dolomite.

R. W. Chapman, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 193–194, 200–201. Described in Safe Harbor area, Pennsylvania, as Antietam schist. Grades upward into Vintage dolomite through zone roughly 10 feet thick.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 39. Referred to as Antietam sandstone. Occurs only in eastern Washington County in foothills of South Mountain and Elk Ridge.

D. M. Scotford, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 51–52, pl. 1. In Sugarloaf Mountain area, Antietam quarzite conformably overlies Harpers phyllite and underlies Frederick limestone. Crops out in two southeast-trending belts, 1 to 2 miles wide, along western part of area. Western belt is tight anticline which forms ridge above surrounding Frederick limestone. Eastern belt, which is discontinuous, is separated from western belt by limestone valley.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as Antietam formation.

Named for exposures near Antietam Creek, north of Potomac River, Washington County, Md.

Antioch Sandstone[1]

Permian: Central southern Oklahoma.

Original reference: D. A. Green, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1465, 1466.

Garvin County.

Antler Peak Limestone

Upper Pennsylvanian and Lower Permian: North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler Peak quadrangle, Nevada: U.S. Geol. Survey Geol. Quad Map [GQ–10]. Name given to limestone beds whose principal exposures underlie Antler Peak and crop out in a belt trending diagonally across the range. Limestones are medium to thick bedded for most part and form prominent outcrops. Thickness at type section 625 feet; east of Copper Basin probably more than 800 feet. Unconformably underlies Edna Mountain formation (new); overlies Battle formation (new).

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2824 (fig. 5), 2843, 2853, (fig. 11). Late Pennsylvanian to early Permian on basis of diversified fauna including fusulinids.

Type section: Antler Peak.

Antlers Sand[1] (in Trinity Group)

Lower Cretaceous (Comanche Series): Southeastern Oklahoma and northeastern Texas.

Original reference: R. T. Hill, 1894, Geol. Soc. America Bull., v. 5, p. 303.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2333 (fig. 2), 2335. Correlation chart of Trinity group shows Antlers sand, undifferentiated, in outcrop in southeastern Oklahoma. Antlers is referred to as having Paluxy-like lithology. Paluxy is not included in Trinity as defined in this study. Term Paluxy is restricted to sandstones and shales which are time-stratigraphic equivalent of, and are laterally continuous with, part of Walnut, which is lowest formation of Fredericksburg group.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 26, pl. 1. Forgotson (1957) has shown that type Paluxy is Fredericksburg. So-called Paluxy of McCurtain County is either upper part of Antlers sand or may be assignable to Rusk sand.

Named for Antlers, Pushmataha County, Okla.

†Antoine Dolomite[1]

Precambrian (lower Huronian): Northwestern Michigan.

Original references: C. R. Van Hise, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 16, 17; 1899, U.S. Geol. Survey Mon. 36, p. XXV, XXVI.

Menominee district.

Antonio slate[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 5.

Well displayed at north end of Manzano Mountains. Derivation of name not given.

Antonito limestone[1]

Pennsylvanian(?): Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 3, 5.

Exposed at southern extremity of Sandia Range. Derivation of name not given.

Antrim Shale[1]

Upper Devonian and Lower Mississippian: Michigan.

Original reference: A. C. Lane, 1901, Michigan Miner, v. 3, no. 1, p. 9.

A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 525. Overlies Squaw Bay limestone (new) of Traverse group.

W. A. Kelly and G. W. Smith, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 3, p. 460. In Afton-Onaway area, overlies Beebe School formation (new) of Traverse group.

G. V. Cohee, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–41, sheet 5. Consists of dark-gray to black hard thin-bedded brittle carbonaceous shale interbedded with some gray shale in lower part; contains some brown argillaceous limestone and dolomite. In eastern Michigan, thickens northward from 130 feet in Washtenaw County to 500 feet in Montmorency County; in western Michigan, underlies Bedford shale; in western Michigan, grades laterally into Ellsworth shale. Upper Devonian and Lower Mississippian.

Named for Antrim County in which shales are exposed.

Anvil Ferruginous Chert Member (of Ironwood Iron-Formation)[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: W. O. Hotchkiss, 1919, Eng. Mining Jour., v. 108, p. 501, 505.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 104 (table 10), 106 (table 11), 107 (fig. 6). Overlies Pence member; underlies Pabst member of Tyler formation. Thicknesses (taken from drill holes) 22½ and 53 feet.

Named for Anvil mine east of Bessemer, Gogebic County, Mich.

Anvil Points Member (of Green River Formation)

Eocene: Northwestern Colorado.

J. R. Donnell, 1953, Rocky Mountain Assoc. Geologists Guidebook Field Conf. May 14–16, chart facing p. 17. Consists of low-grade marlstone, thin-bedded shales, and sandstones alternating with gray and brown shales. Algal bed in lower part. Thickness about 1,500 feet. Underlies Parachute Creek member; overlies Wasatch formation.

Exposed between Rifle and De Beque Canyon.

Anvil Rock Sandstone Member (of Lisman Formation)

Anvil Rock Sandstone Member (of Carbondale Formation)

Anvil Rock Sandstone Member (of McLeansboro Formation)[1]

Pennsylvanian: Western Kentucky and southeastern Illinois.

Original reference: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, p. 45, plate showing section of Lower Coal Measures.

E. J. Harvey, 1956, U.S. Geol. Survey Water-Supply Paper 1356, p. 64, 65–68. Reallocated to Lisman formation. In Henderson [Kentucky] area, underlies Madisonville limestone member; overlies No. 12 coal. In some localities, forms base of formation where No. 12 coal and Providence limestone member have been eroded.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 48 (table 1), 54 (table 3). Member of Carbondale formation. In sequence listed, overlies Conant limestone member (new) and underlies Bankston Fork limestone member.

Named from bluff known as Anvil Rock [southwest of Henshaw near Ohio River] in Union County, Ky.

Anvil Spring Formation

Lower Permian: Southeastern California.

B. K. Johnson, 1957, California Univ., Pubs. Geol. Sci., v. 30, no. 5, p. 382–384, figs. 1, 3. Proposed to include carbonate rocks of Permian age in Manly Peak quadrangle and adjacent Wingate Wash quadrangle to east. Consists of light-gray to white limestones alternating with dark-gray limestones in beds a few feet thick; cherty beds and nodules in middle of section; shales and argillaceous limestones near top; fossiliferous. In Manly Peak quadrangle, has exposed thickness of about 3,600 feet and is divisible into two parts: lower, exposed at Striped Butte, is more than 2,200 feet; upper part, near western edge of area, about 1,400 feet. C. Wrucke, who is credited with name, measured thickness of 4,100 feet in Warm Spring Canyon where he subdivided formation into five members. Base not exposed in Manly Peak quadrangle. In fault contact with Precambrian east of quadrangle. Near Warm Spring, the Permian passes under Tertiary volcanic rocks; unconformably underlies Triassic andesite flows at east edge of quadrangle.

Named from Anvil Spring in Butte Valley, Manly Peak quadrangle, southern Panamint Range, Inyo County.

Anzar phase (of Santa Lucia Series)[1]

Paleozoic(?): Southern California.

Original reference: P. F. Kerr and H. G. Schenck, 1925, Geol. Soc. America Bull., v. 36, p. 470, 471, map.

San Benito County.

Apache Flow or Tongue (of Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 112, 133, 134, 143 (fig. 20). East of type locality, Clayton basalt consists of many long tongues. For purposes of this report, these tongues have been named, from south to north, Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that gave rise to these basalts are unknown.

Forms basalt rim on north side of Apache Canyon, eastern Union County.

Apache Formation

Miocene, upper: Southern California.

T. W. Dibblee, Jr., *in* Chester Stock, 1948, Southern California Acad. Sci. Bull., v. 46, pt. 2, p. 84. Buff-red sand, pebbly sand, and gypsiferous clays. Continental. Equivalent to Santa Margarita formation to west.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2999. Preoccupied name Apache replaced by Quatal formation.

Occurs in Apache Canyon, Ventura County, sec. 2, T. 8 N., R. 23 W., Mount Pinos quadrangle.

Apache Group[1]

Precambrian: Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 13.

N. E. A. Hinds, 1936, Carnegie Inst. Washington Pub. 463, p. 29–34. At and near Roosevelt Dam, comprises (ascending) Scanlan conglomerate, Pioneer shale, Barnes conglomerate, Dripping Springs quartzite, Mescal limestone, unnamed basalt, and Roosevelt member (new). Underlies Troy quartzite.

N. P. Peterson, 1938, Arizona Bur. Mines Bull. 144, Geol. Ser. 11, p. 8–9. In Mammoth mining area, Pinal County, Apache series (group) unconformably overlies Oracle granite (new).

E. D. Wilson, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1113–1164. Group unconformably overlaps Yavapai group, Mazatzal quartzite, and granite in eastern Tonto basin area and the granite at southeastern end of Mazatzal Range. Does not appear farther northwest in central Arizona areas. Apache strata are younger Precambrian and are separated by unconformity from older Precambrian rocks. Discussion of Mazatzal revolution.

J. R. Cooper, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 31, 32 (fig. 13). In Johnson Camp area, Cochise County, comprises (ascending) Scanlan conglomerate, Pioneer shale, Barnes conglomerate, and Dripping Spring quartzite. Overlies Pinal schist, angular unconformity; underlies Bolsa quartzite, angular discordance not apparent in outcrops but regional relations indicate discordance of more than 2° in some parts of mountains.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. In Globe quadrangle, group comprises (ascending) Scanlon conglomerate, Pioneer formation, Barnes conglomerate, and unnamed basalt. Underlies Troy quartzite; overlies Pinal schist. Late Precambrian.

D. W. Peterson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–128. In Haunted Canyon quadrangle, comprises (ascending) Scanlan conglomerate, 6 inches to 12 feet thick; Pioneer formation, 300 to 450 feet; Barnes conglomerate, 6 inches to 30 feet; Dripping Spring quartzite, 350 to 500 feet; Mescal limestone, 250 feet; unnamed basalt, remnants of which may reach about 120 feet. Unconformably overlies Ruin conglomerate; disconformably underlies Troy quartzite. Upper Precambrian.

Named for exposures on west face of Apache Mountains.

Apache Limestone[1]

Permian: Western Texas.

Original reference: K. H. Crandall, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 929, 939–940.

In Apache Mountains, southeastern Culberson County.

†Apache Sandstone[1]

Upper Cambrian: Arizona.

Original reference: D. Hager, 1924, Mining and Oil Bull., v. 10, p. 137.

Grand Canyon.

Apache Sandstone[1]

Upper Cretaceous: Eastern Colorado.

Original reference: C. S. Lavington, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 4, p. 399.

J. M. Mitchell, John Greene, and D. B. Gould, 1956, *in* Rocky Mountain Assoc. Geologists Guidebook to the geology of the Raton Basin, Colorado, p. 131. Listed in catalog of stratigraphic names as Apache Creek sandstone member of Pierre shale.

In Walsenburg district.

Apache Creek Sandstone Member (of Pierre Shale)

Upper Cretaceous: Eastern Colorado.

See Apache Sandstone, Upper Cretaceous.

†Apalachicola Group[1]

Miocene, lower and middle: Northern Florida and southern Georgia.

Original reference: G. C. Matson and F. G. Clapp, 1909, Florida Geol. Survey 2d Ann. Rept., p. 67–69, table opposite p. 50.

Named for exposures along Apalachicola River in western Florida.

Apex Formation

Permian (Wolfcamp): Southern Nevada.

J. E. Welsh, 1960, Dissert. Abs., v. 20, no. 8, p. 3263. Limestones, sandstones, and siltstones which occur in basin facies northwest of structural lineament here designated Las Vegas hinge line. Contains fusulinids of early, middle, and late Wolfcampian.

Type locality and derivation of name not stated. Report discusses biostratigraphy of Pennsylvanian and Permian systems in southern Nevada.

Apex Till

Pleistocene: Southwestern Montana.

W. B. Hall, 1960, Billings Geol. Soc. [Guidebook] 11th Ann. Field Conf., p. 197–199. Till deposited during Marble Point stage (new). Thickness more than 100 feet in places. Average elevation of till 9,000 feet. Near Apex Point, till rests on steeply dipping Cretaceous volcanic shales and bentonites. In some areas, rests on welded tuffs of Pliocene(?) age. Episode represented by Marble Point and Apex tills is probably either early Wisconsin in age or slightly older.

Named for exposures at Apex Point, secs. 27 and 34, T. 9 S., R. 3 E., Gallatin County. Summits appear, but are unnamed, on U.S. Geological Survey Sphinx Mountain quadrangle topographic map. Summit labeled "Apex Point," 2 miles to south, and appearing on Hebgen Dam quadrangle, seems to be an error.

Apishapa Shale (in Colorado Group)[1]

Apishapa Shale Member (of Niobrara Formation)

Upper Cretaceous: Eastern Colorado.

Original reference: G. K. Gilbert, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 567.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10b (col. 48). Shown on correlation chart as member of Niobrara formation. Overlies Timpas limestone member.

K. M. Waage, 1952, Colorado Sci. Soc. Proc., v. 15, no. 9, p. 375 (fig. 1). Thickness 400 feet in Denver-Golden area. Overlies Timpas limestone; underlies Pierre shale.

M. A. Jenkins, Jr., 1957, Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Park Basins, Colorado, p. 53. Believed that names Fort Hays and Smoky Hill have priority over terms Timpas and Apishapa; if used, would help standardize Niobrara terminology in west-central Colorado.

Named for Apishapa River.

Apison Shale[1] Member (of Rome Formation)

Lower Cambrian: Eastern Tennessee, northwestern Georgia, and western North Carolina.

Original reference: C. W. Hayes, 1894, U.S. Geol. Survey Geol. Atlas, Folio 2; Folio 4.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1, pl. 12; pt. 2, p. 44. Variegated shale. Mapped as a basal member of Rome. Underlies an unnamed sandstone-bearing member of Rome.

Named for exposures at Apison, James [now Hamilton] County, Tenn.

Aplington Formation

Lower Mississippian: Northern Iowa.

M. A. Stainbrook, 1950, Jour. Paleontology, v. 24, no. 3, p. 365–385. Dominantly dolomite with subordinate amount of shale and limestone at base. Thickness 25 to 30 feet. Beds formerly included in Sheffield shale. Underlies Chapin limestone; overlies Sheffield shale.

Type section: About one-half mile directly north of Aplington, Butler County, on west side of road. Formation crops out in narrow belt extending from south line of Cerro Gordo County to southwest corner of Butler County.

Apodaca Formation (in Green Canyon Group)

Pennsylvanian (Derry Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 31 (fig. 2), 32, 34, 36. Name applied to top formation of Green Canyon group. Consists of dense gray limestone with masses and lenses of chert, nodular limestone, calcareous shales, black to dark-gray calcareous siltstones, and greenish- to bluish-gray shales. Thickness increases from about 55 feet at type locality to over 150 feet in southern part of state where formation consists of essentially pure limestone. Underlies Hot Springs formation (new); overlies the Arrey formation (new).

M. L. Thompson, 1948, Kansas Univ. Paleont. Contr. 4, Protozoa, art. 1. p. 73 (fig. 8), 74. Underlies Fra Cristobal formation. Name replaces preoccupied Hot Springs formation.

Type section: Eight-tenths of a mile east of Derry, sec. 32, T. 17 S., R. 4 W., Sierra County. Named for Apodaca Creek, a west tributary of Rio Grande.

†Appalachian Group,[1] Series,[1] or System[1]

Paleozoic: Pennsylvania.

Original reference: H. D. Rogers, 1836. Pennsylvania Geol. Survey 1st Ann. Rept., p. 12–22.

†Appanoose Beds or Group

Pennsylvanian (Des Moines Series): South-central Iowa.

Original reference: H. F. Bain, 1896, Iowa Geol. Survey, v. 5, p. 378–394.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 31). Shown on Pennsylvanian correlation chart as a group comprising strata from unconformity below Mulky coal to base of Pleasanton [shale].

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2027–2028. Apparently abandoned in favor of Marmaton group. Appanoose includes some upper Cherokee strata and corresponds to Henrietta group as treated by Cline (1939) and redefined by McQueen (1943).

Named for development in Appanoose County.

Appekunny Argillite[1] } (in Ravalli Group)
Appekunny Formation }

Precambrian (Belt Series): Northwestern Montana, and southeastern British Columbia, Canada.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 322.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1885–1887. Redefined to exclude Rising Wolf member which is placed in Grinnell formation. As redefined, formation includes following members (ascending): Singleshot, Appistoki, and Scenic Point (new). Consists of argillite interbedded with quartzite, conglomerate, and minor beds of argillaceous limestone; prevailingly green, greenish-gray to brownish, with some dull-red, white, and purplish beds; thin-bedded, with fine laminae; massive only in quartz conglomerates and quartzites; grades into adjacent formation. Thickness in east 2,500 to 5,300 feet; in west as much as 10,000 feet. Underlies Grinnell formation; overlies Altyn formation.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 112. Appekunny argillite included in Ravalli group.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 21–27, pls. 1, 2. Middle formation of Ravalli group. Overlies Altyn limestone; underlies Grinnell argillite. Thickness 2,000 to 5,000 feet. Formation as whole consists of dark fine-grained sedimentary rock sufficiently uniform in character so that Willis gave it name of argillite. Lithologic variations exist in both Appekunny and overlying Grinnell to give support to the Fentons (1937) referring to units rather than argillites. The Fentons' members are discussed, but formation is not subdivided in present report. Tentatively concludes that rocks mapped during present investigation as belonging to Appekunny argillite correspond essentially to Appistoki member of the Fentons. On this basis, most of the Fentons' Scenic Point member may have been mapped with Grinnell, and their Singleshot member probably is not exposed in areas mapped for this report.

Excellent exposures occur on northeast spur of Appekunny Mountain, Glacier National Park, Mont. Forms irregular band in northeastern part of park just west of exposures of Altyn limestone that are associated with Lewis overthrust. Another band extends from Canadian border southeastward in western part of park until it joins band in northeastern part of park. Also exposed near Waterton Lake.

Appistoki Member (of Appekunny Argillite[1] or Formation)

Precambrian (Belt Series): Northwestern Montana and southern Alberta, Canada.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1886. Gray, green, olive-brown, and rusty-gray argillites in thin minor, but thick major, beds interbedded with thickly stratified greenish, white, or pink quartzites. Member intergrades with other members, yet preserves fairly well-marked limits. Thickness in Lewis Range 2,000 to 2,200 feet. Underlies Scenic Point member (new); overlies Singleshot member. Type locality designated.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 21–27. Rocks mapped in present investigation as belonging to Appekunny argillite may correspond essentially to Appistoki member of Fenton and Fenton (1937).

Type locality: Appistoki Peak, near Two Medicine Lake, Glacier National Park, Mont.

Applegate Group

Applegate Series

Upper Triassic(?): Southwestern Oregon and northwestern California.

F. W. Libbey and others, 1942, Oregon Dept. Geology and Mineral Industries Bull. 17, p. 21. Mentioned as Applegate series. Names credited to F. G. Wells and P. E. Hotz.

F. G. Wells, P. E. Hotz, and F. W. Cater, Jr., 1949, Oregon Dept. Geology and Mineral Industries Bull. 40, p. 3–4. Assemblage of metamorphosed volcanic rocks with lens-shaped interbeds of quartzite, conglomerate, and marble. Thickness unknown but is probably to be measured in miles, although its apparent thickness may be exaggerated by faulting and closefolding. Underlies Upper Jurassic Galice formation with angular unconformity; no rocks that are known to be older than Applegate group are exposed in Kerby quadrangle, hence basement on which Applegate group accumulated is unknown. Derivation of name given.

F. G. Wells and F. W. Cater, Jr., 1950, California Dir. Mines Bull. 134, pt. 1, chap. 2, p. 81. Geographically extended into California.

F. G. Wells, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–89. Mapped in Medford quadrangle, Oregon-California. Upper Triassic(?).

Named after drainage basin of Applegate River [Kerby quadrangle, Oregon] where group is prevailing country rock.

Appleton Stage[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51–52.

Probably named for Appleton, Pope County, Ark.

†Appomattox Formation[1]

Pliocene(?) and Pleistocene: Atlantic Coastal Plain, Virginia to Alabama.

Original reference: W. J. McGee, 1888, Am. Jour. Sci., 3d, v. 35, p. 125, 328–330.

Typically exposed on and near Appomattox River from its mouth to some miles west of Petersburg, Dinwiddie County, Va.

Apulia Member (of Tully Formation)

Apulia Shale[1] or Limestone[1]

Devonian: New York.

Original reference: T. A. Conrad, 1841, New York Geol. Survey 5th Ann. Rept., p. 31.

G. A. Cooper and J. S. Williams, 1935, Geol. Soc. America Bull., v. 46, p. 790–808. Member of Tully formation. Overlies Tinkers Falls member (new); overlies West Brook member (new). Type section designated.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1787, chart 4. Middle Devonian.

R. E. Stevenson and W. S. Skinner, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 29–33. Tully type section consists of following members: Tinkers Falls, Apulia, and West Brook. In Tully clastic facies, Apulia is represented by Laurens member.

Type section: In ravine adjacent to June's quarry, 1½ miles southwest of Apulia Station, Tully Township.

Aquaqua Formation

See Aguagua [Formation in Tapaliza Group or Member of Tapaliza Formation].

Aquashicola Formation[1]

Silurian: Northeastern Pennsylvania.

Original reference: B. L. Miller, 1911, Pennsylvania Topog. and Geol. Survey Rept. 4, p. 51.

Named for occurrence in valley of Aquashicola Creek.

Aqua Torres Formation

Permian: Southwestern New Mexico.

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1. p. 1154–1155, 1171, pls. 1, 7. Consists of a thin basal conglomerate, a sequence of arkoses, red sandstones, red shales, nodular limestones, and at top gray massive limestone. Thickness about 80 feet. Underlies Abo formation; overlies Pennsylvanian rocks of Virgil age.

R. L. Bates, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 6, p. 1043, 1044. Suggested as being synonymous with Bursum formation and Red Tanks member of Madera limestone.

Exposed in the Arroyo Aqua Torres in southeast portion of mountains and also along Highway 60 east of the thrust faults.

Aquetuck lithofacies (of Leeds facies of Schoharie Formation)

[Devonian]: Eastern New York.

J. H. Johnsen, 1957, Dissert. Abs., v. 17, no. 10, p. 2247. Lower part of Leeds facies, upper part termed Saugerties lithofacies; composed of calcareous mudstone and calcareous siltstone with minor argillaceous limestone and calcareous sandy mudstone. Carries many chert nodules in upper mid-Hudson Valley; chert diminishes rapidly southward. Lower beds intertongue with upper Carlisle Center beds in parts of mid-Hudson Valley.

Type area not stated. Town of Aquetuck is in Albany County.

Aquia Formation[1] **or Greensand** (in Pamunkey Group)

Eocene, lower: Eastern Virginia, Delaware, and Maryland.

Original reference: W. B. Clark and G. C. Martin, 1901, Maryland Geol. Survey, Eocene volume, p. 58.

R. R. Bennett and G. G. Collins, 1952, Washington Acad. Sci. Jour., v. 42, no. 4, p. 114–116. Overlies Brightseat formation (new).

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 22–23. In Prince Georges County, Md., name Aquia greensand is applied to Eocene deposits that intervene between Paleocene Brightseat formation and Nanjemoy formation. Term is equivalent to Aquia formation of Clark and Martin (1901). More specific term greensand is preferred to formation in this region because glauconite is dominant mineral and occurs throughout formation. Estimated thickness 100 feet. Aquia rests unconformably on Brightseat formation or overlaps on older formations.

A. R. Loeblich, Jr., and Helen Tappan, 1957, U.S. Natl. Mus. Bull. 215, p. 177 (fig. 28). Shown on correlation chart as Paleocene.

D. J. Cederstrom, 1957, U.S. Geol. Survey Water-Supply Paper 1361, p. 24, 25–26, pl. 2. Described in York-James Peninsula, Va., where it is exposed at surface near Richmond. Maximum thickness about 125 feet. No unconformity with underlying Mattaponi formation (new) in subsurface. Underlies Nanjemoy formation.

Type locality: Aquia Creek, Stafford County, Va.

†Aquia Creek Series[1]

Lower Cretaceous: Northeastern Virginia.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 326.

Typically developed within vicinity of Aquia Creek, Stafford County.

†Aquia Creek Stage[1]

Eocene: Eastern Virginia and Maryland.

Original reference: W. B. Clark, 1895, Johns Hopkins Univ. Circ., v. 15, no. 121, p. 3.

Named for Aquia Creek, Va.

†Aquidneck Series or Shales[1]

Carboniferous: Southeastern Rhode Island and southeastern Massachusetts.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 348–364, pl. 31, map.

Forms almost whole of Aquidneck Island, near Newport, Newport County, R.I.

Aquinnah Conglomerate[1]

Pleistocene: Southeastern Massachusetts.

Original reference: J. B. Woodworth and E. Wigglesworth, 1934, Harvard Coll. Mus. Comp. Zool. Mem., v. 52, p. 160.

R. F. Flint, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 543. Discussion of beginning of Pleistocene in eastern United States. Inland along Coastal Plain, not only in South Atlantic States but occurring discontinuously from Cape Cod district to lower Mississippi River, are extensive areas of highly quartzose gravel and sand (and along Gulf Coast, silt and clay). These sediments, on Atlantic Coast at least, indicate selective weathering and deposition by streams. They have not been studied as a whole, but throughout long distances they appear to have same general character. They are known under various regional or local names, such as Citronelle formation, Bryn Mawr gravel, Beacon Hill gravel, Manetto gravel, and Aquinnah conglomerate.

Known to occur only at Gay Head Cliffs fold on Marthas Vineyard. Aquinnah is Indian name for Gay Head.

Arago Group[1] **or Formation**

Arago Series

Eocene: Southwestern Oregon.

Original reference: J. S. Diller, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 458–462, 475.

W. H. Twenhofel, 1943, Oregon Dept. Geology and Mineral Industries Bull. 24, p. 3. Referred to as Arago series. Comprises Coaledo formation (above) and Pulaski formation. Unconformably underlies Miocene Empire formation; unconformably overlies Cretaceous Myrtle formation.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 589–590, chart 11. Formation originally named and described by Diller was later divided into lower, or Pulaski formation, and upper, or Coaledo formation, for purpose of distinguishing coal-bearing beds from noncoal-bearing beds. Arago formation used in original sense of Diller is 8,400 feet thick and consists of alternating members of brownish-gray sandy clay shales, medium- and coarse-grained sandstones, shaly sandstones, and occasional layers of conglomerate.

C. E. Weaver, 1945, Washington [State] Univ. Pubs. in Geology, v. 6, no. 2, p. 31–46, pls. 2, 3, 4, 5, 10. Redescribed in Coos Bay area as formation. Divided into three unnamed members. Total thickness 8,370 feet; base not exposed. Consists of shale and sandstone. Underlies Bassendorf formation.

F. G. Wells, P. E. Hotz, and F. W. Cater, Jr., 1949, Oregon Dept. Geology and Mineral Industries Bull. 40, p. 16. Prong of Arago group extends southward into southwestern corner of Kerby quadrangle, where it is exposed for 5 miles along east side of canyon of Illinois River. Beds in this area are referred to as Arago formation because here they cannot be identified with subdivisions of group. Formation is assemblage of lenticular bodies of sandstone and conglomerate in nearly equal amounts with thin interbeds of shale. Characterized by poor sorting, crossbedding, and abrupt lateral and vertical variations. Maximum thickness 500 feet, on ridge south of Indigo Creek; thins rapidly toward east, wedging out completely in less than one-half mile; thins southward to about 250 feet near mouth of Silver Creek. Overlaps Dothan formation.

Well exposed at Cape Arago, Coos Bay quadrangle.

Arakabesan Member (of Ngeremlengui Formation)

Eocene, upper, or Oligocene: Caroline Islands (Palau).

U.S. Army Corps of Engineers 1956, Military geology of Palau Islands, Caroline Islands: U.S. Corps of Engineers, Far East, p. 48–49, pl. 8. Volcanic breccia, volcanic conglomerate, and tuff, with related dikes, sills, and flows. Maximum thickness 4,000 feet or more in Ngardmau area; about 3,000 feet on Arakabesan Island; on north end of Arekalong Peninsula may be as much as 2,000 feet. Uppermost member of formation; overlies Medorm member (new).

Type section: On Arakabesan Island. Extends as broken strip along west coast of Babelthuap Island from village of Ngardmau on Ngardmau Bay south-southwest nearly to village of Medorm. Present on north end of Arekalong Peninsula and on the two islands just north. Composes Malakal Island.

Arapaho Glacial Stage

Pleistocene (middle Wisconsin): North-central Colorado.

R. L. Ives, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 75; 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1059–1060. Covers interval between River and Monarch glacial stages (both new).

Area: Monarch Valley, in Grand County.

Arapahoe Formation[1]

Arapahoe Conglomerate Member (of Laramie Formation)

Upper Cretaceous: Eastern Colorado.

Original reference: G. H. Eldridge, 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 97.

C. H. Dane and W. G. Pierce, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 10, p. 1309–1312, 1320. Dawson arkose merges northward into Arapahoe and Denver formations along foothills of Front Range. Dawson and Arapahoe along this belt overlie, with erosional irregularity, Laramie formation.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 65–86. Discussion of Cretaceous-Tertiary boundary in Denver basin, Colorado. Stratigraphic and paleontologic evidence shows that Laramie formation, Arapahoe formation, and Cretaceous parts of Denver formation and Dawson arkose comprise a unit correlative with Lance formation and its equivalents. Proposed that Laramie be redefined to include all Upper Cretaceous sequence between top of Fox Hills and base of Paleocene and that term Arapahoe as Arapahoe conglomerate member of Laramie be retained for conglomerate immediately overlying present Laramie formation.

S. O. Reichert, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 107–112. Discussion of post-Laramie stratigraphic correlations in Denver basin. Proposed that (1) Laramie-Arapahoe contact remain as originally defined by Emmons, Cross, and Eldridge (1896, U.S. Geol. Survey Mon. 27); and (2) Arapahoe-Denver contact be placed at widespread erosional disconformity at base of lowest, thickest, and most prominent basalt-andesite pebble conglomerate bed in Denver area, instead of at first appearance of andesitic debris as proposed by Emmons, Cross, and Eldridge (1896). Arapahoe and Denver formations can be mapped throughout Denver basin, and these names should replace term "lower Dawson" of Dane and Pierce (1936).

Named for development in Arapahoe County.

Arapien Shale

Upper Jurassic: Central Utah.

S. L. Schoff, 1938, Ohio State Univ. Abs. Doctors' Dissert. 25, p. 377–378. Consists of drab calcareous shale with red patches and intercalated limestone, gypsum, and salt. Highly folded; thickness uncertain, probably between 4,000 and 11,000 feet. Underlies Indianola group (new).

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205-D, p. 122, 123-125. Subdivided into Twist Gulch member above and Twelvemile Canyon member (both new). Underlies Morrison(?) formation. Type area designated.

C. T. Hardy, 1952, Utah Geol. and Mineralog. Survey Bull. 43, p. 1, 11-13, 14-22. Restricted to include only Twelvemile Canyon member. As restricted, thickness 3,000 feet.

Type area: Arapien Valley, which lies parallel to base of Wasatch Plateau about 6 miles southeast of Gunnison. Formation is typically, if not completely exposed, on west side of valley.

Arbuckle Limestone[1] or Group[1]

Upper Cambrian and Lower Ordovician: Southern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55-56. Rank raised to group. Subdivided into (ascending) Fort Sill limestone, Royer marble (dolomite), Signal Mountain limestone, Chapman Ranch dolomite, McKenzie Hill limestone (new), Wolf Creek dolomite (new), Cool Creek limestone, Alden limestone (new), and West Spring Creek formation. Thickness about 9,000 feet. Underlies Simpson group; overlies Timbered Hills group (new).

C. E. Decker, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1311-1321; 1939, Oklahoma Geol. Survey Circ. 22, p. 15, 16 (table 1), 20-23. Divided into nine formations, four of which are Upper Cambrian and five Lower Ordovician. Upper Cambrian formations (ascending): Fort Sill, Royer dolomite, Signal Mountain, and Butterly dolomite (substituted for Chapman Ranch as name for the upper dolomite, and Chapman Ranch placed as basal member of McKenzie Hill formation). Lower Ordovician formations (ascending): McKenzie Hill, Strange dolomite (replaces preoccupied Wolf Creek formation), Cool Creek, Kindblade (replaces preoccupied Alden), and West Spring Creek.

W. E. Ham, 1949, Oklahoma Geol. Survey Circ. 26, p. 19. Restricted to exclude four Cambrian formations which are included in newly defined Blue Creek Canyon group. This classification credited to E. A. Frederickson (unpub. thesis).

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in eight formations. This subdivision follows Decker (1939) with exception that Strange formation is omitted.

Named for Arbuckle Mountains, of which it composes major part of central mass.

Arcadia Clays (in Claiborne Group)[1]

Eocene, middle: Louisiana, Arkansas, Mississippi, and Texas.

Original reference: O. Lerch, 1893, Louisiana Geol. Survey, pt. 2, p. 85.

Named for Arcadia, Bienville County, La.

†Arcadia Marl[1]

Pliocene, lower: Southern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 131-132, 157, 320.

Named for exposures near Arcadia, De Soto County, on Mare Branch, a tributary of Peace River, about 6 miles north of Arcadia.

Arcadia Member (of Trempealeau Formation)

Upper Cambrian (Croixan): Eastern Minnesota and western Wisconsin.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 44, p. 147. Consists of 3-foot basal bed of edgewise conglomerate, flat pebbles of buff siltstone in a greensand matrix, that grades upward into lenticular strata of varied lithology, dominantly dolomitic siltstone. Thickness about 20 feet. Underlies St. Lawrence member; unconformably overlies Bad Axe member, Franconia sandstone.

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 174–175. In basinward exposures, strata of Lodi member of St. Lawrence vertically succeed Black Earth dolomite member. Elsewhere Lodi occurs beneath Black Earth member as well as above it. At Arcadia, these strata beneath the dolomite are regarded by Raasch (1952) as type Arcadia member of Trempealeau. Except for content of *Osceolia* fauna, on which basis they were designated Arcadia member, these beds do not differ from strata above the dolomite.

Type locality: In roadcut and small quarry on State Highway 93, 1 mile east of Arcadia, Trempealeau County, Wis. Continuously extensive north of Black River valley in Wisconsin and Minnesota.

Arcadian Amygdaloid[1] (in Central Mine Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, pt. 2, p. 78, 131, 132, 133, pl. 10.

Named for occurrence at Arcadian mine, Houghton County.

Arcadian Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence at Arcadian mine, Houghton County.

Arcadia Park Formation[1] (in Eagle Ford Group)

Upper Cretaceous (Gulf Series): Eastern Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 270, 425.

W. L. Moreman, 1942, Jour. Paleontology, v. 16, no. 2, p. 192–220. Discussion of paleontology of Eagle Ford group which comprises (ascending) Tarrant, Britton, and Arcadia Park formations.

W. L. Turner, 1951, Field and Laboratory, v. 19, no. 2, p. 51–65. Discussion of geology of Eagle Ford quadrangle, which contains type locality of Eagle Ford formation as well as Moreman's (*in* Adkins, 1932 [1933]) Arcadia Park formation. Moreman's classification of rocks exposed in Eagle Ford quadrangle not applicable for purposes of this study. Eagle Ford formation subdivided into three unnamed lithologic units.

Type locality: Arcadia Park Station, 7 miles west of Dallas, Dallas County.

Arcente Member (of Lake Valley Formation)

Mississippian (Osage): Southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1941, (abs.) Tulsa Geol. Soc. Digest, v. 9, p. 73–75; 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 12, p. 2116, 2120 (fig. 7). Consists of thin evenly bedded gray relatively unfossiliferous shaly siltstone. Basal part over 50 percent shale; upper part slightly thicker bedded and less shaly. Thickness about 230 feet. Underlies Dona Ana member (new); overlies Alamogordo member (new).

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 11 (fig. 4), 15. Overlies Tierra Blanca member (new). Thickness 230 feet in Sacramento Mountains; generally less than 25 feet in San Andres Mountains. Not present in Mimbres Range, Cooks Mountains, and Silver City area.

Type area: Deadman Canyon, sec. 3, T. 17 S., R. 10 E., near Alamogordo. Named for Arcente Canyon which traverses northern end of main anticlinal structure in which Lake Valley beds are exposed.

Arch Marble or Formation (in Evington Group)

Lower Paleozoic(?): South-central Virginia.

W. R. Brown, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1547. Named in sequence of units mapped in James River synclinorium. Younger than Joshua schist (new) and older than Pelier schist (new).

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1), 93. Fine-grained blue-gray micaceous marble, locally arenaceous. Thickness about 400 feet. Included in Evington group (new). Type locality designated.

G. H. Espenshade, 1954, U.S. Geol. Survey Bull. 1008, p. 16–17. Archer Creek formation (new) includes Arch marble and Joshua schist of Brown (1951, 1953).

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2). Age shown on columnar section as Lower Paleozoic(?).

Type locality: Vicinity of The Arch on Norfolk and Western Railroad, 1 mile east of Six Mile Station, Campbell County.

†Archer Beds[1]

Pliocene, lower: Northeastern Florida.

Original reference: W. B. Scott, 1894, Geol. Soc. America Bull., v. 5, p. 594–595.

Named for exposures at Archer, Alachua County.

Archer Creek Formation (in Evington Group)

Paleozoic(?): South-central Virginia.

G. H. Espenshade, 1954, U.S. Geol. Survey Bull. 1008, p. 15 (table 1), 16–17. Green to blue-gray siliceous graphitic schist member, as much as 500 feet thick, forms lower part of formation; bluish fine- to medium-grained marble member, as much as 400 feet thick, lies in upper part of formation and is interbedded with graphitic schist member. Marble commonly forms valleys. Includes Joshua schist and Arch marble of Brown (1951, 1953). Underlies Mount Athos formation; overlies Candler formation.

Named for exposures along Archer Creek about 1½ miles above its confluence with James River. Exposed extensively along James River valley to southwest of Allen Creek, in neighborhood of Jack Mountain and Chestnut Mountain, and southeast of Evington [Campbell County].

Arch Point Basalt

Quaternary: Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaska Volcano Inv. Rept. 2, pt. 2, p. 13, pl. 2; 1955, U.S. Geol. Survey Bull. 1028–A, p. 8–9, pl. 3. One of three extensive lava-flow units filling old canyons and gullies carved in Belkofski tuff (new) and intrusive diorite stocks. Consists of thick lava beds that crop out south of known exposures of Black Point basalt (new). Overlain by Dushkin basalt (new). Sources of flows not exposed.

Well exposed on Arch Point south of Dushkin Lagoon, vicinity of Pavlof Volcano, Alaska Peninsula.

Arch Rock Granite

[Cretaceous]: Eastern California.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2123 (fig. 1). Shown on map in paper dealing with potassium-argon dating of igneous rocks. Age shown on map legend as 95.3 millions of years. Oldest rock dated; older than Gateway granodiorite. [Calkins (1930, U.S. Geol. Survey Prof. Paper 160) referred to biotite granite of Arch Rock. Compiler was unable to locate reference to Arch Rock granite.]

Occurs in Yosemite National Park.

Archuleta shale[1]

Upper Cretaceous: Northwestern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 260; 1915, Conspectus of geologic formations of New Mexico, p. 2, 5.

In San Juan region. Derivation of name not stated.

Archusa Marl Member (of Cook Mountain Formation)

Archusa Marl Member (of Wautubbee Formation)

Eocene: Eastern Mississippi.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull, 48, p. 49–52. Defined as basal member of Wautubbee formation in eastern Mississippi. Interbedded marls and limestones. Thickness 45 to 60 feet; 48 feet at type locality; neither contact exposed. Underlies Potterchitto member (new), and where exposed contact is conformable and gradational; overlies Kosciusko formation, and where exposed contact is disconformable and sharply defined.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Assigned to Cook Mountain formation. Underlies Potterchitto sand member; overlies Sparta sand. Mississippi Geological Survey uses Wautubbee formation instead of Cook Mountain formation.

Type locality: Bluff beneath south end of bridge across Chickasawhay River on U.S. Highway 45, 2 miles south of Quitman, Clarke County. Named for Archusa Springs, a health resort.

Arcola Limestone Member (of Mooreville Chalk)

Arcola Limestone Member (of Selma Chalk)

Upper Cretaceous: Southeastern Alabama and northeastern Mississippi.

L. W. Stephenson and W. H. Monroe, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1655–1657. Defined as member of Selma chalk. Thin but persistent unit, consisting of layers of pure hard limestone, interbedded with chalk. Lies about 300 feet above base of Selma. Thickness about 29 feet.

R. H. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey; W. H. Monroe and D. H. Eargle, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 50. Reallocated to member status in Mooreville chalk. Unconformably underlies Demopolis chalk.

Type exposure: In bluff at old Arcola Landing on Warrior River, NE¼ sec. 4, T. 18 N., R. 3 E., Hale County, about 5 miles northeast of Demopolis, Ala. Unit has been traced from Bullock County westward through Alabama and northward through Mississippi nearly to Mooreville in Lee County.

Arcturus Limestone[1] **or Formation**

Permian: Eastern Nevada and western Utah.

Original references: A. C. Lawson, 1906, California Univ. Pub. Bull., Dept. Geology, v. 4, no. 4, p. 294; A. C. Spencer, 1917, U.S. Geol. Survey Prof. Paper 96, p. 26–28.

E. N. Pennebaker, 1932, Mining and Metallurgy, v. 13, no. 304, p. 164. Overlies Rib Hill formation (new). Most of Rib Hill was formerly included in Ely limestone.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2174–2178. Name Arcturus geographically extended into Confusion Range, Utah, where it replaces terms "Supai?," "Supai equivalents," and Supai sandstone. Consists of poorly indurated yellowish-gray calcareous sandstone with thin ledge-forming interbeds of dark-gray to tan limestone and dolomite. Total thickness uncertain; minimum thickness 2,700 feet, measured southeast of Indian Pass. Conformably overlies Ely limestone; underlies Kaibab limestone of Park City group. Fossils and stratigraphic position suggest formation is early to middle Permian. Pennebaker (1932), in report on Robinson (Ely) mining district, separated a predominantly sandstone unit of Permian age, which he named Rib Hill formation, from beds previously mapped at Rib Hill as Ely limestone by Spencer (1917). Spencer's description of Ely contains no reference to sandstone, yet Rib Hill area, which is underlain by sandstone, was mapped as Ely limestone. Present writers [Hose and Repenning] believe that in vicinity of Rib Hill, where exposures are poor, inclusion of this predominant sandstone sequence in the Ely by Spencer was inadvertent and that it should have been included in Arcturus formation.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 103–106. Arcturus limestone was defined by Lawson (1960) as a shaly limestone sequence stratigraphically underlying "Ruth Limestone" and overlying Ely limestone, in Robinson (Ruth) mining district. Lawson's failure to understand structural complexities within general Ruth area resulted in the naming of "Ruth" and "Ely" limestones, which later were proved equivalent by Spencer (1917). Lawson's original description of Arcturus limestone does not make clear to which unit he was referring, but there is little doubt that Lawson's Arcturus limestone did include those beds later referred to as "Rib Hill" by Pennebaker (1932). Additional work is necessary before formation can be further defined and its regional relationship fully understood. At present time, name Arcturus should be applied to those light-colored platy limestones and thin interbedded silts lying stratigraphically above Riepetown sandstone (name proposed to replace Rib Hill) and below Kaibab formation or Loray formation (new). Outcrops of Arcturus distributed over area of about 4,800 square miles.

W. B. Douglass, Jr., 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 182, 183. In southern Butte Mountains, White Pine County, Nev., Arcturus conformably overlies Carbon Ridge formation. Thickness variable due to angular unconformity at top of unit. Only 264 feet present on west side of range; estimated 2,500 to 3,000 feet present on eastern flank of mountains. Underlies Kaibab(?) formation.

Named for exposures on Arcturus mining claim, NW¼SW¼NE¼ sec. 15, T. 16 N., R. 62 E, White Pine County, Nev.

Arden Granite

Age not stated: Northern Delaware.

R. F. Ward, 1959, Geol. Soc. America Bull., v. 70, no. 11, p. 1427–1429, 1438–1439, pl. 1. Potassium feldspar-bearing rock which, in some places, has composition of true granite. Bordered on three sides by banded gneiss of Wilmington complex (new), and on east covered by Quaternary and Recent sediments.

Underlies approximately 4 square miles in vicinity of Arden, Newcastle County.

Ardian Series or Epoch

Lower Pennsylvanian: North America.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 284, 286–292. Analysis of physical characters and paleontological features of Pennsylvanian rocks in North America leads to conclusion that stratigraphic cleavage at two positions within system has paramount significance. Three series recognized: Ardian-Lower Pennsylvanian, Oklan-Middle Pennsylvanian, and Kawvian-Upper Pennsylvanian. Ardian series includes Springeran and Morrowan rocks which are classed as stages. Thickness of sediments about 5,000 feet in type area where both Springeran and Morrowan stages are present. *Millerella* is only genus of fusulinids in Ardian, and Ardian may be designated as zone of *Millerella*. Rocks of Ardian age probably widespread in Appalachian region; seemingly most rocks referred to lower Pottsville are of Ardian age. Time equivalent is Ardian epoch.

Type sequence: Ardmore basin south of Arbuckle Mountains, southern Oklahoma. Name derived from first syllable of Ardmore.

Ardmore Bentonite Bed (in Pierre Formation)

Upper Cretaceous: Southwestern South Dakota.

R. C. Spivey, 1940, South Dakota Geol. Survey Rept. Inv. 36, p. 3, 23–34. Bentonite bed about 4 feet thick. Occurs near base of Pierre formation. Commercially important.

Named for exposures near Ardmore, Fall River County.

Ardmore cyclothem

See Ardmore Formation (in Cherokee Group)

Ardmore Formation (in Cherokee Group)

†Ardmore Limestone Member (of Cherokee Shale)[1]

Pennsylvanian (Des Moines Series): Northwestern and north-central Missouri, southern Iowa, and southeastern Kansas.

Original reference: C. H. Gordon, 1893, Missouri Geol. Survey Sheet Rept. 2, (v. 9), p. 20.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 195. Cherokee group is divided into 15 cyclic formational units. Admore 13th in sequence (ascending); occurs above Croweburg and below Bevier. Average thickness 5 feet. [For complete sequence see Cherokee group.]

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 53–54. Redefined to include all of limestones (and intervening shale members) between coal [lower Ardmore] and top of Ardmore of previous definitions. Missouri and Kansas Surveys have traced Ardmore toward southwest and showed it to be equivalent to Rich Hill limestone of southeastern Kansas and to Verdigris limestone of northeastern Oklahoma. Has been traced northwestward from Iowa-Missouri line for 135 miles into Iowa. Throughout this distance is best developed limestone in Cherokee group.

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 28, p. 83–89. Formation in Cherokee group. In Missouri overlies Tebo formation (new); underlies Bevier formation. Thickness as much as 17 feet.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 45. Cyclothem redefined to include Croweburg cyclothem of Abernathy (1937).

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 72–74. Verdigris limestone (Smith, *in* Woodruff and Cooper, 1928) comprises bed or beds called Ardmore by Gordon (1893) in Missouri. Term Verdigris has had wider usage than Ardmore and for that reason was adopted at Nevada Conference (Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12) for limestone in Verdigris formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 34, fig. 5. Ardmore limestone, Cherokee group, is exceptionally widespread unit that maintains approximately same characteristics over wide area reaching from Oklahoma to Iowa. Consists of two thin gray limestones separated by thinly laminated dark-gray shale. Ardmore limestone of Iowa is Verdigris limestone of Kansas, Missouri, and Oklahoma, and may be equivalent of lower Oak Grove of Illinois.

Named for Ardmore, Macon County, Mo.

Arecibo Formation[1]

Tertiary: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 10–17.

C. J. Maury, 1919, Am. Jour. Sci., v. 48, no. 285, p. 214 (chart). As shown on correlation chart, comprises (ascending) Lares, Aguadilla, and Quebradillas limestones. Upper Oligocene and lower and middle Miocene.

J. D. Weaver, 1956, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 316. Name not now in use.

Named for exposures in region about Arecibo.

Arendtsville Fanglomerate Lentil (in Gettysburg Shale)[1]

Upper Triassic: South-central Pennsylvania.

Original reference: G. W. Stose, 1929, U.S. Geol. Survey Geol. Atlas, Folio 225.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. C–67, p. 115, 117. In type area in Adams County, the Gettysburg is predominantly a red shale and sandstone with interbedded hard gray to white sandstones in the Heidlersburg member and a coarse fanglomerate called Arendtsville fanglomerate lentil at top.

Forms large hills southwest and west of Arendtsville, Adams County, for which it is named.

Argenta limestone[1]

Pennsylvanian: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 37.

Derivation of name not stated.

Argentine Limestone[1] Member (of Wyandotte Formation)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, western Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. Guidebook 5th Ann. Field Conf., correlation chart.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 106 (fig. 20), 109–110. Mostly very fine grained light-bluish-gray limestone that weathers creamy white, grayish white, or light buff. Bedding thin and uneven; many layers distinctly nodular. Normally, thickest subdivision of Wyandotte formation. Average thickness 20 feet; 30 feet thick at Kansas City. Overlies Quindaro shale member; underlies Island Creek shale member, or, where this shale is absent, underlies Farley limestone member. Disappears south of Lane [Kansas] but is persistent northeastward in Missouri; identified in Iowa and southeastern Nebraska.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 25, fig. 5. Argentine member in Madison County is 18-foot sequence of two or three massive limestones separated by dark-gray to buff calcareous shales. Fossiliferous throughout with *Osagia* and brachiopods. Thickness 12 feet in Union County. Overlies Quindaro shale member; underlies Island Creek shale member.

Type exposure: In quarry south of 26th and Metropolitan Ave., Kansas City, Kans. Named for Argentine Railway Station.

†Arickaree Shale[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 52.

Named for Arikaree River, Cheyenne County.

Arido sandstone[1]

Jurassic: Northeastern Arizona.

Original reference: C. R. Keyes, 1936, Pan-Am. Geologist, v. 65, no. 4, p. 303, 306.

Named for Arido Creek, in northern part of Navajo Reservation.

Arikaree Sandstone,[1] **Formation,** or **Group**

Miocene: Western Nebraska, northeastern Colorado, southeastern Montana, southern South Dakota, and southeastern Wyoming.

Original reference: N. H. Darton, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 4, p. 732, 735, 742, 743–748.

J. B. Hatcher, 1902, Am. Philos. Soc. Proc., v. 41, no. 169, p. 116–119. Redefined and used in group sense to include Monroe Creek above and Gering sandstones. Underlies Loup Fork group; overlies White River group.

C. B. Schultz, 1938, Am. Jour. Sci., 5th ser., v. 35, no. 210, p. 443–444. Suggests continued use of term Arikaree as group name. Redefined to include only Gering sandstone, Monroe Creek, and Harrison formations (the latter as defined by Hatcher 1902). Underlies Marsland formation (new).

A. L. Lugn, 1938, Am. Jour. Sci., 4th ser., v. 36, no. 213, p. 227 (table). Group includes Gering, Monroe Creek, and Harrison formations. Overlies White River group; underlies Hemingford group (new). Thickness 700 to 800 feet.

Billings Geol. Soc. [Guidebook] 2d Ann. Field Conf., 1951, p. 8 (correlation chart). Geographically extended into southeastern Montana.

Edward Bradley, 1956, U.S. Geol. Survey Water-Supply Paper 1368, p. 18–19, pl. 1. Arikaree group (formation in Niobrara County, Wyo.), as described in this report, includes all sediments of Miocene age. The sediments have been divided into Arikaree and Hemingford groups, but in this report these units are not differentiated and are mapped as Arikaree group. Underlies Ogallala formation.

A. F. Agnew, 1957, Geology of the White River quadrangle (1:62,500): South Dakota Geol. Survey. Formation consists of reddish-brown cross-bedded quartzose channel sandstone that is overlain by gray and pinkish unconsolidated tuffaceous quartzose sands. Top of Arikaree arbitrarily drawn at base of lowest pink fine-grained limestone bed. Thickness as much as 82 feet. Overlies Brule formation; underlies Mellette formation (new).

S. G. Collins, 1959, Geology of the Martin quadrangle (1:62,500): South Dakota Geol. Survey. Formation represented by Monroe Creek and Harrison members. Disconformably underlies Valentine formation.

W. D. Sevon, 1959, Geology of the Okreek quadrangle (1:62,500): South Dakota Geol. Survey. Thickness as much as 238 feet including Mellette facies. Underlies Valentine formation of Ogallala group; overlies White River group.

S. G. Collins, 1960, Geology of the Patricia quadrangle (1:62,500): South Dakota Geol. Survey. Group comprises (ascending) Sharps, Monroe Creek, and Harrison formations. Underlies Ogallala group, which here comprises (ascending) Valentine and Ash Hollow formations.

Name Arikaree is applied to formation because Arikaree Indians were at one time identified with area in which it is most largely developed. Well developed in face of Pine Ridge in Sioux County, Nebr., and Converse County, Wyo.

Arikareean Age

Miocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 11, pl. 1. Provincial time term based on the Arikaree group of western Nebraska, Agate being the most typical locality, with the limits as redefined by Schultz (1938) but including Rosebud beds. Includes time between Whitneyan (Oligocene) and Hemingfordian (Miocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

†Arizona Slates,[1] Arizonian Slate[1]

†Arizonan[1]

Precambrian: Southeastern Arizona.

Original reference: W. P. Blake, 1883, Eng. Mining Jour., v. 35, p. 254.

Exposed along sides of Queen Creek valley, west of town of Pinal, Gila County.

Arkadelphia Marl

Arkadelphia Marl (in Navarro Group)[1]

Upper Cretaceous: Southwestern Arkansas, northwestern Louisiana, and northeastern Texas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 53–56, 188.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Arkadelphia marl shown on correlation chart of outcropping formations in southwestern Arkansas. Occurs above Nacatoch sand. Navarro group not used in this area.

C. A. Renfroe, 1949, Arkansas Geol. Survey Bull. 14, fig. 2 (facing p. 8). Arkadelphia formation shown on generalized columnar section of eastern Arkansas. Consists of light-gray calcareous shale, sparingly glauconitic; medium-gray finely micaceous fissile shale near base. Thickness 50 to 150 feet. Overlies Nacatoch formation; underlies Clayton "calcareous" Midway. Navarro group.

Typical outcrops are 2 to 3 miles northwest of Fulton, Hampstead County, Ark., and at numerous localities 5 to 7 miles north and northwest of Hope. It is possible that basal few feet of formation crops out, though not typically, at Arkadelphia.

†Arkansan series[1]

Pennsylvanian: Western Arkansas and eastern Oklahoma.

Original reference: C. R. Keyes, 1901, Iowa Acad. Sci. Proc., v. 8, p. 119–132.

Named for valley of Arkansas River, Ark. and Okla.

†Arkansas Marls[1]

Miocene, upper, and Pliocene: Central southern Colorado.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Colorado and New Mexico 3d Ann. Rept., p. 75–91.

Occupy entire valley of Arkansas River.

Arkansas Novaculite[1]

Devonian and Mississippian: Southwestern Arkansas and southeastern Oklahoma.

Original reference: A. H. Purdue, 1909, Slates of Arkansas: Arkansas Geol. Survey, p. 30, 39–40.

W. H. Hass, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 12, p. 2526–2541. Definition and description based on section at Caddo Gap, Montgomery County, Ark. Lower division: nearly white thick-bedded novaculite; some interbedded greenish-gray and dark-gray shale near base; thickness 466 feet; Lower or Middle Devonian. Middle division: dark-gray and greenish-gray shale; many dark-gray beds of novaculite; thickness 347 feet; Upper Devonian and Mississippian. Upper division: nearly white granular thick-bedded novaculite; thickness 127 feet; Mississippian. Underlies Stanley shale; overlies Missouri Mountain slate (Silurian).

L. S. Griswold (1892, Arkansas Geol. Survey Ann. Rept. 1890, v. 3) described trade name Arkansas stone and (or) novaculite in an economic report on whetstones and novaculites of Arkansas.

Named for quarries in Arkansas. Principal formation in Ouachita Mountains.

†Arkansas Sandstone[1]

Pennsylvanian and Permian: Central southern Colorado.

Original reference: F. M. Endlich, 1874, U.S. Geol. and Geog. Survey Terr. 10th Ann. Rept., p. 312.

Named for proximity to Arkansas River.

Arkill Limestone (in Saavedra Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 8, 11, 15. Slabby grayish-brown and buff arenaceous limestone. Fossiliferous. Thickness about 2 feet. Overlain by a soft white, in some places buff, sandstone. A buff sandstone separates the Arkill from underlying Barata limestone (new).

Type locality of Lowell formation is in southwestern flank of Bisbee anticline, southeast of Bisbee and east of Naco; standard section of Lowell is in Ninety One Hills.

Arkose Ridge Formation

Cretaceous: South-central Alaska.

F. F. Barnes and T. G. Payne, 1956, U.S. Geol. Survey Bull. 1016, p. 10–12. Assemblage of arkose, conglomerate, and shale more than 2,000 feet thick. Arkose is fine grained and conglomeratic in places, but conglomeratic feature nowhere predominates. Rocks are dark brown to gray and contain all essential constituents of granite. On north side of Arkose Ridge, formation believed to rest with sedimentary contact on granite of Talkeetna batholith; on south side of ridge, formation in fault contact with Chickaloon and Matanuska formations. Older than Chickaloon formation and possibly, at least in part, older than Matanuska formation. Upper Cretaceous(?).

U.S. Geological Survey currently designates the age of the Arkose Ridge as Cretaceous on the basis of a study now in progress.

Typically exposed on Arkose Ridge, northwest of Wishbone Hill. In belt extending along northern border of Matanuska Valley west of Chickaloon River.

Arkwright Group

Upper Devonian: Western New York.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 31; 1955, New York State Mus. Sci. Service Circ. 42, p. 9–19. Succession of black and gray shales with some thin siltstone layers. Thickness 1,450 feet. Comprises Canadaway (lower) and Chadakoin formations; thus includes all rocks from base of Dunkirk shale to top of Ellicott shale. Underlies Conewango group; overlies Seneca group.

Name derived from Arkwright Township, Chautauqua County.

Arline Formation

Middle Ordovician (Mohawkian): Eastern Tennessee, northern Georgia, and southwestern Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 41–43, chart 1 (facing p. 130). Mostly cobbly weathering impure limestone containing considerable quantities of fine clastic material. Weathers to yellow-brown soil containing numerous silicified fossils. Thickness about 400 feet. Underlies Red Knobs formation (new); overlies Lenoir formation. Thin remnant underlies Effna calcarenites and reefs at Porterfield quarry, Virginia. Includes Fetzer tongue (new), which is recognized in Virginia, Tennessee, and Georgia. Interfingers with silty calcareous beds of Athens formation in southeastern Tennessee and with Rich Valley formation (new) at Marion, Va., and vicinity. Fingers of Arline appear in Tellico formation in belt along west front of Great Smoky Mountains. Occurs in area for which Porterfield stage is named. Name attributed to B. N. Cooper and G. A. Cooper.

Exposed almost in its entirety on both sides of valley of small stream tributary to Gallagher Creek, 2 miles southwest of railroad switch at Arline on Concord (TVA 138-SW) and Louisville (TVA 138-SE) quadrangles, Tennessee.

Arlington Formation[1]

Mississippian: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 14). Underlies Shoofly formation (Pennsylvanian?); overlies Devonian Taylorsville formation.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California Westwood sheet (1:250,000): California Div. Mines. Water-laid tuff and slate and minor andesitic metabreccia and metaconglomerate. Mapped with Permian marine sedimentary and metasedimentary rocks.

Named for Arlington Heights, Plumas County.

Arlington Gravel Member (of Vashon Drift)

Pleistocene: Northwestern Washington.

R. C. Newcomb, 1952, U.S. Geol. Survey Water-Supply Paper 1135, p. 26, 27, pl. 1. An outwash deposit of sand and gravel forming a thin veneer over a terrace cut mainly in the earlier Stillaguamish sand member (new). Underlies Marysville sand member (new).

Area: Snohomish County; contains Tps. 26-32 N. of the Willamette base line.

†Arlington Lake Beds[1] or Formation

Tertiary, late, and Pleistocene: North-central Oregon.

Original reference: E. T. Hodge, 1930, Monthly Weather Rev., v. 58, p. 405–441.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 869. Abandoned in favor of Shutler formation. Name Arlington preoccupied.

Town of Arlington is near Shutler, Gilliam County.

Armendaris Group

Pennsylvanian (Des Moines Series): New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 41–49. Proposed for all rocks between top of Derry series below and base of Bolander group above. Entirely of marine origin and composed largely of gray to light-gray cherty limestone, with a few thin shale and sandstone beds scattered throughout. Subdivided into three formations (ascending): Elephant Butte, Whiskey Canyon limestone, and Garcia.

Type locality: In north end of Mud Springs Mountains in west end of Whiskey Canyon, in and on either side of westernmost box canyon in southwest part of sec. 1, T. 13 S., R. 5 W., Sierra County. Name is derived from large Armendaris Grant to east and northeast of Hot Springs.

Armendaris limestone[1]

Ordovician: New Mexico.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 259, 260.

Derivation of name not stated.

Armenia Limestone Lentil (of Oswayo Formation)[1]

Devonian or Carboniferous: Central northern Pennsylvania.

Original reference: H. S. Williams and E. M. Kindle, 1905, U.S. Geol. Survey Bull. 244.

Armenia Mountain section, Bradford County.

Armes Gap Sandstone (in Graves Gap Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, 19 pls. 2, 3, 4. Thickness near Armes Gap about 10 feet; 20 to 40 feet in Camp, Austin, Petros, and Fork Mountain quadrangles; from this area thins northward; 20 to 70 feet in a northwest-southeast belt through Lake City, Duncan Flats, Block, Norman and Huntsville quadrangles. Separated from underlying Indian Bluff group (new) by a shale interval as much as 300 feet thick that includes Jordan and Norman Pond coals; separated from overlying Roach Creek sandstone (new) by a shale interval as much as 130 feet thick that includes Pioneer coal.

Named from exposures in Armes Gap, north of Petros, Morgan County.

Armstrong Member (of Cuyahoga Formation)[1]

Armstrong Sandstone Member (of Cuyahoga Formation)

Mississippian: North-central Ohio.

Original reference: G. E. Conrey, 1920, Ohio Geol. Survey, 4th ser., Bull. 24, p. 54.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 49, 50–51. Described as Armstrong sandstone member of River Styx conglomerate facies and Killbuck shale facies of Cuyahoga formation. In River Styx facies, Armstrong includes Rittman conglomerate submember.

E. J. Szmuc, 1958, Dissert. Abs., v. 18, no. 6, p. 2109. Overlies Rittman which is here raised to member status; underlies Wooster member (new) used in place of Black Hand which is here restricted. Lower Mississippian.

Named for exposures near village of Armstrong, Wayne County.

Armuchee Chert[1]

Lower and Middle Devonian: Northwestern Georgia.

Original reference: C. W. Hayes, 1902, U.S. Geol. Survey Geol. Atlas, Folio 78, p. 3.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Underlies Frog Mountain sandstone.

Named for exposures around Armuchee, Floyd County.

Armuelles Formation

Pleistocene: Panamá and Costa Rica.

R. A. Terry, 1941, Geog. Rev., v. 31, no. 3, p. 381 (fig. 5), 382. Conglomerate that passes upward into sandstones and shales. Overlies Charco Azul formation. Thickness more than 4,000 feet. Pleistocene.

A. A. Olsson, 1942, Bulls. Am. Paleontology, v. 27, no. 106, p. 160–161 (8–9); 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 248–249. Beds consist principally of gray well-bedded foraminiferal shales and soft sandstones. Fossils described.

Typically exposed near Puerto Armuelles, Burica Peninsula. Extends into Costa Rica.

Arnheim Shale,[1] **Limestone,**[1] or **Formation** (in Richmond Group)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, west-central Kentucky, and Tennessee.

Original reference: A. F. Foerste, 1905, Science, new ser., v. 22, p. 150.

C. V. Theis, 1936, U.S. Geol. Survey Water-Supply Paper 677, p. 31 (table), 74. Unconformably underlies Fernvale formation and overlies Leipers limestone in south-central Tennessee.

Wilber Stout, K. V. Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 33, p. 113. Formation in Ohio. Subdivided into Sunset member below and Oregonia member above. Underlies Waynesville formation; overlies McMillan formation. Richmond group.

C. W. Wilson, Jr., 1948, Tennessee Div. Geology Bull. 53, p. 11. In proposed changes of nomenclature for Ordovician system of central Tennessee, the Ohio name Arnheim is retained. In case its correlation with strata in Tennessee is seriously questioned, a local name should be applied. Richmond group.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 201–207. Described as dark-blue to blue-gray thin-bedded to massive argillaceous rubbly limestone in Tennessee. Thickness varies from 10 to 20 feet.

Overlies Leipers formation unconformably with single known exception of exposure at Clinton where it overlies Hermitage formation. Underlies Sequatchie formation in western exposures; in southeasternmost exposures is overlain by Fernvale limestone. Locally Chattanooga shale rests on Arnheim.

A. C. McFarlan and W. H. White, 1952, Kentucky Geol. Survey Bull. 10, p. 12. Oregonia member at base of formation in Kentucky.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Arnheim formation in Maysville group shown on generalized stratigraphic column of Ordovician and Silurian rocks exposed in Jefferson and Switzerland Counties. Thickness 70 to 80 feet. Overlies Mount Auburn formation; underlies Waynesville formation of Richmond group. Cincinnatian.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030. If reference section of the Cincinnatian, in Cincinnati region, be considered to include all strata between Point Pleasant (Cynthiana) beds and the Brassfield and their lateral equivalents, it is possible to recognize eight formational units in the sequence. These are (ascending) Eden, Fairview, McMillan, Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations. The Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn define the Richmond stage of the Cincinnatian.

Named for Arnheim, Brown County, Ohio.

Arnold Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Arnold mine, Keweenaw County.

Arnold Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Arnold mine, Keweenaw County.

Arnold Limestone (in Deese Group)

Arnold Member (of Deese Formation)[1]

Pennsylvanian (Des Moines Series): South-central Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 15.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Shown on correlation chart as a limestone in Deese group.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma—a symposium, v. 2. Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 32, 33. Occurs some 3,000 feet above base of Deese group (in maximum section). Includes a very fossiliferous thin-bedded limestone, more or less earthy and lumpy and interbedded with calcareous shale; with maximum aggregate thickness about 100 feet. Rocky Point conglomerate is about 1,400 feet above Arnold. Devils Kitchen conglomerate is 1,800 feet below Arnold.

Named for Arnold's Reef on Arnold Farm in sec. 33, T. 3 S., R. 1 E., north of Ardmore.

Arnoldsburg cyclothem

Pennsylvanian (Monongahela Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 178–181. Embraces interval between Benwood cyclothem (new) below and Lower Union cyclothem (new) above. Includes (ascending) Fulton shale and sandstone, Arnoldsburg redbed, Arnoldsburg limestone, Arnoldsburg underclay, Arnoldsburg coal, and Arnoldsburg roof shale members. In its normal position between Benwood coal bed and Arnoldsburg sandstone, average thickness of cyclothem in Athens County is a little over 16 feet. Individual members do not regularly appear in section, and their thickness frequently exceeds average thickness of entire cyclothem. Where Benwood cyclothem is absent, base of Arnoldsburg is considered to lie above roof shale of Sewickley coal bed; where base of cyclothem is drawn at this position, its average thickness is 71 feet. Under these circumstances, Sewickley sandstone, Tyler redbed, and Benwood limestone members are placed in Arnoldsburg cyclothem. In area of this report, Monongahela series is discussed on a cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Well developed in Athens County.

Arnoldsburg Limestone Member (of Monongahela Formation)

Arnoldsburg Limestone (in Monongahela Formation)[1]

Upper Pennsylvanian: Northern West Virginia and eastern Ohio.

Original reference: W. Stout, 1929, West Virginia Acad. Sci. Proc., v. 3, p. 140, 143.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 10). Shown on correlation chart as formation in Monongahela series. Underlies Uniontown limestone; overlies Benwood limestone.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 37. In Jefferson County, Ohio, Arnoldsburg consists of several layers of gray to buff limestone interbedded with buff calcareous clay shale. Average thickness about 13 feet, more than half of which is calcareous shale. Limestone is overlain by about 30 feet of gray arenaceous shale. Overlies Fulton green shale.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 81. Arnoldsburg limestone and shale member of Monongahela series described in Morgan County. Occurs between Fulton green shale member and Arnoldsburg coal member, although Fulton is not recognized definitely in Morgan County. Thickness 25 to 35 feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 181. In this report [Athens Couty]. Monongahela series is described on a cyclothemic basis. Arnoldsburg limestone member is included in Arnoldsburg cyclothem (new). Thickness 13½ feet.

Named for its close association with the Arnoldsburg sandstone which occurs near Arnoldsburg, Calhoun County, W. Va.

Arnoldsburg redbed member

Pennsylvanian (Monongahela Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 180. Member of Arnoldsburg cyclothem in report on Athens County. Recognized only if Benwood cyclothem is intact. Average thickness 13 feet. Where Arnoldsburg cyclothem is considered to be at base of

Sewickley sandstone, the lateral equivalents of this unit are lost in Tyler redbed and Benwood limestone sections.

Named for Arnoldsburg cyclothem.

Arnoldsburg roof shale member

See Arnoldsburg cyclothem.

Arnoldsburg Sandstone Member (of Monongahela Formation)

Arnoldsburg Sandstone (in Monongahela Formation)[1]

Upper Pennsylvanian: Western West Virginia, eastern Ohio, and southwestern Pennsylvania.

Original reference: R. V. Hennen, 1911, West Virginia Geol. Survey Rept. Wirt, Roane, and Calhoun Counties, p. 57, 202, 505.

W. O. Hickok and F. T. Moyer, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 123, 124 (fig. 29). Geographically extended into Fayette County, Pa., where it is described as medium-grained soft gray-brown sandstone occurring in thin to medium beds. Average thickness about 10 feet. Underlies Uniontown limestone; overlies Benwood limestone.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 37. Overlies Arnoldsburg limestone in Jefferson County, Ohio, and northwestern part of West Virginia.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 82. Arnoldsburg sandstone and shale member of Monongahela series described in Morgan County. Occupies stratigraphic position between overlying Uniontown limestone and underlying Arnoldsburg coal and (or) Arnoldsburg limestone. Consists of erratic development of sandstones and sandy shales ranging in thickness from 4 to 22 feet and averaging about 12 feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158, 181. In this report [Athens County], Monongahela series is described on cyclothemic basis. Arnoldsburg shale and sandstone member is included in Lower Uniontown cyclothem (new). Arnoldsburg sandstone is represented as an olive-gray silty shale about 8 feet thick. Where Lower Uniontown coal is absent, Arnoldsburg sandstone is basal member of cyclothem. Underlies Ritchie redbed member (new).

Named for Arnoldsburg, Calhoun County, W. Va.

Arnoldsburg underclay member

See Arnoldsburg cyclothem.

Aromas Red Sands

Pleistocene, middle(?): West-central California.

J. E. Allen, 1946, California Div. Mines Bull. 133, p. 18 (fig. 2), 43–45, pls. 1, 2, 3. Dark-brown to red friable quartzose sandstone. Thickness 600 to 800 feet; 180 feet at type section. Underlie terrace gravels and alluvium; unconformably overlie all older formations with which they are in contact, successively overlapping upon Santa Lucia granite, San Lorenzo, Vaqueros, volcanics, and Pliocene rocks [Purisima formation].

Type section: In railroad cut 1 mile west of town of Aromas [Monterey County].

Aroostook Limestone[1]

Silurian: Northeastern Maine and western New Brunswick, Canada.

Original reference: H. S. Williams, 1900, U.S. Geol. Survey Bull. 165, p. 21, 44–45.

C. O. Nylander, 1940, Geological formations of the St. John River valley, northern Maine and New Brunswick: Caribou, Maine, p. 11–12 [privately printed]. Noted as occurring in western New Brunswick.

R. L. Miller, 1947, Maine Geol. Survey Bull. 4, p. 7, 10, pl. 2. Composed of three lithologic members: lower slate, middle ribbon limestone, and upper argillaceous limestone. Apparent thickness 18,000 feet; this may be excessive because structure of region is very complex. Underlies sequence of shale and slate (Ashland limestone and shale of former reports); overlies sandstone and conglomerate formation (Sheridan sandstone of former reports).

Occurs in eastern part of Aroostook County, Maine. The Aroostook River cuts the limestone from Wade Township to its junction with St. John River.

Aroostook Falls Diabase[1]

Age(?): Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 115, 175–177.

Named for occurrence at Aroostook Falls, Aroostook County.

Arp Member (of Queen City Formation)

Arp Sand (in Reklaw Formation)

Eocene (Claiborne): Northeastern Texas and Louisiana.

B. W. Blanpied and R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 128 (correlation chart). Shown on correlation chart as Arp sand in Reklaw formation.

H. B. Stenzel, 1953, Texas Univ. Pub. 5305, p. 10 (fig. 3), 83–85. Described as member at base of Queen City formation. Consists of sands, silts, and thinly bedded, silty, carbonaceous shales. Thickness ranges from 48 to 75 feet. Underlies Omen sandstone member; overlies Marquez shale member, Reklaw formation. Type locality designated. Name credited to C. L. Moody.

C. R. Smith, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2520–2521. Member overlies Reklaw formation at alternate type locality of Queen City.

Type locality: Vicinity of Homer Lacey country store on road from Bell Church to Griffin, Henrys Chapel quadrangle. Named from town of Arp in southeastern Smith County, Tex., 6 miles north of mapped area.

Arpin Conglomerate and Quartzite[1]

Precambrian (upper Huronian): Central northern Wisconsin.

Original reference: S. Weidman, 1907, Wisconsin Geol. Nat. History Survey Bull. 16, p. 366.

Exposed immediately south of Arpin, Wood County.

Arrastre Complex

Arrastre Quartzite[1]

Middle Paleozoic(?): Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 351, 353–365, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 471–472. Because Arrastre quartzite is closely involved with much granitic material, it might be better to call combination Arrastre complex. Younger than Cambrian, probably about Middle Paleozoic.

Named for Arrastre Creek, San Bernardino County.

Arrey Formation (in Green Canyon Group)

Pennsylvanian (Derry Series): New Mexico and western Texas.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 31 (fig. 2), 32–33, 35–36. Name used for the basal formation of the Derry series. At type locality, formation is composed of dense massive limestones, highly nodular limestones with irregular interbedded highly calcareous shales and very irregular masses and lenses of chert; northward from type locality, formation is more highly clastic, but southward it is essentially pure limestone. Thickness ranges from 32 feet at type locality to more than 300 feet in Hueco Mountains of western Texas. Underlies Apodaca formation (new).

Type locality: On west-facing slope of hill about three-fourths mile east of Derry, Sierra County, N. Mex. Name derived from village of Arrey on the west side of Rio Grande on Highway 85 about 4½ miles northwest of Derry.

Arriban series[1]

[Tertiary]: New Mexico.

Original references: C. R. Keyes, 1906, Science, new ser., v. 23, p. 921; 1906, Am. Jour. Sci., 4th, v. 21, p. 298–300.

Derivation of name not stated.

Arrow Creek Member (of Colorado Shale)

Lower Cretaceous: Central Montana.

J. B. Reeside, Jr., and W. A. Cobban, 1960, U.S. Geol. Survey Prof. Paper 355, p. 8, 14 (fig. 8), 38, 39, 40, 41, 42, 43, 44. Consists of bentonite, tuff, and porcelanite. Thickness 40 feet in type area. Underlies Mowry member. In Teigen area, the bentonite is 2½ feet thick and is about 50 feet below Mowry member. Thickens northwestward, and top of member gradually approaches base of Mowry.

Type section: North side of Arrow Creek in sec. 23, T. 18 N., R. 10 E., Judith Basin County. Forms conspicuous white outcrop for 35 miles between Belt Butte and Stanford.

Arrowhead Limestone Member (of Monte Cristo Limestone)[1]

Upper Mississippian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 9, 18.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 23). Age shown on correlation chart as Mississippian (Meramecian).

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 42. Commonly alternating layers of fine limestone several inches thick, and thin shale. Thickness about 10 feet. Overlies Bullion dolomite member; underlies Yellowpine member.

Named for Arrowhead prospect, sec. 9, T. 24 S., R. 58 E., Goodsprings quadrangle, Clark County, Nev.

†Arrowmink Arkosic Gneiss[1]

Precambrian: Southeastern Pennsylvania.

Original reference: F. Bascom, 1904, Am. Jour. Sci., 4th, v. 17, p. 143.

In Philadelphia region.

Arroyo Formation (in Clear Fork Group)[1]

Lower Permian (Leonard Series): Central Texas.

Original reference: J. W. Beede and V. V. Waite, 1918, Texas Univ. Bull. 1816, p. 45–46.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 42. Basal formation of Clear Fork group. Underlies Vale formation; overlies Lueders limestone. Thickness about 250 feet.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on stratigraphic table as comprising (ascending) Rainey, Lytle, and Standpipe limestone members. Underlies Vale formation; overlies Lake Kemp formation.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80. Shown on composite columnar section of Permian rocks in Colorado River valley as overlying Lueders limestone.

Occurs on and near Los Arroyo 2¼ miles west of Ballinger, Runnels County.

Arroyo Hondo Formation

Eocene: West-central California.

H. E. Vokes, 1939, New York Acad. Sci. Annals, v. 38, p. 13 (table 1), 27–32. Name applied to strata that have been referred by various writers to Martinez, Meganos, and Tejon stages. Formation includes Cantua sandstone (at base), Ragged Valley shale (new), and an upper white sandstone member (unnamed) 100 to 300 feet thick. Unconformably underlies Domengine formation; uncomformably overlies Moreno formation.

Type section: Along the Arroyo Hondo, north of Coalinga [Fresno County].

Arroyo Hondo Shale Member (of Lodo Formation)

Eocene: West-central California.

R. T. White, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 257. Upper member of Lodo formation (new). Overlies Cantua sandstone member.

R. T. White, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 10, p. 1725 (fig. 1), 1726 (fig. 2), 1735, 1738. Type section designated. Name credited to E. R. Atwill (unpub. paper read before 9th annual meeting of Pacific section of American Association of Petroleum Geologists). Atwill described Arroyo Hondo as a shale formation, with a white arkosic sandstone member at top, lying between Cantua sandstone and restricted Domengine. White found Arroyo Hondo shale genetically a part of Lodo formation, relegated its rank to a member, and excluded from it the white sandstone unit. Vokes (1939) used preoccupied term Arroyo Hondo to include most of Lodo formation and an unnamed sandstone unit between Lodo and Domengine. Vokes also proposed term Ragged Valley shale member to include most of Lodo shale, Cerros shale member, and Arroyo Hondo shale member, all of which were named and defined previous to his designation. Underlies Yokut sandstone (new).

J. E. Schoellhamer and D. M. Kinney, 1953, U.S. Geol. Survey Oil and Gas Inv. Map. OM–128. In Tumey and Panoche Hills area, Fresno County, member consists of 1,040 feet of gray claystone and minor amounts of interbedded siltstone and sandstone. Overlies Cantua sandstone member; where Cantua is not present, it is impossible to distinguish between Cerros and Arroyo Hondo members. Underlies Yokut sandstone.

Type locality: Arroyo Hondo Creek in S½ sec. 14, T. 17 S., R. 13 E. [Fresno County].

Arroyo Penasco Formation

Upper Mississippian: Northern New Mexico.

A. K. Armstrong, 1955, New Mexico Bur. Mines Mineral Resources Circ. 39, p. 3, 6–9. Proposed for the 20 to 150 feet of gray dense fine-grained to oolitic massive- to medium-bedded limestone occurring in Pinos and Penasco Canyons in Nacimiento Mountains. A fossiliferous chert zone some 15 to 20 feet thick occurs at top of formation. Unconformably underlies Pennsylvanian Log Springs formation (new); in some areas, unconformable below Sandia formation; uncomformably overlies Precambrian gneiss.

J. P. Fitzsimmons, A. K. Armstrong, and Mackenzie Gordon, Jr., 1956, Am. Asso. Petroleum Geologists Bull., v. 40, no. 8, p. 1935–1944. Underlies Sandia formation. Fauna described.

Type locality: SW¼SE¼ sec. 5, T. 16 N., R. 1 E., Cuba quadrangle. Named for arroyo 1 mile southeast of type section. Also exposed in San Pedro, Jemez, Sandia, and Sangre de Cristo Mountains.

Arroyo Seco Gravel[1]

Pleistocene: Northern California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Incidental usage on map legend.

A. M. Piper and others, 1939, U.S. Geol. Survey Water-Supply Paper 780, p. 33, 49–55, pl. 1. A pediment gravel. Thickness as much as 19 feet. Underlies Victor formation (new); overlies gravel deposits of uncertain age; in some areas overlies Mehrten formation (new) and in others Laguna formation (new). [This is cited by Wilmarth as "in press."]

Named for Arroyo Seco land grant [along west front of Sierra Nevada] where formation is extensively preserved.

Artemisia Gravel[1]

Pleistocene: Great Lakes region, Ontario, Canada, and Michigan.

Original reference: W. E. Logan, 1863, Canada Geol. Survey Repts. 1843–1863, p. 887, 908–909.

Named for Artemisia Township, Ontario.

Arthur Limestone (in Carbondale Formation)

Pennsylvanian: Southwestern Indiana.

J. A. Culbertson, 1932. The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 3, 5–6. Thin very fossiliferous limestone lying about 10 feet above Petersburg coal.

Occurs between Oakland City and Arthur, Pike County.

Artillery Formation

Eocene, lower(?): West-central Arizona.

S. G. Lasky and B. N. Webber, 1949, U.S. Geol. Survey Bull. 961, p. 14 (table 2), 16–22, pls. 1, 2. Consists of conglomerate, arkose, sandstone, shale, limestone, a little clay, some tuff, and a widespread basalt member. About 2,500 feet thick. Rests with angular unconformity upon rocks of Precambrian complex and Paleozoic(?) sediments. In some areas, unconformably underlies Miocene(?) volcanics; in other places, overlain by Chapin Wash formation, Cobwebb basalt, or Sandtrap conglomerate (all new); on east side of Bill Williams River, overlain by extensive gravel blanket, and in Santa Maria district by Quaternary(?) basalt. In central spur of Artillery Mountains, has been overthrust by Precambrian complex and Paleozoic(?) rocks. Silicified palm roots were collected from some of the limestone beds. Tentatively assigned to lower Eocene (p. 21). Plates 1 and 2 (geol. maps) show age as early Eocene(?).

Named for Artillery Mountains (Mohave County). Formation occupies broad tracts within mapped area and extends far beyond its borders, particularly northward along Big Sandy River and westward into Rawhide Mountains.

Artist Drive Formation

Oligocene and Miocene(?): Eastern California.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 955–956. Comprises 1,000 feet or more of impure well-stratified ash beds that contain remains of fresh-water fish, conformably overlain by alternating basaltic and latitic flows, tuffs, and breccias that are more or less altered. Interlain with volcanics are basin deposits that range from fanglomerate to playa clay and algal limestone. Unconformably underlies Furnace Creek formation. Name credited to T. P. Thayer.

Typically exposed in west face of Black Mountains near Artist Drive in Death Valley.

Arumonogui (Almongui) Agglomerate

See Almongui Agglomerate.

Arundel Formation[1] or **Clay** (in Potomac Group)

Upper Cretaceous: Eastern Maryland.

Original reference: W. B. Clark 1897, Maryland Geol. Survey, v. 1, p. 156, 190.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 5–6. More specific name Arundel clay is preferred because formation consists almost entirely of clay. Unconformably underlies Patapsco formation; unconformably overlies Patuxent formation.

Gerald Meyer, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 95, pl. 3. Gives thickness as much as 200 feet. Clay dips southeast at an average rate of about 45 to 50 feet per mile.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2169 (fig. 1), 2177. Lower Cretaceous. This assignment is made on basis of both floral and faunal evidence. Detailed discussion of problem.

Named for Anne Arundel County.

Arusa Formation

See Aruza Formation.

Aruza Formation (in Tapaliza Group)

Aruza Member (of Tapaliza Formation)

Oligocene: Panamá.

Karl Sapper, 1937, Mittelamerika Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no. 29, p. 132–133, 134 (correlation chart). Arusa formation shown on correlation chart below Aquaqua formation and above Clarita formation (both new). Upper Oligocene.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (chart), 241. Tapaliza can be divided into an upper or Miocene part and a lower or Oligocene part, known respectively as the Aguagua and the Arusa.

R. A. Terry, 1956, California Acad. Sci. Occasional Paper 23, p. 36, 44. Referred to as Aruza formation.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 324. Indicates correct spelling is Aruza.

Dareen area.

Arvada Formation

Pleistocene: Northeastern Wyoming.

L. B. Leopold and J. P. Miller, 1954, U.S. Geol. Survey Water-Supply Paper 1261, p. 8–10, 18, 31. Consists of highly weathered gravel or gravelly sand, generally stained red but containing many cobbles stained with a yellow or yellow-brown limonite. Disconformably underlies Ucross formation (new). Thickness up to 5 feet.

Type locality: At west abutment of highway bridge across Powder River on Highway 16, 3 miles north of Arvada, Wyo.

Arvison Formation

Lower Jurassic: Northern California.

A. F. Sanborn, [1953] Stanford Univ. Abs. Dissert., v. 27, p. 436–437. Fossiliferous strata conformably underlying Potem formation and unconformably overlying Modin formation.

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6, 11–14, pl. 1. Proposed for series of dominantly pyroclastic beds with minor andesitic flows, which are intermediate between Modin and Potem formations and which do not appear to be continuous with Bagley andesite of Diller. Bagley andesite, as traced from its type area into Big Bend region, overlies and is interfingered with basal beds of Potem formation. Because basal strata of Potem appear to lie between Bagley andesite and Arvison pyroclastic accumulations, new name is proposed for the lower beds. Thickness 5,090 feet in type area. Overlies Kosk member (new) of Modin formation.

Type area: Extends from point on Kosk Creek about 1¾ miles south of Arvison Flat to point about 1 mile north of Arvison Flat at contact with underlying Triassic beds, Big Bend quadrangle, Shasta County.

Arvonia Slate[1]

Upper Ordovician: Central Virginia.

Original reference: T. L. Watson and S. L. Powell, 1911, Am. Jour. Sci., 4th ser., v. 31, p. 36–43.

G. W. Stose and A. J. Stose, 1948, Am. Jour. Sci., v. 246, no. 7, p. 393–412. In central Virginia is not restricted to belt of commercial slate but includes a porphyroblastic facies of slate, called knotted slate. Underlies Bremo quartzite (new); overlies Peters Creek formation. Suggested that age may be Silurian or younger.

Exposed at Arvonia.

Asan Limestone

Aquitanian: Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 52, table 4 [English translation in library of U.S. Geol. Survey, p. 62]. Hard red or white limestone that unconformably overlies Fena beds. Oligocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 18–19. Paleontologically same as Tagpochau limestone on Saipan. Aquitanian.

Type locality: Asan, Guam.

Asbury Clay[1]

Miocene, upper: Eastern New Jersey.

Original reference: H. B. Kummel and G. N. Knapp, 1904, New Jersey Geol. Survey, v. 6, p. 145.

Named for development just west of Asbury Park, Monmouth County.

Ashawa till[1]

Pleistocene: Iowa.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203.

Ashawan[1]

Pleistocene: Iowa.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 45, p. 150–151.

Ashbed Amygdaloid (in Portage Lake Lava Series)

Ashbed Amygdaloid (in Ashbed Group)[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 56, 58, 102, 116, 129, chart.

H. R. Cornwall, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–34. Included in Portage Lake lava series.

In old Ashbed mine, Keweenaw County.

Ashbed Flow[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

In old Ashbed mine, Keweenaw County.

†Ashbed Group[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 172–173, 178, 186, pls. 17, 18.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ-27. Name Portage Lake lava series (new) proposed to include Eagle River, Ashbed, Central Mine, and Bohemian Range groups of old reports; these subdivisions are quite arbitrary and depend on continuity of individual flows or conglomerate beds for validity. They are not useful for purpose of this report.

Occurs in old Ashbed mine, Keweenaw County.

Ashby Stage

Middle Ordovician (Mohawkian): North America.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 8, chart 1 (facing p. 130). Mohawkian series divided into five stages (ascending): Whiterock, Marmor, Ashby, Porterfield, and Wilderness. In Hogskin Valley, Elray and Lincolnshire formations comprise Ashby stage. Kay (1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8) places formations of this stage in his Chazyan, but this does not seem justified on paleontological grounds. Name credited to G. A. Cooper and B. N. Cooper.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 93, 94, 95. Virginia sequence consists of Blackford (new), Ashby, Porterfield, and Wilderness stages. Place of Marmor stage is in dispute. Blackford and Ashby stages believed to be Chazyan, but not to constitute whole of that series. They are in a provincial series that is approximately the St. Paul group (Neuman, 1951).

Named from road intersection on Hogskin Creek, in northeast quarter of center subquadrangle of Maynardville (30′) quadrangle, Tennessee.

Ash Creek Group

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 9–10, pl. 1. Eastern of two major subdivisions of Yavapai series. Separated from western subdivision, the Alder group, by Shylock fault. Rocks consist of basaltic, andesitic, rhyolitic, and dacitic flows and pyroclastic rocks and thick sequence of tuffaceous sedimentary rocks containing interbeds of jasper-magnetite and chert. Divided into seven formations. Gaddes basalt (new) is oldest, and is overlain by Buzzard rhyolite (new). Shea basalt, dacite of Burnt Canyon, and Brindle Pup andesite (new), lenticular units about the same age, separate Buzzard rhyolite from younger Deception rhyolite. Grapevine Gulch formation (new) is younger than Deception rhyolite. Group perhaps 20,000 feet thick, not including base or top. Sum of maximum thickness of each formation is 23,500 feet, but because some volcanic formations are lenticular, a lower figure is more accurate estimate for group as a whole.

Named from Ash Creek, which cuts through a representative section south of Mingus Mountain, Jerome area, Yavapai County.

Ash Creek Series

Precambrian: New Mexico.

C. H. Hewitt, 1959, New Mexico Bur. Mines Mineral Resources Bull. 60, p. 12–13, 33, 53–57, 104–105, pls. 1, 12. Contains seven metasedimentary rock types grouped into four mappable units (not in stratigraphic sequence): sericite phyllite and andalusite-sericite schist; cordierite hornfels; spotted andalusite hornfels, biotite hornfels, and diopside quartzite; serpentine-carbonate rocks. Maximum exposed thickness approximately 5,800 feet. Younger than Bullard Peak series (new). Occurs as complex xenoliths or roof pendants in Burro Mountains granite.

Named for Ash Creek Canyon, Big Burro Mountains area. Underlies about 1½ square miles in secs. 9, 16, 17, 21, and 22, T. 18 S., R. 18 W., Grant County.

Asher Formation[1]

Permian: Central and southern Oklahoma.

Original reference: G. D. Morgan, 1924, Oklahoma Bur. Geology Bull. 2, p. 141–142, pls. 3, 27, map.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1519 (fig. 1). Shown on graphic section of "Wanette" time division of Permian sediments. Included in Pontotoc terrane. Gradational equivalent of Stratford shale.

Named for development at and west of Asher, Pottawatomie County.

Asherville Alluvium

Pleistocene(?): Southeastern Missouri.

Willard Farrar and Lyle McManamy, 1937, Missouri Geol. Survey and Water Resources 59th Bienn. Rept., app. 6, p. 38–41. Composed of reddish, angular sand grains, with a small amount of red to light-brown clay. Thickness varies from 18 to 80 feet. Overlies Powell(?) and Ripley formations and also loess.

Found in vicinity of Asherville in sec. 15, T. 26 N., R. 8 E., Puxico quadrangle [Stoddard County].

Ash Hollow Formation (in Ogallala Group)

Ash Hollow Member (of Ogallala Formation)

Ash Hollow Series or Formation

Pliocene: Western Nebraska, western Kansas, South Dakota, and southeastern Wyoming.

Henry Engelmann, 1876, *in* Appendix 1 *of* Report of explorations across the Great Basin of the territory of Utah for a direct wagon route from Camp Floyd to Genoa, in Carson Valley, in 1859, by Capt. James H. Simpson, Engineer Dept., U.S. Army: Washington, U.S. Govt. Printing Office, p. 260–262, 283. Near junction of North and South Forks of Platte River, first rocky strata were observed. They continue along South Fork, cropping out at intervals at one or the other side of river, and were found most developed in Ash Hollow where they attain thickness of over 250 feet. This series is composed of an alternation of loose, finely sandy, and of harder rocky strata, the latter consisting of fine or coarse drift-sand, generally cemented by carbonate of lime, forming more or less calcareous sandstones, and gritty, very impure limestones. Probably Pliocene-Tertiary. Fossilized seeds present in rocks near forks of Platte River. From Ash Hollow westward, strata gradually assume different appearance, and instead of being calcareo-arenaceous they become more purely arenaceous and, finally, argillo-arenaceous. This formation is older than Ash Hollow series. Term Ash Hollow formation used on page 283.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, no. 213, p. 223–224, 227. Name Ash Hollow formation applied to "mortar beds" of Ogallala group.

Thickness 100 to 250 feet. Underlies Sidney gravel formation; overlies Valentine formation.

A. L. Lugn, 1939, Am. Jour. Sci., v. 237, no. 6, p. 435–436; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1260–1261. At type locality, where they overlie about 55 feet of Brule formation, beds belonging to Ash Hollow formation consist of layers of gravel, sand, silt, and fine sandy clay, with some beds of volcanic ash, all more or less indurated into hard caliche beds at regular intervals. Thickness 250 to 275 feet. Term Ash Hollow is not a new or even recent name as was supposed by Lugn (1938). Term Ash Hollow formation was applied to exactly same beds in Ash Hollow Canyon by Engelmann (1876).

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 139–145. Subdivided to include (ascending) Wray channel, Minnechaduza, and Feldt Ranch beds (all new).

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 18 (fig. 8), 19 (fig. 9), 20. Geographically extended into Kansas where it is considered member of Ogallala formation. Underlies Kimball member; overlies Valentine member.

A. L. Lugn and B. W. Brown, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1384. Geographically extended into southeastern Wyoming.

J. S. Carey and others, 1952, Kansas Geol. Survey Bull. 96, pt. 1, p. 9–13, 27. In Norton County, Kans., includes (ascending) Calvert ash bed and Reager ash bed (both new).

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 253–255. In northwestern Kansas, includes (ascending) Rawlins (new), Fort Wallace (new), Dellvale (new), Reager, and Reamsville (new) volcanic ash beds.

R. E. Stevenson, 1959, Geology of the Dallas quadrangle (1:62,500) : South Dakota Geol. Survey. Geographically extended into Dallas quadrangle, South Dakota. Bulk of formation consists of interbedded buff to greenish-tan fine-grained arkosic sand and ledge-forming vuggy calcareous arkosic sandstone; beds of greenish-tan fine-grained clayey and silty arkosic sand locally present; some of strata are ashy, and some contain white dense limestone concretions. Maximum thickness 110 feet. Includes Bijou facies. Underlies Herrick formation.

Type section: Exposures in Ash Hollow Canyon southeast of Lewellen, Garden County, Nebr.

Ashishik Basalt

Tertiary and Quaternary: Southwestern Alaska.

F. M. Byers, Jr., and others, 1947, U.S. Geol. Survey Alaska Volcano Inv. Rept. 2, pt. 3, p. 25, 27, 38, pl. 3. Consists of a sequence of massive basalt flows with minor interbedded tuff-breccia and tuff; individual flows range in thickness from 20 to 60 feet. Thickness 500 feet measured on cliff west of New Jersey Creek, but base not exposed. Underlies Crater Creek basalt (new).

F. M. Byers, 1959, U.S. Geol. Survey Bull. 1028–L, p. 309–311, pl. 41. As redefined in this report, includes most of bulk of Okmok Volcano and comprises Ashishik basalt, tuff breccia, and tuff, that part of Crater Creek basalt on outer flanks of Okmok Volcano, Idak basalt, excepting the mass of Mount Idak, and basalt flows of Hill 1200 (Byers and others, 1947). Ashishik basalt is subdivided into three lithologic units: mafic phenocryst basalt, palagonitized pyroclastic rocks, and aphyric (nonporphyritic) feldspathic basalt. Separated from younger Crater Creek basalt by erosional surface. Separated from Crater Creek by fault on north wall of Okmok Caldera. Latest Tertiary and Quaternary.

Named for exposures in east-facing cliff, 2 to 3 miles south of Ashishik Point at northernmost part of Umnak Island.

Ashland Formation

Silurian: Northeastern Maine.

W. H. Twenhofel, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1978–1979; 1941, Jour. Paleontology, v. 15, no. 2, p. 170–172, 173–174. Defined to include Ashland limestone, Ashland shale, and Graptolite shale of Williams (1900). Field relations and fossils suggest that Graptolite shale and Ashland shale are parts of one stratigraphic unit, that strata designated Ashland limestone are lenses of limestone in this shale, and that Sheridan sandstone succeeds Ashland shale. Thus interpreted, section becomes (descending) Sheridan formation, Ashland formation, Aroostook formation.

W. S. White, P. E. Cloud, Jr., and Josiah Bridge, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1939–1940. Stratigraphic sequence given (descending): Ashland formation, Aroostook formation, Sheridan sandstones.

Named for exposures in Ashland village, Aroostook County.

Ashland Limestone[1]

Silurian: Northeastern Maine.

Original reference: H. S. Williams, 1900, U.S. Geol. Survey Bull. 165, p. 21, 51, 52, 54.

W. H. Twenhofel, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1978–1979; 1941, Jour. Paleontology, v. 15, no. 2, p. 170–172, 173–174. Included in Ashland formation (new).

Named for exposures in Ashland village (in a ledge opposite Ashland Hotel), Aroostook County.

Ashland Limestone

Ashland limestone facies (of Callaway Formation)

Middle Devonian: Northeastern Missouri.

E. B. Branson, 1941, Kansas Geol. Soc. Guidebook 15th Ann. Field Conf., p. 81, 83, 85. Compact, fossiliferous limestone. Maximum thickness about 15 feet. In type area, uncomformably underlies Callaway limestone; unconformably overlies Jefferson City dolomite. Crops out in sec. 1, T. 47 N, R. 12 W.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 37–39. Term Ashland is preoccuped. Unit is herein referred to as Ashland limestone facies to denote *Rensselandia*-bearing beds of Callaway formation. Type locality redesignated due to typographical error in original description.

Type locality: NE¼SW¼ sec. 1, T. 46 N., R. 12 W., Boone County, about 0.3 mile north of Sycamore School, along an old abandoned roadway, 9 miles north-northwest of Jefferson City. Type locality covers only about 10 acres. Name derived from village of Ashland.

Ashland Limestone[1]

Pennsylvanian: Southeastern Nebraska.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 7, 24.

Named for town of Ashland.

Ashland Mica Schist[1]

Ashland Series

Precambrian: Eastern Alabama.

Original reference: E. A. Smith and H. McCalley, 1904, Alabama Geol. Survey Bull. 9, p. 8.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1379. Considered as part of the Carolina gneiss or series.

F. R. Hunter, 1944, Alabama Geol. Survey Bull. 54, p. 13, 14. Referred to as Ashland series. Described as containing a variety of metasedimentary rocks that have been severely folded and faulted. Bordered on west by Hillabee chlorite schist and on the east by Pinckneyville granite (known to be younger than Ashland). Area of report covers Coosa County.

Named for exposure around Ashland, Clay County.

Ashland Shale[1]

Silurian: Northeastern Maine.

Original reference: H. S. Williams, 1900, U.S. Geol. Survey Bull. 165, p. 21, 45, 49–51.

W. H. Twenhofel, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1978-1979; 1941, Jour. Paleontology, v. 15, no. 2, p. 170–172, 173–174. Included in Ashland formation (new).

In Ashland village, along road opposite the hotel, and southward toward Masardis, Aroostock County.

†Ashley Marl[1]

†Ashley River Beds or Marl[1]

†Ashley-Cooper Beds or Marl[1]

Eocene, upper: Southern South Carolina.

Original reference: M. Tuomey, 1848, Agric. Survey South Carolina 1st Rept., p. 162–169, 190, 211.

Named for exposures along Ashley River, Dorchester County.

Ashley Hill Limestone[1]

Cambrian: Eastern New York.

Original reference: T. N. Dale, 1893, U.S. Geol. Survey 13th Ann. Rept., pt. 2, p. 312.

J. C. Craddock, 1957, Geol. Soc. America Bull., v. 68, no. 6, p. 694–695. Ashley Hill conglomerate mentioned under section headed Schodack shale and limestone. Rock sequence crops out on west ridge of Ashley Hill. Sequence begins with dark-gray quartzite and is succeeded by sequence of limestone, shale, and limestone conglomerate which is not known elsewhere in Kinderhook quadrangle. A crystalline limestone pebble in Ashley Hill conglomerate contains *Botsfordia caelata.* On basis of lithologic, stratigraphic, and fossil evidence, conglomerate and underlying limestone and shale are correlated with Schodack shale and limestone. Underlying quartzite is probably equivalent to Diamond Rock quartzite (Ruedemann, 1930, New York Mus. Bull. 285).

Occurs at Ashley Hill, in northeast corner of Chatham Township, Columbia County, about 1 mile north of Rayville or Rider's Mills Station on Lebanon Springs Railroad, and 2 miles south of Brainard, in Nassau.

Ash Mountain Complex

Paleozoic(?)-Mesozoic(?): Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 6–7, pl. 1. Four rock types are mapped together as Ash Mountain complex. Major type is dark-gray fine-grained rock of quartz diorite composition which is intruded by a fine-grained lighter gray rock also of quartz diorite composition. The two fine-grained types are dissimilar to the plutonic types in mapped area and are possibly altered metamorphic rocks. Smaller amounts of quartz diorite, resembling material of Giant Forest pluton, and Cactus Point pluton, are present within the complex.

Named for exposures in vicinity of Ash Mountain Park headquarters, Sequoia National Park.

Ashnola Gabbro[1]

Carboniferous(?): Southwestern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

Lies 2 miles east of Ashnola River, British Columbia and Washington.

Ashokan Formation (in Hamilton Group)

Ashokan Beds[1]

Ashokan Shales and Flags

Middle Devonian: Eastern New York.

Original reference: A. W. Grabau, 1917, Geol. Soc. America Bull., v. 28, p. 954.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 267–273. Referred to as Ashokan shale and flags.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW–20, p. 15, pl. 2. Described as a formation consisting of tough laminated arkosic flagstones containing interbedded shales which weather red or brown. Sandstones are generally coarse grained and range from thin beds to flags thick enough to be quarried. Maximum thickness in Albany County nearly 350 feet. Outcrop area small. Overlies Mount Marion formation; underlies Kiskatom formation.

Named for exposures in Ashokan district, west of Kingston.

Ashtabula Till

Pleistocene (Wisconsin): Northern Ohio and northwestern Pennsylvania.

V. C. Shepps and others, 1959, Pennsylvania Geol. Survey Bull., 4th ser., G–32, p. 10 (fig. 3), 13 (fig. 4), 45, pl. 1. Gray to bluish-gray, moderately pebbly silt till deposited during Ashtabula advance near close of Cary time. Younger than Hiram till (new). Name credited to G. W. White (in press).

G. W. White, 1960, U.S. Geol. Survey Bull. 1121–A, p. 2 (table 1), 3 (fig. 1), 10–11. Thickness generally more than 25 feet and probably exceeds 50 feet in many places; at type section 19½ feet. Surface material in many areas. Overlies bedrock, Hiram till, or, in places where Hiram is absent, an earlier, coarser till. Youngest glacial deposit in Ohio. Type section designated.

Type section: Roadcut at top of bluff on east side of valley of Ashtabula River at Plymouth-Sheffield Township line, 1 mile south of northwest corner of Sheffield Township and 3 miles east of southeast corner of Ashtabula corporation line, Ashtabula County, Ohio.

†Ashton Schists[1]

Precambrian: Northeastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 106, 107.

Occurs at Ashton, Providence County.

†Aspalaga Clay or Marl[1]

†Aspalaga phase (of Chattahoochee Formation or Waldo Formation)[1]

Miocene, lower: Florida and southern Georgia.

Original reference: L. C. Johnson, 1892, Geol. Soc. America Bull., v. 3. p. 128–132.

Probably named for exposures at Aspalaga, Liberty County, Fla.

Aspen Shale[1]

Aspen Shale Member (of Mancos Shale)

Lower Cretaceous: Southwestern Wyoming, eastern Idaho, northwestern Montana, and northeastern Utah.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 97 (table 1), 100 (table 2), 101–102. Member of Mancos shale in Uinta Basin, Utah. Overlies a lower unnamed shale member; underlies a middle unnamed shale member. Thickness 15 to 95 feet.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1), 839–840. Mapped in north-central Wasatch Mountains where it is about 250 feet thick. Underlies Frontier formation; overlies Kelvin(?) formation.

L. S. Gardner, 1944, U.S. Geol. Survey Bull. 944–A, p. 6, pl. 1. Mapped in Irvine quadrangle, Idaho. Thickness 2,015 feet. Underlies Frontier formation; overlies Bear River formation.

W. A. Cobban and J. B. Reeside, Jr., 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1893. Age designated as Lower Cretaceous on basis of ammonite fauna.

Teng-Chien Yen, 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 760–761. Bear River formation in type area underlies Aspen shale. On basis of fauna, Bear River strata are assigned to Upper Cretaceous (Cenomanian).

A. La Rocque and C. D. Edwards, 1954, Geol. Soc. America Bull., v. 65, no. 4, p. 315–326. Cretaceous Bear River and Aspen section in Willow Creek, 6 miles southeast of junction of Hoback and Snake Rivers, Teton County, Wyo., described in detail including position and nature of its faunas. Bear River is 539 feet thick, and Aspen 1,307 feet. On lithologic and paleontologic grounds, Bear River-Aspen contact is placed lower than in earlier reports. Aspen section contains 63 feet of porcellanite, which suggests prolonged volcanic activity in region. Conflicting age assignments for Bear River and Aspen discussed. Suggested that this conflict may be due to complex intertonguing between the two formations.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 356 (table 1), 367, 368, pl. 1. Mapped in Lima region, Montana. Overlies Kootenai formation. Upper(?) Cretaceous.

D. M. Kinney, 1955, U.S. Geol. Survey Bull. 1007, p. 98. In this report [Uinta River-Brush Creek area, Duchesne and Uintah Counties, Utah], term Mowry is used in preference to Aspen for lower dark-gray fissile shale member of Mancos.

J. B. Reeside, Jr., and W. A. Cobban, 1960, U.S. Geol. Survey Prof. Paper 355, p. 7–11. Short summary of Aspen shale included in report on Mowry shale and contemporary formations in United States and Canada. Note on type area.

Named for former station at Aspen, on now abandoned alinement of Union Pacific Railroad. Old Aspen was at center of sec. 29, T. 14 S., R. 118 W., Uinta County, Wyo., about 20 miles northeast of southwest corner of the State.

As Perdido Beds

See Asuberudido Beds.

Aspermont Dolomite[1]

Aspermont Member (of Dog Creek Formation)

Permian: North-central Texas and southwestern Oklahoma.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull., v. 1, sec. opposite p. 96.

R. L. Clifton, 1942, Jour. Paleontology, v. 16, no. 6, p. 686, 687. Middle member of Dog Creek formation. Shown on chart as underlying unnamed shales and gypsums below Childress member and overlying shales above Guthrie member. Noted as occurring in Harmon County, Okla.

Probably named for Aspermont, Stonewall County, Tex.

Asphalto Lake Bed[1]

Pliocene: Southern California.

Original reference: J. G. Cooper, 1894, California Acad. Sci. Proc., 2d ser., v. 4, p. 168.

Probably named for exposures at or near Asphalto, a village near McKittrick, Kern County.

Asphalt Ridge Sandstone (in Mesaverde Group)

Upper Cretaceous: Northeastern Utah.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 99 (table 2). 110–111, pl. 1. Defined as lower of two basal marine sandstones of Mesaverde group in Vernal (Utah) region. Usually a single massive yellow to white soft sandstone bed bounded on top by a thin tongue of Mancos shale and on bottom by main body of Mancos shale. Upper boundary transitional; in some places it is impossible to draw a sharp line between Asphalt Ridge and overlying Rim Rock sandstone (new). Thickness about 100 feet.

Typically exposed in Asphalt Ridge. Traced, with interruptions, from north end of Asphalt Ridge to the Rim Rock at Green River, where it feathers out into main body of Mancos shale.

Asphaltum Sandstone[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: J. R. Bunn, 1930, Oklahoma Geol. Survey Bull. 40PP, p. 10.

G. W. Chase, 1954, Oklahoma Geol. Survey Mineral Rept. 26, p. 1–2, 4–5. Discussion of occurrence of radioactive material in sandstone lenses of southwestern Oklahoma. These sandstone lenses are associated with a crossbedded bituminous gray sandstone shown on Geologic Map of Oklahoma (Miser, 1954). Age of sandstone is given by Miser as probably equal to that of base of Garber sandstone of northern Oklahoma. Crossbedded bituminous sandstone was mapped in Cotton County and part of Tillman County as upper part of Auger conglomerate in upper part of Wichita formation by Munn (1914). Auger conglomerate extends from Cotton County into Jefferson County where it was mapped by Bunn (1930) as Ryan-Asphaltum sandstone. Crossbedded bituminous gray sandstone occurs in upper part of Asphaltum sandstone. Ryan sandstone is almost entirely crossbedded dark-gray sandstone.

Exposed in vicinity of Asphaltum, Jefferson County.

Aspinwall Limestone Member (of Onaga Shale)

Aspinwall Limestone Member (of Chicago Mound Formation)

Aspinwall Limestone or Shale (in Admire Shale)[1]

Permian: Southeastern Nebraska, eastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 9, 17, 29.

G. E. Condra, 1935, Nebraska Geol. Survey Paper 9, p. 9. Permian. Underlies Hawxby shale formation; overlies Towle shale formation.

R. C. Moore, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 99. Noted as persisting into northern Oklahoma. Lowermost limestone of Admire group.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 37. Basal member of Chicago Mound formation (new); underlies Hawxby shale member. Thickness 1 to 3 feet.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Reallocated to member status in Onaga shale (new). Underlies Hawxby shale member; overlies Towle shale member.

Type locality: Aspinwall [now abandoned], Nemaha County, Nebr.

Assabet Quartz-Diorite

Upper Paleozoic(?): Eastern Massachusetts.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 46, pl. 1. Medium grained, medium to dark gray, and slightly to moderately foliated. Composed chiefly, and in order of abundance, of andesine, hornblende, quartz, and biotite.

Type locality: Exposures on Hill 272 in northeast corner of Maynard. The main tongue-shaped mass of rock extends from Maynard northeastward into Concord quadrangle. Named for exposures near Assabet River in town of Maynard.

Assumption Coal Member (of Spoon Formation)

Pennsylvanian: Southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 45 (table 1), pl. 1. Assigned member status in Spoon formation (new). Present in lower part of formation. Coal named by Cady (1935, Illinois Geol. Survey Bull. 62). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Mine, NE¼NW¼ sec. 2, T. 12 N., R. 1 E., Christian County.

Astoria Formation

Astoria Shale[1]

Miocene, middle: Northwestern Oregon and southwestern Washington.

Original reference: E. D. Cope, 1880, Am. Nat., v. 14, p. 457–458; 1880, Am. Phil. Soc. Proc., v. 19, p. 62.

H. V. Howe, 1926, Pan-Am. Geologist, v. 45, no. 4, p. 295–306. In city of Astoria [type locality], formation consists of a lower sandstone member, probably more than 150 feet thick, overlain by a succession of sandy shales, about 1,000 feet thick, and these in turn by a second sandstone member.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 173, 175–187; C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 184, chart. Formation consists of sandy clay shales with brown sandstone in upper part, in Grays Harbor area; becomes progressively more sandy toward the lower Columbia River and prevailingly massive brown medium-grained sandstone in northwest Oregon. Basaltic flows are intercalated in southwest Washington and increase in importance until, east of Portland, the formation is composed almost entirely of basalt. Thickness varies from 1,500 to as much as 12,000 feet. In some areas underlies Montesano formation; unconformably overlies Twin Rivers formation.

W. C. Warren, Hans Norbisrath, and R. M. Grivetti, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 42. In Clatsop and Tillamook Counties, Oreg., the Astoria reported as overlying beds of Blakeley age.

W. R. Rau, 1948, Jour. Paleontology, v. 22, no. 6, p. 774–782. Foraminiferal fauna indicates an age of lower to middle Miocene; some evidence indicates upper lower Miocene (upper Saucesian).

Well exposed in the city of Astoria, Oreg., on south side of Columbia River near its mouth. Formation has been folded into a syncline whose axis trends northwest through city of Astoria.

†Astoria Group[1]

Miocene: Northwestern Oregon and southwestern Washington.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 223–227.

Named from Astoria, Clatsop County, Oreg.

†Astoria Sandstone[1]

Miocene: Northwestern Oregon and southwestern Washington.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 223–227.

Named from Astoria, Clatsop County, Oreg.

Asuberudido (As Perdido) Beds

Eocene(?): Mariana Islands (Saipan).

Risaburo Tayama, 1952. Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 47–48, table 4 [English translation in library of U.S. Geol. Survey, p. 57]; S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 19. Oldest fossiliferous beds on island. Upper member consists of (ascending) tuff, conglomerate, agglomerate, shale, limy tuff; lower member is thick, false-bedded sandy tuff cut by small faults. Underlie andesite.

Typical outcrop at Asuberudido (also spelled Asuberudedo).

Asuncion Group or Formation

Upper Cretaceous: West-central California.

N. L. Taliaferro, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 11, p. 2095. Upper Cretaceous sediments (Asuncion group) rest on lower Upper Cretaceous (Jack Creek formation) with angular unconformity up to 70°, and overlap all older rocks. Asuncion group is thickest and most widespread of all divisions in Santa Lucia Range.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 132–134, pt. 2 [preprint 1941]. Name Asuncion group is used to include all of Upper Cretaceous beds in central Coast Ranges above Pacheco group (new). Asuncion group consists of over 10,000 feet of coarse conglomerates, sandstones, and shales, which, in Santa Lucia Range, unconforably overlie Pacheco sediments and overlap onto all older rocks, Shasta, Knoxville, and Franciscan, and basement complex. In Santa Lucia Range, group is subdivided into Cantinas sandstones, Godfrey shales, and Piedras Altas formation (all new). On west side of San Joaquin Valley, group is divided into Panoche (restricted), Moreno, and Garzas formations. Majority of beds previously mapped in this region [central Coast Ranges] as "Chico" belong to Asuncion group. The two groups are separated by Santa Lucian orogeny.

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 484–512. In this report, which discusses Cretaceous of Santa Lucia Range, both terms, Asuncion group and formation, are used. Asuncion group is separated from older Pacheco group by Santa Lucian orogeny. Asuncion formation unconformably overlies Jack Creek formation of Pacheco group. Ordinarily in fault contact with Lower Cretaceous Marmolejo formation (new), though in some areas there is angular discordance. Type section stated. Anderson's Upper Cretaceous Paskenta and Horsetown groups are considered faunal stages.

F. M. Anderson, 1958, Geol. Soc. America Mem. 71, p. 30–71. Discussion of subdivisions of Pacific Coast Upper Cretaceous. Taliaferro's terms Asuncion and Pacheco groups are used. All strata definitely referable to Senonian are included in Lower Asuncion group, and strata of probable Maestrichtian age are included in Upper Asuncion group.

Type section: In Asuncion Grant, in southeast part of Adelaida quadrangle where there are good exposures of all phases along Santa Rita Creek, Templeton-Cayuocos Road, and road past Asuncion School.

Asuncion Limestone

Pleistocene: Mariana Islands (Tinian).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]. Named on correlation chart. Correlated with Chatcha [Chacha] limestone of Saipan, Peleliu limestone of Palau, and Fais limestone of West Caroline. [Appears to be same as Sonson limestone (Tayama, 1952).]

Asylum terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703 (fig. 8), 1707, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Asylum is applied to a terrace deposit younger than Uvalde and older than Capitol (new). Thickness near Austin about 15 feet. Name Asylum was applied to a terrace by Hill and Vaughan (1898, U.S. Geol. Survey 18th Ann. Rept).

Named for occurrence at Austin State Hospital, Austin, Travis County. Present along Colorado River.

Atalaya Limestone

Upper Cretaceous: Puerto Rico.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 47, 48 (table 4). Incidental mention. [May be synonymous with Las Marias limestone.]

Occurs in Atalaya Mountains, Lares district.

Atarque Member (of Mesaverde Formation)

Upper Cretaceous: Northwestern New Mexico.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 11, 35, 60, pl. 12. Nonmarine deposit composed of sandstones, shales, carbonaceous shales, and thin seams of coal. Thickness about 127 feet. Lowest Mesaverde in area. Underlies Horsehead tongue (new) of Mancos shale.

Occurs near village of Atarque, Valencia County, and also in Zuni Indian Reservation, McKinley County.

†Atascadero Formation[1]

Upper Cretaceous: Southern California.

Original reference: H. W. Fairbanks, 1904, U.S. Geol. Survey Geol. Atlas, Folio. 101.

Named for exposures along Atascadero Creek, San Luis Obispo County.

Atascosa Formation

Cenozoic(?): Southern Arizona.

B. P. Webb and K. C. Coryell, 1954, U.S. Atomic Energy Comm. RME-2009, p. 7, pl. 1. Consists of coarse conglomerates and some thin interbedded lava in upper section. Becomes increasingly tuffaceous toward base. Tuffs well bedded; one unit up to 500 feet thick. Thickness about 800 feet. Conformably overlies Montana Peak formation (new).

Named because of its prominent outcrops in Atascosa Range, Ruby quadrangle.

Atchinson Formation

Tertiary: Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a) 18–20, 61, 63. In most places, basal unit of this formation is black breccia composed of angular blocks of augite andesite lava; about 500 feet thick and grades irregularly into unbroken flow-rock in Atchinson Mountain; locally at base are found a little white limestone and red sandstone gravel. Upper unit is a red to red-brown monolithic breccia. Thickness ranges from a fraction of a foot to about 500 feet. Overlies Rencher and Grass Valley formations (both new).

Mapped in northern half of Pine Valley Mountains, Washington and Iron Counties. Named for exposures on Atchinson Mountain.

Atchison Formation

Pleistocene: Northeastern Kansas and southern Nebraska.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 12 (fig. 5), 15. Sand and silt, well sorted; sand and gravel at base; commonly thinly laminated in upper part. Comprises pro-Kansas outwash of early Kansas age. Not recognized beyond limits of Kansas glaciation. Maximum thickness in Atchison County, 80 feet; commonly 40 feet. Underlies Kansas glacial till; overlies Nebraska till.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 51, 62 (fig. 2), 70–74, pl. 1. Extended into Nebraska where it overlies Red Cloud formation. Type locality designated.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, p. 55 (fig. 1). In revised classification, Atchison is basal member of unnamed formation in upper part of Meade group.

Type locality: Exposures in creek bank in SE¼SW¼ sec. 2, T. 6 S., R. 20 E., Atchison County, Kans.

†Atchison shale[1]

Pennsylvanian: Northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

Original reference: C. R. Keyes, 1899, Am. Geologist, v. 23, p. 309.

Named for Atchison County, Mo.

Athelstane Granite[1]

Precambrian: Wisconsin.

Original reference: C. C. Wang, 1932, Geol. Soc. China Bull., v. 11, no. 4, p. 426–428.

Athens Group[1]

Pennsylvanian: Appalachian Basin.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 178.

Named for Athens County, Ohio.

Athens Marble[1]

Silurian: Central western Illinois.

Original reference: A. H. Worthen, 1866, geology: Illinois Geol. Survey, v. 1, p. 1933; 1882, Econ. Geology, v. 1, p. 102–103. Menard County.

Athens Shale or **Limestone**

Athens Shale (in Blount Group)[1]

Middle Ordovician: Eastern Tennessee, northern Alabama, western North Carolina, and western Virginia.

Original reference: C. W. Hayes, 1894, U.S. Geol. Survey Geol. Atlas, Folio 4, p. 2.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 159–170. Formation has three distinct facies in Virginia; gray to black shale, sandstone, and limestone. Thickness varies from a few feet on western margins to perhaps 5,000 to 10,000 feet in large area in southern Washington County, Va., and northern Sullivan County, Tenn. In all areas in Virginia where Holston limestone and Athens are both present, Athens is underlain by Whitesburg limestone; locally overlies Lenoir limestone; in Rich Valley underlies Ottosee limestone; in Shenandoah, Rockingham, Montgomery, and Pulaski Counties, underlies Chambersburg limestone; in some areas, underlies Lowville-Moccasin formation. In Blount group. Chazyan series.

Charles Butts, 1940, U.S. Geol. Survey Geol. Atlas, Folio 226. Described in Montevallo and Columbiana quadrangles, Alabama, where it is 12 to 350 feet thick. Unconformable above Lenoir limestone and below Little Oak limestone.

C. E. Decker, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 1, p. 1–145. Discussion of graptolites of Athens shale. Shale occurs in narrow long strip for about 700 miles in Appalachian Valley from central Alabama, across northwestern Georgia, eastern Tennessee, and western part of Virginia. Athens graptolite fauna is repeated in Normanskill shale of New York. Normanskill-Athens fauna extends northeastward across New England, eastern Quebec, New Brunswick, and Newfoundland, a total distance of 2,300 miles. If westward extent is considered, including Womble shale of Arkansas and Stringtown shale and lower Viola limestone of Oklahoma, there is total extent of Athens fauna for 2,800 miles in North America.

John Rodgers, 1952, Geology of the Athens quadrangle, Tennessee (1:24,000): U.S. Geol. Survey Geol. Quad. Map. Commonly yellow-weathering blue calcareous shale or shaly limestone. Thickness 400 feet. Underlies Holston limestone; overlies Lenoir limestone. Hayes (1895, Folio 20) and Keith (1896, Folio 25) recognized that Athens they mapped is lateral equivalent of what they mapped as Chickamauga limestone, which corresponds to Lenoir limestone of Athens area. Keith mapped typical Athens as grading laterally along strike into less argillaceous limestone in Oostanaula Valley less than 10 miles northeast of Athens. Unfortunately, evidence of this lateral gradation of Athens shale into Lenoir limestone has since been overlooked by most geologists, and Athens has been mistakenly placed above the Holston instead of below. Only lowest beds of Lenoir in Sweetwater Valley are equivalent to Lenoir at Athens and farther southeast, the rest being equivalent to Athens shale. Middle Ordovician.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 72–80, pls. Name Athens shale was proposed by Hayes and first used by him in Kingston folio for Upper Ordovician shale, here assigned to Reedsville shale, in belt next northwest of Whiteoak Mountain fault. In Cleveland folio (1895), which includes type locality, Hayes used name Athens for the shale here in question, between a thin "Chickamauga" limestone (Lenoir of Rodgers, 1953 [1952]) and the "Tellico sandstone" (Holston marble of Rodgers, 1953 [1952]). For present map, the thin underlying limestone is included at base of Athens. Athens in belt between Knoxville and Rocky Valley faults and Chestuee and Dumplin Valley faults consists partly of shaly nodular limestone like that in contiguous Lenoir limestone and partly of blue yellow-weathering very calcareous shale similar to that in Ottosee shale. The two grade into each other, and the formation is perhaps more generally shaly limestone than true shale. No black or noncalcareous shale and no sandstone are present. Thickness 800 to 1,100 feet. At Athens, the "shale" is exposed along southwest side of Oostanaula Creek southwest of Etowah road, but better section is exposed along Athens branch of Louisville and Nashville Railroad and along stream just north. Decker (1952) called railroad locality the type locality of Athens. Lenoir limestone and Athens shale grade into each other in vague belt near Monroe-McMinn County line. This gradation was observed and mapped by Keith (1896, Loudon folio), and it is difficult to understand how Keith's field observations could have been so long overlooked while attempt was made to fit Athens shale into the column above Holston formation instead of below. In western Sevier County, some sandstone layers in Sevier shale contain hematite and grade into red-weathering calcareous sandstone like that in Holston formation. In Blount County, detailed work by Neuman has shown that such sandstone layers occur at intervals through several thousand feet of shale. In this area, Keith (1895, Knox folio; 1896, Loudon folio) mapped some of these sandstone layers; a lower group he mapped as Tellico sandstone separating Athens shale below from Sevier shale above, and a thick persistent layer above the middle he mapped as a sandstone lentil in Sevier shale. Correlation of these layers is in dispute. Lower group of layers constitutes type Tellico sandstone as mapped by Keith on Tellico River, Monroe County (1896, Loudon folio). To the compiler [Rodgers], thick middle layer is representative in this belt [southeast of Chestuee and Dumplin Valley faults and of Saltville fault northeast of Morristown] of sheet of red sandstone and lime-sandstone forming Holston formation, and it is mapped as such from western edge of Sevier County through Blount and Monroe Counties. Shale below it is called Athens, and shale above it Ottosee. By this correlation, the lower group of layers, typical Tellico of Keith, occurs within Athens and becomes Tellico sandstone member of Athens; the higher and more lenticular layers correspond to limestone and sandstone lenses and layers in the typical Ottosee shale. Neuman disagrees with this correlation; he believes the whole shale sequence here called Sevier is younger than Holston formation in what is herein termed the standard belt. [See Holston limestone.]

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145, 148, 149, 154. Discussion of Middle Ordovician of Tellico-Sevier belt, eastern Tennessee. Classification used does not agree with that used by Rodgers (1953). Blockhouse shale (new) was included in lower part of Athens by Rodgers. Tellico formation, as defined in present report, includes upper part of Athens. Believed that Rodgers' introduction of terms Ottosee shale and Holston formation and continued use of Athens shale give these terms time-stratigraphic rather than rock-unit status.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 57. Term Blount group discarded.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 43–45. Proposed that name Athens be restricted to type region where formation proves to be a facies of Arline formation (new). At type section, Athens rests on thin tongue of "Chickamauga" limestone, identified in this belt as Lenoir, overlain by thin bed of impure limestone, Fetzer tongue (new) of Arline formation. Athens shale of Georgia is thinned representative of Paperville formation (new). Athens shale of Alabama is papery black shale herein named Columbiana formation. Athens shale of Virginia has been renamed, in Bristol area and Catawba Valley, Paperville formation. Graptolite shales in Saltville thrust block are herein named Rich Valley formation. Ash-weathering black limestones of Virginia, called Athens by Butts, were regarded as facies of Edinburg formation for which Campbell's (1905) name "Liberty Hall" was revived by Cooper and Cooper (1946).

Named for exposures at Athens, McMinn County, Tenn.

Athensville Coal Member (of Modesto Formation)

Pennsylvanian: Southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1), pl. 1. Name introduced for coal formerly called Upper Scottville. Stratigraphically above Rock Branch coal member (new) and below Scottville limestone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: SE¼NW¼SW¼ sec. 16, T. 12 N., R. 9 W., Macoupin County. Name derived from village of Athensville, Greene County, about 4½ miles to southwest of type locality.

Atherton Clay[1]

Mississippian: Southern Indiana and northwestern Kentucky.

Original reference: A. F. Foerste, 1910, Kentucky Geol. Survey Rept. Prog. 1908 and 1909, p. 76, 83, 84.

Derivation of name not stated.

Atherton Formation

Pleistocene: South-central Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 19–20, 21, pl. 1. Formation, as defined by W. J. Wayne (in preparation), includes a number of interrelated unnamed facies, all of which are a part of, or are closely associated with, sands and gravels that were deposited along melt-water streams during glacial ages. Only two of the major facies of formation are present in Huron area, and only one of these is exposed at surface. Windblown sand facies is exposed on valley slopes along East Fork of White River; thickness probably does not exceed 20 feet. Outwash sand and gravel facies present in valley of White River to a depth of 60 feet or more below present river level; exact distribution unknown as deposits are covered by alluvial sands of Martinsville formation (new). Sand and gravel facies probably intertongues with lower part of Prospect formation (new). Part is Wisconsin but part may be Illinoian or older.

Type locality and derivation of name not stated.

Athertonville facies (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 148–154. Consists of limestone in upper half; lower strata generally siltstone and silty, gritty shales. Thickness 175 to 200 feet. Includes near base, Rolling Fork limestone (above) and Ginseng siltstone members (both new) of Brodhead formation. Merges with Pilot Knob facies (new) on west and with Liberty facies (new) on east. Underlies Floyds Knob formation; overlies New Providence formation, Keith Knob and Junction City facies (both new).

Named for village of Athertonville, on U.S. Highway 68, northwestern La Rue County. Entire Brodhead formation is exposed along secondary road which ascends valley side of Rolling Fork of Salt River, one-fourth mile north of village.

Athol Shale[1]

Middle Devonian: Western New York.

Original reference: A. W. Grabau, 1930, Science Quart. Nat. Univ. Peking, China, v. 1, no. 4, p. 322–326.

Exposed on the Lake shore (Eighteen-mile Creek region) at Athol Springs and Bay View, Erie County.

Atkinson Formation

Upper Cretaceous: Subsurface in Georgia, Alabama, and Florida.

P. L. Applin and E. R. Applin, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 26. Comprises subsurface deposits of early Upper Cretaceous sequence occurring between base of beds of Austin age and top of Lower Cretaceous. On basis of differences in lithology, formation is divided into three unnamed members.

Name derived from Atkinson County, Ga., where Sun Oil Co. drilled Doster-Ladson Well 1 (lot 71, Land District 7).

Atlantic Amygdaloid (in Ashbed Group)[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Atlantic mine, Houghton County.

Atlantic Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Atlantic mine, Houghton County.

†Atlantic Group[1]

Tertiary: Atlantic Coastal Plain.

Original reference: O. Meyer, 1888, Am. Geologist, v. 2, p. 88–89, 93–94.

Comprises the Atlantic States proper from New Jersey to Florida.

Atlantic Muck

Pleistocene and Recent: Panamá.

[T. F. Thompson], 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 23. Heterogeneous mixture of alluvially deposited silts, clays, and carbonaceous material within which are beds of marine origin containing Pleistocene and early Recent forms of mollusks and corals.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 324. Informal name. Marine deposits contain numerous species of mollusks, nearly all of which are Recent.

Present on Atlantic side of Panama Canal.

Atlas Formation[1]

Quaternary: Southern California.

Original reference: A. C. Lawson, 1906, California Univ. Pub., Dept. Geology Bull., v. 4, p. 431–462.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 673. Quaternary. Older than Tank volcanics.

Derivation of name not stated.

Atoka Formation[1]

Atoka Series

Atoka(n) Stage

Middle Pennsylvanian: Eastern Oklahoma, western and southwestern Arkansas, eastern New Mexico, and central and western Texas.

Original reference: J. A. Taff and G. I. Adams, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 273.

C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 504–507; C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 24–35, pl. 1. Formation, in Muskogee-Porum district, subdivided into 12 units, 6 sandstone members each overlain by an unnamed shale unit. Sandstone members (ascending): Coody (Coata), Pope Chapel, Georges Fork, Dirty Creek, Webbers Falls, and Blackjack School. Thickness about 600 feet. Overlies Bloyd formation of Morrow group; underlies Hartshorne sandstone. Basal formation of Des Moines group. Atoka, Hartshorne, McAlester, and Savanna formations and a part of Boggy shale are directly traceable into Winslow formation as heretofore mapped in Muskogee quadrangle.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 858, 859. Overlies Barnett Hill formation (new). Unit here termed Barnett Hill was locally assigned by Taff to Atoka formation but in other areas was included in Wapanucka.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 156. Discussion of main divisions of Pennsylvanian system. Pronounced unconformities are reported within thick type Atoka section; hence it is thought to represent considerable length of time and complex geologic history. If Atoka division is not given rank of series, it might be given rank of group; if time-rock term stage is to be used for Paleozoic rock divisions as it is in Europe and as it has been introduced for Mesozoic and Cenozoic rocks of United States, this division could appropriately be called Atoka stage.

R. C. Spivey and T. G. Roberts, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 185–186. Raised to series rank and defined to include all beds from top of Wapanucka limestone, Morrow series, to base of Hartshorne sandstone, Des Moines series. As thus defined, includes

Marble Falls, Smithwick, and overlying *Fusulinella* (restricted)-bearing beds of central and north Texas, Derry series of New Mexico and west Texas, and equivalent beds in other areas as equivalence is established.

C. A. Moore, 1947, Oklahoma Geol. Survey Bull. 66, p. 17 (table 1), 50–52, measured section. Detailed discussion of Morrow series in northeastern Oklahoma. All sections measured in Morrow series were carried at least to base of Atoka sandstone and, where possible, to top of hills, so as to include a portion of Atoka formation. Locally thin-bedded, generally medium- to coarse-grained crossbedded sandstone rests on upper part of Bloyd shale in all areas except northward from Yonkers, where Bloyd was removed by pre-Atoka erosion, and Atoka is in contact with Hale formation. Top of Atoka not present in area. These post-Morrow beds in Adair and most of Cherokee Counties were called Winslow (Taff, 1905, U.S. Geol. Survey Geol. Atlas, Folio 122; 1906, U.S. Geol. Survey Geol. Atlas, Folio 132) and, in Wagoner and Mayes Counties, have been referred to Cherokee. Croneis (1930, Arkansas Geol. Survey Bull. 3) first used term Atoka for beds called Winslow in Arkansas, and Wilson (1937) recognized Atoka, Hartshorne, McAlester, and Savanna formations in Muskogee area, replacing general term Winslow. Des Moines series.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 292. Rocks of Oklan series (new) are divisible into two stages, Atokan (or Derryan) and Desmoinesian.

T. A. Hendricks and Bryan Parks, 1950, U.S. Geol. Survey Prof. Paper 221–E, p. 69 (table), 70–73, pl. 11. Discussion of Fort Smith district, Arkansas. Atoka formation, oldest bedded rock exposed in area, crops out in five parts of district; largest area of outcrop is in southern part of district. Consists chiefly of alternating beds of sandstone and shale, the shale being more abundant, and locally contains discontinuous streaks of coal and coaly shale. Thickness about 6,900 feet south of Backbone Mountain; about 3,300 feet near Mansfield. Underlies Hartshorne sandstone, minor unconformity. Atoka formation of Fort Smith district is identical with Atoka formation in Oklahoma.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1935–1953. Formation, in Arkansas, subdivided to include Greenland sandstone member (new) at base. Overlies Bloyd shale of Morrow group. Exact position of boundary between Morrow group and Atoka locally difficult to determine on purely physical stratigraphic basis in Washington County.

J. A. Reinemund and Walter Danilchik, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–192. Formation described in Waldron quadrangle, Scott County, Ark. Composite section of measured outcrops of Atoka across Waldron syncline shows that about 11,800 feet of strata assigned to formation crop out between top of formation, 4 miles north of Waldron and Ross Creek fault, 3½ miles south of Waldron. Rocks underlying those exposed in Waldron syncline crop out in Brushy Mountain anticline where they have combined stratigraphic thickness of about 7,200 feet. Total thickness in northern part of Waldron quadrangle, north of Ross Creek fault, appears to be at least 19,000 feet. In southern part of quadrangle, stratigraphic thickness in Black Fork syncline is estimated at about 18,500 feet, but highest and lowest strata are not present.

Overlies Johns Valley shale; underlies Hartshorne sandstone. (Stratigraphic equivalence of Hartshorne in Waldron quadrangle with Hartshorne in Fort Smith district and eastern Oklahoma is in doubt). Atoka formation is included in Atoka series.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 82–86, pls. Discussion of south and west flanks of Ozark uplift, northeastern Oklahoma. Atoka formation is widespread from Arkansas line westward to Arkansas River southeast of Muskogee. Thins northward from maximum of 600 feet southeast of Muskogee to 0 near Adair where it is truncated and overlapped by younger units. Northward thinning is by convergence, loss of lower member by progressive northward overlap and unconformity above. Webbers Falls member believed to be most extensive. Lies with unconformity upon Bloyd, Hale, and Fayetteville formations. Truncated by erosion and overlapped northward by shales, clays, and sandstones of Hartshorne-McAlester sequence. Assigned to Atoka series of Middle Pennsylvanian age.

J. G. Blythe, 1959, Oklahoma Geol. Survey Circ. 47, p. 5–74. Discussion of Atoka formation on north side of McAlester basin. Formation passes northward into a platform facies, thins, and is overlapped by Desmoinesian rocks. Facies changes and thinning of section north of Arkansas River made it unwise to attempt perfect identification of the rapidly thinning shelf-facies section with member as described in Muskogee-Porum area. Webbers Falls sandstone provided persistent marker unit and made it possible to identify Blackjack School member. Georges Fork and Dirty Creek members could not be identified north of Arkansas River and were mapped as one unit. Likewise Coody and Pope Chapel were mapped as one unit. Thickness 37 to 508 feet.

O. B. Shelburne, 1960, Oklahoma Geol. Survey Bull. 88, p. 17 (fig. 2), 41–44, 63, 64, pl. 1. Formation is 6,800 feet thick in Boktukola syncline; an unknown thickness has been removed by erosion. Basal part of formation is Morrowan. Contains sandstone mold faunas similar to Honess' (1924, [Oklahoma] Bur. Geology Circ. 3) "Morrow fauna" and spiculite cherts which may be partially equivalent to Chickachoc chert. Middle and upper parts of formation of Boktukola syncline are equivalent to Atoka formation of frontal Ouachitas. Harris Creek syncline is fan fold which exposes Atoka formation rather than anticline of Stanley shale as shown on Geologic map of Oklahoma. Overlies Johns Valley formation in Boktukola and Harris synclines. Morrowan-Atokan.

Named for Atoka, Atoka County, Okla., which is situated on outcrop of formation.

Atolia Quartz Monzonite[1]

Cretaceous(?): Southern California.

Original reference: C. D. Hulin, 1925, California State Mining Bur. Bull. 95, p. 33–42, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 509–510, table 4. Mentioned in discussion of crystalline rocks of southern California. Listed on table as Late Mesozoic.

U.S. Geological Survey currently designates the age of the Atolia as Cretaceous(?) on the basis of a study now in progress.

Named for exposures at and around Atolia, San Bernardino County.

Atrasado Member (of Madera Limestone)

Pennsylvanian: West-central New Mexico.

V. C. Kelley and G. H. Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. Thin- to thick-bedded gray to dark-gray limestone, gray and red shale, and red to light-reddish-brown and gray conglomeratic sandstone. Thickness 550 to 800 feet. Underlies Red Tanks member (new); conformably overlies Gray Mesa member (new).

Occupies tops of Gray Mesa and Monte de Belen; exposed in other parts of Lucero Uplift, Valencia and Socorro Counties.

Atrypa limestone[1]

Upper Devonian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 78.

Name derived from Atrypa Peak, in Eureka district.

Attalla Chert Conglomerate Member (of Chickamauga Limestone)[1]

Attalla Formation

Middle Ordovician: North-central Alabama.

Original reference: C. Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 45, 53, 55. Referred to as Attalla formation. Butts applied name Attalla to a coarse conglomerate, 20 to 40 feet thick, at base of Chickamauga limestone in Birmingham Valley. Conglomerate is patchy in occurrence. This conglomerate, together with red and green shales at base of the Chickamauga which the writer [Cooper] includes in name Attalla, is suggestive of Blackford lithology of Tennessee and Virginia but obviously deposited at a different time than Blackford. Except for Butts' use of name Chickamauga in Alabama, term has passed into disuse.

Named for exposures at Attalla, Etowah County.

Attica Shale[1] (in Naples Group)

Upper Devonian: Western New York.

Original references: G. H. Chadwick, 1919, Geol. Soc. America Bull., v. 30, p. 157; 1923, Geol. Soc. America Bull., v. 34, p. 69.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 63, no. 12, pt. 1, chart 4. Shown on correlation chart as overlying Cashaqua shale and underlying Grimes sandstone or Angola shale. Included in Naples group.

R. G. Sutton, 1960, New York State Mus. Bull. 380, p. 10–11, 19. Name Attica shale, formerly applied to Naples strata above Cashaqua formation in Lake Erie region, is herein abandoned, and term Rhinestreet black shale is applied westward to Lake Erie.

Probably named for exposure at Attica, Wyoming County.

Attleboro Sandstone[1]

Carboniferous: Southeastern Massachusetts and Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 144, 151–152.

Named for exposures in town of North Attleboro, Bristol County, Mass.; also exposed in vicinity of Deantown, in Attleboro Township.

Attwood Series[1]

Carboniferous(?): Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 10.

Mapped at and around Attwood Mountain, British Columbia.

Atwater Member (of Crooked Creek Formation)

Pleistocene (Kansan and Yarmouthian): Southwestern Kansas.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1), 58. Named and described as consisting of sandy silt, silt, silty clay, and clay which contains Pearlette ash lentil, when present; massive caliche generally present at top of member. Thickness about 50 feet. Overlies Stump Arroyo sand and gravel member; underlies Kingsdown formation.

Type section: In N½ sec. 21, T. 33 S., R. 28 W., on east side of Crooked Creek, Meade County. Name derived from old Atwater post office.

Atwater Creek Shale[1]

Middle Ordovician: Eastern New York.

Original reference: Rudolf Ruedemann, 1921, New York State Mus. Bull. 227, 228, p. 124–126, 130.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 286, pl. 4. Arenaceous transitional facies between black Deer River shale and sandy Lorraine shale of northwestern New York. Thickness at type locality about 70 feet.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, p. 286, chart 2 (column 19). Placed in Utica shale (restricted).

Type area: Atwater Creek, west of Martinsburg, Lewis County.

Aubrey Group[1]

Pennsylvanian and Permian: Northern Arizona, southeastern Nevada, and southern Utah.

Original reference: G. K. Gilbert, 1875, U.S. Geog. and Geol. Survey W. 100th Meridian, v. 3, p. 176–185, 197.

T. F. Stipp and H. M. Beikman, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–201. Group includes (ascending) Supai formation, Hermit shale, Coconino sandstone, Toroweap formation, and Kaibab limestone. Overlies Redwall limestone; underlies Moenkopi formation.

Named for exposures at Aubrey Cliff, which faces Aubrey Valley, in northern Arizona and stretches southeast nearly to Camp Apache.

†Aubrey Limestone[1]

Permian: Northern Arizona, southeastern Nevada, and southern Utah.

Original reference: G. K. Gilbert, 1875, U.S. Geog. and Geol. Survey W. 100th Meridian, v. 3, p. 171–187, figs. 81, 82.

Named for exposures at Aubrey Cliff, which faces Aubrey Valley, in northern Arizona and stretches southeast nearly to Camp Apache.

†Aubrey Sandstones[1]

Permian: Northern Arizona, southeastern Nevada, and southern Utah.

Original reference: G. K. Gilbert, 1875, U.S. Geog. and Geol. Survey W. 100th Meridian, v. 3, p. 171–187, figs. 81, 82.

Named for exposures at Aubrey Cliff, which faces Aubrey Valley, in northern Arizona and stretches southeast nearly to Camp Apache.

Aubreyan series[1]

Carbonic: Northern Arizona.

[Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 251, 336.]

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart), 223. Includes (ascending) Chiquito sandstones, Huethawali limestone, Havasupai sandstones, Wompats limestone, and Kanab limestones (new). Unconformably overlies Tusayan series (new). Of Carbonic age.

In Grand Canyon region.

Auburn Chert[1]

Middle Ordovician (Trentonian): East-central Missouri.

Original reference: R. R. Rowley, 1908, Missouri Bur. Geology and Mines, 2d ser., v. 8, p. 14, 16.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, p. 262–263, chart 2 (column 51). Placed in lowest Trentonian to conform to placement of Spechts Ferry shale with which it is correlated.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 27, pt. 1, p. 117. Has been suggested that Auburn chert be included in Plattin group; brachiopods are not in accord with this suggestion. Here suggested that formation may be chertified Decorah of Missouri-Barnhart formation (new) rather than Plattin and correlation should be with Guttenberg member of Decorah.

Forms surface stone of Auburn, Lincoln County.

Auburn Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northeastern Missouri, southeastern Nebraska, and northern Oklahoma.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 30.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 18. Geographically extended into Iowa and Missouri.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 56 (fig. 21), 60, 70 (fig. 25). Somewhat complex and variable unit composed chiefly of shale containing minor amounts of sandstone and limestone, part of which is chalky. Contains two or more local coal beds. Near Kansas River, contains lenses of crossbedded limestone and conglomerate and coquinoid masses of molluscan and algal remains as much as several feet thick; locally contains dark shale-bearing ostracodes and pelecypods. Thickness in Kansas ranges from about 20 to 70 feet. Underlies Reading limestone; overlies Wakarusa limestone.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1). Wabaunsee group redefined. Auburn shale overlies Wakarusa limestone member of Bern limestone (new); underlies Reading limestone member of Emporia limestone.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 54–55. Term is applied to sandstone-shale sequence between Wakarusa and Reading limestones. Auburn is continuous from southeastern Nebraska across

Kansas into northern Oklahoma, where it has been traced into southern Lincoln County. South of Lincoln County, limiting limestones pinch out, and Auburn cannot be distinguished from adjacent shales. Thickness 65 to 70 feet in Pawnee County. Overlies Wakarusa limestone; underlies Reading limestone member of Emporia limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Bull. 15, p. 13, fig. 5. Upper part of greenish-gray clayey shale; in center shale is deep red to maroon, silty, and micaceous; this middle part commonly contains leaf prints and carbonaceous films; lower part is silty, dark gray to black, and locally carbonaceous. Thickness about 35 feet. Underlies Reading limestone; overlies Wakarusa limestone. Wabaunsee group.

Type locality: Not designated but undoubtedly in vicinity of Auburn, Shawnee County, Kans. Good exposures along Wakarusa Creek near NE cor. sec. 26, T. 13 S., R. 14 E., southwest of Auburn.

Auger Conglomerate Lentil (in Wichita Formation)[1]

Permian: Southwestern Oklahoma.

Original reference: M. J. Munn, 1914, U.S. Geol. Survey Bull. 547, p. 23–26.

G. W. Chase, 1954, Oklahoma Geol. Survey Mineral Rept. 26, p. 1, 2, 3–4. Discussion of radioactive material in sandstone lenses of southwestern Oklahoma. These sandstones are associated with a crossbedded bituminous gray sandstone shown on Geologic Map of Oklahoma (Miser, 1954). Age of sandstone is given by Miser as probably equal to that of base of Garber sandstone of northern Oklahoma. The crossbedded bituminous sandstone was mapped in Cotton County and parts of Tillman County as upper part of Auger conglomerate in upper part of Wichita formation by Munn (1914). Auger conglomerate extends from Cotton County into Jefferson County where it was mapped by Bunn (1930, Oklahoma Geol. Survey Bull. 40PP) as Ryan-Asphaltum sandstone.

Named for old Fort Auger and Auger Creek, Tillman County.

Au Gres Limestone

See Point aux Gres Limestone.

†Augusta limestone,[1] group,[1] or stage[1]

Mississippian: Iowa, Illinois, and Missouri.

Original reference: C. R. Keyes, 1893, Iowa Geol. Survey, v. 1, p. 59–71.

Named for Augusta, Des Moines County, Iowa.

Augusta Mountain Formation

Middle Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]. Limestone and dolomite with some intercalated shale. At type locality subdivided into three unnamed members. Total thickness about 2,500 feet. Conformably underlies Cane Spring formation (new); conformably overlies Favret formation (new).

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Overlies Panther Canyon formation (new).

Type locality: Augusta Mountain.

Augustinillo Formation (in Jacaguas Group)

Eocene, middle: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 94–103, geol. map. Consists of 17,000 feet of marine sediments. Includes Collores member (new) to east and Monserrate member (new) to west. Interfingers with Naranjo formation (new). May interfinger with Río Culebrinas formation to west.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Cong., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 83, 84–85. Text states that Augustinillo is in Guayabal group. Footnote states that the Guayabal is currently called Jacaguas group.

Typically exposed in area to east and west of Cerro Augustinillo. Crops out in Ponce, Jayuya, and Adjuntas quadrangles.

Aunuu Tuff

Aunuu Island Tuff

Recent: Samoa Islands (Aunuu).

R. A. Daly, 1924, Carnegie Inst. Washington Pub. 340, p. 113, pl. B (geol. map). Mapped as Aunuu Island tuff. Referred to in text as Aunuu cone and crater.

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285 (table 1), pl. 1 (geol. map). Aunuu tuff about 200 feet thick.

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 153. Referred to Aunuu Island formations. A tuff cone, consisting of palagonitic tuff containing fragments of reef limestone. Recent.

Occurs on Aunuu Island.

Aurela Ridge Group or Granulites

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 231–274, geol. map. Essentially granulites; associated with minor amphibolites, mylonitic plutonic rocks, and plutonic intrusives. Separated from Cucamonga Canyon group (new) by Cucamonga Canyon thrust. Alf (1948, Geol. Soc. America Bull., v. 59, no. 11) referred to these rocks as "pyroxene dioritic gneiss," but term is misleading and is therefore discarded.

Named for exposures on Aurela Ridge in Cucamonga quadrangle, San Bernardino County. Occurs in an east-northeast-trending belt with a maximum width of about three-fourths of a mile.

Aurora Siltstone Member (of Orangeville Shale)

Aurora Sandstone Member (of Orangeville Shale)[1]

Mississippian: Northeastern Ohio.

Original reference: C. S. Prosser, 1912, Ohio Geol. Survey, 4th ser., Bull. 15, p. 123, 209, 211.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 44–45. Listed as a submember of Orangeville shale member of Tinkers Creek facies of Cuyahoga formation.

J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 42. Composed predominantly of siltstone. At type locality, lies upon about 12 feet of grayish-black and very dark gray shale of the Orangeville which includes Sunbury member. Maximum thickness about 6 feet.

Named for exposures on Aurora Creek in northwest part of Portage County.

†Ausable Granite[1]

Precambrian: Northeastern New York.

Original reference: J. F. Kemp, 1894, New York State Mus. 47th Ann. Rept.

Quarried near Keeseville, Essex County.

Ausable Sandstone[1]

Upper Cambrian: Eastern New York.

Original reference: H. I. Alling, 1919, New York State Mus. Bull. 207, 208, p. 113–145.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 329. Name was briefly mentioned by Alling (1919), and never since used, for basal Potsdam underlying the white Potsdam or "Keeseville" sandstone. Probably not valid unit.

Austell Granite

Precambrian(?): Northwestern Georgia.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 41–42. Described as an augen gneiss.

Exposed in an elongate area extending from Austell, Cobb County, southwestward across Douglas County, into eastern Carroll County.

Austin Chalk[1]

Austin Group

Upper Cretaceous (Gulf Series): Eastern Texas.

Original reference: B. F. Shumard, 1860, St. Louis Acad. Sci. Trans., v. 1, p. 583, 585.

L. W. Stephenson, 1937, U.S. Geol. Survey Prof. Paper 186–G, p. 133–146. Consists of interbedded layers of hard chalk, softer chalk, and chalky marl; some of marly layers are strongly argillaceous as in upper part that Adkins (1932 [1933]) called Burditt marl. Estimated thickness at type locality 420 feet. Relation of faunal zones in upper part of Austin chalk to top of chalk indicates presence of unconformity of regional extent separating the Austin and beds of Austin age from overlying Taylor marl and beds of Taylor age. Time value of this unconformity varies from place to place along strike.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 34–39. Austin group comprises Ector tongue, Bonham clay, Blossom sand, Brownstown marl, Gober tongue, Austin chalk, and Burditt marl. Below Taylor group and above Eagle Ford group. Foraminifera described.

Type area: Travis County. Named for Austin.

†Austin Marble[1]

Lower Cretaceous (Comanche Series): Southeastern Texas.

Original reference: R. T. Hill, 1889, Texas Geol. Survey Bull. 4, p. xxii.

Named for occurrence at Austin.

Austin Glen Member (of Normanskill Formation)

Middle Ordovician: Eastern New York.

Rudolf Ruedemann, 1942, New York State Mus. Bull. 327, p. 28. Incidental mention in discussion of Cambrian and Ordovician fossils.

Rudolf Ruedemann, 1942, New York State Mus. Bull. 331, p. 93 (fig. 35), 102, 107–108, 115–116, geol. map [1946]. Grit and shale with lenses of mud pebbles and arkosic conglomerate. Thickness varies; more than 500 feet. Overlies Mount Merino member; underlies Rysedorph conglomerate. Derivation of name given.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 14). Shown on correlation chart as Mohawkian (Trentonian).

Named for Austin Glen in Catskill Valley near village of Catskill [Catskill quadrangle]. Exposed in creek bed where it forms a north-south striking anticline, giving an outcrop of 355 feet length across the strike.

Austinville Dolomite Member (of Shady Dolomite)

Lower Cambrian: Southwestern Virginia.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 41, 42, 51–52. Defined as middle member of Shady dolomite. Thick-bedded coarsely crystalline nearly white light-gray to cream-colored dolomite. Thickness about 1,000 feet. Underlies Ivanhoe limestone member; overlies Patterson limestone member.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 115. Name Austinville not used because dolomite exposed at Austinville is regarded as Ledger dolomite and not part of Shady dolomite.

Named for town of Austinville, Wythe County.

Au Train Formation

Lower and Middle Ordovician: Northern Michigan.

W. K. Hamblin, 1958, Michigan Dept. Conserv., Geol. Survey Div. Pub. 51, p. 6 (fig. 1), 115–120, pls. 2, 4. Dominantly medium- to fine-grained dolomitic sandstone. Comprises two unnamed members. Lower member, approximately 100 feet thick, characterized by abundant glauconite which occurs as disseminated grains in dolomitic sand and concentrated in thin dark-green beds. Thin beds of glauconite more abundant near base of section at 3- to 12-foot intervals. Bedding in glauconitic member thin and undulatory; color buff to brownish gray, except for more glauconitic areas where color is speckled green or solid dark green. Some of more dolomitic beds blue to bluish gray. Much of weathered surface a definite brown. In upper member, glauconite completely absent and thin sandstone lenses numerous. Sandstone beds, more than 10 feet thick, also present. Sandstone characteristically medium to fine grained and contains few thin lenses of blue to greenish shale. Maximum thickness of formation, indicated in core samples, slightly more than 300 feet but only lower 125 feet exposed at type locality. Overlies Miners Castle member (new), Munising formation with unconformity. Hamblin, following Grabau (1906), proposes that Au Train formation be used for these rocks, which had been included under Hermansville limestone.

U.S. Geological Survey currently designates the age of the Au Train as Lower and Middle Ordovician on the basis of a study now in progress.

Type locality: Au Train Falls, in Alger County, where rocks are best exposed and sections are thickest.

Auts Canyon Formation (in Sheeprock Group)

Precambrian: West-central Utah.

DeVerle Harris, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 1, p. 6, 8–15, pl. 1. Succession of phyllites, phyllitic quartzites, quartzites, feldspathic quartzites, and graywacke conglomerate semischists that comprises allochthon of Sheeprock thrust. Total measured thickness 5,559 feet. Underlies Ekker formation (new).

Measured in Aut's Canyon, Dutch Peak area, Sheeprock Range, Tooele County.

Aux Sable Limestone[1]

Upper Ordovician: Northeastern Illinois

Original reference: J. R. C. Evans, 1926, Chicago Univ., Abs. Theses, Sci. serv., v. 2, p. 199–200.

Type locality not stated.

Aux Vases Sandstone[1]

Aux Vases Formation

Aux Vases Sandstone (in New Design Group)

Upper Mississippian (Chester Series): Eastern Missouri, southwestern Illinois, and southern Indiana.

Original reference: C. R. Keyes, 1892, Geol. Soc. America Bull., v. 3, p. 295.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 134; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 823–824. Basal formation of newly defined New Design group. Commonly a brownish massive fine-grained crossbedded sandstone. In Missouri more or less variegated shaly beds occur in both upper and lower parts of formation and middle massive sandstone is more yellowish; in Perry County, is coarser grained and locally resembles St. Peter formation. Basal conglomerate present in many places in both Illinois and Missouri. Thickness varies because of deposition upon uneven surfaces of Ste. Genevieve and St. Louis limestone and because it suffered erosion before deposition of Renault limestone. In Monroe County, Ill., overlapped by Renault; elsewhere attains thickness of 80 to 100 feet.

C. A. Malott, 1946, Jour. Geology, v. 54, p. 322–326. Geographically extended into southern Indiana where it underlies Paoli limestone and overlies Ste. Genevieve limestone.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations in southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 11–12. Aux Vases typically rests on Bryantsville breccia. Varies from thin shaly beds only a few inches thick to a hard cross-laminated calcareous sandstone 1 to 8 feet thick. At many places, welded directly with base of Paoli limestone without sign of break between the two. Extends throughout outcrop area of base of Chester, except locally; about 6 miles northwest of Greencastle, Putnam County, Pennsylvanian Mansfield sandstone cuts below it at Mississippian-Pennsylvanian contact.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 23, pl. 1. Because Indiana exposures contain variety of rock types and mixtures of rock types, Indiana Geological Survey uses term Aux Vases formation. Term New Design group not used in Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 49–50. Term Aux Vases rejected in Indiana. Unit formerly called Aux Vases is included in Paoli limestone as herein redefined.

Named for exposures on Aux Vases River, Ste. Genevieve County, Mo.

Auxvasse Creek Sandstone Member (of Callaway Limestone)[1]

Devonian: East-central Missouri.

Original reference: F. B. Conselman, [1935], Missouri Acad. Sci. Proc., v. 1, p. 105, 108–113, 119.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 3, p. 144. Discussion of stratigraphy of Independence shale of Iowa. Stratigraphically, Independence corresponds to 15-foot bed of sandstone which crops out about 10 miles south of Hannibal, Mo. At this locality, Callaway limestone has typical Cedar Valley fossils and limestone below the Cooper is in every way similar to Davenport member of Wapsipinicon. This sandstone appears to be the same one previously designated as Auxvasse Creek sandstone member of Callaway. It seems to be a continuation of the sandstone below Cedar Valley to north in southeast Iowa and of Independence shale farther north.

Occurs in Auxvasse Creek quadrangle, Callaway County.

Ava Shale (in Pottsville Formation)[1]

Ava Shale (in Tradewater Group)

Pennsylvanian: Southwestern Illinois.

Original reference: T. B. Root, 1928, Illinois Geol. Survey Rept. Inv. 16, p. 9, 10, pls. 1, 2.

H. R. Wanless and Raymond Sevier, 1956, Illinois Geol. Survey Circ. 217, pl. 1 (column 5). Shown in Tradewater group. Lies below Makanda formation and above Boskydell sandstone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 28, 54, 55, 56. Presentation of new rock-stratigraphic classification of Pennsylvanian strata of Illinois. Term Tradewater group discontinued; hence terms Ava, Makanda, and Boskydell are discontinued.

Avant Limestone Member (of Iola Limestone)

Avant Limestone Member (of Ochelata Formation)[1]

Pennsylvanian (Missouri Series): Northwestern Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 31, 37.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40, 43. Reallocated. Comprises upper member of Iola formation. Underlies Lane-Vilas shale; overlies Muncie Creek shale member, Iola formation. Equivalent to Raytown in Kansas.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 82–83, pl. 11. Described as limestone, sandy limestone, calcareous shale, and clay shale. Locally interfingers with underlying Muncie Creek shale member. Underlies Wann formation. Type locality designated.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 32–33. Member of Iola. Avant is 55 feet thick at type locality. Only upper part of this thick phase extends across Tulsa County. There are sandy limestone beds in sec. 4, T. 20 N., R. 10 E., that occupy same stratigraphic position as basal bed of Avant at Avant and they extend across Tulsa County. The two sets of calcareous beds are called colloquially upper and lower Avant and are thought to mark limits of Avant member, which contains more shale than limestone at south side of western Tulsa County. In Creek County, a prominent escarpment that extends from north line to south side of sec. 20, T. 14 N., R. 9 E., is capped by sandy limestone that represents Avant limestone member, but upper limit of member cannot be determined. This limestone grades into basal part of massive sandstone, Tiger Creek sandstone of Fath (1925), that caps the escarpment southward.

Type locality: In T. 23 N. [Rs. 12 and 13 E.]. Named for Avant, Osage County.

Avawatz Formation

Pliocene, lower: Southern California.

P. C. Henshaw, 1939, Carnegie Inst. Washington Pub. 514, p. 5–7, 8, 16 [preprint]. Proposed to include Tertiary series of sedimentary rocks which lie immediately to south and west of eastern end of Avawatz Mountains. Roughly divided into four members: a coarse conglomerate (fanglomerate); green and brown clays (lake beds); resistant breccia (atmoclastic breccia); and arkosic sands and tuffs (fluviatile deposits). Overlies basement complex of metamorphic and plutonic rocks; unconformably underlies a coarse conglomerate believed to be Quaternary in age. Thickness over 1,000 feet, possibly several thousands of feet.

Area is in Avawatz Mountains quadrangle. A fossil locality lies on southeasternmost flank of Avawatz Mountains, 10 miles by road northwesterly from town of Silver Lake on Tonopah and Tidewater Railroad.

Avenal Sandstone[1]

Eocene: Southern California.

Original reference: F. W. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 164–168.

J. A. Cushman and S. S. Siegfus, 1942, San Diego Soc. Nat. History Trans., v. 9, no. 34, p. 390. Listed as underlying Canos siltstone member of Kreyenhagen shale at Garza Creek, Kings County.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 46, 50–51. In Tent Hills area, overlies Acebedo formation (new).

Exposed at Tar Springs and at Sulphur Springs on Zapato Chino Creek, Diablo Range.

Averill Granite[1]

Age(?): Northeastern Vermont.

Original reference: R. A. Schroeder, 1921, Vermont State Geol. Rept. 1919–1920, p. 39–42.

B. K. Goodwin, 1959, Dissert. Abs., v. 20, no. 5, p. 1740. Granitic rocks occupy about two-thirds of Island Pond area. Three major granitic bodies are present: Averill granite, Nulhegan quartz monzonite (new), and Echo Pond granitic complex (new).

Underlies and surrounds Big Averill Lake and all but a small part of Little Averill Lake, Essex County.

Avery Shale[1]

Middle Devonian: Western New York.

Original reference: A. W. Grabau, 1930, Sci. Quart. Nat. Univ. Peking, China, v. 1, no. 4, p. 323–326.

On Eighteen-Mile Creek. Derivation of name not stated.

Avila Member (of Serpiente Sandstone)

Upper Cretaceous: Southern California.

O. T. Marsh, 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 21–24, pls. 1, 2. Large tongue of concretionary sandstone, 2,710 feet thick; lies between upper and lower portions of Torcido member. To north, member extends outside mapped area for an undetermined distance; at its southern end, it tapers and pinches out about one-half mile south of Avila Canyon.

Named for occurrence in vicinity of Avila Canyon, Orchard Peak area, Kern County.

Avilton Conglomerate[1]

Upper Devonian: Western Maryland.

Original reference: C. K. Swartz and others, 1913, Maryland Geol. Survey Middle and Upper Devonian volume, p. 352, 383–385.

Named Avilton because of its occurrence in immediate vicinity of post office of that name on Pea Ridge.

Avis Limestone (in Hinton Formation[1] or Group)

Avis Limestone Member (of Pennington Formation)

Mississippian (Mauch Chunk Series): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 347.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 174, 175, pl. 15. Avis limestone member near top of Pennington formation in Burkes Garden quadrangle. Consists of 15 to 40 feet of bluish-gray shaly limestone. Underlies Falls Mills sandstone member.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 97, 98, 99). In Virginia, limestone in Pennington formation. Elsewhere considered in Hinton group. Locally, in West Virginia, overlies Payne Branch sandstone.

Type locality: Vicinity of Avis and Hinton, Summers County, W. Va.

Avis Sandstone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 345.

Type locality: High up sides of mountains in vicinity of Hinton and Avis, Summers County. Also observed in Mercer County.

Avis Sandstone Member (of Graham Formation)

Avis Sandstone Formation (in Thrifty Group)

Avis Sandstone Member (of Thrifty Formation)[1]

Upper Pennsylvanian: North-central Texas.

Original reference: P. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Thrifty group (redefined).

D. A. Myers, 1960, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec., [Guidebook] Ann. Field Trip, p. 49 (fig. 2), 50, 56. Reallocated to member status in Graham formation. A channel-fill deposit. Overlies Wayland shale member; underlies Ivan limestone member.

Named for town of Avis, Jack County. Typically developed in Jack, Young, and Stephens Counties.

Avis Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 346–352.

Type locality: Region around Avis, Hinton, and Bellepoint, Summers County. Also in Mercer County.

Avoca Limestone Member (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, northwestern Missouri, and northern Oklahoma.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 44, 45, 47.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 155; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17. Avoca limestone member of Lecompton formation; overlies King Hill shale member; underlies Tecumseh formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16 p. 23. In Nebraska, underlies Kenosha shale member of Tecumseh formation. Thickness 1 to 4 feet or more in Iowa, Nebraska, and northwestern Missouri; becomes cryptozoon-bearing limestone and thicker in southern Kansas and Oklahoma. Type locality stated.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 19, fig. 5. Consists of two thin fossiliferous dark- to bluish-gray limestones separated by dark-gray fossiliferous shale. Thickness about 2 feet in western Mills County; not differentiated in northeastern Adair County.

Overlies King Hill shale member; underlies Kenosha shale member of Tecumseh shale.

Type locality: On south branch Weeping Water Creek, 3 miles east of Avoca, Otoe County, Nebr.

Avon Shale and Limestone (in Pottsville Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

Derivation of name not stated, but probably named for Avon, Fulton County.

†Avondale Limestone[1]

Precambrian: Southeastern Pennsylvania.

Original reference: P. Frazer, 1883, Pennsylvania 2d Geol. Survey Rept. C_4, p. 307, 321, 322.

Avondale, Kennett Square, and other places in Chester County.

†Avondale Series[1]

[Precambrian]: Pennsylvania.

Original reference: A. C. Hawkins, 1924, Am. Jour. Sci., 5th, v. 7, p. 355–364.

Vicinity of Avondale, Chester County, Pa.

Avon Park Limestone

Avon Park Limestone (in Claiborne Group)

Eocene, middle: Florida (subsurface and surface).

P. L. Applin and E. R. Applin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1678 (table 1), 1680, 1686–1688. Name used for upper part of late middle Eocene which, in well samples, shows distinct faunal and lithologic characteristics. Mainly cream-colored highly microfossiliferous chalky limestone throughout its known extent. Thickness varies; 50 feet or less in northeast Florida where only basal part is present; 450 to 650 feet in southern part of peninsula. Underlies Ocala limestone; in region of Tallahassee overlies Tallahassee limestone (new), elsewhere overlies Lake City limestone (new). Tentatively correlated with Yegua formation (Claiborne). Avon Park limestone, Tallahassee limestone (with its equivalent nonfossiliferous facies), and Lake City limestone represent Claiborne group in peninsular Florida, and where all three units are present they appear to make, in most places, a conformable sequence.

D. B. Ericson, 1945, Science, new ser., v. 102, no. 2644, p. 234. Suggests abandoning name in favor of Gulf Hammock formation because outcrops have been discovered in Levy and Citrus Counties.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Used on correlation chart as name of surface formation.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 95–111, pl. 1. Surface exposures described. As used in this report, Avon Park is a series of pasty to fragmental marine carbonate beds containing a distinct fauna and considerable amounts of peat, lignite, and plant remains. Unconformably underlies Inglis member (new) of Moodys Branch formation; unconformably overlies Lake City limestone. Name Gulf Hammock abandoned. Claiborne group.

Type well: At Avon Park Bombing Range, Polk County, Fla., sec. 31, T. 32 S., R. 30 E. Samples from well are indexed at No. W–668 in files of Florida Geological Survey. Surface outcrops in Citrus and Levy Counties.

Axemann Limestone (in Beekmantown Group)[1]

Lower Ordovician: Central Pennsylvania.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 552, 653, 660, 674, pl. 27.

E. O. Ulrich and G. A. Cooper, 1938, Geol. Soc. America Spec. Paper 13, p. 23. Fossiliferous pure Upper Canadian limestone, 158 feet thick, at Bellefonte, Pa. Here it rests on about 500 feet of dolomite [Nittany] containing unquestionable Cotter fossils; succeeded by Bellefonte dolomite which extends upward, with thickness of 2,140 feet, to boundary between Canadian and Ordovician systems. Suggests term Nittany be abandoned.

F. M. Swartz, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1555, 1556 (fig. 19). Medium-bedded bluish limestone. Thickness 500 feet. Underlies Bellefonte dolomite; overlies Nittany dolomite, Beekmantown group.

Crops out 1 mile east of Axemann, Centre County.

Axes Creek phase (of Cherry Creek Series)

Precambrian: Southwestern Montana.

E. S. Perry, 1948, Montana Bur. Mines and Geology Mem. 27, p. 2, pl. 2B. Name suggested for zones of marble in Cherry Creek series. On Axes Creek at least six marble members are present, and some are 400 to 800 feet or more thick. Amount of marble in series decreases eastward, and members cannot be correlated readily between Dillon and Ennis.

Well exposed on Axes Creek in Beaverhead County.

Axtell Formation

Pliocene or Pleistocene: Central Utah.

E. M. Spieker, 1949, Utah Geol. Soc. Guidebook 4, p. 38, geol. map. Youngest bedrock in area. Conglomerate containing pebbles, cobbles, and boulders of all other bedrock formations including lava. At type locality, conglomerate is 50 to 75 feet thick and dips northward about 21° in an angular unconformity over west-dipping Green River limestone. Probably late Tertiary.

W. N. Gilliland, 1949, Ohio State Univ. Abs. Doctors' Dissert. 57, p. 71, 72. Overlies Bald Knoll formation (new) with angular discordance.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., no. 7, p. 11 (table 1), 50–52, pl. 2. In some areas in Gunnison quadrangle, overlies Bald Knoll formation with angular unconformity, and in some areas overlies unnamed pyroclastics and associated sediments with angular discordance. Spieker tentatively assigned Axtell to late Pliocene or early Pleistocene because it is obviously younger than all bedrock in region. Mapped as Pliocene.

Type locality: Stretch about 2 miles east of Axtell on eastern margin of Sevier Valley between abandoned plant of Great Western Salt Company and Willow Creek.

Aycross Formation

Eocene, middle: Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 10, 11 (fig. 2), 66–73, pl. 17. Proposed for middle Eocene sequence lying unconformably upon all older rocks from Precambrian to lower Eocene and which is unconformably overlain by strata of upper Eocene age. Consists of variegated clays, acidic andesite tuffs, conglomerates, and bentonite beds.

Changes in physical appearance rapidly in short distances. Thickness at type locality about 1,000 feet; in some areas less than 100 feet. In type area, formation was deposited on a surface of high relief cut in folded and faulted rocks. In places there is angular discordance of 90° with underlying strata, whereas in adjacent localities only a few miles distant there is only slight erosional unconformity. Shown on columnar section as unconformably underlying Tepee Trail formation (new) and unconformably overlying Wind River formation.

R. L. Hay, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1880, 1892–1896. West and south of Anchor post office, Masursky (1952, Wyoming Geol. Assoc. Guidebook 7th Ann. Field Conf., map) mapped beds equivalent to Pitchfork formation (new) as Aycross. He showed Aycross strata extending as far south as Owl Creek Range, where, on axis of range, they pinch out between limestone of Paleozoic age and Tepee Trail formation. It is believed that use of Aycross for these beds is misleading, as beds considered Aycross in Bighorn basin may never have been continuous with beds of Aycross south of Owl Creek Range, in Wind River basin. As used here, Pitchfork formation includes beds in Bighorn basin named Aycross by Masursky.

Type area: North side of North Mesa in secs. 7, 8, 17, and 18, T. 7 N., R. 5 W., Fremont County, about 1 mile southeast of A Cross Ranch. Named derived from A Cross Ranch on East Fork River at Duncan.

Ayer Granite[1] **or Granodiorite**

Late Paleozoic(?): Eastern Massachusetts, northeastern Connecticut, and southeastern New Hampshire.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 86, 223–228.

R. H. Jahns, 1942, Am. Geophys. Union Trans., v. 23, pt. 2, p. 341–342. Referred to as Ayer granodiorite in Lowell area, Massachusetts.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Mapped as Ayer granodiorite. Upper Devonian(?).

M. P. Billings, J. B. Thompson, Jr., and John Rodgers, 1952, Geol. Soc. America Guidebook for field trips in New England, p. 45. Listed with units included in New Hampshire magma series.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 47–48, pl. 1. Described in Hudson and Maynard quadrangles, Massachusetts, as Ayer granite. Light to medium gray, moderately coarse grained. Consists of two mappable facies, a porphyritic and nonporphyritic. Late Paleozoic(?).

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 68. Discussed with units included in Hillsboro plutonic series (new) which may belong to New Hampshire magma series.

Type area extends from Hampstead, N.H., to point between Harvard and Bolton, Mass., and is 6 miles across at its widest part, between Harvard and East Groton, Mass.

Ayers Cliff Formation

Ayers Cliff Member (of Waits River Formation)

Middle Ordovician (Trentonian or younger): Northern Vermont, and Quebec, Canada.

C. G. Doll, 1951, Vermont Geol. Survey Bull. 3, p. 15, 22–24, pl. 1. Belt of impure limestones, calcareous sandstones, and minor slates. Thickness about 4,500 feet. Unconformably underlies Barton River formation; overlies Northfield slates. Newly defined terms Ayers Cliff, Barton River, and Westmore formations make terms Waits River formation (Currier and Jahns, 1941), and Tomifobia formation (Clark, 1934) inadequate.

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 16. Name Ayers Cliff retained as member of Waits River formation although Ayers Cliff does not crop out in area of this report [Lyndonville quadrangle].

Type section: In series of roadcuts beginning one-half mile west of village of Ayers Cliff at south end of Lake Massawippi in Canada. Good exposures occur at Coventry Falls in the Black River, on Stony Hill, 2 miles northwest of Irasburg, and on shore of Lake Memphremagog. Formation is traceable from vicinity of Round Hill [Irasburg quadrangle] northward into Canada.

Ayers Landing Member (of Caloosahatchee Marl)

Pleistocene: Southern Florida.

J. R. DuBar. 1957, Illinois Acad. Sci. Trans., v. 50, p. 192 (table 1). Table shows Ayers Landing as uppermost member of Caloosahatchee. Overlies Bee Branch limestone member (new); underlies Okaldakoochee marl member (new) of Fort Thompson formation.

J. R. DuBar, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 136 (fig. 4), 144. Shell bed that conformably overlies Bee Branch member in many localities between La Belle and Fort Denaud. At many localities, unit is very arenaceous, and calcium carbonate content is mainly in form of mollusk shells. Thick beds are generally only slightly consolidated. Sands are usually tan to yellow brown, and fossils nearly white. At some localities, unit is better consolidated, much more calcareous, concretionary, and fine grained. Both facies are massive and generally without stratification. Thickness 2½ to 8½ feet; unit is discontinuous, being absent or greatly thinned over the arches.

H. S. Puri and R. O. Vernon, 1959. Florida Geol. Survey Spec. Pub. 5, p. 192, 193, 194. Thickness 3.1 feet at type locality, herein stated. Here, overlies Bee Branch member and underlies Fort Thompson formation(?). Includes shell bed, marine limestone, and *Panope* faunizone. Entire upper section of Caloosahatchee, which is called Ayers Landing marl by DuBar (1958), was included in Fort Thompson formation by Parker and Cooke (1944, Florida Geol. Survey Bull. 27) and Parker and others (1955, U.S. Geol. Survey Water-Supply Paper 1255) and considered to be Pleistocene in age.

Type locality: DuBar's section A35, (SW¼NW¼ sec. 1) T. 43 S., R. 28 E., Hendry County. Section measured on right bank of Caloosahatchee River about 90 yards upstream from Turtle Creek, in vicinity of Ayers Landing.

Ayiyak Member (of Seabee Formation)

Upper Cretaceous: Northern Alaska.

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 253–254, figs. 4, 5. Greenish-gray somewhat tuffaceous siltstone and silt shale. Sandstone, although a subordinate lithologic constituent, forms important part. Sandstones are light tan to light chocolate brown, slightly tuffaceous, hard, and clean and weather to light buff. Member becomes progressively more shaly toward base, and limestone lenses and beds occurr in this shaly part.

Locally, "salt-and-pepper" sandstone near base. Thickness at type locality 360 feet. Underlies nonmarine beds of Tuluvak tongue of Prince Creek formation; overlies dark clay shale typical of Seabee formation and is mappable unit in southernmost exposures of the marine formation. Cannot be differentiated from rest of formation north of Umiat-Maybe Creek area.

Type locality: Along east fork of Tuluga River, lat 68°50′ N., and between long 151°28′ W. and 151°35′ W. Named from Ayiyak River along which it is exposed.

Aylesworth Limestone Member (of Pottsville Formation)[1]

Pennsylvanian: Northwestern Illinois.

Original reference: T. E. Savage, 1930, Illinois Acad. Sci. Trans., v. 22, p. 498.

McDonough County. Derivation of name not stated.

Aylor Member (of Big Saline Formation)

Lower Pennsylvanian: Central Texas.

F. B. Plummer, 1947, Jour. Paleontology, v. 21, no. 2, p. 142, 143, 144; 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 196, 197; 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 64–66. Consists of light-gray crystalline limestone and oolite. In vicinity of Colorado River, oolite increases in thickness to form a lentil 5 miles long and 10 to 100 feet thick. Underlies Lemons Bluff member; overlies Gibbons member.

Type section: On Aylor Bluff in McAnnelly's Bend of Colorado River [San Saba County].

Aylor Bluff member

See Aylor Member.

Aymamón Limestone

Miocene, lower: Puerto Rico.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85, sheets 1, 2. Includes uppermost Tertiary of northern coastal belt. Consists almost entirely of very dense conchoidally fracturing limestone of white, light-gray, buff, and rose colors; unit is quite uniform in lithology over its entire outcrop and throughout its entire thickness. In Aymamón Mountains, shows sharply defined uniform bedding, the beds averaging between 1 and 2 meters in thickness. Top of limestone is erosion surface developed since end of Tertiary deposition; hence thickness varies with irregularities of that surface. Greatest thickness is in area west of Isabela, where beds capping outer sea cliffs are estimated to be 325 to 350 meters above base of limestone. Overlies Aguada limestone (new). Includes units formerly termed Quebradillas limestone and Los Puertos limestone.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 34–35, pl. 2. Described in San Juan metropolitan area where it conformably overlies Aguada formation. Thickness may be over 2,000 feet at latitude of coast.

W. H. Monroe, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B356, B358 (fig. 1642). Oligocene and Miocene sequence in north-central Puerto Rico is (ascending) San Sebastián formation. Lares limestone, Cibao formation, Aguada limestone, and Aymamón limestone. Aymamón consists of more than 200 meters of very pure limestone, generally stratified to massive but locally consisting of breccia.

Named from Aymamón Mountains, an area of rugged limestone hills, west of Río Guajataca and about midway between towns of San Sebastián and Quebradillas.

Azotea Tongue (of Seven Rivers Formation)

Azotea Tongue (of Carlsbad Limestone)[1]

Permian: Southeastern New Mexico.

Original reference: W. B. Lang, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7, p. 847 (fig. 5), 868.

A. M. Morgan, 1938, New Mexico State Engineer 12th-13th Bienn. Repts., p. 172. Underlies Three Twins member of Chalk Bluff formation; overlies Seven Rivers gypsiferous member of Chalk Bluff formation.

U.S. Geological Survey has abandoned term Carlsbad and currently classifies the Azotea as a tongue of Seven Rivers Formation.

Caps western Azotea Mesa, Pecos Valley.

Aztec Sandstone[1]

Jurassic(?): Southeastern Nevada.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 9, 35.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, no. 5, p. 929 (table 1), 931. Shown on table of formations of Muddy Mountain area, Nevada, as underlying Upper Cretaceous Willow Tank formation (new) with angular unconformity and overlying Chinle formation. Thickness about 2,500 feet.

C. R. Longwell, 1952, Utah Geol. Soc. Guidebook 7, p. 34 (fig. 4), 35. In Frenchman Mountain area, Nevada, underlies Thumb formation (new) with angular unconformity. In Muddy Mountains, underlies Willow Tank formation and overlies Chinle formation.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 48, pl. 1. Described as a red sandstone made up of lenses of sand mostly 10 to 25 feet thick; these lenses are made up of laminae, ½ to 2 inches thick, that have parallel strike and dip within the lenses. Thickness 2,100 feet at northern edge of Goodsprings quadrangle; 800 feet thick in Ivanpah quadrangle where it overlies Chinle formation. In Ivanpah quadrangle, overlain by 50 feet of limestone and dolomite beds mapped with Aztec.

Name derived from Aztec Tank [Goodsprings quadrangle], a natural depression in the sandstone several hundred feet east of Contact mine.

Aztecan series[1]

Cretaceous: Colorado, New Mexico, and Arizona.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico, p. 2, 5.

San Juan region.

Azuero Formation[1]

Cretaceous(?): Azuero Peninsula, Panamá.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 237.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 324. Poorly defined name for basement altered volcanic rocks. Late Jurassic or Early Cretaceous age suggested.

On west side of Azuero Peninsula.

Babcock Hill Member (of Onondaga Formation)

Middle Devonian: East-central New York.

R. E. Stevenson, 1949, New York State Sci. Service Rept. Inv. 3, p. 7, 8. Named and described as thin- to medium-bedded gray fine-grained fossiliferous limestone with abundant nodular and irregularly bedded cream-colored to black chert. Thickness 36 to 50 feet. Underlies unnamed member; overlies Springfield Center member (new).

Occurs in area of Herkimer-Otsego County line.

Babeldoab Agglomerate

See Babelthuap Agglomerate.

Babelthuap (Babeldoab) Agglomerate

Eocene: Caroline Islands (Babelthuap).

Risaburo Tayama, 1935, Tohoku Univ. Inst. Geology and Paleontology Contr. in Japanese Language, no. 18, p. 13, 18–20, 40–41 [English translation in library of U. S. Geol. Survey, p. 21–24, 46–48]. Massive unstratified agglomerate. Lower part is dark-green or blackish augite andesite; upper part black pyroxene andesite with light-colored hornblende andesite agglomerate at top. Conformably, and locally disconformably, underlies Ngardok (Galdog) formation.

U.S. Army Corp of Engineers, 1956, Military geology of Palau Islands, Caroline Islands: U.S. Army Corp of Engineers Far East, p. 38–40, pls. 4, 8, 9. Thickness probably 2,000 feet but may exceed 5,000 feet; data uncertain because of lack of continuous section and recognizable beds for correlation; numerous fractures and faults and dips varied. Base not exposed; grades upward into Aimeliik formation. Believed to be Eocene; diagnostic fossils not found.

Exposed on Babelthuap, Korror, Ngarebobasang (Arakabesan), and Makarakar.

Baby Capulin Basalt

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, pt. 2. p. 132, 144, pls. 1b, 13. Medium dark-gray porphyritic vesicular basalt. Usually has scattered, large olivine phenocrysts. This flow was last volcanic event of northwestern Union County. Baby Capulin basalt lies within levees of Twin Mountain (new) or Purvine Hills basalt (new).

Derived from vent of Baby Capulin, a small cinder cone that lies about midway between Capulin Mountain and Folsom village, in sec. 36, T. 30 N., R. 28 E.

Babylon cyclothem (in Abbott Formation)

Babylon cyclothem (in Tradewater Group)[1]

Pennsylvanian: West-central Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 189, 192.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 65, 201, 202, 203. Cyclothem occurs near base of Tradewater group and in sequence underlies Tartar cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2). Included in Abbott formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Named from exposures along Spoon River one-half mile north of Babylon, in NE¼NE¼ sec. 14, T. 7 N., R. 1 E., Fulton County.

Babylon Sandstone Member (of Abbott Formation)

Babylon Sandstone (in Tradewater Group)

Pennsylvanian: West-central Illinois.

Original reference (cyclothem): H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 189, 192.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 37, 78. Babylon sandstone is normally basal Pennsylvanian member in western Illinois. Sandstone is medium grained, well sorted, and free from feldspar, mica, and argillaceous matter. Occurs below Babylon coal.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 65, 201, 202, 203. Babylon sandstone, present in practically all parts of area where cyclothem occurs, has maximum exposed thickness of 25 feet. Cyclothem occurs near base of Tradewater group and in sequence underlies Tartar cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1). Included in Abbott Formation (new). Occurs at base of formation below Manley coal member (new). Provisionally correlated with Grindstaff sandstone member in southern Illinois; pending further study both names are retained. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Along Spoon River one-half mile north of Babylon, in NE¼NE¼ sec. 14, T. 7 N., R. 1 E., Fulton County.

Baca Formation

Eocene(?): Central New Mexico.

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 61. Coarse conglomerate, red and white sandstone, and red clay. Thickness of conglomerate ranges from 80 to 140 feet. Total thickness of formation in Baca Canyon 694 feet. Unconformably overlies all Cretaceous formations in area; underlies Datil formation. Eocene(?).

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 23–26, pl. 1. Age designated as Upper Cretaceous(?) to Eocene(?) on plate 1. Baca Canyon section measured by Wilpolt and others here cited as type section. Thickness in Puertecito quadrangle ranges from a fraction of a foot to as much as 700 feet.

Type section: In Baca Canyon from which unit is named, in secs. 4, 5, 8, 9, T. 1 N., R. 4 W., north Bear Mountain, Socorro County.

Bachelor Formation

Lower Mississippian: East-central and southwestern Missouri.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 94–98. Proposed for a basal Mississippian sandstone that cuts across time zones ranging in age from oldest Mississippian to as late as early Osagean.

With exception of Siphonodella zone at base, lithology is varied although it consists dominantly of pale buff quartz sandstone of medium grain size, moderately well to poorly sorted. Over most of extent, including Siphonodella zone, thickness of unit is to be measured in inches rather than feet. In Callaway County, average thickness is perhaps less than 2 feet; in east-central Callaway and western Montgomery Counties, thicknesses of as much as 8 to 10 feet may be found. Unconformable above underlying strata; subjacent beds range from Jefferson City Ordovician to late Massie Creek (new); conformable with overlying strata—Burlington or Chouteau.

Type locality: Exposure in SE¼NW¼SW¼ sec. 9, T. 48 N., R. 8 W., Callaway County. Named for exposures to east, west, and south of Bachelor.

Bachelor Creek Limestone[1] Member (of Howard Limestone)

Pennsylvanian (Virgil Series): Southern Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 21, 94, 96.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 57 (fig. 22), 63. Basal member of Howard limestone. Underlies Aarde shale member; overlies Severy shale. Locally two beds separated by shale. Thickness as much as 8 feet.

Type locality: Bachelor Creek, sec. 33, T. 25 S., R. 11 E., about 5 miles east of Eureka, Greenwood County, Kans.

Backbone Limestone[1]

Devonian: Southwestern Illinois.

Original reference: T. E. Savage, 1920, Am. Jour. Sci., 4th, v. 49, p. 169–178.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 127, 128; 1940, Illinois Geol. Survey Rept. Inv. 71, p. 23–24. Known only in Union and Jackson Counties. Estimated thickness 230 feet. Thins and disappears southward or, in that direction, has been so completely weathered that it cannot be identified. Believed to overlie Grassy Knob chert. May have been included in Clear Creek in many places.

Well exposed near southern end of Devil's Backbone Ridge, a short distance north of Grand Tower, Jackson County.

Backwater Creek Shale Member (of Fort Scott Formation)

See Blackwater Creek Shale Member (of Fort Scott Formation).

Bacon Limestone Member (of Ferry Lake Formation)

Lower Cretaceous (Glen Rose): Eastern Texas (subsurface).

W. V. Jones, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 6, p. 839–845. Name given to a lenticular limestone developed at the base of the Ferry Lake. Thickness varies from 18 to 28 feet; extends from 7,287 to 7,312 feet in discovery wells.

Type well; Tide Water Associated Oil Co. and Seaboard Oil Co. A. J. Bacon No. 1, New Hope field, Franklin County. Alternate type locality (designated because of poor core from type well): Suite of cores from Tide Water Associated Oil Co. and Seaboard Oil Co. F. M. Anderson No. 1, in the C. F. McKenzie (Abstract 307) Survey, Franklin County.

Bacon Bend Member (of Sevier Formation)

Middle Ordovician: Eastern Tennessee.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145 (table), 160, 162–164, pl. 27. Unit at top of formation in which gray calcareous shale and sandstone have submarine slump structures; also contains even-bedded beds of gray and red calcareous mudrock. Thickness 40 to 165 feet. Underlies Bays formation; overlies main body of Sevier formation.

Name taken from meander neck of same name on Little Tennessee River (Vonore quadrangle), Monroe County. Type section about 1 mile northeast of southeast end of prominent bluffs that overlook river.

Bacon Ridge Sandstone

Upper Cretaceous: Northwestern Wyoming.

J. D. Love and others, 1948, Wyoming Geol. Survey Bull. 40, p. 2–3, 4–5, 21–24, 32–34. Name applied to thick sequence of marine sandstone; overlies about 2,000 feet of shale that in turn overlies Frontier formation as defined in central Wyoming. Measured sections show thicknesses of 318, 714, and 925 feet.

Well exposed along both sides of Bacon Ridge, in T. 41 N., R. 111 W., Teton County.

Bad Axe Member (of Franconia Sandstone)[1]

Upper Cambrian: Southeastern Minnesota and western Wisconsin.

Original reference: A. C. Trowbridge and others, 1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf., p. 81, 92, 134, 140, 159, 431, 446, figs. 1, 2.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1238 (table 2), 1239; C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 30, 40–41, measured section. In Minnesota, underlies Nicollet Creek member (new) of St. Lawrence formation.

G. O. Raasch, 1951, Illinois Acad. Sci. Trans., v. 44, p. 141, 147. Underlies Arcadia member (new) of Trempealeau formation.

R. R. Berg, 1953, Jour. Paleontology, v. 27, no. 4, p. 553, 554, 555; 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 864–865. Franconia member names used by Twenhofel, Raasch, and Thwaites (1935, Geol. Soc. America Bull., v. 46, no. 11) are geographic names applied to faunal zones. New member names are proposed to designate rock types because distribution of faunal zones in formation is largely independent of natural rock units. Bad Axe member is *Dikelocephalus postrectus* zone. This fauna is present in Reno member.

Named for Bad Axe River, near Franconia, Chisago County, Minn.

Baden Sandstone[1]

Pennsylvanian: Central eastern Missouri.

Original reference: H. A. Wheeler, 1895, St. Louis Acad. Sci. Trans., v. 7, p. 125.

Named for exposures at Baden, St. Louis County.

Bader Limestone (in Council Grove Group)

Bader Formation (in Council Grove Group)[1]

Permian: Northeastern Kansas and southeastern Nebraska.

Original references: R. C. Moore, M. K. Elias, and N. D. Newell, 1934, Stratigraphic sections of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita, Kans. [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]; G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 4, 7.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 61–62. Contains (ascending) Eiss limestone, Hooser shale, and Middleburg limestone, units that were named by Condra as members of the Garrison formation. Type exposure noted.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46. Underlies Easly Creek shale; overlies Stearns shales. Wolfcamp series.

Type exposure is near Bader, Chase County, Kans.

Badger Shale

Lower Cretaceous(?): Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 9–12, pls. 1, 2. Dark-green silty clay shale with gray buff-weathering calcareous nodules: some very fine-grained arkosic graywackes with abundant fragments of carbonized wood on bedding planes; contains two tuffaceous graywackes. Thickness 3,620 feet at type locality; 3,710 feet in Annette quadrangle southwest of Orchard Peak. Underlies Risco formation (new); at type locality, contact is conformable; in Annette quadrangle, thrust contact. Lower contact is everywhere a fault, generally, a thrust surface along which serpentine has been squeezed. This unit has been designated as Shasta by previous workers.

Type locality: Badger Ridge, 1½ miles west of Cottonwood Pass, Orchard Peak area, Tent Hills quadrangle, northwestern Kern County.

Badger Butte Quartz-Biotite Norite

Lower Cretaceous(?): Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 193–195, 235. A medium-grained dark-gray rock with a crude parallelism of plagioclase. Intruded by, and nearly surrounded by, Bald Mountain tonalite (new).

Exposed in area near Badger Butte, in Elkhorn Mountains [Grant County]. Forms part of Bald Mountain batholith.

Badito Formation[1]

Pennsylvanian and Permian(?): Central southern Colorado.

Original reference: R. C. Hills, 1900, U.S. Geol. Survey Geol. Atlas, Folio 68.

R. B. Johnson, 1958, U.S. Geol. Survey Bull. 1042–0, p. 559–560. On flanks of Greenhorn anticline, consists of from 200 to 382 feet of rocks lithologically similar to Sangre de Cristo formation and rests on Precambrian rocks. Locally underlies Ocate sandstone. Pennsylvanian and Permian(?).

Probably named for Badito Peak or town of Badito, just west of Walsenburg quadrangle and in Huerfano quadrangle.

Badito Quartzite Member (of Hopewell Series)

Precambrian (Proterozoic): North-central New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13, (table 1), 21, pl. 2. Consists of bluish-gray quartzite, unquestionably of sedimentary origin. At mouth of Picuris Canyon, it has been converted to quartz-muscovite schist.

Occurs in Picuris area along north side of Rio Pueblo gorge and in a long strip extending from mouth of Picuris Canyon across south and east spurs of Picuris Peak, Taos and Rio Arriba Counties.

Bad River Dolomite[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: C. R. Van Hise, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 338.

N. K. Huber, 1959, Econ. Geology, 1959, no. 1, p. 85 (table 1). Included in Animikie series. Overlies Sunday quartzite; underlies Palms quartzite with uncomformity.

Named for occurence at Bad River, in Penokee Gap section, Wisconsin.

†Bad River Gabbro[1]

Precambrian (Keweenawan): Northwestern Wisconsin and northern Michigan.

Original references: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 115, 134, 135; 1883, U.S. Geol. Survey Mon. 5, p. 40–41, 144, 155, 377, 435.

Largely developed in Bad River region, Ashland County, Wis., and exposed on Bad River, Iron County, Wis.

†Bad River Sandstone[1]

Precambrian (Keweenawan): Northwestern Wisconsin.

Original reference: E. T. Sweet, 1876, Wisconsin Acad. Sci., Arts., and Letters Trans., v. 3, p. 40–55.

Largely represented on Bad River, Ashland County.

Badwater Greenstone (in Baraga Group)

Precambrian (Animikie Series): Northern Michigan and northeastern Wisconsin.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 37. Uppermost formation in group. Lies stratigraphically above Michigamme slate; relationship is based on top directions established by graded bedding in Michigamme and ellipsoidal structures in the greenstone; this relationship is important in that it establishes not only the position of the greenstone but of sequence of rocks [Paint River group] that overlies it in Florence district of Wisconsin and Iron River-Crystal Falls district of Michigan. Maximum thickness attained is several miles; beds now exposed are about vertical. Map patterns reveal mound-like piles in which thicknesses of several miles diminish to the vanishing point within as little as 15 miles along the strike.

Named for extensive exposures in secs. 1, 2, and 11, T. 40 N., R. 31 W., in vicinity of Badwater Lake, Dickinson County, Mich.

Baga Shale and Limestone (in Joserita Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12. Dark-gray and greenish impure limestone in places lens shaped and grading laterally into white shale. Thickness 7 feet.

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Bagley Andesite[1]

Lower(?) Jurassic: Northern California.

Original reference: J. S. Diller, 1960, U.S. Geol. Survey Geol. Atlas, Folio 138.

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6, 14, pl. 1. As traced from its type area into Big Bend region, overlies and is interfingered with basal beds of Potem formation. Term Arvison formation is proposed for series of dominantly phyroclastic beds, which are intermediate between Modin and Potem formations and which do not appear to be continuous with Bagley. Estimated thickness of Bagley in Big Bend area, 700 feet. Since Bagley andesite appears to be volcanic facies of Potem formation, its age and correlation in this area are considered to be same as that of the Potem—Lower and Middle Jurassic.

Named for Bagley Mountain in northeast corner of Redding quadrangle.

Bagnell glaciation

Bagnell till[1]

Pleistocene (pre-Nebraskan): Missouri.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203, 208, 217.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 68, no. 2, p. 129. Referred to as glaciation.

Bailey Limestone[1]

Bailey Limestone (in Helderbergian Group)

Lower Devonian: Eastern Missouri and southwestern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, v. 2, 2d ser., p. 110.

J. M. Weller *in* J. M. Weller and G. E. Ekblaw, 1940, Illinois Geol. Survey Rept. Inv. 70, p. 7, 11; J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 21–22; 1944, Illinois Geol. Survey Bull. 68, p. 89, 94. Described in Illinois where it is included in Helderbergian group. Thin-bedded very earthy and siliceous formation that contains much chert; limestone is medium gray, dense or slightly shaly and commonly occurs in beds less than 4 inches thick. Thickness more than 200 feet and may be as much as 350 feet. Contact with underlying Bainbridge not observed; may be transitional. Underlies Grassy Knob chert; contact transitional.

Carey Croneis, 1944, Illinois Geol. Survey Bull. 68, p. 103 (chart), 105–111. Described in southeastern Missouri where neotype area is designated.

Continuous exposures of entire formation not available. In Perry County, three more or less characteristic divisions showing gradational contacts are recognized: lower, thin- to medium-bedded gray and buff limestones, with interbedded shales and cherts—125 feet, middle, medium- to thick-bedded blue and buff limestones, with large flint concretions—75 feet; upper, very thin-bedded limestones and interbedded cherts—100 feet. Greatest thickness probably occurs in Perry County, either in region between Wittenberg and Neelys Landing, or in neotype area near Red Rock Landing. If partially covered exposure at Red Rock Landing is actually a continuous section, beds have thickness of more than 300 feet, and possibly nearly 400 feet. Thins both north and south from Red Rock Landing and at westernmost exposure in Ste. Genevieve County is at least 200 feet. No undoubted contacts with subjacent or superjacent formations have been clearly observed, although contact with underlying Bainbridge can be located near village of Lithium Springs. Youngest part of underlying Bainbridge apparently considerably older than youngest America Silurian beds, and oldest Bailey is presumably younger than oldest known Devonian. Presumably unconformable with overlying Little Saline formation in Ste. Genevieve County; contact with overlying Clear Creek should also be disconformable because variations in thickness of Bailey suggest post-Bailey pre-Clear Creek erosion.

J. M. Weller and others, 1952, Illinois Geol. Survey Bull. 76, p. 56. Bailey limestone is very cherty and siliceous, light to dark brownish gray, and very fine grained. A more cherty upper part has been described from outcrops in Union County and called Grassy Knob chert, but subsurface studies in Illinois fail to separate this from rest of formation, and it is believed that the greater part of chert in the outcrops is due only to local leaching of limestone and concentration of silica in post-Devonian times. Helderbergian group.

J. E. Lamar, 1959, Illinois Geol. Survey Rept. Inv. 211, p. 18. Exact thickness not known. Maximum observed thickness 130 feet, but total thickness may be between 300 and 400 feet. Basal beds of formation are greenish or gray shale that grades down into shale of upper part of underlying Bainbridge group.

Neotype area: Outcrops in river bluffs at and north of Red Rock Landing, Perry County, Mo. Here beds crop out in fault block tilted toward river and are exposed southeastward along fault zone in a narrow discontinuous band almost to Brazeau Creek in NW¼ sec. 11, T. 34 N., R. 13 E. Ulrich (1904) gave name Bailey to strata considered to be identical with or equivalent to rocks comprising Meek and Worthen's (1866, Illinois Geol. Survey, v. 2) "Lower Helderberg group" exposed in bluffs of Mississippi River at and above Red Rock Landing, Mo. Name was derived from settlement of Bailey's Landing, which was apparently at or near present site of Grand Eddy. Boat landing has been abandoned owing to changes in river channel, and outcrops mentioned by Meek and Worthen have been buried under alluvium. Inasmuch as no Devonian rocks are exposed at Grand Eddy neotype area is herein designated.

Bailey Spring Limestone[1]

Upper Mississippian and Lower Pennsylvanian: Eastern Nevada.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171, p. 7, 21.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). On correlation chart of recommended revision of stratigraphic units pertaining to Great Basin, Bailey Spring limestone is shown equivalent to Ely limestone; Ely is recommended term. Pennsylvanian. Pioche district, as used in this report, extends north to Dutch John Mountain, approximately 40 miles north of Pioche.

Present in large areas southeast of Bailey Spring, on western side of Bristol Range, Pioche district, Lincoln County.

Baileyville Member (of Stonehenge Limestone)

Lower Ordovician (Canadian): Central Pennsylvania.

A. C. Donaldson, 1960, Dissert, Abs., v. 20, no. 9, p. 3693. Characterized by algal and aphanitic limestones. Overlies Graysville member (new); underlies Logan Branch member (new).

Type locality and derivation of name not stated.

Bainbridge Limestone[1]

Bainbridge Formation

Bainbridge Group

Middle Silurian: Eastern Missouri and southwestern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, v. 2, 2d ser., p. 110.

J. R. Ball, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 4, p. 595–601. Described at designated type section as Bainbridge formation. Includes some red, strongly mottled, argillaceous limestones; some poorly bedded, greenish-gray earthy limestones; and a unit of finely laminated dark brown shale in which *Cyrtograptus ulrichi* Ruedemann is conspicuous fossil. Thickness more than 100 feet, but base is below water level and a railroad bridge is against foot of bluff.

J. M. Weller, 1940, *in* J. M. Weller and G. E. Ekblaw, Illinois Geol. Survey Rept. Inv. 70, p. 10–11; J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 21. In Illinois, Bainbridge limestone overlies Sexton Creek limestone; contact with underlying Bailey limestone not observed. Thickness about 40 feet south of Thebes.

J. R. Ball, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 1, p. 7–11. Includes Osgood member below and Laurel member above.

Carey Croneis, 1944, Illinois Geol. Survey Bull. 68, p. 110. In Missouri, underlies Bailey limestone though no undoubted contacts have been observed. Youngest part of Bainbridge is apparently considerably older than youngest American Silurian.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 12–18. Redefined as group. Consists of Niagaran strata of belt east and south of Ozarks. Characterized by two lithologically well-differentiated formations, St. Clair below, and Moccasin Springs (new) above. Formations extend considerably beyond area under consideration; at their geographic limits both formations interfinger with other Niagaran formations. Group is distinguished by its red, pink, and purplish colors, predominance of limestone, absence of chert, and comparative persistence of lithologic types over wide areas. Underlies tapering wedge of Thorn group (new). [Report deals with Niagaran reefs in Illinois and their relation to oil accumulation; much data relative to thickness and distribution of units are based on subsurface studies.]

A. J. Boucot, 1958, Jour. Paleontology, v. 32, no. 5, p. 1029–1030. Bainbridge limestone considered to be of lower Ludlow or highest Wenlock, that is, early Late or latest Middle Silurian, because of occurrence of Ludlovian and highest Wenlock eospiriferids of the *Eospirifer nobilis* type.

Type section: In head of small box canyon in SE¼SE¼NW¼ sec. 24, T. 32 N., R. 14 E., along Bainbridge Creek, near Moccasin Springs, Cape Girardeau County, Mo.

†Bainbridge Marl[1]

Eocene, upper: Southwestern Georgia.

Original reference: A. F. Foerste, 1894, Am. Jour. Sci., 3d, v. 48, p. 41–54.

Named for exposures at Bainbridge, Decatur County.

Bainbridge residual beds[1]

Oligocene and Miocene: Southwestern Georgia.

Original reference: W. H. Dall and J. Stanley Brown, 1894, Geol. Soc. America Bull., v. 5, p. 170.

Named, apparently, for exposures at or in vicinity of Bainbridge, Decatur County.

Baird Shale[1] or **Formation**

Mississippian: Northern California.

Original reference: H. W. Fairbanks, 1894, Am. Geologist, v. 14, p. 28.

C. A. Lamey, 1948, California Div. Mines Bull. 129, pt. K, p. 141 [1946]. Listed in Shasta County as Baird formation consisting of tuff, sandstone, and shale. Underlies Permian(?) McCloud limestone.

I. E. Klein, W. P. Irwin, and B. A. Ogle, 1960, Sacramento Geol. Soc. Ann. Field Trip, June 3–5, geol. map. Map explanation shows Baird formation as Pennsylvanian.

A. H. Coogan, 1960, California Univ. Pubs. Geol. Sci., v. 36, no. 5, p. 243–255. Baird formation, according to Diller (1906, U.S. Geol. Survey Geol. Atlas, Folio 138), consists of lower 500 feet of white and purple tuff and tuffaceous slaty sedimentary rocks, and an upper 200 feet of tuffaceous and siliceous slate. Near McCloud River bridge, the Baird is present on both sides of river and is said to be disconformably beneath McCloud limestone. Although well-documented fossiliferous beds of the Baird have a Mississippian fauna, presence of *Staffella?* in beds a few feet below Baird-McCloud contact at this locality indicates that here topmost beds of the Baird formation are at least Pennsylvanian and may be Permian in age.

Prominantly exposed on west side of [McCloud] River just above Baird Post Office [Shasta County].

†Baker Limestone[1]

Lower Silurian: Western Tennessee.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 397, 402.

Named for Baker, Davidson County.

Baker Member (of Ladd Formation)

See **Baker Canyon Conglomerate Member** (of Ladd Formation).

Baker Canyon Conglomerate Member (of Ladd Formation)

Baker Member (of Ladd Formation)

Upper Cretaceous: Southern California.

W. P. Popenoe, 1937, Jour. Paleontology, v. 11, no. 5, p. 380. Named Baker member of Ladd formation. Gray to brownish massive- to thick-bedded boulder conglomerate below, grading up into thick bedded to shaly arkosic soft brown sandstone above; sandstones at top highly fossiliferous. Thickness about 200 feet. Underlies Holz member of Ladd formation (both new); overlies Trabuco formation.

W. P. Popenoe, 1941, Jour. Geology, v. 49, no. 7, p. 740. Referred to as Baker conglomerate member of Ladd formation.

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166, 168 (fig. 2), 170–171. Renamed Baker Canyon member of Ladd formation. Name Baker preoccupied. Derivation of name given.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map 154. Shown on map legend as Baker Canyon conglomerate member of Ladd formation.

Named for its development in Baker Canyon, north of Silverado Canyon, Santa Ana Mountains.

Baker Lake Porphyry

Tertiary: Central Colorado.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 83, pl. 1. Quartz monzonite porphyry, coarser and darker gray than typical Eshe porphyry. Block jointing has broken rock units into slabs from a few inches to a few feet in diameter. Talus obscures contacts with surrounding sediments.

Exposed in northwestern part of South Park in secs. 17, 19, 20, 28, 29, and 30, T. 7 S., R. 75 W., and secs. 24 and 25, T. 7 S., R. 76 W., Park County. Outcrop is 4 miles long and averages one-half mile wide. Central part of outcrop has been eroded to a depression which now holds Baker Lake.

Baker Pond Gneiss (in Oliverian Magma Series)

Upper Devonian(?): West-central New Hampshire.

J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle (1:62,500): New Hampshire Highway Dept. Fine-grained gray gneiss, locally containing microcline phenocrysts. Largely quartz monzonite with some granodiorite. Border phase is dark-greenish-gray quartz diorite gneiss. Included in Oliverian magma series whose age is younger than Lower Devonian and is probably Upper Devonian.

Mapped in the area around Upper Baker Pond, which is located on the border of the Mount Cube and Rumney quadrangles.

Bakerstown Clay[1]

Pennsylvanian (Conemaugh Series): Western West Virginia.

[Original reference]: C. E. Krebs and D. D. Teets, Jr., 1914, West Virginia Geol. Survey Kanawha County, p. 177.

J. B. McCue and others, 1948, West Virginia Geol. Survey [Repts.], v. 18, p. 14. Bakerstown underclay, 3 to 10 feet thick, commonly occurs below Bakerstown coal which is generally 160 to 190 feet above base of Conemaugh series.

Occurrences noted in Barbour, Braxton, Kanawha, Lewis, Roane, and Upshur Counties.

Bakerstown Sandstone (in Conemaugh Formation)[1]

Bakerstown shale and sandstone member

Pennsylvanian: Southwestern Pennsylvania and eastern Ohio.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. xlx (preface), 305–308.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 120. Geographically extended into Athens County, Ohio, where it is called Bakerstown shale and (or) sandstone member of Anderson cyclothem in Conemaugh series. Lesley applied name in Pennsylvania to sandstone underlying Bakerstown (Anthony) coal and overlying Lower Barren Measure (Conemaugh) red shales, which rest on Pine Creek (Wilgus?) coal. Heretofore member has been unnamed in Ohio or called Anderson as by Flint (1951, Ohio Geol. Survey, 4th ser., Bull. 48). In Athens County, Bakerstown member has maximum and minimum thickness of 32 and 3 feet, respectively, with average thickness of 13 feet. Where underlying Cambridge and Wilgus members [of Wilgus cyclothem] are absent or indistinct and replaced by sandy and shaly beds, it is difficult to separate Bakerstown member from Buffalo member and undifferentiated Buffalo-Bakerstown shale and sandstone members attain considerable combined thickness. Stratigraphically below Bloomfield limestone member [of Anderson cyclothem]. Bloomfield member is well developed only in Muskingum County.

Name first used in Allegheny County, Pa.

Bakersville Gabbro[1]

Precambrian(?): Western North Carolina.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 5.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 25; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Dense, hard unmetamorphosed rock, nearly black when fresh but becoming reddish brown on weathering. Composed chiefly of plagioclase, hornblende, and pyroxene in crystals of medium size with small amounts of magnetite, epidote, and garnet as accessory minerals. Texture usually massive and granular, but locally becomes aplite. Exact age still in doubt. Some recent workers believe Bakersville may have been emplaced between late Ordovician or early Silurian and the Triassic.

U.S. Geological Survey currently designates the age of the Bakersville as Precambrian(?) on the basis of a study now in progress.

Named for Bakersville, Mitchell County.

Bakken Formation

Upper Devonian(?) and Lower Mississippian: Subsurface in North Dakota and Montana, and Manitoba and Saskatchewan, Canada.

J. W. Nordquist, 1953, Billings Geol. Soc. Guidebook 4th Ann. Field Conf., p. 72–74, figs. 4, 5. Consists of two black fissile shales separated by light-gray to gray-brown fine-grained calcareous sandstone interbedded with minor amounts of gray-brown cryptocrystalline limestone. Thickness 105 feet in type well. Occurs between depths of 9,615 and 9,720 feet. Overlies Three Forks formation; underlies Lodgepole formation.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2328. Overlies Three Forks formation in standard subsurface section of Three Forks. Devonian(?) and Lower Mississippian.

U.S. Geological Survey currently designates age of the Bakken as Upper Devonian(?) and Lower Mississippian on basis of study now in progress.

Type well: Amerada Petroleum Corporation-H. O. Bakken No. 1 deep test, center SW¼NW¼ sec. 12, T. 157 N., R. 95 W., Williams County, N. Dak.

Bakoven Shale[1] (in Hamilton Group)

Middle Devonian: Eastern New York.

Original reference: G. H. Chadwick, 1933, Am. Jour. Sci., 5th, v. 16, p. 480, 483.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180. Beds hitherto classified as "Marcellus" shale (Bakoven of Chadwick) immediately underlie Stony Hollow member (new) of Marcellus and are now proved to be equivalent of Union Springs member of Marcellus.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1733, chart 4. Represents easternmost known facies of Union Springs shale.

Winifred Goldring and G. A. Cooper, 1943, New York State Mus. Bull. 332, p. 240–249. In Coxsackie quadrangle, forms narrow belt for full length of area. In upper part, it is entirely included in Hamilton escarpment which rises abruptly above Onondaga Flats. Further south, in part, it forms east face of Hamilton Hills and, in part, underlies a hilly valley occupied in extreme south by Hollister Lake and a branch of the Catskill. Thickness for this area between 180 and 200 feet. Not in contact with Onondaga in this quadrangle. Stony Hollow member (new) of Marcellus overlies Bakoven shale. Bakoven shale of Chadwick now represents gray shale facies of Union Springs member of Marcellus.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW–20, p. 8 (table 1), 11 (fig. 3), 15. Bakoven, formerly termed "Marcellus shale," is basal formation of Hamilton group in Albany County. Typically black pyritiferous fissile shale. Thickness about 200 feet. Underlies Mount Marion formation; overlies Onondaga limestone. Middle Devonian.

Type section (partial): Where Catskill-Palenville Road crosses Kaaters Kill. Bakoven is local Dutch name of valley produced by the shale.

Balaklala Rhyolite[1]

Middle Devonian: Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Survey Geol. Atlas, Folio 138.

A. R. Kinkel, Jr., and J. P. Albers, 1951, California Div. Mines Spec. Rept. 14, p. 4. Name restored as formal stratigraphic unit because new evidence indicates formation is composed principally of extrusive rhyolite and pyroclastics and not intrusive alaskite porphyry as considered by Graton (1910) who abandoned the name.

A. R. Kinkel, Jr., W. E. Hall, and J. P. Albers, 1956, U.S. Geol. Survey Prof. Paper 285, p. 1, 17–32, pl. 1. Composed of soda-rich rhyolitic flows and pyroclastic material. Subdivided into three units: lower nonporphyritic rhyolite, middle medium-phenocryst rhyolite, and upper coarse-phenocryst rhyolite. Probably 3,500 feet thick in central part of district, but forms volcanic pile that thins on edges. Conformably overlies, and in some areas interfingers with, Copley greenstone; underlies Kennett formation.

I. E. Klein, 1960, Sacramento Geol. Soc. [Guidebook] Field Trip June 3, 4, and 5, p. 11. Intruded by Mule Mountain granite (new).

Named for fact it forms hills about Balaklala mine, Redding quadrangle. Rhyolite crops out in a belt 16 miles long and 5 miles wide that strikes N. 15° E. from south half of Whiskeytown quadrangle to southwest quarter of Behemotosh quadrangle.

Balanos Beds

See **Bolanos Pyroclastic Member** (of Umatac Formation).

Bald Crater Basalt Flow

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 33. Name applied to basalt flow on Bald Crater. [See Timber Crater Basalt Flow.]

Bald Crater is north and west of Crater Lake.

†Bald Eagle Conglomerate,[1] Formation, or Sandstone

Bald Eagle Member (of Juniata Formation)

Upper Ordovician: Central Pennsylvania.

Original reference: A. W. Grabau, 1909, Jour. Geology, v. 17, p. 235.

Bradford Willard and A. B. Cleaves, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1165–1198. Term Oswego apparently misapplied in Pennsylvania. For beds commonly referred to by that name, term Bald Eagle (Grabau, 1909) is revived and treated as basal member of Juniata. This new application of term restricts Martinsburg at top. Grades upward into red Juniata. Where Juniata is absent, underlies Tuscarora sandstone; overlies Martinsburg formation, in some areas the Fairview member. Thickness varies from 10 feet to as much as 124 feet.

F. M. Swartz, 1948, Pennsylvania Geologists Guidebook 14th Ann. Field Conf., p. 4–5, diagram. At its type section, Bald Eagle formation is about 650 feet thick and consists of poorly winnowed unfossiliferous graywacke-type sandstones, virtually without pebbles except for shale-chips of intraformational type. Formation includes a middle strong ridge-making sandstone member, underlain by weaker shale and sandstone member. Eastward toward Lewistown, ridge-making member of Bald Eagle sandstone becomes conglomeratic, with pebbles of vein quartz, quartz-veined quartzites, cherts and jaspers, and rarely of quartz-veined metaargillites. This conglomerate is here named Lost Run conglomerate. Overlies Reedsville shale and at eastern limit Martinsburg shale; underlies unnamed sandstone member of Juniata.

F. M. Swartz, 1955, Pennsylvania State Univ., Dept. Geology Contr. 3, 58 p. Bald Eagle sandstone, in type area, subdivided into Centennial School sandstone and shale member below and Spring Mount sandstone member (both new). Underlies East Waterford red sandstone member (new) of Juniata; overlies Reedsville shale.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook for Field Trips, Pittsburgh Mtg., p. 7, pl. 1. Formation comprises typically dark-gray, greenish, well-cemented, poorly sorted graywacke and orthoquartzite. Basal part commonly conglomeratic. Thickness 30 feet at Susquehanna Gap; nearly 1,000 feet in central Pennsylvania. Underlies Juniata formation. Contact with underlying Reedsville transitional: contact arbitrarily placed at youngest occurrence of *Orthorhynchula*.

Named for Bald Eagle Mountain at Tyrone, Blair County.

Bald Hill Agglomerate Member (of Tuscan Formation)

[Pliocene]: Northern California.

R. C. Treasher, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1257. Tuscan formation is subdivided into five members. Bald Hill agglomerate is second in sequence (ascending). Underlies Seven-Mile tuff and sand member; overlies Supan tuff and sand member.

Occurs at Iron Canyon dam site near Red Bluff, Tehama County.

Bald Hill Granite Gneiss[1]

Precambrian: Southeastern New York.

Original reference: C. E. Gordon, 1911, New York State Mus. Bull. 148, p. 11, 14–16, 20–21, 32, 34, 40.

Composes Bald Hill, Poughkeepsie region.

Bald Hill Limestone (in Tradewater Formation)[1]

Pennsylvanian: Southeastern Illinois.

Original reference: G. H. Cady, 1926, Illinois State Acad. Sci. Trans., v. 19, p. 263.

Exposed in railroad cut east of Stonefort as a discontinuous layer a few inches thick but is more typically developed at Bald Hill, about 2 miles southeast of Stonefort, Saline County, on north side of Big Four Railroad.

Bald Hill Sandstone (in Tradewater Formation)[1]

Pennsylvanian: Southeastern Illinois.

Original reference: G. H. Cady, 1926, Illinois State Acad. Sci. Trans., v. 19, p. 258, 263.

Occurs along crest of hill north of Stonefort, that is, Stonefort Hill, and is exposed on low knoll upon which Mitchellville, Saline County, is located.

Bald Hill Shale (in Henshaw Formation)[1]

Pennsylvanian: Western Kentucky.

Original reference: L. C. Glenn, 1922, Kentucky Geol. Survey, ser. 6, v. 5, p. 118.

Named for Bald Hill, just east of Dixon.

Bald Hills Formation

Upper Cretaceous: Northern California.

M. A. Murphy and P. U. Rodda, 1960, Jour. Paleontology, v. 34, no. 5, p. 835–858. Conglomerate, sandstone, and mudstone. Thickness 1,870 feet at type locality. Conformably overlies Ono formation; conformably underlies unnamed Upper Cretaceous mudstone unit. Molluscan fauna described.

Type section: In Bald Hills along Crow Creek in secs. 25, 26, and 31, T. 30 N., R. 7 W., Mount Diablo base and meridian, Shasta County.

Baldhills Member (of Isom Formation)

Eocene(?) or Oligocene, lower(?): Southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 99. Porphyry of latitic composition, glassy to lithoidal in texture, black to dark red brown in color, with strong platy parting and blocky fracture. Exhibits some features of ignimbrites of very highly welded type, but has some internal structural features indicative of viscous flow. Lower member of formation; underlies Hole-in-the-Wall member (new). Discussion of ignimbrites of area.

Named for occurrence in Baldhills ridge (Three Peaks quadrangle) which trends northward from type locality of Isom formation, Iron Springs district.

Bald Knob Shale (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1915, West Virginia Geol. Survey Rept. Boone County, p. 497.

Named for Bald Knob post office, Boone County.

Bald Knoll Formation

Eocene, upper, or Oligocene, lower: Central Utah.

W. N. Gilliland, 1949, Ohio State Univ. Abs. Doctors' Dissert. 57, p. 71; 1951, Nebraska Univ. Studies, new ser., no. 9, p. 11 (table 1), 43–47, pl. 2. Succession of light-green, light-tan, gray, and white clays with interbedded siltstone, sandstone, and minor amounts of soft limestone of the same colors. Thickness at type locality about 600 feet; elsewhere may be as much as 800 to 1,000 feet. Underlies Axtell formation with angular discordance; overlies Crazy Hollow formation.

D. P. McGookey, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 5, p. 605, 606–608. Gray Gulch formation as designated by Spieker (1949) includes strata equivalent to Bald Knoll formation of Gilliland (1951), part of Bullion Canyon volcanics of Callaghan (1939), and a previously unnamed interval that was mapped as Gray Gulch(?) formation by Lautenschlager (1952, unpub. thesis). Proposed herein that term "Gray Gulch" be abandoned and term "Bald Knoll formation" be used for lower part of interval formerly assigned to Gray Gulch. Thickness about 1,049 feet on Lost Creek. Underlies Dipping Vat formation (new); overlies Crazy Hollow formation. Eocene.

Type locality: At mouth of Bald Knoll Canyon in southwest corner of Gunnison quadrangle.

Bald Mountain Dacite[1]

Tertiary: Central southern Colorado.

Original reference: W. Cross, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 295.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 197. In Silver Cliff-Rosita region, the volcanics, in order of decreasing age, consist of Rosita fragmental andesite, Bunker massive andesite, Fairview diorite in dikes cutting earlier andesite. Bald Mountain dacite flows, rhyolite in dikes, eruptive channels and flows, Pringle andesite, trachyte flows, and Bassick agglomerate.

Named for Bald Mountain, Custer County.

Bald Mountain Formation

Precambrian: Northeastern Utah.

D. J. Jones, 1955, Utah Geol. Mineralog. Survey Bull. 51, p. 13, 14, fig. 2. Series of buff-colored thin-bedded quartzites and metamorphosed conglomerate. Many thin layers of brown and green shale in between layers of quartzite. Thickness about 1,250 feet.

Named from Bald Mountain, Uinta Mountains, where formation is well exposed.

Bald Mountain Gneiss[1]

Precambrian: Northeastern Oregon.

Original references: W. D. Smith and E. L. Packard, 1919, Oregon Univ. Bull., v. 16, no. 7, p. 105; 1919, Jour. Geology, v. 27, p. 105.

Bald Mountain Lake Beds Member (of Esmeralda Formation)[1]

Miocene, upper, and Pliocene, lower: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

Composes upper part of Bald Mountain within 400 feet of its top. Manhattan district.

Bald Mountain Limestone[1]

Lower Ordovician: Eastern New York and western Vermont.

Original reference: W. W. Mather, 1843, Geology New York, v. 1, p. 367.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Shown on correlation chart for Vermont. In Taconic sequence, Bald Mountain limestone occurs above Deepkill shale and below Normanskill formation. Taconic sequence occupies a range that extends southward from Brandon, Vt., into Massachusetts and Connecticut.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76. Only lower part of Bald Mountain is Canadian; upper part is of Black River and Trenton ages.

Named for occurrence on Bald Mountain, Washington County, N.Y.

Bald Mountain Tonalite

Lower Cretaceous(?): Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 197–204, 235. Medium-grained fairly uniform pale-blue-gray tonalite with some dark minerals. Intrudes Permian sedimentary and volcanic sequence and Triassic ultramafic-gabbroic series. Intruded by Mount Ruth leucogranodiorite and Red Mountain leucogranodiorite (both new). Surrounds Badger Butte quartz-biotite norite (new). Grades into Anthony Lake granodiorite (new) near center of batholith; this transition zone is intruded by Elk Peak quartz monzonite (new).

Characteristically exposed on Mount Ireland (Bald Mountain), in Elkhorn Mountains [Grant County]. Major rock component of Bald Mountain batholith.

Bald Peak Basalt[1] (in Berkeley Group)

Bald Peak Formation (in Contra Costa Group)

Pliocene: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 2, map.

D. E. Savage, B. A. Ogle, and R. S. Creely, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1511. Bald Peak formation included in sequence of formations (in west-central Contra Costa County) for which a new group name is proposed [name not given]. Sequence (ascending): Orinda, Moraga, Siesta, Bald Peak, and unnamed formation.

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 143. Noted as Bald Peak lavas, which are chiefly flows of basalt and andesite. Interbedded with and overlies Siesta formation.

C. R. Ham, 1952, California Div. Mines Spec. Rept. 22, p. 15. Included in Contra Costa group (new).

Forms large part of Bald Knob, east of Berkeley, Contra Costa County.

Bald Rock Conglomerate Member (of Lee Formation)[1]

Pennsylvanian: Southwestern Virginia.

Original reference: J. B. Eby, 1923, Virginia Geol. Survey Bull. 24, p. 65.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 14. Middle of three conglomerates in the type Lee—the Bee Rock at top and an unnamed zone at base.

Named for Bald Rock, about 4 miles west of Dungannon, Wise County.

Bald Rock Granite

Late Jurassic(?): Northern California.

Anna Hietanen, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 583, 584. Named in a petrographic discussion of rocks of the area.

Report on the Merrimac area, Plumas National Forest, Butte and Plumas Counties.

Baldwin Formation

Mississippian (Chester Series): Southwestern Illinois.

J. M. Weller, 1939, *in* Stuart Weller and J. M. Weller, Illinois Geol. Survey Rept. Inv. 59, p. 10 (fig. 2), 12, 13; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 837. Proposed for strata formerly known as upper Okaw or Plum Creek beds. Consists of more or less sandy beds at bottom and top separated by shale and dark-gray somewhat cherty limestone; these three parts are equivalent to Tar Springs, Vienna, and Waltersburg formations of southern Illinois, but the sandstones are erratically developed and it is impractical to map them separately. Thickness 60 to 75 feet. Conformably underlies Menard limestone; locally overlies Okaw limestone unconformably and rests on different members of it in different places.

Name derived from town on east side of Kaskaskia River in Randolph County. Outcrops extended from near Baldwin to Fort George and thence along Mississippi bluff to mouth of Marys River.

Baldwin Gneiss

Precambrian(?): Southern California.

R. B. Guillou, 1953, California Div. Mines Spec. Rept. 31, p. 5, 6–7, pl. 1. Chiefly fine-grained gneiss and schist and augen gneiss. Includes two ages of pre-Mississippian granitic intrusives. Thickness about 2,000 feet. Gneiss is in reverse fault contact with Chicopee formation (new) east of Baldwin Lake and with Furnace limestone to south. West of Doble mine, gneiss is in fault contact with Chicopee formation and overthrust by Saragossa quartzite. Intruded by Cactus quartzite. Gneisses and associated granitic intrusions were included in Saragossa quartzite by Vaughan (1922).

Type locality: East of Baldwin Lake, San Bernardino Mountains, San Bernardino County.

Baldwin Sandstone Member (of Mesaverde Formation)

Upper Cretaceous: Central Colorado.

E. C. Dapples, 1939, Econ. Geology, v. 34, no. 4, p. 371. Name proposed for strata, near village of Baldwin, identified earlier (W. T. Lee, 1912) as Bowie member. Contains several coal beds locally. Underlies Rollins sandstone member.

Village of Baldwin located in Anthracite-Crested Butte coal district, Gunnison County.

Baldwin Corner Formation

Lower Ordovician: East-central New York.

John Rodgers *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., 1952, Geol. Soc. America Guidebook for Field Trips in New England, p. 35 (table 2), 53 (road log). Gray or yellow earthy fine-grained dolomite with persistent limestone layers near middle and at base. Thickness 120 feet. Underlies Great Meadows formation (new); overlies Whitehall formation. Formerly included in Whitehall formation. Refers to R. H. Flower (unpub. ms.).

Occurs in Fort Ann quadrangle.

Baldwinsville Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Central eastern Illinois.

Original reference: J. E. Lamar and H. B. Willman, 1934, Illinois Geol. Survey Bull. 61, p. 129–138.

Derivation unknown.

Baldy Hill Formation (in Dockum Group)

Triassic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, pt. 2, p. 31, 35–38, pls. 1a, 1b, 2. Consists of silty mudstone, with beds of ledge-forming sandy mudstone and very fine-grained sandstone in type section where it is 115 feet thick. A 13-foot interval of claystone present near bottom of section. Formation characterized by purple color, which mottles orange, gray red, light to medium gray, and light olive. Nodules of red and yellow chalcedony and some silicified wood present below top of unit. Several sandstone beds present at base of formation where it underlies Travesser formation (new) 1 or 2 miles east and northeast of type section.

Type section: Measured 2,000 feet north of Baldy Hill at sec. 36, T. 32 N., R. 32 E., Union County. Exposed in an area of about 8 square miles on the former Baker Ranch, just north of junction of New Mexico Highways 325 and 370. Named from Baldy Hill.

Baldy Mountain Member (of Davis Creek Formation)

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Named as lower member of formation. Underlies Buck Island member (new); overlies Round Mountain member of Little Valley formation (both new). Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Balfour Formation

Oligocene, lower: Central Colorado.

J. H. Johnson, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 77. Consists of brown clays and sandy shales with interbedded flows and trachyte and fragmental volcanic material. Underlies Antero formation (new); overlies Denver formation.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 34 (table 7), 61–63, pl. 1. Sequence of stream-channel, flood-plain, alluvial-fan, deltaic, and true lake sediments. Thickness 0 to 200 feet. Relation to Denver formation nowhere exposed; may prove to be merely topmost part of the Denver.

Area: Best exposed north of Balfour in T. 13 S., R. 75 W. Scattered outcrops occur within area extending from R. 74 to R. 76 W., and from T. 14 to T. 12 S., Park County.

Ballard Formation (in Meade Group)

Pleistocene (Nebraskan and Aftonian): Southwestern Kansas.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1), 56. Name proposed to include deposits between Rexroad formation below and Crooked Creek formation above in southwestern Kansas. Thickness about 20 feet. Includes Angell member (new) at base and Missler member. Separated by erosional unconformities from both underlying and overlying formations.

Type locality: On Big Springs Ranch in secs. 7 and 17, T. 32 S., R. 28 W., Meade County. Named from Louise Ballard Ranch which is shown on Meade County Platt book as saving included the present Big Springs Ranch.

Ballard Harmon Sandstone[1]

Mississippian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 244.

Quarried on southwest side of Tug Fork, just below mouth of Ballard Harmon Branch, McDowell County.

†Ballast Point silex bed[1] (in Tampa Limestone)

Miocene, lower: Central Florida.

Original reference not stated.

Named for exposures at Ballast Point, Tampa, Hillsborough County.

Ballena Gravel[1]

Eocene: Southwestern California.

Original reference: W. J. Miller, 1935, Geol. Soc. America Bull., v. 46, no. 10, p. 1556–1561.

Type locality: Southwest of Ballena, San Diego County.

Ballou Clay (in Allegheny Formation)[1]

Pennsylvanian: Ohio.

Original reference not stated.

In Muskingum County.

Balmville Limestone Member (of Wappinger Limestone)[1]

Middle Ordovician: Southeastern New York.

Original reference: F. Holzwasser, 1926, New York State Mus. Bull. 270, p. 38–41, 43.

E-an Zen, 1960, (abs.) Geol. Soc. American Bull., v. 71, no. 12, pt. 2, p. 2009. Discussion of time and space relationships of Taconic rocks in western Vermont and eastern New York. Within southern Taconic area, Normanskill and higher rocks are autochthonous; they rest in normal succession on Whipple-correlative Balmville limestone member of Wappinger limestone.

Crops out north of Balmville, Orange County.

Balsora Limestone (in Palo Pinto Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: G. Scott and J. M. Armstrong, 1932, Texas Univ. Bull. 3224, p. 24.

Occurs along Boone Creek. Named for outcrop in valley of a small stream 1 mile west of Balsora, Wise County.

Baltic Amygdaloid[1] (in Bohemian Range Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, pt. 2, p. 135, 136.

T. M. Broderick, C. D. Hohl, and H. N. Eidemiller, 1946, Econ. Geology, v. 41, no. 7, p. 678 (fig. 1). Name used on geologic section of Michigan copper district.

Named for occurrence in Baltic mine, Houghton County.

Baltic Conglomerate[1] (in Bohemian Range Group)

Precambrian: Northern Michigan.

Original reference: A. C. Lane, 1906, Mines and Minerals, v. 27, p. 204–206.

Named for occurrence in Baltic mine, Houghton County.

Baltic Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

H. R. Cornwall, 1951, Geol. Soc. America Bull., v. 62, no. 2, p. 194. Ophitic basalt of the Baltic flow overlies No. 3 conglomerate in Michigan copper district.

Michigan copper district on Keweenaw Peninsula in Houghton and Keweenaw Counties.

Baltic Sandstone[1] (in Bohemian Range Group)

Precambrian: Northern Michigan.

Original reference: A. C. Lane, 1911, Michigan Geol. and Biol. Survey Pub. 6, geol. ser. 4, p. 495, 499.

Probably named for its occurrence near Baltic mine or at or near town of Baltic, Houghton County.

Baltic West Amygdaloid[1] (in Bohemian Range Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named because it is usually the first amygdaloid west of Baltic lode.

Baltic West Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Baltic mine, Houghton County.

Baltimore Gabbro or Gabbro Complex

Paleozoic (post-Lower Ordovician): Eastern Maryland.

Ernst Cloos and H. G. Hershey, 1936, Natl. Acad. Sci. Proc., v. 22, no. 1, p. 71, 78. Baltimore gabbro is intrusive into Glenarm series.

Ernst Cloos and others, 1936, Maryland Geol. Survey, v. 13, p. 33 (table 1), 217–236, pl. 1, 41. Post-Lower Ordovician. Gabbro occurs in peneplained area and occupies a structural basin in the Glenarm series and Baltimore gneiss.

Norman Herz, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 979–1015. Discussed as Baltimore gabbro complex. Intrudes Wissahickon and Peters Creek and is cut by quartzose intrusives including Relay diorite, Port Deposit granodiorite gneiss, and Ellicott City granite. The Relay occurs persistently along southeast margin of gabbro.

Complex comprises an area of about 50 square miles in Piedmont of Baltimore City and County and Howard County.

Baltimore Gneiss[1]

Precambrian: Northern Maryland, southeastern Pennsylvania, and central northern Virginia.

Original reference: G. H. Williams and N. H. Darton, 1892, U.S. Geol. Survey map of Baltimore to accompany "Guide to Baltimore" prepared for Baltimore meeting Am. Inst. Mining Engrs. Feb. 1892, p. 88, 139.

Ernst Cloos and others, 1936, Maryland Geol. Survey, v. 13, p. 33 (table 1), 217, pl. 1. Baltimore gabbro occurs in peneplained area and occupies a structural basin in Glenarm series and Baltimore gneiss.

Chi-shang Ch'ih, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 924. Northwest of Philadelphia, the Wissahickon is cut off by Cream Valley fault which brings it into contact with Baltimore gneiss.

Norman Herz, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 980. Unconformable below Glenarm series, lowest unit of which is Setters quartzite.

R. H. Jahns and W. R. Griffitts, 1953, U.S. Geol. Survey Prof. Paper 248–C, pt. 4, p. 172. Geographically extended into Anna River area, Virginia, where it forms a well-defined belt on east side of area; west of gneiss is Wissahickon schist.

Named for outcrops in city of Baltimore, Md., along banks of Jones Falls and Gwynns Falls.

†Baltimorean Formation[1]

Lower Cretaceous: Eastern Maryland.

Original reference: P. R. Uhler, 1888, Am. Philos. Soc. Proc., v. 25, p. 48.

Well developed in city of Baltimore.

Banbury Formation or **Basalt** (in Idaho Group)

Banbury Volcanics[1]

Pliocene, middle: Southern Idaho.

Original references: H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932); 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 31 (table), 50–51, pl. 5. Volcanics crop out fairly continuously as a series of even-bedded massive basalt flows more than 300 feet thick. Stratigraphic section shows Banbury volcanics above Raft lake beds and below Hagerman lake beds.

U.S. Geological Survey currently classifies the Banbury Basalt as a formation in Idaho Group on basis of study now in progress.

Named for exposures near Banbury Hot Springs, sec. 33, T. 8 S., R. 14 E., Twin Falls County.

Bandelier Tuff

Bandelier Rhyolite Tuff

Pleistocene: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103. Named as sixth in a list of seven Quaternary formations in area. Older than Santa Clara basalt (new); locally overlies Puye gravel (new).

V. C. Kelley and Caswell Cooper, 1952, New Mexico Univ. Pubs. in Geology 4, p. 114 (fig. 14). Pleistocene.

Occurs in Abiquiu quadrangle, Rio Arriba County.

Bandera Shale[1] (in Marmaton Group)

Bandera Shale Member (of Oologah Limestone)

Bandera Shale (in Henrietta Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas, southwestern Iowa, and northeastern Oklahoma.

Original reference: G. I. Adams, 1903, U.S. Geol. Survey Bull. 211, p. 32.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 292, 321–325, pl. 1. Subdivided to include Bandera Quarry sandstone member (new). Overlies Laberdie limestone member (new) of Pawnee limestone; underlies Tina limestone member of Altamont limestone. Thickness commonly 50 feet. Included in Marmaton group. Note on type exposure.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v .25, no. 1, p. 26–27 (fig. 2). Columnar section shows Bandera shale in Henrietta group.

L. M. Cline and F. C. Greene, 1950, Missouri Geol. Survey and Water Resources Rept. Inv. 12, p. 15–17. Geographically extended into Missouri. Underlies Altamont formation, in some areas Amoret limestone member. [Amoret replaces Tina.] Overlies Pawnee formation, Coal City member.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 28. Term Oologah is extended to Kansas-Oklahoma line to include (ascending) Pawnee limestone, Bandera shale, and Altamont limestone as members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 31, fig. 5. In southwestern Iowa, formation comprises rocks between Altamont formation above and Pawnee formation below. Not subdivided, and where Amoret member of Altamont is missing it is not possible to differentiate the formations. Bandera is well exposed below the Amoret and above Coal City limestones in ravine in NW¼ sec. 26, T. 75 N., R. 26 W., Madison County. Here it consists of 10 feet of red and green mottled clay and shale at top followed by 15 feet of green micaceous crossbedded sandstone and siltstone below. Marmaton group.

Named from Bandera Station in sec. 29, T. 25 S., R. 23 E., Bourbon County, Kans.

Bandera Quarry Sandstone Member (of Bandera Shale)

Pennsylvanian (Des Moines Series): Southeastern Kansas and northeastern Oklahoma.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 292. Name applied to sandstone lenses in the Bandera shale.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 196. Gray and brown sandstone, generally thin bedded, locally "flagstones;" lenticular. Thickness as much as 30 feet; average 15 feet.

J. M. Jewett, 1945, Kansas Geol. Survey Bull. 58, p. 35, 37, 38, pl. 3. Sandstone is commonly well bedded and is fine and micaceous; locally the sandstone occupies entire Bandera section; where present, it is generally separated by shale ranging in thickness from a few feet to 20 or more feet.

C. M. Cade 3d, 1953, Tulsa Geol. Soc. Digest, p. 132 (fig. 2), 136–137. Geographically extended into Nowata and Craig Counties, Okla., where it occurs near top of Bandera shale, about 10 feet below base of the Altamont. A channel filling; most exposures show even bedding that is continuous for many miles. Locally contains thin shale members. Thickness of sandstone group is 11 feet.

Nearly all local occurrence is in flagstone quarries in vicinity of center of north line of SW¼ sec. 29, T. 25 S., R. 23 E., Bourbon County, Kans.

Bangor Beds (in Martinsburg Shale)[1]

Upper Ordovician: Southeastern Pennsylvania.

Original references: C. H. Behre, Jr., 1926, Jour. Geology, v. 34, p. 485–487; 1927, Pennsylvania Geol. Survey, 4th ser., Bull. M–9, p. 33, 104–107, maps.

Quarried at Bangor, Northampton County.

Bangor Limestone[1]

Upper Mississippian: Alabama, northwestern Georgia, and central and eastern Tennessee.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. on Cahaba coal field, p. 155–157, map.

W. B. Jones, 1928, Alabama Geol. Survey Circ. 8, p. 13–15. Includes Burgess oolite and Rockwood oolite.

W. B. Jones, 1939, Econ. Geology, v. 34, no. 5, p. 575–578. Includes Spout Spring oolite (new) near base. Overlies Hartselle sandstone.

G. W. Stose, 1952, Washington Acad Sci. Jour., v. 42, no. 8, p. 214, 242 (fig. 1). In Murphree Valley anticline, Alabama, Bangor is fossiliferous cliff-making limestone about 600 feet thick. Underlies Pennington shale; overlies Tuscumbia limestone.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey County Rept. 3, p. 57–64. In Madison County, composed of about 350 to 420 feet of crystalline and oolitic limestone, dolomite, and shale. Overlies Hartselle sandstone; underlies Pennington formation; where Hartselle is missing, unconformably overlies Gasper formation.

Named for development at Bangor, Blount County, Ala.

Banjo Point Formation

Oligocene to Miocene: Alaska.

H. A. Powers, R. R. Coats, and W. H. Nelson, 1960, U.S. Geol. Survey Bull. 1028–P, p. 536–539, pl. 69. Bedded marine sandstone, conglomerate, tuffaceous shale, and some lapilli tuff of basaltic composition. Everywhere, top of formation is the present erosion surface. Could be as little as 400 feet thick; no marker beds could be traced through the many fault blocks to permit reconstruction of complete section, but partial section (considered type section) is about 138 feet thick, base not exposed. Unconformably overlies Amchitka formation (new). West of Banjo Point is in fault contact with Chitka Point formation (new). On basis of meager fauna, age range is considered Oligocene to Miocene.

Type section: Exposed on north coast at Banjo Point, Amchitka Island (Aleutian Islands). Occupies entire width of island westward from Makarius Bay to about 5 miles west of Banjo Point, and also several square miles of Saint Makarius Point; present on north coast west of Kirilof Point.

Bankston cyclothem

See Bankston Fork cyclothem.

Bankston Fork cyclothem (in Carbondale Formation)

Bankston Fork cyclothem (in McLeansboro Group)

Pennsylvanian: Southern Illinois.

J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). In list of upper Pennsylvanian cyclothems, Bankston Fork occurs below Sparland cyclothem and above Jamestown cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. On correlation chart, Bankston cyclothem is shown as including (ascending) Anvil Rock sandstone, Bankston Fork limestone, and Bankston coal. Underlies Cutler cyclothem (new); overlies Jamestown cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), 54 (table 3). In Carbondale formation.

Type locality not given; however, type locality of Bankston Fork limestone is in Saline County.

Bankston Fork Limestone Member (of Carbondale Formation)

Bankston Fork Limestone (in McLeansboro Formation)[1]

Bankston Fork Limestone (in McLeansboro Group)

Pennsylvanian: Southern Illinois and western Kentucky.

Original reference: G. H. Cady, 1926, Illinois State Acad. Sci. Trans., v. 19, p. 257, 261, 262.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, pl. 1. Included in Bankston cyclothem, McLeansboro group. On correlation chart, shown below Bankston coal and above Anvil Rock sandstone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 48 (table 1), pl. 1. Reallocated to member status in Carbondale formation (redefined). Name Allenby coal member proposed for coal formerly called Bankston so that name may be restricted to Bankston Fork limestone. Stratigraphically above Anvil Rock sandstone member. Correlation chart shows Bankston Fork in western Kentucky. Type locality stated; location given by Cady (1926) incorrect. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NW¼ sec. 19, T. 19 S., R. 5 E., Saline County, Ill.

Banner Limestone

Pennsylvanian(?) or Permian(?): Northeastern Nevada.

A. E. Granger and others, 1957, Nevada Bur. Mines Bull. 54, p. 116, pl. 14. Thick-bedded grayish-blue limestone, altered to silicates in wide zone adjoining quartz monzonite contact; conglomerate at base grading into quartzite. Estimated thickness 500 to 1,100 feet. Unconformably overlies Rio Tinto formation (new); underlies Nelson amphibolite (new). Fauna suggests age assignment of probably Pennsylvanian or Permian(?). Mapped in Carboniferous(?).

Map shows Banner Hill in Elko County.

Bannock Volcanic Formation[1]

Precambrian or Lower Cambrian: Southeastern Idaho.

Original reference: A. L. Anderson, 1928, Idaho Bur. Mines and Geology Pamph. 38, p. 3.

J. C. Ludlum, 1942, Jour. Geology, v. 50, no. 1, p. 88–89. Stratigraphically restricted to exclude upper sediments which are renamed Pocatello formation. Redefined as a series of lavas, tuffs, and volcanic breccias. Minimum thickness 400 feet. Precambrian.

Named for its occurrence in Bannock Range, Bannock County.

Baraboo Quartzite[1]

Precambrian: Central southern Wisconsin.

Original reference: R. D. Irving, 1877, Geology Wisconsin, v. 2, p. 504–519, 539, 542.

N. A. Riley, 1947, Jour. Geology, v. 55, no. 6, p. 453–475. Discussion of structural petrology of Baraboo quartzite. Thickness more than 4,000 feet. Underlies Seeley slate; overlies rhyolite, tuff, and granite. Algonkian.

Type locality and derivation of name not stated. Crops out in Baraboo area, Sauk and Columbia Counties.

Baraboo series[1]

Precambrian: Central southern Wisconsin.

Original reference: S. Weidman, 1904, Wisconsin Geol. and Nat. History Survey Bull. 13, Econ. ser. no. 8, p. 4, 22, 161, 162, 169–171.

In Baraboo region, Sauk County.

Baraga Group

Precambrian (Animikie Series) : Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 27, 30 (table 1), 35–36. As defined, comprises most of strata referred to as Upper Huronian of previous reports, namely, Goodrich quartzite (basal formation), and Michigamme slate, the lower part of which in Marquette district includes Bijiki iron-formation member, Clarksburg volcanics member, and Greenwood iron-formation. In Iron and Dickinson Counties, six formations are represented: Goodrich quartzite (lowermost unit), Hemlock formation, Fence River formation, and its probable correlative, Amasa formation, Michigamme slate, and Badwater greenstone (new). In the sequence, Baraga is younger than Menominee group and older than Paint River group (new).

Named for Baraga County in which rocks of group are widely exposed.

Baranos Beds

See Bolanos Beds, Andesite, or Formation.

Barata Limestone (in Saavedra Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11. Streaked calcareous sandstone near the top and fossiliferous limestone below. Thickness 2 feet. Separated from overlying Arkill (new) by 12 feet of buff sandstone.

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Bar B Formation (in Magdalena Group)

Pennsylvanian: Southwestern New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 93–94, 253–254, figs. 2, 11. Consists dominantly of thin-bedded limestone and shale in alternating thin intervals. Cherty and noncherty limestone present. Chert commonly mottled and weathered tan or yellowish brown. Uppermost beds intercalated with reddish-brown siltstone, limestone conglomerate, and calcareous sandstone through interval of about 50 feet. Comprises upper third of group and is 339 feet thick at type section. Underlies Abo formation with transitional contact; conformably overlies Nakaye formation (new). Whereas 80 percent of Nakaye formation is limestone and remainder shale, ratio is nearly reversed in the Bar B formation.

Type section: In Caballo Mountains on South Ridge, sec. 10, T. 15 S., R. 4 W., Sierra County. Name taken from Bar B Draw east of Blue Mountain where, near head of draw formation is widely exposed.

Barbacoas Formation

Oligocene(?): Panamá.

R. T. Hill, 1898, Harvard Coll. Mus. Comp. Zoology Bull., v. 28, no. 5, p. 183–187, 206, 209. Loosely cemented white earthy rock composed of firm fine particles, apparently siliceous, but water sorted, and showing distinct lines of lamination, in alternating degrees of fineness and coarseness. Grades down into mass of brownish rock called San Pablo phase of Barbacoas. Term Panamá formation used to include analogous deposits of Barbacoas, San Pablo, and Miraflores.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 325. An informal name for tuff at a now submerged locality in Canal Zone. Oligocene(?).

At Barbacoas, Canal Zone.

Barberian series

Mesozoic (Early Cretacic): Southwestern Kansas and New Mexico.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 2, p. 105 (chart), p. 147-149; no. 3, p. 201. Name applied to early Cretacic rocks of Kansas. Includes Kiowa and Garrett shales. Term also extended into New Mexico.

Named for Barber County, Kans.

Barboursville Silts

Pleistocene (Illinoian): Western West Virginia.

D. P. Stewart, 1952, West Virginia Acad. Sci. Proc., v. 23, p. 113–115. Name applied to silts in vicinity of Barboursville. Thickness about 85 feet. Silts believed to have been deposited during slack water stage when waters of Cincinnati River and its tributaries were backed up behind Illinoian ice.

Barboursville is on Mud River in Cabell County. Silts extend from river southward to valley walls.

†Barclay Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: J. W. Beede, 1902, Kansas Univ. Sci. Bull., v. 1, p. 175.

Probably named for Barclay, Osage County.

Bardons Peak Grabbro (in Duluth Gabbro Complex)

Precambrian (middle Keweenawan): Northeastern Minnesota.

R. B. Taylor, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 1, p. 42, 46 (table 1), 56. Name applied to a coarse-grained melagabbro in the Duluth gabbro complex. Unit is approximately 200 feet thick, dips irregularly about 35° to northeast, and can be traced for about 1½ miles.

Exposed along Canadian National Railroad, northwest of Duluth, in St. Louis County.

Bar Harbor Series[1]

Bar Harbor detrital facies (of Frenchman Bay Series)

Silurian: Southeastern Maine.

Original reference: N. S. Shaler, 1889, U.S. Geol. Survey 8th Ann. Rept., pt. 2, p. 1037, 1047–1052, 1060, map.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1797. Considered facies of Frenchmans Bay series (new). Interfingers with, and is of same age as, Cranberry Island volcanic facies. Silurian.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 172–173. Detrital facies consists of thin-bedded or shaly-looking submetamorphosed quartzose silts. Developed extensively in northern and northeastern parts of Mount Desert Island.

C. A. Chapman and P. S. Wingard, 1958, Geol. Soc. America Bull,. v. 69, no. 9, p. 1194. Correlation table shows Bar Harbor series Lower or Middle Devonian.

Named for Bar Harbor Landing, Mount Desert Island, Hancock County.

Baring Migmatites

[Paleocene or older] : Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. Were thrust over Stillaguamish rocks, producing intense cataclasis and truncation of earlier structures in autochthon and allochthon.

In central part of Skykomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

†Barker Formation[1]

Middle and Upper Cambrian: Central northern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 3. Mentioned in discussion of history of work on Cambrian system in and near western Montana.

Well exposed near Barker and in broad valley of Pilgrim Creek and cliffs to north, Fort Benton region.

Barker Porphyry[1]

Post-Cretaceous: Central Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 56.

F. C. Armstrong, 1957, Econ. Geology, v. 52, no. 3, p. 221. Mentioned in report of Montana as a source area of uranium. Locally Flathead quartzite has been intruded by post-Cretaceous Wolf and Barker porphyries.

Forms Big Baldy Mountain to south of Barker, Little Belt Mountains.

Barker Quartzite[1]

Lower Cambrian: Southwestern Vermont.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 401.

Probably named for Barker Hill, 4 miles east of north from Castleton, Rutland County.

Barker Syenite[1]

Age(?) : Montana.

Original reference: L. V. Pirsson, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 465–468.

Forms intrusive mass north of Barker, Cascade County.

Barker Dome Tongue (of Cliff House Sandstone)

Upper Cretaceous: Northwestern New Mexico and southwestern Colorado.

P. T. Hayes and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144, sheet 1. Most extensive tongue of basal Cliff House sandstone in Menefee formation in Barker Dome-Fruitland area is here named Barker Dome tongue. Southwestern wedge-edge of this tongue trends N. 45° W., as determined by exposures in Mancos Canyon and at Barker Dome. From this depositional edge, tongue extends approximately 2½ miles northeastward before it coalesces with main body of Cliff House sandstone. Contacts are sharp.

Crops out on Barker Dome, Southern Ute Dome, and in upper drainage of Barker Creek, San Juan County, N. Mex.; also in walls of Mancos Canyon, Colo.

Barkerian series[1]

Cambrian: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Barkley quartzites[1]

Lower Cambrian: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 38.

Derivation of name not stated.

Barlow Cove Formation

Permian and Triassic(?): Southeastern Alaska.

Fred Barker, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–100. Largely chlorite-epidote-albite schist with minor amounts of augite-bearing volcanic flow breccia, andesite, quartz-pebble graywacke conglomerate, laminated massive homogeneous graywacke, and black slate. Well-defined member of chlorite-epidote-albite schist, slate, graywacke, and quartz-pebble conglomerate, approximately 300 to 800 feet thick extends from Barlow Cove to Lone Mountain and delineates Lone Mountain fold. Total thickness approximately 6,500 feet. In contact with Retreat group (new) along bedding fault. Underlies Symonds formation (new).

U.S. Geological Survey currently designates the age of the Barlow Cove Formation as Permian and Triassic(?) on basis of study now in progress.

Type locality: Along eastern shore of Barlow Cove, Juneau (B–3) quadrangle. Extends from south boundary of the quadrangle northward to Barlow Point and Hump Island.

Barlow Pass Volcanics

Eocene: Northwestern Washington.

J. A. Vance, 1957, Dissert, Abs., v. 17, no. 9, p. 1985. About 4,000 feet of gently folded andesitic and basaltic and subordinately acidic flows, with prominent arkosic interbeds.

Occurs in Sauk River area in northern Cascades.

Barlow Ranch Beds

Pleistocene, lower: Southern California.

J. E. Eaton, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, no. 2, p. 124. Statement is made that Arnold tentatively correlated Barlow Ranch beds with upper San Pedro series or Palos Verdes formation of typical locality.

J. E. Eaton, 1943, California Div. Mines Bull. 118, pt. 2, p. 204, 205 (fig. 86) [preprint 1941]. Shown as underlying Hall Canyon and overlying San Pedro marine beds.

Occurs in Los Angeles and Ventura Basins.

Barnard Gneiss[1]

Cambrian or Ordovician: Southeastern and east-central Vermont.

Original reference: C. H. Richardson, 1924, Vermont State Geologist Rept. 1923–1924, p. 91–92.

P. H. Osberg, 1952, Vermont Geol. Bull. 5, p. 116. Lower and Middle Ordovician.

Well exposed in Barnard Township, Windsor County.

Barnegat Limestone[1]

Lower Cambrian to Middle Ordovician: Southeastern New York.

Original reference: W. W. Mather, 1838, New York Geol. Survey 2d Rept., p. 168–169.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 329, 343. Rejected because of lack of usage.

Extends from Barnegat up Wappingers' Creek, by Pleasant Valley and Pine Plains into Columbia County, and on south it passes from Milton to Newburg; on the west down the great valley through New Jersey into Pennsylvania.

Barnes Conglomerate Member (of Dripping Spring Quartzite)

Barnes Conglomerate (in Apache Group)[1]

Precambrian: Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. Composed of smooth, ellipsoidal pebbles in matrix of coarse arkosic sand firmly cemented by silica in Globe quadrangle. Thickness 6 inches to 50 feet; commonly 10 to 20 feet. Overlies Pioneer formation; underlies Dripping Spring quartzite.

U.S. Geological Survey currently classifies the Barnes Conglomerate as a member of Dripping Springs Quartzite on the basis of a study now in progress.

Forms conspicuous strata girdle about Barnes Peak, Globe district.

Barneston Limestone (in Chase Group)

Barneston Formation (in Chase Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, ser. 2, p. 41.

R. C. Moore, 1936, Kansas Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12 (fig. 4), 69 (fig. 45). Includes Oketo shale member (new).

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44–45. Includes (ascending) Florence limestone, Oketo shale, and Fort Riley limestone members. Thickness 80 to 90 feet. Underlies Holmesville shale member of Doyle shale; overlies Blue Springs shale member of Matfield shale. Wolfcamp series.

Type locality: In bluffs west and southwest of Barneston, Gage County, Nebr.

Barnett Shale[1] **or Formation**

Mississippian: Central Texas.

Original references: F. B. Plummer and R. C. Moore, 1921 [1922], Texas Univ. Bull. 2132, p. 24–31; R. C. Moore and F. B. Plummer, 1922, Jour. Geology, v. 30, no. 1, p. 25 (chart), 26–28.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 52–59. Sellards (1932 [1933], Texas Univ. Bull. 3232) designated unit Barnett formation, and present report [Ellenburger group of central Texas] follows this emendation. Although Barnett strata are largely shale in east and north and contain fauna similar to that of Moorefield formation and Ruddell shale of Arkansas, strata of Barnett age in southwestern part of Llano region grade laterally into detrital limestone containing fossils of strong Keokuk affinities and lesser affinities with younger strata. Only section described by Plummer and Moore (1921) was presumably above type section of Chappel limestone and about 2.2 airline miles southwest along Simpson Creek fault zone from type locality. This is locality 205–T–24 from which Plummer and Scott (1937, Texas Univ. Bull. 3707) collected goniatities, and it shows best section of the Barnett in vicinity of type locality. Formation ranges in thickness and character from 40 to 50 feet of mostly shale in vicinity of type locality to featheredge on one hand, and on the other hand to thickness of about 140 feet of mostly crinoidal limesands in Bear Spring area in Mason County. Formation was considered to be probably Pennsylvanian at time of its description but is now commonly accepted as Mississippian. Lower limit of age is fixed as Keokuk but upper limit might be as high as Ste. Genevieve. Present authors consider it unlikely that any part of Barnett is as young as Chester as it is their opinion that it is actually entirely pre-St. Louis if not pre-Spergen.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 32–46. Formation occurs as narrow band of outcrop between Marble Falls and Ellenburger along almost entire area of Ellenburger outcrop. It is thin and entirely absent in places around Brady and absent along most of Ellenburger border south of Colorado River in Marble Falls, Spicewood, and northeast Kimble County districts. Thickness 5 to 90 feet. In some areas, underlies Sloan formation of Marble Falls group; overlies Chappel limestone which is herein subdivided into [ascending] Kings Creek marl, Ives conglomerate, Espey Creek limestone, and Whites Crossing coquina members.

W. H. Hass, 1953, U.S. Geol. Survey Prof. Paper 243–F, p. 69–94. Formation, in Llano region, contains two conodont faunal zones. Upper zone is restricted to that part of formation which in this report is regarded as being definitely of Meramec age and possibly also partly of Chester age; lower zone is regarded as being Osage (Keokuk) age. For most part, base of Barnett is easily recognized, though it is now known that, at many localities, a thin sequence of Mississippian and Devonian beds is present between the Barnett and Ellenburger groups. Opinions differ as to where base of Barnett should be drawn in southwest quadrant of region, as beds occur there which some stratigraphers place in Chappel limestone but which others place in Barnett formation (Cloud and Barnes, 1948; Plummer, 1950).

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 808, 810, pl. 2. Plummer's (1950) Whites Crossing coquina member of Chappel formation is an echinodermal limestone facies in lower part of Barnett formation. In some areas, Chappel limestone is missing, and the Barnett overlies Houy formation (new).

Named from Barnett Springs, about 5 miles east of San Saba, near which is typical exposure of the shale.

Barnett Hill Formation

Bendian (Morrow Series): Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 858, 859, 902–912. Proposed for uppermost formation of series in area; unit formerly considered unnamed upper member of Wapanucka here restricted to exclude the Barnett Hill. Consists of calcareous, fossiliferous sandstones and shales; siliceous shale near base; changes laterally within short distances; typically an overlapping deposit. Thickness varies; at first type section 415 feet; at second type section 760 feet. Underlies Atoka formation; north of Arbuckles and in frontal Ouachitas overlies Wapanucka (restricted); in southern Ouachitas overlies Round Prairie formation (new). Morrow series is here included above Pushmataha series in upper part of the Bendian period.

R. B. Laudon, 1958, Oklahoma Geol. Survey Circ. 46, p. 20. Harlton suggested separation of Barnett Hill formation containing an unquestionable Morrow fauna from the Atoka. Barnett Hill has been included in the Wapanucka but lithologically is almost inseparable from the overlying Atoka, and for this reason its status as a separate formation is open to criticism. Subsequent workers have not separated the Barnett Hill from the Atoka.

Type locality: Barnett Hill, 1 mile north of Clarita, sec. 2, T. 1 S., R. 8 E., Coal County. Second type locality: Goose Creek in secs. 19 and 20, T. 1 N., R. 8 E.

Barnhart Formation

Ordovician: Eastern Missouri.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1 p. 116. Name proposed for the "Decorah" of Missouri which overlies Plattin group and underlies Kimmswick formation. Consists of about 20 feet of greenish shale with interbedded thin limestones, all abundantly fossiliferous.

Type section: At Koch Valley School on U.S. Highway 61–67, 2 miles south of Barnhart, Kimmswick (15′) quadrangle, Jefferson County.

Barnsdall Formation (in Ochelata Group)

Pennsylvanian (Missouri Series): North-central Oklahoma.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 119, 120, 121. Consists of sandstone and limestone. At Kansas-Oklahoma line, consists of Birch Creek limestone at base and two unnamed shale members that are separated by inconspicuous unnamed sandy limestone less than 2 feet thick. Southward this unnamed sandy limestone grades into sandstone continuous with Okesa sandstone member. Farther south, the Okesa is much thicker at the expense of the two shale members, and includes, as its basal bed, limy sandstone that is equivalent to Birch Creek limestone.

Upper shale member contains Wildhorse dolomite bed only a few feet below the top of formation. Unconformably overlies Wann formation; conformably underlies Tallant formation (new). Thickness about 100 feet.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 38–41, pls. Extends from Kansas-Oklahoma line southward through western Washington County, eastern Osage County, western Tulsa County, and western Okfuskee County to Canadian River. Thicknesses: 100 feet at Kansas-Oklahoma line, T. 29 N., R. 12 E.; 110 feet in T. 23 N.; 45 feet in T. 22 N.; 190 feet in T. 19 N., R. 9 E., western Tulsa County. Irregular in thickness in Creek County, ranging upward from about 140 feet in T. 18 N. to 200 feet in north part of T. 17 N., and thence downward to about 100 feet in south part of T. 14 N. Includes Okesa sandstone member. Rests unconformably upon Wann formation across Creek County, truncates Iola formation in southern Creek County, and rests unconformably upon Chanute formation. In Creek County, conformable with Tallant formation above but is overlain unconformably by lower Virgil rocks across most of Okfuskee County to south.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 18–20. Wildhorse dolomite member, which occurs near top of formation in Osage County, is not found south of Arkansas River.

Type locality: Area between Barnsdall and Wolco, T. 24 N., R. 11 E., Osage County. Name is from town of Barnsdall, formerly Bigheart. This is same town from which Bigheart sandstone was named (White and others, 1922). Type locality of Bigheart is in hills west of the town, and name of town has been changed to Barnsdall. Town now called Bigheart is in sec. 3, T. 27 N., R. 10 E., Osage County, and is on the outcrop of neither Barnsdall formation or Bigheart sandstone.

†Barnstable Series[1]

Pleistocene: Southeastern Massachusetts.

Original reference: N. S. Shaler, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 503–593.

Named for occurrence at Barnstable, Barnstable County.

Barnwell Sand[1] or Formation[1] (in Jackson Group)

Eocene, upper: Southwestern South Carolina and eastern Georgia.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 17

C. W. Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 61–67. In this report, Cooke and Shearer's (1918, U.S. Geol. Survey Prof. Paper 120) usage is adopted, except that part of the so-called Congaree clay is restored to the McBean formation. Further subdivided in Georgia to include Sandersville limestone member in upper part. Thickness estimated as less than 200 feet in eastern Georgia and a little more than 200 feet in Twiggs County, where Twiggs member accounts for nearly half the thickness. Unconformably overlies McBean formation and overlaps beyond it across Tuscaloosa formation to crystalline rocks of Piedmont; toward southwest end of outcrop area, merges laterally into Ocala limestone; at most places, the Flint River formation or Hawthorn formation overlaps beyond seaward edge of Barnwell and lies unconformably on it.

P. E. LaMoreaux, 1946, Georgia Geol. Survey Bull. 50, pt. 1, p. 3 (fig. 1), 9–22. In east-central Georgia divided into three members: basal Twiggs clay member, Irwinton sand member (new), and unnamed thin upper member of coarse red sand with flat rounded beach pebbles. East of Ogeechee River, formation is undifferentiated. This study indicates that no part of the so-called Congaree clay or Twiggs clay is of Claiborne age, and that base of Barnwell in this area is base of Twiggs clay member which rests unconformably on the Tuscaloosa except where channel sands are present.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 20, 26–27. Discussed in South Carolina where it is undifferentiated and is only true representative of the Jackson among outcropping formations. Large part of deposits formerly mapped as Barnwell have proved to be Congaree. Name Barnwell formation was applied to leached residues of sandy limestone, and no type locality was ever designated. It now appears that actually the railroad cut at Barnwell was made in a part of Miocene Hawthorn formation, although many geologists must have regarded it as typical Barnwell. Residues of limestone of Jackson age certainly are present elsewhere in Barnwell County beneath Hawthorn cover, and there is no reason why name Barnwell cannot be applied to unleached Jackson beds farther downdip even though type area falls entirely within area of solution.

J. F. L. Connell, 1958, Southwestern Louisiana Jour., v. 2, no. 4, p. 321–322, 327–329, 343 (fig. 15). Basal part of Barnwell, extending from central Georgia to Savannah River, is termed Twiggs clay member. Conformably above the Twiggs is Irwinton sand member, which is overlain by much localized unit, the Sandersville member. In a few areas near overlap of Barnwell on Precambrian crystalline rocks, the Upper Sand member (LaMoreaux, 1946) is designated as part of the Barnwell. In present investigation, stratigraphically higher beds of argillaceous red sand making up typical uppermost Barnwell were found to crop out above the Irwinton and Upper Sand members in Glascock and Jefferson Counties. As much as 7 to 15 feet of massive brilliant- to dark-red fine-grained argillaceous unconsolidated quartz sand occurs in these two counties. To southwest, in Crawford County, 40 feet of these uppermost Barnwell sands occur at Rich Hill, and south of town of Roberta. At this locality, these sands lie with conformity on Twiggs clay, the Irwinton and Upper Sand members being absent. North of Fort Valley, Peach County, summits of highest hills are capped by dark-red argillaceous quartz sand unlike the Irwinton and Upper Sand members. The uppermost sands are herein designated Roberta sand member.

Type area: Barnwell County, S.C.

Barrack Mountain Granite Gneiss[1]

Precambrian(?): Northwestern Connecticut.

Original reference: W. M. Agar, 1929, Am. Jour. Sci., 5th, v. 17, p. 204, 211.

Rock forms Barrack Mountain, 1 mile south of Falls Village, Litchfield County.

Barranquitas Shaly Limestones[1]

Upper Cretaceous: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 29.

J. D. Weaver, *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 316–317, Upper Cretaceous.

Crop out in northwest-southwest belt of unknown extent, in vicinity of Barranquitas in central Puerto Rico and form crest of island in that area.

Barranquitas-Cayey Series

Lower Cretaceous: Puerto Rico.

E. T. Hodge, 1920, New York Acad. Sci., Scientific Survey of Porto Rico and the Virgin Islands, v. 1, pt. 2, p. 132–137. Chiefly shales and shaly limestones with numerous limestone lenses and an occasional bed of tuff and conglomerates. Thickness 2,000 to 3,000 feet. Lower part grades into Rio de la Plata series; upper part forms sharp contact with Sierra de Cayey series.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 37, 38, 39. Lower Cretaceous.

Named from two villages situated on rocks in northeast corner and in eastern margin of Coamo-Guayama district.

Barre Granite[1]

Devonian: East-central Vermont.

Original reference: C. H. Richardson, 1902, Vermont State Geologist 3d Rept., p. 61–98.

V. R. Murthy, 1957, Vermont Geol. Survey Bull. 10, p. 70–73. Barre granite is an elongated, oval-shaped body that crops out in northwestern and west-central parts of East Barre quadrangle. Outcrop is confined to Westmore formation except at eastern margin, near East Barre village, where it extends a short distance in Waits River formation.

Occurs mostly in Barre Township, Washington County, with small area in Williamstown Township, Orange County.

Barre Group

Silurian: Eastern Vermont.

V. R. Murthy, 1958, Jour. Geology, v. 66, no. 3, p. 276, 278–282, 286 (fig. 4). Proposed that section regarded as Waits River formation by Currier and Jahns (1941) be elevated to status of group—to be called Barre group. Includes (ascending) Barton River, Westmore, and Waits River (redefined) formations. In its stratigraphic limits, group is identical with old Waits River formation. Overlies Northfield slate.

Type locality and derivation of name not given. Report includes Barre-East Barre area.

Barree Limestone[1]

Silurian: Central Pennsylvania.

Original reference: I. C. White, 1885, Pennsylvania 2d Geol. Survey Rept. T_3, p. 132–133.

Outcrop belt crosses Little Juniata River at Barree forge, and it is quarried for flux at Barree furnace, Huntingdon County.

Barree Shales[1]

Silurian: Central Pennsylvania.

Original reference: I. C. White, 1885, Pennsylvania 2d Geol. Survey Rept. T_3, p. 133.

Exposed along river bank below Barree furnace, Huntingdon County.

Barrelian series[1]

Cambrian: California.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 56, p. 76.

Barrel Spring Formation[1]

Barrel Spring Formation (in Eureka Group)

Middle Ordovician: East-central California.

Original reference: F. B. Phleger, 1933, Southern California Acad. Sci. Bull., v. 32, pt. 1, p. 1–6.

R. L. Langenheim, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2086 (fig. 2), 2087 (fig. 3), 2091–2092. Described in Mazourka Canyon area, Independence quadrangle. Thickness about 100 feet at Mexican Gulch to 150 feet at Lead Canyon Trail. Consists of sandstone, shale, and limestone. Divided into four unnamed members. Overlies Mazourka formation; underlies unnamed unit referred to as undifferentiated upper part of Eureka group.

H. R. Pestana, 1960, Jour. Paleontology, v. 34, no. 5, p. 109–112. Underlies Johnson Spring formation (new), which is name proposed for undifferentiated upper part of Eureka group of Langenheim and others (1956).

Well exposed in Barrel Spring Canyon and in each of next four canyons to the north, Inyo Range.

Barrett Shale[1]

Lower Cretaceous: Northeastern Wyoming and western South Dakota.

Original reference: W. P. Jenney, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 593, fig. 122, map.

Mapped at and around Barrett, Crook County, Wyo.

Barrigada Limestone

Miocene, upper, and Pliocene: Mariana Islands (Guam).

H. T. Stearns, 1940 (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1948. Includes quantities of reef talus; now forms northern plateaus of island.

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 59, table 4 [English translation in library of U.S. Geol. Survey, p. 69]. Older than Merizo limestone.

U.S. Geological Survey currently designates age of Barrigada Limestone as upper Miocene and Pliocene on basis of study now in progress.

Forms northern plateau of island.

Barrington Clays[1]

Pleistocene (Wisconsin Stage): Rhode Island.

Original reference: J. B. Woodworth, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 987–988, chart opposite 988, pl. 62.

Present in town of Barrington, Bristol County.

Barron Quartzite[1]

Precambrian (Keweenawan): Northwestern Wisconsin.

Original reference: N. H. Winchell, 1895, Am. Geologist, v. 16, p. 150–162.

E. F. Bean, 1959, Geologic map of Wisconsin (1:1,000,000): Wisconsin Geol. Nat. History Survey. Varies from soft sandstone to hard vitreous quartzite. Maximum known thickness 600 feet. Average thickness probably not more than 200 feet. Exact correlation not known; probably Upper Keweenawan.

Present in eastern part of Barron County.

Barrow Trail Member (of Schrader Bluff Formation)

Upper Cretaceous: Northern Alaska.

C. L. Whittington, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 246, 249, 250–251, fig. 5. More than one-half the member at type locality is fine- to very fine-grained light-gray to olive-gray thick-bedded sandstone, in part bentonitic to tuffaceous. Interbedded with sandstone are clay shale, siltstone, bentonite, and tuff. Marine fossils found at five horizons from 40 feet to 525 feet above base. A minor nonmarine tongue of Prince Creek formation represented in this type section by a 2-foot coal bed about 170 feet above base. Thickness 575 feet in vicinity of Umiat, at least 700 feet and possibly as much as 900 feet at Schrader Bluff. Underlies Sentinel Hill member; overlies Rogers Creek member (new.) Rogers Creek and Barrow Trail members defined to include rocks overlying Tuluvak tongue of Prince Creek formation that were formerly included in Tuluga member.

Type locality: Bluffs along north side of Colville River, 3 to 5 miles northeast of Umiat Mountain. Named from Barrow Trail, and old tractor trail which, in the area from 13 to 28 miles west of Umiat Mountain, follows cuesta formed by sandstones of this member.

Barryville Member[1] (of Shohola Formation)

Barryville parvafacies (in Shohola facies group)

Upper Devonian: Southeastern New York and northeastern Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4 p. 571, 586–587.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7). Shown as a parvafacies.

Well displayed on New York side of Delaware River in vicinity of Barryville, Sullivan County, N.Y.

Barstovian Age

Miocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 12, pl. 1. Provincial time term based on Barstow formation, San Bernardino County, Calif., and specifically on fossiliferous tuff member in Barstow syncline and its fauna. Covers interval between Hemingfordian (Miocene) and Clarendonian (Pliocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

Barstow Formation[1]

Miocene, middle and upper: Southern California.

Original reference: O. H. Hershey, 1902, Am. Geologist, v. 29, p. 369–370.

F. M. Byers, Jr., 1960, U.S. Geol. Survey Bull. 1089–A, p. 26–35, pls. 1, 2. Described in Alvord Mountain quadrangle, where it consists of three members: lower that consists of 500 to 600 feet of interbedded sandstone and pebble conglomerate overlain by 200 to 300 feet of tuff, tuffaceous sandstone, siltstone, and volcanic pebble conglomerate; tuffaceous middle member about 25 feet thick that comprises two or three, rarely more, friable white granular tuff beds and intervening clastic beds; upper member, as much as 500 feet thick, of sandstone, siltstone, and conglomerate. Maximum thickness about 1,500 feet. Conformably overlies Spanish Canyon formation (new) and rests unconformably on older formations. Upper contact conformable and gradational with overlying granitic fanglomerate in downfaulted block of fanglomerate at NW cor. sec. 30, T. 12 N., R. 4 E. Main contact around north side of Alvord Mountain is slight angular unconformity, in which upper part of Barstow and lower part of granitic fanglomerate are missing. Middle and late Miocene on basis of vertebrate fossils.

Type section: Near Barstow, San Bernardino County.

Bartholomew Siltstone Member (of Orangeville Shale)

Mississippian: Northwestern Pennsylvania.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1347, 1351, 1364; J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 18 (fig. 9), 42–43. Name proposed for gray or brownish-gray siltstone at or near base of Orangeville shale. Characterized by many short curved or curly markings which generally have a random distribution; in unweathered state, markings are darker than rest of siltstone. Thickness less than 1 foot. Occurs 8 feet above base of Orangeville at type locality; overlies Shellhammer Hollow formation (new) in some other areas. Lower Mississippian.

Type locality: Bartholomew Quarry section 1 mile northwest of Littles Corner on a small run, Hayfield Township, Crawford County. Also occurs in Erie and Venango Counties.

Bartlett Barren Member (of Crevasse Canyon Formation)

Bartlett Barren Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1925, U.S. Geol. Survey Bull. 767.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2153 (fig. 3), 2156, 2157. In revised nomenclature of Mesaverde group, San Juan basin, New Mexico, Bartlett barren member is reallocated to Crevasse Canyon formation. Overlies Dalton sandstone member; underlies Gibson coal member.

Named for exposures near old Bartlett mine shaft, McKinley County.

Bartlett Island Schist

Bartlett Island Series[1]

Precambrian or Cambrian: Southeastern Maine.

Original reference: N. S. Shaler, 1889, U.S. Geol. Survey 8th Ann. Rept., pt. 2, p. 1037, 1038–1041, 1060.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1797. Age no greater than Cambrian. Older than Frenchmans Bay series.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 172, 176. Referred to as Bartlett's Island schist. Was incorrectly renamed Ellsworth schist.

Named for development on Bartlett Island located off west coast of Mount Desert Island, Hancock County.

Bartolo conglomerate

Miocene and Pliocene: Southern California.

G. J. Bellemin, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 652 (fig. 1), 658. Named as one of five conglomerates interbedded in Miocene and Pliocene shales of Puente Hills, Los Angeles County.

Crops out in a nameless canyon in northern section of the hills, due east of Bartolo Station on Union Pacific Railroad.

Barton Clay (in Conemaugh Formation)[1]

Barton clay shale member

Pennsylvanian (Conemaugh Series): Central eastern Ohio.

Original reference: R. E. Lamborn, 1930, Ohio Geol. Survey Bull. 35, p. 137–138.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 68, 70. Barton clay shale included in Barton cyclothem although not present in area of report, Perry County.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 46–47, fig. 7. In Morgan County, Barton clay shale member (of Conemaugh series) includes the 6 to 11 feet of section between Ewing limestone member below and Barton coal member above.

First described in Jefferson County. Named for association with Barton coal.

Barton cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 16. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 68–71, table 1, geol. map. Includes (ascending) Cow Run shale and (or) sandstone, 30 feet; Ewing limestone, 3 to 8 feet; and Barton clay shale and Barton coal (absent in Perry County). Occurs below Harlem cyclothem and above Anderson cyclothem. In area of this report, Conemaugh series is described on a cyclothemic basis; seven cyclothems are named. [For sequence see Mahoning cyclothem.]

Exposed in Perry County.

Barton Gneiss[1]

Precambrian: Northeastern New York.

Original reference: J. F. Kemp, 1898, Am. Inst. Mining Engineers Trans., v. 27, p. 178, map and cross sections.

Occurs near Port Henry, Essex County.

Barton Group (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: J. J. Stevenson, 1877, Pennsylvania 2d Geol. Survey Rept. K_2, p. 67.

Barton Limestone (in Conemaugh Formation[1] or Group)

Pennsylvanian: Western Maryland and southwestern Pennsylvania.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 573.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C-26, p. 96-97. In Fayette County, Barton limestone occurs 8 feet below Barton coal, which is separated from overlying Morgantown sandstone by 12 feet of black shale. Limestone is 3 feet thick, dark gray, knobby, and impure. Directly overlies Birmingham red shale.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook for Field Trips, Pittsburgh Mtg., p. 69 (fig. 4). Barton limestone shown on generalized columnar section for Pennsylvanian of western Pennsylvania. Above upper Grafton sandstone and below Barton (Elk Lick) coal. Conemaugh series.

First described in Allegany and Garrett Counties, Md.

Barton Red Shale (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 65.

In Potomac basin.

Barton Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 573.

Allegany and Garrett Counties.

Barton Canyon Member (of Windfall Formation)

Cambrian: Eastern Nevada.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 161. Name applied to marker bed near base of formation. Consists of 25 to 35 feet of homogeneous medium- to light-gray aphanitic or finely clastic limestone in beds 2 to 3 feet thick.

Named from exposures in Barton Canyon of Cherry Creek Range, Ely quadrangle.

†Barton Creek Limestone[1]

Lower Cretaceous (Comanche Series); Central Texas.

Original reference: R. T. Hill and R. A. F. Penrose, Jr., 1889, Am. Jour. Sci., 3d, v. 38, p. 470.

Exposed on Barton Creek near Austin above the ford, also in high bluffs of the Colorado at and opposite Johnson's quarry; also in west bluff of Mount Bonnel, Travis County.

Barton Creek Limestone (in Millsap Lake Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1929, Texas Bur. Econ. Geology, geol. map of Palo Pinto County.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec. [Guidebook] May 11-12, p. 70. Listed in summary of nomenclature of Morrow, Bend, and Strawn series, Fort Worth basin area. Millsap group, Strawn series. Lies lower in section than Santo limestone and above Buck Creek sandstone. Name not now in use.

Barton Creek, Palo Pinto County.

Barton River Formation (in Barre Group)

Barton River Member (of Waits River Formation).

Silurian or Devonian: Northeastern Vermont.

C. G. Doll, 1951, Vermont Geol. Survey Bull. 3, p. 15, 25–32. Lower part of formation consists of mostly slates and phyllites intercalated with limestones and calcareous schists. Calcareous rocks are more abundant toward top; phyllites most common at top. Thickness difficult to determine because of overturning, about 8,800 feet. Underlies Westmore formation (new); unconformably overlies Ayers Cliff formation. No recognizable fossils found; assigned to Silurian because of stratigraphic position.

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 12, 16–19, pl. 1. Rank reduced to member of Waits River formation; age given as Lower(?) to Middle(?) Devonian. Base not exposed in area of this report [Lyndonville quadrangle].

V. R. Murthy, 1958, Jour. Geology, v. 66, no. 3, p. 277, 279. Formation included in Barre group (new). Waits River formation restricted in this report. Formation crops out in belt about 1½ miles wide in northwestern corner of East Barre quadrangle, where it is in contact with Northfield slate and has total outcrop width of about 6½ miles. Average dip of beds of unit is taken at 45°, and, assuming that repetition of beds due to minor isoclinal folds is compensated by tectonic thinning, approximate thickness of formation is about 21,700 feet. Doll (1951) considered Barton River formation equivalent to middle part of present Barre group, but in view of the fact that it lies immediately above Northfield slate in Barre area, present writer [Murthy] considers this equivalent to lower part of Barre group. Age controversial.

Type locality: In Newport City in low cut along main highway to Derby and on south flank of Shattuck Hill, Memphremagog quadrangle. Named from good exposures on higher slopes of Barton River valley. Continuous from southern border of Memphremagog quadrangle, northeastward into Canada.

Basco Formation

Ordovician: Northeastern Nevada.

D. W. Lovejoy, 1959, Geol. Soc. America Bull., v. 70, no. 5, p. 545–551, 559, pl. 1. Consists of four members: basal calcareous siltstone that includes a sandstone bed and lenses of altered peridotite; lower chert; shale; upper chert. Thickness about 1,750 feet. Calcareous siltstone contains Lower Ordovician graptolites and shale contains Middle Ordovician graptolites. Underlies Silurian siltstone.

Type locality: Valley slopes north and south of Basco Creek, Elko County. Crops out in thrust slice southwest of Lone Mountain. Belt of outcrop trends northwest and is about one-half mile wide and 2½ miles long.

Bascom Formation (in Stockbridge Group)

Bascom Formation (in Beekmantown Group)

Ordovician: West-central Vermont and northwestern Massachusetts.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524, 539, 540, 542–545. In addition to limestone, formation contains dolomite, sandstone, quartzite, limestone breccia, and sandy calcareous shales. Variation in lithology very distinctive. Four zones recognized. Generalized section for Hinesburg synclinorium is (ascending) white marble or limestone with thin sandy or argillaceous stripes; buff dolomite and thin-bedded dolomitic quartzites; "curdled" limestone, some bedded dolomite; and thin-bedded slaty quartzites and sandstones. Thickness approximately 375 feet. Underlies Bridport dolomite (new) conformably; overlies Cutting dolomite (new) conformably. Underlies Crown Point limestone east of meridian of Cornwall, west-central Vermont. Corresponds to Division D of the "Calciferous" (Brainerd and Seely, 1890, Am. Mus. Nat. History Bull., v. 3). Strata in west-central Vermont designated as lower Chazy (Brainerd, 1891, Geol. Soc. America Bull., v. 2, p. 299) actually appear to be uppermost Bascom beds of Beekmantown group (Beekmantownian).

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 27–28. In Castleton area, formation is included in Valley sequence. Overlies Columbian marble member of Boardman formation (new). Estimated thickness about 500 feet.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Included in Stockbridge group in Cheshire quadrangle, Massachusetts. Overlies Shelburne marble; underlies Berkshire schist, unconformity. Bascom may include beds that are equivalent in time to rocks of Chazyan age in Vermont.

W. M. Cady and E-an Zen, 1960, Am. Jour. Sci., v. 258, no. 10, p. 728–739. Bascom underlies the Chipman herein reduced to formation rank to include Burchards, Weybridge, Beldens, and Bridport members. Age of Chipman designated Lower Ordovician, Beekmantown age. [See Chipman formation, this reference.]

Named for "Bascom's Ledge" in eastern Shoreham Township, Addison County, Vt.

Baseline Sandstone

Upper Cretaceous: Southeastern Nevada.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, no. 5, p. 929 (table 1), 932–933, pl. 5. Friable sandstone, gray, reddish, and variegated. Contains many lenticular beds of conglomerate, some very coarse, especially in upper part. Change in textural character, together with the average higher coloration in upper part of section, is basis for dividing formation into two members. Maximum thickness of lower member about 2,000 feet; of upper member about 1,500 feet. Upper member restricted to a belt west of the Baseline fault; this member with part of lower member as well, eroded from eastern (upthrown) fault block. Overall thickness more than 3,000 feet. Underlies Overton fanglomerate with angular unconformity; overlies Willow Tank formation (new). Previously a part of Overton fanglomerate.

Exposed along Baseline Wash in Muddy Mountains, Clark County.

Basey Formation

Middle Jurassic: Northeastern Oregon.

W. R. Richardson, 1960, Dissert. Abs., v. 20, no. 11, p. 4367. Weberg, Warm Springs, and Basey (new) formations are lateral equivalents of Snowshoe formation.

Type locality and derivation of name not stated. Report discusses Izee area, Grant County.

Bashi Formation (in Wilcox Group)[1]

Bashi Marl Member (of Hatchetigbee Formation or Wilcox Formation)

Eocene, lower: Southern Alabama, Georgia, and southeastern Mississippi.

Original reference: A. Heilprin, 1882, Philadelphia Acad. Nat. Sci. Proc. 1881, p. 158–159.

V. M. Foster, 1940, Mississippi Geol. Survey Bull. 41, p. 53–61. Formation as described by Smith and Johnson (1887, U.S. Geol. Survey Bull. 43) is marked by 2 feet of lignitic and lignite clay at base overlain by 35 to 40 feet of yellowish crossbedded sand which grades upward into 25 feet or more of gray lignitic sandy clays and associated beds of lignite; top of formation is marked by 15 to 30 feet of glauconitic marl; passes up without apparent break into overlaying lignitic sands and clays of Hatchetigbee formation. Essentially same section, with exception of the basal lignite, is present in Mississippi, extending from southeastern corner of Lauderdale County to Meridian, near center of the County. In this area, typical Bashi marl is overlain by bed of sandy clay and silt which reaches thickness of 30 feet in some areas, and grades upward into lignitic sand and silt. This unit is here placed in Bashi formation although it has been considered to be basal Hatchetigbee by some earlier workers. Overlies Holly Springs formation.

L. D. Toulmin, Jr., 1944, Southeastern Geol. Soc. [Guidebook] 1st Field Trip, p. 9. Formation is here considered to be restricted to fossiliferous marine greensand marl, 6 to 20 feet thick in central and western Alabama, and to equivalent sand, clay, and fossiliferous marl beds, 40 feet thick or more, in eastern Alabama. Overlies Tuscahoma formation which includes about 70 feet of strata formerly included in the Bashi; underlies Hatchetigbee formation. Formation extends across state.

F. S. MacNeil, 1944, Southeastern Geol. Soc. [Guidebook] 2d Field Trip, p. 27–28; 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 22. Proposed that Bashi marl be allocated to member status in Hatchetigbee formation. Thickness 2 to 25 feet; in some places splits into two or three distinct beds and there thickness is greater.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Mapped as marl member of Wilcox formation.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart. 29. Correlation chart of outcropping Tertiary formations of Eastern Gulf region shows Bashi marl member of Hatchetigbee extending into Georgia.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 182–188, pls. 1, 5. Basal member of Hatchetigbee formation. Thickness about 40 feet in Kemper County. Overlies Tuscahoma sand.

Named for exposures on Bashi Creek, Clarke County, Ala., especially at Wood's Bluff, Tombigbee River, just below mouth of Bashi Creek.

†Bashi Marl[1]

Eocene, lower: Southwestern Alabama.

Original reference: E. A. Smith, 1887, U.S. Geol. Survey Bull. 43, p. 39, 43–46, 69.

Named for exposures on Bashi Creek, Clarke County.

Basic City Shale Member (of Tallahatta Formation)

†Basic Claystone (in Claiborne Group)[1]

Basic Claystone Member (of Tallahatta Formation)

Eocene, middle: Southeastern and north-central Mississippi.

Original reference: E. N. Lowe, 1919, Mississippi Geol. Survey Bull. 14, p. 74–75.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 15–24, fig. 1, pl. 2, profile C. Basic claystone member is stratigraphic and lithologic equivalent of type section of Tallahatta formation in Alabama. Term Basic is used here because it was found necessary to set up another member in Mississippi. Typical Tallahatta buhrstone section, herein called Basic claystone member, is well developed throughout eastern Mississippi, but, in central and western parts of its outcrop, the typical facies is largely replaced by sand section herein named Neshoba member. Thickness in eastern Mississippi 50 to 115 feet; 10 to 90 feet in central part of outcrop; 5 to 30 feet through southern and central Montgomery County. Overlies Meridian sand. At type locality, overlain by Winona greensand. In this report, base of Claiborne is placed at base of Basic member.

G. F. Brown and R. W. Adams, 1943, Mississippi Geol. Survey Bull. 55, p. 43–44, 55–56, pl. 1. Term Basic [pronounced like classic] was used by Lowe (1919) as member of Tallahatta formation for lightweight material, typically exposed in cuts on Gulf, Mobile, and Ohio Railroad in vicinity of Basic Station, Clarke County, which he described as claystone or diatomaceous earth. Other workers have indicated that indurated deposits at Basic are contemporary with Tallahatta shales and interfinger with them in northern Mississippi. As strike of member is followed northwest from Basic, beds become more fissile and laminated, although locally thin lenses retain structural characteristics of claystone or siltstone, by which terms they have long been designated. Although much of the member consists of sand in northern Mississippi, the identifying characteristic over larger areas is lightweight shale. It seems advisable to retain term "Basic" for this member and, to prevent confusion from mispronunciation, to designate it Basic City shale member. In area of this report [Grenada, Montgomery, and Yalobusha Counties], Basic City conformably overlies Meridian sand member of Tallahatta and underlies Winona sand member of Lisbon formation. Thickness irregular due to nature of lower contact; 78 feet on Gunby Hill, Montgomery County.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas. Inv. Prelim. Chart 29. Correlation chart shows Basic City shale member underlies Neshoba sand member and overlies Meridian sand member; interfingers with Holly Springs sand member; in some areas underlies Winona formation.

Type locality: Deep cut on railroad just north of Basic City, a railroad station in northwestern Clarke County.

Basin Rhyolite [in Basin Ridge Group]

Tertiary: Central Colorado.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 100–101. Yellowish buff to gray and characteristically aphanitic except for a few widely scattered phenocrysts of biotite and feldspar. Maximum thickness measured 300 feet. Relationship with underlying rocks not definite, but near southern end of Basin Ridge, rhyolite thought to lie either directly on Pierre shale or very nearly so.

Caps central part of Basin Ridge and occupies center of Basin Ridge syncline. Known in outcrops extending from about middle of east line of sec. 20, T. 9 S., R. 76 W., to northern boundary of sec. 27, T. 10 S., R. 76 W., South Park, Park County. Average width of outcrop is 2 miles.

Basin Shale[1]

Upper Cretaceous: Northern Wyoming.

Original reference: F. F. Hintze, 1915, Wyoming State Geol. Bull. 10, on Basin and Greybull oil and gas fields, Bighorn County, Wyo., p. 17, 24–29.

Basin and Greybull oil fields, Bighorn County.

Basin Creek Member (of Katalla Formation)

Oligocene: Southeastern Alaska.

D. J. Miller, D. L. Rossman, and C. A. Hickcox, 1945, Preliminary report on petroleum possibilities in the Katalla area, Alaska: U.S. Geol. Survey, p. 7 (table), 9–10; 1945, Geologic and topographic map and sections of the Katalla area, Alaska: U.S. Geol. Survey War-Minerals Inv. Prelim. Map. Alternating beds of very fine grained massive gray sandstone and gray sandy shale. Beds range in thickness from 1 to 50 feet and average about 10 feet for sandstone and 25 feet for shale. Some sandstone beds are glauconitic. Shale contains many round calcareous concretions from 1 to 6 inches in diameter at least 40 percent of which contain fossil crabs. Thickness 550 to 1,000 feet; average about 700 feet. Underlies Burls Creek shale member; overlies Split Creek sandstone member. Name first used as member of Burls Creek formation in unpublished manuscript by oil-company geologists.

Named for Basin Creek, Katalla area, where member is well exposed.

Basin Ridge Group

Tertiary: Central Colorado.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 95–101, pl. 1. Thick series of volcanic rocks, flow breccias, tuffs, and rhyolites. The various flows thin toward the south. Thick red and white tuff-breccia and variolitic andesite breccia are the most persistent lenses. Agglomerate, which thickens southward with thinning of flows, is well exposed toward southern end of Basin Ridge. Volcanics consist of lower variolitic andesite member and upper red and white member. Near Basin Ridge gap, lower member comprises augitic variolitic andesite breccia, augitic andesite variolite, variolitic tuff, and hornblendic andesite flow variolite —thickness, 1,000 to 1,150 feet; upper member consists of gray porphyry flow, red breccia, agglomerate, red and white tuff-breccia, and hornblende andesite—thickness, 640 to 715 feet. [Uppermost in group is Basin rhyolite (new).] Mapped on plate 1 as Denver Basin group.

Underlies northern two-thirds of Basin Ridge, extending from a point about 2 miles southwest of Como, into sec. 10, T. 11 S., R. 76 W., South Park, Park County. Two outliers, structurally and lithologically similar to Basin Ridge volcanics, form hills approximating in area 1 square mile each, in sec. 7, T. 9 S., R. 76 W.; sec. 12, T. 9 S., R. 77 W.; and secs. 29 and 32, T. 8 S., R. 76 W.

Bas Obispo Formation[1]

Oligocene(?): Panamá.

Original reference: D. F. MacDonald, 1913, Geol. Soc. America Bull., v. 24, p. 708.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 21–32, 51 (fig. 4), pl. 1. Bas Obispo formation and Las Cascadas agglomerate are entirely volcanic. They are interpreted to represent pyroclastic rocks that accumulated at periphery of a volcanic pile. Bas Obispo is thought to grade into Bohio formation. Thickness unknown. Volcanic rocks now included in Bas Obispo formation and Las Cascadas agglomerate were named Obispo formation or Obispo breccia by Howe (1907). Emendation to Bas Obispo formation and splitting off of younger part as Las Cascadas agglomerate were proposed by MacDonald. Doubtfully referred to Oligocene because of inferred relations to Bohio formation.

Type region: Northern part of Gaillard Cut, where it is oldest formation exposed.

Bass Limestone (in Unkar Group)[1]

Precambrian (Grand Canyon Series): Northern Arizona.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (table), 110. In Grand Canyon series. Rapid alternation of layers of limestone and shale, bedding surfaces of which are often notably sun cracked. Thickness 300 feet. Overlies Newberry formation (new); underlies Hakatai shale.

R. P. Sharp, 1940, Geol. Soc. America Bull., v. 51, no. 8, p. 1242. In Hotauta Canyon, overlies Hotauta conglomerate.

J. H. Maxson, 1942, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1963, 1964. Thickness 250 feet in Bright Angel quadrangle. Underlies Hakatai shale; overlies fractured Archean basement.

Named for Bass Canyon, Grand Canyon region, where typically exposed

Bassendorf Shale[1]

See **Bastendorff Shale,** correct spelling.

Bassick Agglomerate[1]

Tertiary: Central southern Colorado.

Original reference: W. Cross, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 307.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 197. In Silver Cliff-Rosita region, volcanics, in order of decreasing age, consist of Rosita fragmental andesite, Bunker massive andesite, Fairview diorite in dikes cutting earlier andesite, Bald Mountain dacite flows, rhyolite in dikes, eruptive channels and flows, Pringle andesite, trachyte flows, and Bassick agglomerate.

Composes Bassick Hill and greater part of Mount Tyndall, Custer County.

†Bassimenan Lake Granite[1]

Precambrian (Laurentian): Northeastern Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. Nat. History Survey Final Rept., v. 4.

Well exposed on islands and along south shores of Bassimenan Lake.

Bass Islands Dolomite[1]

Bass Islands Group

Upper Silurian: Southeastern Michigan and northern Ohio, and western Ontario, Canada.

Original reference: A. C. Lane, C. S. Prosser, W. H. Sherzer, and A. W. Grabau, 1909, Geol. Soc. America Bull., v. 19, p. 554.

Wilber Stout, 1941, Ohio Geol. Survey, 4th ser., Bull. 42, p. 38–40, chart facing p. 46. Rank raised to group in Ohio. Includes (ascending) Greenfield, Tymochtee, Put-in-Bay, and Raisin River formations. Thickness 400 to 700 feet; average about 570 feet. Unconformable above Niagara group and below Oriskany formation.

K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv., Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 26, 32, 33, 35 (table 1), 71, 110. In proposed classification for Mackinac Straits region, term Bass Island is used as group. Includes St. Ignace formation (new). Bass Island overlies Salina formation everywhere beneath surface in Southern Peninsula. In different parts of this area, variously overlain by Garden Island(?) formation, Bois Blanc, Sylvania, and Detroit River rocks. Silurian (Cayugan). Discussion of use of term Bass Islands vs. Bass Island. Original use of term was Bass Islands. [U.S. Geological Survey retains original spelling Bass Islands.]

Named for group of islands in western Lake Erie.

Bass Mountain Diabase[1]

Bass Mountain Basalt

Mississippian: Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Survey Geol. Atlas, Folio 138.

N. E. A. Hinds, 1940, 6th Pacific Sci. Cong. Proc. for 1939, p. 283–284. Referred to as Bass Mountain basalt. Exposed in two principal areas. Along Middle Salt Creek, volcanics rest unconformably on Copley metaandesite and Kennett formation and are interbedded with and overlain by Bragdon strata. On Bass Mountain, it appears eruptions took place contemporaneously with deposition of Bragdon sediments.

Named for fact it forms southern slope of Bass Mountain, Redding quadrangle.

†Basswood Granite[1]

Precambrian (Laurentian): Northeastern Minnesota.

Original reference: A. Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept.

Occupies all the Minnesota shores of Basswood Lake except southwest shore of Arm 1, Vermilion district.

Bastard Limestone[1]

[Lower Devonian]: New York and Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. G_7, p. 97–98.

Bastendorff Shale[1]

Eocene and Oligocene: Southwestern Oregon.

Original reference (Bassendorf): H. G. Schenck, 1927, California Univ. Pub. Dept. Geol. Sci. Bull., v. 16, no. 12, p. 454, 457, 459.

J. E. Allen and E. M. Baldwin, 1944, Oregon Dept. Geology and Mineral Industries Bull. 27, p. 27–29, pl. 3. Bastendorf [Bastendorff] shale at beach section consists of 1,845 feet of shale and 60 feet of sandstone plus covered thickness of 1,000 feet which to south along creek appears to be shale, giving total of 2,905 feet. Overlies Coaledo formation of Arago group; underlies Tunnel Point sandstone. Uppermost Eocene and possibly lower Oligocene in part.

Typical exposure at Bastendorff (Bassendorf) Beach, in sec. 3, T. 26 S., R. 14 W., Coos Bay district.

Bastimentos Shale

Miocene, middle: Panamá.

R. A. Terry, 1956, California Acad. Sci. Occasional Paper 23, p. 52, 77. Massive, poorly bedded soft gray clay shale at base of Gatun formation. Interfingers with Minitimi limestone. Overlies Conch Point shale, which it resembles closely. On Columbus Island, surface structure is gently rounded dome on which early Miocene Conch Point shale crops out at crest, over an area about 1 mile in diameter, surrounded by middle Miocene Bastimentos shale. Seismograph survey indicated structure is cut by fault striking N. 24° E.

Occurs on Isla Colón (Columbus Island) and Isla Bastimentos (Provision Island).

Bastrop Park terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941, Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703–1704, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Bastrop Park is proposed for a terrace deposit of siliceous gravel with elevation of 525 feet at Bastrop State Park. Younger than Gay Hill (new); older than Uvalde from which it is differentiated by lack of calcareous material. Thickness as much as 20 feet.

Present at Bastrop State Park, about 1½ miles east of Bastrop, Fayette County. Part of the park and National Youth Administration camp are located on this deposit.

Batamote Andesite

Pliocene(?): Central southern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 48–49, pl. 1. Comprises three principal varieties of basaltic andesite flows: dense dark-gray rock that weathers reddish brown with small rare crystals of hornblende and feldspar; platy dark-gray brown-weathering, generally more or less vesicular, finely porphyritic rock; and the most widespread variety, medium-gray, generally massive though locally platy, aphanitic olivine andesite, which forms bulk of Black, Batamote, and Childs Mountains. Some flows may be true basalts. At Black Mountain, basaltic andesite consists of dark flow breccias and massive flows that range in thickness from about 20 to 60 feet and average about 30 feet. Full thickness 1,348 feet. Unconformably overlies Childs augite latite (new) in Batamote and Childs Mountains and the Cardigan gneiss and conglomerate elsewhere.

James Gilluly, 1946, U.S. Geol. Survey Prof. Paper 209, p. 9, 45–46, pls. 3, 21 [1947]. Scoriaceous red basalt and andesite breccia form what is probably the throat of a volcano (Batamote Peak) and cinder cones (Childs Mountain).

Named from Batamote Mountains, the bulk of which are made up of the andesite. Most widespread of the bedrock formations in Ajo quadrangle.

Bat Cave Limestone or Formation (in El Paso Group)

Lower Ordovician: Southwestern New Mexico.

V. C. Kelley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2201 (table). On table only. Thickness from fraction of a foot to over 1,000 feet. Underlies Cable Canyon sandstone (new); overlies Sierrite limestone (new).

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 45–52, 53, fig. 4. At type section, formation composed of a lower light-colored slope-forming unit and an upper somewhat darker and banded cliff-forming unit. Lower unit contains many biostromes and bioherms distributed irregularly in thin- to medium-bedded limestone. Biostromes and bioherms predominantly stromatolitic and surrounded and interspersed with much detrital limestone. Stromatolitic rock is light to medium gray and weathers very light gray. Upper unit consists of medium- to thick-bedded alternating dark- and medium-gray limestone, dolomitic limestone, and some dolomite. Most beds are very fine grained. Chert occasionally present in beds or intervals as nodules and bands. Chert weathered light brown to dark brown. A few beds in upper unit are biostromal. Solution caverns commonly exposed in cliffs of upper unit, and large masses of collapse breccia present. Thickness ranges irregularly from 216 feet at Molinas Canyon to 305 feet at Mud Springs Mountains. Unconformably underlies Cable Canyon sandstone; conformably overlies Sierrite limestone. Type location and areal distribution indicated.

Type locality; North side of Cable Canyon, Caballo Mountains. Formation named from Bat Cave whose opening is prominent landscape mark on sheer cliff in upper part of unit, a few hundred yards northwest of type section.

Bates Limestone

Middle Silurian: Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Metamorphosed limestone. Thickness of individual beds varies from a fraction of a foot to several feet. Cut by granitic, aplitic, and basic dikes. Older than Thorncrag limy gneiss of Tacoma series (both new); younger than Androscoggin gneiss and schist (new). Cambro-Ordovician(?).

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. Middle Silurian.

L. W. Fisher, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 81. Included in Androscoggin series.

Type locality: City quarry located in low hill known locally as "West Rose Hill", in southern part of city of Lewiston, Androscoggin County.

Bates Hole Formation[1]

Eocene: Wyoming.

Original reference: F. B. Weeks, 1902, U.S. Geol. Survey Bull. 191.

In valley of Bates Creek, Natrona County.

†Batesville Ash Bed[1]

Upper Ordovician (Richmond) : Northeastern Arkansas.

Original reference: J. F. Williams, 1891, Arkansas Geol. Survey Ann. Rept 1890, v. 2, p. 373–375.

Named for Batesville, Independence County.

Batesville Sandstone[1]

Batesville Formation

Upper Mississippian: Northern Arkansas, southern Missouri, and northeastern Oklahoma.

Original reference: J. C. Branner and F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. xiii, 26, 49–53.

R. A. Brant, 1941, *in* Tulsa Geol. Soc. [Guidebook] Field Trip, Oct. 18, strat. sections. In Tulsa-Choteau-Grand River area, underlies Grand River formation (new) and overlies Hindsville formation.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 266–267. Geographically extended into southern Missouri where it underlies Fayetteville formation; in some areas conformably overlies Hindsville limestone and in other areas unconformably overlies Keokuk limestone.

Named for Batesville, Independence County, Ark.

Bath Sandstone Submember (of Pony Spring Siltstone Member[1] of Maroon Formation)

Permian: Central Colorado.

Original reference: D. B. Gould, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, p. 973, 990, 995, 1000.

C. A. Arnold, 1941, Michigan Univ. Mus. Paleontology Contr., v. 6, no. 4, p. 59–70. Mentioned in discussion of some Paleozoic plants from central Colorado and their stratigraphic significance. Bath submember has yielded *Walchia* sp. *Walchia* has been found in Pennsylvanian strata as well as Permian and is, therefore, not a strict time marker, but rather a reflection of environment.

Forms prominent ridge that separates Platte and Arkansas drainage for several miles northwest of summit of Trout Creek Pass, where there is the abandoned town of Bath, Park and Chaffee Counties.

Battell Member (of Monastery Formation)

Lower Cambrian: West-central Vermont.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 43, 44. Black graphitic quartz-muscovite schist with large porphyroblasts of albite. A few lenses of white to gray dolomitic marble occur at base. Beds of porphyroblastic albite-quartz-chlorite-muscovite schist are also associated with this unit. Thickness varies from a featheredge to a maximum of 80 feet. Underlies undivided part of Monastery formation (new) ; overlies Tyson member (new) of Monastery formation.

Named from exposures in Hancock Branch on southeast slope of Battell Mountain in Rochester area. No other good exposure.

Battery Formation[1]

Pleistocene: Northwesetrn California.

Original reference: J. H. Maxson, 1933, California Jour. Mines and Geology, v. 29, nos. 1–2, p. 136, map.

William Back, 1957, U.S. Geol. Survey Water-Supply Paper 1254, p. 17 (table), 24–31, pl. 5, Battery formation, as used in this report [Smith River plain, Del Norte County], includes related continental deposits consisting of contemporaneous stream gravels and elongate sand ridges. These ridges may not be of aqueous origin, but they are composed of reworked marine sediments and therefore are related to Battery formation. Thickness as much as 66 feet; 28 feet at Pebble Beach. Where Pliocene sediments [St. George formation] remain, the Battery overlies them with slight unconformity; in rest of area, overlies Dothan rocks of Jurassic age with angular unconformity; underlies terrace deposits.

Named for exposures at Battery Point southwest of Crescent City, Del Norte County.

Battery Rock cyclothem (in Caseyville Formation)

Battery Rock cyclothem (in Caseyville Group)

Pennsylvanian: Southern Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). Caseyville group includes (ascending) Lusk, Battery Rock, and Pounds cyclothems.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 5, 9, pl. 1. Includes (ascending) Battery Rock (Lick Creek) sandstone or conglomerate, Sellers limestone, Battery Rock coal, and Drury shale, Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), 54 (table 3), pl. 1. In Caseyville formation (redefined) above Lusk cyclothem and below Pounds cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Sec. 26, T. 11 S., R. 2 E., Hardin County.

Battery Rock Sandstone Member (of Caseyville Formation)

Battery Rock Conglomerate

Battery Rock Formation (in Caseyville Group)

Lower Pennsylvanian: Southern Illinois and northern Kentucky.

D. D. Owen, 1856, Kentucky Geol. Survey Rept. 1854 and 1855, p. 49. Incidental mention as Battery Rock conglomerate.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 36, 37–38. Formation has maximum thickness of more than 200 feet and consists of two nearly equal parts: Battery Rock sandstone below and Drury shale member above. The sandstone is medium to coarse grained, crossbedded, and massive; it ranges from less than 50 to more than 100 feet in thickness. Transition from sandstone to Drury shale member is locally abrupt, but elsewhere thin-bedded and shaly sandstone beds make determination of sharp boundary impossible; thin beds of massive sandstone also are locally present above Battery Rock member so that, where exposures are discontinuous, its upper limit is difficult to determine. Underlies Pounds formation (new); probably unconformable but actual contact rarely exposed. Unconformably overlies Lusk formation (new) except in parts of northwestern Union County where it overlaps Chester strata. Relations to Lick Creek sandstone at Cedar Bluff not entirely clear, and use of this name for widespread sandstone at base of Battery Rock is questionable.

H. R. Wanless, 1944, Geol. Soc. America Mem. 13, p. 136. Lick Creek sandstone now considered to be Battery Rock.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 29, 30, 44 (table 1), 61, pl. 1. Termed sandstone member of Caseyville formation (redefined). In southeastern Illinois, occurs above Lusk shale member and below Sellers limestone member; in southwestern Illinois, occurs above Wayside sandstone member and below Drury shale member. Thickness 98 feet in type section of Caseyville. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: Along Ohio River bluff, sec. 26, T. 11 S., R. 10 E., Shawneetown quadrangle, Hardin County, Ill.

Battie Quartzite[1]

Cambrian(?): Central southern Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 3.

H. W. Allen, 1951, Maine State Geologist Rept. 1949–1950, p. 79. Sequence of metamorphosed sedimentary rocks in area of Rockland quadrangle, Knox County, is (ascending) Islesboro formation containing Coombs limestone member at top; Battie quartzite; Penobscot formation; and Rockland formation consisting of Weskeag quartzite member at base, a siliceous limestone member above the quartzite, and Rockport limestone member at top.

Named for development on Mount Battie, a small mountain on mainland north of Camden, Knox County, in Rockland quadrangle.

Battiest Chert Member (of Tenmile Creek Formation)

Mississippian (Meramecian): Southeastern Oklahoma.

O. B. Shelburne, Jr., 1959, Dissert. Abs., v. 20, no. 3, p. 998; 1960, Oklahoma Geol. Survey Bull. 88, p. 16, 17 (fig. 2), 18–19, pl. 1. Proposed for chert member in middle part of formation. Battiest chert member was named Smithville chert lentil by Miser and Honess (1927); this name was little used and was abandoned by Oklahoma Geological Survey in 1957. Where best exposed, west of Battiest, member is 15 feet thick and consists of 3-inch beds of dark cherty siliceous shale interbedded with black siliceous shale; one 6-inch bed of black chert is cut by veins of milky quartz. Near Beachton (in type area of Honess' and Miser's Smithville chert) member consists of 15 feet of blue-black chert and siliceous shale which is poorly exposed in series of tight folds trending east-west.

Well exposed along half-section- and section-line roads near village of Battiest in secs. 7 and 8, T. 2 S., R. 23 E., McCurtain County. Area is Boktukola syncline.

Battle Formation or Conglomerate

Middle Pennsylvanian: North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–10]. Reddish-brown to dark-red conglomerate, with interbedded sandstone, shale, and thin limestone beds. Lower beds conglomerates; middle beds interbedded conglomerate, sandstone, and shaly sandstone; upper beds interbedded pebble conglomerate, sandstone, shale, calcareous shale, and limestone. Shale and limy beds metamorphosed to hornfels, and conglomerates and sandstones to quartzite near intrusive bodies; generally bleached white or light gray. Thickness at type locality 700 feet. Rests unconformably on three older formations of lower plate sequence. Lower Pennsylvanian.

H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle. Nevada: U.S. Geol. Survey Quad. Map [GQ-15]. Underlies Antler Peak limestone conformably in Battle Mountain.

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2824 (fig. 5), 2825 (fig. 6), 2841–2842. Highway limestone in Osgood and Edna Mountains is facies of Battle formation.

Type section: In Cow Canyon, a tributary of Galena Canyon, southeast flank of Antler Peak, Antler Peak quadrangle.

Battle Ax Basalts

Pliocene and Pleistocene: Northwestern Oregon.

T. P. Thayer, 1936, Jour. Geology, v. 44, no. 6, p. 706, 709 (fig. 2), 713 (fig. 3). Tentatively correlated with Minto lavas on basis of petrographic similarity and comparative amount of dissection of flows.

Source of basalts is near Battle Ax Mountain, northeast of Detroit, Marion County. Basalts form prominent cliffs for about 4 miles along north wall of Breitenbush River valley.

Battleground Schist[1]

Ordovician to Mississippian: Northwestern South Carolina and southern North Carolina.

Original reference: A. Keith and D. B. Sterrett, 1931, U.S. Geol. Survey Atlas, Folio 222.

W. R. Griffitts and J. C. Olson, 1953, U.S. Geol. Survey Prof. Paper 248–D, p. 204, 206. Mentioned in discussion of mica deposits in Shelby-Hickory district, North Carolina.

W. C. Overstreet and Henry Bell, 3d, 1960, South Carolina Div. Geology Geol. Notes, v. 4, no. 4, p. 27–30, fig. 1. Battleground schist described in Kings Mountain belt, Laurens County, S.C. Precambrian(?) or Paleozoic (?).

U.S. Geological Survey currently designates the age of the Battleground Schist as Ordovician to Mississippian on basis of study now in progress.

Named for exposures on Kings Mountain Battleground, York County, S.C.

Battle Mountain Formation

Pennsylvanian (Des Moines) : Northwestern Colorado.

C. A. Arnold, 1941, Michigan Univ. Mus. Paleontology Contr., v. 6, no. 4 p. 60, 68. Mentioned in discussion of Paleozoic plants from central Colorado. Name credited to K. G. Brill (unpub. thesis) who considered formation to be Lower Pennsylvanian (Des Moines) on basis of invertebrates.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1376 (fig. 1), 1378 (fig. 2), 1379–1385. Proposed for sequence of lower Pennsylvanian rocks which lies unconformably on Mississippian and older rocks and which is disconformably overlain by State Bridge formation. Composed chiefly of grits and sandstones with thick beds of shale and conglomerate; occasional beds of limestone and dolomite which range from a few inches to 30 feet in thickness. About 4,300 feet thick in north part of area; more than 7,900 feet farther south; nearly

1,600 feet are porphyry sills of Cenozoic age. In early reports, sequence of sediments here assigned to Battle Mountain was divided into six formations on basis of lithology or color; these were (ascending) Weber formation, Robinson limestone, White Quail limestone, Maroon formation, Jacque Mountain limestone, and Wyoming formation. As here defined Battle Mountain includes (ascending) Belden shale (new), Robinson limestone, and Jacque Mountain limestone members. Report covers Gore area, Eagle and Summit Counties.

Type section: North side Turkey Creek; section begins on top of Hill 11610 (Minturn quadrangle) west of Dagett Pass (Shrine Pass Road) about 6 miles east of Red Cliff, Eagle County. Name derived from Battle Mountain 3½ miles northeast of Red Cliff.

Battle Spring Formation

Eocene, lower and middle: Southwestern Wyoming.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 101 (chart), 103. Very coarse grained to pebbly arkosic sandstone with small amounts of bright-green claystone that contains abundant large angular grains of clear quartz. Sandstone crossbedded. Inferred thickness about 3,300 feet but probably is greater. Unconformably overlies Fort Union formation; partly underlies and intertongues with Morrow Creek member of Green River formation. Intertongues to the south with Red Desert (new), Niland (new), and Cathedral Bluffs tongues of Wasatch formation; and with Luman (new) and Tipton tongues of Green River formation.

Typical exposures southwest of Battle Spring Flat and southeast of Lost Creek Butte, Sweetwater County. Underlies most of eastern part of Great Divide Basin. Base of formation exposed on north slope of Flattop Buttes and at a point about 10 miles west of Rawlins in NW pt. T. 21 N., R. 89 W.

Bauers Tuff Member (of Quichapa Formation)

Oligocene: Southwestern Utah and eastern Nevada.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90, 91–94. An ignimbrite that differs from younger Leach Canyon tuff member by (1) lower content of pyrogenic mineral grains, (2) absence of foreign rock fragments, and (3) higher induration. In about 95 percent of its outcrop, consists of three intergrading but sharply contrasted phases: basal vitrophyre, about 10 feet thick; middle lithoidal phase characterized by a conspicuous compaction foliation, 150 to 200 feet thick; and an upper nonfoliated lithoidal phase, 10 to 40 feet thick. At type locality, overlies Swett tuff member and underlies Harmony Hills tuff member (both new); elsewhere lava flows or other volcanic rocks of local origin and extent are present at contacts. Zircon age of Leach Canyon tuff member is 28 million years; this suggest that Quichapa formation is Oligocene. Discussion of ignimbrites of area.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 138 (fig. 3). Geographically extended into eastern Nevada.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 37. Described in Washington County where it is as much as 200 feet thick. Overlies Leach Canyon tuff member; underlies Little Creek breccia member (new).

Type locality: Bauers Knoll, Cedar City Northwest quadrangle, Iron Springs district, Utah.

Baum Limestone Member (of Paluxy Sand)

Baum Lentil or Limestone (in Trinity Formation)

Lower Cretaceous: Southern Oklahoma.

Ardmore Geological Society, 1938, Ardmore Geol. Soc. [Guidebook] Field trip to the Lower Pennsylvanian of the Berwyn and Baum areas, Apr. 23, p. 7 (stop 3). Name Baum lentil proposed for marly limestone in basal Trinity. Type locality stated.

C. W. Tomlinson, 1952, *in* Ardmore Geol. Soc. [Guidebook] Field Trip, p. 3, 4. Mentioned in road log as Baum limestone at base of Trinity.

J. R. Wayland, 1954, Am. Assoc. Petroleum Geologist Bull., v. 38, no. 11, p. 2400–2406. Formally proposed. Consists of four intergrading lithofacies: (1) basal red clay, which disappears eastward, (2) limestone conglomerate, which is best developed at northern margin of outcrop near Arbuckle Mountains, (3) massive fine-grained limestone, which is the thickest and most widely distributed of the units, and (4) arkosic limestone and calcareous arkose, present only in eastern outcrop area near Ravia. Because of irregular distribution, each of these units locally is at base of the Baum. Thickness ranges from 13 feet on Turkey Creek, where top and base are exposed, to maximum of 73 feet on Washita River where base is not exposed and top is eroded. In vicinity of type locality, the Baum rests on steeply dipping Pennsylvanian rocks; it disappears westward, apparently by interfingering with Paluxy sand; in easternmost outcrop rests on Precambrian granite and pre-Pennsylvanian highly folded rocks; in Ardmore basin, rests on steeply dipping Pennsylvanian shales and sandstones, northern extent is marked here by steep escarpment at top of Sycamore limestone (Mississippian).

Type locality: Hill in NE¼SE¼ sec. 36, T. 3 S., R. 3 E., 1.2 miles east of Baum, Carter County. Three of the lithofacies are exposed here.

Bautista Beds[1]

Pleistocene: Southern California.

Original reference: C. Frick, 1921, California Univ. Pub., Dept. Geol. Bull., v. 12, p. 283–288.

Occur in Bautista Badlands or Bautista Creek area, San Jacinto quadrangle.

Baxter Shale[1]

Upper Cretaceous: Southwestern Wyoming.

Original reference: A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

J. D. Love, J. L. Weitz, and R. R. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Mapped in southwestern Wyoming. According to map legend, occurs above Frontier formation and below Blair formation.

R. J. Weimer, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 1, p. 8, 9. Discussion of Upper Cretaceous stratigraphy, Rocky Mountain area. Baxter (Mancos) shale consists of 3,000 to 4,000 feet of marine shale between Mesaverde group and Frontier formation.

Exposed in Baxter Basin. Named for exposures in vicinity of Baxter, Sweetwater County.

Baxter Hollow Granite

Age not stated: South-central Wisconsin.

R. M. Gates, 1942, Am. Mineralogist, v. 27, no. 10, p. 699–711. The "normal" granite is red to light pink and very fine grained and contains few dark minerals. Only some of the pegmatoid veins approach coarseness of a normal granite. Other rock types associated with the granite and which generally grade into one another are biotite hybrid, pegmatite hybrid, porphyroblastic hybrid, arkose, sheared rock, and cleavelandite dike rock. Intrusive into Baraboo quartzite.

Granite found only at Baxter Hollow of Baraboo district [Sauk County].

Bayard Formation[1]

Lower Pennsylvanian: Northeastern West Virginia and western Maryland.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

Exposed all around Bayard, Grant County, W. Va.

Bayard paleosol complex

Oligocene, upper, to Miocene: Northwestern Nebraska.

C. B. Schultz and T. M. Stout, 1955, Nebraska Univ. State Mus. Bull., v. 4, no. 2, p. 46, fig. 10. Proposed for paleosol soil capping top of Whitney member of Brule formation and extending into Gering formation.

Occurs in Castle Rock section near Bayard, Morrill County.

Bay de Noc Limestone

Bay de Noc Member (of Stonington Beds)[1]

Upper Ordovician: Northern Michigan.

Original reference: R. C. Hussey, 1926, Michigan Univ. Mus. Geol. Contr., v. 2, no. 8, p. 113–150.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 46). Shown on correlation chart as Bay de Noc limestone underlying Ogontz limestone and overlying Bills Creek shale.

Well exposed along east shore of Little Bay de Noc, from 1½ miles north of Stratton's farm northward, and also south to Stonington post office, Delta County.

Bayfield Gravel[1]

Pliocene(?): Southwestern Colorado and northwestern New Mexico.

Original reference: W. W. Atwood and K. F. Mather, 1932, U.S. Geol. Survey Prof. Paper 166.

V. C. Kelley, 1949, New Mexico Univ. Pubs. in Geology 4, fig. 2. Geographically extended into San Juan County, N. Mex. Name appears only on chart.

Named for occurrence on several hills a few miles north of Bayfield, La Plata County, Colo.

Bayfield Group[1]

Precambrian: Northwestern Wisconsin.

Original reference: F. T. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 25.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1480–1483. Group subdivided by Thwaites into (ascending) Orienta, Devils Island, and Chequamegon sandstones. Overlies Oronto group.

Jacobsville sandstone in Michigan believed to be eastern equivalent of Bayfield group.

G. O. Raasch, 1950, Illinois Acad. Sci. Trans., v. 43, p. 137–150. Discussion of Cambrian-Keweenawan boundary. Suggested that Bayfield sediments are continental deposits of Middle and quite possibly also of Early Cambrian age laid down in structural basins at or after close of the Algonkian. Term Chequamegon dropped; unit is Port Wing brownstone member (new) or Orienta formation repeated by faulting. In this report, term Bayfield embraces the following: Red Clastics, Fond du Lac, or Hinckley in Minnesota and in Michigan the Jacobsville sandstone.

Named for occurrences in Bayfield County.

Bayhorse Dolomite[1]

Cambrian(?): Southern central Idaho.

Original reference: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth.

C. P. Ross, 1937, U.S. Geol. Survey Bull. 877, p. 11 (correlation chart), 12-14. Commonly massive thick-bedded dolomite, in part oolitic. Thickness about 1,000 feet. Overlies Garden Creek phyllite; underlies Ramshorn slate. Cambrian(?).

Named for town and creek in Custer County. Best exposed near town.

Bayloran series[1]

[Permian]: North-central Texas.

Original reference: C. R. Keyes, Pan-Am. Geologist, 1932, v. 57, p. 337, 350–355.

Named for Baylor County.

Bay Mud Formation

Quaternary, late: Western California.

P. D. Trask and J. W. Ralston, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1081, 1082. Silty clay containing grains of wind-blown sand; upper part includes thin layers of fine- to medium-grained sand alternating with silty clay. Thickness ranges from a few inches to as much as 150 feet. Overlies Merritt sand; youngest formation in area.

D. H. Radbruch, 1957, U.S. Geol. Survey Misc. Geol. Inv. Map I–239. Overlies Temescal formation, Merritt sand, or Alameda formation.

Crops out on east side of San Francisco Bay near Francisco-Oakland Bay Bridge.

Bayne Formation } (in Puget Group)
Bayne Series[1] }

Eocene: Western Washington.

Original reference: G. W. Evans, 1912, Washington Geol. Survey Bull. 3, p. 42–49.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology 4, p. 55, 56, 60. Lowest formation of group in Green River area. Consists of alternating strata of massive sandstone, shaly sandstone, sandy shale, carbonaceous shale, and coal beds of varying degrees of purity. Thickness in Green River Canyon about 3,000 feet; base not exposed. Underlies Franklin formation; eastward from Green River Canyon, formation passes unconformably beneath Pleistocene lavas and tuffs. Formations in Green River Canyon are involved in anticlinal and synclinal folds whose axes trend northeast.

Named for town of Bayne, King County.

Bayou Calamus Lentil (in Verda Member of Yazoo Clay)

Eocene (Jackson): Central Louisiana.

J. Huner, Jr., 1939, Louisiana Dept. Conserv. Geol. Bull. 15, p. 159–161. Term applied to fossiliferous marine lentil about 32 feet thick in Verda member; stratigraphically and lithologically similar to Saddle Bayou lentil described by Fisk (1938) in Grant Parish; may be equivalent of Saddle Bayou, but the two units are separated by many miles of territory in which no similar beds occur.

Typical exposure occurs in erosion gully 75 yards east of road in SW¼ NW¼ sec. 24, T. 12 N., R. 4 E., Caldwell Parish. Named for exposure in ravines at head of Bayou Calamus.

Bayou Chicot Limestone[1]

Upper Cretaceous(?): Southwestern Louisiana.

Original reference: G. D. Harris and A. C. Veatch, 1899, Louisiana Geol. Survey, pt. 5, Rept. for 1899, p. 61.

Outcrops about 8 miles southwest of Bayou Chicot post office, Evangeline County.

Bayou Lenann Member (of Pendleton Formation)

Eocene, lower: Northwestern Louisiana and northeastern Texas.

Richard Wasem and L. J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 184 (fig. 4), 186. Consists of glauconitic fossiliferous marine sand that grades upward into lignitic silt. Thickness approximately 90 feet. Underlies Slaughter Creek member (new); overlies beds of Marthaville age.

Typically exposed on Bayou Lenann, sec. 12, T. 6 N., R. 13 W., Sabine Parish, La. Traced from vicinity of Geneva, Tex., to Hagewood, Natchitoches Parish, La.

Bayou Manard Member (of Moorefield Formation)

Mississippian (Chesterian): Northeastern Oklahoma.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 51–54, pls. 1–5. At type locality, composed of black argillaceous limestones and interbedded black calcareous shales; limestones vary from lithographic to medium crystalline; strata are commonly jointed in proximity to major faulting, forming large rectangular blocks; lithology fairly constant eastward to vicinity of Stilwell where it intergrades with medium-crystalline limestone of overlying Lindsey Bridge member (new). Northward along Grand River in Mayes and Wagoner Counties, consists of lower sequence of blue-gray dense fine-grained to lithographic limestone with thin beds and nodules of black chert succeeded by upper thin to platy weathering limestone. Maximum thickness 65 feet. Lies unconformably upon Tahlequah member and, in different areas, upon other older Mississippian rocks, Keokuk chert, Reeds Spring formation, and Chattanooga black shale.

Type locality: Southeast of Muskogee and Fort Gibson in SE¼ sec. 19, T. 15 N., R. 20 E., southwest of bridge over Bayou Manard, Muskogee County. Named for exposures along Bayou Manard.

Bay Point Formation

Pleistocene: Southern California.

L. G. Hertlein and U. S. Grant 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 63 (fig. 4), 71–72. A deposit of crossbedded sands and silt. Thickness generally 5 to 10 feet, but maximum thickness may be 20 feet or more. Overlies Sweitzer formation.

Named from its exposures along west shore of Bay Point in Mission Bay, San Diego County.

Bayport Limestone[1] (in Grand Rapids Group)

Mississippian: Michigan.

Original reference: A. C. Lane, 1899, U.S. Geol. Survey Water-Supply Paper 30, p. 81.

G. H. Pringle, 1937, Michigan Dept. of Conserv., Geol. Survey Div. Prog. Rept. 3, p. 14. At Point au Gres, 6 feet of Bayport limestone occur along lake shore on west side of point. This is limestone named Pointe aux Gres by Douglass.

G. M. Ehlers and W. E. Humphrey, 1944, Michigan Univ. Contr. Mus. Paleontology, v. 6, no. 6, p. 114–117. Description of fauna from Point au Gres limestone at Grand Rapids. History of nomenclature reviewed, and reference made to work of Lane (1893, 1895, 1899, 1900, 1909). Concluded that Point au Gres, instead of "Grand Rapids" or "Bayport," should be used for limestone under discussion. Usage is based on definition of Point au Gres by Douglass (1841 [1839]). Continued reference to limestone as "Bayport" would be unfortunate because this name and "Grand Rapids" were used only in casual manner by Lane.

Named for outcrops at Bayport, Huron County, where it is quarried.

Bays Formation

Bays Sandstone[1] or Limestone[1]

Middle Ordovician: Northeastern Tennessee and southwestern Virginia.

[Original reference]: Bailey Willis, 1893, U.S. Geol. Survey 13th Ann. Rept., pt. 2, pls. 60, 61.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1178. Discussion of lower Middle Ordovician of southwest Virginia and northeast Tennessee. Measured sections compared with revised classification of Tazewell County, Va., (Cooper and Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6). "Mosheim," "Ottosee," and "Bays" should be discontinued as definite formational names. Moccasin is equivalent to "Bays" formation in its type area along Bays Mountain. It is equal to Bays as mapped in Knoxville folio (Keith, 1895), but not equivalent to "Bays" of other folios in area, where it is mapped for younger Juniata formation. As Bays has been often misused and is not as widely used as the Moccasin, it would best be discontinued.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 68, 78, fig. 4. Includes much siltstone and shale and some limestone as well as sandstone; hence, here called Bays formation. Overlies Ottosee shale.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145 (chart), 164–165, 166 (table 3), pl. 28. Formation described in Tellico-Sevier belt, eastern Tennessee, where it is characterized by red calcareous mudrock and siltstone. Thickness 400 feet at northeastern end of exposures; about

1,000 feet at southwest. Overlies Bacon Bend member (new) of Sevier formation; underlies Chattanooga shale. Term Bays sandstone was first used by Willis (1893), who gave its thickness for several sections but did not describe the rocks. Term was subsequently used in Estilville (Campbell, 1894). Knoxville (Keith, 1895), Morristown (Keith, 1896), and Greenville (Keith, 1905) folios; the latter two contain the type locality of the formation. In latter two folios, the name was applied erroneously in Clinch Mountain belt to a unit of Upper Ordovician rocks now known as Juniata formation. Outcrops of Bays formation in present report are in same structural belt as type area of formation. Middle Ordovician.

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Quad. May GQ–76. Formation described in Shooks Gap quadrangle, Tennessee, where it is about 700 feet thick. Overlies Ottosee shale; underlies Martinsburg shale. Bays is correlative, at least in large part and possibly exactly, with Moccasin formation of northwestern part of Ridge and Valley province.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 45, 97. Overlies Wassum formation (new).

Named for exposures in Bays Mountains of Hawkins and Greene Counties, Tenn.

Bay State Dolomite Member (of Nevada Formation)

Middle Devonian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 41, 45–46, pl. 2. Proposed for massive-bedded and dark-colored dolomites overlying Woodpecker limestone member (new) in vicinity of Eureka. Thickness 600 to 850 feet. Slight thickening to the north and west. Basal unit of member is a light-gray dolomite sand, that locally contains fragments of boulders of dolomite and siltstone, which forms a sharp contact with underlying Woodpecker limestone member. Contact with overlying Devils Gate limestone is gradational.

Type locality: Section above the mine in Mining Canyon. Well exposed in vicinity of Bay State mine on Newark Mountain.

Bayview Granodiorite[1]

Probably Jurassic or Cretaceous: Northern Idaho.

Original reference: J. L. Gillson, 1927, Jour. Geology, v. 35, no. 1.

Named for exposures around Bayview, Kootenai County.

Bay View Avenue lenses[1]

Upper Cretaceous: Southeastern New Jersey.

Original reference: J. K. Prather, 1905, Am. Geologist, v. 36, p. 171, 172.

Bay View Avenue Sand[1]

Upper Cretaceous: Southeastern New Jersey.

Original reference: J. K. Prather, 1905, Am. Geologist, v. 36, p. 171, 172, 175.

Extends from Bay View Avenue Station near Atlantic Highlands some 800 feet in direction of Hiltons.

†Bazoo Porphyry[1]

Eocene: Colorado.

Original reference not given.

Named from its occurrence in Bazoo claim, Leadville district.

Beach Mountain Paramphibolite[1]

Precambrian: New York.

Original reference: H. L. Alling, 1927, Geol. Soc. America Bull., v. 38, p. 798–799.

In eastern Adirondacks.

Beacon Flat Formation

Permian (Wolfcampian-Leonardian): Northeastern Nevada.

T. G. Fails, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 10, p. 1695 (fig. 1), 1697–1699. Proposed for a three-member unit 2,800 feet thick. The 550-foot lower member of gray silty calcarenites and chert beds contains Wolfcampian-Leonardian boundary; alluvium covers undescribed middle member; cherty fossiliferous, gray calcarenites make up the 1,150-foot-thick upper member. Conformably overlies Buckskin Mountain formation (new); conformably underlies Carlin Canyon formation (new).

Type section: Lower member, on north side Humboldt River at Carlin Canyon, in SE¼SE¼NW¼ sec. 15, and NE¼NE¼SW¼ sec. 15, T. 33 N., R. 53 E.; upper member, SW¼SE¼ sec. 14 and NW¼ sec. 23, T. 33 N., R. 53 E., Elko County. Poorly exposed on a broad almost featureless plateau, Beacon Flat, north and east of low hills formed by Buckskin Mountain formation.

Beacon Hill Gravel[1]

Pliocene(?): New Jersey.

Original reference: R. D. Salisbury, 1894, New Jersey Geol. Survey Ann. Rept. 1893, p. 47–57, 67–72.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 4 (fig. 2), 61–62. Continental; consists of quartz gravel with some chert and sandstone. Thickness 0 to 20 feet. Overlies Cohansey sand. Youngest Tertiary formation in New Jersey. Considered Pliocene, but difficult to differentiate from supposed Pleistocene material [Bridgeton, Pensauken, and Cape May].

Well developed and exposed on summit of Beacon Hill, 3 miles south of Matawan, Monmouth County.

Beacon Peak Dolomite Member (of Nevada Formation)

Lower Devonian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 41, 42, pl. 2. Composed of beds of dense, sometimes porcellaneous, light-olive-gray to slightly brownish creamy-gray dolomite that weather to a pale gray to white and has a faint blue tinge. Some is clastic in origin. Individual beds probably average a foot in thickness. A number of thin brown-weathering sandstone interbeds in upper half of member. Thickness 470 to 940 feet, the larger thickness being to the north. Unconformably overlies Lone Mountain dolomite and is rather sharply gradational with overlying Oxyoke Canyon sandstone member (new).

Type locality: Well exposed on lower west slope of Beacon Peak in Oxyoke Canyon, vicinity of Eureka.

Bead Lake Formation (in Newport Group)

Precambrian: Northeastern Washington and western Idaho.

M. C. Schroeder, 1952, Washington Div. Mines and Geology Bull. 40, p. 7 (table), 10–11, pl. 1. Fine-grained argillaceous and quartzitic sandstones with quantities of light-colored argillite and light-colored arenaceous argillite. Thickness about 12,500 feet. Injected by Marshall diorite (new).

Underlies No Name argillite (new), contact gradational; base of formation not exposed.

Crops out in Bead Lake district, Pend Oreille County, Wash.

Beadle Green Granite[1]

Age(?): Northeastern Vermont.

Original reference: C. H. Richardson and C. K. Cabeen, 1923, Vermont State Geologist Rept. 1921–1922.

Occurs on Crompton Hill in southwest corner of Randolph Township, Randolph quadrangle, Orange County.

Bead Mountain Limestone Member (of Belle Plains Formation)[1]

Bead Mountain Formation (in Belle Plains Group)

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 426.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in the Belle Plains herein redefined and given group status. Includes Beaverburk member. Overlies Valera shale and anhydrite; underlies Grape Creek formation of Clyde group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorodo River valley as uppermost member of Belle Plains formation. Overlies Valera shale member; underlies Grape Creek limestone member of Clyde formation; boundary somewhat arbitrarily defined.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 274, pls. 11, 12. Member forms prominent escarpment in Brazos River drainage area. Consists of alternating beds of limestone and shale; limestone beds range in thickness from 1 to about 15 feet, and shale beds range in thickness from less than 1 foot to 65 feet. Overlies Valera shale member; underlies unnamed shale member at base of Clyde formation.

Named for Bead Mountain, Coleman County.

Bealville Fanglomerate

Oligocene: Southern California.

T. W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 12 (fig. 2), 36-37, pls. 1, 2, 3. Defined as the unsorted boulder-gravel facies of both overlying Walker and Bena formations. At type section, formation consists of granitic fanglomerate that dips southward and attains a thickness of over 7,000 feet. West of type section, grades laterally into both Walker and Bena (new) formations.

Type section: Exposed along highway southward from Ilmon, Breckenridge Mountain quadrangle, Kern County.

Bean Canyon Formation[1]

Bean Canyon Series[1]

Paleozoic(?): Southern California.

Original reference: E. C. Simpson, 1934, California Jour. Mines and Geology, v. 30, no. 4, p. 371–401, map.

U.S. Geological Survey currently designates the age of the Bean Canyon Formation as Paleozoic(?) on basis of study now in progress.

Named for exposure in Bean Canyon in northwest corner of Elizabeth Lake quadrangle, Los Angeles and Kern Counties.

Bear Formation

Paleocene: Central Montana.

G. G. Simpson, 1937, U.S. Natl. Mus. Bull. 169, p. 15 (chart), 17–20, pls. 1, 2. Name applied to unit, 500 to 600 feet thick, that occurs above Hell Creek formation and below the Fort Union (No. 1 or Lebo). Consists of alternating pale crossbedded sandstones and shales. Contains turtle bones but no dinosaurs or mammals. All beds are tilted, but no evidence of angular unconformity. Change from Hell Creek to Bear is more abrupt than from Bear to Fort Union No. 1, the latter being transitional through a thickness of 15 to 20 feet, boundary here being taken arbitrarily at a local shell lens. Discussion of Cretaceous-Tertiary transition.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, pl. 1. Shown on correlation chart below Lebo formation and above Hell Creek formation. Fort Union series, Puercan.

Typically developed around Bear Butte, Sweetgrass and Wheatland Counties.

Bear Branch Limestone Member (of Olive Hill Formation)[1]

Bear Branch facies (of Ross Limestone Member of Ross Formation)

Lower Devonian: Western and central Tennessee.

Original reference: C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 738.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 282 (fig. 3), 283, 297–299. In this report [Pre-Chattanooga stratigraphy of central Tennessee], Dunbar's (1919, Tennessee Div. Geology Bull. 21) classification of Lower Devonian is modified. Bear Branch limestone is interpreted as a restricted facies equivalent to upper part of Ross limestone member of Ross formation herein defined to include all beds overlying Decatur limestone and underlying Flat Gap or Harriman formations. Facies is unconformably overlain by Flat Gap limestone or by Hardin sandstone member of Chattanooga shale. Includes interbeds referred to as Decaturville chert zone. Thickness at Olivehill approximately 45 feet.

Named for exposure on Bear Branch, about 2 miles southeast of Olive Hill [Olivehill], Hardin County.

Bear Canyon Sandstone Member (of Kreyenhagen Formation)

Eocene, upper: Northern California.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 211 (fig. 5), pl. 3. Proposed for persistent sandstone occurring about one-third of distance above base of Kreyenhagen on southwest side of Butts Ranch syncline. Thickness 100 to 300 feet. Overlies an unnamed unit, 300 to 1,000 feet thick, of foraminiferal clay-shales and platy shales, with some interbedded sandstone and limestone, and a thin glauconitic sandstone at base. Unit is faunally equivalent to Canoas siltstone member in Coalinga district. Underlies an unnamed upper member 500 to 1,500 feet thick consisting of siliceous and calcareous foraminiferal platy shales and some limestone.

Type locality: Bear Canyon, 1 mile north of Big Oak Flat, San Benito County.

Bear Creek Shale (in Clinton Formation)[1]

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 53–54, 154, 155. Chadwick used term Bear Creek to designate dark pelecypod-bearing shales which were supposed to underlie the Furnaceville in town of Wolcott. However, no such shale exists beneath the Furnaceville, but there is a shale above the ore which contains the fauna. Bear Creek is herein redefined to apply to pelecypod-bearing shales and argillaceous limestones on Bear Creek, in eastern part of town of Wolcott. As redefined, is argillaceous facies of Reynales limestone. At type locality, is a dark-gray thin-bedded silty slightly calcareous shale with argillaceous limestone layers; both shales and limestones pyritic. Lower 7 feet are about half shale and half argillaceous limestone; next 6 feet are mostly shale. Top of formation is marked by an 8-inch limestone layer which in turn is overlain by 3 inches of hematitic limestone. Underlies lower Sodus shale.

Type locality: Town of Wolcott, Wayne County. Exposed on small tributary of Black Creek which is known locally as Bear Creek; tributary enters Black Creek a little north of where southwest road from Fair Haven crosses Black Creek.

Bear Gulch Limestone Member or Lentil (in Tyler Formation)

Bear Gulch Tongue (in Cameron Creek Member of Tyler Formation)

Mississippian: Central Montana.

G. H. Norton, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 58, 59 (fig. 5), 60 (fig. 6), 62. Limestone lentil or member in the Tyler formation. Overlain by Amsden sandstone.

R. P. Willis, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1942 (fig. 2), 1953, 1954. Bear Gulch referred to as tongue in Cameron Creek member.

Named for exposures in Bear Gulch, sec. 35, T. 14 N., R. 21 E., Fergus County.

Bear Island Granodiorite

Age uncertain: District of Columbia and eastern Maryland.

Ernst Cloos *in* Ernst Cloos and C. W. Cooke, 1953, Geologic map of Montgomery County and District of Columbia (1:62,500): Maryland Dept. Geology, Mines and Water Resources. Light discordant granodiorite, mostly unfoliated and massive. Contains plagioclase, quartz, potash feldspar, muscovite, biotite, and, as accessories, topaz, rutile, zircon, and garnet. Composition variable. Alteration common.

Mapped in District of Columbia and northward to vicinity of Bethesda, Md. Named for occurrence near Bear Island on the Potomac.

Bear Mountain Basalt

Pliocene: Northern California.

H. A. Powers, 1932, Am. Mineralogist, v. 17, no. 7, p. 260–261. Light-gray loose-textured uniform-grained rock in which clear yellow olivine grains are conspicuous in network of colorless plagioclase crystals. Covered by Warner basalt on northern and eastern sides.

Occurs on Bear Mountain in Modoc Lava-Bed quadrangle.

Bear Mountain Granite[1]

Precambrian(?): Central northern Colorado.

Original reference: H. B. Patton, 1909, Colorado Geol. Survey 1st Rept., p. 128, map.

Forms summit of Bear Mountain, Summit County.

Bear Mountain Granite

[Precambrian]: Central Texas.

R. E. McAdams, 1936, Am. Mineralogist, v. 21, p. 129, 133, 134, 135. Bear Mountain granite believed to be younger than Wolf Mountain (new) and Lone Grove granites.

Present near Fredericksburg, Llano County.

Bearpaw Shale (in Montana Group)[1]

Upper Cretaceous: Northern, eastern, and southern Montana and central Wyoming, and Alberta, Canada.

Original references: J. B. Hatcher and T. W. Stanton, 1903, Science, new ser., v. 18, p. 211–212; 1905, U.S. Geol. Survey Bull. 257.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 6–65, pl. 6. Described in Crazy Woman Creek area, Johnson County, Wyo., where it overlies Parkman sandstone and underlies Lance formation. Consists mainly of dark-greenish-gray shale with light-gray siltstone laminae. Upper Cretaceous.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 108 (fig. 1), 116 (fig. 7), 117–118. On northwest flank of Sweetgrass arch, northwestern Montana, present only in area north of Dupuyer Creek. Consists largely of dark-gray marine shale that contains ferruginous concretions, bentonite, and thin layers of sandstone. Thickness 225 to 400 feet. Overlies Two Medicine formation. Upper part of Bearpaw passes westward and southwestward into shallow-water sandy unit that is treated herein as a separate unit and designated as Bearpaw-Horsethief transition.

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, pl. 7. Plate 7 shows that Livingston formation intertongues with Claggett, Judith River, Bearpaw, Lennep, Hell Creek, Tullock, and Lebo formations.

W. P. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 59, pls. In Buffalo-Lake De Smet area, northeastern Wyoming, consists of thin sequence of marine shale that is conformable with both underlying Parkman sandstone and overlying Lance formation. Thickness about 200 feet.

Named for exposures around north, east, and south borders of Bearpaw Mountains, Mont.

Bear Pond Limestone Member (of Seboomook Formation)

Lower Devonian: West-central Maine.

A. J. Boucot, Charles Harper, and Keith Rhea, 1959, Maine Geol. Survey Spec. Geol. Studies Ser. 1, p. 7, 8, map. Blue gray on fresh surfaces and gray on weathered surfaces; contains subrounded to subangular granite pebbles up to 2 inches across; fragments of brachiopods, corals, and crinoid stems; angular black calcite crystals or fragments up to coarse sand size; brown and white mica flakes; some pyrite and other iron-sulfide crystals. Observed only at one outcrop where it is 10 feet stratigraphically above a slate exposure; neither top nor bottom of unit exposed. Thickness about 10 feet.

Exposed in NW cor. T. 3, R. 5, in area west of Beck Pond and Bear Pond, Spencer quadrangle, Somerset County.

Bear Pond Schist[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Catamount schist and below Beech Mountain amphibolite.

Type locality: Bear Pond, Ticonderoga Township, Essex County.

Bear River Formation[1]

Lower Cretaceous: Southern Wyoming, southeastern Idaho, and northeastern Utah.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Colorado and New Mexico, 3d Ann. Rept. Hayden Survey, p. 91, 92.

D. A. Andrews and C. B. Hunt, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 70. Mapped in Utah. Lower Cretaceous.

J. D. Vine and G. W. Moore, 1952, U.S. Geol. Survey Circ. 212, p. 3, 4, 5. In Bonneville County, Idaho, underlies Wayan formation and overlies Tygee sandstone of Gannett group. Thickness 152 feet. Lower Cretaceous.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 958. Age mentioned as Lower Cretaceous.

Teng-Chien Yen, 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 757–764. In type area, overlain by Aspen shale and underlain by Beckwith formation. Aspen shale has been considered Lower Cretaceous on basis of ammonite fauna. If this age determination is considered conclusive, then Bear River beds should be assigned to Lower Cretaceous. However, on basis of fauna, Bear River strata are here assigned to level near base of Upper Cretaceous (Cenomanian).

A. La Rocque and C. D. Edwards, 1954, Geol. Soc. America Bull., v. 65, no. 4, p. 315–326. Cretaceous Bear River and Aspen section in Willow Creek, 6 miles southeast of junction of Hoback and Snake Rivers, Teton County, Wyo., described in detail including position and nature of its faunas. Bear River is 539 feet thick, and Aspen 1,307 feet. On lithologic and paleontologic grounds, Bear River-Aspen contact is placed lower than in earlier reports. Conflicting age assignments for Bear River and Aspen discussed. Suggested that this conflict may be due to complex intertonguing between the two formations.

J. D. Vine, 1959, U.S. Geol. Survey Bull. 1055–I, p. 259 (table), 262–263. In Bonneville County Idaho, unconformably underlies Wayan formation and conformably overlies Tygee sandstone of Gannett group. Thickness 300 to 500 feet. Lower two-thirds of formation consists of dark-gray ferruginous carbonaceous shale and siltstone interbedded with thin beds of dark-brown sandstone. Upper third consists of prominent ledge of medium-grained gray to brown quartzite or sandstone 75 feet thick. Overlain by black shale, thin beds of fine-grained brown sandstone, coaly shale, and black fossiliferous granular limestone. Upper and lower contacts of formation, as described herein follow usage of

L. S. Gardner (oral commun. 1952). Bear River formation, as used herein, includes strata included in Tygee formation by Kirkham (1924). Lower Cretaceous.

First mentioned in vicinity of Bear River City, Wyo.

Bear River Formation

Bear River Series[1]

Miocene, upper: Northern California.

Original reference: W. Stalder, 1915, California State Mining Bur. Bull. 69, p. 447–449.

G. C. Gester, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 205. Referred to as Bear River formation in Eel River basin. Consists of marine shale with hard calcareous members. Thickness 1,000 feet. Underlies Wildcat series; overlies Franciscan.

Occurs in Humboldt County.

Bear Run cyclothem

Pennsylvanian (Pottsville Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 4. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser.. Bull. 48, p. 24–28, table 1, geol. map. Includes (ascending) Massillon shale and (or) sandstone, 20 feet thick; Bear Run clay, 3 feet; and Bear Run coal. Occurs above Quakertown cyclothem and below Vandusen cyclothem. In area of this report, Pottsville series is described on cyclothemic basis; 10 cyclothems are named. [For sequence see Anthony cyclothem.]

Exposed in Perry County.

Bear Run Member (of Pottsville Formation)[1]

Pennsylvanian (Pottsville Series): Southern Ohio.

Original reference: H. Morningstar, 1922, Ohio Geol. Survey Bull. 25, p. 13, 25–28, 299–300.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull, 39, p. 86–89. Sandstone and shale member varies from about 20 to 60 feet; average 30 feet; proportions of sandstone and shale vary locally. Horizon is defined by Bear Run coal and clay beds beneath and Vandusen clay and coal above.

Type locality and derivation of name not given.

Bear Spring Formation

Middle Devonian: Central Texas.

V. E. Barnes, P. E. Cloud, Jr., and L. E. Warren, 1947, Geol. Soc. America Bull., v. 58, no. 2, p. 136–138. Name applied to fossiliferous and in part cherty limestones of lower Middle Devonian age that occur in an ancient collapse structure. Rocks are fine to coarse grained; color varies—white to cream colored, yellowish or greenish brown to buff, bronze, olive brown, ivory, or nutria; over lower part of collapsed area, considerable dull-white to speckled-gray porcelaneous to semiporcelaneous chert occurs in float. At type locality, a patch of rocks, 240 feet long in northeast-southwest direction and 140 to 160 feet wide, has collapsed into limestones of Lower Ordovician Gorman formation and is in part overlapped by rocks of Mississippian age.

Type locality: Near head of east fork of a draw that enters south side of valley of Honey Creek about 280 feet upstream from rock cabin on Roy Zesch Ranch, Mason County.

Bear Springs Basalt

Tertiary, upper: Southwestern New Mexico.

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 39 (table 3), 48–49, pl. 1. Flows of purple fine-grained porphyritic iddingsite-bearing rock, at times scoriaceous. Thickness about 150 feet. Unconformable contacts with Razorback formation below and Santa Fe(?) formation above.

W. E, Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 34–36, pl. 1. In Dwyer quadrangle, composed of flows, breccias, agglomerates, conglomerates, and, rarely, chocolate-colored sandy tuffs. Groundmass is gray to black.

Elston (1957) cites Jicha (1954) as designating type locality in sec. 25, T. 18 S., R. 9 W., Lake Valley quadrangle. Named from outcrop at intersection of secs. 17, 18, 19, and 20, T. 20 S., R. 8 W., about one-half mile distant from Bear Springs Canyon (Jicha, 1954, p. 48). [However, pl. 1 does not show unit mapped at this locality.]

Beartooth Quartzite[1]

Upper(?) Cretaceous: Southwestern New Mexico.

Original reference: S. Paige, 1916, U.S. Geol. Survey Geol. Atlas, Folio 199.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 283 (fig. 5), 285, pl. 1. In Santa Rita area, is 50 to 120 feet thick and consists of light-colored massive conglomerate, vitreous quartzite, and sandstone with a few shaly layers. Underlies Colorado formation; unconformably overlies Syrena (upper Magdelena) or Abo.

C. H. Hewitt, 1959, New Mexico Bur. Mines Mineral Resources Bull. 60, p. 78–80. Described in northern Big Burro Mountains-Redrock area, where, in vicinity of Slate Creek and Fox Tail Creek, it forms cliffs 100 to 125 feet high. Lies unconformably on Precambrian granite (Burro Mountain granite). In many areas, Colorado shale crops out in valleys or saddles between Beartooth quartzite and overlying lavas.

Named for Beartooth Creek, near Fort Bayard, Silver City region.

Beartooth Butte Formation[1]

Lower Devonian: Northwestern Wyoming and Montana.

Original reference: E. Dorf, 1934, Jour. Geology, v. 42, p. 723–737.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1746, chart 4. Placed in Oriskany lower Onondaga position opposite that portion of Nevada limestone, only other known Lower Devonian of the West. Lower, and Lower or Middle Devonian.

Named for occurrence on Beartooth Butte, in SW cor. T. 58 N., R. 105 W., Park County, 3 miles south of Montana line, just northwest of Beartooth Lake, and in Crandall quadrangle (of Absaroka folio).

Bearwallow Conglomerate (in Pottsville Group)[1]

Lower Pennsylvanian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44.

Named for Bearwallow Ridge, west of Dry Fork, McDowell County, W. Va.

Bear Wallow facies[1] (of Edwardsville Formation)

Lower Mississippian: Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 288–293.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, p. 1. Facies nomenclature discussed. Correlation chart lists Bear Wallow facies of Edwardsville formation.

Name derived from Bear Wallow, a prominent upland, 3 miles northeast of Nashville, Brown County.

Bearwallow Schist

Age not stated: Western North Carolina.

C. E. Hunter and P. W. Mattocks, 1936, TVA Div. Geology Bull. 4, p. 13–14. Essentially mica, garnet, and kyanite schist. Kyanite only makes small part of schist. Division of the Buck Ridge schist (new).

Outcrops on west side of gap at head of Bear Creek and also one-half mile southwest of Ledger Schoolhouse, Spruce Pine quadrangle.

Beattie Limestone (in Council Grove Group)

Beattie Formation (in Council Grove Group)[1]

Permian: Northeastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1, p. 13.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46–47. Beattie limestone includes (ascending) Cottonwood limestone, Florena shale, and Morrill limestone members. Thickness 15 to 25 feet. Underlies Stearns shale; overlies Eskridge shale. Wolfcamp series.

Type locality: Beattie, Marshall County, Kans.

Beattyville Shale (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky.

Original references: A. M. Miller, 1917, Table of geological formations of Kentucky: Lexington, Ky., Univ. Book Store, p. 2; 1919, Kentucky Dept. Geology and Forestry, ser. 5, Bull. 2, p. 10 (table), 147 (table).

A. C. McFarlan, 1954, Kentucky Geol. Survey Spec. Pub. 4, p. 11–14. In Natural Bridge State Park, area consists of succession of shales and thin sandstones up to 30 feet thick. Underlies Rock Castle conglomerate; overlies Mississippian Mammoth Cave limestone. Locally absent.

Apparently named for Beattyville, Lee County.

Beaufort Formation

Paleocene: Eastern North Carolina (subsurface).

P. M. Brown, 1959, North Carolina Div. Mineral Resources Bull. 73, p. 8 (table 4), 12–13, 29–30, 37–38, 45, 51–52, 64, 71. Variable composition, ranging from green glauconite sands containing about 90 percent glauconite to gray argillaceous sands containing about 5 percent glauconite; indurated shell-limestone intercalations common; euhedral pyrite common accessory; fossiliferous. Type well penetrated 65 feet of Paleocene strata between depths of 150 and 215 feet. Well logs show formation underlies Castle Hayne limestone or Yorktown formation, or locally, an unnamed middle(?) Miocene unit; overlies Upper Cretaceous Peedee formation. Midway age.

Type locality: Well 215 feet deep, drilled in 1952 for Nelson Motel at Chicowinity, Beaufort County. Recognized in wells in Martin, Bertie, Hertford, Gates, and Chowan Counties.

Beaumont Clay[1]

Beaumont Formation

Pleistocene: Eastern Texas and southwestern Louisiana.

Original reference: W. Kennedy, 1903, U.S. Geol. Survey Bull. 212, p. 20, 27, pls. 1, 2.

W. A. Price, 1939, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1875. Lake Charles and Ingleside formations (both new) replace Beaumont formation.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1708–1709. Quaternary deposits of Texas Coastal Plain between Brazos River and Rio Grande are divided into (ascending) Willis, Gay Hill, Bastrou Park, Uvalde, Asylum, Capitol, Beaumont (Sixth Street), Live Oak Bar (approximately of Beaumont age), First Street, Riverview, and Sand Beach terrace deposits.

J. A. Doering, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1830–1831. In southwestern Louisiana, Beaumont formation is divided into Oberlin (Lower Beaumont) and Eunice (upper Beaumont).

Named for Beaumont, Jefferson County, Tex.

Beauvais Sandstone[1]

Middle Devonian: Eastern Missouri.

Original reference: C. L. Dake, 1918, Missouri Bur. Geology and Mines, v. 15, 2d ser., p. 88, 174–175.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 123–124. Predominantly white sand. Thickness as much as 50 feet. Overlies Grand Tower limestone; underlies St. Laurent.

Type exposures along Little Saline Creek, in Beauvais Township, Ste. Genevieve County.

Beaver division[1] (of Leon Series)

Upper Cambrian or Lower Ordovician: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. 259–306, pl. 3.

Named for Beaver Creek, Burnet County.

Beaver Gypsum[1]

Permian: Western Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 359, 363.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 106. Rejected by Oklahoma Geological Survey. Name preoccupied.

Named for occurrence near Beaver City and in Beaver County.

†Beaver Limestone[1]

Lower Cambrian: Eastern Tennessee.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16.

Named for Beaver Ridge, north of Knoxville, Knox County.

†Beaver Sandstone (in Pottsville Group)[1]

Pennsylvanian: Eastern Kentucky.

Original reference: I. B. Browning and P. G. Russell, 1919, Kentucky Geol. Survey, 4th ser., v. 5, pt. 2, p. 11–18.

Exposed in Magoffin County.

Beaver Basin Formation

Pleistocene: Southeastern Utah.

G. M. Richmond, 1956, Dissert. Abs., v. 16, no. 6, p. 1128. Consists of two members that comprise 10 lithofacies, including till, rock glaciers, and various alluvial, colluvial, and eolian deposits. Tills form two sets of upper canyon end moraines. Weakly developed Pack Creek soil is formed on lower member where it is overlain by upper member. Moderately developed Castle Creek soil is formed on upper member and on deposits of the lower member not overlain by the upper member. Older than Gold Basin formation (new); younger than Placer Creek formation (new).

Located in La Sal Mountains area.

Beaver Bay Complex (in Keweenawan Group)

†Beaver Bay Diabase[1]

†Beaver Bay Group[1]

Precambrian: Northeastern Minnesota.

Original reference (Beaver Bay Group): R. D. Irving, 1883, U.S. Geol. Survey, 3d Ann. Rept., p. 143–146, pl. 14.

F. F. Grout and G. M. Schwartz, 1939, Minnesota Geol. Survey Bull. 28, p. 12, 13, 32–33. Beaver Bay complex is an expansion of phrase Beaver Bay group as used by Irving and Beaver Bay diabase as used by Winchell (1899, Minnesota Geol. and Nat. History Survey Final Rept., v. 4). Diabases and related basic rocks of complex form largest exposures in southern Lake County; they form bluffs and ridges up to 300 feet high. Intrusives that follow the structure, dipping toward Lake Superior, form northward-facing escarpments and more gentle back slopes, but transgressive and dikelike masses may form bluffs facing in other directions. Beaver Bay diabase is sill-like with minor irregularities and several petrographic facies. In table of formations, Beaver Bay complex is listed above Keweenaw Point volcanics (new); ages of both are middle Keweenawan.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3). Beaver Bay complex included in middle part of Keweenawan group.

H. M. Gehman, 1958, Minnesota Univ. Center for Continuation Study, Gen. Ext. Div., Inst. of Lake Superior Geology, Apr. 21–22, p. 1. Complex comprises three gabbroic intrusions: Beaver River gabbro, Beaver Bay ferrogabbro, and Black Bay gabbro (all new). Gabbros intrude North Shore Volcanic group (new) which is considered middle Keweenawan.

Exposed on Beaver Bay.

Beaver Bay Ferrogabbro (in Beaver Bay Complex)

Precambrian: Northeastern Minnesota.

H. M. Gehman, 1958, Minnesota Univ. Center for Continuation Study, Gen. Ext. Div., Inst. of Lake Superior Geology, Apr. 21–22, p. 1. Second intrusion of the complex. Younger than Beaver River gabbro (new). Surrounded and intruded by Black Bay gabbro (new).

In southeastern Lake County.

Beaver Bend Limestone[1]

Beaver Bend Limestone (in West Baden Group)

Beaver Bend Limestone Member (of Renault Formation)

Mississippian (Chester Series) : Southwestern Indiana and central northern Kentucky.

Original reference: C. A. Malott, 1919, Indiana Univ. Studies, v. 6. no. 40, p. 7–20.

R. E. Stouder, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 3, p. 268 (fig. 1), 269, 270 (fig. 3), 271, 273. In Meade, Hardin, and Breckinridge Counties, Ky., Beaver Bend limestone is considered member of Renault formation. Overlies Mooretown sandstone member; underlies Sample sandstone. Unit has been placed in Gasper oolite and referred to as Renault limestone, but always undifferentiated. Thickness 14½ feet at Ohio River and as far south as Webster and Lodiburg, both in Breckinridge County; 38 feet in western part of Big Clifty quadrangle.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 825; J. M. Weller and others, 1948, Geol. Soc. America Bull. v. 59, no. 2, chart 4 (column 76). Considered member of Renault formation in Indiana.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7, 13. Renault formation of standard Chester column has triple expression in southern Indiana (ascending) : Paoli limestone, Mooretown sandstone, and Beaver Bend limestone. Each of these is a distinct stratigraphic unit in parity with other formations of the Chester and deserves a name in its own right. Thicker sections of Beaver Bend are downdip away from eastern outcrop margin; in places along higher margin, unit is quite thin and locally absent. In western Putnam County, cut out and overlapped by Pennsylvanian Mansfield sandstone.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 24, pl. 1. Beaver Bend limestone in Indiana is light gray, oolitic, crystalline, and thick bedded to massive. Thickness 1 to 20 feet. Overlies Mooretown sandstone: underlies Sample sandstone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 46–47, pl. 1. Included in West Baden group (redefined). Brown-gray thick-bedded finely crystalline fossiliferous limestone 8 to 27 feet thick. Overlies Bethel formation; underlies Sample formation.

Named for exposures at conspicuous bend in Beaver Creek, just east of Huron, Lawrence County, Ind.

Beaverburk Limestone (in Wichita Group)[1]

Beaverburk Member (of Bead Mountain Formation)

Permian (Leonard Series) : North-central Texas.

Original reference: J. A. Udden and D. M. Phillips, 1912, Texas Univ. Bull. 246, p. 31–36, 42–43.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on chart as a member of Bead Mountain formation.

Named for exposures in basin of Beaver Creek and around Burk, Wichita County.

†Beaver Creek Chalky Member (of Niobrara Formation)[1]

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

Abandoned by U.S. Geological Survey as corollary of action transferring Sage Breaks member to Carlile shale; this left Beaver Creek as only representative of Niobrara formation. Consequently, formation name only is used in the area.

Named for exposures along Beaver Creek, in T. 46 N., R. 64 W., Weston County, Wyo.

Beaver Creek Member (of New Providence Formation)

Beaver Creek sand[1]

Lower Mississippian: South-central Kentucky.

Original reference: D. C. MacLachlan, 1928, Michigan Acad. Sci. Arts, and Letters, Papers, v. 8, p. 298, 302.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77. Beaver Creek member of New Providence formation in area of Forbush facies.

Occurs in Pulaski, Russell, and Wayne Counties.

Beaver Dam Black Shale Member (of Needmore Shale)

Middle Devonian: Central Pennsylvania.

Bradford Willard *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 141, 153. Name proposed for thick black shale near middle of Needmore shale. Unit also listed in table 20 as part of Selinsgrove limestone which overlies Needmore shale. Contains few scattered calcareous concretions; none near base. Thin sandstone partings in lower part. Thickness 78 feet.

F. M. Swain, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2867. Redefined as Beaverdam Run member of Newton Hamilton formation (new).

Type locality: In large cuts on the Pennsylvania Railroad east of Newton Hamilton, Mifflin County. Named from brook at type locality.

Beaverdam Sand

Pleistocene (Aftonian): Southeastern Maryland (subsurface and surface)

W. C. Rasmussen and T. H. Slaughter, 1955, Maryland Dept. Geology, Mines and Water Resources Bull. 16, p. 113, 115 (table 17), 116. Composed of unconsolidated white to buff medium-grained quartz sand, with small quantities of coarse and fine sand, pebbles and granules, and a minor admixture of white silt. Thickness as much as 72 feet. In some places, underlies Walston silt (new); in others the Pamlico formation.

Reference locality: Test hole, Wi-Cf 63, 2 miles east of Salisbury, Wicomico County. Crops out in banks and roadcuts surrounding Schumaker Pond. Named for Beaverdam Creek, each branch of Wicomico River, because of its prominent occurrence in and beneath drainage basin of that stream.

Beaverdam Creek Augen Gneiss

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Geol. Survey Bull. 72, p. 32-34, pl. 1. Dark-gray rock banded by red-brown biotite, with coarse gray microcline metacrysts, which are deformed into augen, and blue quartz grains. Derived when granitic solutions related to Striped Rock granite injected Saddle gneiss (new).

Named from occurrence on Beaverdam Creek southeast of Independence, Grayson County. Wide distribution in belt that extends from Baxter Ferry on New River southwestward to Penitentiary Ford on same river.

Beaverdam Run Member (of Newton Hamilton Formation)

Upper Devonian: Central Pennsylvania.

F. M. Swain, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2860 (fig. 2), 2867. At type section, consists of 18 to 20 feet of dark-gray to black thinly laminated to fissile and papery shale, weathering greenish gray; pyritiferous nodules of black chert occur at several levels; at base is 6-inch unit of dark-gray very argillaceous and carbonaceous fine- to coarse-grained calcareous sandstone representing reworked Ridgeley and resting with sharp contact on that formation. Underlies Hares Valley limestone and shale member (new). This member was named Beaver Dam black shale member of Needmore by Willard and others (1939). Willard's original definition as the black shale in the middle part of the section is here discarded and member redefined.

Type section: In railroad cut northeast of Newton Hamilton, Mount Union quadrangle, corresponding with type section of formation. Named from Beaverdam Run which empties into Juniata River, 1½ miles northeast of Newton Hamilton.

Beaver Divide Conglomerate Member (of White River Formation)

Beaver Divide Conglomerate Member (of Chadron Formation)

Oligocene, lower: Southwestern Wyoming.

R. L. Nace, 1939, Wyoming Geol. Survey Bull. 27, p. 11 (table), 32–34, pl. 1. Proposed for basal conglomerate of Chadron. Gray to nearly black cross-bedded boulder and pebble conglomerate in matrix of coarse tuffaceous calcareous sandstone. Thickness varies; as much as 68 feet. Disconformable above Continental Peak formation (new).

F. B. Van Houten, 1950, U.S. Geol. Survey Oil and Gas Inv. Map OM–113. In this report, unit is referred to as Beaver Divide conglomerate member of White River formation.

F. B. Van Houten, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–140. Member of White River formation. Conformably overlies Sand Draw sandstone lentil (new) in Long Creek-Beaver Divide area, Fremont County. Maximum thickness about 80 feet. Grades upward into typical Wind River rocks by introduction of more sandy and silty matrix and reduction in number of conglomerate lenses.

Named for occurrence in Beaver Divide area. Well exposed on east side North Oregon Butte, west-central part sec. 2, T. 26 N., R. 101 W., Sweetwater County.

Beaverhead Formation

Beaverhead Conglomerate

Upper Cretaceous, Paleocene, and Eocene: Southwestern Montana and east-central Idaho.

A. J. Eardley, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1552. Cited as conglomerate of Upper Cretaceous or Paleocene age.

W. R. Lowell and M. R. Klepper, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 235–243. Beaverhead formation proposed for sequence of conglomerate, sandstone, siltstone, and limestone that crops out over area of at least 400 square miles in Beaverhead County, Mont., and extends across Montana-Idaho boundary. Divided into four mappable units at type section. Top and bottom members dominantly conglomerate; intermediate member consists of two mappable units: a lower thick massive limestone, locally concretionary, and an upper sequence of interbedded siltstone, sandstone, arkose, limestone, and subordinate conglomerate. Approximately 9,700 feet thick at incomplete section where neither top nor base is exposed. Rests unconformably upon rocks as young as Colorado group and as old as early Paleozoic, and it probably rests unconformably upon rocks as young as Montana group and as old as Precambrian. Unconformably overlies Kootenai, Dinwoody, Thaynes, Phosphoria, Quadrant, and Madison. At McKnight Canyon section, base of section is marked by high-angle normal faults which have dropped the Beaverhead against Triassic Thaynes formation and Mississippian Madison. Contact between Beaverhead and Pennsylvanian Quadrant obscured by talus. At top of section, a plate of Madison limestone has been thrust over Beaverhead formation. Unconformably overlain by fluviatile or lacustrine beds of Eocene or Oligocene age. Age designated as probably late Cretaceous to early Eocene.

Type locality: Near mouth of McKnight Canyon, 6 miles west of Dell, Beaverhead County, Mont.

Beaverhead Granite

Eocene: Southwestern Montana and east-central Idaho.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 370–372, pl. 1. Moderately coarse-grained granite ranging from light gray to pink and light green. Cut by coarse quartz veins and small aplite dikes of same composition as main body but of much finer texture. More than 6 miles long and 2 miles wide in outcrop. Underlies Medicine Lodge volcanics (new).

Crops out in Beaverhead Range along Idaho-Montana state line. Described from occurrences in Beaverhead County, Mont.

Beaver Lake Alluvium

Quaternary: Southwestern Utah.

P. J. Barosh, 1960, Utah Geol. and Mineralog. Survey Bull. 68, p. 28–29. Most extensive alluvium formation in area. Consists mainly of silt, sand, and gravels with only small amount of pebbles and larger clasts.

Present in Beaver Lake Mountains, Beaver County.

Beaver Lake Dolomite

Upper Ordovician(?)-Silurian: West-central Utah.

P. J. Barosh, 1960, Utah Geol. and Mineralog. Survey Bull. 68, p. 14, 20–22, 49. Chiefly dark- to medium-gray mottled or laminated dolomite, which weathers a lighter gray; contains few beds of edgewise conglomerate; fossiliferous. Base not exposed; thickest measurable section is 200 feet on northwest side of Lime Mountain; estimated minimum exposed thickness 400 feet. Conformable below Lime Mountain dolomite (new); stratigraphically above but not in contact with Burrows(?) limestone. Metamorphosed rocks on west flank of Lime Mountain are considered altered equivalent of the Beaver Lake.

Crops out in northern part of Beaver Lake Mountains area around northern base of Lime Mountain and ridges to northwest of it, Beaver County.

Beaver Mountain Group[1]

Mesozoic or Tertiary: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 7, 8.

Exposed in section running from Champion Station eastward into Beaver Mountain, British Columbia.

Beaver River Formation (in Pottsville Group)[1]

Pennsylvanian: Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia(?).

Original reference: J. P. Lesley and I. C. White, 1876, Pennsylvania 2d Geol. Survey map of Beaver County.

Typical section is along Big Beaver River and Connoquenessing Creek in Beaver County, Pa.

Beaver River Gabbro (in Beaver Bay Complex)

Precambrian: Northeastern Minnesota.

H. M. Gehman, 1958, Minnesota Univ. Center for Continuation Study, Gen. Ext. Div., Inst. of Lake Superior Geology, Apr. 21–22, p. 1. Oldest intrusion of complex. Followed by Beaver Bay ferrogabbro intrusion (new). Intrudes North Shore volcanic group (new).

In southeastern Lake County.

Beavertown Marl (in Brassfield Limestone)[1]

Silurian: Southwestern Ohio.

Original reference: A. F. Foerste, 1885, Denison Univ. Sci. Lab. Bull. 1, p. 65.

Located at various localities in vicinity of Dayton and near Beavertown, southeast of city and southeast of Soldiers Home, west of city.

Bechler Conglomerate,[1] Redbeds, Shale, or Formation (in Gannett Group)

Lower Cretaceous: Southeastern Idaho and western Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 76, 82.

L. S. Gardner, 1944, U.S. Geol. Survey Bull. 944–A, p. 7. In Irwin quadrangle, referred to as Bechler shale, 35 feet thick. Underlies Draney limestone; overlies Peterson limestone.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 43, pl. 1. In Ammon quadrangle, Idaho, predominantly sandstone with scattered beds of conglomerate. Unit involved in folds and faults; full thickness not exposed; 1,000 feet of formation may be present. Overlies Peterson limestone; unconformably underlies Wayan formation. Early Cretaceous.

C. A. Moritz, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 65 (table 1), 67 (fig. 2), 68. Referred to as Bechler formation in Gannett Hills area, Wyoming, where it is about 1,000 feet thick and consists of sandstones, siltstones, conglomerates, a few thin coarsely crystalline limestones, shales, and mudstones. Overlies Peterson limestone; underlies Draney limestone.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 56, pl. 21. In Jackson Hole area, Bechler "conglomerate" member of Gannett group is a 100- to 150-foot interval of weak beds consisting almost entirely of light-blue, purplish, or reddish-gray shale.

Overlies Peterson limestone member and underlies Draney limestone member.

W. L. Stokes, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 80, 81 (fig. 1). In western Wyoming, normally underlies Draney limestone and overlies Peterson limestone; where in contact with Ephraim conglomerate, separation of the two is difficult.

Named for Bechler Creek which enters Stump Creek from north about one-fourth mile north of mouth of Boulder Creek, T. 6 S., R. 45 E., Boise meridian, Bannock County, Idaho.

Becket Granite Gneiss[1]

Precambrian: Western Massachusetts, western Connecticut, and southwestern Vermont.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 18, 31–38, pl. 34.

J. W. Clarke, 1958, Connecticut Geol. Nat. History Survey Quad. Rept. 7, p. 4. Informaly called gneissic granite and trondhjemite in report on Danbury quadrangle.

Named for occurrence at Becket, Mass.

Beckett Limestone (in Plattin Group)

Middle Ordovician: Southwestern Missouri.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2049–2052. Named as the second of four formations in the group. Fucoidal fine-textured calcite limestone having layers of intraformational calcarenite and carbonate pebble conglomerate; nodular chert common in upper part. Thickness at type section 117 feet. Overlies Bloomsdale formation (new); in southern areas, disconformably overlain by Hager formation (new); north of western St. Louis County, overlain by Macy formation (new); in Franklin, Montgomery, and Callaway Counties, succeeding beds are Devonian and Mississippian.

Type section: Below roadcuts along Missouri Highway 25, in NW¼ sec. 27, T. 38 N., R. 8 E., Ste. Genevieve County. Name derived from Beckett Hills.

Beckler Quartz Diorite

[Paleocene or older]: Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. Probably an offshoot from the Mount Stuart batholith. Intruded Tonga formation (new). Produced late-kinematic contact minerals up to warm-mesozonal grade.

Between central and eastern part of Skyhomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

Beck Pond Limestone

Lower Devonian: West-central Maine.

A. J. Boucot, Charles Harper, and Keith Rhea, 1959, Maine Geol. Survey Spec. Geol. Studies, Ser. 1, p. 9–19, 24, map. Subdivided into five members (ascending): member 1, predominantly coarse gray-green quartzose limestone containing one or two stromatoporoid biostromes with some of the sandy layers well crossbedded; member 2, chiefly stromatoporoid biostromes interlayered with minor amounts of gray-green quartz-rich limestone containing some coral and stromatoporoid fragments; member 3, similar to member 1 and has also distinct bedding and crossbedding;

member 4, light-colored granite-boulder conglomerate containing boulders but to 15 feet across; member 5, coarse-grained gray-green calcareous quartz conglomerate similar to member 4 but containing more fossils, which are concentrated in certain layers. Thickness about 750 feet. In some areas, unconformably overlain by slate of Seboomook formation. Overlies pre-Silurian granitic basement complex; contact not exposed. A body of diabase intrudes both the Beck Pond and the granite.

W. A. Oliver, Jr., 1960, U.S. Geol. Survey Bull. 1111–A, p. 1–22, pls. Rugose corals described. Corals comparable to Beck Pond species are found in Coeymans limestone in New York and in Keyser limestone of Late Silurian and Early Devonian(?) age in Maryland and West Virginia.

Type area: On south part of low hill in NW cor. T. 3, R. 5, in area west of Beck Pond and Bear Pond, Spencer quadrangle, Somerset County.

Becks Limestone

Upper Devonian: Northern Utah.

N. C. Williams, 1940, Compass, v. 20, no. 2, p. 76 (fig. 1), 77. Becks limestone overlies Swan Peak(?) formation and is in turn overlain by Madison-Brazer limestones of Mississippian age.

J. E. Brooks, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 55. In areas of Becks Spur and City Creek Canyon, Edvalson (1947, unpub. thesis) described section of Upper Devonian rocks to which he applied name Becks formation. Underlies the Madison and rests on quartzose sandstones and quartzites which were provisionally referred to Swan Peak quartzite. Granger and Sharp (1952) applied name City Creek to these same rocks. Granger (1953, p. 2) abandoned name City Creek and applied name Pinyon Peak.

Granger (1953, U.S. Geol. Survey Circ. 296) did not use term City Creek. It is inferred that he abandoned the term in favor of Pinyon Peak.

Probably named for Becks Spur, Wasatch Mountains, Salt Lake County. Also recognized in City Creek Canyon.

Beck Spring Dolomite

Precambrian (Pahrump Series): Southern California.

D. F. Hewett, 1940, Washington Acad. Sci. Jour., v. 30, no. 6, p. 240; 1956, U.S. Geol. Survey Prof. Paper 275, p. 26, 28, pl. 1. Consists largely of beds of light-bluish-gray dolomite, 2 to 4 feet thick, separated by layers of shaly material; contains numerous beds of oolite several feet thick. No clearly identifiable fossils present, but layers of roundish concretions about one-half inch in diameter may be of algal origin. Thickness about 1,000 feet. Conformably underlies Kingston Peak formation (new); conformably overlies Crystal Spring formation (new).

L. A. Wright, 1952, California Div. Mines Spec. Rept. 20, p. 7 (fig. 3), 12, 13. Described in Superior talc area, Death Valley region. This is most westerly known occurrence of unit. Composed mostly of light-brown fine-grained dolomite containing subordinate olive-gray to light-brown quartzite and shale; dolomite beds are commonly 2 to 10 feet thick and locally contain thin siliceous layers parallel with bedding; quartzite and shale layers range in thickness from a few inches to as much as 20 feet and are most abundant in upper 200 feet of formation. Thickness about 1,300 feet. Overlies Crystal Spring formation; underlies Kingston Peak formation.

Crops out in belt 6 miles long on north slope of Kingston Range, Ivanpah quadrangle. Name derived from Beck Spring on north slope of range.

Beckwith Formation[1]

Jurassic and Cretaceous: Southwestern Wyoming and northeastern Utah.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56.

D. A. Andrews and C. B. Hunt, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 70. Shown on map legend of northeastern Utah. Jurassic and Cretaceous.

W. L. Stokes, 1955, Wyoming Geol. Soc. Guidebook 10th Ann. Field Conf., p. 80. Originally included beds now constituting Preuss, Stump, and present Gannett group. Remainder of Beckwith has been treated differently. Some workers have retained name Beckwith for restricted part, others have attempted to distinguish members of Gannett within it, and still others have treated it as undifferentiated Gannett. This situation has led to general abandonment of term Beckwith, but problem of just which members, if any, of the Gannett can be recognized in areas where Beckwith has long been used is not settled.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Mapped in southwestern Wyoming.

Named for development on Beckwith Ranch, just east of Beckwith Station on Oregon Short Line, Lincoln County, Wyo.

Becraft Limestone[1] **or Sandstone** (in Helderberg Group)

Becraft Limestone Member (of Helderberg Limestone)

Lower Devonian: Eastern New York, western Maryland, New Jersey, Pennsylvania, Virginia, and northern West Virginia.

Original reference: J. Hall, 1893, New York State Geol. 12th Ann. Rept., p. 9-13.

Winifred Goldring, 1931, New York State Mus. Handb. 10, p. 190, 370, 377. Underlies Alsen limestone (new).

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G-19, p. 62-65. At Becraft Mountain, opposite Catskill, N.Y., New Scotland beds are overlain by Becraft limestone, 45 feet thick and consisting of light-gray crystalline in part crinoidal beds. Above Becraft are 25 feet of Alsen limestone. Becraft continues southward to Kingston, where it is 35 feet thick, and into New Jersey, where it is 15 to 20 feet thick. Alsen beds disappear southward and are displaced by Port Ewen beds. In Pennsylvania, Becraft and Port Ewen occur as units to which these names can be applied only in eastern part of Monroe County. Mandata shale and Licking Creek limestone of central and south-central Pennsylvania are partially of these ages.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 279-286. Referred to as member of Helderberg in Virginia and West Virginia. In Virginia, the Becraft is generally bounded by New Scotland limestone but, in places perhaps, by Tonoloway limestone where rest of Helderberg is absent. Bounded above by either Oriskany sandstone or Onondaga formation, as the sequence varies from place to place. Thickness about 50 feet to about 100 feet.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 126. Swartz (1929) named Rocky Gap sandstone from Rocky Gap, Bland County. Butts

(1940) used name Becraft for this sandstone throughout southwestern Virginia; this use should be abandoned, and term Rocky Gap continued.

H. P. Woodward, 1948, West Virginia Geol. Survey, v. 15, p. 95–97. In most previous reports dealing with Helderberg group in the Virginias, a so-called Becraft limestone has been recognized and described. It is now believed, on evidence presented by F. M. Swartz, that the horizon so identified lies at a higher level than the true Becraft in New York. According to this interpretation, whatever representation the true Becraft has in West Virginia must come below cherty beds of Port Ewen (previously called, in part "Shriver" chert) and above cherty beds of New Scotland. This interval is occupied by soft gray calcareous shale that contains late New Scotland fauna with sparse forms of probable Becraft affinity.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 83–84. In Maryland, Becraft member of Helderberg is an arenaceous limestone interbedded with black chert. Present only in Washington County where it is 85 feet thick. In Cumberland and Keyser sections, member is missing, but it continues into Virginia where it was described by Butts (1940). Overlies New Scotland member.

Named from Becraft Mountain, Columbia County, N.Y.

Bedford Augen Gneiss[1]

Age(?): Southeastern New York.

Original reference: C. R. Fettke, 1914, New York Acad. Sci. Annals, v. 23, p. 239.

Southeast and south of Bedford village, Westchester County.

Bedford Clay (in Pottsville Formation)[1]

Bedford clay member

Pennsylvanian: Eastern Ohio.

[Original reference]: Wilber Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 93.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 36, table 1. Member of Bedford cyclothem in report on Perry County. Average thickness 3 feet. Lies below Bedford coal and above Bedford shale and sandstone member. Pottsville series.

Bedford cyclothem

Pennsylvanian (Pottsville Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 7. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 36–39, table 1. geol. map. Includes (ascending) Bedford shale and (or) sandstone, 17 feet thick; Bedford clay, 3 feet thick; coal; and upper Mercer flint and limestone, 2 feet thick. Occurs below Tionesta cyclothem and above Middle Mercer cyclothem. In area of this report, Pottsville series is described on cyclothemic basis; 10 cyclothems are named. [For sequence see Anthony cyclothem.]

Exposed in southeastern Perry County.

†Bedford Limestone[1]

Mississippian: Indiana.

Original reference: C. E. Siebenthal and T. C. Hopkins, 1897, Indiana Dept. Geol. and Nat. Res. 21st Ann. Rept., p. 291.

Named for Bedford, Lawrence County, where it is extensively quarried.

Bedford shale and (or) sandstone member

See Bedford cyclothem.

Bedford Shale[1] or **Formation**

Devonian and Mississippian(?): Eastern Ohio, northeastern Kentucky, and southwestern Pennsylvania.

Original reference: J. S. Newberry, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 21.

Wallace de Witt, Jr., 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 21. Bedford shale has been traced across Ohio and into Pennsylvania where it lies below the Berea and above Cussewago sandstone. In Pennsylvania, name Cussewago was first applied to this shale by White (1881, Pennsylvania 2d Geol. Survey Rept. Q_4), and later name Hayfield was substituted by Chadwick (1925, Geol. Soc. America Bull., v. 36, no. 3). The Hayfield has been found to be Bedford in present investigation. Name Bedford has priority; hence term Hayfield is invalid.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1354–1357; J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Paper 259, p. 13, 21–25. At type locality, composed of about 85 feet of light-gray silty shale, many platy siltstones, and some hard discordal limy nodules. A wedge of red shale, which is 25 feet thick in Independence Township and thins to featheredge on Cuyahoga-Lake County line, present in upper part of formation north of type locality. In eastern half of Cuyahoga County, contains two members: Sagamore siltstone and Euclid siltstone. Thins eastward from type locality to about 45 feet in western Trumbull County. Overlies Cleveland shale member of Ohio shale; contact gradational. Upper contact irregular in area between Cuyahoga County and Trumbull County, because Berea sandstone fills deep channels into, and in some places through, the Bedford. Traced into vicinity of Meadville, Crawford County, Pa. East of Grand River, underlain by Cussewago sandstone and overlain by siltstone facies of Berea. In vicinity of Meadville, Bedford shale and overlying siltstones of Berea sandstone grade laterally into Shellhammer Hollow formation (new) and lose identity as individual formations.

U.S. Geological Survey currently designates age of Bedford as Devonian and Mississippian(?) on basis of study now in progress.

Type locality: On Tinkers Creek, near Bedford, Bedford Township, Cuyahoga County, Ohio.

Bedford Canyon Formation

Triassic(?) and Jurassic: Southern California.

E. S. Larsen, 1948, Geol. Soc. America Mem. 29, p. 18–22, pl. 1. Name proposed for group of mildly metamorphosed slates and argillites with some quartzites and a few thin lenses of limestone. Thickness unknown because base is not exposed and top is a surface of erosion; probably 20,000 feet exposed in Santa Ana Mountains. Unconformably underlies Santiago Peak volcanics (new). Smith (1898) used term Santa Ana for a limestone in these slates in western part of Santa Ana Mountains.

Merrill (1914) called the slates the Santa Ana metamorphic strata. Since Santa Ana has been used for Tertiary strata in California, name Bedford Canyon is used here.

Rene Engel, 1959, California Div. Mines Bull. 146, p. 17. Santa Ana formation includes Bedford Canyon formation and Santiago Peak volcanics of Larsen (1948).

U.S. Geological Survey currently designates age of Bedford Canyon Formation as Triassic(?) and Jurassic on the basis of a study now in progress.

Named for Bedford Canyon, Orange County, where formation is well exposed. Formation lies west of main batholith (of southern California) and underlies much of Santa Ana Mountains. Regional strike of formation is about N. 30° W., approximately parallel to Santa Ana Mountains and the coast. Regional dip is to east; averages about 50° in Santa Ana Mountains and a little steeper to the east.

Bedias Sandstone Member[1] (of Wellborn Formation)

Eocene, upper: Southeastern Texas.

Original reference: B. C. Renick, 1936, Texas Univ. Bull. 3619, p. 26–28, table opposite p. 17.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2627, 2628. Incidental mention in discussion of Wellborn sandstone which is here considered a formation, undivided.

Named for exposures at Bedias, Grimes County.

Beebe Beds

Middle Devonian: Northeastern Michigan.

W. A. Kelly, 1940, Michigan Acad. Sci., Arts and Letters Sec. Geology and Mineralogy [Guidebook] 10th Ann. Field Excursion [p. 1]. Upper half of section at Afton cannot be definitely correlated with section near Lake Huron, and provisional names, Afton beds, Marvin beds, and Beebe beds, are used in place of Alpena, Norway Point, Potter Farm, Partridge Point, and Squaw Bay, employment of which would imply stricter correlation than is justified.

Present in Black Lake-Afton area.

Beebe Limestone[1]

Beebe Limestone (in West Castleton Formation)

Lower Cambrian: Southwestern Vermont.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 402.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 2. Massive but discontinuous unit in West Castleton formation (new).

Named for exposures near Beebe Pond, in Hubbardton, Rutland County.

Beebe Limestone[1]

Upper Devonian: Central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 202.

In Ithaca region.

Beebe School Formation (in Traverse Group)

Middle Devonian: Northern Michigan.

W. A. Kelly and G. W. Smith, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 3, p. 448 (fig. 1), 449, 450 (fig. 2), 456 (fig. 3), 459 (fig. 5), 460–461. Name applied to limestone and shale beds which overlie Gravel Point formation and underlie Antrim shale. Subdivided into four unnamed members (ascending): massive biostrome composed of unoriented coralla, fragmentary remains of crinoids, Bryozoa, and Brachiopoda; thin-bedded light-gray brown-weathering cherty limestone with some very fossiliferous layers; yellow-weathering calcareous shale interbedded with thin highly fossiliferous limestone layers; prevailingly thin-bedded dark-gray, weathering to light-gray and buff, fine- to medium-textured limestone interbedded with shaly limestone and shale. Thickness 70 feet.

Exposed in front and back slopes of a series of low cuestas which trend in northwest direction from Beebe School which is in sec. 14, T. 34 N., R. 2 W., Cheboygan County.

Bee Branch Limestone Member (of Caloosahatchee Marl)

Pleistocene: Southern Florida.

J. R. DuBar, 1957, Illinois Acad Sci. Trans., v. 57, p. 192 (table 1). Table shows Bee Branch limestone as middle member of Caloosahatchee underlies Ayers Landing member (new); overlies Fort Denaud member (new).

J. R. DuBar, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 136 (fig. 4), 143-144. Relatively hard solution-riddled marine limestone or marl unit. Consists of two principal facies, one of which, represented at type locality, is a massive hard calcareous ledge-forming bed; the other is softer, less consolidated, more arenaceous, and more distinctly concretionary. Thickness a few inches to about 5 feet; average about 2½ feet. Conformably overlies Fort Denaud member; conformably underlies Ayers Landing member. Where erosion has been extensive, overying beds may belong to either Fort Thompson or Pamlico formation, and contact is unconformable.

J. R. DuBar, 1958, Florida Geol. Survey Bull. 40, p. 58–61. Report does not use either Fort Denaud member or Ayers Landing marl member; underlying and overlying units referred to as lower Caloosahatchee beds and upper Caloosahatchee shell bed.

Type locality: Along Caloosahatchee River in Hendry County near its confluence with tributary called Bee Branch.

Beech Granite[1]

Beech Granite Gneiss

Precambrian: Western North Carolina and eastern Tennessee.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 3.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 19; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Beech granite gneiss consists of Beech granite as mapped by Keith. Three varieties of granite are present: one is a coarse-grained, usually porphyritic rock, another is medium to fine grained, and the third is a coarse red variety. Unit has been greatly changed by metamorphism. Precambrian(?).

Named for Beech Mountain, Cranberry quadrangle, Watauga (now Avery) County, N.C.

Beech Member (of Valcour Formation)

Middle Ordovician (Chazyan): Northwestern Vermont, and northeastern New York.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 825 (fig. 4), 826 (fig. 5), 833, 836–838. Upper member of formation. Overlies Hero member (new) from which it differs both lithologically and faunally, being essentially the *Rostricellula plena* zone. Well exposed beds at Rockwell Bay include principal lithic variants. Basal 35 feet is fossiliferous calcarenite somewhat dolomitized and enclosing two reef lenticles. Succeeding 41 feet has medium-bedded calcarenites, irregularly dolomitized, succeeded by shaly calcargillite with massive zoaria of *Anolotichia* sp. and *Stromatotrypa* sp. Upper 51 feet is gray medium- to coarse-grained calcarenite having cross-stratified beds, with *Rosticellula, Mimella,* and ramose trepostomes. Top contact not exposed here but where it is exposed on northern tip of Valcour Island, brown-weathering dolomite is succeeded by "Lowville" calcilutite. Thickness near Rutland Station, South Hero, 86 feet.

Type section: Along Beech Bay, South Hero, Vt.

Beechatuda Tongue (of Cliff House Sandstone)

Upper Cretaceous: Northwestern New Mexico.

P. T. Hayes and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144, sheet 1. Described as tongue of Cliff House sandstone in Menefee formation. Southeastward rise of about 90 feet in stratigraphic position of base of Cliff House sandstone is involved. Contacts are sharp.

Exposed in Beechatuda Draw in northwestern part of secs. 5 and 6, T. 30 N., R. 15 W., San Juan County, and can be traced approximately 2½ miles along the outcrop.

Beech Creek Limestone Member (of Golconda Formation)

Beech Creek Limestone[1] (in Stephensport Group)

Beech Creek Limestone Member (of Paint Creek Formation)

Upper Mississippian (Chester Series): Southwestern Indiana and central northern Kentucky.

Original reference: C. A. Malott, 1919, Indiana Univ. Studies, v. 6, no. 40, p. 7–20.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 828; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 76). Considered member of Paint Creek formation in Indiana.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7, 14–17, 73. Paint Creek of standard Chester column has triple expression in southern Indiana (ascending): Reelsville limestone, Elwren sandstone, and Beech Creek limestone. Each of these is a distinct stratigraphic unit in parity with other formations of the Chester and deserves a name in its own right. At designated type section, Beech Creek limestone is 24½ feet thick. Persistent through area of outcrop except where it is truncated and overlapped by Pennsylvanian Mansfield.

A. C. McFarlan and others, 1955, Kentucky Geol. Survey, ser. 9, Bull. 16, p. 18, 20. Beech Creek (lower Golconda) underlies Fraileys (middle Golconda) shale (new).

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 25, 72–78, pl. 1. Thickness 8 to 33 feet in Indiana. Gray fine- to coarse-grained crystalline limestone weathering to rough cubical blocks; large crinoid stems common. Underlies Cypress sandstone; locally transition contact separates the two. Overlies Elwren sandstone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman. 1960. Indiana Geol. Survey Bull. 20, p. 36 (table 5), 41–42, pl. 1. Lowermost formation in Stephensport group (redefined). Thickness 12 to 18 feet. Underlies Big Clifty formation; overlies Elwren formation of West Baden group.

U.S. Geological Survey currently classifies the Beech Creek as a member of Golconda Formation in Kentucky, on basis of study now in progress.

Type section: At Ray's Cave, NE¼NW¼ sec. 13, T. 7 N., R. 4 W., one-fourth mile north of State Road 54 at Ridgeport, and 3½ miles southwest of Solsberry, Greene County, Ind. Named for exposures along Beech Creek.

Beech Creek Shale (in Chester Group)[1]

Mississippian: Southwestern Indiana.

Original reference: W. N. Logan, 1926, Indiana Dept. Conserv., Div. Geol. Pub. 55.

Beecher Dolomite Member (of Bluebell Formation)

Upper Ordovician and Silurian: Central Utah.

Paul Billingsley *in* J. M. Boutwell, 1933, 16th Internat. Geol. Cong. [United States] Guidebook 17, Excursion C–1, p. 110 (fig. 14). Name appears on stratigraphic column of Tintic district. Overlies Eagle member (new); underlies Dora member (new).

T. S. Lovering and others, 1949, Econ. Geology Mon. 1, p. 7 (table 1). Upper 60 feet light-gray lithographic dolomite; overlies well-bedded fine-grained blue-gray dolomite; 26-foot bed strongly mottled blue-gray dolomite 62 feet above base. Thickness 212 feet.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 141. Suggested that strata which comprise Beecher dolomite of older reports be referred to Laketown dolomite in Boulter Mountains quadrangle.

Type locality and derivation of name not stated.

Beecher Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 33, figs. 3, 9. Dolomite, pure, nonshaly, noncherty; thick bedded. Thickness about 3½ feet. Shown on columnar section as underlying Eagle Point member (new) and overlying St. James member (new).

Occurs in Dixon-Oregon area.

Beecher Island Shale Member (of Pierre Shale)[1]

Upper Cretaceous (Gulf Series): Northeastern Colorado and northwestern Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull. 32, no. 7.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 22. Gray shale; irregular concretionary limestone near top; limonite concretions throughout; thin beds of bentonite and limestone concretions in lower part. Thickness 100 feet. Uppermost member of Pierre shale; overlies an unnamed shale member, 500 to 600 feet thick, that in turn overlies Salt Grass shale member.

Named for exposures at Beecher Island, Yuma County, Colo.

Beech Mountain Amphibolite[1]

Precambrian (Grenville) : Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082-E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Bear Pond schist.

Named for occurrence on Beech Mountain, southeast of Graphite, Warren County.

Beech River Shaly Limestone Member (of Brownsport Formation)[1]

Beech River Formation (in Brownsport Group)

Middle Silurian: Western and central Tennessee.

Original reference: W. F. Pate and R. S. Bassler, 1908, U.S. Natl. Mus. Proc., v. 34, p. 410-432.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as basal formation of Brownsport group.

T. W. Amsden, 1949, Yale Univ. Peabody Mus. Nat. History Bull. 5, p. 25. In area of this report [western Tennessee], there does not seem to be any valid basis for subdividing the Brownsport into three members or formations. Here proposed that terms "Beech River," "Bob," and "Lobelville" be abandoned.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 257-262, figs. 77, 78, 80, 81, 82. Beech River formation included in Brownsport group. Argillaceous formation consisting of interbedded shaly limestone and calcareous shale that begins with widespread basal limestone that ranges from 1 to 12 feet in thickness. Thickness of formation as much as 60 feet. Overlies Dixon formation with apparent conformity; underlies Bob limestone into which it seems to grade by progressive replacement of one by the other or by interbedding of the two facies; locally contact is sharp. Where Bob limestone has been removed by erosion, Beech River is overlain by Decatur limestone, a Devonian formation, or the Chattanooga shale; where the Bob may be locally absent due probably to nondeposition, the Beech River is overlain by Lobelville formation, and in such cases the two cannot be separated lithologically.

Named for Beech River, Decatur County.

Beechwood Limestone Member (of Sellersburg Limestone)[1]

Beechwood Formation (in Hamilton Group)

Middle Devonian: Central northern Kentucky and southern Indiana.

Original reference: C. Butts, 1915, Kentucky Geol. Survey, 4th ser., v. 3, pt. 2, p. 118, 120.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1057, 1064-1065, 1067. Rank raised to formation at top of Hamilton group. Overlies Silver Creek formation in Clark County, Deputy formation (new) in Jennings County, and Jeffersonville formation in Bartholomew County. Difficult to distinguish from Swanville formation (new) on lithology alone. and unit termed Swanville has been regarded as a continuous bed of Beechwood; however, the two have not been found in the same section at any place. Close relationship of Silver Creek and Beechwood implied by their treatment as member of Sellersburg does not exist; their fossils represent separate time divisions in standard Hamilton scale. The two are separated by an erosional disconformity.

J. B. Patton and T. A. Dawson *in* H. H. Murray, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 42, pl. 1. Beechwood is not necessarily younger than all other Hamilton beds of southeastern Indiana. It is present nearly everywhere the Silver Creek is identifiable, but its thickness varies within small areas, and at places it is absent. At such places, Silver Creek lithology extends to top of Hamilton section; absence of Beechwood does not decrease thickness of Hamilton; this fact suggests that the same time of deposition is represented, where Beechwood is not found, by beds that have Silver Creek lithology. Indiana Geological Survey used term Beechwood for a member at top of Hamilton sequence.

Named for Beechwood Station, Jefferson County, Ky. Exposed in stream a few rods north of Shelbyville turnpike, one-half mile south of Beechwood.

Beehive Formation[1]

Precambrian: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 7.

Typical occurrence on Beehive Mountain, north of Lost Creek, British Columbia.

Beehive Rhyolite

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 740–741. Described as massive porphyritic biotite rhyolite. Makes up two intersecting dikes which form a small but prominent spire called Beehive Peak. Believed to represent a volcanic neck. Spire rises above a mass of biotite rhyolite believed to have come from the volcanic neck.

Exposed in and around Beehive Peak, Tucson Mountains, Pima County.

Beehive Mesa Alluvium

Pleistocene or Recent: Southern California.

B. F. Howell, Jr., 1954, California Div. Mines Bull. 170, map sheet 10. Shown on stratigraphic column as bedded dark fan remnants as much as 100 feet thick. May be same age as Kagel or Lopez alluvium.

Occurs in Little Tujunga area, Los Angeles County.

Beekmantown Group,[1] Limestone,[1] Shale, or Dolomite

Lower Ordovician: New York, western Maryland, Pennsylvania, Tennessee, Vermont, and Virginia.

Original reference: J. M. Clark and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

John Rodgers, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 98. There were three major pre-Chazy invasions of Champlain area during early Paleozoic, instead of two as commonly suggested. The first corresponds to Potsdam-Little Falls sequence in Mohawk Valley; the third gave the type "Beekmantown" (including Fort Cassin strata). Middle invasion, newly recognized, correlates with the Chepultepec and Gasconade formations. These facts indicate that name "Beekmantown" should be redefined or perhaps abandoned altogether.

John Rodgers, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1573–1588. Name Beekmantown was originally proposed for entire Calciferous (Brainerd and Seely, 1890, Am. Mus. Nat. History Bull., v. 3), but since it became evident that Calciferous spanned break between Cambrian and Ordovician (or Ozarkian and Canadian of Ulrich), term has been restricted to Ordovician (Canadian part of sequence). There has been no general agreement as to position of this break in Champlain sequence. Ulrich and Cushing (1911, New York State Mus. Bull. 140) considered break to lie between middle of Division A [of Calciferous] and base of Division C [of Calciferous] in section at Ticonderoga where upper part of Division B [of Calciferous] is lacking. They considered that the missing beds were part of the overlying formation, whereas actually they form a unit with the underlying, but in any case they excluded the Whitehall beds (new) at Ticonderoga from the Beekmantown. However, Whitehall is now correlated with beds considered basal Ordovician (although Ulrich holds they are upper Ozarkian), and hence, if term Beekmantown is to be used for Ordovician Calciferous, in its use in Champlain Valley it should be extended to cover Whitehall formation.

E. O. Ulrich and G. A. Cooper, 1938, Geol. Soc. America Spec. Paper 13, p. 23. Term should either be abandoned entirely or restricted to beds between Upper Cambrian Potsdam and Theresa sandstones and base of Chazyan in vicinity of Beekmantown. As term is used in this paper [Ozarkian and Canadian brachiopods], it refers solely to Middle Cambrian lithological and faunal facies on west side of Champlain basin and to north at Beauharnois near southwestern angle of Province of Quebec. The fauna, characterized by species of *Lecanospira*, is of northern origin and widely distributed in both Cordilleran and Appalachian troughs and in Missouri, Oklahoma, and Texas.

B. L. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–48, p. 241–249. Formation described in Northampton County where it constitutes surface indurated rocks in broad band from 1½ to 4 miles in width extending continuously across the county between Lehigh and Delaware Rivers. An isolated fault block area of Allentown, Beekmantown, and Jacksonburg in vicinity of Portland extends from Delaware River in gradually narrowing band to Johnsonville. The band of Beekmantown limestones is bounded on south by older and underlying Allentown strata and on north by younger and overlying Jacksonburg limestones. Estimated thickness 1,000 to 1,200 feet, perhaps less in vicinity of Delaware River.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 102–119. In Virginia, Beekmantown group (formation) is overlain by limestones of Chazyan age (Murfreesboro, Lenoir, and Mosheim) and underlain by Chepultepec limestone. Three distinct facies present: dolomite in area southwest of Lexington and in northwestern belts from Lee County to Highland County; dolomite and limestone southwest of Frederick County; and dominantly limestone in Frederick and Clarke Counties.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 53–66. Term Beekmantownian series used to include the following formations in Minnesota: Kasota sandstone, Blue Earth siltstone, Oneota dolomite, Root Valley sandstone, and Shakopee dolomite. Formations carry fauna distinctly older than usual formations of Ordovician or those commonly referred to as Canadian. Shakopee dolomite underlies St. Peter sandstone of Chazyan series. Term Ozarkian has been applied to these Minnesota formations.

R. R. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 2036. Upper Cambrian (Hoyt) fossils have been found in upper part of Division B of "Calciferous" formation. Previous workers have considered these beds Tribes Hill (Beekmantown) in age. Tribes Hill and *Lecanospira* faunas were found above crossbedded base of Division C. Thus, Hoyt fauna overlies Little Falls dolomite in Champlain and Mohawk Valleys instead of underlying it as previously designated. Since a recognized late Upper Cambrian fauna underlies standstone at base of Division C and an accepted Lower Ordovician fauna overlies it, base of the Beekmantown must be moved up to base of Division C. Thus Cambrian-Ordovician boundary should be placed at base of Division C.

R. R. Wheeler, 1942, Am. Jour. Sci., v. 240, no. 7, p. 518–524. Cambro-Ordovician correlations revised in Champlain, Hudson, Mohawk, and St. Lawrence Valleys. Revisions involve definitions and succession of previously accepted Cambro-Ordovician formations (Upper Cambrian Potsdam, Theresa, Hoyt, and Little Falls and Lower Ordovician Whitehall, Tribes Hill, and Beekmantown). Lower "typical" Theresa is physically and faunally differentiated from "Upper Theresa" (now Heuvelton member of Tribes Hill formation); Hoyt fauna occurs in lower half of emended Whitehall formation above Little Falls dolomite; a new, upper (Skeene) member of Whitehall formation represents late Cambrian offlap; two marine cycles, represented by Tribes Hill formation (containing Norton-Heuvelton, Fort Ann-Bucks Bridge, Benson-Ogdensburg members) and Cassin formation, constitute Beekmantown series. Each revised unit is tied in with Division A through E of original "Calciferous" formation.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54 no. 1, p. 862–865. In Tazewell County, Va., Cliffield formation (new) disconformably overlies Beekmantown dolomite.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 27-33. Formation described in Burkes Garden quadrangle where its maximum thickness is about 1,000 feet. Equivalents of the Nittany and Bellefonte are present, but Stonehenge or its equivalent, the Chepultepec, does not appear to be present. Overlies Copper Ridge formation; underlies Blackford member of Cliffield formation.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 522 (fig. 3), 524 (table), 539–548. Mappable units of Beekmantown group of west-central Vermont correspond with few exceptions to "Divisions B, C, D, and E" of Brainerd and Seely (1890, Am. Mus. Nat. History Bull. 3). They are here called (ascending) Shelburne marble, Cutting dolomite (new), Bascom formation (new), and Bridport dolomite (new), respectively. Overlies Upper Cambrian Clarendon Springs dolomite; underlies Chazyan Crown Point limestone.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Group, in Hollidaysburg-Huntingdon quadrangles, Pennsylvania, comprises (ascending) Mines dolomite, Larke dolomite, Nittany dolomite, Axemann limestone, and Bellefonte limestone. Overlies Gatesburg formation; underlies Carlim limestone.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 71, 72. In Shenandoah Valley, New Market limestone (new) overlies Beekmantown group.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1402 (fig. 2). Term Beekmantownian series used on table of classification of sections along Allegheny synclinorium. Followed by Chazyan series.

C. R. Fettke, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1460 (fig. 2). Term Beekmantownian used on correlation chart of Middle and Lower Ordovician and Cambrian formations around northern rim of Appalachian basin. It is interval between Upper Cambrian Croixian and Middle Ordovician Chazyan.

F. M. Swartz, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1550–1563. Discussion of outcrop areas of Lower Ordovician Beekmantown sediments in New York, Pennsylvania. and Maryland. Tribes Hill limestone of Tribes Hill region, Mohawk Valley, represents thin featheredge of Beekmantown deposits lapping from south onto margin of old Adirondack Peninsula. In Taconic plate, Beekmantown sediments of overthrust mass or allochthone consist of Schagticoke shale and all but topmost part of Deepkill shale. In central Pennsylvania, Beekmantown group consists of (ascending) Stonehenge limestone, Nittany dolomite, Axemann limestone, and Bellefonte dolomite.

C. E. Prouty, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1598 (fig. 1). Discussion of Trenton and sub-Trenton stratigraphy of northwest belts of Virginia and Tennessee. Generalized section shows Beekmantown group comprises (ascending) Chepultepec, Longview, Kingsport, and Mascot dolomites. [These formations included in Knox group by some authors.] Occurs above Upper Cambrian Copper Ridge dolomite and below Blackford formation of Cliffield group (Chazyan).

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 35–37. Described as Beekmantown dolomite in Elkton, Va., area. Overlies Conococheague limestone; underlies unit of thin limestones of Middle Ordovician age.

R. B. Neuman, 1951, Geol. Soc. America Bull., v. 62, no. 3, p. 278. Group underlies St. Paul group (new), which name replaces Stones River group of Maryland and adjacent states. Thickness about 2,500 feet near Pinesburg Station, Washington County, Md.

Carlyle Gray, 1951, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 136, p. 7–12. Described in Berks County. Thickness 1,000 to 2,000 feet. Subdivided into lower limestone member, middle interbedded member, middle dolomite member, upper limestone member, and an uppermost member of massive dolomites and interbedded limestone and dolomite. Underlies Annville limestone. Beekmantown fossils were reported in Coplay formation by Miller (1911, Pennsylvania Geol. Survey, 3d ser, Rept. 4). Thereafter term Beekmantown gradually replaced term Coplay for rocks between Allentown and Jacksonburg formations.

H. P. Woodward, 1951, West Virginia Geol. Survey, v. 21, p. 70–107. Beekmantown group (limestone or dolomite) described in West Virginia. As used herein, term refers to body of calcareous Lower Ordovician rocks above Stonehenge-Chepultepec limestone, which formation has been withdrawn from Beekmantown and treated separately. Believed that representatives of Nittany and Bellefonte dolomites occur in Beekmantown, but precise identification is withheld until further correlations and field evidence have been reviewed and studied. Underlies Chazyan group.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 73. Advocates discontinuation of name Beekmantown unless it is relegated to Middle Cambrian (Roubidoux), the only known Canadian rocks outcropping in vicinity of Beekmantown, N.Y.

W. J. Sando, 1956, Geol. Soc. America Bull., v. 67, no. 7, p. 935-936; 1957, Geol. Soc. America Mem. 68, 161 p, pls. Beekmantown group of Maryland comprises (ascending) Stonehenge limestone, Rockdale Run formation (new), and Pinesburg Station dolomite (new). Aggregate thickness about 3,600 feet. Term Beekmantown as used herein applies to beds between Conococheague formation below and St. Paul (Stones River) group above. This usage, however, does not necessarily imply exact equivalence with type section. Reference section designated.

J. P. Hobson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 12, p. 2710–2722. Group, in Berks County, comprises (ascending) Stonehenge, Rickenbach (new), Epler (new), and Ontelaunee (new) formations. Thickness about 2,305 feet. Underlies Jacksonburg limestone. Lower boundary drawn at base of exposures above concealed interval. Hence Cambrian-Ordovician boundary cannot be placed in area of this report because of poor exposure.

F. M. Swartz and R. B. Thompson, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 1–14. In Franklin County, Beekmantown dolomite is 2,300 feet thick, including at base Stonehenge limestone member, 500 feet thick. Underlies Social Island limestone memper (new) of Row Park limestone of St. Paul group.

Bradford Willard, 1958, Pennsylvania Acad. Sci. Proc., v. 32, p. 177–182. Beekmantown has for some years been used to include Ordovician part of dolomitic limestones in Lehigh and Delaware Valleys. Name is not appropriate because of lack of correlation with type Beekmantown and because of presence of post-Beekmantown fossils. Wherry's (1909) Coplay limestone is reinstated for Lower and lower Middle Ordovician beds between Upper Cambrian Allentown and Middle Ordovician Jacksonburg formations.

C. W. Welby, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 22–23. Group, in central Champlain Valley comprises (ascending) Whitehall formation, Cutting formation, Cassin limestone, and Bridport dolostone. Overlies Ticonderoga formation (new); underlies Day Point formation of Chazy group.

C. E. Prouty, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G–31, p. 5. Stose and Jonas (1927) mapped argillaceous limestone between Susquehanna and Lehigh Rivers that have same stratigraphic position as Jacksonburg, below Martinsburg and above Beekmantown. They assigned name Leesport formation to these rocks. Name Leesport as defined and mapped should not be considered a valid formation and should be redefined or renamed. Interval between Beekmantown group and Martinsburg formation, embodying essentially the Leesport in east-central Pennsylvania and in a restricted sense, the Jacksonburg of eastern Pennsylvania and western New Jersey is herein divided into (ascending) Annville, Myerstown, and Hershey limestone.

W. M. Cady and E-an Zen, 1960, Am. Jour. Sci., v. 258, no. 10, p. 735 (fig. 4). In west-central Vermont, group comprises (ascending) Shelburne formation, Cutting dolomite, Bascom formation, and Chipman formation. Overlies Clarendon Springs dolomite; underlies Middlebury limestone.

Reference section (Sando): Begins at top of Beekmantown group exposed in Potomac River bluff about 1,000 feet west of intersection with southwest face of Pinesburg Station quarry and continues westward along abandoned Chesapeake and Ohio Canal for 1 mile, Washington County, Md. Named for exposures at Beekmantown, Clinton County, N.Y.

Beekmantownian[1] Series

Lower Ordovician: North America.

Original reference: A. W. Grabau, 1909, Jour. Geology, v. 17, p. 209–252.

See **Beekmantown Group, Limestone, Shale,** or **Dolomite.**

Beeman Formation (in Magdalena Group)

Pennsylvanian (Missourian): Southeastern New Mexico.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93. Appears only on columnar section. Consists of shale, argillaceous limestone, and conglomerate. Bioherms at base locally. Thickness as much as 500 feet. Underlies newly named Holder formation and overlies newly named Gobbler formation.

In Sacramento Mountains, Otero County.

Bee Rock Sandstone Member (of Lee Formation)

Bee Rock[1] Conglomerate or Sandstone Member (of Lee Formation)

Lower Pennsylvanian: Southwestern Virginia.

Original reference: J. J. Stevenson, 1881, Am. Philos. Soc. Proc., v. 19, p. 96.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 88; 1946, Geol. Soc. America Mem. 13, p. 136. Topmost conglomeratic sandstone of Lee formation.

Exposed at Bee Rock in Big Stone Gap, Wise County.

Bee Spring Sandstone[1] Member (of Caseyville Formation)

Pennsylvanian (Pottsville): Western central Kentucky.

Original reference: C. J. Norwood, 1876, Kentucky Geol. Survey, v. 1, new ser., pt. 6, p. 16, 42, 52–55.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 77. Massive slightly conglomerate sandstone. Top member of Caseyville formation. Equivalent to Makanda sandstone.

Named from Bee Spring Edmonson County.

Bee Tree Shale (in Breathitt Formation)

Pennsylvanian: Southeastern Kentucky.

A. F. Crider, 1916, Kentucky Geol. Survey [Rept.], 4th ser., pt. 1, p. 138, 142; H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 88, 136. Name applied to bed of shales 45 or more feet thick that overlies a 25- to 30-foot shale interval above Elkhorn coal and below Amburgy coal.

Exposed on Bee Tree branch of Smoot Creek, Letcher County.

Begg Formation

Upper Triassic: Northeastern Oregon.

W. R. Dickinson, 1960, Dissert, Abs., v. 20, no. 11, p. 4367. Upper Triassic sequence includes Begg, Brisbois, and Rail Cabin formations. Thickness of sequence, which is overlain by Lower Jurassic Graylock formation (new), is nearly 15,000 feet.

Type locality and derivation of name not stated. Report discusses Izee area, Grant County.

Beidell Quartz Latite

Beidell Latite-Andesite[1]

Miocene(?): Southwestern Colorado.

Original reference: Whitman Cross and E. S. Larsen, 1935, U.S. Geol. Survey Bull, 843, p. 63–64, pl. 1.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 83–86, pl. 1. Flow and clastic beds redescribed as quartz latite. Underlies Conejos quartz latite in most places; on its northern borders, it irregularly underlies Tracy Creek quartz latite.

Receives its name from old mining camp of Beidell, around which it is best developed, Del Norte quadrangle, Saguache County. Also present in adjacent Saguache quadrangle.

Beil Limestone Member (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, and eastern Kansas.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, 2d ser., p. 48.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 23–24; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 66. Consists of two limestones separated by shale. Thickness 3 to 6 feet in Nebraska and 4 to 12 feet in Kansas. Underlies King Hill shale member; overlies Queen Hill shale member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 19, fig. 5. Consists of two limestones separated by shale. Upper limestone light gray, dense, massive, with abundant *Osagia.* Shale is buff and calcareous, grading into limestones above and below, and carries profusion of coral *Campophyllum torquim.* Lower limestone fossiliferous and argillaceous. Thickness 3 to 6 feet. Underlies King Hill shale member; overlies Queen Hill shale member.

Type locality: Missouri River bluff near mouth of Kenosha Valley, 2 miles south and 1 mile east of Rock Bluff, Cass County, Nebr. Name derived from Beil Farm. Occurs from southwestern Iowa to Oklahoma.

Beirdneau Sandstone Member (of Jefferson Formation)

Upper Devonian: Northern Utah.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1139, 1140. Composed wholly of buff-weathering sandstones. Thickness 820 to 920 feet. Overlies Hyrum dolomite member (new); gradational contact. Unconformably underlies Madison formation.

Named for continuous exposure about base of Beirdneau Peak, Logan quadrangle.

Belcher Member (of Bluestone Formation)

Mississippian (Chester Series): Southeastern West Virginia and southwestern Virginia.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 184–185, pl. 15. Beds classified by Reger (1926) as Lower Belcher shale, Lower Belcher sandstone, Upper Belcher shale, and Upper Belcher sandstone, are grouped into single member and named Belcher member of Bluestone formation. Thickness 80 to 100 feet. Underlies Bratton member; overlies Mud Fork member (new).

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 97, 98). Shown on correlation chart as Belcher beds in Bluestone formation or group.

Type locality: Along Bluefield-Princeton Road across Big Ridge, near Belcher School, Mercer County, W. Va. Well exposed along Road 656 about 1½ miles north of Bailey, Tazewell County, Va.

Belcher Sandstone (in Bluestone Formation)[1]

Belcher Shale (in Bluestone Formation)[1]

Mississippian (Chester Series): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 294, 318–320.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 184. Beds classified by Reger (1926) as Lower Belcher shale, Lower Belcher sandstone, Upper Belcher shale, and Upper Belcher sandstone are herein grouped together and defined as Belcher member of Bluestone formation.

Units are exposed just north of Belcher School, Mercer County, W. Va.

Belchertown Tonalite[1]

Carboniferous(?): Central Massachusetts and northern Connecticut.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 243–248, pl. 34.

M. E. Willard, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–85. Described in Williamsburg quadrangle, Massachusetts, as typically light-gray equigranular medium- to coarse-grained tonalite Contains orbicular and lenticular concentrations of hornblende. Angular to subrounded xenoliths of quartzite, quartz-mica schist, phyllite, and amphibolite present. Foliation present throughout. Cut by small aplitic dikes of similar composition. Intrudes Brimfield schist at type locality. Carboniferous(?).

Named for occurrence at Belchertown, Mass.

Belden Granodiorite

[Jurassic]: Northern California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 6. Discussed in report dealing with potassium-argon age determinations. Age given as 135.7 million years. Pluton from which collections were made is intrusive into slates of Carboniferous age and into metavolcanic rocks of possible Jurassic age.

Present near town of Belden on Feather River Highway, Plumas County.

Belden Shale or **Formation**

Belden Shale Member (of Battle Mountain Formation)

Pennsylvanian: Northwestern Colorado.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1376 (fig. 1), 1383–1384, 1385–1387. Proposed as member of Battle Mountain formation to replace name Weber shale in area. Composed of 100 to 200 feet of black and dark-gray carbonaceous shale and argillaceous limestone with thin beds of dark-colored sandstone; thin seams of impure coal present locally. Thickness at type locality about 125 feet. Underlies Robinson limestone member; unconformably overlies Leadville limestone.

K. G. Brill, Jr., 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 624–627. Rank raised to formation. Replaces Weber shale as applied to basal Pennsylvanian in Colorado, and is Des Moines in age. Base is clearly defined erosional contact with the pre-Pennsylvanian; underlies Maroon formation.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 192–193. Described in Pando area. Following usage of Brill (1944), term Belden shale is applied to dark Pennsylvanian shales and limestones unconformably overlying Leadville dolomite—the beds formerly called Weber(?) shale. Thickness 25 to 200 feet. Underlies Minturn formation (new). Grades upward into overlying Minturn formation.

R. L. Langenheim, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 552 (fig. 3), 556, 557, 559–561. Described in Crested Butte quadrangle, Gunnison County, where it is 451 to 555 feet thick, and underlies Gothic formation (new).

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 16–17. Discussed in Garfield quadrangle, Chaffee and Gunnison Counties. Maximum thickness about 1,110 feet. At most places, three units can be distinguished: lower, 200 to 500 feet, chiefly dark shale or argillite; middle, 400 to 700 feet, limestone and shale in which either one or the other may predominate: upper, about 200 feet, contains more quartzite than underlying beds. Grades into overlying Minturn; contact arbitrarily placed where quartzite and micaceous shales of Minturn exceed limestone and shale of Belden. Overlies Leadville; locally overlies Manitou. In Monarch and Tomichi districts, Crawford (1913) used term Garfield formation for lower 2,600 feet of Pennsylvanian section. In present usage, Belden shale corresponds to lower 1,110 feet of Crawford's Garfield formation.

Type section: North side of Rock Creek Valley along U.S. Highway 24 (1938) 0.2 mile north of Gilman, Eagle County. Name derived from station of Belden on Denver and Rio Grande Western Railroad.

Beldens Formation

Beldens Member (of Chipman Formation)

Lower Ordovician: West-central Vermont, and southern Quebec, Canada.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524, 550–552. Bright, orange-buff-weathering dolomite in beds 1 or 2 feet thick interbedded with snow-white marbly limestone. Near base, rock is duller buff or gray and less dolomitic, marble beds are less abundant, and mottled blue-gray limestones are the interbeds. Includes Weybridge member (new). Maximum thickness 600 to 700 feet. Underlies Middlebury limestone (new); overlies Crown Point limestone. Inasmuch as Day Point beds thin or pinch out, north of west-central Vermont, and inasmuch as the Valcour undergoes considerable change in lithology and obliteration of fossils eastward from Lake Champlain, Crown Point limestone is only term used along Lake Champlain appropriate in eastern area. Terms Beldens formation, Weybridge member of Beldens, and Middlebury limestone are here applied to beds probably mainly equivalent to the Valcour. Middle Ordovician (Chazyan).

Marshall Kay, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1172. In Highgate Springs sequence, the Beldens, about 500 feet thick, underlies Carman quartzite (new). Oldest exposed formation. Chazy.

Marshall Kay and W. M. Cary, 1947, Science, v. 105, no. 2736, p. 601. Included in Chipman group (new). Overlies Burchards limestone (new).

Marshall Kay, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1476. Beldens calcite marble of Middlebury synclinorium, west-central Vermont, has been classed as upper Chazyan because it succeeds *Maclurites*-bearing beds, recently called Burchards, long thought to be middle Chazy Crown Point. The Beldens in Middlebury synclinorium underlies Middlebury slaty argillicalcilutite; in Highgate Springs sequence to northwest, the Beldens is separated by succeeding Carman quartzite from Youngman slate in Vermont, and near St. Dominique, Quebec, the Beldens and Carman underlie calcarenites like those in the Day Point. The Beldens is interpreted as a calcitic facies of Bridport dolomite and of the upper Canadian series; the two facies are continuous in outcrop in Cornwall and Shoreham, and each has interbeds of the dominant lithology of the other; Weybridge quartz-silty facies of Beldens in Middlebury synclinorium has such genera as *Goniotelus* and *Syntrophia* in Orwell, Cornwall, and Weybridge, supporting late Canadian classification. Bridport is uppermost part of Beekmantown.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 65–96. Described in detail in Highgate Springs slice that extends from north of St. Dominique, Bagot County, Quebec, to northwestern Chittenden County, Vt., a distance of about 90 miles. Best sections of Beldens are (1) in lowland northwest of escarpment west of St. Dominque, one-half mile north of highway; (2) in hill south of Highway 104, one-half mile east of Swanton, Vt.; (3) west of road to Tuller School, one-half mile northeast of St. Albans Bay village, Vermont; and (4) on Mill River south of St. Albans Bay. The sections near St. Albans expose contact with younger Carman quartzite. Most striking feature about Beldens in Highgate slice is that it is persistent throughout belt of exposure, yet in no place has underlying Burchards been definitely recognized, yet the Beldens commonly lies directly beneath Lower Cambrian rocks of Rosenberg slice, as well displayed in Fonda quarry. Canadian. Ordovician classification discussed.

W. M. Cady and E-an Zen. 1960, Am. Jour. Sci., v. 258, no. 10, p. 728–739. Rank reduced to member status in the Chipman, herein reduced to rank of formation. Lower Ordovician (Beekmantown). [See Chipman formation, this reference.]

Named for exposures southeast of Beldens and west of highway north from Middlebury, Addison County, Vt.

Belfast Bed[1]

Upper Ordovician(?): Southwestern Ohio.

Original reference: A. F. Foerste, 1896, Cincinnati Soc. Nat. History Jour. v. 18, p. 161, 189, 190.

Named for Belfast, Highland County.

†Belfast Beds[1]

Mississippian: Southeastern Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 43, 47, 214.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 812. Name Belfast has been proposed for Salem formation in Iowa. [Van Tuyl's proposal referred to representatives of Spergen limestone.]

Named for exposures near town of Belfast, Lee County.

Belgium Member[1] (of Lake Church Formation)

Devonian: Southeastern Wisconsin.

Original reference: G. O. Raasch, 1935, Kansas Geol. Soc. Rept. 9th Ann. Field Conf., p. 260, 262, 263.

Probably named for town in Ozaukee County.

Belknap Flows, Tuff

Recent: Southwestern Oregon.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, no. 3, p. 56, 62, pl. 10. Discussion of volcanoes of Three Sisters region. Name Belknap is applied to flow that issued from Belknap Crater.

Belknap Crater is south of Mount Washington and west of Little Belknap Crater.

Belknap Limestone Member (of Thrifty Formation)

Belknap Limestone Member (of Harpersville Formation)[1]

Upper Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31, 39.

U.S. Geological Survey currently classifies the Belknap as a member of the Thrifty Formation. Term Harpersville is abandoned.

Named for old Fort Belknap, Young County. Typical exposures are in vicinity of Newcastle.

Belknap Syenite[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1903–1904, pl. 1. Typically coarse-grained aggregate of feldspar and hornblende without visible quartz. Fracture of rock rough and hackly. Intrudes older schists of the area. Angular blocks occur as inclusions in Sawyer quartz syenite. Contact with Albany syenite shows latter chilled against the Belknap. Assigned to White Mountain magma series.

Type locality: Elliptical body occurring on Belknap and Gunstock Mountains in the Belknap Range.

Belkofski Tuff

Tertiary, upper: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, p. 12, pl. 2; 1955, U.S. Geol. Survey Bull. 1028–A, p. 6–7, pl. 3. Thick series of well-bedded tuff composed largely of fine to coarse lithic tuff, ranging in color from green to purple to gray. Beds have been intensely silicified and sericitized in vicinity of diorite stocks that intrude them. Beds are gently undulating with average dips of 5° to 10°. Plant fossils, principally silicified and carbonized trunks of trees and impressions of conifer needles, present in lower part of formation beds 1 to 5 centimeters thick of silicified and carbonized plant remains present. Thickness more than 3,000 feet. Unit cut by stocks of quartz diorite, by basaltic plugs and necks, by thick sills of andesite, and by smaller sills and dikes of basalt and andesite. Conformably overlies nonfossiliferous beds of green arkose; lava flow units —Black Point basalt, Arch Point basalt, and Dushkin basalt (all new) —fill canyons and gullies carved in tuff and intrusive diorite stocks; probably comparable in age to Cathedral Valley agglomerate (new). Evidence indicates a post-Eocene, pre-Pleistocene age; tentatively assigned to late Tertiary.

Beds crop out principally around Belkofski Bay and on Belkofski Point, vicinity of Pavlof Volcano, Alaska Peninsula.

Bell Shale[1] (in Traverse Group)

Middle Devonian: Northeastern Michigan.

Original reference: A. W. Grabau, 1902, Michigan Geol. Survey Rept. 1901, p. 191, 210.

G. M. Ehlers and R. E. Radabaugh, 1937, Michigan Acad. Sci., Arts, and Letters, Sec. Geology and Mineralogy [Guidebook] 7th Ann. Field Excursion [p. 8–9]; 1938, Michigan Acad. Sci., Arts, and Letters, Papers, v. 23, p. 442. Base of Traverse group. Overlies Rogers City limestone (new).

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 578–580. Underlies Rockport Quarry formation and overlies Rogers City limestone in Thunder Bay area. Thickness 11 feet. Data on Grabau's locality.

Type locality not mentioned by Grabau, but he probably named formation from claypits (now abandoned) near former settlement of Bell. Workings still visible along country road in SE¼ sec. 11, T. 33 N. R. 8 E., Presque Isle County. Bell was situated on False Presque Isle Harbor in sec. 13, T. 33 N., R. 8 E. Bell post office was in SE cor. NE¼ sec. 34, same township.

Bella Shale[1]

Bella Shale Member (of Percha Shale)

Upper Devonian or Lower Mississippian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1908, Am. Inst. Mining Engineers Bi-Monthly Bull. 19, p. 7-21.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228 (table). Assigned to Linnian series.

M. A. Stainbrook, 1947, Jour. Paleontology, v. 21, no. 4, p. 298. Considered upper member of Percha shale. Upper part of Percha also termed Box member by Stevenson (1944). There is little doubt that the Bella and Box were proposed for identical divisions of Percha, and there is little reason to replace earlier name. Percha of early Mississippian age.

Named for Bella mine, near Lake Valley, Sierra County.

Bellaire Sandstone (in Conemaugh Formation)[1]

Bellaire sandstone and shale member

Pennsylvanian: Eastern Ohio.

Original reference: D. D. Condit, 1912, Ohio Geol. Survey, 4th ser., Bull. 17, p. 20, 22.

D. L. Norling, 1958, Ohio. Geol. Survey Bull. 56, p. 62–63. Bellaire sandstone well represented in Morgan County [this report]. Occurs between Upper and Lower Little Pittsburgh coals when those thin beds are present. In absence of nonpersistent coaly streaks, Bellaire comprises interval between Lower Pittsburgh and Upper Pittsburgh limestone. Thickness of Bellaire member 10 to 20 feet. Strata consist of tan to buff fine- to medium-grained thin platy bedded sandstone which varies in amount of included sandy shales. Conemaugh series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 156. Condit (1912) named a sandstone closely underlying the Pittsburgh coal Bellaire for city of Bellaire, Ohio. He stated in same description that it [Bellaire] "is also prominent in Pennsylvania where it has been called Lower Pittsburgh sandstone." Stout (in Brownocker and Dean, 1929, Ohio Geol, Survey Bull. 34) placed the Bellaire in Upper Little Pittsburgh cyclothem rather than in its correct position as correlative of Lower Pittsburgh sandstone, that is, as basal member of Pittsburgh. cyclothem. Unless it can be demonstrated that Lower Pittsburgh sandstone is absent in type area of Bellaire sandstone, then Stout's correlation of Bellaire sandstone is in error as indicated by Condit's original definition.

Named for Bellaire, Belmont County.

Bell Canyon Formation (in Delaware Mountain Group)

Permian (Guadalupe Series): Western Texas and southern New Mexico.

P. B. King, 1940, *in* R. K. DeFord and E. R. Lloyd, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 4 (fig. 2), 8. Shown on correlation chart as uppermost formation in group. Occurs above Cherry Canyon formation (new).

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 581–586, pl. 2. Consists of sandstones and interbedded limestones. Thickness about 700 feet. Includes (ascending) Hegler limestone, Pinery limestone, Rader limestone. and Lamar limestone members. Conformably underlies anhydrites and limestones of Castile formation; overlies Cherry Canyon formation. Grades northwestward into Capitan limestone.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 53–59, pl. 3 [1949]. In southern part of Guadalupe Mountains, the Bell Canyon is 670 to 1,040 feet thick and consists of sandstone with some thin dark-gray limestone beds. In northern Guadalupe Mountains, grades into Capitan limestone; here it is 1,500 to 2,000 feet thick. Hegler, Pinery, and

Rader members are closely spaced in lower fourth of formation, and are separated by several hundred feet of sandstone from Lamar member; about half way between Rader and Lamar member is an unnamed "flaggy limestone bed."

N. D. Newell and others, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 15, 53. Includes McCombs limestone member (new) between Lamar limestone member above and Rader limestone member below.

Named for Bell Canyon, a gorge that drains eastward from Rader Ridge to old route of U.S. Highway 62, where it joins Lamar Canyon, Culberson County, Tex. Crops out in broad belt between crest of Delaware Mountains and Gypsum Plain on the east; lower part extends into Guadalupe Mountains, or into reef zone at margin of Delaware basin.

Belle City Limestone[1]

Pennsylvanian (Missouri Series): Central Oklahoma.

Original reference: G. D. Morgan, 1924, [Oklahoma] Bur. Geology Bull. 2, p. 123–125, pls. 3, 27, map.

W. F. Tanner, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 2047 (fig. 2), 2048 (fig. 3). Underlies Hilltop formation (new); overlies Nellie Bly formation or Francis formation.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 78–84, pls. 1, 2. In Seminole County, consists of upper and lower limestones separated by a dark shale. Maximum thickness 36 feet, thins northward. In central part of county, lies conformably between Nellie Bly and Hilltop formations; in southern part, the Vamoosa locally rests unconformably on the Belle City, which in turn is conformable with underlying Nellie Bly; between Belle City and Vamoosa are isolated outliers of red or blue shale which probably belong to Hilltop. In Pontotoc County, to the south, the Belle City is truncated by Ada formation. Type locality stated.

Type locality: Village of Belle City, SW¼ sec. 35, T. 8 N., R. 7 E., Seminole County.

Bellefonte Dolomite (in Beekmantown Group)[1]

Lower Ordovician: Central Pennsylvania and northern Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 552, 553, 652–660, pl. 27.

B. N. Cooper, 1939, Virginia Geol. Survey Bull. 55, p. 20–22, pls. 1, 3. Present locally in Draper Mountain area, Virginia. Maximum thickness less than 50 feet. Conformably overlies Draper dolomite member (new) of Nittany formation; unconformably underlies Mosheim limestone of Stones River group. Canadian. [Term Beekmantown not used in this report.]

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Bellefonte dolomite includes all dolomite above Axemann limestone and below Carlim limestone in Hollidaysburg-Huntingdon quadrangles. Thickness about 1,000 feet south of Roaring Spring; about 1,250 feet east of Williamsburg. Beekmantown group.

H. P. Woodward, 1951, West Virginia Geol. Survey, v. 21, p. 72, 74–76. Term Bellefonte tentatively applied to upper member of Beekmantown.

Application of term Bellefonte here does not necessarily imply precise correlation with Bellefonte of central Pennsylvania. Term Beekmantown used as both formation and group.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Uppermost formation in Beekmantown group.

Named for exposures at Bellefonte, Centre County, Pa.

Belle Fourche Shale

Belle Fourche Shale Member (of Cody Shale or Colorado Shale)

Belle Fourche Shale Member (of Graneros Shale)[1]

Upper Cretaceous: Wyoming, Montana, North Dakota, and South Dakota.

Original reference: A. J. Collier, 1920, U.S. Geol. Survey Press Bull. 9065.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. Shown on correlation chart as Belle Fourche shale; occurs above Mowry shale and below Greenhorn limestone.

B. C. Petsch, 1949, South Dakota Geol. Survey Rept. Inv. 65, p. 8, 9–10. Belle Fourche shale member is uppermost part of Graneros. Estimated thickness 580 feet. Includes Orman Lake limestone (new) near middle. Overlies Mowry shale member; underlies Greenhorn formation.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2197. Formations in Black Hills that are equivalent in Colorado shale are Fall River sandstone, Skull Creek shale, Newcastle sandstone, Mowry shale, Belle Fourche shale, Greenhorn formation, Carlile shale, and Niobrara formation. Belle Fourche shale of northern Black Hills consists of 565 feet of dark bluish shale, with many beds of bentonite and ferruginous concretions. In central Montana, it is represented by 240 to more than 315 feet of similar beds in middle of Colorado shale. Westward these beds become increasingly sandier and much thinner, and on west flank of Sweetgrass arch as little as 13 feet of sandy shale is of Belle Fourche age.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 12 (fig. 3), 17–21, pls. 1, 2. Basal member of Cody shale in Hardin district, Montana and Wyoming. Underlies Greenhorn member; overlies Mowry shale. Thickness about 482 feet. Includes Soap Creek bentonite bed in upper half. Rocks of this interval have, in part, been designated Frontier formation in publications dealing with this district (Thom and others, 1953; Richards and Rogers, 1951; Knechtel and Patterson, 1952).

U.S. Geological Survey currently classifies the Belle Fourche as a member of the Colorado Shale in Montana on the basis of a study now in progress.

Named for exposure along Belle Fourche River in vicinity of Wind Creek, Crook County, Wyo.

Belle Plains Formation (in Wichita Group)[1]

Belle Plains Group

Permian: Central and central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Texas Univ. Bull. 2132, p. 192–198, charts.

M. G. Cheney, 1904, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 93. Rank raised to group and expanded below to include Elm Creek limestone and Jim Ned shale (new), which strata had been included in the Admiral herein given group status and stratigraphically restricted above. As redefined, the Belle Plains includes (ascending) Jim Ned Shale, Elm Creek limestone, Jagger Bend limestone, Valera shale and anhydrite, and Bead Mountain limestone. Underlies Clyde group.

R. C. Moore, 1948, *in* M. G. Cheney, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, sheets 3, 4. Formation further subdivided to include Voss shale member between Jagger Bend limestone member above and the Elm Creek limestone member below.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim, Map 80, sheet 2. Described in Colorado River valley as a formation. Consists mainly of gray limestone beds, 1 to 5 feet thick, separated by shale or marl in beds of comparable thickness. Near Colorado River is 400 feet thick. Includes (ascending) Jim Ned shale, Elm Creek limestone, Voss shale, Jagger Bend limestone, Valera shale, and Bead Mountain limestone members. Overlies Admiral formation; underlies Grape Creek member of Clyde formation; boundary somewhat arbitrarily defined.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 272–274, pls. 11, 12. Formation described in Brazos River area where it is 525 to 640 feet thick. Consists of six members as listed by Moore (1949). Overlies Admiral formation; underlies Clyde formation.

Named for town of Belle Plains, Callahan County.

Bellepoint Limestone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 298, 365.

Type locality: In vicinity of Bellepoint, Summers County, and well exposed on Keeney Mountain road east of Hinton.

Bellepoint Member (of Columbus Limestone)[1]

Middle Devonian: Central Ohio.

Original reference. C. K. Swartz, 1907, Johns Hopkins Univ. Circ. 7, p. 62.

J. W. Wells, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 276 (fig. 1). Shown on generalized section of Franklin and Delaware Counties as underlying Ebersole chert member or Marblehead member where the Eversole is absent; overlies Bass Island.

Named for Bellepoint, Delaware County.

Bellepoint Sandstone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties. p. 297–298, 360–368.

Type locality: In bluffs of New and Greenbrier Rivers near Bellepoint, Summers County; also seen in Mercer County.

Bellepoint Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297–298, 362–371.

Type locality: In road which ascends Wolf Creek Mountain just southeast of Bellepoint; also observed in Giles and Tazewell Counties, Va.

Belleville Formation[1]

Pleistocene: Central northern Kansas.

Original reference: M. E. Wing, 1930, Kansas Geol. Survey Bull. 15, p. 12, 19.

V. C. Fishel, 1948, Kansas Geol. Survey Bull. 73, p. 89–95. Does not agree with Lugn's (1934) proposal to abandon name in favor of Grand Island formation. Name Belleville is retained in this report to designate stream-deposited sand and gravel in Republican that occurs in and near channel of ancestral Republican River and below loess. Overlies Greenhorn limestone. Pleistocene.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 110. Used by Wing (1930) for beds which are now, at least in part, Sanborn formation.

Probably named for occurrence near Belleville, Republic County, Kans.

Bellevue Limestone Member (of McMillan Formation)[1]

Bellevue Formation (in Maysville Group)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and central northern Kentucky.

Original reference: J. M. Nickles, 1902, Cincinnati Soc. Nat. History Jour., v. 20, p. 82.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Shown on chart of Ordovician rocks exposed in Jefferson and Switzerland Counties as Bellevue formation. Blue to dark-gray irregularly bedded rubbly highly argillaceous limestone; contains clay partings and fossils. Thickness 25 to 35 feet. Underlies Corryville formation; overlies Fairmount formation.

Named for old Bellevue House, a landmark, now disappeared, at bend in Clifton Avenue, Cincinnati, Ohio.

Bell Hill Dolomite

Middle Silurian: Northwestern Utah.

F. W. Osterwald, 1953, U.S. Geol. Survey Trace Elements Inv. Rept. TEI-330, p. 105; M. H. Staatz and F. W. Osterwald, 1959, U.S. Geol. Survey Bull. 1069, p. 19 (fig. 2), 23–25, pl. 1. Made up of two members: lower eight-ninths is dark-gray coarse-grained clastic dolomite; upper one-ninth is light-gray fine-grained dolomite. In northern part of Spor Mountain, a 28-foot-thick dolomite bed with distinctive contorted, convoluted appearance occurs approximately 40 feet from top of unit. Thickness 395 to 430 feet. Overlies Floride dolomite and underlies Harrisite dolomite (both new).

Type section: On steep mountainside one-half mile north of Floride mine, NE¼ sec. 3, T. 13 S., R. 12 W., Juab County. Named for Bell Hill mine on southern end of Spor Mountain.

Bellingham Beds[1]

Eocene: Northwestern Washington.

Original reference: L. G. Hertlein and C. H. Crickmay, 1925, Am. Philos. Soc. Proc., v. 64, no. 2, p. 225–226.

Bellingham Bay region.

Bellingham Conglomerate[1]

Pennsylvanian: Southeastern Massachusetts and northeastern Rhode Island.

Original reference: G. R. Mansfield, 1906, Harvard Coll. Mus. Comp. Zool. Bull., v. 49, geol. ser., v. 8, no. 4, p. 99.

G. M. Richmond, 1951, *in* G. M. Richmond and W. B. Allen, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 5, p. 15–16, pl. 1. Described in two small structural basins in Georgiaville quadrangle, Rhode Island. Unconformably overlies Absalona and Woonasquatucket formations (both new) and Blackstone series. Age considered Carboniferous and probably Pennsylvanian.

Outcrop area extends from near North Bellingham, Mass., southward into Rhode Island.

Bellisle Mountain Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 121, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined. Bellisle Mountain is fourth in known sequence; younger than Mud Hill and older than Robinson Mountain. Consists of single flow 15 to 20 feet thick and with well-developed platy structure.

Bellisle Mountain is small volcanic peak 10 miles west of Union County on Johnson Mesa in northeastern Colfax County.

Bell Mountain Quartz Diorite

Late Paleozoic or Mesozoic: Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 504. Cuts Paleozoic metasediments and is intruded by Victorville quartz monzonite.

Occurs in several parts of Victorville area, San Bernardino County.

†Bell Mountain Sandstone Member (of Miguel Formation)[1]

Upper Cretaceous: Southwestern New Mexico.

Original reference: D. E. Winchester, 1920, U.S. Geol. Survey Bull. 716-A.

C. H. Dane, A. A. Wanek, and J. B. Reeside, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 187. Abandoned because unit that was so named is merely an upfaulted duplication of Gallego sandstone member of Gallup sandstone.

Well exposed near foot of Bell Mountain, T. 3 N., R. 9 W., Socorro County.

Bellows Falls Granite Gneiss[1]

Post-Ordovician: Southeastern Vermont and southwestern New Hampshire.

Original reference: E. Hitchcock, 1823, Am. Jour. Sci., 1st, v. 6, p. 11–12, map dated 1822.

Extends from village of Bellows Falls, Vt., south into Westminster and east across Connecticut River into Walpole, N.H.

†Bellowspipe Formation[1]

Ordovician: Northwestern Massachusetts.

Original reference: T. N. Dale, 1894, U.S. Geol. Survey 14th Ann. Rept., pt. 2, p. 559, 562.

On Mount Greylock, Berkshire County.

Bellowspipe Limestone[1]

Ordovician: Northwestern Massachusetts.

Original reference: T. N. Dale, 1891, Am. Geologist, v. 8, p. 1–7.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Most previous authors have drawn upper contact of Berkshire schist below Bellowspipe limestone but validity of this limestone as a formation is questionable. Within Cheshire quadrangle [this report], Bellowspipe limestone grades into rocks, both above and below, that are clearly Berkshire schist. Furthermore its eastern and western areas of outcrops differ lithologically and are at different stratigraphic horizons, so they cannot be traced into each other.

Named for occurrence at the "Bellows Pipe," in notch between Ragged Mountain and Greylock.

†Bellowspipe Quartzite[1]

Ordovician: Southwestern Massachusetts.

Original reference: T. N. Dale, 1894, U.S. Geol. Survey 14th Ann. Rept., pt. 2, p. 559, pl. 71.

In Monument Mountain, in southwest part of Berkshire County.

Bell Ranch Formation (in San Rafael Group)

Upper Jurassic: Northeastern New Mexico.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2006, fig. 2. Alternating sequence of light-gray sandstone and brownish-red siltstone beds. The alternating, parallel beds are 2 to 10 feet thick, in sharp contrast to massive Entrada sandstone below and poorly bedded Morrison formation above. Small nodules of gypsum present in uppermost bed of siltstone in northeastern part of area, and in vicinity of Colorado line, thin beds of gypsum found within beds of siltstone. Thickness 66 feet at type locality; ranges from 0 to about 65 feet in the area. Formerly called Wanakah formation in this area.

Type section: At Carpenter's Point, 18 miles southeast of Bell Ranch headquarters and 13 miles northwest of Tucumcari. Named from Bell Ranch and proposed that name be used in Tucumcari-Sabinoso area and in northeastern New Mexico.

Bells Landing Marl Member (of Tuscahoma Sand)[1]

Eocene, lower: Southwestern Alabama.

Original reference: E. A. Smith, 1883, Alabama Geol. Survey Prog. Rept. for 1881–82, p. 256, 321.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 65, pl. 3. Described in Choctaw County where it lies about 25 feet above the Greggs Landing marl member and about 120 feet below Bashi marl member of Hatchetigbee formation.

Named for exposures at Bells Landing, on Alabama River, in Monroe County.

†Bells Landing Series[1]

Eocene, lower: Southwestern Alabama.

Original reference: E. A. Smith and L. C. Johnson, 1887, U.S. Geol. Survey Bull. 43, p. 46–51.

Named for exposures at Bells Landing, on Alabama River, in Monroe County.

Bellton coal group (in Greene and Washington Formations)[1]

Permian: Northern West Virginia and southwestern Pennsylvania.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 32, 34.

Named for Bellton, Marshall County, W. Va.

Bell Top Formation

Miocene: Southwestern New Mexico.

F. E. Kottlowski, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 145, 148 (chart). Consists of pumice, soft pinkish rhyolite tuffs, vitrophyre flows and dikes, banded rhyolite flows and domes interbedded with light-colored pumiceous and tuffaceous sand and sandstone, and a few lenses of stream gravel. Thickness more than 800 feet. Underlies Uvas basalt (new); overlies unnamed rhyolite.

Exposed in Las Cruces region of Rio Grande Valley.

Bellvale Flags[1]

Bellvale Sandstone[1]

Bellvale Sandstone Member (of Marcellus Formation)

Middle Devonian: Southeastern New York and northern New Jersey.

Original reference: N. H. Darton, 1894, Geol. Soc. America Bull., v. 5, p. 367, 373.

Bradford Willard, 1937, Am. Jour. Sci., 5th ser., v. 33, no. 196, p. 271, 272. In proposed stratigraphic nomenclature for Green Pond Mountain area, New Jersey, Bellvale sandstone is considered member of Marcellus formation. Overlies Cornwall shale member of Onondaga formation; passes gradually upward into continental Skunnemunk conglomerate.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1794, chart 4. Bellvale sandstone shown on correlation chart below Skunnemunk conglomerate and separated from underlying Cornwall shale by a unit termed Bakoven(?)

Name derived from Bellvale Mountain, Orange County, N.Y.

Bell Valley Andesite (in Garren Group)

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad Map 21. Name proposed for a thick sequence of dark-gray olivine andesite flows. Maximum exposed thickness 610 feet on Chipsa Mountain. Youngest volcanic formation in area.

R. K. DeFord and others, 1958, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec., Guidebook Apr. 10, 11, 12, p. 31 (fig. 14). Generalized columnar section shows Bell Valley andesite above Means trachyte.

Type section: North side of Chipsa Mountain, Wylie Mountains area, Jeff Davis County. Name derived from Bell Valley on north side of Chipsa Mountain.

Bellwood Dolomite

Silurian (Niagaran): Northeastern Illinois.

T. E. Savage *in* C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 536, chart 3. Proposed for beds formerly called Waukesha dolomite in northeastern Illinois. Underlies Racine dolomite; overlies Joliet dolomite (restricted).

H. B. Willman, 1943, Illinois Geol. Survey Rept. Inv. 90, p. 29. Term Bellwood as used by Savage (1942) includes strata herein considered Waukesha and Racine.

Well exposed in vicinity of Bellwood, Cook County.

Belmont facies[1] (of Locust Point Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 143–145.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. Correlation chart lists Belmont facies of Locust Point formation.

Name derived from village of Belmont situated on State Highway 46, 1 mile east of Monroe-Brown County line, SW¼SW¼ sec. 6, T. 8 N., R. 2 E.

Belmont Fanglomerate

Pliocene(?): Northeastern Nevada.

T. E. Eakin, 1960, Nevada Dept. Conserv. Nat. Resources Rept. 1, p. 26. Chiefly unbedded gravel and fanglomerate. Unconformable above Lake Newark formation (new); unconformable below alluvium. Name credited to F. L. Humphrey (in press).

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 46, pl. 1. Formal proposal of name. Composed of unsorted and generally massive limestone, sand and pebbles, chert pebbles, and locally quartzite and granitic debris. Drill hole near Monte Cristo penetrated 1,200 feet of gravel without encountering bedrock. Upper formational contact arbitrarily placed because no clearly defined boundary between fanglomerate and recent alluvium and reworked gravels was recognized. Overlies Lake Newark formation (new) or bedded gravels which possibly correlate with Lampson formation (new).

Name derived from Belmont Canyon, White Pine mining district, White Pine County.

Belmont Porphyry[1]

Tertiary, upper(?): Central western Montana.

Original reference: J. Barrell, 1907, U.S. Geol. Survey Prof. Paper 57.

Mapped on and around Mount Belmont, 1 mile west of Marysville, Lewis and Clark County.

Beloit Dolomite[1]

Middle Ordovician: Eastern Wisconsin and northeastern Illinois.

Original reference: F. W. Sardeson, 1896, Am. Geologist, v. 18, p. 356–368.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 113. Listed among upper Mississippi Valley formations not in general use.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 262–264. In eastern part of zinc-lead mining district and farther east, strata of Platteville, Decorah, and Galena age are dolomite, and gross lithology of the three formations is somewhat similar. This eastern area is the type for Sardeson's (1896) Beloit formation. However, since term Beloit has been virtually forgotten and terms Platteville and Decorah have been used consistently since 1906, they are retained in this report.

Named for exposures at Beloit, Wis.

Belridge Diatomite

Miocene, upper: Southern California.

S. S. Siegfus, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 1, p. 25. Name applied to diatomite facies that has not been clearly differentiated from typical Reef Ridge shale lithology into which it grades laterally.

Umberto Young, 1943, California Div. Mines Bull. 118, pt. 3, p. 523–524. Consists largely of both massive and bedded white punky diatomaceous shale which weathers to a yellowish gray and is interbedded with thin lenses of white quartz sand; also occasional interbeds of dark-grayish brown siltstone and some sandstone and conglomerate reefs. Thickness about 1,200 feet. Unconformably underlies Etchegoin formation; overlies McLure shale.

Occurs in Midway-Sunset area in San Joaquin Valley.

Belt Series[1]

Precambrian: Montana, Idaho, and Washington, and British Columbia, Canada.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110, p. 15–20.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1873–1970. Belt series, within its northern basin, is divisible into facies that differ in lithology, stratigraphic sequence, thickness, recorded conditions of deposition, fauna, and flora. Of these facies, following are herein defined: Meagher, Blackfoot Canyon, Glacier Park, Galton, Purcell, and Coeur d'Alene. Comprises (ascending) Ravalli, Piegan (new), and Missoula groups. Following formations described: Altyn, Appekunny, Grinnell, Siyeh, Spokane, and Miller Peak.

Charles Deiss, 1943, Geol. Soc. American Bull., v. 54, no. 2 ,p. 211–218. In Saypo quadrangle, Montana, only upper Belt rocks are exposed. Series divided into (ascending) Miller Peak argillite, Cayuse formation (new), Hoadley formation (new), and Ahorn quartzite (new). Formations are equivalent in age to lower and middle part of Missoula group of Clapp and Deiss (1931).

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1096–1099. In Borah Peak quadrangle, Idaho, Belt series subdivided into (ascending) Lemhi and Swauger quartzites (both new).

Russell Gibson, 1948, U.S. Geol. Survey Bull. 956, p. 8–19, pl. 1. Thickness 40,000 feet in Libby quadrangle, Montana. Comprises five formations (ascending): Prichard, Ravalli, Wallace, Striped Peak, and Libby (new). Prichard, Wallace, and Striped Peak correlated with formations of same name in Coeur d'Alene district; the Ravalli correlated with Burke formation, Revett quartzite, and St. Regis formation of that district.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 111–113. Proposed to include lower part of Belt series in Ravalli group with exception of Prichard formation and Neihart quartzite, the middle part in the Piegan group, and upper part in Missoula group. Name North Boulder group proposed for hitherto unnamed components of Belt series in isolated exposures near Jefferson River, southeast of Butte. Relations between North Boulder group and units farther north are not clear. The North Boulder may be equivalent in age to some part of Missoula group or to part of that group and part of Piegan group.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 16–57, pls. 1, 2. Discussion of Belt series in Glacier National Park and Flathead region, Montana. Terms Ravalli, Piegan, and Missoula groups are used but their limits are redefined. Table compares present terminology with that used by Fenton and Fenton (1937).

W. H. Nelson and J. P. Dobell, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–296. Belt series, in Bonner quadrangle, Montana, comprises (ascending) Piegan group with Newland limestone, and Missoula group consisting of (ascending) Miller Peak argillite, Bonner quartzite (new), McNamara argillite, Garnet Range quartzite, and Pilcher quartzite (new).

A. B. Campbell, 1960, U.S. Geol. Survey Bull. 1082–I, p. 551–569, pl. 28. St. Regis-Superior area, Mineral County, Mont., is underlain by about 50,000 feet of metasedimentary rocks of Belt series. Lower part of Belt series is divided into (ascending) Prichard, Burke, Revett, St. Regis, and Wallace formations; upper part, or Missoula group, is divided into (ascending) Spruce, Lupine, Sloway, and Bourchard formations (all new), and an unnamed feldspathic quartzite.

Name derived from extensive development in Big Belt and Little Belt Mountains of central Montana.

Belton Sand (in Chanute Formation)

Pennsylvanian (Missouri Series): Northwestern Missouri.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, p. 20–25, pl. 1. Consists of main lens, elongated in general northeast-southwest direction and three smaller disconnected lenses, at about same horizon, which have slightly different alignment. Total area about 8 square miles. Stratigraphically replaces Westerville limestone of Kansas City group and all or parts of shale above and below this horizon in area where it is present. Varies from 0 to 34 feet in thickness and occurs at depth of 59 to 152 feet below surface in wells.

Present under all or parts of secs. 1, 2, 3, 4, 7, 8, 9, 10, 11, 12, 13, 14, 16, 17, 19, 20, and 30, T. 46 N., R. 33 W., Cass County. Derivation of name not stated but town of Belton lies in this area.

Belva Shale[1]

Pennsylvanian: Western Arkansas.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Probably named for Belva, Scott County.

†Belvidere Shale[1] (in Dakota Group)

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: R. T. Hill, 1859, Am. Jour. Sci., 3d, v. 50, p. 208–234.

R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.; Wichita [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21-23]. Underlies Ellsworth formation (new); overlies Cheyenne sandstone. Comprises (ascending) Kiowa shale, Marquette sandstone, and Mentor sandstone member. Dakota group.

R. C. Moore and K. K. Landés, 1937, Geologic map of Kansas (1:500,000): Kansas Geol. Survey. Mapped with Dakota group.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 154. Kiowa shale as herein defined probably contains stratigraphic units formely called "Greenleaf sandstone," "Mentor beds," and others, and is in part equivalent to "Belvidere formation," "Medicine bed," "Elk River beds," and others.

Named for Belvidere, Kiowa County.

Belvidere Mountain Amphibolite[1] (in Camels Hump Group)

Cambrian: Northwestern Vermont.

Original reference: S. B. Keith and G. W. Bain, 1932, Econ. Geology, v. 27, no. 2, p. 173–174.

A. L. Albee, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–102. Very coarse-grained amphibolite with large blades of dark-green hornblende, porphyroblasts of dark-red almandite garnet, and segregations of epidote. Assigned to Camels Hump group as upper formation. Maximum thickness about 1,000 feet. Underlies Ottauquechee formation; overlies undivided Camels Hump group. Type locality cited.

Named for exposures on Belvidere Mountain [in Jay Peak quadrangle], 3½ miles north-northwest of The Knob.

Bena Gravels

Miocene, lower and middle: Southern California.

T. W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 12 (fig. 2), 38–40, pls. 1, 2, 3. Series of terrestrial gravels of lower and middle Miocene age conformably overlying Walker formation and Ilmon basalt (new) and unconformably underlying Kern River gravels in lower Caliente Canyon. In Cottonwood Canyon (outside mapped area), Bena gravels overlie Freeman-Jewett shale and grade laterally into marine Olcese sandstone and Round Mountain silt. Considered continental facies of lower and middle Miocene marine formations of eastern San Joaquin Valley. Thickness at type locality about 2,500 feet.

Type locality: Hills 3 miles southeast of Bena, Breckenridge Mountain quadrangle, Kern County. Also well exposed from Bena northwestward into Cottonwood Canyon.

Benbolt Limestone or Formation

Middle Ordovician: Southwestern Virginia and northeastern Tennessee.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 833–836, 868–871. In Tazewell County, strata embraced by Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Benbolt is applied to unit which includes second zone of coarse-grained limestone (zone 10), *Opikina* beds (zone 11), *Chasmatopora* beds (zone 12), and zone of crossbedded limestone (zone 13). Zones 10 and 11 are designated Shannondale limestone member; zones 12 and 13 Burkes Garden limestone member. Maximum thickness 325 feet. Overlies Cliffield formation (new); underlies Gratton limestone (new). Benbolt is probably the same as Butts' Lenoir of certain areas, and, in western Tazewell County and in Burkes Garden, comprises part of Butts' Ottosee.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66, p. 138 (fig. 12), 139–140, 141 (fig. 13). In Russell County, overlies Rockdell limestone (new) and underlies Wardell formation.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists, v. 30, no. 7, p. 1160–1165. Discussion of lower Middle Ordovician of southwest Virginia and northeast Tennessee. Detailed sections measured along seven belts were compared with revised classification of Tazewell County, Va. The Blackford, Five Oaks, Lincolnshire, Thompson Valley (new), upper Peery, Benbolt, Wardell, Bowen, Witten, and Moccasin formations extend into Tennessee. Benbolt is well developed in St. Paul belt from Narrows, Va., southwest to and beyond Heiskell, Tenn. At Heiskell, Ulrich (1911) assigned name Heiskell, though without definition, to beds which there presumably contain Benbolt and Wardell formations. In absence of Gratton calcilutite, Benbolt and Wardell formations are essentially inseparable lithologically. Where contact between Benbolt and Wardell cannot be accurately drawn, the two should be combined under Sevier formation as defined in this report.

Type section: About 1⅛ miles south of Benbolt, west of Tazewell County Farm. Named after historic homestead in east environs of Tazewell, Va.

Benbrook Limestone Member (of Goodland Formation)

Lower Cretaceous (Comanche Series): Northeastern Texas.

B. F. Perkins, 1957, Dissert. Abs., v. 17, no. 6, p. 1310; 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 17 (fig. 7), 18 (fig. 8), 19, 20–21. Proposed for upper section of thick limestones and marly limestones of Goodland formation. At type locality, consists of 70 feet of thick limestone and marly limestone units alternating with thinner marls. Overlies Marys Creek member (new); underlies Kiamichi formation.

Type locality: Along Marys Creek on Rowan Ranch, 2.7 miles northwest of town of Benbrook, Tarrant County.

†Bend Formation[1]

Lower and Middle Jurassic: Northern California.

Original reference: J. S. Diller, 1895, U.S. Geol. Survey Geol. Atlas, Folio 15.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 976. Abandoned in favor of Potem formation.

Crops out along western arm of Great Bend of Pit River, Gold Belt region.

Bend Group[1]

†Bend (Bendian) Series[1]

Lower and Middle Pennsylvanian: Central Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., pl. 3, p. lxv.

N. H. Darton, L. W. Stephenson, and Julia Gardner, 1937, Geologic map of Texas (1:500,000): U.S. Geol. Survey. Group as mapped includes Marble Falls limestone and Smithwick shale.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). 82–83. Marble Falls and Smithwick deposits as seen at outcrop form natural unit structurally that has been referred to as Bend series or Bend group. When studied regionally, including areas where covered by later sediments, these beds are divisible into three lesser groups. In this report, these groups are termed Marble Falls, Big Saline (new), and Smithwick. Big Saline and Smithwick are groups in Lampasas series (new), and Marble Falls is group in Morrow series. Term group has broad meaning and wide application without regard to series boundaries; hence continued use, when needed, of term Bend group does not appear inconsistent with usage of these lesser group names proposed here.

R. C. Spivey and T. G. Roberts, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 185–186. Report proposes that term Atoka formation be elevated to Atoka series and defined to include all beds from top of Morrow series to base of Des Moines series. This would include the Marble Falls and Smithwick. Term Atoka is preferred to redefinition of Lampasas series or of older term Bend group or series.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec., Spring Mtg. and Field Symposium May 11, 12, p. 70. Bend series, as presently recognized, includes Smithwick formation and Marble Falls, exclusive of that part of Marble Falls which may be of Morrowan age.

R. C. Moore, 1958, Introduction to historical geology: New York, McGraw-Hill Book Co., p. 244 (fig. 10, 11). Diagrammatic section shows the Bendian occupying interval between Morrowan below and Desmoinesian above.

R. C. Moore, ed., 1960, Treatise on invertebrate paleontology, pt. 1, Mollusca 1: Lawrence, Kans., Univ. Kansas Press, p. xxi. List of divisions of geologic column shows Bendian stage in lower part of Oklan series, Middle Pennsylvanian.

Named for exposures at McAnnelly's Bend of Colorado River, San Saba County.

Ben Day Porphyry

Tertiary, lower: Southwestern Texas.

R. L. Ives, 1941, Am. Jour. Sci., v. 239, no. 5, p. 344, 347. Dense grayish porphyry with light-colored glassy-appearing phenocrysts, some of which iridesce like labradorite. Arrangement of phenocrysts in some of the darker porphyries is very regular.

Occurs as sheets, dikes, and necks in Mitre Peak area, which lies across Brewster-Jeff Davis County line, roughly 12 miles northwest of Alpine.

Bendian Period

Post-Chester-pre-Des Moines: Midcontinent.

Original reference (Bend Series): E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., pl. 3, p. lxv.

B. H. Harlton, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 8, p. 1018–1049. On basis of paleontological and diastrophic evidence, term Bendian is proposed for new period to include that part of section between Chester group of Mississippian age and Des Moines series of Pennsylvanian age. Bendian period in midcontinent is divided into Lower, Middle, and Upper Bendian. In Ardmore basin, Lower Bendian is represented by basal Springer formation, Middle Bendian by middle and upper Springer formation, and Upper Bendian by lower and middle Dornick Hills formation. These formations are correlated with Hot Springs sandstone, Stanley shale, Jackfork sandstone, and Johns Valley shale, the Bendian representatives in Ouachita Mountains. Carboniferous stratigraphy of Ouachita Mountains is made up of Mississippian part of Arkansas novaculite, Bendian Hot Springs sandstone, Stanley shale, Jackfork sandstone, Johns Valley shale, and Pennsylvanian Atoka formation.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 852–914. Bendian period subdivided into two series, Pushmataha (new) below and Morrow above.

B. H. Harlton, 1959, *in* The geology of the Ouachita Mountains—a symposium: Dallas Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 130–139. Discussion of age classification of upper Pushmataha series in Ouachita Mountains. [Term Bendian period not used in this paper.]

Benevides Formation

Cretaceous (Comanche Series): Southwestern Texas.

D. L. Amsbury, 1957, Dissert. Abs., v. 17, no. 9, p. 1981; 1958, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 22. Lower part dark-gray shales; overlain by yellow-brown skeletal calcarenite that forms prominent cap rock. Thickness 125 to 150 feet. Overlies Finlay limestone; underlies Loma Plata limestone (new).

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 23. Described in Van Horn Mountains where it is 160 feet thick. Concordantly overlies Finlay limestone and underlies Loma Plata limestone.

Type section: One and one-half miles southwest of Cleveland triangulation station, Pinto Canyon area, Presidio County. Named from Benevides Ranch.

Benezette Limestone Member (of Pocono Formation)[1]

Mississippian: Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1885, Pennsylvania 2d Geol. Survey Rept. R_2, p. 104–105.

Crops out 1 mile west of village of Benezette, Elk County.

Ben Hur Limestone

Middle Ordovician: Southwestern Virginia.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104 (2 sheets). Buff-weathering shaly limestone with a few interbeds of purer crystalline limestone. Thickness 127 to 153 feet. Underlies Hardy Creek limestone; overlies Woodway limestone (new). Same as lower unnamed member of Moccasin limestone on U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table 1), 33–34, 56–58. 117, pl. 1. Further described and type section given. Thickness at type locality 125 feet. Discussion of correlation problems and summary of nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

Type section: Along railroad cut of Louisville and Nashville Railroad 1,000 feet west of railroad station at Ben Hur, Lee County.

Benito Sandstone (in Panoche Group)

Upper Cretaceous: Central California.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec., Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Green micaceous sandstone 1,100 feet thick. Overlies Redil shale (new); underlies Ciervo shale (new). Name credited to D. W. Sutton (1960, unpub. thesis).

Type locality: Papanatas Canyon, Fresno County. Name derived from Benito Hill, near center south line sec. 32, T. 14 S., R. 11 E.

Benner Group or Formation

Benner Limestone (in Black River Group)

Benner Limestone (in Hunter Group)

Middle Ordovician (Bolarian): Central and south-central Pennsylvania.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Name applied to limestone in Black River group. Includes Stover and Snyder members. Thickness 189 feet in type section.

G. M. Kay, 1944, Jour. Geology. v. 52. no. 1, p. 15–19. Subdivided into Snyder member (lower) and Stover member (upper). Overlies Hostler member of Hatter formation. Underlies Valley View member of Curtin limestone in northwestern outcrops as at Bellefonte; disconformably underlies Nealmont limestone from Union Furnace southeastward as it thins by loss of upper beds. Derivation of name, distribution, and more exact location of type section stated.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. [1402], 1409. Assigned to Hunter group and Hunterian subseries (Bolarian series). Comprises lower and greater part of group.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 97, 102. Rank raised to a group; term replaces Hunter group for application to upper Bolarian series.

Carlyle Gray, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as Benner formation.

Type section: In Pennsylvania Railroad cut at Union Furnace, Huntingdon County. Named for Benner Township, Centre County, where recognized in section near Bellefonte. Present throughout central Pennsylvania southeastward to western belts of Cumberland Valley.

Bennerian Stage

Middle Ordovician (Bolarian): Virginia and West Virginia.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 100. Name applied to later of two stages of Bolarian epoch in discussion of Middle Ordovician formations of eastern and southern West Virginia and western Virginia.

[Name probably derived from Brenner Township, Centre County, Pa., for which Benner limestone (and group) is named.]

Bennett Formation

Pliocene, lower: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

Bennett Shale[1] Member (of Red Eagle Limestone)

Permian: Southeastern Nebraska and northeastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 86, 88, 185.

R. C. Moore, 1935, Rock formations of Kansas in Kansas Geol. Soc.: Wichita [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]; G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 8. Rank reduced to member status in Red Eagle formation. Overlies Glenrock limestone member; underlies Howe limestone member.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. As currently defined, consists of shale and, locally, some impure limestone; shale is characteristically dark gray to black in lower part and light gray in upper part; brachiopods abundant locally in black shale; grades into limestone southward from Elk County, Kans. Thickness 2½ to 15 feet. Underlies Howe limestone member; overlies Glenrock limestone member. Wolfcamp series.

Type locality: Along Little Nemaha and its branches south of Bennett, Lancaster County, Nebr.

Bennett Bridge Beds[1]

Upper Ordovician: Northern New York.

Original reference: R. Ruedemann, 1925, New York State Mus. Bull. 258, p. 87–89, 131, 141, 149, 154.

Exposed along upper Sandy Creek and at Bennett Bridge, below Salmon Falls, Oswego County.

Bennettsville facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 149–163.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 75; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. Bennettsville is one of eight facies of Carwood formation.

Name derived from village of Bennettsville, 3¼ miles southeast of Carwood, east-center sec. 14, T. 1 S., R. 6 E., Clark County.

Bennington Limestone[1]

Lower Cretaceous: Southeastern and central southern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Shown on correlation chart above Bokchito formation and below Woodbine sand.

Named for Bennington, Bryan County.

Bennington Quartzite[1]

Lower Cambrian: Southwestern Vermont.

Original reference: C. D. Walcott, 1896, U.S. Geol. Survey Bull. 134, p. 33.

In Bennington County.

Bens Creek Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 204.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 77. Massive sandstone in Kanawha group between Eagle above and Bens Creek coals.

Named for Bens Creek, Mingo County.

Benson Dolomite Member (of Tribes Hill Formation)

Lower Ordovician: East-central New York.

R. R. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939. Named as member of Tribes Hill.

R. R. Wheeler, 1942, Am. Jour. Sci., v. 240. no. 7, p. 518, 522. Top unit in Tribes Hill in Champlain and Hudson Valleys. Overlies Fort Ann limestone member; disconformably underlies Cassin formation. Represents divisions C 4 and D 1 of Brainerd and Seely's "Calciferous." [See 1890 and 1891 references under Beekmantown group.]

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 74. Name preoccupied; unit is middle Canadian in age, not Tribes Hill (lower Canadian). Subdivisions of Tribes Hill in Champlain Valley are poorly defined and can not be used in Mohawk Valley.

Occurs in Champlain and Hudson Valleys.

Benson facies (of Cow Bayou Member of Logansport Formation)

Paleocene (Midway): Northwestern Louisiana.

G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 112–114. Named as lower facies of member. Consists of wedge(?) of chocolate-brown lignitic clays with interbedded gray silts; carries marine and brackish water microfauna and macrofauna. Transitional into underlying Lula facies.

Type locality: Exposures in roadcut on north side of State Highway 745, one-half to three-fifths mile west of Benson, in SW¼NE¼ sec. 9, T. 10 N., R. 13 W., De Soto Parish.

Benson Limestone[1]

Mississippian: Utah.

Original reference: F. F. Hintze, Jr., 1913, New York Acad. Sci. Annals, v. 23, p. 109, 113.

Named for occurrence in Reade [Reed] and Benson Ridge, just above old mine workings of same name, in Salt Lake County.

†Benson Limestone[1] (in Lexington Group)

Benson Limestone (in Lexington Limestone)

Middle Ordovician: Central Kentucky.

Original reference: A. F. Foerste, 1913, Kentucky Geol. Survey, 4th ser., v. 1, pt. 1, p. 380, 389, 429, 430.

D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 41, 42; 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 13–14. Considered uppermost formation in Lexington group.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1635–1636. Occurs at top of lower Lexington limestone; overlies Jessamine limestone; underlies Brannon limestone in middle Lexington. Thickness 40 to 75 feet. South from central Bluegrass area includes Perryville facies (until recently regarded as post-Woodburn in age and referred to as Perryville formation).

Named for Benson, Franklin County.

Bent Beds (in Bluestone Formation or Group)

See Bent Mountain Member (of Bluestone Formation).

Bent Limestone (in Bluestone Formation)[1]

Bent Sandstone (in Bluestone Formation)[1]

Bent Shale (in Bluestone Formation)[1]

Mississippian (Chester Series): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 293, 316.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 186. Reger's (1926) subdivisions of the Bluestone, Lower Bent shale, Bent limestone, Upper Bent shale, and Bent sandstone are herein defined as Bent Mountain member of Bluestone formation. Reger's Lower Bent shale and Bent limestone are the same as his Upper Bent shale; a double thickness of Upper Bent shale, produced by close folding, is exposed along Road 656 about 1½ miles north of Bailey; here, Reger apparently mistook the repeated Upper Bent shale for his Lower Bent shale and Bent limestone; the Bent sandstone of Reger, which overlies the Upper Bent shale on Bent Mountain, W. Va., is not present in area of this report [Burkes Garden quadrangle].

Type locality: Bent Mountain, Mercer County, W. Va., 1.2 miles southeast of Pride.

Bentley Formation

Bentley Member

Pleistocene: Central and southwestern Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 78 (fig. 6), 157–160. The series of Pleistocene deposits in Grant and La Salle Parishes is divided into four members, their names corresponding to the four distinct depositional terrace surfaces: Williana (oldest), Bentley, Montgomery, and Prairie. Bentley member consists of sequence which grades from coarse basal materials to silty clays in upper part of section; differs from Williana sediments in that they are thinner, and show greater variation in central and upper parts of sequence. Average thickness less than 60 feet. Unconformably overlies Miocene Catahoula formation; along eastern valley wall of Nantaches Lake is in unconformable contact with Jackson Eocene.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 177–180, pl. 1. Rank raised to formation. Described in Rapides and Avoyelles Parishes where along walls of Red River Valley it has an average thickness of 80 to 100 feet; locally overlies undifferentiated Fleming formation.

Well exposed along State Highway 19 between Bentley and Colfax, Grant Parish, and between Trout and White Sulphur Springs, La Salle Parish, and on U.S. Highway 71 between Grant-Rapides Parish line and Bayou Rigolette.

Bent Mountain Member (of Bluestone Formation)

Mississippian (Chester Series): Southeastern West Virginia and southwestern Virginia.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 186, pl. 15. Bent Mountain member, as herein defined and used, consists of four of Reger's (1926) subdivisions of the Bluestone, Lower Bent shale, Bent limestone, Upper Bent shale, and Bent sandstone. In Burkes Garden quadrangle, member consists of only lower 60 feet of member as developed at type locality; most of the 60-foot section is red and green shale and mudrock. Overlies Hunt member (new). Reger's Lower Bent shale and Bent limestone are same as his Upper Bent shale. Double thickness of Upper Bent shale, produced by close folding, is exposed along Road 656 about 1½ miles north of Bailey; here, Reger, apparently mistook the repeated Upper Bent shale for his Lower Bent shale and Bent limestone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 97, 98). Shown on correlation chart as Bent Mountain beds (or Bent beds) in Bluestone formation or group.

Type locality (Reger, 1926): On Bent Mountain, Mercer County, W. Va., 1.2 miles southeast of Pride.

Benton Sand[1]

Tertiary: Southeastern Missouri.

Original reference: C. F. Marbut, 1902, Missouri Univ. Studies, v. 1, no. 3, p. 18, 23, 32.

Named for exposures at Benton Ridge, Scott County.

Benton Shale[1] or **Formation** (in Colorado Group)

Benton Group

Lower and Upper Cretaceous: Southeastern Montana, eastern Colorado, northwestern Iowa, southern Minnesota, northeastern New Mexico, South Dakota, and eastern Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1862, Philadelphia Acad. Nat. Sci. Proc., v. 13, p. 419, 421.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 14. Name Benton, given by Meek and Hayden to include section now classed as Carlile, Greenhorn, and Graneros, is no longer in use except at places where the Greenhorn is poorly developed or absent. This condition does not obtain in Nebraska, and name Benton is dropped.

B. C. Petsch, 1946, South Dakota Geol. Survey Rept. Inv. 53, p. 17 (fig. 5), 43–47. Discussion of geology of Missouri Valley in South Dakota. Text refers to Benton group as comprising Graneros shale, Greenhorn limestone, and Carlile shale. Group is exposed along Missouri River from St. Helena in Cedar County, Nebr., to Ponca State Park in Nebraska. Exposures are also present in Iowa along bluffs of Big Sioux River from Akron to Sioux City and along tributaries to the Bix Sioux in Union County, S. Dak. Table of formations (fig. 5) shows Benton formation, in Colorado group, comprises Graneros, Greenhorn, and Carlile as members.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 51–52, measured secs., pl. 1. In South Park, Colo., the Benton of Colorado group, consists mainly of black shale; some sandstone, limestone, and bentonite beds present. Thickness 410 to 460 feet. Conformably overlies Dakota formation, underlies Niobrara formation, probable unconformity.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1001. Benton formation listed in geologic succession in central Minnesota.

K. M. Waagé, 1952, Colorado Sci. Soc. Proc., v. 15, no. 9, p. 373 (fig. 1). Benton shale shown on generalized stratigraphic section of rocks exposed in Denver-Golden area. Thickness 480 feet. Overlies Dakota sandstone; underlies Timpas limestone.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. In northwestern part of Mora County, N. Mex., formation represented by equivalents of Graneros shale, Greenhorn limestone, and Carlile shale. Thickness 395 feet. Overlies Dakota sandstone; contact with Niobrara formation not observed in area.

K. M. Waagé, 1955, U.S. Geol. Survey Prof. Paper 274–B, p. 15, 28, 34, 37, 39, 46. In northern Front Range, Colo., overlies South Platte formation (new) of Dakota group.

A. B. Shaw, 1957, Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Park Basin, Colorado, p. 49 (fig. 1), 50. Name Benton has been used for many years in North Park, Colo., and is still useful in group sense to include all rocks from Thermopolis shale through Frontier sandstone, that is, from top of Dakota sandstone of Cloverly group to base of Niobrara formation. This definition does not coincide with Benton shale as used in northern Front Range for interval from top of South Platte formation of Dakota group to base of Timpas limestone member of Niobrara formation.

M. A. Jenkins, Jr., 1957, Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Parks Basin, Colorado, p. 52–53, pl. 1. Formation, in Red Dirt Creek area, Grand County, Colo., consists of 418 feet of black to dark-gray fissile shale containing bentonite seams. Contains Codell sandstone member. Graneros, Greenhorn, and Carlile members not recognized in this area. Conformably overlies Dakota formation; underlies Niobrara formation.

T. A. Steven, 1960, U.S. Geol. Survey Bull. 1082–F, p. 336 (table 1), 346–348, pl. 12. Discussion of Northgate district, Colorado. Benton shale of Early and Late Cretaceous age consists of 665 feet of dark-gray thin-bedded shale with interbedded bentonite layers. Overlies Dakota group with contact gradational; underlies Niobrara formation.

Named for Fort Benton, on Missouri River, about 40 miles below Great Falls, Mont.

Benwood cyclothem

Pennsylvanian (Monongahela Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 176–178, 179 (map 23). Embraces interval between Sewickley cyclothem (new) below and Arnoldsburg cyclothem (new) above. Where complete, displays normal suite of members (ascending) : Sewickley shale and sandstone, Tyler redbed, Benwood limestone, Benwood underclay and coal, and Benwood roof shale. Average thickness 65 feet. Cyclothem is seldom found intact; commonly upper limit cannot be determined owing to absence of members above Benwood limestone and below Arnoldsburg redbed. In area of this report, Monongahela series is described on cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Present in Bern, Canaan, Lodi, Rome, and Alexander Townships of Athens County.

Benwood Limestone Member (of Monongahela Formation)

Benwood Limestone and Shale (in Monongahela Group)

Benwood limestone and shale member

Pennsylvanian: Northern West Virginia, western Maryland, eastern Ohio, and western Pennsylvania.

Original reference: M. R. Campbell, 1903, U.S. Geol. Survey Geol. Atlas, Folio 94, p. 10.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 100, 121–123, 124 (fig. 29). In Fayette County, Benwood limestone is divided into several parts by intervening sandstones, shales, and a coal and black shale horizon. Coal is present in only a few sections, but the black shale is persistent and is used to divide Benwood into an upper and lower part. Lower Benwood overlies Upper Sewickley coal and underlies Benwood coal; Upper Benwood underlies Arnoldsburg sandstone. Included in Monongahela group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 76–80, geol. map. Ohio Geological Survey recognizes the Benwood member (Monongahela series) as that section of limestones and shales between Upper Sewickley sandstone and Fulton green shale member. Basal boundary indefinite in many areas as the limestone occurs just above Meigs Creek coal when Upper Sewickley sandstone is absent; upper boundary uncertain because of inconspicuous development or absence of Fulton green shale. Benwood consists of thick sequences of limestones in many areas and of alternations of limestone and calcareous shales in other localities; some exposures consist almost entirely of calcareous shales. Thickness in Morgan County 25 to 35 feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 177–178. Limestone member of Benwood cyclothem (new) in report on Athens County. Name is used for fresh-water limestone above Sewickley sandstone and below Fulton green shale. In Athens County, unit lacks division of upper and lower units as in Pennsylvania. A highly variable unit a few inches to 38 feet thick. Occurs as nodules or ledges and is interbedded with calcareous clay shale of redbed type (Tyler redbed member).

Named from town of Benwood, Marshall County, W. Va.

Benwood roof shale member

Benwood underclay member

See Benwood cyclothem.

Berdoo Granite

Precambrian: Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 473, 491. Name applied to granite occurring in Chuckwalla complex.

Named for its occurrence in Berdoo Canyon, Little San Bernardino Mountains, Riverside County.

Berea Sandstone[1] or Formation

Devonian or Mississippian: Ohio, northeastern Kentucky, southern Michigan, western Pennsylvania, and northern West Virginia.

Original reference: J. S. Newberry, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 21, 29.

Wallace de Witt, Jr., and D. F. Demarest, 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1357; J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1955, U.S. Geol. Survey Prof. Paper 259, p. 28–40, pls. Three phases of Berea sandstone recognized. First and oldest is massive medium-grained sandstone which fills channels that were scoured into and at some places through Bedford shale. Similar appearance of Cussewago sandstone and coarse aggregates of grains found in channel sandstone phases of Berea has led some geologists to conclude that the Cussewago was part of the Berea. Second or fluviatile phase of Berea sandstone lies above channel phase in sheet 20 to 35 feet thick with thickest part in western Cuyahoga County, Ohio; feathers out in area of valley of Grand River in western Ashtabula County. Third is marine siltstone phase about 5 to 20 feet thick with thinnest part in western Cuyahoga County; thickens to east. Lenses of silty gray shale and very thin ripple-marked siltstone in many sections of the Berea have been cited by some geologists as evidence that the Berea is a tripartite formation composed of two sandstone members separated by a shale member. Irregular occurrence of lenses of silty shale in the Berea does not support this hypothesis. Siltstone facies thins eastward from 15 feet at Wick, Ohio, to 7 feet at Bartholomew quarry section near Littles Corner, Pa. In this section, the siltstone facies of Berea was identified as Corry sandstone by White (1881). Much of resulting confusion of correlations came from this identification. At Bartholomew quarry, the 7 feet of Berea is underlain by 22 feet of Bedford shale. The Berea thins rapidly across Hayfield Township and grades laterally into Shellhammer Hollow formation (new) in vicinity of Meadville. Throughout northern Ohio and northwestern Pennsylvania, upper contact of Berea sandstone is sharp, although it is overlain conformably by Orangeville shale. In northern Ohio, pyritic cap rock of the Berea grades upward in a distance of 2 inches into basal part of Sunbury member of Orangeville. In northwestern Pennsylvania, where pyritic cap rock is absent, Sunbury member of Orangeville is conformable on siltstone facies of Berea sandstone.

U.S. Geological Survey currently designates the age of the Berea as Devonian or Mississippian on the basis of a study now in progress.

Named for Berea, Cuyahoga County, Ohio.

Berenda limestone[1]

Paleozoic (Devonic) : New Mexico and Arizona.

Original reference: C. R. Keyes, 1906, Jour. Geology, v. 14, p. 147–154.

[C. R.] Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228 (table). Table shows Berenda included in Devonic of Arizona. Assigned to Linnian series. Older than Escacado limestone (new) ; younger than Bella shale.

Probably named for Berenda Valley, N. Mex.

Bergen Shale Member (of Lykins Formation)

Permian; North-central Colorado.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 31, 33, 35, fig. 7. Thin-bedded red arenaceous shales and mudstones containing numerous small irregular spots and streaks of bluish green. Thickness at type section 62 feet; at Ralston Creek 35 feet. Underlies Glennon limestone member (new) ; overlies Falcon limestone member (new).

Type locality: In roadcut on Highway 74 just west of business district of town of Morrison and in west fork of Glennon Canyon, Golden-Morrison area. Named from Bergen irrigation ditch, which cuts through Lyons sandstone in Turkey Creek, sec. 12, T. 5 S., R. 70 W., Morrison quadrangle.

Berger Formation (in Wilcox Group)

Eocene: Central Arkansas.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 11 (fig. 4), 38–46, plates. Proposed to include all terrestrial rocks between unconformity at top of marine sediments of Midway group and unconformity at base of Saline formation (new). Comprises section of gray and greenish-gray silty clay and argillaceous sand and some interbedded lignite and sideritic layers; where formation abuts nepheline syenite masses, it includes many bauxite deposits of Arkansas region and associated kaolinitic fragmental underclay. Contains three distinct facies: deposits of bauxite, bauxitic clay, and kaolinitic clay; deposits of lignite, lignitic clay, and gray silty clay that overlies bauxite deposits in many open-pit mines; deposits of gray "salt and pepper" or grayish-green sand that occupy channels in lignitic beds in overburden sections at several bauxite pits, that underlie lignite beds locally in several of the drilled areas, and that form major part of formation downslope from bauxite area. Thickness 0 to 347 feet; surface outcrops reach maximum of 25 feet; drill-hole data show greater thicknesses. Rests upon eroded surface of Wills Point formation; along lower slopes of nepheline syenite hills, generally overlaps Wills Point and rests on residual clay or on rocks of Paleozoic age; in larger subsurface valleys where Wells Point has been removed, Berger rests upon the Kincaid or upon basement rocks.

Type section: South side of Chicago, Rock Island, and Pacific Railroad tracks on east side of viaduct and road crossing tracks at Brittain siding, Pulaski County, in SE¼SW¼ sec. 5, T. 1 S., R. 12 W., three-fourths mile southwest of Berger. Exposed in a narrow discontinuous band of outcrop as much as 1½ miles wide. Outcrop area extends northeastward from Hurricane Creek in Saline County to northeast end of Fourche Mountain in Pulaski County. West of Hurricane Creek, wedges out beneath Saline formation. At east end of outcrop area, truncated by Quaternary sediments of Arkansas River flood plain.

Bergman Group[1]

Lower and Upper Cretaceous: Northwestern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 246.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, pl. 1 (facing p. 245). Age shown on correlation chart as Lower Cretaceous in both Koyukuk Valley and Kobuk Valley areas.

T. G. Payne, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–84. Mostly marine. Age given on chart as Albian and Cenomanian.

U.S. Geological Survey currently designates the age of the Bergman Group as Lower and Upper Cretaceous on the basis of a study now in progress.

Named for Bergman trading post on Koyukuk River in Koyukuk-Kobuk region.

Berino Member (of Magdalena Formation)

Pennsylvanian (Strawn): Western Texas.

L. A. Nelson, 1937, Colorado Univ. Studies, v. 25, no. 1, p. 89. In Franklin Mountains, Texas, formation is divided into (ascending) La Tuna, Berino, and Bishops Cap members (all new).

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 167, 168–169. Predominantly limestone; fossiliferous. Thickness about 555 feet. Derivation of name given.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 23. On basis of fusilinid studies, seems inadvisable to apply Nelson's terms to Pennsylvanian rocks of central New Mexico.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 25. Berino is Strawn in age, but might include some Bend in lower parts.

Named from Berino, Dona Ana County, N. Mex., on Santa Fe Railroad about 4 miles north of Texas-New Mexico boundary.

Berkeley Group[1]

Pliocene: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pub., Dept. Geol. Bull., v. 2, p. 375, map.

Group includes Bald Peak Basalt, Moraga Formation, and Siesta Formation.

Named for occurrence east of Berkeley, Alameda County.

†Berkshire Limestone[1]

Lower Cambrian to Lower Ordovician: Western Connecticut, Massachusetts, and Vermont.

Original reference: E. Hitchcock, 1833, Rept. on Geol., Min., Bot., and Zool. of Massachusetts, p. 297–305.

Berkshire Schist[1]

Berkshire Formation

Middle Ordovician: Western Massachusetts, western Connecticut, eastern New York, and southwestern Vermont.

Original reference: T. N. Dale, 1891, Am. Geologist, v. 8, p. 1–7.

E. P. Kaiser, 1945, Geol. Soc. America Bull., v. 56, no. 12, pt. 1, p. 1089–1090. Abandoned in eastern part of Taconic Range, Vt. Mettawee and Schodack formations are extended to this area to replace the Berkshire.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 38–40. Locally abandoned in Castleton quadrangle, Vermont, where name is replaced by Hortonville slate and phyllites of Mendon series. Remainder of Berkshire south of Castleton River mapped as Nassau formation.

E. N. Cameron, 1951, Connecticut Geol. Nat. History Bull. 76, p. 8–9. Included in Mount Prospect complex (new). Formation is complex series of mica gneisses, feldspathic quartz mica schists, and micaceous quartzites.

R. M. Gates, 1952, *in* R. M. Gates and W. C. Bradley, Connecticut Geol. Nat. History Survey Misc. Ser. 5, p. 7, 8. Formation abandoned in New Preston quadrangle, Connecticut. Replaced by Waramaug formation (new) because these rocks differ from Berkshire of past and present definitions.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Berkshire of this report [Cheshire quadrangle, Massachusetts] includes some rocks mapped as Berkshire, Hoosac, and Greylock by Pumpelly, Wolff, and Dale (1894, U.S. Geol. Survey Mon. 23) and as Hoosac, Normanskill, and Rowe by Prindle and Knopf (1932). Consists of lower schistose marble, schistose quartzite, and graphic schist; black muscovite-quartz-albite-schist; and schistose marble. Transgresses older formations from west to east and from north to south. Most authors have drawn upper contact below Bellowspipe limestone, but validity of this limestone as a formation is questionable. In this report, color was used as primary distinction between Berkshire and overlying Greylock schist. Overlies Bascom formation. Middle Ordovician.

Named for occurrence in Berkshire County, Mass.

Berkshire County Series[1]

Precambrian: Western Massachusetts.

Original reference: W. O. Crosby, 1876, Rept. on geol. map of Massachusetts, p. 40.

Berkshire County.

Berlin Clay[1]

Pleistocene, upper: Connecticut.

Original reference: R. F. Flint, 1933, Geol. Soc. America Bull., v. 44, no. 5, p. 965–987.

Underlies parts of eastern Berlin Township.

†Berlin Gneiss[1]

Post-Lower Devonian: Northern New Hampshire.

Original reference: C. H. Hitchcock, 1873, Rept. Geol. Survey New Hampshire 1872, p. 7.

R. W. Chapman, 1935, Am. Jour. Sci., 5th ser., v. 30, no. 179, p. [404], 405–406. Described as a trondhjemite composed of quartz, oligoclase, biotite, and muscovite. Assigned to New Hampshire magma series.

R. W. Chapman, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1075–1077. Named abandoned in Percy quadrangle; unit assigned to Oliverian magma series.

Named for Berlin Township in village of Berlin, Coos County.

Berlin Group (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q.

In Allegheny County.

†Berlin Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: F. and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. H_3, p. 223, 286, 292.

At Forwardstown, Somerset County.

Berlin Rhyolite Gneiss[1]

Precambrian (pre-Huronian?): Central southern Wisconsin.

Original reference: R. D. Irving, 1877, Geology Wisconsin, v. 2, p. 520.

Crops out at Berlin, Green Lake County.

Berlin Volcanics

Oligocene: Northwestern Oregon.

I. S. Allison and W. M. Felts, 1956, Geology of Lebanon quadrangle, Oregon (1:62,500): Oregon Dept. Geology and Mineral Industries. Tentative name Berlin volcanics used by Felts (1936, unpub. thesis) is abandoned in favor of Mehama volcanics.

Bermeja Complex

Upper Cretaceous or older: Southwestern Puerto Rico.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 197; 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 323–324, pl. 1. Serpentinite, silicified porphyritic volcanics, and fine-grained silicified sediments or volcanics, with minor spilite, amphibolitized spilite, and amphibolite. Diorite plug intrudes complex. Oldest rocks in area; exposed only in some anticlinical cores. Unconformably overlain by a sequence of shallow-water sediments and extrusive and pyroclastic volcanics, Cretaceous to Eocene in age; in most parts of area lava flows, the Río Loco formation, is at base of sequence. Where Río Loco is absent, underlies Mayagüez group (new). Age unknown. Age determinations in basal Mayagüez rocks resting unconformably on serpentinite show that Bermeja complex is older than Santonian-Campanian and possibly older than Cenomanian.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm., and Princeton Univ. Dept. Geology, p. 20, 21. Mattson restricts word complex to basement rocks. He applied term Bermeja complex to these rocks which include amphibolites, serpentinites, and metamorphosed cherts. In present report, term deformed sequence is applied to the folded, faulted, intruded, but unmetamorphosed rocks that rest unconformably on Bermeja complex. Bermeja complex crops out only in southwestern Puerto Rico. Here it is overlain unconformably by Río Loco formation, oldest unit of deformed sequence. In Barranquitas quadrangle in south-central Puerto Rico, the Río Loco underlies a formation containing fossils of Cenomanian-Turonian age. Bermeja complex must be Cenomanian or older in age.

Complex is exposed in greatest variety in Sierra Bermeja.

Bern Limestone (in Wabaunsee Group)

Pennsylvanian (Virgil Series) : Northeastern Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276–2277. Defined to include persistent escarpment-forming limestone and associated strata which occur between Auburn shale above and Scranton shale below. Thickness ranges from about 7 feet to 35 feet; average 20 feet. Comprises (ascending) Burlingame limestone, Soldiers Creek shale, and Wakarusa limestone members.

Type section: In roadcut in SE¼SE¼ sec. 7, T. 1 S., R. 13 E., about one-half mile north and 1 mile west of Bern, Nemaha County. Name derived from town of Bern in northern part of county.

Bernadotte cyclothem[1]

Pennsylvanian: Central western Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

Derivation of name not stated.

Bernadotte Sandstone Member (of Abbott Formation)

Bernadotte Sandstone (in Pottsville Formation)[1]

Bernadotte Sandstone (in Tradewater Group)

Pennsylvanian: Northern Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 70–72, 203. In original description, Savage correlated this bed with massive sandstone that terminates outcrop of No. 1 coal and Seville limestone at type outcrop of Seville cyclothem. At south end of this cyclothem, sandstone thickens to abont 16 feet and rests directly on a coal. Savage believed this was No. 1 coal and considered Seville limestone cut out by sandstone. Outcrops now available show that No. 1 coal and Seville limestone thin out as they rise above sandstone and that coal that underlies sandstone in Pope Creek is Tarter coal. Bernadotte is older than No. 1 coal rather than younger. Occurs at base of Seville cyclothem. Type outcrop given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 45 (table 1), 63. pl. 1. Allocated to member status in Abbott formation (new). Above Pope Creek coal member (new). Thickness about 16 inches. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type outcrop: Road and ravine just southwest of Bernadotte. SW¼ sec. 19, T. 5 N., R. 2 E., Vermont quadrangle, Fulton County.

Bernal Formation

Permian: Central northern New Mexico.

V. C. Kelley, 1949, New Mexico Univ. Pubs. in Geology 2, fig. 2. Name appears on composite stratigraphic chart of formations in Socorro and Santa Fe Counties.

J. E. Allen and S. M. Jones, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1320. Red quartz sandstone and shale 354 feet thick. Overlies upper Permian San Andres limestone. Triassic(?).

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. As defined herein, consists of brownish-red siltstone and fine-grained sandstone; in southern part of area, a single bed of gray to brown medium-grained sandstone about 1 foot thick is interbedded with the reddish-brown rocks. Average thickness 100 feet; 126 feet about 1 mile east of Ocate. Overlies Glorietta sandstone member of San Andres formation; disconformably underlies Santa Rosa sandstone. Has been considered a part of San Andres. Appears to be correlative with parts of Chalk Bluff formation of southeastern New Mexico and possibly Whitehorse sandstone of Oklahoma. Permian.

[Replaced by Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4).]

Type sequence: Near villages of Bernal and Chapelle, San Miguel County.

†Bernalillan series[1]

Permian: New Mexico.

Original reference: C. R. Keyes, 1936, Pan-Am. Geologist, v. 66, no. 1, p. 42.

Bernalillo shale[1]

Permian: Central northern New Mexico.

Original reference: C. R. Keyes, 1903, Ores and Metals, v. 12, p. 48.

In Sandia Mountains. Derivation of name not given.

Bernardston Formation[1]

Silurian and Devonian(?): Central and western Massachusetts, southwestern New Hampshire, and southeastern Vermont.

Original reference: J. D. Dana, 1873, Am. Jour. Sci., 3d ser., v. 6, p. 339–352.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, p. 1747, chart 4. Age of limestone shown as Lower or Middle Devonian.

Robert Balk, 1956, U.S. Geol. Survey Geol. Quad. Map GQ 90. Further described in Bernardston quadrangle, Massachusetts. Most common rock type is glossy sericitic minutely stratified light-gray phyllite locally merging into dark-gray and black slate. At the base is fine-grained dark-gray phyllite with thin quartz interbeds. Includes lenses of aphanitic laminated light-gray metatuff, well-foliated fine-grained amphibolite, massive greenish-gray diabase, light-gray fine-grained rhyolite, and white and yellow-brown quartz and quartz conglomerate. Latter are important horizon marker. Fossiliferous coarsely crystalline limestone at one locality. Thickness several thousand feet. Conformably overlies Leyden argillite. Silurian(?) or Devonian(?).

A. J. Boucot and others, 1958, Geol. Soc. America Bull., v. 69, no. 7, p. 855–870. Lower part of Bernardston formation in Massachusetts contains fossils of probable Silurian age. On lithologic basis, it is possible that lower part of Bernardston, including conglomerates, quartzites, and calcareous quartzite, is lateral equivalent of Clough formation and that limestone associated with Bernardston is lateral equivalent of Fitch formation.

Named for occurrence at Bernardston, Franklin County, Mass.

†Bernardston Limestone[1]

Lower and Middle Devonian: Western and central Massachusetts and New Hampshire.

Original reference: J. D. Dana, 1877, Am. Jour. Sci., 3d v. 14, p. 379–387.

G. A. Cooper, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart in Massachusetts and New Hampshire. Age given as Lower or Middle Devonian.

First described near Bernardston, Mass.

Berne Member[1] (of Cuyahoga Formation)

Berne Member (of Logan Formation)

Lower Mississippian: South-central Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 660, 667, 669, 674–682.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 1), 55–56. Berne conglomerate member included in Pretty Run sandstone facies (new) of Logan formation. Underlies Byer sandstone member; overlies adjoining Granville and Killbuck facies of Cuyahoga formation. Thickness a few inches to 16 feet; commonly 1 to 3 feet. Age given as Lower Mississippian.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 3 (table 1), 98–101. Report refers to unit as Berne member, or pebble bed, of Cuyahoga formation. Overlies Black Hand member in Granville and Hocking Valley provinces. In a 1910 manuscript, Hyde referred to Berne as Hanover pebble bed.

Named for exposures in Berne Township, Fairfield County.

Berne Member (of Marcellus Shale)[1]

Middle Devonian: Eastern New York.

Original reference: G. A. Cooper, 1933, Am. Jour. Sci., 5th, v. 26, p. 544, 548.

Winifred Goldring, 1946, New York State Mus. Bull. 332, p. 238, 249. Cooper proposed name Berne member for shale interval between Onondaga limestone and Otsego member, an interval considered equivalent of Union Springs, Cherry Valley, and Chittenango members of Marcellus. Recent work has shown presence of Cherry Valley or Cherry Valley equivalent in the Helderbergs and southward. Cooper (p. 249) restricts Berne to the Chittenango sandy equivalent about 100 to 150 feet thick. As thus restricted, the Berne extends from its type locality around northeast end of Catskills at least as far south as Mt. Marion and Haliha Hill north of Kingston.

Type section: In hill south of Berne, Berne-Durham quadrangle, Albany County.

†Berners Formation[1]

Paleozoic(?), Triassic, and Jurassic: Southeastern Alaska.

Original reference: A. Knopf, 1911, U.S. Geol. Survey Bull. 446, p. 14–19, map.

Well exposed along west shore of Berners Bay and along Lynn Canal from Point St. Mary to mouth of Independence Creek; also on east shore of Berners Bay.

†Berry Formation

Eocene to Miocene, lower: West-central California.

R. R. Thorup, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1958. Listed as underlying Vaqueros formation (restricted) and overlying The Rocks sandstone (new). Thickness about 1,000 feet.

R. R. Thorup, 1943, California Div. Mines Bull. 118, pt. 3, p. 464 (fig. 190), 465. Usually white poorly sorted, poorly bedded, feldspathic, considerably crossbedded conglomeratic sandstone; red beds in upper part; probably of continental origin. Upper part of formation appears to grade into Vaqueros formation; contact of the two is placed at lowest occurrence of finer grained sandstone. Oligocene. Derivation of name given.

M. N. Bramlette and S. N. Daviess, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 24. Age may be Eocene to lower Miocene and may vary in different areas.

Type locality: SE¼ sec. 26, T. 20 S., R. 6 E., Junipero Serra quadrangle, Monterey County. Named for typical exposures near Berry Ranch.

Berryessa Formation

Cretaceous: Central California.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 22 (fig. 4), 31, 33–35, pl. 1. Introduced to designate sandstone, siltstone, and shale between Lower Cretaceous Oakland conglomerate and Tertiary Monterey formation. In western limb of Tularcitos syncline, thickness about 1,000 feet at Berryessa Creek; 1,600 feet at Alum Rock Canyon; 2,000 feet near Hendricks Ranch; may be thicker south of there, but base has not been mapped accurately, and top is clearly faulted; no complete section exposed in eastern limb of syncline. About 1 mile south of Alum Rock Canyon, Monterey formation overlaps Berryessa completely. Formation consists of rocks called Chico by Lawson (1914, U.S. Geol. Survey Geol. Atlas, Folio 193) and included in Knoxville by Templeton (1913, Geol. Soc. America Bull., v. 24, p. 96). Intruded by Alum Rock rhyolite (new). Name Berryessa does not imply that its exact age and stratigraphic position are known, but rather is an attempt to avoid the confusion associated with name Chico.

Type locality: On Berryessa Creek, San Jose-Mount Hamilton area, in central Coast Ranges, about 50 miles southeast of San Francisco; both top and base are exposed at type locality. Crops out on both sides of Tularcitos syncline; one band extends along Calaveras fault from vicinity of Calaveras Reservoir to Halls Valley a short distance east of San Felipe Valley; other band extends from Scott Creek across Alum Rock Canyon, then is faulted out for a distance of 3 miles and reappears west of Masters Hill and extends southeast to Panochita Hill, faulted segments reach edge of mapped area southeast of San Felipe Valley.

Bertha Limestone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 393.

Named for association with Bertha sandstone and Upper Bertha shale, but not exposed at type locality of Bertha shale. Observed, however, at other localities in Summers County, in Monroe and Mercer Counties, and also in Tazewell and Giles Counties, Va.

Bertha Sandstone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Mercer, Monroe, and Summers Counties, p. 299, 391.

Type locality: Along mountain road which ascends from Bertha toward Low Gap School, Summers County. Also exposed in Monroe County and in Tazewell County, Va.

Bertha Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 392–394.

Occurs in Mercer, Monroe, and Summers Counties.

Berthelet Member[1] (of Milwaukee Formation)

Middle Devonian: Southeastern Wisconsin.

Original reference: G. O. Raasch, 1935, Kansas Geol. Soc. 9th Ann. Field Conf., p. 262, 265.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart above the Thiensville and below the Lindwurm. Middle Devonian.

Type locality: Milwaukee Cement quarry, Milwaukee County. Probably named for village of Berthelet.

Bertie Limestone (in Salina Group)

Bertie Formation

Bertie Group

Bertie Limestone Member (of Salina Formation)[1]

Upper Silurian: Western and east-central New York, and Ontario, Canada.

Original reference: E. J. Chapman, 1864, A popular and practical exposition of the minerals of Canada, p. 190.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Bertie waterlime listed as top formation in Salina group. Occurs above Camillus shale. Cayugan series.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 5–14, fig. 1. Bertie formation, in east-central New York, comprises (ascending) Fiddlers Green dolomite member, unnamed member, and Williamsville dolomite member. Overlies Camillus shale and merges eastward into Brayman shale (redefined). Underlies Cobleskill.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Formation, in central New York, consists of three members (ascending) Fiddlers Green, Forge Hollow (new), and Williamsville. Fiddlers Green dolomite continues westward into Falkirk member of Bertie. Overlies Salina formation; underlies Cobleskill, Cayugan series.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Rank raised to group. Includes rocks between base of Oatka and top of Williamsville. In western New York, comprises (ascending) Oatka shale, Falkirk dolomite, Scajaquada shale, and Williamsville waterlime. In central New York comprises (ascending) Fiddlers Green dolomite, Forge Hollow shale, and Oxbow dolomite (new). In Canastotan and Murderian stages (both new).

Named for exposures at Bertie (and in Bertie Township), Ontario, about 6 miles west of Buffalo, N.Y.

Bertram Dolomite[1]

Silurian (Niagaran): Eastern Iowa.

Original reference: W. H. Norton, 1895, Iowa Geol. Survey, v. 4, p. 135–138.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Bertram dolomite above Gower dolomite.

Named for Bertram, Linn County.

Berwick Formation (in Merrimack Group)

Berwick Gneiss[1]

Probably Ordovician and Silurian: Southwestern Maine and southeastern New Hampshire.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

Jacob Freedman, 1950, Geol. Soc. America Bull., v. 61, no. 5, p. 453 (fig. 2), 456–459, 475–476, pl. 1. Termed a formation. Consists of black, gray, and green phyllite, quartz-mica schist, quartzite, actinolite-quartz granulite, actinolite granulite, biotite-actinolite schist and actinolite amphibolite in the biotite metamorphic zone. Similar rocks in garnet zone. Well-bedded and lacking in gneissic structure. Maximum thickness in Mount Pawtuckaway quadrangle, New Hampshire, 7,000 feet. Silurian(?).

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Includes Gove member which was reallocated from Littleton formation. Included in Merrimack group in New Hampshire. Probably Ordovician and Silurian.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 41–43. Age tentatively considered Silurian.

Named for development at Berwick, York County, Maine.

Berwick Quartz Diorite[1]

Devonian(?): Southwestern Maine.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 153.

About 2 miles east of Berwick, York County.

Berwyn Conglomerate[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: J. T. Richards and R. A. Birk, 1925, Am. Assoc. Petroleum Geologists Bull., v. 9, no. 6, p. 983, 987-988.

Named for occurrence south of town of Berwyn, Carter County.

†Berwyn Member (of Skaneateles Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 219, 221.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180–181. Name abandoned. Replaced by Butternut shale member (new).

Derivation of name not stated, but probably is village in Tully quadrangle.

Bessemer Clay

Pennsylvanian (Pottsville): Northeastern West Virginia.

W. A. Tallon, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 17. Hammond clay grades downward into horizon here named Bessemer clay.

Type locality and derivation of name not given. Hammond clay occurs in vicinity of Hammond, Marion County.

Bessemer Granite[1]

Ordovician to Mississippian: Southern North Carolina and northwestern South Carolina.

Original reference: A. Keith and D. B. Sterrett, 1917, U.S. Geol. Survey Bull. 660-D, p. 129.

W. R. Griffitts and J. C. Olson, 1953, U.S. Geol. Survey Prof. 248–D, p. 204. Incidental mention in discussion of Shelby-Hickory district, North Carolina.

H. W. Jaffe and others, 1959, U.S. Geol. Survey Bull. 1097-B, p. 116. Lead-alpha age 491 millions of years.

U.S. Geological Survey currently designates the age of the Bessemer Granite as Ordovician to Mississippian on the basis of a study now in progress.

Named for fact that one of the minor bodies of granite underlies Bessemer City, Gaston County, N.C.

Bessemer Sandstone or Quartzite

Precambrian (Proterozoic): Northwestern Michigan.

W. A. Seaman *in* A. K. Snelgrove, W. A. Seaman, and V. L. Ayres, 1944, Michigan Dept. Conserv. Geol. Survey Div. Prog. Rept. 10, p. 16. Bessemer sandstone or quartzite and overlying lava flows which are cut by felsite and then by olivine diabase dikes, belong to lower part of Sibley series.

Occurs in Houghton, Ontonagon, and Gogebic Counties.

Bessie Member (of Quartermaster Formation)[1]

Permian: Western Oklahoma.

Original reference: H. L. Griley, 1933, Pan-Am. Geologist, v. 59, no. 3, p. 234.

Bethany Falls Limestone Member (of Swope Formation)

Bethany Falls Limestone (in Kansas City Group)[1]

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: G. C. Broadhead, 1868, St. Louis Acad. Sci. Trans., v. 2, p. 320.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Uppermost member of Swope limestone (or formation). Overlies Hushpuckney shale member; underlies Galesburg formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 40. Thickness about 22 feet in south-central Iowa; 12 feet, Sarpy County, Nebr.; about 20 feet at Kansas City, Mo.; 12 to 27 feet in eastern Kansas, average 18 feet; pinches out near Oklahoma line.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 28, fig. 5. Uppermost member of Swope. Composed of thick limestone beds containing thin shale partings which are usually quite calcareous and fossiliferous. Uppermost beds generally algal and occasionally oolitic but have fine-grained texture in basal sections. Average thickness about 16 feet. Overlies Hushpuckney shale member; underlies Galesburg shale.

Named for exposures at falls of Big Creek, near Bethany, Harrison County, Mo.

†Betheden Formation

Paleocene or Eocene: East-central Mississippi.

F. F. Mellen, 1939, Mississippi Geol. Survey Bull. 38, p. 26–28. Includes all residual material at top of Midway and below Midway-Wilcox unconformity; includes deposits of bauxite, kaolin, bauxitix and kaolinitic clays and the overlying lignite. Thickness approximately 25 feet. Gradationally overlies Porters Creek formation; unconformably underlies Fearn Springs formation, or the Ackerman formation where Fearn Springs is absent.

F. S. MacNeil, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 5, p. 1070. Fearn Springs and Betheden appear to be intraformational. Recommended that name Betheden be abandoned and that Fearn Springs include both units.

Type locality: At Livingston Spring, 50 yards south of highway at Betheden, SW¼SE¼ sec. 23, T. 16 N., R. 13 E., Winston County.

Bethel Granite[1]

Devonian: Southeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Probably named for Bethel, which is in northwest part of Windsor County.

Bethel Group[1]

Upper Cambrian: Southeastern Vermont.

Original reference: C. H. Richardson, 1927, Vermont State Geologist 15th Rept., p. 127–158.

Probably named for Bethel, Windsor County.

Bethel Pyroxene Diorite[1]

Age(?): Eastern New York.

Original reference: R. Balk, 1936, Geol. Soc. America Bull., v. 47, no. 5, pl. 1.

Dutchess County.

Bethel Sandstone[1]

Bethel Formation (in West Baden Group)

Bethel Sandstone (in New Design Group)

Upper Mississippian (Chester Series): Western Kentucky, northwestern Alabama, southeastern Illinois, southern Indiana, and northeastern Mississippi.

Original reference: C. Butts, 1917, Mississippian series in western Kentucky: Kentucky Geol. Survey, p. 63.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 826–827. Assigned to New Design group (new). In standard Mississippian section, underlies Paint Creek formation and overlies Renault formation. Sandstone is brownish moderately fine grained, in part massive and crossbedded and in part more thinly and evenly bedded; locally conglomeratic at base. Not more than 10 feet thick in Union County, Ill.; in southwestern part of county and in southeastern Perry County, Mo., cannot be recognized sufficiently to separate Renault and Paint Creek formations. Thickness in southern Johnson County, Ill., 12 feet; thickens to east to 50 feet in Ohio River bluff below Golconda; on both sides of river near Shetlerville at least 100 feet thick. Thins southward in Kentucky and not recognized beyond Elkton, Todd County.

D. J. McGregor, T. G. Perry, and W. J. Wayne, 1957, Indiana Geol. Survey Field Conf. Guidebook 9, p. 6, pl. 3. In this report [southwestern Indiana], Bethel formation is used in place of Mooretown sandstone. Stratigraphic position is below Beaver Bend limestone and above Paoli limestone.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. In northwestern Alabama, beds described by Butts (1926, Alabama Geol. Survey Spec. Rept. 14) as Bethel sandstone are included in Tanyard Branch member of Pride Mountain formation (both new).

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 47, pl. 1. Lowermost formation in West Baden group (redefined). Thickness 16 to 35 feet. Underlies Beaver Bend limestone; overlies Paoli limestone of Blue River group (new).

Named for exposures in vicinity of Bethel School, 3½ miles west of Marion, Crittenden County, Ky.

Bethel Schist[1]

Upper Cambrian: Southeastern Vermont.

Original reference: C. H. Richardson, 1924, Vermont State Geologist 14th Rept., p. 82–83.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 42 (table 2), 43 (table 3), 50-51. In Rutland area, "Bethel" formation resembles Pinney Hollow formation. There is possibility that the "Bethel," as mapped to the east, actually represents structural repetition of the Pinney Hollow. There is a question as to proper subdivision of unit mapped as "Bethel." About 6,000 feet of rock is exposed with no horizons detected. The ill-defined term "Bethel" is herein applied to the entire unit; however, it may include the Stowe and parts of Moretown formations in an unknown structural relationship. The "Bethel" overlies Ottauquechee formation. Cambro-Ordovician.

First described in Bethel Township.

Bethlehem Gneiss[1] (of New Hampshire Plutonic Series)

Upper Devonian(?): New Hampshire.

Original reference: C. H. Hitchcock, 1872, Rept. Geol. Survey New Hampshire, 1871.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 504–506, 536–538. Unit should be called gneiss, not granodiorite gneiss, because it ranges in composition from granite to quartz diorite.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Belongs to New Hampshire plutonic series of Upper Devonian(?) age.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 55, 57. Summary discussion. Type locality for unit as currently defined.

Type locality: Exposures on Green Mountain, 2 miles southwest of Landaff, Moosilauke quadrangle. Named for town of Bethlehem, Grafton County.

Bethpage Gravel[1]

Miocene: Southeastern New York.

Original reference: C. P. Berkey and J. F. Sanborn, 1923, Am. Soc. Civil Engrs. Trans., v. 86, no. 1509, p. 75, pl. 3.

J. H. Sanford, 1938, New York State Water Power and Control Comm. Bull. GW-7, p. 11, 12, 18. Crosby's use of term Bethpage gravels mentioned in discussion of geologic history of Long Island.

First described in pits in central part of Long Island.

†Bettles Group[1] or Series[1]

Silurian: Northern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 475.

Excellent exposures on lower part of Bettles River, where mountains which these rocks compose rise 2,000 feet or more above river. Principal capping rock over 2,000 square miles of upper waters of Chandlar and Koyukuk Rivers.

Beulah Limestone[1]

Mississippian: Eastern Colorado.

Original reference: A. E. Brainerd, H. L. Baldwin, Jr., and I. A. Keyte, 1930, Kansas Geol. Soc. Guidebook 4th Ann. Field Conf., p. 84, 86, 88, 90, 94.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 39; 1951, World Oil, v. 133 (Oct.), p. 89–91. Upper finely sandy and finely oolitic limestone beds of sequence previously called Madison in vicinity of Beulah are considered as formation and here named Beulah limestone. Name Beulah was used by Brainerd, Baldwin, and Keyte (1930) to refer to beds now known as Williams Canyon limestone. Original authors abandoned name before it came into common use. Name Beulah is only one suitable for the limestone in this locality and is therefore used. Predominantly pink- to red-stained, white to buff, finely oolitic limestone; concentrations of reddish-yellow dense chert and pyrite present in uppermost layers, and traces of red sandy chert. Thickness at type section 53 feet. Overlies Hardscrabble limestone (new); underlies arkosic beds of Fountain formation; both contacts unconformable. Meramec(?).

Type section: In NW¼ sec. 4, T. 23 S., R. 68 W., Pueblo County. Restricted to isolated exposure on South Hardscrabble Creek in Custer County and to the almost continuous upper ledge in cliffs north and west of Beulah, Pueblo County.

†Beulah Shale[1] or Clays[1]

Upper Jurassic: Northeastern Wyoming and South Dakota.

Original reference: W. P. Jenney, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 593, fig. 122, map.

In Hay Creek coal field; also 3 or 4 miles north of Beulah, in Red Water Valley, Crook County, Wyo.

Beulah Church Sand Lentil (in Slaughter Creek Member of Pendleton Formation)

Eocene, lower: Northwestern Louisiana.

Richard Wasem and L. J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 184 (fig. 4), 187. Consists of 2 to 4 feet of glauconitic, sparingly fossiliferous sand about 30 feet below top of member.

Well developed at type locality of Slaughter Creek member on Slaughter Creek, Sabine Parish.

Beverly Syenite[1]

Late(?) Paleozoic: Northeastern Massachusetts.

Original references: C. H. Clapp, 1910, Igneous rocks of Essex County, Mass.; B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, map; C. H. Clapp, 1921, U.S. Geol. Survey Bull. 704, p. 85–89.

U.S. Geological Survey currently designates the age of the Beverly Syenite as Late(?) Paleozoic on the basis of a study now in progress.

Named for occurrence at Beverly, Essex County.

Bevier cyclothem

See Bevier Formation (in Cabaniss Group).

Bevier Formation (in Cabaniss Group)

Bevier Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Western Missouri, southeastern Kansas, and northeastern Oklahoma.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 19, 23; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 195. Cherokee group divided into 15 cyclic formational units. The Bevier, fourteenth in sequence (ascending), overlies the Ardmore and underlies the Mulky. Average thickness 9 feet. [For complete sequence see Cherokee group.]

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 28, p. 89–90, 94. Formation comprises Bevier coal with underlying gray clay and overlying black slate. Thickness in Callaway County about 6 feet; 3 feet in Macon County. Overlies Ardmore formation; underlies Lagonda formation. Cherokee group.

W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. Generalized section of strata exposed in Carroll and Livingston Counties shows Bevier formation above Wheeler formation (new) and below Lagonda formation. Cabaniss group.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic column as Bevier formation in Cabaniss group. Overlies Verdigris formation; underlies Lagonda formation.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as Bevier coal cycle in Senora formation in Oklahoma. Overlies Verdigris coal cycle and underlies Lagonda coal cycle. Cabaniss group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 78–80. Formation consists of two members: Bevier coal and its underclay. Thickness 8 inches to 8 feet. Overlies Verdigris formation; underlies Lagonda formation. Cabaniss subgroup of Cherokee group. Note on derivation of name.

Name Bevier was originally applied by McGee (1888, St. Louis Acad. Sci. Trans., v. 5) to coal mined at Bevier, Macon County, Mo.

†Bexar[1]

Upper Cretaceous (Gulf Series): Southern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 114.

Probably named for Bexar County.

Bexar Shale Member (of Pearsall Formation)

Cretaceous (Comanche Series); Subsurface in eastern and southern Texas and northern Louisiana.

J. M. Forgotson, Jr., 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 91 (chart); 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2333 (fig. 2), 2337 (fig. 3), 2346–2350. Proposed for upper of three members of Pearsall formation; includes interval between either base of Rodessa formation, Hensell sand, or Glen Rose undifferentiated, and top Cow Creek or James limestone member. In type well, occupies interval from 3,320 to 3,340 feet and consists essentially of black calcareous shale and thin dense finely crystalline limestone beds. Bexar is a sedimentary wedge that thickens into basin with greatest thickening southward from Llano uplift. Depositional edge of Bexar on flanks of Llano uplift is missing owing to an unconformity at base of Hensell sand so that, on outcrop, Hensell sand rests directly on Cow Creek limestone member.

Type well: Ralph E. Fair, Jack Woodward, Inc., and F. B. Lafevre's Pauline Lyro Well 1 in the J. M. Bustillo Survey 29, Bexar County, Tex.

Bibb Dolomite[1]

Upper Cambrian: Northern central Alabama.

Original reference: E. O. Ulrich, 1915, U.S. Nat. Mus. Bull. 92, v. 1, p. vii; v. 2, pl. 2.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart as Upper Cambrian. Occurs above Ketona dolomite and below Copper Ridge dolomite.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 23. Listed with formations of Cambrian or Ordovician age.

Named for exposures at Bibb Furnace, about 2 miles west of Brierfield, Bibb County.

Bickett Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 301, 430.

Type locality: On northwest angle of Bickett Knob, Monroe County. Also observed in Mercer and Summers Counties, W. Va., and in Giles County, Va.

Bickford Granite[1] (of New Hampshire Plutonic Series)

Upper Devonian(?): North-central New Hampshire.

Original reference: C. R. Williams, 1934, Appalachia, v. 20, no. 4, p. 69–78.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Mapped with same symbol as Concord granite under name of "binary granite." Belongs to New Hampshire plutonic series of Upper Devonian(?) age.

Typically exposed on Bickford Mountain, Franconia quadrangle.

Bicknell Sandstone[1]

Upper Jurassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map 1–175. Shown on paleotectonic map as underlying Hinchman sandstone and unconformably overlying unnamed volcanic rocks that overlie Mormon sandstone.

Named for Bicknell's ravine, Mount Jura, near Taylorsville, Plumas County.

†Bicknell Tuff[1]

Upper Jurassic: Northern California.

Original reference: A. Hyatt, 1892, Geol. Soc. America Bull., v. 3, p. 407.
Taylorsville region.

Bidahochi Formation[1]

Pliocene: Northeastern Arizona and northwestern New Mexico.

Original reference: A. B. Reagan, 1924, Pan-Am. Geologist, v. 41, p. 357 (map), 366.

C. A. Repenning and J. H. Irwin, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1821–1826. Comprises three unnamed members: lower, 214 feet thick, banded gray, brown, and pink flat-bedded mudstone and argillaceous fine-grained sandstone and a few beds of white rhyolitic ash; middle volcanic member, 5 to 100 feet thick; upper, 274 feet thick, predominantly white to very pale brown crossbedded, poorly cemented medium- to fine-grained argillaceous sandstone and a few beds of white rhyolitie ash. Thickness of formation at reference section herein designated 488 feet; volcanic member not present as mappable unit. Overlies Wingate sandstone, angular unconformity. Pliocene.

E. M. Shoemaker, F. S. Hensley, Jr., and R. W. Hallogen, 1957, U.S. Atomic Energy Comm. TEI Rept. 690, p. 389–398. Formation divided into six members for mapping purposes. Four lower members constitute conformable sequence of claystone and siltstone or very fine grained sandstone that corresponds approximately to "lower member" of Repenning and Irwin (1954). Fifth member, informally referred to as White Cone member includes beds designated as "volcanic member" as well as beds included in "upper member" by Repenning and Irwin. Sixth member is mostly cross-stratified sandstone with minor interbedded claystone.

Type locality not stated; Reagan mapped formation 15 to 20 miles to north and east of settlement of Bidahochi, near Twin Buttes, Ariz. Reference section: Pueblo Colorado Wash 15 miles east of Bidahochi.

Bidarka Formation

Lower Jurassic: Southwestern Alaska.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1), 205. Comprises 1,000 feet of massive to thin-bedded tuffaceous sandstone and interbedded calcareous shale and limestone in lower part and 1,300 feet of dark-gray-black shale with occasional thin beds of light-colored, coarse-grained, well-indurated sandstone in upper part. Underlies Kialagvik formation and overlies Kamishak formation.

In Cold Bay district.

Biddeford Granite[1]

Post-Carboniferous(?): Southwestern Maine.

Original references: C. H. Hitchcock, 1861, Maine Bd. Agr. 6th Ann. Rept., p. 193; F. J. Katz, 1917, U.S. Geol. Survey Prof. Paper 108, p. 177.

Jacob Freedman, 1950, Geol. Soc. America Bull., v. 61, no. 5, p. 476. Incidental mention in report on stratigraphy and structure of Mount Pawtuckaway quadrangle, New Hampshire.

Occurs in Biddeford, Kennebunkport, Kennebunk, and Dayton Townships, York County.

Biddie Knob Formation

[Lower Cambrian]: West-central Vermont.

E-an Zen, 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1829–1830. Revised stratigraphic sequence proposed for north end of slate belt, Taconic Range. Consists of three major units: basal purple and green chloritoid slate (Biddie Knob formation); an intermediate Bull formation; and a black slate formation (the Hooker). Fossils in Bull and Hooker formations indicate that bulk of section is early Cambrian.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 1. Underlies Mettawee member of Bull formation.

Type locality and derivation of name not stated.

Bidwell Coal Member (of Spoon Formation)

Pennsylvanian: Southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 45 (table), 65, pl. 1. Proposed for previously unnamed coal. Forms lowermost member of Spoon formation (new) in southeastern part of state. Underlies New Burnside coal member (new). Thickness about 6 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼SE¼SW¼ sec. 5, T. 11 S., R. 4 E., Johnson County. Named for exposures about three-fourths mile northeast of Bidwell School.

Bienevides Formation

See Benevides Formation.

Big A Sandstone Member (of Supai Formation)

Big A standstone facies (of Supai Formation)

Permian: Central Arizona.

R. L. Jackson, 1951, Plateau, v. 24, no. 2, p. 84–91. Winters (unpub. thesis) recognized four members of Supai in Fort Apache area: Corduroy (new), Fort Apache, Big "A," and Amos Wash (new). In area of present report [Fossil Creek], Supai comprises (ascending) Packard Ranch (new), Oak Creek (new), Big A sand facies, and Corduroy sand facies.

First described near Fort Apache, Ariz.

Big Baldy Granite

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec, Rept. 53, p. 14, pl. 1. Medium grained, contains small amounts of dark mineral. Sparsely porphyritic with potash feldspar phenocrysts. May be in part correlative with Cactus Point granite (new).

Named for Big Baldy, highest point on prominent ridge in northwest part of area, Sequoia National Park. Exposed over an area of about 4 square miles and bounded on east and west by metamorphic rocks.

Big Basin Formation

Big Basin Sandstone (in Cimarron Group)[1]

Permian: Central southern Kansas and northwestern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 46–48.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1760–1761 (fig. 1), 1764–1765 (fig. 3), 1813–1814. Overlying Day Creek dolomite are 65 feet of Permian red beds which Cragin named Hackberry shales and Big Basin sandstone. Name Hackberry being preoccupied, it has been dropped but Big Basin has been retained. Because these strata can be considered one formation of sand beds interstratified with beds of silty and sandy shale, they are herein considered to be one formation and all beds between Day Creek dolomite and top of Permian red beds of Kansas (here covered by Cretaceous) are termed Big Basin formation. Should further work establish correlation of lower shaly part of formation with Doxey shale member of Oklahoma Quartermaster formation, name Big Basin would be restricted to the sand beds alone, the possible equivalent of Elk City sandstone member of Quartermaster. At present, interrelations of type Quartermaster with Day Creek dolomite and so-called Cloud Chief member of Whitehorse have not been definitely established. Writer [Norton] believes that Evans (1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4) was not justified in attempting to drop Kansas nomenclature. Lowermost 25 feet is silty shale, and lower 7 feet of this shaly member is gray-green at some localities. Upper and more prominent part of formation consists of 40 feet of sandstones and sandy shales, both locally lithified to varying extent. Kiger division of Cimarron series.

Named for Big Basin, a depression in Clark County, Kans.

Big Bend facies[1]

Big Bend magnafacies[1]

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

Original reference: K. E. Caster, 1934, Bull. Am. Paleontology, v. 21, no. 71.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 46. Complete succession of magnafacies as outlined by Caster for southern New York and northwestern Pennsylvania is not represented in Genesee group. At Cayuga, except for Genesco shale, group is presumably within the Big Bend magnafacies, for it is lithologically like Ithaca beds which Caster (1934) placed in that magnafacies. If facies are to be given names and more or less specific boundaries, Starkey tongue of the Sherburne, penetrating the shales to the west, might be treated as a tongue of the Big Bend magnafacies, though its extension away from main mass of magnafacies is far more limited than that of the black shales. With so many variations in ideal sequence of magnafacies and parvafacies, it is inadvisable to extend terms into western and central New York.

Named for exposures along Allegheny River from Kinzua through Big Bend, Warren County, Pa., and on to Warren, Pa.

Big Bend Gravel[1]

Pleistocene: Northwestern Pennsylvania.

Original references: E. H. Williams, Jr., 1917, Pennsylvania glaciation, First phase; 1917, Am. Philos. Soc. Proc., v. 59, p. 68–75.

Named for Big Bend, Warren County.

Big Blue Group[1]

Big Blue Series[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 5.

J. E. Adams and others, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1677–1678. In Oklahoma and Kansas, Leonard series extends from the horizon near top of Herington limestone up to top of Dog Creek shale—that is, to base of Whitehorse group. Therefore, formations of Big Blue and Cimarron series of Kansas and Nebraska should be reclassified according to assignments in Wolfcamp, Leonard, and Guadalupe series.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 40. Term Wolfcamp supplants term Big Blue, which has heretofore been used as name of lowermost series in Permian in northern midcontinent area. Big Blue series included some higher beds which are now assigned to the Leonard series. Boundary between Wolfcamp and Leonard in Kansas is drawn at top of Nolans formation.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 24, 30–31. Nebraska Geological Survey continues use of Big Blue series. As here considered, includes section between top of Herington limestone and the unconformity at horizon of Brownwille limestone; includes redefined Chase group, Council Grove group, and Admire group.

Named for Big Blue River, which, in northern Kansas, cuts deeply into these rocks.

Big Blue Serpentinous Member (of Temblor Formation)[1]

Miocene, middle: Southern California.

Original reference: R. Anderson and R. W. Pack, 1915, U.S. Geol. Survey Bull. 603.

Named for exposures in Big Blue Hills.

Big Branch Formation[1] (in Dornick Hills Group)

Pennsylvanian (Desmoinesian): Southern Oklahoma.

Original reference: F. W. Floyd and D. C. Nufer, 1935, Tulsa Geol. Soc. Digest, 1934, p. 10–11.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1. Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 140–142. Description of type locality as taken from personal communication by Nufer: 800 feet of section, lower part gray shale with one thin sand bed near middle, upper 400 feet mainly shale with sandstones, chert conglomerate, and several limestones near top of section; placed in geologic column as that unit from top of Pumpkin Creek limestone down to top of Lester limestone; fauna is Des Moines in age and has no Morrow characteristics, and should be removed from the Dornick Hills. This definition is modified by raising base of Big Branch formation from top of Lester limestone to top of Frensley limestone member of Lake Murray formation. Underlies Deese formation.

C. W. Tomlinson and William McBee, Jr., 1959 *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 30. Maximum thickness about 450 feet. Includes Pumpkin Creek limestone member at top. Overlies Frensley limestone; underlies unnamed unit at base of Deese group. Desmoinesian.

Type locality: Exposures along Big Branch of Washita River in NW¼ sec. 11, T. 3 S., R. 2 E., Carter County.

Big Branch Gneiss

Precambrian: Central Texas.

V. E. Barnes, 1940, *in* Geol. Soc. America [Guidebook] 53d Ann. Mtg., p. 53 (geol. map). Shown on geological map of Cut Off Gap area.

V. E. Barnes, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 56–57 [1945]. Predominantly medium- to dark-gray, medium- to fine-grained quartz diorite composition. Intrudes Valley Spring gneiss and Packsaddle schist. Granites of area and their pegmatites and aplites intrude Big Branch gneiss. Derivation of name given.

Frederick Romberg and V. E. Barnes, 1949, Geophysics, v. 14, no. 2, p. 152–153, fig. 1. Coal Creek serpentine mass is bordered along south and for half of its distance along north by Big Branch gneiss. On map legend Big Branch gneiss is placed above Red Mountain gneiss and below Coal Creek serpentine.

V. E. Barnes, [1952?], Geologic map of the Blowout quadrangle, Blanco, Gillespie, and Llano Counties, Texas (1:31,680): Texas Univ. Bur. Econ. Geology. Most abundant Precambrian rock in quadrangle. Intruded Packsaddle schist and Valley Spring gneiss. Age relation of Red Mountain gneiss and Big Branch gneiss not known. They may be nearly same age and derived from common source. Age relation to Coal Creek serpentine also in question.

Occurs in northeastern Gillespie and northwestern Blanco Counties. Name derived from Big Branch of Coal Creek.

Big Buffalo Series[1]

Lower Ordovician: Northern Arkansas.

E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 27.

Named for exposures on Buffalo River (formerly called Buffalo Fork of White River), in Newton County.

Big Butt Quartzite

Precambrian (Ocoee Series): Western North Carolina and eastern Tennessee.

G. W. Stose and A. J. Stose, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1233. Big Butt quartzite caps Bald Mountains and also occurs in Murphy syncline where it is overlain by Valleytown formation.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 272–273, 284–285. Thick-bedded white granular quartzite and interbedded argillite and fine-grained greenish arkose. On Big Butt, formation consists of two beds of massive quartzite, each about 30 feet thick, separated by approximately 100 feet of arkose and argillite. Northeast of the Big Butt, the quartzite caps Rich Mountain and in vicinity of Nolichucky River forms Jump Hill and caps Stony Point; at these places, the quartzite is enclosed in main syncline of Ocoee series and overlies Nantahala slate. One mile southeast of Murphy, Big Butt quartzite makes prominent ridge which is cut through by Hiwassee River; in exposures on north side of river, quartzite is 200 feet thick and consists of two layers of massive thick-bedded white quartzite with thinner beds of dark-banded white and blue, irregularly bedded quartzite in middle. In northern part of Ellijay quadrangle, quartzite is apparently 500 to 600 feet thick but thins southwestward and is not known south of Ellijay. In Murphy syncline, Keith, (1907, U.S. Geol. Survey Geol. Atlas, Folio 143) and La Forge and Phalen (1913, U.S. Geol. Survey Geol. Atlas, Folio 187) mapped a white quartzite—the Tusquitee—which overlies Nantahala slate and underlies Brasstown schist and Valleytown formation. At most places, Keith mapped the quartzite in two parallel lenticular bands with anticlines of Nantahala slate between. These white quartzite are herein correlated with Big Butt quartzite, and intervening slaty beds are regarded not as Nantahala slate but as part of the Big Butt quartzite equivalent to the fine-grained arkosic quartzite and argillite that separate the two quartzite beds of the Big Butt on Bald Mountain. Keith (1905, U.S. Geol. Survey Geol. Atlas, Folio 118) termed the quartzite Nebo and the softer beds Murray shale, which are names that properly should be applied only to Lower Cambrian formations; hence, new name for the youngest formation of Ocoee series in Bald Mountains is proposed.

Named from the Big Butt, northeast culmination of Bald Mountains on Tennessee-North Carolina line.

Bigby Limestone[1]

Bigby facies (of Bigby-Cannon Limestone)

Middle Ordovician: Central Tennessee.

Original reference: C. W. Hayes and E. O. Ulrich, 1903, U.S. Geol. Survey Geol. Atlas, Folio 95, p. 2.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 2 (fig. 1), 80, 107–121. Bigby limestone grade laterally into Cannon limestone; the two are contemporary facies of unit here termed Bigby-Cannon limestone which overlies Hermitage formation and underlies Catheys formation. All included in Nashville group.

Named for exposures on Big Bigby Creek, Maury County.

Big Clifty Sandstone[1] **Member** (of Golconda Formation)

Big Clifty Formation (in Stephensport Group)

Upper Mississippian: Western Kentucky and southern Indiana.

Original reference: C. J. Norwood, 1876, Kentucky Geol. Survey, new ser., v. 1, pt. 6, p. 10, 13, 15, 16, 51, 73, 369.

D. H. Swann and Elwood Atherton, 1948, Jour. Geology. v. 56, no. 4, p. 277–278. Sandstone lenses occur sporadically in lower part of Golconda (Indian Springs) shale as far west as Marion County, Ill. Eastward these coalesce into a continuous sandstone unit which has its maximum thickness in a belt extending through eastern Gibson County, Ind., and Daviess County, Ky. There are places where the sandstone is more than 100 feet thick and lies on an unconformable surface which cuts into and even through Beech Creek limestone. This is most continuous and most prominent sandstone in lower and middle Chester of Indiana and Kentucky outcrop belt. Name "Big Clifty" was applied to this sandstone by Norwood (1876). Name has been little used since sandstone has generally been considered equivalent to Cypress sandstone, previously named in Illinois. Northeast of line extending from Shawneetown, Ill., through Dixon and Greenville, Ky., Big Clifty is separated from true Cypress by sheet of Beech Creek (Barlow) limestone; southwest of this line along outcrop belt through Christian and Caldwell Counties, Ky., Big Clifty may lie directly on true Cypress.

A. C. McFarlan and others, 1955, Kentucky Geol. Survey, ser. 9, Bull. 16, p. 18. Name Haney limestone is proposed for the "Golconda" as recognized east of Todd County, Ky., and north into Indiana. Abandoned name Big Clifty returns to use for sandstone that underlies the Haney and caps the Dripping Springs escarpment from Todd County eastward and northward to Ohio River. Because Big Clifty is represented by little or no sandstone in westernmost Kentucky outcrop and subsurface, in Illinois outcrop, and most of Illinois subsurface, name is unsuitable to these areas, and name Fraileys shale is proposed for interval between Haney and Beech Creek limestone wherever sandstone is insignificant or lacking.

D. J. McGregor, T. G. Perry and W. J. Wayne, 1957, Indiana Geol. Survey Field Conf. Guidebook 9, p. 6, pl. 2. Name Big Clifty formation is used here instead of Cypress as it now appears practically certain that name Cypress has been incorrectly used in Indiana. Formation consists of medium-bedded fine-grained sandstone with gray shale locally at base. Thickness 25 to 40 feet. Underlies Golconda formation; overlies Beech Creek limestone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 40–41, pl. 1. Included in Stephensport group (redefined). Includes shale unit formerly considered to be lower part of Golconda formation. Thickness 42 to 56 feet. Underlies Golconda limestone; overlies Beech Creek limestone.

U. S. Geological Survey currently classifies the Big Clifty Sandstone as a member of Golconda Formation on the basis of a study now in progress.

Named for exposures on Big Clifty Creek, Grayson County, Ky.

Big Cottonwood Formation

Big Cottonwood Quartzite Series[1]

Big Cottonwood Series

Precambrian: Central northern Utah.

Original reference: S. F. Emmons, 1895, U.S. Geol. Survey 16th Ann, Rept., pt. 2, p. 362.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1130 (table). Table of summary of formations in Logan quadrangle, Utah, lists Precambrian Big Cottonwood Canyon series below Cambrian Brigham quartzite.

M. D. Crittenden, Jr., 1950, Utah Geol. and Mineralog. Survey [Utah Geol. Soc.] Guidebook 5, pl. 61–65. Formation consists of white or greenish quartzite and brown, green, or deep-blue-purple shale or slaty shale. Thickness 12,000 to 16,000 feet. Underlies unnamed tillite; overlies "the Metamorphic complex."

M. D. Crittenden, Jr., B. J. Sharp, and F. C. Calkins, 1952, Utah Geol. Soc. Guidebook 8, p. 3–4, pl. 1. Term Big Cottonwood series is here proposed as designation for 16,000-foot sequence of alternating rusty-weathering white or greenish quartzites and variegated red, greenish, and blue-purple shales that crop out in lower gorge of Big Cottonwood Canyon. Unconformably overlies Little Willow series (new); underlies Mineral Fork tillite (new). Precambrian.

R. E. Cohenour, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 36, 37 (fig. 2). Big Cottonwood series discussed in Uinta-Wasatch Mountain junction and part of central Utah. Diagram shows Big Cottonwood above Little Willow series and below Mineral Fork tillite and Mutual quartzite in Wasatch Mountains and below Sheeprock series in Sheeprock Mountains. Correlates with Uinta Mountain group in eastern Uinta Mountains.

Name proposed for sequence which crops out in lower gorge of Big Cottonwood Canyon, in Wasatch Mountains.

Big Cottonwood Formation[1]

Upper Cretaceous: Southwestern Minnesota.

Original reference: F. W. Sardeson, 1908, Geol. Soc. America Bull., v. 19, p. 221–242.

Outcrops on Big Cottonwood River and in neighboring parts of Minnesota Valley.

Big Cottonwood Canyon Series

See **Big Cottonwood Formation.**

Big Creek Shale Member (of Carbondale Formation)[1]

Big Creek Shale (in Carbondale Group)

Pennsylvanian: Western and northern Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 108–110, geol. sections 18, 19, 44. Included in Brereton cyclothem, Carbondale group. Thickness 10 to 30 feet; in Havana quadrangle 11 feet thick. Upper part of underlying Cuba sandstone is commonly shaly, and boundary between it and Big Creek shale is indefinite at many places. Stratigraphically below Herrin (No. 6) coal.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 48 (table 1), pl. 1. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Carbondale is redefined as formation and includes Big Creek shale member which lies above Vermilionville sandstone member and below Herrin (No. 6) coal member.

Type locality: Along Big Creek in T. 7 N., R. 4 E., Canton quadrangle, Fulton County. Named from outcrops along Big Creek in T. 7 N., R. 4 E., Fulton County.

†Big Deciper Calcareous Sands[1]

Upper Cretaceous (Gulf Series): Southern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72, 77, 79, 188.

Named for exposures in bluffs of Big Deciper Creek, 6 miles south of Arkadelphia, Clark County.

†Big De Gray horizon[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann, Rept. 1888, v. 2, p. 79, 81, 188.

Named for occurrence in bed of Big De Gray Creek, near McCaulley's, Clark County.

Big Elk Sandstone Member (of Colorado Shale)[1]

Upper Cretaceous: Central southern Montana.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Bull. 691–F, p. 189, 195–198.

H. D. Hadley, P. J. Lewis, and R. B. Larsen, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 135. Big Elk sandstone and Mosby sandstone of central Montana probably equivalent to part of Frontier formation.

Named for exposures in Big Elk Dome, in west part of Musselshell Valley.

Bigelow Formation (in Council Grove Group)[1]

Permian: Northeastern Kansas and southeastern Nebraska.

Original references: R. C. Moore, M. K. Elias, and N. D. Newell, 1934, Stratigraphic sections of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita, Kans. [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21-23]; G. E. Condra, 1935, Nebraska Geol. Survey Paper 8.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 65. Proposed that Bigelow be dropped as stratigraphic term and that Crouse limestone, Blue Rapids shale, and Funston limestone be recognized as formations. Gives derivation of name.

Named from Bigelow, Marshall County, Kans.

Big Falls Picritic Basalt (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 231 (table), 238–241, pl. 1. Characterized by prominent phenocrysts of augite and olivine. Commonly very vesicular pahoehoe, locally aa. Typically consists of many thin flow units ranging in thickness from 1 or 2 feet to 20 feet. Maximum thickness about 134 feet. Basal unit of series; lies on eroded surface of Kula lavas; in sea cliff east of Hanawi Stream fills gorge cut completely through

Kula lavas into Honomanu basalts. Stratigraphically below Makapipi basalts (new).

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 77–78. Exposed along narrow band with outcrop area of about 0.1 square mile along east side of Hanawi Gulch, in Nahiku area along northeast side of island. Pleistocene(?).

Named for occurrence at Big Falls on Hanawi Stream, Haleakala (East Maui) volcano.

Bigford Member (of Mount Selman Formation)[1]

Eocene, middle: Southern Texas.

Original reference: A. C. Trowbridge, 1923, Geol. Soc. America Bull., v. 34, p. 75; 1923, U.S. Geol. Survey Prof. Paper 131–B, p. 92.

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 243–C, p. 37. Because of similarity of their stratigraphic position above Carrizo sand and similarity of ferruginous beds partly composing them, Reklaw and Bigford members of the Mount Selman have been regarded as contemporaneous. Geographic and stratigraphic positions of the fossiliferous ferruginous sandstones north of Leming, Atascosa County, suggest that they represent eastward extension of Bigford from Frio County. If Leming and Scruggs Creek localities should prove to represent same zone, then on the assumption that the conglomerate is basal part of Reklaw, it would appear that the Bigford is not exact equivalent of the Reklaw, but is older and intervenes between the Carrizo sand and the Reklaw.

Named for Bigford Ranch, Webb County.

Bigfork Chert[1]

Middle Ordovician: Southwestern Arkansas and southeastern Oklahoma.

Original reference: A. H. Purdue, 1909, Geol. Soc. America Bull., v. 19, p. 557; 1909, Slates of Arkansas; Arkansas Geol. Survey, p. 30, 35.

B. H. Harlton, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 4, p. 781 (fig. 2), 782, 783–787. Geographically extended into Ouachita Mountains, southeastern Oklahoma, where it is well exposed at Black Knob Ridge and in the Potato Hills. At Black Knob Ridge, light- to dark-gray hard cryptocrystalline well-bedded cherty highly siliceous limestone with thin layers of coarsely crystalline limestone; upper part consists of alternating chert and marly shale or shale beds ranging from 1 inch to 2 feet in thickness. About 600 feet thick. Conformably underlies Polk Creek shale; overlies Womble shale. Upper Ordovician.

Named for exposures over large area around Bigfork post office, Montgomery County, Ark.

Big Glass Mountain Complex[1]

Recent: Northern California.

Original reference: H. A. Powers, 1932, Am. Mineralogist, v. 17, no. 7, p. 280–282.

In Modoc Lava Bed quadrangle.

Bigheart Sandstone Member (of Tallant Formation)

Bigheart Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Central northern Oklahoma.

Original reference: L. C. Snider, 1911, Oklahoma Geol. Survey Bull. 7, p. 221.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 119–120, 121–122. Reallocated to member status in Tallant formation (new).

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 32–39, pl. 1. Basal member of Tallant. Revard sandstone member lies near top of formation. Average thickness between 10 and 35 feet.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 21–22, pls. In Pawnee County, Bigheart is thick resistant bed of fine- to coarse-grained sandstone. Massive to well bedded to crossbedded; contains silty or shaly streaks. Thickness 50 to 72 feet. Basal member of Tallant. Separated from overlying Revard sandstone member by unnamed shale member approximately 100 feet thick.

Named for exposures west of Barnsdall (formerly called Bigheart), Osage County.

Big Hill Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 117 (fig. 17), 119, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined. Big Hill is second in known sequence; younger than Emery Peak and older than Mud Hill.

Big Hill is deeply eroded cone composed of tuff, spatters, and minor amounts of lava, Union County.

Big Hill Beds[1] or Member (of Richmond Formation)

Big Hill Limestone

Upper Ordovician: Northern Michigan.

Original reference: R. C. Hussey, 1926, Michigan Univ. Mus. Geol. Contr., v. 2, no. 8, p. 115–150.

R. C. Hussey, 1952, Michigan Dept. Conserv., Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 14 (table). Table shows Big Hill [member] of Richmond formation; occurs above Stonington [member].

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 46). Chart shows Big Hill limestone overlying Ogontz limestone.

Beds exposed from crest of Hinkins Hill (also known as Big Hill) north to east end of Maywood road, Delta County.

Bighorn Dolomite,[1] Limestone, or Group

Upper Ordovician: Wyoming and southern Montana.

Original reference: N. H. Darton, 1904, Geol. Soc. America Bull., v. 15, p. 394–401.

C. W. Tomlinson, 1917, Jour. Geology, v. 25, no. 2, p. 113, 118 (fig. 2); no. 3, p. 253–257. Bighorn dolomite divisible into nine members. Members 5 to 7 constitute a distinct and widely developed unit. In Goose Creek Ridge section, there is little ground for differentiating these three from each other but lowest Richmond fauna occurs in beds there marked as member 6. In Crandall Creek and Dead Indian Creek sections, there is conspicuous surface of disconformity with a basal breccia, at base of member 6. It probably represents the hiatus which was inferred by Darton between Trenton and Richmond members of the Bighorn. In Teton Range, there is an unconformity at base of member 6. Blackwelder proposes recognition of members 6 and 7 in that region, and of corresponding strata in Gros Ventre Range, as a distinct formation, to be called the Leigh.

Eliot Blackwelder, 1918, Washington Acad. Sci. Jour., v. 8, no. 13, p. 419–420. From Teton Range eastward at least to middle of Wind River Mountains and north into Absaroka Range, the massive member, the Bighorn dolomite, is overlain by a thin persistent layer, the Leigh dolomite member. The Leigh is commonly 30 to 40 feet thick, and, in most if not in all localities, is limited both above and below by disconformities.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1092. In Wind River Canyon area, Wyoming, Big Horn [Bighorn] dolomite overlies Boysen formation (new).

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 17-20, pl. 17. Formation in southern Absaroka Range, Wyo., comprises three members: Lander sandstone, about 7 feet high; massive middle dolomite member, 180 feet thick; and Leigh dolomite member, 25½ feet thick. Overlies Gallatin formation; underlies Darby formation.

Erling Dorf and Christina Lochman, 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 543, 554 (fig. 2). In southern Montana, overlies Grove Creek formation (new).

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 124 (table 1), 129. Bighorn dolomite in this report [Wind River Mountains] is 200 to 300 feet thick. Overlies Lander sandstone; and underlies Darby formation. No lithologic or faunal unit comparable with Leigh dolomite member of Gros Ventre Range recognized in area of report.

H. R. Wanless, R. I. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 14–15, pls. Bighorn dolomite is prominent in eastern Teton and southwest Gros Ventre Ranges where it overlies Boysen limestone (formation). Also exposed in Snake River Canyon, on either side of St. John thrust, and in the sheets west of Ferry Peak and Needle Peak thrusts. It is oldest exposed stratum both in northern Grayback Ridge, resting on Darby thrust where it overlies overturned Cretaceous Bear River shales, and in Shepherd Creek on western side of Hoback Range, where it is partially exposed in faulted anticline about one-half mile east of Hoback fault. Also exposed in southwestern and West Jackson Hole Buttes. Thickness 60 to 620 feet. Upper part of Bighorn was designated Leigh member by Tomlinson (1917), but, since its Ordovician age is doubted, it is herein considered separate formation and its thickness is not included in above-mentioned thicknesses. Leigh formation is overlain by Darby formation.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 45–48, pl. 6. Described in Crazy Woman Creek area, Johnson County, Wyo., where it overlies Gallatin limestone and Gros Ventre formation, undivided, and unconformably underlies Madison limestone. Consists of three major units: basal 65 feet, light-gray to brick-red, very fine-grained to coarse-grained almost pure quartz sandstone; middle, about 250 feet of dense massive dolomite; upper, about 40 feet of white-weathering slabby argillaceous dolomite.

M. M. Knechtel, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1994–1995. In Little Rocky Mountains, Mont., overlies Emerson formation (new). Upper Ordovician.

R. J. Ross, Jr., 1957, U.S. Geol. Survey Bull. 1021–M, p. 446 (fig. 68), 447–448. Discussion of Ordovician fossils from wells in Willston basin, eastern Montana. Term Bighorn group used to include (ascending) Red River and Stony Mountain formations in subsurface. Overlies Winnipeg formation.

P. W. Richards and C. L. Nieschmidt, 1957, Billings Geol. Soc. Guidebook 8th Ann. Field Conf., p. 54–62. Bighorn dolomite crops out in south-central Montana and northern Wyoming throughout Absaroka Range, Beartooth and Pryor Mountains, and all but southern part of Bighorn Mountains. Missing from Big Snowy and Little Belt Mountains and Bridger Range in Montana; occurrence west of Yellowstone National Park spotty. Maximum thickness about 500 feet in Bighorn Mountains near Montana-Wyoming border east of map area. Thinner southward, westward, and northward from that area. Merges eastward into Red River and Stony Mountain formations. Bighorn is restricted for this report to area north of Wind River basin, Wyoming—that is, north of approximately the 43°30′ parallel of latitude—to the predominantly carbonate rocks. As thus restricted, divided into two main units which are distinguished in map area except in Pryor Mountains and on north flank of Beartooth Mountains. Lower three-fourths of lower unit is massive cliff-forming dolomite, and upper one-fourth is thin-bedded dolomite; unit is 210 to 260 feet thick. Massive lower part of lower unit is evidently Tomlinson's units 3 and 4, and white blocky dolomite at top of lower member is Tomlinson's unit 5. Upper unit is a 1- to 3-fold sequence of lower unit, but the massive- and thin-bedded parts are neither as thick nor as continuous in upper unit as in the lower. Upper unit, as here described, includes Tomlinson's units 6 to 9 inclusive. Tomlinson said his units 6 and 7 are Leigh dolomite member. However, the writers [Richards and Nieschmidt] do not believe that these two units are necessarily the stratigraphic equivalent of Leigh dolomite member as defined in Teton Range by Blackwelder, and name Leigh is not applied in area of this report. Overlies Cambrian Grove Creek formation throughout Beartooth Mountains and adjacent areas; underlies Devonian strata throughout all but far southeast corner of area; in that area and to the south, underlies Madison limestone. Unconformably underlies Devonian strata. Unconformity marked in some places by channel deposits which, in Park County, Wyo., were named Beartooth Butte formation by Dorf (1934). Jefferson formation overlies Beartooth Butte formation and the Bighorn beyond edges of Beartooth Butte formation.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 13–17, pls. Thickness 370 to 395 feet in Buffalo-Lake De Smet area, Wyoming. Includes sandstone member at base, massive cliff-forming dolomite member in middle, and thin-bedded dolomite and dolomitic limestone member at top. Overlies Gallatin and Gros Ventre formations, undifferentiated; underlies Madison limestone.

Named for exposures in Bighorn Mountains, Wyo.

†Bighorn glacial epoch[1]

Pleistocene (pre-Wisconsin): Colorado.

Original references: W. W. Atwood and K. F. Mather, 1912, Science, new ser., v. 35, p. 315; 1912, Jour. Geology, v. 20, p. 388; 1912, Geol. Soc. America Bull., v. 23, p. 732.

Biglow Glacial Substage

Pleistocene (Tazewell): West-central Colorado.

R. L. Nelson, 1954, Jour. Geology, v. 62, no. 4, p. 329–331, fig. 2, table 4. Time of Wisconsin glaciation in Frying Pan Valley during which outwash deposits and Biglow moraines were deposited. Older than Ivanhoe glacial substage (new); younger than Thomasville glacial substage (new).

Deposits mapped in vicinity of Biglow. In Frying Pan River drainage just west of Continental Divide in Sawatch Range.

Big Mountain Shale Member (of Keyser Limestone)[1]

Lower Devonian: Northern West Virginia and western Virginia.

Original reference: F. M. Swartz, 1929, U.S. Geol. Survey Prof. Paper 158–C, p. 29.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 38, 42–44, 226. Dark thin-bedded calcareous shale with thin limestone bands and locally partly knobby or irregular bedding. Relatively unfossiliferous limestones; contacts with adjacent units are sharp. Passes laterally into lower part of Clifton Forge sandstone of Alleghany County, Va., and adjacent areas in West Virginia.

Named from Big Mountain about 1½ miles west of village of Upper Tract, Pendleton County, W. Va.

Bignell Loess

Bignell Formation (in Sanborn Group)

Bignell Silt Member (of Sanborn Formation)

Pleistocene and Recent: Southwestern Nebraska and northwestern Kansas.

C. B. Schultz and T. M. Stout, 1945, Am. Jour. Sci., v. 243, no. 5, p. 241–244. Formation consists of gray loess. Separated from "Peorian" loess by prominent soil and overlain by complex top soil.

J. C. Frye and O. S. Fent, 1947, Kansas Geol. Survey Bull. 70, p. 50–51. Geographically extended into Kansas where it is considered silt member of Sanborn formation. Occurs above Brady soil at top of Peoria silt member. Thickness in Rice County, 1½ feet.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 138–140. Member forms thin discontinuous widely distributed deposits over northwestern part of Kansas. Commonly less than 10 feet thick; resembles underlying Peoria loess in lithology; contains distinctive, though sparse, molluscan fauna. Rests on Brady soil. Caryan-Mankatoan.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Formation at top of Sanborn group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on correlation chart as Bignell Formation. [Kansas does not use term Sanborn group].

Type locality: About 1.7 miles due south of Bignell, southeast of North Platte, in E½E½ sec. 3, T. 12 N., R. 29 W., Lincoln County, Nebr.

Big Oak Flat Shale and Sandstone Member (of Panoche Group)

Upper Cretaceous: Northern California.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 200, 203–204, 226 (fig. 5), pl. 3. Lower part, 300 to 350 feet thick, is interbedded brownish sandstone and clay-shale, with limestone concretions; upper part is foraminiferal clay-shale, 200 to 300 feet thick. Unconformably overlies Call sandstone member (new) on southwest limb of Butts Ranch syncline; underlies Lodo formation. Considered younger than Butts Ranch shale (new); may be younger than Moreno shale which does not appear on southwest side of syncline.

Type locality: Small northeast-trending canyon 1 mile northwest of Big Oak Flat, San Benito County. Named for Big Oak Flat. Exposed only on southwest side of Butts Ranch syncline.

Big Rock Conglomerate Member (of Kiawa Mountain Formation)

Precambrian: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 1, 10, 24–25, pl. 1. Consists of dark- to medium-gray quartz-pebble conglomerate with intercalated slightly feldspathic quartzite. Most pebbles are light-gray quartz; a few are red and black quartz. Crossbedding common, and current bedding commonly well defined by laminae of iron oxide as well as by layers of differing grain size. Pebbles mostly in the 1- to 5-inch range are well to poorly sorted and highly rounded. Thickness 50 to 200 feet. Underlies lower quartzite member; overlies Ortega quartzite; appears to pinch out east of Poso Spring.

Extends along its strike from NE¼ sec. 20, T. 27 N., R. 8 E., to Big Rock syncline (0.2 mile northwest of Big Rock) and north to Poso anticline; also in SE¼SW¼ sec. 23, T. 27 N., R. 8 E., Las Tablas quadrangle.

Big Run Sandstone

Pennsylvanian (Monongahela Series): Eastern Ohio.

A. T. Cross, W. H. Smith, and Thomas Arkle, Jr., 1950, Field guide for special conference on the stratigraphy, sedimentation, and nomenclature of the Upper Pennsylvanian and Lower Permian strata (Monongahela, Washington, and Greene series) in the northern portion of the Dunkard Basin of Ohio, West Virginia, and Pennsylvania: West Virginia Geol. and Econ. Survey, Sec. 12–A, 12–B, Stop 15 [pl. 1]. Big Run sandstone shown on profile of Uniontown to middle Benwood strata on Ohio Route 7, north of Powhatan. Description reads Lower Uniontown (Big Run sandstone). Columnar section [pl. 1] shows Big Run sandstone above Lower Uniontown coal and below Uniontown coal (No. 10).

Big Saline Formation (in Bend or Marble Falls Group)

Big Saline Group

Big Saline Member (of Marble Falls Formation)

Pennsylvanian: North-central Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 83–85. In much of north-central Texas, type Marble

Falls beds are unconformably overlain by group of shales, sandstone, and limestone, which is herein named Big Saline group. Underlies Smithwick group. Big Saline beds have commonly been included with the Marble Falls. Group is represented by some 50 feet of fusulinid-bearing limestones and shales in east-central McCulloch County; beds become more shaly eastward and identity at outcrop becomes less certain. Northward in subsurface, beds attain thickness of at least 400 feet in Ranger area and are divisible into two formations De Leon and Sipe Springs (both new). Lampasas series.

F. B. Plummer, 1944, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 33, p. 6, 7; 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 65, 67, 68, 73. Member of Marble Falls formation. Overlies Sloan member (new); underlies Lemons Bluff member (new).

F. B. Plummer, 1947, Jour. Paleontology, v. 21, no. 2, p. 142, 143–145. Formation, east of Cavern Ridge, includes (ascending) Gibbons conglomerate, Aylor oolite, Lemons Bluff spiculite, and Brister limestone members; west of Cavern Ridge includes (ascending) Gibbons, Brook Ranch, Lemons Bluff, and Soldiers members. Overlies Sloan formation; underlies Smithwick formation. Bend (Atoka) group.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 56 (fig. 13), 57–77. Here assigned to Marble Falls group, Bend series.

Type locality: Near mouth of Big Saline Creek in eastern Kimble County.

Big Snowy Group[1] or Formation

Mississippian and Pennsylvanian: Central Montana.

Original reference: H. W. Scott, 1935, Geol. Soc. America Proc. 1934, p. 367.

O. A. Seager, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 863. In subsurface in Cedar Creek anticline, southeastern Montana, Big Snowy group includes (ascending) Charles (new), Kibbey, and Otter formations. Underlies Amsden formation; overlies Madison (Pahasapa of Black Hills).

L. L. Sloss, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 65 (chart), 67, 68 (cross section). Restricted at base to exclude Charles formation (subsurface and surface?) which is here assigned to Madison group. As restricted, includes (ascending) Kibbey, Otter, and Heath formations. Underlies unit referred to as lower Amsden.

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 329–349. Big Snowy group of Scott is expanded and redefined to include, in ascending order, not only Kibbey sandstone, Otter formation, and Heath formation of his original report, but also three overlying formations—Cameron Creek, Alaska Bench limestone, and Devils Pocket formation. Scott's (1935) Amsden consisted of a lower red shale, siltstone, and sandstone member (Cameron Creek of this report) and an upper gray limestone member (Freeman's Alaska Bench limestone). Underlies Triassic(?) or Permian(?) and Pennsylvanian undifferentiated, or locally Ellis group; overlies units of Madison group. Thickness 1,509 feet at standard section herein suggested. Mississippian and Pennsylvanian.

O. D. Blake, 1959, Billings, Geol. Soc. Guidebook 10th Ann. Field Conf., p. 64 (fig. 1), 65–68. Includes unit termed Lombard facies.

Standard section: Composite of Stonehouse Ranch and State Road No. 25 sections. Upper part of section was measured in secs. 31 and 32,

T. 11 N., R. 21 E., and lower part was measured in sec. 30, T. 11 N., R. 21 E., and sec. 25, T. 11 N., R. 20 E., Big Snowy Mountains. Named for extensive distribution and exposures in Big Snowy Mountains. Also exposed in Little Belt Mountains, Castle Mountains, and Lombard Hills.

Big Spring Member (of Conococheague Formation)

See Big Spring Station Member (of Conococheague Formation)

Big Springs Limestone Member (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 44, 47.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 153. Big Springs limestone member of Lecompton formation; underlies Queen Hill shale member; overlies Doniphan shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 20, fig. 5. Thickness about 1 foot in Iowa, Missouri, and Nebraska; average about 2 feet in Kansas. Type locality stated. G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24.

Commonly one massive light- to dark-gray argillaceous bed. Very fossiliferous in some outcrops. Thickness 1 to 1½ feet. Underlies Queen Hill shale member; overlies Doniphan shale member.

Type locality: North of Big Springs, Douglas County, Kans.

Big Spring Station Member (of Conococheague Formation)

Upper Cambrian: Northwestern Maryland and southwestern Pennsylvania.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources, Washington County [Rept. 14], p. 45, 55–56. Name Big Spring member applied to basal unit of the Conococheague as described in section measured at Big Spring, Md. Consists mainly of dolomite, shale, sandstone beds, oolite and cryptozoon limestone. Thickness 312 feet. Underlies dolomite beds in middle part of formation; overlies Elbrook formation. Name credited to J. L. Wilson.

J. L. Wilson, 1952, Geol. Soc. America Bull., v. 63, no. 3, p. 307–308, pl. 3. Formally proposed as Big Spring Station member. Member is best defined by abundant beds of platy yellow-weathering dolomitic siltstone or silty dolomite and coarsely arenaceous dolomite or siliceous orthoquartzite; some of the latter beds are 4 to 5 feet thick, although generally the rock type occurs in thinner layers interbedded with typical laminated limestone of the higher Conococheague. Upper boundary arbitrarily drawn at top of uppermost orthoquartzite or very arenaceous limestone within lower group of Conococheague sandstones; lower limit of member (and formation) arbitrarily drawn at lowest of these sandstone beds; the buff-yellow weathering silty dolomite in the Big Spring Station is the same type as that in underlying Elbrook formation, and boundary between the two units is gradational if sandy layers are not considered.

Carlyle Gray and A. A. Socolow, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 148–150. Snitz Creek member of Conococheague has same stratigraphic position of, and is lithologically similar to, Big Spring Station member (Wilson, 1952) of Conococheague formation.

Type section: At railroad cuts north of and in fields west of Big Spring Station on Western Maryland Railroad about 3 miles south of Clear Spring, Washington County, Md.

Big Spruce Knob Sandstone[1]

Mississippian: Southern West Virginia.

Original reference: D. B. Reger, 1920, West Virginia Geol. Survey Rept. Webster County, p. 214, 221–223.

Named for exposure at base of Big Spruce Knob, Pocahontas County.

Big Spruce Knob Shale[1]

Mississippian: Southern West Virginia.

Original reference: D. B. Reger, 1920, West Virginia Geol. Survey Rept. Webster County, p. 214, 223–224.

Exposed on Big Spruce Knob, Pocahontas County.

Big Stone Gap Member (of Chattanooga Shale)[1]

Mississippian (Kinderhookian): Southern Tennessee and southwestern Virginia.

Original reference: J. H. Swartz, 1927, Am. Jour. Sci., 5th, v. 14, p. 485–499.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 93, 94, 96, 97). Shown on correlation chart as overlying Olinger shale and locally the Chemung. Mississippian (Kinderhookian).

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 26. At locality 228 (near Apison, Hamilton County, Tenn.), black shale identified as Big Stone Gap member of Chattanooga by Swartz is placed in Maury formation as herein defined. This stratigraphic assignment made because beds in question either contain conodonts like those of Maury formation of Tennessee or have lithology similar to that formation.

Extends continuously from Chattanooga area to Big Stone Gap, Va., and beyond.

Big Stone Gap Shale[1] or Siltstone

Upper Devonian and Lower Mississippian: Southwestern Virginia.

Original reference: G. W. Stose, 1923, Virginia Geol. Survey Bull. 24.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 143–144, pl. 15. Stose (1923) named Big Stone Gap shale from Big Stone Gap, Va. Swartz (1926 [1927]) proposed that Big Stone Gap be used as name for upper member of Chattanooga formation. Present writer [Cooper] agrees with Swartz's restriction of name but doubts advisability of designating the shale as a member. Geographic distribution of unit is sufficiently extensive for shale to be regarded as formation. In Burkes Garden quadrangle [this report], Big Stone Gap shale is present only in belt immediately north of St. Clair fault. Where well exposed near south edge of Bluefield, formation consists of about 10 feet of black fissile shale. This shale was identified as Sunbury shale by Reger (1926, West Virginia Geol. Survey Rept. Mercer, Monroe and Summers Counties), but this correlation has scant supporting evidence. Writer traced black shale zone at base of the Price from Bluefield, Va., southwestward to Duffield, Scott County and is satisfied that the black shale at Bluefield is upper part of Big Stone Gap shale of Stose and the Big Stone Gap member of Chattanooga formation of Swartz. Underlies Price formation; overlies "Chemung." Mississippian (Kinderhook).

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Described in Duffield quadrangle as Big Stone Gap siltstone. This formation was defined as shale by Stose. Consists of about 200 feet of dark-gray to grayish-black carbonaceous siltstone with some interbeds of dark-gray carbonaceous shale. Overlies a 400-foot sequence of siltstone (Portage shale as used by Stose, 1923); underlies Price siltstone. On basis of conodonts collected in Duffield quadrangle and near Big Stone Gap, Hass believed formation to be Late Devonian and Early Mississippian in age.

Named for Big Stone Gap, southwestern Virginia.

Big Thompson Metasediments

Big Thompson Schist[1]

Precambrian: Central northern Colorado.

Original reference: M. B. Fuller, 1924, Jour. Geology, v. 32, p. 51–63.

M. F. Boos, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1372. Estes Park beds (new) of Big Thompson series of metasedimentary formations and Longs Peak (Silver Plume) and Mount Olympus granitic rocks constitute bedrock of Estes Park Valley.

B. D. Hudson, 1959, Dissert, Abs., v. 19, no. 10, p. 2578. Metasediments are oldest rocks in area near mouth of Big Thompson Canyon. Quartzite, micaceous quartzite, feldspathic quartzite, quartz schist, and mica schist interbedded in a relatively undeformed sequence at least 13,000 feet thick.

Named for Big Thompson River, which, in traversing eastern slope of Front Range, has exposed a complete section of the schist.

Big Valley Bed (in Strawn Group)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 380.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg. and Field Symposium, May 11, 12, no. 70. Underlies Brown Creek bed; overlies Bull Creek sandstone. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Big Valley, Mills County.

Big Wash Andesite

Tertiary: Northwestern Arizona.

B. E. Thomas, 1949, Econ. Geology, v. 44, no. 8, p. 667, fig. 2. Andesite flow which lies unconformably on rhyolite tuff and breccia of Kingman series (new).

B. E. Thomas, 1953, Geol. Soc. America Bull. v. 64, no. 4, p. 408. Thickness of flow 50 to 60 feet. Platy jointing well developed in the bed.

Only occurrence is west of Chloride, on north side of mouth of Big Wash, on west flank of Cerbat Mountains, Mohave County.

Bijiki Iron-Formation Member (of Michigamme Slate)[1]

Precambrian (Animikie Series): Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 596.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 36. Lower part of Michigamme slate in Marquette district includes Bijiki iron-formation, Clarksburg volcanics, and Greenwood iron-formation members. Animikie series.

Named for exposures near mouth of Bijiki River.

Bijou Formation

Miocene-Pliocene: South Dakota.

R. E. Stevenson and L. A. Carlson, 1950, Areal geology of Bonesteel quadrangle (1:62,500): South Dakota Geol. Survey. Interbedded bentonitic clay, sandy siltstone, sandstone, and pebble conglomerate. Stratigraphically above Elk Butte member of Pierre formation and below Herrick gravels (new).

R. E. Stevenson, 1953, South Dakota Acad. Sci. Proc., v. 32, p. 86–89. Characterized by green siliceous coarse quartzose sandstone which makes up about 21 percent of formation. This siliceous sandstone occurs as discontinuous lenses. Bulk of formation consists of greenish to gray bentonitic clay. Thickness, determined from exposures and drill holes, 38 to 54 feet. Barstovian-Clarendonian.

R. E. Stevenson, 1957, South Dakota Acad. Sci. Proc., v. 36, p. 134–138. As herein revised, consists of lenses and thin beds of greenish siliceous sandstone which may be found interbedded with strata of Pliocene or Miocene age (unnamed upper Miocene, Valentine, or Ash Hollow). That is, the Bijou represents a discontinuous facies of greenish silica-cemented sandstone in Miocene and Pliocene rocks of south-central South Dakota.

Typical section: SW¼NE¼ sec. 30, T. 96 N., R. 67 W., Gregory County. Named from exposures in Bijou Hills.

Bilk Creek Sandstone Member (of Wanakah Formation)

Bilk Creek Sandstone Member (of Morrison Formation)

Upper Jurassic: Southwestern Colorado.

M. I. Goldman and A. C. Spencer, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1748 (fig. 2), 1750, 1752 (fig. 3), 1753 (table 1). Proposed as member of Morrison formation. About 20 feet of sandstone or sandy beds capped by carnelian sandstone. Underlies Wanakah marl member; overlies Pony Express limestone member. [See La Plata sandstone.]

E. B. Eckel, 1949, U.S. Geol. Survey Prof. Paper 219, p. 27 (table), 28–29, pl. 2. Reallocated to member status in Wanakah formation. Overlies Pony Express member and underlies unnamed marl member.

Named for exposures along highway about 6 miles west of Telluride, along San Miguel Valley, opposite mouth of Bilk Creek, Ouray County.

Billings Member (of Wellington Formation)

Permian: North-central Oklahoma.

G. O. Raasch, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1928. Thickness 52 feet. Underlies Antelope Flats member (new); overlies Midco (lacustrine) member (new).

W. F. Tanner, 1959, Jour. Sed. Petrology, v. 29, no. 3, p. 327 (table 1). Table shows Billings Pool member above Midco member and below Antelope Flats member.

Type locality and derivation of name not stated.

Billings Pool Member (of Wellington Formation)

See Billings Member (of Wellington Formation).

Bills Creek Beds[1] or Member (of Richmond Formation)

Bills Creek Shale

Upper Ordovician: Northern Michigan.

Original reference: R. C. Hussey, 1926, Michigan Univ. Mus. Geology Contr., v. 2, no. 8, p. 113–150.

R. C. Hussey, 1952, Michigan Dept. Conserv. Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14 (table), 40–45. Overlie Haymeadow Creek member (new) of Trenton formation. Unit termed Haymeadow Creek was formerly included in basal Bills Creek beds. Maximum thickness of beds 80 feet; lower 20 feet are now correlated with Collingwood which some workers consider late Trenton. Thickness at type locality about 62 feet. Underlie Stonington beds [or member] of Richmond. Contact with overlying Stonington beds is disconformable.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 46). Chart shows Bills Cheek shale below Bay de Noc limestone.

Type locality: Along Bills Creek, sec. 7, T. 41 N., R. 20 W., sec. 12, T. 41 N., R. 21 W., 5 miles northeast of Rapid River, Delta County.

Biloxi Sand[1]

Pleistocene: Southern Mississippi, and southeastern Louisiana.

Original reference: L. C. Johnson, 1891, Geol. Soc. America Bull., v. 2, p. 24-25.

Named for Biloxi, Harrison County, Miss.

Bimber Run Conglomerate Member[1] (of Venango Formation)

Upper Devonian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 86, table opposite p. 61.

Bradford Willard, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 14, 243. Listed as member of Venango formation. Underlies North Warren shale member. Upper Devonian. Bimber Run and North Warren are part of Caster's (1934) Salamanca formational suite.

Named for occurrence on Bimber Run and south of its mouth in Watson Township, Warren County.

†Bingen Formation[1] or Sand[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas, northwestern Louisiana, and southeastern Oklahoma.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 56–58.

Named for exposures near Bingen, Hempstead County, Ark.

Bingham Quartzite[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 33–37, map sections.

Includes following units: Phoenix Limestone Lentil, Tilden Limestone Lentil, Yampa Limestone Lentil, Highland Boy Limestone Member, Commercial Limestone Member, Jordan Limestone Member, Lenox Limestone Member, and Butterfield Limestone Member.

In Bingham district.

Binghamton Drift

Binghamton Substage

Pleistocene (Wisconsin): New York and Pennsylvania.

Paul MacClintock and E. T. Apfel, 1944, Geol. Soc. America Bull., v. 55, no. 10, p. 1145 (fig. 1), 1155–1159, pl. 1. Based primarily on lithologic differences, three Wisconsin drift sheets are recognized (ascending) Olean, Binghamton, and Valley Heads. Binghamton drift differs from Olean drift in having abundance of both igneous erratics and limestone. These two constituents, being more conspicuous than the drab gray and browns of the local plateau, give Binghamton drift a brighter look.

L. C. Peltier, 1949, Pennsylvania Geol. Survey, 4th ser., Bull. G 23, p. 4 (table 1), 16 (fig. 5), 19–20, table 5. Referred to as Binghamton substage in discussion of glacial geology of Susquehanna River terraces. Discussion also of Binghamton till, sand, and loess. Overlies Olean and constitutes youngest glacial deposits in this part of Pennsylvania.

Named for exposures near Binghamton, Broome County, N.Y. Drift border passes from Ohio into Pennsylvania 16 miles southwest of Newcastle and enters New York from Pennsylvania on east side of Conewango Valley, 3½ miles east of Fentonville and 9 miles southeast of Jamestown.

Binnewater Sandstone (in Salina Formation)[1]

Silurian: Southeastern New York.

Original reference: C. A. Hartnagel, 1905, New York State Mus. Bull. 80, p. 342–357.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 46–51. Not present in Catskill and Kaaterskill quadrangles. Rock called Binnewater by field parties is of later age and is here called Fuyk sandstone a facies of the Rondout.

Named for occurrence at Binnewater, 7 miles southwest of Kingston, Ulster County.

Birch Creek Limestone Member (of Barnsdall Formation)

†Birch Creek Limestone Bed (in Ochelata Formation)[1]

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Bull. 686–D, p. 17–19.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 120. Reallocated to member status in Barnsdall formation (new). At state line, Barnsdall consists of Birch Creek limestone at base and two unnamed shale members that are separated by unnamed sandy limestone less than 2 feet thick.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 29–30. Varies laterally from lens to lens; occurs at more than one horizon and represents more than one environment.

Named for exposure in bluffs on north side of Birch Creek, near eastern edge of SE¼ sec. 25, T. 24 N., R. 10 E., Osage County.

Birch Creek Schist[1]

Precambrian: Eastern and south-central Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 140–145, 224.

F. F. Barnes and others, 1951, U.S. Geol. Survey Bull. 963–E, p. 146–147, pl. 18. Oldest formation exposed in Healy-Lignite area, south-central Alaska. Unconformably underlies unnamed coal-bearing formation.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Name appears on map legend under Lower Precambrian rocks and Paleozoic rocks.

Clyde Wahrhaftig, 1958, U.S. Geol. Survey Prof. Paper 293–A, p. 8, pls. 1, 2, 3. Predominantly quartz-serite schist; locally contains layers of quartzite and black carbonaceous schist. In fault contact with Cantwell formation. Occupies east-trending belt from 3 to 12 miles wide in north part of Alaska Range.

Named for exposures in Birch Creek district, central eastern Alaska.

Bird Iron-Bearing Member (of Hemlock Formation)

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 36. Consists of oolitic hematite-chert, highly ferruginous quartzite and schist, and breccia made up of angular chert and jasper fragments in a matrix of hard blue hematite. Member attains a maximum thickness of 300 feet and lies about 1,300 feet below the top of formation. Overlain and underlain by greenstone.

Named for the Bird Exploration in sec. 13, T. 43 N., R. 32 W., Iron County.

Birdbear Formation (in Jefferson Group)

Upper Devonian: Subsurface in North Dakota and Montana.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2292 (fig. 2), 2302–2303 (fig. 4), 2318–2322. Proposed for widespread beds of light-colored finely crystalline dolomite and limestone that overlie the Duperow and underlie the Three Forks in Williston basin and central Montana. Thickness ranges from fraction of a foot to 125 feet; in type well 90 feet. Replaces term Nisku formation now restricted to type area in central Alberta.

Type section: Interval between depths of 10,310 and 10,400 feet in Mobil Producing Company's Birdwell No. 1, in sec. 22, T. 149 N., R. 91 W., Dunn County, N. Dak.

Bird Creek Limestone (in Wabaunsee Group)

Bird Creek Limestone Member (of Buck Creek Formation)[1]

Bird Creek Limestone Member (of Vamoosa Formation)

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Bull. 686–L, p. 137, pl. 21.

K. E. Masters, 1957, Shale Shaker, v. 7, no. 5, p. 8–10. Reallocated to member status in upper part of Vamoosa formation. Report covers Prague area in Lincoln and Pottawatomie Counties.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 25 (table 2), 48–50, pl. 1. In Pawnee County, consists of single bed of limestone resting on Severy shale. Extends into Creek County on south, where its southern extent is not known. Thickness about 2 feet in type area; less than 1 foot to 1½ feet in Pawnee County. Underlies Hallett shale. In Wabaunsee group.

Named for exposures on valley sides of Bird Creek and tributaries in T. 27 N., R. 8 E., Osage County.

Birdhead Sandstone Member (of Cloverly Formation)

Birdhead Sandstone Member (of Thermopolis Shale)[1]

Upper Cretaceous: Central southern Montana and northern Wyoming.

Original reference: W. T. Thom, Jr., and others, 1935, U.S. Geol. Survey Bull. 856.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 43. Birdhead sandstone, which was tentatively correlated with Newcastle sandstone of Black Hills and Powder River Basin areas and Muddy sandstone of Bighorn Basin and included in Thermopolis shale by Thom and others (1935), is top of Cloverly formation as herein described. Member is mostly fine-grained sandstone, in part silty and argillaceous. Commonly 10 to 15 feet thick. Not sharply set off from underlying beds; overlain by zone of black shale with hard ironstone concretions, this shale is basal unit of Thermopolis shale.

Birdhead Coulee cuts across the sandstone in T. 3 S., R. 27 E., Yellowstone County, Mont.

Bird Mountain Grit[1]

Cambrian or Ordovician: West-central Vermont.

Original reference: T. N. Dale, 1893, U.S. Geol. Survey 13th Ann. Rept., pt. 2, p. 337–340.

E. P. Kaiser, 1945, Geol. Soc. America Bull., v. 56, no. 12, pt. 1, p. 1084, 1090. Considered a thick facies of Zion Hill formation of Lower Cambrian age.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 40, 41-42. Represented as several lenses of coarse clastics interbedded with rocks of Nassau formation. Name used only in lithologic sense to designate a facies of Nassau formation. Some exposures mentioned.

Exposed on top of Bird Mountain, Rutland County, on large hill 2 miles southwest, and in scattered patches and lenses nearby.

Birdsong Shale[1] **(in Linden Group)**

Birdsong Shale Member (of Ross Formation)

Lower Devonian: Western and central Tennessee.

Original reference: C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 741.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 280, 282 (fig. 83), 292–296. Rank reduced to member status in Ross formation (new). Conformably overlies Rockhouse limestone member; unconformably underlies Flat Gap limestone, Harriman formation, or Camden formation; grades southward into Ross limestone member of Ross formation. Basal 8 to 10 feet of Birdsong as described by Dunbar (1919, Tennessee Div. Geology Bull. 21) is Rockhouse limestone member of this report. Thickness 25 to 40 feet; locally 60 feet. Includes interbeds referred to as Decaturville chert zone.

Typically developed along valley of Birdsong Creek, Benton County.

Bird Spring Formation[1]

Upper Mississippian, Pennsylvanian, and Lower Permian: Nevada, California, and Utah.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 9, 21.

N. D. Newell, 1948, Geol. Soc. America Bull., v. 59, no. 10, p. 1056 (fig. 2). Geographically extended into Confusion Range, Utah, where it is about 2,600 feet thick and underlies Supai(?). Pennsylvanian.

R. B. Kraetsch and R. L. Jones, 1951, Utah Geol. Soc. Guidebook 6, p. 60–62. Fusulinids from Bird Spring indicate that formation transcends Pennsylvanian-Permian boundary in Confusion Range area.

J. C. Hazzard, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881–885. Extended into northern part of Nopah Range, Calif., where it is about 1,110 feet thick and overlies Yellowpine limestone member of Monte Cristo limestone. Lower and Middle Pennsylvanian.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 42–45, pl. 1. Mapped in Ivanpah quadrangle, California. Pennsylvanian.

C. W. Merriam and W. E. Hall, 1957, U.S. Geol. Survey Bull. 1061–A, p. 4–5, 7. Keeler Canyon formation (new) of Pennsylvanian to early Permian age includes rocks that have been referred to provisionally as Bird Spring(?) formation (McAllister, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–95). Bird Spring formation is not wholly Pennsylvanian but embraces Upper Mississippian and Permian.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2170. Name Ely limestone extended into Confusion Range where it replaces term Bird Spring formation.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). In Spring Mountain area, Nevada, underlies Spring Mountain formation (new) and overlies Illipah formation.

Mark Rich, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 2039. Bird Spring formation near Lee Canyon, Clark County, Nev., consists of more than 7,000 feet of predominantly carbonate beds that show no apparent major lithologic breaks. Megafossils from basal 500 feet indicate that lower 100 feet is Chesterian in age and that Mississippian-Pennsylvanian boundary occurs within a transitional interval. Fusulinids collected from remaining 6,500 feet of formation indicate that following divisions of Pennsylvanian and Permian are represented: Morrowan, Atokan, Desmoinesian, Missourian, Virgilian, Wolfcampian, and Leonardian. Pennsylvanian-Permian boundary is also gradational. A total of 2,600 feet of Chesterian and Pennsylvanian beds and 4,500 feet of Permian is present. Upper limit of formation could not be determined because of truncation by faulting.

Underlies large area in Bird Spring Range, Nev.

†Birdsville Formation[1] or Group[1]

Mississippian: Western Kentucky and southeastern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, v. 2, ser. 2, p. 109.

Named for Birdsville, Livingston County, Ky.

Birkmose Member (of Franconia Formation)

Upper Cambrian: Central Wisconsin and eastern Minnesota.

R. R. Berg, 1951, Minnesota Geologist, v. 8, no. 4, p. [1]; 1953, Jour. Paleontology, v. 27, no. 4, p. 554, 555 (fig. 2); 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 862–863, measured sections. Consists of two rock types: greensand, a fine-grained crossbedded glauconitic sandstone; and wormstone, a massive buff to orange glauconitic sandstone that contains linear masses of gray silt; top of member contains a 2-foot bed of glauconitic, dolomitic, flat-pebble conglomerate. Thickness at type locality 27 feet; in Houston County, Minn., 10 to 18 feet. Overlies Woodhill member (new); underlies Tomah sandstone and shale member (new).

Type section: Along State Highway 35, center sec. 25, T. 29 N., R. 20 W., St. Croix County, Wis. Named from exposures north of Birkmose Park in Hudson, Wis.

†Birmingham Breccia[1]

Lower Ordovician: Northern central Alabama.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. Cahaba coal field, p. 152.

Named for exposures at Birmingham, Jefferson County.

Birmingham Red Bed (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland and Pennsylvania.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 63, pl. 6.

Birmingham Shale Member (of Conemaugh Formation)[1]

Birmingham redbed member

Birmingham shale member

Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K, p. 79.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 57–58, geol. map. Birmingham shale member (of Conemaugh series) shown on geologic column of Ohio as interval between Skelly limestone member below and Elk Lick shale and limestone member above. Inasmuch as latter members are not represented over much of Ohio, the Birmingham usually includes all strata between Skelly limestone and Morgantown sandstone; in many areas, a development of thick sandstones occurs throughout interval from Gaysport limestone, or Ames limestone, to top of Morgantown or even stratigraphically higher. In Morgan County [this report], where Skelly limestone is present, the Birmingham consists of 10 to 18 feet of variegated gray to chocolate-brown clay shale which is partly sandy and locally contains siderite nodules.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 147–148. Member of Elk Lick cyclothem in report on Athens County. Stephenson (1876) named Birmingham member from Birmingham Station near Pittsburgh, Pa. Its stratigraphic position, broadly limited, is between Duquesne and Elk Lick coals, and it may coalesce with redbeds above and below to fill much of interval between Ames limestone and Pittsburgh coal. Johnson (1929, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 27) has shown that in type area there is facies relationship between redbed and (or) shale and sandstone and that in places sandstone largely or entirely replaces redbed lithology. Condit (1912, Ohio Geol. Survey, 4th ser., Bull. 17) reported that the Morgantown (Upper Grafton of present report) locally replaces Birmingham redbed in eastern Ohio. Thickness as much as 22½ feet.

Named for exposures at Birmingham Station, west of Pittsburgh, Allegheny County, Pa.

Bisbee Group[1] **or Formation**

Lower Cretaceous (Comanche Series): Southeastern Arizona and southwestern New Mexico.

Original reference: E. T. Dumble, 1902, Am. Inst. Mining Engrs. Trans., v. 31, p. 696–715.

A. A. Stoyanow, 1937, Geol. Soc. America Proc. 1936, p. 296, 297 (table). Group includes (ascending) Morita, Mural, and Hay Flat (new) formations.

B. S. Butler, E. D. Wilson, and C. A. Rasor, 1938, Arizona Bur. Mines Bull. 143, Geol. Ser. 10, p. 24-26. Sandstone and shale of Bisbee group intruded by Uncle Sam porphyry and Schieffelin granodiorite (both new).

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 527–540; 1947, U.S. Geol. Survey Prof. Paper 208, p. 13 (table), 16–26, pl. 1. In Little Hatchet Mountains, N. Mex., group includes (ascending) Broken Jug limestone, Ringbone shale, Hidalgo volcanics, Howells Ridge formation, Corbett sandstone, Playas Peak formation, and Skunk Ranch formation (all new).

James Gilluly, 1945, Am. Jour. Sci., v. 243, no. 12, p. 645–646. Formation, in Tombstone area, consists of series of gray, brown, and red-brown sandstones interfingering with shale and a minor amount of limestone; locally a basal conglomerate. Thickness about 3,000 feet. Unconformably underlies Bronco volcanics (new); unconformably overlies Pennsylvanian Naco limestone.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 8–12. Sequence in group is (ascending) Glance conglomerate, Morita formation, Lowell formation (new), Mural limestone, and Cintura formation.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 70–79. In central Cochise County, Ariz., group includes (ascending) Glance conglomerate, Morita formation, Mural limestone, and Cintura formation. Where units are not differentiated, Bisbee is mapped as formation, about 3,600 feet thick; unconformably overlies Naco group.

F. F. Sabins, Jr., 1957, Geol. Soc. America Bull., v. 68, no. 10, p. 1323, 1324 (table 1), 1325, pl. 1. In Cochise Head and western part of Vanar quadrangle, Arizona, group is about 2,600 feet thick and includes Glance conglomerate at base and undifferentiated rocks above. Unconformably overlies older rocks; underlies Nipper formation (new). Where Nipper formation is absent underlies Faraway Ranch formation.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 11 (table 2), 43–53, pl. 1. In Peloncillo Mountains, N. Mex., and Ariz., group is divided into (ascending) McGhee Peak formation, Carbonate Hill limestone, Still Ridge formation, and Johnny Bull sandstone (all new). Formations have not been correlated with Ransome's or Stoyanow's formations in southeastern Arizona, nor with Lasky's formations in Little Hatchet Mountains. Overlies Naco group which here includes Chiricahua limestone at top; underlies Upper Cretaceous volcanic sequence.

Named for exposures at Bisbee, Ariz.

Biscara intrusive andesite

Miocene(?) or Pliocene(?) : North-central New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 64, pl. 1. Eastward forked dike of andesine-hornblende-biotite andesite porphyry. Dike consists of breccia in which fragments of tuff, conglomerate, and dark felsite are cemented by andesite porphyry. Thickness about 350 feet at western end, where the two forks join; north fork about 150 feet and south fork about 100 feet. Intrudes Biscara member (new) of Los Pinos formation.

In Canon del Agua, 2 miles northeast of Las Tablas, Las Tablas quadrangle, Rio Arriba County.

Biscara Member (of Los Pinos Formation)

Miocene(?) or Pliocene(?) : North-central New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 3, 38, 44, pl. 1. Interlayered tuffaceous sandstone, tuff, conglomerate, and volcanic flow breccia. Conglomerate, with fragments of gray, brown, and dark-red andesite and quartz latite, graywacke, and tuff forms most of the unit. Maximum observed thickness 650 to 700 feet on west side of Canon del Agua. Successively overlapped from south to north by Jarita basalt member (new), an associated gray tuff, and Cordito member (new). Name credited to Butler (unpub. dissert.).

Named after exposure in Biscara Canyon about 1 to 5 miles from its mouth (Butler). These strata of the type locality, however, are here included in Biscara-Esquibel member (new). Mapped in lower Tusas Valley east of Tusas Canyon, from 1.3 miles north of Petaca to a point about 3.5 miles north-northwest of Las Tablas, Las Tablas quadrangle, Rio Arriba County.

Biscara-Esquibel member (of Los Pinos Formation)

Miocene(?) or Pliocene(?) : North-central New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 3, 38, 45–46, pl. 1. Consists of interbedded conglomerate, tuff, and graywacke. Conglomerate with fragments of andesite, latite, tuff, sandstone. and flow breccia. Thickness about 300 feet near head of the Rio Tusas and about 1,100 feet in northeastern part of T. 28 N., R. 8 E. Laps onto Precambrian rocks in vicinity of Hopewell. A composite of two members that were named by Butler (unpub. dissert.) after type areas in Biscara and Esquibel Canyons.

Exposed from SW. cor. T. 28 N., R. 9 E., to northern boundary and part of the western boundary of the Las Tablas quadrangle, Rio Arriba County.

Bisher Limestone

Bisher Formation[1]

Middle Silurian: Southwestern Ohio and northern Kentucky.

Original reference: A. F. Foerste, 1917, Ohio Jour. Sci., v. 17, p. 189, 190.

A. C. McFarlan and W. H. White, 1952, Kentucky Geol. Survey, ser. 9, Bull. 10, p. 12, 13. Bisher formation or dolomite discussed in report dealing with Boyle-Duffin-Ohio shale relationships.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Formation shown on correlation chart above Ribolt shale and below Lilley formation. Niagaran series.

Typically exposed northeast of Bisher Dam, about 1 mile south of Hillsboro, Highland County, Ohio.

Bishop Conglomerate[1]

Oligocene or Miocene: Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 44, 62, 169.

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 578 (fig. 2), 616–617. Crops out in Strawberry Valley quadrangle, Utah. Where best exposed about 100 feet thick. Rests unconformably on older formations, and in mapped area commonly has gentle north dip; this dip, together with slight lithologic difference, is main basis for separating unit from Uinta formation.

M. D. Picard, 1957, Jour. Sed. Petrology, v. 27, no. 4, p. 373. Oligocene-Miocene(?).

Caps Bishop Mountain, now known as Pine Mountain, Sweetwater County, Wyo.

Bishop sandstone[1]

Upper Jurassic: Northeastern Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 301.

Flamingo Gorge area. Derivation of name not stated.

Bishop Tuff

Pleistocene: East-central California.

C. M. Gilbert, 1938, Geol. Soc. America Bull., v. 49, no. 12, p. 1833–1860. Name applied to welded rhyolite tuff having areal extent of 400 square miles and average thickness of 500 feet. In upper parts, pumice lapilli are imbedded in porous vitric-crystal matrix. Thick sections show structural and textural gradation from top to bottom, wherein, at base vitric constituents are compressed, distorted, and aligned in the horizontal plane, and structure becomes very compact; sorting poor; bedding conspicuously absent; well-developed columnar jointing is distinctive feature.

W. C. Putnam, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1939. In sequence of events, Bishop tuff is shown occurring above Sherwin till.

W. C. Putnam, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1281, 1286 (fig. 4), 1289–1290. Sequence shows Bishop tuff as erupted between Aeolian Buttes (new) and Sherwin glacial stage.

W. C. Putnam, 1960, California Univ. Pubs., Geol. Sci., v. 34, no. 5, p. 235–237, map 1. Bishop tuff was erupted a short time after Sherwin glacial stage, being emplaced as a succession of nueés ardentes with maximum thickness of more than 750 feet in Owens Gorge, where base is unexposed. Followed by Tahoe glacial stage.

Occurs in area between Bishop and Mono Lake.

Bishop Brook Limestone[1] (in Manlius Group)

Bishop Brook Limestone Member (of Manlius Limestone)

Lower Devonian: Central New York.

Original reference: Burnett Smith, 1929, New York State Mus. Bull. 281, p. 27, 32.

G. H. Davis 3d, 1953, New York State Mus. Circ. 35, p. 8, 10. Discussion of contact between Manlius limestone and Coeymans limestone in upper New York State. In section measured in quarry at Manlius, units exposed are Bishop Brook limestone, Pools Brook limestone, and Jamesville limestone. Pools Brook and Jamesville represent upper two members of the Manlius while Bishop Brook limestone is considered Coeymans in age. Boundary between Manlius limestone and Helderbergian limestone exposed in this area is marked by conspicuous disconformity which occurs between Pools Brook and Bishop Brook limestones. Although Bishop Brook is definitely Helderbergian in age, no conclusive evidence that unit is western extension of Coeymans was found.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7; 1956, Dissert. Abs., v. 16, no. 1, p. 102. Coeymans limestone of central New York, overlying Jamesville member of Manlius, is entirely younger than Coeymans of eastern New York. Name Deansboro is proposed for this part of Coeymans. "Bishop Brook" is merely reappearance of the Deansboro at Manlius beneath pre-Onondaga unconformity.

Exposed on hillside east of Manlius village, Onondaga County. Named for Bishop Brook northeast of Manlius.

Bishop Creek Granite

Upper Jurassic or Lower Cretaceous(?): Eastern California.

G. A. Schroter, 1938, Eng. Mining Jour., v. 139, no. 4, p. 43. Even granular to porphyritic quartz monzonite; locally as acidic as granite or as basic as diorite.

Occurs on east flank of Sierra Nevada Mountains, southwest of Bishop, in Inyo County.

Bishop Mountain Conglomerate[1]

Miocene(?): Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 44, 62, 109.

Caps Bishop Mountain now known as Pine Mountain, Sweetwater County, southwestern Wyoming.

Bishops Cap Member (of Magdalena Formation)

Pennsylvanian (Strawn) : Western Texas.

L. A. Nelson. 1937, Colorado Univ. Studies, v. 25, no. 1, p. 89. In Franklin Mountains, Texas, formation divided into (ascending) La Tuna, Berino, and Bishops Cap members.

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 166–168, 170 (fig. 5). Predominantly limestone with minor amounts of sandstone and conglomerate; fossiliferous. Thickness about 625 feet. Between exposed top of formation and base of exposed Permian Hueco, thickness of approximately 1,800 feet of sediments, probably Pennsylvanian, is covered by alluvium. Derivation of name given.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 23. On basis of fusulinid studies, it seems inadvisable to apply Nelson's terms to Pennsylvanian rocks of central New Mexico.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 25. Lower part of Bishops Cap is middle Strawn (Upper Pennsylvanian), but no diagnostic fossils have been reported from upper 392 feet.

Named for Bishops Cap Peak about opposite Filmore, Dona Ana County, N. Mex.

Bishops Lodge Member (of Tesuque Formation)

Miocene, middle(?) : Central New Mexico.

F. E. Kottlowski, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 148 (chart). On chart only. Near base of formation. Age shown as Miocene.

Brewster Baldwin, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 118. Just north of Santa Fe, 50 to 530 feet of light-gray volcanic-derived sandstone and silt, with minor tuff beds, were measured by Kottlowski (Spiegel and Baldwin, unpub. ms.). This tuffaceous unit in places rests conformably on as much as 100 feet of pinkish-tan Precambrian-derived sandstone typical of the Tesuque formation, although Cabot (1938) extended Picuris tuff southward to include exposures just north of Santa Fe, Kottlowski is proposing name Bishops Lodge member for following reasons: (1) Bishops Lodge member is interbedded with lower part of Tesuque; (2) Cabot's treatment of Picuris tuff is generalized, whereas study of Santa Fe area is detailed; and (3) exact correlation with type Picuris tuff is not possible at present.

W. W. Boyer, 1959, Jour. Sed. Petrology, v. 29, no. 1, p. 64–72. Discussion of playa deposit in Bishops Lodge member of Tesuque. Discovery of marked disconformity at top of playa beds separating them from overlying Tesuque formation, coupled with changes in lithology, mode of sedimentation, and nature of terrain supplying the sediments suggests that Bishops Lodge member and beds underlying it should be separated from Tesuque formation.

In Santa Fe region.

Bison Banded Member[1] (of Hennessey Shale)

Permian: Central northern Oklahoma.

Original reference: F. L. Aurin, H. G. Officer, and C. N. Gould, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, p. 786–799.

Named for fact that it is exposed on all sides of Bison, Garfield County.

Bissell Formation (in Tropico Group)

Miocene or Pliocene: Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 137 (fig. 1), 138, 141–142. Arkosic sandstone, granitic conglomerate, green-gray siltstone, interbedded limestone, dolomite, chert, and siliceous shale; nonfossiliferous, may be in part a lacustrine facies of Fiss fanglomerate (new). Thickness about 845 feet. Conformably overlies Gem Hill formation (new); unconformably underlies fanglomerate of probable Pleistocene age.

Type locality: An east-trending ridge in N½ sec. 11, T. 10 N., R. 11 W., in Bissell Hills, Rosamond quadrangle, Kern County.

Bissett Conglomerate[1]

Triassic: Western Texas.

Original reference: P. B. King, 1927, Am. Jour. Sci., 5th ser., v. 14, p. 212–221.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 663. Bissett conglomerate, when first described, was considered to be of Permian age, but was shown to be separated from Permian limestones below and from the Cretaceous above by unconformities. Subsequent study of vertebrates and plants from one locality in formation demonstrates that they are Triassic in age, and Bissett is now so classified. Some exposures to the northwest that have been mapped as Bissett may be much younger and belong to basal Cretaceous (Trinity).

Named for exposures on northwest and northeast flanks of Bissett Mountain, southwestern part of Glass Mountains.

Bistineau Member (of Hall Summit Formation)

Paleocene (Midway): Northwestern Louisiana and northeastern Texas.

P. D. Meager and L. C. Aycock, 1942, Louisiana Dept. Conserv. Geol. Pamph. 3, p. 13. Named in stratigraphic summary of Louisiana lignite district. Name credited to G. Murray, Jr.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 48 (fig. 2), 59. Typically calcareous silt and shale. Attains maximum thickness of 100 feet in type area. Overlies Grand Bayou member; contact gradational. Largely covered by Quaternary deposits over northern half of Sabine uplift. Paleocene. Type locality designated. Mapped in Texas.

G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 132–134, pl. 10. Includes all sediments stratigraphically between Grand Bayou member and overlying basal sand of Marthaville formation; beds are conformable with and transitional into overlying and underlying sediments.

Type locality: Exposures in T. 15 N., R. 10 W., in southwestern Bienville Parish, La., and particularly those in secs. 9 and 10 along Louisiana Highways 5650, 933, and 1154, from Ringold to Lake Bistineau. Outcrop belt extends into Shelby County, Tex.

Bitter Creek Formation[1]

Triassic or Jurassic: Northwestern British Columbia, Canada, and southeastern Alaska.

Original references: R. G. McConnell, 1911, Canada Geol. Survey Summ. Rept. 1910, p. 63; 1912, Canada Geol. Survey Summ. Rept. 1911, p. 57; 1913, Canada Geol. Survey Mem. 32, p. 12.

Portland Canal region, British Columbia.

†Bitter Creek Group[1]

Eocene: Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original references: E. D. Cope, 1872, Philadelphia Acad. Nat. Sci. Proc., v. 24, p. 279; 1872, Am. Philos. Soc. Proc., p. 481.

Exposed along Bitter Creek, a small tributary of Green River in Wyoming, from Black Butte northwest to Salt Wells Station on Union Pacific Railroad and at some other points west of Salt Wells, Sweetwater County, Wyo.

Bitter Creek Sandstone, Formation, Beds, or Sand

Miocene, middle: Southern California.

T. W. Dibblee, Jr., 1951, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec. [Guidebook], Stop 2, p. 1–2. Consists of light-buff medium-grained semifriable arkosic sandstone containing reefs of *Ostrea bourgoisii*, *Pecten ostrellanus*, and several species of *Astrodapsis*. Formation is sandy facies of Monterey shale in Cuyama Valley. Thickness about 1,400 feet. Underlies Santa Margarita sandstone; overlies Monterey shale. [Road log accompanying report refers to Bitter Creek sands.]

I. T. Schwade, 1954, California Div. Mines Bull. 170, map sheet 1. Middle Miocene sediments in Cuyama Valley exhibit considerable lateral variation both in outcrop and subsurface. Westernmost exposures shown on map are entirely Monterey shale, chiefly siliceous; in subsurface, a short distance to east, the first fingers of sandstone, locally called Bitter Creek, have been noticed. Largely at expense of the shale, but in addition with each unit exhibiting considerable thickening, the sandstones become dominant sedimentary feature of Middle Miocene section in central part of Cuyama Valley and hills to south. On north side of Caliente Mountain, the Bitter Creek forms prominent part of section, but less dominantly so than in area to south. This unit, made up chiefly of fine silty locally crossbedded fossiliferous sandstone, is considered to represent a large middle Miocene delta. To east, Bitter Creek beds interfinger with, and progressively grade into terrestrial conglomerates and red beds locally called Caliente formation.

D. E. Savage, 1957, (abs.) Geol. Soc. America Bull., v. 68, no. 12, pt. 2, p. 1845. Shown on chart as marine formation unconformably underlying Caliente formation. Thickness about 1,000 feet.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2991. Preoccupied term Bitter Creek replaced by Branch Canyon formation (new).

Type locality: At Bitter Creek, Cuyama Valley. Crops out prominently on both sides of Salisbury Canyon.

Bitterroot period[1]

Precambrian: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46, p. 203.

Bitterwater Formation

Pliocene, upper, and Quaternary: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

Bivouac Formation

Pliocene, upper, or Pleistocene: Northwestern Wyoming.

J. D. Love, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1899, 1907–1911, fig. 1. Slightly lithified conglomerate with minor amounts of very soft sandstone, siltstone, claystone, and pumicite, and one welded tuff. Conglomerate is brownish gray, soft, porous, and poorly stratified. Welded rhyolite tuff is most conspicuous feature of formation, and crops out in cliffs on north and east sides of Signal Mountain where it is about 60 feet thick. Tuff is about 700 feet above lowest exposures of formation. Minimum thickness for formation on Signal Mountain is about 1,000 feet. Unconformably overlain and surrounded by several sequences of Pleistocene glacial and interglacial deposits. Unconformably overlies Teewinot formation (new).

Type section: On Signal Mountain, secs. 19 and 20, T. 45 N., R. 114 W., Teton County, south of town of Moran and east of Jackson Lake. Name derived from Bivouac Peak, a prominent peak in Teton Range, directly west of type section.

Biwabik Iron-Formation[1] (in Animikie Group)

Precambrian: Northeastern Minnesota.

Original reference: C. R. Van Hise and C. K. Leith, 1901, U.S. Geol. Survey Ann. Rept., pt. 3, p. 353, 358–370.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1044–1050. Animikie group comprises (ascending) Pokegama quartzite, Biwabik iron-formation series, and Virginia slate. Detailed discussion of nature of contact of Biwabik iron-bearing formation with Virginia slate. Later Precambrian.

Named for Biwabik mine, one of earliest and largest mines located on formation, Mesabi district. Biwabik is Chippewa word for piece or fragment of iron.

Blach Ranch Limestone Member (of Thrifty Formation)[1]

Blach Ranch Limestone (in Graham Group)

Upper Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132; 1922, Jour Geology, v. 30, p. 23, 31.

Wallace Lee, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 58–61. Blach Ranch limestone member is first reliable datum above Avis sandstone member. In southern part of Young County, consists of two limestones separated by 2 to 3 feet of bluish clay. Separated from overlying Breckenridge limestone member by unnamed interval of shale and sandstone.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, fig. 4. Shown on generalized columnar section of Brazos River area as Blach Ranch limestone in Graham group. Occurs below Breckenridge limestone and above Ivan limestone.

L. F. Brown, Jr., 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 41, p. 14–17, pl. 1. Plummer and Moore (1921) proposed term Blach Ranch for "a limestone which occurs about 30 feet in most sections above the Ivan member." They described the limestone from "typical exposures in vicinity of Blach Brothers Ranch east of Breckenridge." However, type locality that is given for section (id., p. 156) measured on "Blach Brothers Ranch four miles east of Crystal Falls." Plummer and Moore described the limestone as light gray, massive, weathering to large buff or brown slabs or rounded boulders, and rather fossiliferous. They reported average thickness to be 3 or 4 to as much as 8 feet. Type Blach Ranch limestone redescribed and locality noted. Blach Ranch limestone is uniform persistent unit throughout area. Lower limestone is about 1.4 feet thick and separated by about 1 foot of shale from upper 0.8- to 1-foot limestone bed. About 1 foot of platy, argillaceous, fossiliferous limestone commonly occurs at top of upper bed. Separated from overlying Breckenridge limestone member by unnamed shale member 30 to 50 feet thick.

Type section (redescribed): On original Black Brothers Ranch, now two ranches owned by heirs Jack and Bill Black and B. H. Trammell of Breckenridge. Type section is 3¾ miles east of Crystal Falls, northeast of Breckenridge in north-central Stephens County. Ranch name was misspelled in original description. Limestone crops out in north-south belt across Black and Trammell Ranches. New type section is in and near railroad cut on Chicago, Rock Island, and Pacific Railroad.

Black Flint Member (of Pottsville Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: H. Morningstar, 1922, Ohio Geol. Survey, 4th ser., Bull. 25, p. 130.

Crops out in Jackson County and southwestern part of Vinton County.

Black Bay Gabbro (in Beaver Bay Complex)

Precambrian: Northeastern Minnesota.

H. M. Gehman, 1958, Minnesota Univ., Center for Continuation Study, Apr. 21–22, p. 1. Generally coarse-grained with numerous coarser pegmatitic zones. Youngest intrusion of the complex. Forms dikes and small sills surrounding and intruding Beaver Bay ferrogabbro (new).

In southeastern Lake County.

Black Bear Quartz Gabbro

Lower Cretaceous(?): Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 195–196, 235. Moderately dark-colored rock with average grain size between 1 and 2 millimeters. Contains scattered crystals of dark-green amphibole with maximum length about 7 millimeters. Cuts Elkhorn Ridge argillite; brecciated contacts sharp. Assumed to be older than Bald Mountain tonalite (new).

Characteristically exposed near Black Bear mine, on southeast slopes of Hunt Mountain, in Elkhorn Mountains [Grant County]. Forms part of Bald Mountain batholith.

†Black Bluff Group, Clay, or Series (in Midway Group)[1]

Eocene, lower: Southern Alabama.

Original reference: E. A. Smith and L. C. Johnson, 1887, U.S. Geol. Survey Bull. 43, p. 61–62.

Named for exposures at Black Bluff, on Sucarnoochee Creek, at its junction with Tombigbee River, in Sumter County.

Black Butte Flow

Age not stated: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 310. Hornblende-mica dacite. Discussed under general heading of pre-Lassen dacite flows which include Manzanita dacites, Crescent Cliffs flow, Loomis Peak flow, etc.

Exposure of pre-Lassen dacite is mapped in vicinity Black Butte, Tehama County, Lassen Volcanic National Park.

Black Butte Gravel

Black Butte Till

Eocene: Southwestern Montana.

H. W. Scott, 1938, Jour. Geology, v. 46, no. 4, p. 628–635. Unconsolidated glacial deposits composed of rocks ranging in size from clay particles to boulders 5 feet in diameter. Underlies mid-Tertiary volcanics and rests upon upturned truncated Lower Cretaceous sediments. Tentatively correlated with Ridgway and Gunnison tillites of Colorado.

J. A. Mann, 1954, Yellowstone-Bighorn Research Proj. Contr. 190, p. 37–41. Proposed that name be changed to Black Butte gravel because theory of glacial origin calls for conditions of topography and climate which are not only difficult to explain but which are seemingly in opposition to available evidence.

Type locality: West side of Black Buttes, a prominent physiographic feature that rises 1,000 feet above surrounding area, in Gravelly Range of Tobacco Root Mountains.

†Black Butte Quartzite[1]

Upper Cretaceous: Southwestern Wyoming.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 160.

Caps Black Butte, southwest of Black Butte Station, on Union Pacific Railroad, Sweetwater County.

Black Butte Tongue (of Mancos Shale)

Black Butte Tongue (of Rock Springs Formation)

Upper Cretaceous: Southwestern Wyoming.

L. A. Hale, 1950, Wyoming Geol. Soc. Guidebook 5th Ann. Field Conf., p. 52–53, fig. 1. Tongue of Rock Springs formation. Sediments are characteristic of deposition in shallow-water near-shore environment. Shale is commonly sandy and contains much carbonaceous material. Thickness 860 feet. Overlies Chimney Rock tongue (new).

L. A. Hale, 1955, Wyoming Geol. Soc. Guidebook 10th Ann. Field Conf., p. 90 (fig. 1), 92, 93 (fig. 3). Lithologically similar to Blair formation, both being zones of lateral and vertical transition between typical marine and continental lithology. Equivalent to Rangely tongue (new) of Mancos. Figure 3 shows Black Butte tongue of Mancos.

Named for exposures along Black Butte Creek, sec. 36, T. 18 N., R. 102 W., Sweetwater County. Occupies strike valley between Chimney Rock escarpment and cliffs of overlying Ericson formation.

Black Canyon Group

Tertiary(?) (pre-Pliocene): Northwestern Arizona and southeastern Nevada.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1417–1419. Complex assemblage of andesitic lava flows, volcanic breccias (both flow breccias and tuff-breccias), and tuffaceous sandstone layers, with numerous intrusive masses. Underlies Muddy Creek formation with angular unconformity.

F. A. Nickell, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 12, p. 1804 (fig. 2). Includes monzonite, andesite, latite, basalt, and breccia.

Exposed in upper Black Canyon, Mohave County, Ariz., and Clark County, Nev.

Black Canyon Schist[1]

Precambrian (Gunnison River Series): Central western Colorado.

Original reference: J. F. Hunter, 1925, U.S. Geol. Survey Bull. 777.

Occurs throughout area, with many interruptions, from Cochetopa Creek down Gunnison nearly to mouth of Smiths Fork.

Black Crater Formation[1]

Tertiary, upper: Central northern Oregon.

Original reference: E. T. Hodge, 1927, Geol. Soc. America Bull., v. 38, p. 163.

The basalts of Black Crater cover large area on east slope of Cascade Mountains.

Black Creek Formation[1]

Upper Cretaceous: Eastern South Carolina and western North Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 13, 14.

C. W. Cooke, 1936, U.S. Geol. Survey Bull. 867, p. 25–39. Consists principally of very dark gray laminated clay and micaceous sand. Clay predominates at typical exposures, which represent lower part of formation, but sand is more abundant in Snow Hill member at top. No reliable estimates of thickness in South Carolina [this report]. Unconformably overlies Tuscaloosa formation; unconformably underlies Peedee formation or younger deposits.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2178–2184. In South Carolina, Middendorf member of Black Creek formation (herein revived as equivalent of upper part of Cooke's (1936) Tuscaloosa formation) is shown to contain plant remains essentially equivalent to those of lower Black Creek formation of North Carolina; lower part of Cooke's Tuscaloosa is herein referred to as Lower Cretaceous(?) (undifferentiated). Includes Snow Hill member at top. Underlies Peedee formation.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243-B, p. 21. Beds mapped as Black Creek by Cooke (1936) in western Sumter County, S.C., are now regarded as Black Mingo as herein restricted.

P. M. Brown, 1959, North Carolina Div. Mineral Resources Bull. 73, p. 9 (table 1), 10–11. Described in Greenville area where it is exposed along streams in northern part of Greene and Pitt Counties. North and east of Pitt County, formation has been recognized only in subsurface. Thickness 75 to 150 feet. Comprises an unnamed lower member and Snow Hill marl member at top. Unconformably overlies Tuscaloosa formation, exhibiting transgressive offlap relationship; underlies Peedee formation.

C. E. Brett, 1959, Elisha Mitchell Sci. Soc. Jour., v. 75, no. 2, p. 69–70. Upper Cretaceous formations of North Carolina Coastal Plain are (ascending) Middendorf, Black Creek shale, and Peedee. On basis of present study, it is believed that term Snow Hill calcareous member of Black Creek formation should be dropped from literature and that sediments at Snow Hill be included in Peedee formation. Division of either Black Creek or Peedee formations into members is not warranted. Term Black Creek formation should connote dark-gray to black laminated shales with intercalations of clean sand lying conformably beneath Peedee formation.

Named for exposures along Black Creek in Darlington and Florence Counties, S.C.

†Black Earth Dolomite Member (of St. Lawrence Formation)[1]

Upper Cambrian (Croixan): Southern Wisconsin and northern Illinois.

Original reference: E. O. Ulrich, 1916, Geol. Soc. America Bull., v. 27, p. 477–478.

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 169 (fig. 2), 173, 180, 181, 182. Basal member of formation. Commonly sandy dolomite and interbedded dolomitic siltstone and fine-grained sandstone; in vicinity of Black Earth and Madison and at localities along Mississippi Valley, generally massive, brown to buff, slightly glauconitic, with algal structures locally. Distinctly glauconitic facies occur along Minnesota River valley, especially at St. Lawrence where beds described as St. Lawrence limestone by Winchell resemble upper strata of Franconia formation (Reno member of Berg, 1954). In basinward facies, where it rests directly on Franconia greensand, the Black Earth contains only small amounts of interbedded dolomitic siltstone and sandstone; elsewhere, in shoreward direction member is higher in the stratigraphic column and rests on strata of Lodi member. Thickness ranges from 8 to 13 feet in basinward facies, as at St. Lawrence, Lake City, Gotham, Spring Green, and Madison; shoreward to north thins to one-half to 3 feet at Goodenough Hill, Wilton, and Menomonie.

Well developed west of Madison in hills bordering valley of Black Earth Creek, between Black Earth and Mazomanie, Dane County, Wis.

Blackfoot Formation[1]

Blackfoot Limestone Member (of Siyeh Limestone)

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. D. Walcott, 1906, Geol. Soc. America Bull., v. 17. p. 5, 9, 11.

C. E. Erdmann, 1944, U.S. Geol. Survey Water Supply Paper 866–B, p. 48. One of several names used for upper limestone member of Siyeh limestone. In Belt series.

Named for exposures in canyon of North Fork of Blackfoot River, where entire section is exposed. In Mission Range.

Blackfoot Canyon facies (of Belt Series)

Precambrian: Western Montana.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. American Bull., v. 48, no. 12, p. 1877. Within its northern basin, Belt series is divisible into facies that differ in lithology, stratigraphic sequence, thickness, recorded conditions of deposition, fauna, and flora. Blackfoot Canyon facies characterized by development of Grinnell and Appekunny silt-clay argillites in place of the calcareous Chamberlain, and by great thickness of Siyeh, Spokane, and Sheppard, or Helena.

In Glacier National Park.

Blackfootian series[1]

Precambrian (Belt Series): Montana, and Alberta, Canada.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44, p. 217, 218.

Blackford Formation

Blackford Member (of Cliffield Formation or Lurich Formation)

Blackford facies (of Murfreesboro Formation)

Middle Ordovician: Southwestern Virginia, northwestern Georgia, and northeastern Tennessee.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 126, 127, 132–133. Blackford facies of Murfreesboro is commonly composed, in lower 70 feet or less, of a heterogenous sequence of red shale, red mottled argillaceous dolomite, gray shale, gray clay, and gray magnesian crumbly limestone; basal bed is, in places, a massive layer or two, as much as 5 feet thick, of dull gray dolomitic rock containing many angular fragments of residual chert. Above variegated lower part of facies is 100 to 300 feet of layers of chert which is derived from thin-bedded limestone. Occurs, in general, southeast of belt in which St. Clair facies (new) is found. Well exposed in Scott, Russell and Tazewell Counties.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 823–826, 862–863, 864, 884 (fig. 3). Butts (1940) included in the Blackford the basal clastics, ash-gray shale, and blocky chert beds as recognized in Tazewell County. Assignment to the Murfreesboro is incorrect, and reference to the Murfreesboro age of Blackford facies should be discontinued. It is herein proposed to use the name Blackford for the same succession but to drop the facies designation in favor of term member of Cliffield formation (new). As defined, member includes zones 1 to 3 of the Cliffield. Thickness as much as 165 feet. Overlies Five Oaks limestone member (new); disconformable on Beekmantown.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 55–57, pl. 8. Blackford is used herein as name of formation occurring between Clinch and Walker Mountains, where it includes beds of same age as included in Blackford member of Cliffield formation as recognized northwest of Clinch Mountain. Underlies Five Oaks herein given formational rank. Thickness in Burkes Garden quadrangle not more than 60 feet; probably averages less than 25 feet.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66, p. 42. Restricted to the succession of ash-gray shales and underlying basal clastics; zone of blocky chert formerly classed with the Blackford is here named Elway limestone.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1145–1148. Geographically extended into northeastern Tennessee.

A. C. Munyan, 1951, Georgia Geol. Survey Bull. 57, p. 54–59. Formation geographically extended into Georgia where it overlies Newala formation and in some areas Knox dolomite.

A. T. Allen, 1953, Georgia Geol. Survey Bull. 60, p. 179. In Graysville area, Blackford is thin red argillaceous limestone with few scattered grains of sand. Overlies Knox dolomite.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 69, 95 (fig. 8). Basal member of Lurich formation (new).

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Blackford formation as mapped in Duffield quadrangle includes Tumbez limestone.

Well exposed along U.S. Route 19 at several places between Pounding Mill Branch and Pisgah Chapel, Tazewell County, Va., and near Blackford, Russell County.

Blackford Stage

Ordovician (Chazyan): Virginia.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 93, 94, 95. Name given to provincial stage in Virginia which includes rocks between the Canadian [series] and Elway and Lincolnshire formations of the type Ashby [stage]. Name used in place of Marmor stage, which is based on formations in Tennessee, and has type section isolated from other post-Canadian stages of Appalachian region. Older than Ashby stage; these two believed to be Chazyan but not to constitute the whole of that series. Approximately equivalent to lower part of St. Paul group (Neuman, 1951).

Name probably derived from Blackford, 2 miles southeast of Honaker, Russell County, for which Blackford formation is named.

Black Hand Formation[1] or Sandstone

Mississippian: Central Ohio.

Original reference: L. E. Hicks, 1878, Am. Jour. Sci., 3d, v. 16, p. 216, 217.

Gordon Rittenhouse, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 58. Incidental mention of Black Hand sandstone in discussion of distribution of types of Berea sand in West Virginia, eastern Ohio, and western Pennsylvania.

Probably named for Black Hand, Licking County.

Black Hand Member[1] (of Cuyahoga Formation)

Mississippian: Central and southern Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 657, 667–682, 757–779.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 49–50. Seven lithologic facies, each subdivided into a varying number of members and submembers are recognized in Cuyahoga formation. Black Hand shale is member of Killbuck shale facies (new); Black Hand conglomerate is member of River Styx (new), Toboso, and Hocking Valley conglomerate facies. Overlies Armstrong sandstone member. Thickness 75 to 80 feet.

E. J. Szmuc, 1958, Dissert. Abs., v. 18, no. 6, p. 2109. Crossbedded pebbly sandstone. Uppermost member of Cuyahoga. In Cuyahoga, Summit, Medina, and Lorain Counties, term Wooster shale member (new) is used in place of Black Hand, because term Black Hand is restricted to the pebbly sandstone. Intertongues with Wooster shale and, in parts of Wayne, Medina, and Ashland Counties, the sandstone is completely replaced by shale.

Named for exposures at Black Hand, Licking County.

Blackhawk Breccia[1]

Pleistocene: Southern California.

Original reference: A. O. Woodford and T. F. Harriss, 1928, California Univ. Pub., Dept. Geol. Sci. Bull., v. 17, p. 267, 279–283.

Typically developed at mouth of Blackhawk Canyon, San Bernardino County.

Blackhawk Formation (in Mesaverde Group)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, p. 443.

D. J. Fisher, 1936, U.S. Geol. Survey Bull. 852, p. 10 (table), 12–14. In Book Cliffs coal field, formation includes all but lower part of unit as exposed a few miles to west where first defined. Consists of three sandstone-bearing members; both lower and middle members overlain by tongues of shale that locally contain coal. In eastern Utah, sandstones give way to Mancos shale.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, figs. 2, 3, pl. 3. Base of formation, as redefined in Book Cliffs, is at base of Spring Canyon sandstone of Clark (1928, U.S. Geol. Survey Bull. 793). In most outcrops, formation overlain disconformably by Castlegate member of Price River formation. Consists of six prominent littoral marine sandstone tongues and many lesser ones, all of which project eastward into Mancos, where they lose their identity by grading into shale. Above each of them and below next succeeding littoral marine sandstone, lagoonal deposits of sandstone, shale, and coal are developed. Six principal members are (descending) Desert (new), Grassy (new), Sunnyside (new), Kenilworth (new), Aberdeen, and Spring Canyon (new). This division possible only where basal littoral marine sandstones are developed. Not included in Mesaverde group—a term no longer used in Book Cliffs. Of Montana age.

Named for prominent exposures near Blackhawk, a mining community on east front of Wasatch Plateau. Also exposed in Book Cliffs.

Blackhawkian[1]

Pleistocene: Iowa.

Original reference: C. R. Keyes, 1930, Pan-Am. Geologist, v. 54, p. 377.

Black Hill Rhyolite[1]

Tertiary: Colorado.

Original reference: W. Cross, 1886, U.S. Geol. Survey Mon. 12, p. 349.

Forms Black Hill, about 18 miles southeast of Leadville, Lake County.

Black Hill Shale[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, 1885, Washburn Coll. Lab. Nat. History, v. 1, no. 3, p. 90.

Named for Black Hill, Comanche County.

Blackhorse shales[1]

Upper Cretaceous: Central northern South Dakota and southwestern North Dakota.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 37, no. 1, p. 63–64.

Blackhorse Butte is conspicuous landmark in Schanasse County, S. Dak.

Blackiston Formation (in New Albany Shale)

Blackiston Member (of New Albany Shale)

Upper Devonian: Southeastern Indiana, northern Kentucky, and southern Ohio.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 835, 837, 840 (fig. 3), 842–847, 860 (fig. 4), 868, 877. Contains two unnamed members with different facies of black shale. Layers of gray shale are interbedded with black shale of both members in middle third of formation. There are 40 or more layers of gray shale from one-half to 8 inches thick, separated by black shale 1 inch to 5 feet thick; total thickness of this zone is 27 feet. Thickness of formation 75 feet. Disconformably overlies Blocher formation (new); underlies Sanderson formation (new). In parts of Kentucky, overlies Trousdale formation; thickness in Bullitt County 35 feet.

H. H. Murray and others, 1955, Indiana Geol. Survey Field Conf. Guidebook, 8, p. 43, pl. 1. Indiana Geological Survey uses term Blackiston with member rank.

Well exposed in vicinity of Blackiston Mill, old land-mark and recreation center, on Silver Creek, Clark County, Ind. Section from base of Blackiston to top of New Albany is exposed from Armstrong's bend along Silver Creek to Blackiston Mill and west along Mount Tabor Creek to a point near Mount Tabor Church. Middle zone of gray shale is persistent throughout Indiana, Kentucky, Ohio, and Tennessee.

Blackjack Basalt[1]

Miocene: Southeastern Oregon.

Original references: K. Bryan, 1929, U.S. Geol. Survey Water-Supply Paper 597, p. 55; 1930, Jour. Geology, v. 39, p. 504.

Named for fact it caps Blackjack Butte, Malheur County.

Blackjack Creek cyclothem

See Blackjack Creek Limestone Member (of Fort Scott Limestone)

Blackjack Creek Limestone Member (of Fort Scott Limestone)

Pennsylvanian (Des Moines Series): Western Missouri, southwestern Iowa, eastern Kansas, and northeastern Oklahoma.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 26–27 (fig. 2), 36–37, 67. Proposed for lowermost limestone in Fort Scott. Occurs below Houx limestone member (new). Base of Marmaton group in Kansas and Henrietta group in Missouri. Traced into Appanoose County, Iowa.

J. M. Jewett, 1951, Kansas Geol. Survey Bull. 38, p. 304–305. Underlies Little Osage shale member (new). Overlies Cherokee shale. Thickness about 5 feet in Bourbon County; 16 feet or more in Labette County.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 99. Blackjack Creek cyclothem consists of sandy shale, underclay, coal (Mulky bed), black shale, and limestone (Blackjack Creek limestone) belonging in lower part of Fort Scott limestone. Average thickness about 15 feet.

F. C. Greene and W. B. Howe, 1952, Missouri Geol. Survey and Water Resources Inf. Circ. 8, p. 2, 19. Thickness in Missouri about 7 feet. Forms base of Marmaton group.

W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. Generalized section of strata in Carroll and Livingston Counties, Mo., shows Blackjack Creek limestone member overlying Excello formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 33, fig. 5. One of thickest and most persistent limestones in Des Moines series in Iowa. Light gray to light blue gray; weathers brown to buff; varies from massive to slabby. Thickness 1 to 4 feet. Base of formation; separated from Houx limestone member shale interval 2 to 10 feet thick.

Type locality: Outcrops in Johnson County, Mo., 4 miles southeast of Fayetteville, along Blackjack Creek.

Blackjack Knob Member (of Theodosia Formation)

Lower Ordovician: Southern Missouri and northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 25, 31, pl. 2. Upper member of formation. Overlies Lutie member (new); unconformably underlies Cotter formation. Thickness as much as 180 feet. Includes Gainesville sandstone (new) near base; upper part is a monotonous sequence of alternating gray, slightly cherty, finely crystalline dolomite and argillaceous dolomite.

Type section: On north side of Blackjack Knob, Protem quadrangle, in eastern Taney County, Mo.

Blackjack School Sandstone Member (of Atoka Formation)[1]

Middle Pennsylvanian: Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 56. Thin massively bedded sandstone. Thickness 25 to 40 feet in type area. Overlies unnamed shale above Webber[s] Falls member; underlies unnamed shale at top of formation.

Named for exposures at and around Blackjack School, sec. 9, T. 11 N., R. 19 E., Muskogee County.

Black Knob Dolomite (in Pacheta Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12, 27. Yellow dolomite, pinkish when fresh, in places silicified. Thickness in Ninety One Hills area 30 feet; on Black Knob Ridge 56 feet. Overlies Cienda limestone (new); underlies Black Knob quartzite (new).

In standard section of Lowell formation in the Ninety One Hills and exposed on Black Knob Ridge, Cochise County. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Black Knob Quartzite (in Pacheta Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12, 27. Greenish quartzite in places overlain with buff and white speckled sandstone. Contains large silicified tree trunks. Whitish-gray limestone at base. Thickness in Ninety One Hills area 30 feet; on Black Knob Ridge, where it consists of buff and white quartzite beds, 412 feet. Underlies Joserita member (new) and overlies Black Knob dolomite (new).

In standard section of Lowell formation in Ninety One Hills and exposed on Black Knob Ridge. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Black Lake lagunal facies.

Middle Devonian: Northeastern Michigan.

[G. M. Ehlers], 1938, Michigan Acad. Sci. Arts and Letters Sec. Geology and Mineralogy [Guidebook] 8th Ann. Field Excursion, [fig. 2] after p. 8. Shown on columnar section between the Rockport below and the Ferron Point above.

W. A. Kelly, 1940, Michigan Acad. Sci. Arts and Letters Sec. Geology and Mineralogy [Guidebook] 10th Ann. Field Excursion, [fig. 1]. Probaby a lagunal facies of the Rockport.

Occurs in Black Lake Quarry, Black Lake-Afton area.

Blacklead Limestone[1]

Mississippian and Pennsylvanian: Northern Idaho.

Original reference: A. L. Anderson, 1930, Idaho Bur. Mines and Geology Pamph. 34.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 701, chart. Age shown on chart as Mississippian and Pennsylvanian.

Lies far back in Clearwater Mountains at head of Cayuse Creek, a tributary of North Fork of Clearwater River. Also present in a high valley between Blacklead Peak and Rhodes Creek, Orofino region.

Blackleaf Formation (in Colorado Group)

Blackleaf Sandy Member (of Colorado Shale)[1]

Lower Cretaceous: Northwestern and central Montana.

Original reference: E. Stebinger, 1918, U.S. Geol. Survey Bull. 691-E, p. 154, 158-164.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2787-2793; 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89-90. Rank raised to formation and subdivided into (ascending) Flood, Taft Hill glauconitic, Vaughn bentonitic, and Bootlegger members (all new). Overlies Kootenai formation with obscure disconformity having hiatus that may be as much as 100 feet; underlier Marias River shale (new). Ranges in thickness on Sweetgrass arch from 600 feet north of Cut Bank to more than 800 feet south and east of Conrad.

Named for exposures along Blackleaf Creek in sec. 18, T. 26 N., R. 8 W., and vicinity, Teton County. Formation occurs in country between Missouri River and international boundary and between Rocky Mountain front and about Range 8 East.

Black Mesa Basalt[1]

Quaternary: Western Oklahoma and northern New Mexico.

Original reference: A. C. Shead, 1923, Oklahoma Univ. Bull. 271, new ser., p. 108–113.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103. In Abiquiu quadrangle, New Mexico, Quaternary formations overlie pre-Quaternary rock with angular unconformity, and comprise Canjilon till (new); Canones andesite (new), Vallecito basalt (new), and Black Mesa basalt, which were poured out high-level erosion surfaces; Puye gravel (new), which overlies erosion surface at an intermediate level, and is overlain, locally, by Bandelier rhyolite tuff (new), and Santa Clara basalt (new).

Named for exposures on Black Mesa, extreme northwestern part of Oklahoma Panhandle.

Black Mingo Formation[1]

Eocene, lower: Eastern South Carolina.

Original references: E. Sloan, 1905, Geognostic map of South Carolina: South Carolina Geol. Survey; 1907, Summ. Mineral Resources of South Carolina, p. 12, 16; 1908, Catalogue of mineral localities of South Carolina: South Carolina Geol. Survey, ser. 4, Bull. 2, p. 449.

C. A. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 20–21. Black Mingo was referred to as being of Wilcox age (Cooke, 1936, U.S. Geol. Survey Bull. 867) because of presence of *Ostrea arrosis* Aldrich. Although this oyster was stated by Aldrich to be from the Nanafalia, and has since been found to be restricted to it, in the correlation table Black Mingo was placed opposite Tuscahoma sand of Alabama because of occurrence in both of *Turritella mortoni* Conrad, a species now known to be abundant in both the Tuscahoma and Nanafalia. Mapped with this oyster-bearing bed were underlying siliceous clay shales and an overlying massive red sand now known to be of early Claiborne age. A revised map would show the Black Mingo to be confined to a much smaller area, chiefly along valley floors. Beds mapped by Cooke (1936) as Black Creek (Cretaceous) in western Sumter County are now regarded by MacNeil as Black Mingo as here restricted to the siliceous clay-shale and oyster-bearing bed, whereas the overlying more widely distributed sands in Richland, Lee, Sumter, Clarendon, and Williamsburg Counties that were mapped as Black Mingo are now placed by MacNeil in the Congaree formation of early Claiborne age. Some beds in Warley Hill section, considered by Cooke (1936) to be McBean, are now recognized as belonging to Black Mingo. Black Mingo formation, as mapped by Cooke (1936), is now known to have included some beds of early Claiborne age, and (even as here restricted) may include beds of both early Eocene and Paleocene ages. Further subdivision of formation is deferred until more definite evidence of Paleocene age is produced. If lower shales of Black Mingo should prove to be of Paleocene age, one of Sloan's names (1907, 1908) Rhems shale or Lang Syne shale may be available. Included in Wilcox.

Exposed along Black River from Brewington Lake, Clarendon County, to mouth of Black Mingo Creek, up which it is exposed to a point between Rhems and General Marion Bridge.

Black Mountain Andesite

Pliocene(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 49. Black Mountain andesite appears to underlie Childs latite (new) at north end of Childs Mountain. Elsewhere, rests on the latite, and, though the latite may be merely an intercalation in the Black Mountain, it is equally possible that apparent occurrence of the Black Mountain beneath the latite is due to faulting.

At north end of Childs Mountain, Ajo quadrangle, Pima County.

Black Mountain Basalt Flow[1]

Pleistocene: Southern California.

Original reference: C. L. Baker, 1912, California Univ. Pub., Dept. Geol. Bull., v. 7, p. 121–142.

C. D. Hulin, 1925, California State Mining Bur. Bull. 95, p. 20–61. Derivation of name given. Very late Pliocene or early Pleistocene.

T. W. Dibblee, Jr., 1952, California Div. Mines Bull. 160, p. 30, pls. 1, 2, 3. Described in Saltdale quadrangle as a black to gray-black fine-grained diabase-textured vesicular basalt flow, 50 to 150 feet thick; no superjacent strata. Younger than Ricardo formation and older than oldest terrace deposits in area. Probably Pleistocene.

Named for flows on Black Mountain, 7 miles west of El Paso Peak, Kern County.

Black Mountain Granite[1]

Black Mountain Leucogranodiorite

Age not stated: Southeastern Vermont.

Original reference: C. H. Richardson, 1933, Vermont State Geologist 18th Rept., p. 349–357.

M. S. Church, 1937, Jour. Geology, v. 45, no. 7, p. 763–774. Described as a leucogranodiorite which intrudes interbedded rather gneissoid schists. Texture generally medium grained. Outcrop area described.

Forms Black Mountain and occurs on both sides of the West River at village of West Dummerston, Windham County.

Black Mountain Volcanics[1]

Triassic, Jurassic or Cretaceous: Southern California.

Original reference: M. A. Hanna, 1926, California Univ. Pub. Geol. Sci. Bull., v. 16, no. 7, p. 187–246.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 22–23. Name Black Mountain preoccupied. Unit renamed Santiago Peak volcanics.

Well developed on Black Mountain, north part of La Jolla quadrangle, San Diego County.

Black Patch Grit[1]

Lower Cambrian: Eastern New York and western Vermont.

Original reference: T. N. Dale, 1899, U.S. Geol. Survey 19th Ann. Rept., chart opposite p. 178.

George Theokritoff, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 55. Locally, West Castleton formation contains lenses of a dark-gray calcareous grit with conspicuous rounded quartz grains. Dale (1899) named such beds Black Patch grit.

Black Peak Granodiorite and Quartz Diorite

Cretaceous: Northwestern Washington.

Peter Misch, 1952, The Mountaineer, v. 45, no. 13, p. 4 (geol. map), 16–17. Occurs on eastern and western borders of Skagit gneiss. On eastern border, is similar to Chilliwack granodiorite. On west has apparently formed Skagit gneiss, just as Chilliwack rocks have on opposite side of gneiss region. Original eastern contact of Black Peak granodiorite and quartz diorite not preserved because younger intrusive granite occurs (Golden Horn granodiorite, new). To north, down Granite Creek, the Black Peak granodiorite narrows rapidly, and, in lower Granite Creek, across Ruby Creek, and in upper Skagit Valley (Ross Lake), it is reduced to narrow migmatitic belt in which patches of directionless granodiorite have grown in schists and amphibolites which separate Skagit gneiss from Cretaceous phyllites and slates to east.

Black Peak is on border between Chelan County and Skagit County.

Black Point Ash[1]

See Diamond Head Ash.

Black Point Basalt

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, p. 13, pl. 2. Oldest of three extensive lava-flow units filling old canyons and gullies carved in Belkofski tuff (new) and intrusive diorite stocks. Basalt is dark-reddish-brown dense even-textured rock composed of abundant very small phenocrysts; contains a higher percentage of phenocrysts than the other two flows. Crops out south of Arch Point basalt (new).

Crops out at tidewater in Long John Lagoon and along the beach in Chinaman Lagoon in vicinity of Pavlof Volcano, Alaska Peninsula. Forms large domical hill near Black Point.

Black Point Basalt[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrog. Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 78. Thin lava flow of nepheline basanite, 6 to 25 feet thick, and associated dike of similar composition. Rests on reef limestone correlated with plus 95-foot (Kaena) stand of sea, and on Diamond Head tuff. Overlain by beach limestone of plus 25-foot (Waimanalo) stand of sea.

Name after Black (Kupikipikio) Point, on southeast side of Diamond Head, which consists chiefly of this lava. Exposed over about 40 acres on south side of island, 9½ miles west of Makapuu Head.

Black Point Dolomite Member (of Cherry Creek Series)

Precambrian: Southwestern Montana.

E. S. Perry, 1948, Montana Bur. Mines and Geology Mem. 27, p. 7. Name suggested for dolomitic marble occurring in Cherry Creek series. Weathers to dirty-brown granular surfaces which look dark in distance. Bedding at Black Point nearly vertical. Repetition of beds, either by folding or faulting, may account for the 1½ mile width of the outcrop.

In area about 5 miles long and 1½ miles wide, between Johnny Gulch and Cherry Creek, Madison County. Marble forms conspicuous ridge known locally as Black Point.

Black Point Limestone

Pleistocene: Oahu Island, Hawaii.

H. T. Stearns, 1940, Hawaii Div. Hyrdography Bull. 5, p. 53; G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 78–79. Fossiliferous reef limestone. Underlies Diamond Head tuff and Black Point basalt. Extends to altitude of about 48 feet.

Type locality: East shore of Black (Kupikipikio) Point. Limited exposures on Black Point, on southeast side of Diamond Head, on south coast of Oahu, 9½ miles west of Makapuu Head. Highest marine limestone known on leeward side of Koolau Range.

†Black Prairie Series[1]

Upper Cretaceous (Gulf Series): Texas and Arkansas.

Original reference: R. T. Hill, 1889, Texas Geol. Survey Bull. 4, p. xii–xiv.

Named for Black Prairie of eastern Texas and Arkansas.

Black Prince Limestone

Upper Mississippian or Lower Pennsylvanian(?): Southeastern Arizona.

T. M. Romslo, 1949, U.S. Bur. Mines Rept. Inv. 4505, p. 5. Incidental mention. Limestones of Carboniferous period consisting of Escabrosa, Black Prince, and Naco formations in order named, overlie Martin limestone in Johnson Camp area.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 13–15. Comprises basal shale member and upper limestone member. Shale, 10 to 20 feet thick, is red to maroon or purple with scattered nodules or pebbles of chert and limestone, lenses of chert conglomerate and, locally thin beds of limestone. Limestone unit consists of 100 to 140 feet of nearly pure limestone in 1- to 4-foot beds. Limestone is medium to coarse grained and light gray to pink; pink beds most conspicuous in upper part. Thickness: 119 feet in Gunnison Hills; 131 and 155 feet in Little Dragoons; 168 feet in Johnny Lyon Hills. Separated from overlying Horquilla limestone (new) of Naco group by 30 to 65 feet of weak rocks which generally are concealed and form topographic sags. Underlies Escabrosa limestone, contact drawn at base of thin but persistent shale member which contrasts with pure limestone beds above and below. Where shale is missing, it is difficult to separate the Black Prince and Escabrosa.

Type section: On west slope of Gunnison Peak 4½ miles southeast of Black Prince mine (from which unit takes its name) in Johnson mining district at east base of Little Dragoon Mountains, central Cochise County.

Black River Group[1] or Formation

Middle Ordovician: New York and Pennsylvania, and Ontario, Canada.

Original reference: L. Vanuxem, 1842, Geology of New York, pt. 3, p. 38-45.

C. Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 525, 533, 537. In central Pennsylvania, includes Rodman limestone.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 249–251. Black River group comprises (ascending) Pamelia, Lowville, and Chaumont formations. Underlies Trenton group; overlies Beekmantownian.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 178–199. In Virginia only the Lowville-Moccasin and Chambersburg limestones can be definitely recognized as members of Black River group. Eggleston limestone may correspond to Watertown and Amsterdam limestones of New York and also to Chambersburg limestone. Underlies Martinsburg shale; overlies Blount group.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Group in central Pennsylvania includes Valentine limestone, 0 to 145 feet (Lowville); Benner limestone (new) (Pamelia), comprising Stover and Snyder members. Mohawkian series. Underlies Nealmont limestone of Trenton group; overlies "Carlim group," Chazyan(?) series.

F. P. Young, Jr., 1943, Am. Jour. Sci., v. 241, no. 3, p. 143–166; no. 4, p. 211–240. Black River group, with overlying Trenton group, constitutes Mohawkian series of Middle Ordovician. Formations of group, Pamelia, Lowville, and Chaumont, have their type localities in New York. In northwestern New York, Black River group, or some part of it, is present as a belt extending from north of Ingham Mills, Herkimer County, northwestward along Black River valley to Watertown, N.Y., and Thousand Island region. Interrupted by St. Lawrence River, it continues westward across southern Ontario to Lake Simcoe area. Probable that group is also represented on Manitoulin and St. Joseph Islands, Lake Huron. Beds are thus present nearly continuously for distance of about 120 miles in New York and 150 miles in southeastern Ontario.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 189, 192–193 (table 1), 194 (table 2). Group, in central Pennsylvania includes Benner limestone below and Curtin limestone (new) above. The Curtin contains Valley View limestone member (new) and Valentine limestone member. Overlies Chazyan Hatter formation; underlies Nealmont limestone of Trenton group.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 819–886. In Tazewell County, Va., strata embraced by Chazyan and Black River groups of Butts (1940) are divisible into 29 distinctive zones, most of which have distinctive faunal and lithologic features. Detailed work led to recognition of inconsistencies in use of stratigraphic names Stones River, Murfreesboro, Mosheim, Lenoir, Blount, Holston, Ottosee, Lowville, and Moccasin. Revised stratigraphic nomenclature proposed. Name Lowville should not be used in area until regional studies demonstrate true relationships of supposedly Lowville beds to Pamelia-Lowville-Chaumont succession of New York and Ontario. Name Lowville-Moccasin not acceptable because it implies that Moccasin red beds are of Lowville age.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1401. Rocks younger than Canadian or Beekmantownian and older than Cincinnatian series are commonly referred to Middle Ordovician and placed in two series: Chazyan and Mohawkian. Proposed that latter be divided into Bolarian and Trentonian. Term Black River does not lend itself to conversion to series name (Black Riverian). Suggested that term Bolarian series be used for Chazyan to Trentonian interval.

R. C. Hussey, 1952, Michigan Dept. Conserv., Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13–14, 17–22. Black River formation represented by Bony Falls member (new). Underlies Chandler Falls member (new) of Trenton formation.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 66, no. 3, p. 247–298, chart 2. Middle Ordovician strata along Black River valley, west of Adirondacks, has long been considered standard for this part of column in North America, lower part constituting Black River stage and upper part Trenton stage. Kay has proposed to reject Black River as major unit in standard section and replace it with Bolarian series. Thus he would recognize in Middle Ordovician not one series (Champlainian) but three—Chazyan, Bolarian, and Trentonian. Pros and cons of proposal discussed. Majority of committee favored retaining traditional three stages—Chazyan, Black River, and Trentonian on present chart. Black River and Trentonian compose the Mohawkian stage.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 7–9, chart 1. Terms Chazyan and Black River stages not used in this report. Interval subdivided into Marmor, Ashley, Porterfield, and Wilderness stages (all new). Trenton stage restricted by removal of Rockland which has mostly fossils derived from underlying Black River and Witten. Term Black River used on correlation chart to include the Pamelia, Lowville, and Chaumont.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 65–96. Discussion of Ordovician Highgate Springs sequence of Vermont and Quebec and Ordovician classification. Blackriveran series seems to be contained in Bolarian series of the Appalachians, but lowest Bolarian seems older and equivalent to upper Chazyan. Isle La Motte formation classified as Blackriveran and correlated with Chaumont limestone of Black River group of New York.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30, 32. Black River group in northern New York divided into three formations, Pamelia, Lowville, and Chaumont, which have been treated as stages. Cooper (1956) divided rocks that he considered younger than type Chazyan into Ashley, Porterfield, and Wilderness "stages," the latter extending into the lowest Trenton of New York; these stages are in continuous stratigraphic succession in the Appalachians, but their correlation with New York is uncertain. On the other hand, the Pamelian, Lowvillian, and Chaumontian are quite provincial and relatively sparse in fauna; methods of carrying correlations to them and distinguishing their equivalents are inadequate. Blackriveran series comprises (ascending) Pamelian, Lowvillian, and Chaumontian stages.

Named for exposures in cliffs of Black River, N.Y.

†Black River Iron-Bearing Schists[1]

†Black River Iron-Bearing Series[1]

†Black River Falls Iron-Bearing Schists[1]

Precambrian (lower? Huronian): Southwestern Wisconsin.

Original reference: C. R. Van Hise, 1892, U.S. Geol. Survey Bull. 86, p. 190, 195, pl. 3, map.

Probably named for exposures at Black River Falls, Jackson County.

Black River Stage

Blackriveran Series

See **Black River Group.**

†Black Rock Diabase[1]

Black Rock Diabase Breccia (in Granby Tuff)

Triassic: Central Massachusetts.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, Mon. 29, p. 17–18, pl. 34.

Robert Balk, 1957, Geol. Soc. America Bull., v. 68, no. 4, p. 496–497, pl. 1. Diabase breccia consisting of fragments of diabase, tuffaceous diabase, tuff and sedimentary rocks in matrix of vesicular or compact diabase. Cuts sediments above Holyoke diabase sheet and basal members of Granby tuff; relation to diabase flow in Granby tuff unknown. Triassic.

Named for Black Rock south of Mount Holyoke, Mount Holyoke quadrangle.

Black Rock Formation[1]

Lower Ordovician: Northern Arkansas.

Original reference: G. C. Branner, 1929, Geologic map of Arkansas.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 53). Shown on correlation chart above Smithville limestone and below Everton formation. Chazyan.

Mapped at and around Black Rock, Lawrence County.

Blackrock Limestone[1]

Precambrian: Southeastern Idaho.

Original reference: A. L. Anderson, 1928, Idaho Bur. Mines and Geology Pamph. 28, p. 4.

J. C. Ludlum, 1942, Jour. Geology, v. 50, no. 1, p. 92–93. Overlies Pocatello formation (new); unconformably underlies Brigham quartzite. Maximum thickness 535 feet. Precambrian. Spelling Blackrock used rather than Black Rock as used by Anderson (1928) because former spelling now appears on U.S. Geological Survey topographic map of Pocatello quadrangle.

Named because of occurrence along Blackrock Creek, about 2 miles northeast of Portneuf Siding. Best exposed on north side, where it can be traced up Blackrock Creek several miles.

Blackrock Quartzite

Carboniferous(?): Northeastern Nevada.

A. E. Granger and others, 1957, Nevada Bur. Mines Bull. 54, p. 113, pl. 14. Discussion of Elko County. A thrust fault crops out south of Rio Tinto mine and divides Paleozoic rocks into two groups of formations which as yet cannot be correlated. The "footwall" quartzite is only formation of upper plate group that crops out in area shown on plate 14. This is Blackrock quartzite of Stephens (unpub. rept.) Rocks are light-colored medium-grained quartzite. Stephens estimates minimum thickness of 1,000 feet.

Type locality and derivation of name not stated.

Blacksburg Schist[1]

Ordovician to Mississippian: Northwestern South Carolina and southern North Carolina.

Original reference: A. Keith and D. B. Sterrett *in* G. F. Loughlin and others, 1921, North Carolina Geol. and Econ. Survey Bull. 28, p. 28, 73.

T. L. Kesler, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 756, 763 (fig. 2). Incidental mention in report on metamorphic rocks in central Carolina piedmont.

U.S. Geological Survey currently designates the age of the Blacksburg as Ordovician to Mississippian on the basis of a study now in progress.

Named for development in Blacksburg, Cherokee County, S.C.

Blacks Fork Glaciation

Blacks Fork glacial stage[1]

Pleistocene: Northeastern Utah and southwestern Wyoming.

Original reference: W. H. Bradley, 1936, U.S. Geol. Survey Prof. Paper 185.

Ernest Antevs, 1945, Am. Jour. Sci., v. 243-A, table 2. Shown on correlation chart as older than Smith Fork stage (Wisconsin).

U.S. Geological Survey has amended the name Blacks Fork glacial stage to Blacks Fork Glaciation to comply with Stratigraphic Code adopted in 1961.

Named for extensive moraines left by its glaciers in valley of Blacks Fork, Utah.

Blacks Fork Member (of Bridger Formation)[1]

Eocene: Southwestern Wyoming.

Original reference: H. E. Wood 2d 1934, Am. Mus. Nat. History Bull. 67, art. 5, p. 241–242.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 15, pl. 1. Basal member of Bridger. Underlies Twin Buttes member. Early Bridgerian.

Named from Black's Fork of Green River which flows past most of best known exposures.

Blacksmith Limestone[1]

Middle Cambrian: Northeastern Utah and southeastern Idaho.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 6, 7.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1112–1113, 1117 (fig. 4), 1121. As amended, 450 feet thick at type section. Consists of white-gray, dull-steel-gray, and in upper 60 feet dark-lead-gray fine- to medium-grained usually thick-bedded dolomite and interbedded magnesian limestone. Overlies Ute limestone (emended); underlies Bloomington limestone.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1130, 1133. Described in Logan quadrangle, Utah, where it forms prominent cliffs. Thickness near Call's Fort 800 feet; on High Creek 710 feet.

Type locality: Blacksmith Fork Canyon, about 8 miles above its mouth and 15 miles east of Hyrum, Cache County, Utah.

Blacksnake Sandstone Member (of Hance Formation)[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 80, pl. 16.

Cumberland Gap district.

Blackstone Series[1]

Precambrian(?): Eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 8, 104–109.

Alonzo Quinn, R. G. Ray, and W. L. Seymour, 1948, *in* Alonzo Quinn and others, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 3, p. 9-13, geol. map; A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Name revived for stratified metamorphosed sedimentary and igneous rocks of Precambrian(?) age in Pawtucket quadrangle. Includes (ascending) Mussey Brook schist (new), Westboro quartzite, Sneech Pond schist (new), Hunting Hill greenstone (new), and related rocks. Unconformably underlies Pennsylvanian rocks. Cut by two groups of intrusive rocks. Replaces Marlboro formation of Emerson (1917) which is abandoned in this area; includes Westboro quartzite, which Emerson placed below the Marlboro, in a higher stratigraphic position.

A. W. Quinn, 1953, New York Acad. Sci. Trans., ser. 2, v. 15, no. 8, p. 266. Thickness about 10,000 feet in type area.

G. E. Moore, Jr., 1958, U.S. Geol. Survey Geol. Quad. Map GQ–105. Metasedimentary rocks of Hope Valley quadrangle, which occur as inclusions on roof pendants in Hope Valley alaskite gneiss and other intrusives, are correlated with Blackstone series on basis of similarity in lithology, structure, and metamorphism. Blackstone series in Hopewell quadrangle includes wide variety of lithologic types. In most parts of area, these types are intimately interlayered and are not mapped separately.

Named for typical development in lower course of Blackstone River between Woonsocket and Pawtucket, Providence County.

Blacksville Limestone (in Washington Formation[1] or Group)

Permian: Northern West Virginia and southwestern Pennsylvania.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 36.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser. Bull. C–26, p. 135, 150. Lies 210 feet above top of Waynesburg coal which is considered base of Washington group. Thickness including local coals 5 to 20 feet. Occurs below Middle Marietta sandstone and coals and above Lower Marietta sandstone.

Named for village of Blacksville, Monongalia County, W. Va.

Blacktail Formation[1]

Precambrian (Belt Series): Northern Idaho.

Original references: J. L. Gillson, 1925, Am. Min., v. 10, p. 189; 1927, Jour. Geology, v. 35, no. 1, p. 1–32.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 6 (fig. 4). Shown on correlation chart of Belt series in Idaho. Thickness 8,300 feet. Correlates with Creston formation in Boundary County and Priest River National Forest and with St. Regis formation in Coeur d'Alene Mountains, Idaho and Mont. Occurs above Burke formation and below Wallace formation in Pend Oreille region.

Type locality: Blacktail Mountain, near Talache.

Blacktail Formation

Cenozoic(?): Southeastern Arizona.

H. E. Enlows, 1955, Geol. Soc. America Bull., v. 66, no. 10, p. 1217. Thick section of andesitic and dacitic lavas, breccias, and tuffs. Part of formation may be equivalent to Bonita Park formation (new). Also may be correlative with Faraway Ranch formation. Name credited to Raydon (unpub. thesis).

In Portal area, Cochise County.

Blacktail Granite Gneiss

Precambrian (pre-Beltian): Southwestern Montana.

E. W. Heinrich, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1329. Pre-Beltian red granite cutting both Pony and Cherry Creek rocks.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 351. Name Dillon granite gneiss introduced by Henrich (1953) to replace term Blacktail previously used for same unit (Heinrich, 1950) because latter term is preoccupied.

Near Dillon Beaverhead County.

Blacktail Deer Creek Basalts

Miocene, lower: Southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 374, pl. 1. Named for several basalt flows that are associated with Blacktail Deer Creek formation. Composed of dark locally vesicular groundmass with phenocrysts of feldspar.

Exposed in a northeast-southwest zone northwest of the Snowcrest Range, between U.S. Highway 91 and Blacktail Creek, Beaverhead County.

†Blacktail Deer Creek Beds[1]

Blacktail Deer Creek Formation

Miocene, lower: Southwestern Montana.

Original reference: E. Douglass, 1902, Am. Phil. Soc. Trans., v. 20, new ser., pt. 3, p. 237–245.

C. W. Hibbard, and K. A. Keenmon, 1950, Michigan Univ. Mus. Paleontology Contr., v. 8, no. 7, p. 193–204. Termed Blacktail Deer Creek formation. Thickness at type section, herein designated, about 400 feet; lower and upper limits not definitely established. Beds dip 5° W.; nearby underlying basalts dip to west as much as 30°. Beds from which vertebrate remains were removed consist of varying sequence of light-colored clays, volcanic ash, sandstones, and fine conglomerates; no fossils found in upper 370 feet of beds although they are lithologically similar to fossil-bearing beds. Lower Miocene.

Type section: Near center sec. 8, T. 11 S., R. 6 W., Beaverhead County. Map by the Forest Service, 1947, shows creek as Dry Blacktail Creek. Beds are exposed in west flank of gentle anticline and crop out one-half mile west of West Fork Road, at a point one-half mile southwest of junction of East Fork and West Fork Roads which follow upper tributaries of Blacktail Creek. This is locality described by Douglass.

†Blackwater Formation[1]

Pennsylvanian: Northeastern West Virginia and western Maryland.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

On Blackwater River below Davis, W. Va.

Blackwater Shale and Limestone[1] (in Kanawha Group)

Pennsylvanian: Northeastern West Virginia.

Original reference: D. B. Reger, 1923, West Virginia Geol. Survey Rept. Tucker County, p. 198, 209–210.

J. C. Ludlum, 1958, West Virginia Geol. Survey State Park Ser. Bull. 6, p. 23. Thickness 32 feet. Overlies Lower Gilbert sandstone; underlies Winifrede limestone horizon. Kanawha group. Pottsville series.

Named for exposures on north side of Blackwater River, 2 miles southwest of Davis and one-half mile below Blackwater Falls, Tucker County.

Blackwater Creek Shale (in Little Osage Shale Member of Fort Scott Formation)

Backwater Creek Shale Member (of Fort Scott Formation)

Pennsylvanian (Des Moines Series): Northwestern Missouri.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Gray argillaceous shale; locally red. Thickness 19 to 25 feet. Below Higginsville limestone and above Houx limestone. Name appears as Backwater Creek.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 6, fig. 1. Shale at top of Little Osage member of Fort Scott formation. A channel-type sandstone, herein named Flint Hill, occurs above the Blackwater Creek from northern Boone County into southeastern Grundy County.

Type locality and derivation of name not given. First noted in Jackson and Cass Counties.

†Bladen Formation[1]

Bladen Member (of Black Creek Formation)

Upper Cretaceous: Coastal Plain of North Carolina and South Carolina.

Original reference: L. W. Stephenson, 1907, Johns Hopkins Univ. Circ. 71, p. 93–99.

S. D. Heron, Jr., 1958, South Carolina Div. Geology Bull., v. 2, nos. 11–12, p. 85, chart 1. Stephenson's (1907) term Bladen is here applied to lower member of Black Creek formation.

S. D. Heron, Jr., and W. H. Wheeler, 1959, Geol. Soc. America, Southeastern Sec. Guidebook for Coastal Plain Field Trip, p. 5–6, 19. Consists of alternating thin beds of clay and sand, masses of relatively pure loose sand, lignitized wood, and marcasite in basal portion followed by medium to coarse sand and clayey sand; more than 50 percent of member is sand. Thickness about 16 feet. Outcrop relations of Cape Fear, Middendorf, and Bladen units are open to several interpretations; view that Middendorf represents an updip part of the Bladen seems preferable. Bladen rests on the Cape Fear in downdip exposures, and Middendorf rests on the Cape Fear in updip exposures in Fort Bragg.

Named for exposures in Bladen County, N.C., especially along Cape Fear River.

Blaine Gypsum or **Formation**[1] (in Nippewalla, El Reno, or Pease River Group)

Blaine Gypsum (in Double Mountain Group)

Permian: Western Oklahoma, southern Kansas, and northern Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 47.

Noel Evans, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4, p. 405–432. Formation includes Medicine Lodge, Shimer, Lovedale (new), and Haskew (new) gypsum members.

D. A. Green, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1468–1469. In central and west-central Oklahoma, includes (ascending) Medicine Lodge, Alabaster (new), Shimer, Lovedale, and Haskew members. Thickness about 125 feet.

N. H. Darton, L. W. Stephenson, and Julia Gardner, 1937, Geologic map of Texas (1:500,000): U.S. Geol. Survey. Mapped in Double Mountain group.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1764 (fig. 3), 1766, 1793–1799. In Kansas, included in Salt Fork division of Cimarron series. Includes (ascending) Medicine Lodge, Nescatunga (new), Shimer, and Haskew gypsum members. Overlies Flowerpot shale; underlies Dog Creek shales.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 3). Included in El Reno (San Andres) group in Texas.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Included in El Reno group in Texas; Double Mountain group abandoned.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 158, 161 (fig. 4). In Kansas, included in Nippewalla group. Comprises (ascending) Medicine Lodge, Nescatunga, Shimer, and Haskew gypsum members. Thickness about 50 feet. Underlies Dog Creek shale; overlies Flowerpot shale.

Robert Roth, 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 893–907. Included in Pease River group in Texas.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 16–28, pl. 1. In Carter area, redefined to include all strata, characterized by thick gypsum beds, that lie between Flowerpot shale below and Dog Creek shale above. Comprises (ascending) Haystack gypsum, Cedartop gypsum, Collingsworth gypsum, Mangum dolomite, and Van Vacter gypsum (new) members. Three intervening shale beds are unnamed. The thin Chaney and Kiser gypsums are excluded from the Blaine and placed in underlying Flowerpot shale. Thickness 130 to 140 feet. El Reno group.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 24 (fig. 16), 27–34, pl. 1. Described in Harper County where it consists of four gypsum members interbedded with red shales and some dolomite, which lie above the Flowerpot shale and below the Dog Creek. Named members are (ascending) Medicine Lodge, Nescatunga, Shimer, and Haskew. Thickness about 90 feet. El Reno group. Guadalupian.

Type locality: In Salt Creek (Henquenet's) Canyon, northern Blaine County, Okla.

Blair Formation (in Mesaverde Group)[1]

Upper Cretaceous: Southwestern Wyoming and northeastern Utah.

Original reference: A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

W. R. Hansen and M. G. Bonilla, 1954, Colorado Sci. Soc. Proc., v. 17, no. 1, p. 4 (fig. 1), 9–10. Geographically extended into Daggett County, Utah, where it is about 360 feet thick in Flaming Gorge area; underlies Rock Springs formation, and overlies Hilliard shale. Toward the east, intertongues with upper part of Hilliard shale, and at east end of Antelope Flat is entirely replaced by the Hilliard.

Named for exposures at Blair Ranch, east of Aspen Mountain, Sweetwater County, Wyo.

Blakeley Formation[1]

Blakeley Stage

Oligocene: Western and southwestern Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 15, p. 10–22.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 114–115. Type section of the Blakeley comprises sandstones, shales, and conglomerates, exposed in sea cliffs along entrance to Bremerton Inlet, an arm of Puget Sound. Lowermost beds occur at Orchard Point and consist of conglomerates; uppermost strata are also composed of conglomerates cropping out at north entrance of Blakeley Harbor on southern portion of Bainbridge Island. Fossiliferous horizon within formation from which bulk of fauna of the Blakeley have been obtained, occurs at Restoration Point about one-third the thickness of the formation downward from the top. Term Blakeley was applied by Weaver (1912) to section consisting of about 8,000 feet of shales, sandstones, and conglomerates at Restoration Point. At the time that report was written, the writer [Weaver] had in mind the entire sequence of beds between Port Blakeley and Orchard Point, but as result of incomplete statement referred only to Restoration Point. Formation has thickness of 8,900 feet including about 1,800 feet of conglomerate at base and 1,300 feet of conglomerate at top. Between are 4,800 feet of massive and stratified sandy shales, and thick members of interstratified conglomerate. It is possible lower Orchard Point conglomerate (new) may belong to middle Oligocene, and represent equivalent of Lyre formation (new).

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, chart 11. Shown on correlation chart as stage and formation.

J. W. Durham, 1944, California Univ. Dept. Geol. Sci. Bull., v. 27, no. 5, p. 113. Faunal studies indicate upper part of Twin River formation is younger than fossiliferous type Blakeley formation.

C. V. Fulmer, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1340–1341. Weaver (1912) applied name Blakeley formation to Bainbridge Island section consisting of approximately 8,000 feet of conglomerates, sandstones, siltstones, and shales. Later, Weaver included in Blakeley a basal conglomeratic unit exposed at Orchard Point. Strata consisting of type Blakeley, as recognized by Weaver, can be grouped into three units. Lowermost 845 feet consists of well-bedded, hard, marine, gray sandstones, and massive conglomerates, the Orchard Point member. Middle unit consists of about 4,000 feet of marine hard massive gray-tan siltstone interbedded with thin hard fine-grained sandstone; soft limonitic-stained sandstone largely covered with beach gravels; and massive dark-gray silty shale. This unit is Restoration Point member and contains the typical Blakeley molluscan faunule. Upper unit consists of about 4,650 feet of massive nonmarine conglomerates interbedded with thin gray sandstones, and soft carbonaceous shale. Recommended that Blakeley be restricted to Orchard Point and Restoration Point members, and that overlying nonmarine conglomeratic interval be referred to a new formation.

R. D. Brown, Jr., and H. D. Gower, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2496–2497. Blakeley formation as used by Weaver is included in redefined Twin River formation.

Type section: Restoration Point, Kitsap County, opposite Seattle, at entrance to Bremerton Navy Yard. Highest strata crop out on north shores of Blakeley Harbor.

Blakely Sandstone[1]

Lower Ordovician: Southwestern Arkansas and southeastern Oklahoma.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 676.

W. D. Pitt, 1955, Oklahoma Geol. Survey Circ. 34, p. 23–24. As defined by Miser (1917, U.S. Geol. Survey Bull. 660), lies stratigraphically above Mazarn shale and below Womble shale. In Oklahoma, Honess (1923, Oklahoma Geol. Survey Bull. 32) mentioned two general outcrops of Blakely. One in sec. 16, T. 5 S., R. 23 E., and southwest therefrom, where Honess noticed that the only good exposure is the lower 10 to 15 feet at bottom of cliff on Glover Creek. A series of beds distinct lithologically from Mazarn shale below and Womble siltstone above was noted by present writer [Pitt] near above location. This could be designated as separate formation, but, if it were designated in this way, it is recommended that it not be called Blakely because of findings of current field work in Blakely type area. Other occurrence of Honess' Blakely sandstone is in sec. 25, T. 5 S., R. 23 E., and parts of neighboring sections. Honess noted that "there is some doubt about correlation with the beds to the north" because the "sandstones are not bronze colored." Present writer disagrees with Honess' correlation. Honess' two occurrences of Blakely sandstone are not similar lithologically because the outcrops in the two areas represent two stratigraphic units rather than one stratigraphic unit with several facies. Outcrop that Honess describes as Blakely sandstone consists of one sandstone bed 15 feet thick, which is not at all similar to the 400 feet of interbedded shale and sandstone that Miser describes as Blakely at type locality.

Named for Blakely Mountain, Garland County, Ark.

Blanca Tuff[1]

Miocene: Southern California.

Original reference: W. W. Rand, 1931, Mining in California, v. 27, no. 2, p. 217.

On Santa Cruz Island. Derivation of name not stated.

Blancan Age

Pliocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 12, pl. 1. Provincial time term, based on the local fauna at "Mt. Blanco" and adjoining draws, near "old rock house," north of Crawfish Draw, Crosby

County, Tex. Covers an interval in the upper Pliocene above the Hemphillian age. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence, see under Puercan.]

Blanchester Member (of Waynesville Formation)

Blanchester division (in Richmond Group)[1]

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

Original reference: A. F. Foerste, 1909, Denison Univ. Sci. Lab. Bull. 14, p. 291.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on generalized section of Ohio as uppermost member of Waynesville formation. Overlies Clarksville member; underlies Liberty formation.

Named for Blanchester, Clinton County, Ohio.

Blanco Formation[1]

Pliocene, middle: Texas and Kansas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxxi, pl. 3.

G. L. Evans and G. E. Meade, 1944, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 485–507. Blanco beds consist mainly of well-bedded light-gray calcareous sands and clays with some fresh-water limestones, tuffs, diatomite, and coarse gravels. Thickness 56 to 74 feet. Unconformably underlain by reddish-brown sands and clays of middle Pliocene and overlain by widespread sheet of surface sands of probably eolian origin. Nebraskan age. Pleistocene age assignment based upon Meade's study of faunas. Blanco beds are believed to be lacustrine deposits laid down in broad shallow basins rather than deposits of a large stream valley as was interpreted by earlier writers.

G. L. Evans, 1949, West Texas Geol. Soc. Guidebook Field Trip 2, Nov. 6–9, p. 7–8. Unconformably overlies Bridwell formation (new).

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 58–68. In Kansas, as in other areas of the Great Plains, deposits correlated with Blanco formation commonly are coarse textured in lower part and grade upward into finer textured clastics. Although conformable and gradational, these contrasting lithologies merit recognition as named members. In Nebraska, equivalent units are named Holdrege and Fullerton formations; in Kansas, these names are used to designate comparable members of Blanco formation. In central Kansas, Blanco formation was described by Fent (1950) who proposed name Chase Channel formation, containing Holdrege and Fullerton members, for these deposits in Rice County. In this area, formation known primarily from test hole data. South and southeast of Rice County, the Blanco crops out along valleys of Arkansas, Chickaskia, and Ninnescah Rivers in Harper, Kingman, Reno, and Sedgwick Counties. Quantitatively, the Blanco in Kansas has its maximum development in southwestern area where it attains maximum thickness of more than 250 feet. In this area, Smith (1940) described and named Rexroad formation from exposures now classed as Blanco formation. Frye and Hibbard (1941) redescribed these beds as Rexroad member of Ogallala formation. At type locality and west of Channing, Tex., in central Meade County, Kans., and in Rice County, Kans., Blanco beds are overlain by Meade formation (in Texas classed as Tule), including Sappa member with Pearlette volcanic ash bed. At all of these localities, unconformable relationships of Blanco to Pliocene Ogallala formation is clear. Pleistocene (Nebraskan).

Named for Blanco Canyon, Dickens County, and Mount Blanco post office, Crosby County, Tex.

Blanco Sandstone (in Puente Formation)

Miocene, upper: Southern California.

M. L. Krueger, 1943, California Div. Mines Bull. 118, p. 363. Shown on structure section as underlying Cubierto shale (new) and overlying Papel Blanco shale (new).

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 521. Light-colored medium- and coarse-grained sandstone 337 feet thick. Upper part of Puente. Measured section noted.

Exposed in Slaughter Canyon in southeastern Puente Hills, between Chino and the Santa Ana River, San Bernardino County.

Blanco Basin Formation[1]

Oligocene(?): Southwestern Colorado.

Original reference: E. S. Larsen, 1935, U.S. Geol. Survey Bull. 843.

F. B. Van Houton, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 387 (table 1), 388. There is no evidence for assigning Telluride and apparently equivalent Blanco Basin formation an Oligocene(?) age. They are more probably arkosic border facies of upper Paleocene and lower Eocene San Jose (Wasatch formation).

Named for development about Blanco Basin, central part of Summitville quadrangle.

†Blanco Canyon Beds[1]

Pliocene: Panhandle of Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxxi, pl. 3.

Named for Blanco Canyon, Dickens County, and Mount Blanco post office, Crosby County.

†Blan[d]ford Limestone[1]

Precambrian: Western Massachusetts.

Original reference: E. Hitchcock, 1883, Rept. Geol., Min., Bot., and Zool. of Massachusetts, p. 305.

Exposed in northwestern part of town of Blan[d]ford, Hampden County.

Blandford Serpentine and Pyroxenite[1]

Age(?): Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 85.

Blaylock Sandstone[1]

Silurian: Southwestern Arkansas and southeastern Oklahoma.

Original reference: A. H. Purdue, 1909, (abs.) Geol. Soc. America Bull., v. 19, p. 557.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Silurian.

W. D. Pitt, 1956, Ardmore Geol. Soc. Guidebook Ouachita Mountains Field Conf., p. 39. Consists of thin-bedded sandstones and dark shales which weather red or brown. Sandstones are silty, normally greenish gray or brown on fresh fracture. Thickness 670 to slightly over 800 feet. Overlies Polk Creek shale; underlies Missouri Mountain shale.

Named for Blaylock Mountain, Montgomery County, Ark.

Bledsoe Limestone[1]

Silurian (Niagaran): Western and central Tennessee.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 397, 402.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 269–270, fig. 80. In this report, all occurrences of post-Waldron Silurian strata in Central Basin are called Bledsoe limestone. Thickness 18 feet at Bakers Station, 35 feet at Shackle Island, and 80 feet at Bransford. Conformably overlies Waldron shale; unconformably overlain by either Pegram formation or Chattanooga shale.

Named for Bledsoe, Sumner County.

Blind Lake Glaciation or **Drift**

Pleistocene, upper: South-central Utah.

R. F. Flint and C. S. Denny, 1958, U.S. Geol. Survey Bull. 1061-D, p. 117 (fig. 25), 125–126, pl. 6. Drift consists of three small deposits marked at their peripheries by end moraines varying from a few feet to 60 feet in height. Largest mass extends only 1 mile beyond toe of cliff, down to an altitude of 9,900 to 10,200 feet, and includes basins of Blind and Pear Lakes. Second deposit marked by moraine that forms basin of Fish Creek Lake. Third includes small basin of Clark Lake. Pinedale(?) stage.

Type locality: In Fish Creek-Grover drift lobe, on flanks of Boulder Mountain, Wayne and Garfield Counties.

†Bliss Basalt[1] or Volcanics

Pleistocene: Southern Idaho.

Original references: H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932); 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 78–79, pl. 5. Thickness of volcanics about 100 feet. Contemporaneous with McKinney basalt and probably a part of it.

Type locality: Bliss Cone and Bliss Bridge, sec. 11, T. 6 S., R. 12 E., Twin Falls County, also Bliss Spring, Gooding County.

Bliss Sandstone[1]

Bliss Formation

Upper Cambrian and Ordovician: Western Texas and southern New Mexico.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 27.

P. B. King, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 153–156. Type Bliss has hitherto been classed as Cambrian, but paleontological evidence for this is questionable. Type locality may be Ordovician.

H. E. Rothrock, C. H. Johnson, and A. D. Hahn, 1946, New Mexico Bur. Mines Mineral Resources Bull. 21, p. 19–20. In this report, Bliss sandstone in New Mexico is considered to be of Cambrian age because of (1) valid evidence in Silver City area and in Sierra Caballos, (2) presence of thick sandstones of known Cambrian age in southeastern Arizona, and (3) lithologic and stratigraphic similarity between Silver City and Sierra Caballos occurrences and outcrops of basal sandstones called Bliss in Cooks Peak and in Mimbres, Florida, Organ, and San Andres Mountains.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 67–69, 369 [1946]. Age of Bliss sandstone remains unsettled, but evidence seems slightly to favor its tentative consideration as Lower Ordovician.

V. C. Kelley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2200–2213. Sandstone underlies Sierrite limestone (new) of El Paso group. Upper Cambrian.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 31 (table), 33–39. Designated as formation because of diverse lithology. Overlies Precambrian; underlies Sierrite formation of El Paso group. Thickness 110 to 160 feet. Cambrian. Area of report is Caballo Mountains.

R. H. Flower, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 2054–2055. Paleontological evidence indicates that base of Bliss may be as old as middle of Franconia and its top may extend into basal Ordovician.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 14-16. Bliss sandstone in San Andres Mountains considered to be Ordovician in age. At base of Bliss, however, are unfossiliferous beds lithologically similar to those bearing Upper Cambrian fossils in Caballo and San Diego Mountains. Summary discussion of unit.

Named for Fort Bliss, southeastern part of Franklin Mountains, El Paso County, Tex.

Blocher Formation (in New Albany Shale)

Blocher Member (of New Albany Shale)

Middle Devonian: Southeastern Indiana.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 835, 837, 840–842. Thinly laminated black shale that locally contains sandstone lenses ½ to 1 inch thick in basal part. Contains conodont fauna. Commonly 8 to 10 feet thick, but ranges from 2 to 15 feet. Locally includes, at top, an additional bed 1 to 3 feet thick composed of black shale and layers of sandstone. Underlies Blackiston formation (new) with contact disconformable; overlies limestones of Hamilton age; at type locality overlies Swanville limestone.

H. H. Murray and others, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 43, pl. 1. Indiana Geological Survey uses term Blocher with member rank.

Type section: One and one-half miles southeast of Blocher, Scott County, 1 mile east of Baltimore and Ohio Railroad, on Highway 50.

Block Limestone[1] Member (of Cherryvale Formation)

Block Limestone Member (of Sarpy Formation)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., Guide Book, p. 85, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 94–95. Member of Cherryvale; underlies Wea shale member; overlies Fontana shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma with proviso that some differences may be required by regional variation.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 38. In Nebraska, basal member of Sarpy formation (new). Underlies Wea shale member of Sarpy; overlies Fontana formation; thickness one-third to two-thirds foot. Thickness in Iowa 4 feet. Type locality stated.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Gray limestone nodules enclosed in gray shale matrix. Thickness one-half foot. Member of Cherryvale; underlies Wea shale member; overlies Fontana shale member.

Type locality: Roadcuts near center south line sec. 6, T. 18 S., R. 24 E., and center west line sec. 18, T. 19 S., R. 23 E., Miami County, Kans. Named for hamlet of Block, Miami County.

Blockhouse Shale

Middle Ordovician: Eastern Tennessee.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145, 148–154, table 3, pl. 28. Dark-gray calcareous shale with thin beds and lenses of dark-gray dense limestone forms main body of unit 150 to 950 feet thick. In southwestern part of Tellico-Sevier belt, these fine-grained rocks are partly replaced by fine- to coarse-grained Toqua sandstone member (new) which underlies unnamed shale member. Thin argillaceous limestone forms basal member, and term Whitesburg limestone member is applied to it. Overlies Lenoir limestone; underlies Tellico formation. Blockhouse shale as defined in this report was included by Keith (1895, U.S. Geol. Survey Geol. Atlas, Folio 16) and Rodgers (1953) in lower part of Athens shale.

Type section: Base of section 800 feet southwest of bench mark F132Y (elevation 972 feet) extending southeastward up a gullied hillside, Blockhouse quadrangle, Blount County.

Bloody Run zone[1]

Upper Devonian: North-central Iowa.

Original reference: C. L. Fenton and C. L. Webster, 1924, Univ. Michigan Pub., Contr. Mus. Geol., v. 1, frontispiece, map.

Bloomfield Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: W. Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 242.

M. T. Sturgeon and others 1958, Ohio Geol. Survey Bull. 57, p. 120–121. Member of Anderson cyclothem, Conemaugh series. Underlies Anderson clay member; overlies Bakerstown shale and (or) sandstone member.

According to Waagé (1950, Maryland Dept. Geology, Mines and Water Resources Bull. 9) Hennen and Reger (1914) named an equivalent limestone in Preston County, W. Va., the Albright limestone. Thus, Albright has precedence over Bloomfield. Recommended that Albright replace Bloomfield if and when positive correlation is determined.

Named for exposures west of Bloomfield, Muskingum County.

Bloomfield sand[1]

Eocene: Southeastern Missouri.

Original reference: C. R. Keyes, 1894, Missouri Geol. Survey, v. 4, p. 30.

Named for Bloomfield, Stoddard County.

Bloomfield Sandstone (in Cayuga Group)[1]

Silurian: Central Pennsylvania.

Original reference: E. W. Claypole, 1885, Pennsylvania 2d Geol. Survey Rept. F_2, p. 54, 401.

Underlies New Bloomfield, and exposed on road to Newport, one-half mile east of town. Perry County.

Bloomingdale Limestone Member[1] (of Conococheague-Copper Ridge formation)

Upper Cambrian: Eastern Tennessee.

Original reference: C. R. L. Oder, 1934, Jour. Geology, v. 42, no. 4, p. 478–479, 492, 496.

C. E. Resser, 1938, Geol. Soc. America Spec. Paper 15, p. 3, 18. Abandoned. Morristown and Bloomingdale limestone members (Oder, 1934) are parts of the Copper Ridge or Conococheague; use of these terms does not seem warranted.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 33. It is now thought that most of strata placed in Bloomingdale by Oder belong in lower part of Chepultepec dolomite as now recognized.

Type section: Along a branch of Reedy Creek 1½ miles northwest of Bloomingdale 4 miles northeast of Kingsport, Sullivan County.

Bloomington Drift, Substage

Pleistocene (Wisconsin): Northern Illinois.

H. B. Willman and others, 1942, Illinois Geol. Survey Bull. 66, p. 145 (fig. 85), 146 (fig. 86), 158–159. Consists largely of pink till, locally underlain by outwash gravel of advancing glacier and overlain by outwash gravel of retreating glacier. Maximum thickness about 50 feet. Most commonly overlies earlier Wisconsin deposits, but in large areas rests directly on bedrock, and in some places overlies Sangamon deposits and Illinoian drift; mostly overlain by Cropsey, Farm Ridge, Chatsworth, and Marseilles drifts. [Report lists six drifts in the Tazewell; for sequence see under Shelbyville.]

Leland Horberg, 1951, Illinois Geol. Survey Bull. 75, pt. 1, p. 19. In Peoria area, Bloomington drift is listed as older than Metamora drift and younger than Leroy drift.

J. L. Hough, 1958, Geology of the Great Lakes: Urbana, Univ. Illinois Press, p. 94. Listed as glacial substage (late Tazewell).

Named for Bloomington, McLean County. Widely distributed throughout Marseilles-Ottawa-Streater area.

Bloomington Formation[1]

Middle Cambrian: Southeastern Idaho and northeastern Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 6, 7.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1110–1112, 1117 (fig. 4), 1121–1122. Described in Blacksmith Fork area, Utah, where it is 1,275 feet thick; Hodges member about 163 feet thick. Overlies Blacksmith dolomite (emended); underlies Nounan dolomite.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 651–653, 672, 673 (fig. 3). Consists of basal tawny-olive shale and interbedded thin layers of light- to dark-gray limestone (Hodges shale member), overlain by middle unit of thinly to thickly bedded, light- to dark-gray limestone about 720 feet thick, overlain by an upper tawny-olive shale unit with some interbedded platy limestone, the Calls Fort member (new). Total thickness 1,495 feet. Overlies Blacksmith dolomite; underlies Nounan formation.

Type locality: About 6 miles west of Bloomington, Bear Lake County, Idaho. Bloomington Creek, near type locality, passes through formation. Crops out throughout southeastern Idaho and northeastern Utah as far south as northern margin of Great Salt Lake and Brigham City. Recognized in Lakeside Range, on west margin of Great Salt Lake.

Bloomsburg Redbeds (in Cayuga Group)[1]

Bloomsburg Formation (in Cayuga Group)

Upper Silurian: Central and southern Pennsylvania, western Maryland, western Virginia, and northern West Virginia.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. G_7, p. 252.

C. K. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1184, measured section. Red sandstone and shale. Thicknesses: about 2,000 feet at Lehigh Gap; 1,815 feet southwest of New Ringgold; and 1,900 feet near Delaware Water Gap. Underlies and intertongues with Poxono Island shale; overlies [southeastern Pennsylvania] Clinton shale and Tuscarora sandstone at Schuylkill River and Shawangunk conglomerate at Delaware River.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 149–150. Term Bloomsburg facies applied to red phase of Cayugan series. This term replaces units previously called Bloomsburg "shale" or Bloomsburg "sandstone." Green or brown sandstone of western Silurian belt cannot properly be called "Bloomsburg" as it is not the true facies to which that name is now restricted. Term Williamsport sandstone is herein revived and redefined to include the green or brown sandstone. Williamsport is basal member of Cayugan group. Identity of Williamsport in eastern Silurian outcrops is obliterated by or absorbed in red nonmarine Bloomsburg facies.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as Niagaran and Cayugan.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 77. Bloomsburg formation in Cayuga group. Has been considered member of Wills Creek in Maryland. Thickness 20 to 200 feet. Underlies Wills Creek shale; overlies McKenzie formation.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 5, 20, 22, 31, pl. 1. Formation, in central Pennsylvania, consists of red fine-grained siltstone with some interbedded sandstone and shale. Lower part of section generally calcareous and commonly contains green interbeds, lenses, and blebs, while upper part is commonly very sandy. In Loysville quadrangle, a lenticular clean white quartzose sandstone (Bridgeport member) occurs in middle of unit. Thickness 1,000 feet at Susquehanna Gap; 500 feet in Loysville area; 200 to 400 feet in west-central part of state. Underlies Wills Creek formation; overlies Mifflin formation (new) in Mifflinton [Mifflintown] area; elsewhere overlies McKenzie formation. Eastward, the Bloomsburg includes more and more of both the McKenzie and the Wills Creek until in eastern Pennsylvania the Bloomsburg occupies a 2,000-foot section.

Named for exposures at Bloomsburg, Columbia County, Pa.

Bloomsdale Formation (in Plattin Group)

Middle Ordovician: Southeastern Missouri.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2046–2048. Named as lowermost formation of group. Dominantly fine-textured well-bedded dolomite, with interbeds of light-gray-weathering oolitic and carbonate pebble-bearing calcilutite; green shale layers common; sparsely fossiliferous. Thickness at type locality 61 feet. Overlies Rock Levee formation; overlapped by Beckett formation (new).

Type section: In bed of stream rising in SW¼NE¼ sec. 15, T. 38 N., R. 8 E., 3½ miles east of Bloomsdale, near Belleville School, Ste. Genevieve County.

Blossburg[1]

Blossburg Red Beds

Upper Devonian: New York and central northern Pennsylvania.

Original reference: G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, no. 2, p. 99, 279, 282, 357.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart shows Blossburg red beds in New York. Above "Mansfield beds." Upper Devonian.

First mentioned in Tioga County, Pa.

Blossom Sand[1]

Blossom Sand (in Austin Group)

Upper Cretaceous (Gulf Series): Northeastern Texas.

Original reference: C. H. Gordon, 1909, Am. Jour. Sci., 4th, v. 27, p. 371, 373.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Shown on correlation chart above Bonham equivalents and below Brownstown marl.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 35, fig. 1. Included in Austin group. Foraminifera described.

Named for Blossom, Lamar County.

†Blount Group[1]

Middle Ordovician: Eastern Tennessee, Alabama, northwestern Georgia, western Virginia, and West Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 379, 382, 413, 567, 576, 627, pl. 27.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 23 (table 1), 147–183. Group comprises (ascending) Holston limestone, Whitesburg limestone, Athens shale, Tellico sandstone, Ottosee limestone—Sevier shale. Nowhere, so far as known, are all formations present in continuous vertical section. Overlies Stones River group; underlies Black River group. Chazyan series.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 819–886. Revised stratigraphic nomenclature proposed for lower Middle Ordovician succession of Tazewell County and other parts of southwestern Virginia. Further use of terms Stones River, Murfreesboro, Mosheim, Lenoir, Blount, Holston, Ottosee, Lowville, and Lowville-Moccasin seems inadvisable. In Tazewell County, part of Ulrich's Blount group (upper Chazy) occurs beneath beds containing fauna of Murfreesboro limestone of Central basin of Tennessee.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 27–29, geol. map. Group in Georgia comprises (ascending) Holston marble, Athens shale, Tellico formation, and Ottosee (Sevier) shale. Overlies Stones River group.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 57. No complete section of Blount group has ever been found; at present the idea that such a unit exists, intermediate between the Chazy and Black River and represented only in southern Appalachians, has been completely discarded.

Named for Blount County, Tenn.

Blounts Creek Member (of Fleming Formation)

Miocene: Central Louisiana.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 118 (fig. 26), 168–170, 174, geol. map. Uppermost member of formation. Consists of group of silty clays and sands; some beds as much as 10 feet thick. Thickness about 500 feet. Overlies Castor Creek member (new); underlies Quaternary deposits.

Well exposed south of Hinestone in northern slopes of Blounts Creek, Rapides Parish.

Blowing Rock Gneiss[1]

Precambrian: Western North Carolina.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 3.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 18; J. L. Stuckey, 1958, Geologic map of North Carolina (1: 500,000): North Carolina Div. Mineral Resources. Consists of two varieties, one containing large porphyritic crystals of orthoclase feldspar embedded in groundmass of quartz, feldspar, biotite, and muscovite, and the other consisting of the same minerals in grains of uniform size. Precambrian (?)

Named for Blowing Rock in Cranberry quadrangle, Watauga County.

†Blowout Mountain Sandstone (in Double Mountain Group)[1]

Permian: Central northern Texas.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull., v. 1, p. 95, 96, 98, pl.

Named for exposure in Blowout Mountain, southwest of Merkel, Taylor County.

Bloyd Shale[1] or Formation

Lower Pennsylvanian (Morrow Series): Northwestern Arkansas and eastern Oklahoma.

Original reference: A. H. Purdue, 1907, U.S. Geol. Survey Geol. Atlas, Folio 154.

C. A. Moore, 1947, Oklahoma Geol. Survey Bull. 66, p. 38–39, strat. sections. Formation geographically extended into northeastern Oklahoma, where it contains representatives of both the Brentwood and Kessler limestone lentils as recognized in Washington County, Ark. Thickness 191 feet at Arkansas-Oklahoma line; thins westward.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1942–1945, 1948 (fig. 2). Shale consists of (ascending) Brentwood limestone member, Woolsey member (new) composed of terrestrial sediments, and an unnamed shale division, which includes Kessler limestone lentil and which represents the upper half to two-thirds of formation. Overlies Prairie Grove member (new) of Hale formation; underlies Greenland sandstone member (new) of Atoka formation.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 80–82, strat. sections, pls. 4, 5. Formation described and mapped on south and west flanks of Ozark uplift. Traced around various outliers and fault blocks from Arkansas line westward to Arkansas River valley, northward to Mayes-Wagoner County line, where it is beveled by pre-Atoka erosion. A sequence of alternating shales and limestones; thin coal bed. Maximum thickness 225 feet in Stilwell area; 58 feet at Braggs Mountain. Conformable and gradational with underlying Hale; unconformable with overlying Atoka.

Named from Bloyd Mountain, 9 miles southwest of Fayetteville, Washington County, Ark.

†Blue chert series[1]

Devonian(?): Northwestern California.

Original reference: O. H. Hershey, 1906, Am. Jour. Sci., 4th, v. 21, p. 58–66.

Klamath Mountains. Named for its most characteristic constituent, blue chert.

Blue conglomerate (in Conococheague Formation)

Upper Cambrian: Central Pennsylvania.

Carlyle Gray and D. M. Lapham, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 149 (fig. 3), 150. Local name applied to conglomerate in lower part of Conococheague in Cornwall district.

Blue Ball Fire Clay (in Allegheny Formation)[1]

Pennsylvanian: Central Pennsylvania.

Original reference: H. M. Chance, 1884, Pennsylvania 2d Geol. Survey Rept. H_7.

In Clearfield County.

Blue Beach Conglomerate

Cretaceous: Virgin Islands.

P. T. Cleve, 1871, Kongl Svenska Vetenscaps Akad. Handlengar, v. 9, no. 12, p. 4–5. Dark-bluish-green conglomerate on breccia. Thickness as much as 2,000 meters. Cretaceous.

R. W. Imlay, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 1007. Similar to Mount Eagle series on St. Croix.

D. J. Cederstrom, 1950, U.S. Geol. Survey Water-Supply Paper 1067, p. 17. Term "blue beach" was originally used by Cleve (1871) to apply to conglomerate or breccia having angular pieces of dark porphyry or felsite and rounded scoriaceous stones cemented together by greenish matrix, probably derived from decomposed hornblende, which is widely distributed in St. Thomas. Term has since been used loosely and is now used by natives of St. Croix to apply to all older dark indurated rocks of the island.

Exposed on St. Thomas Island.

Bluebell Dolomite[1]

Upper Ordovician, Silurian, and Devonian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

Paul Billingsley *in* J. M. Boutwell, 1933, 16th Internat. Geol. Cong. [United States] Guidebook 17, Excursion C–1, p. 110 (fig. 14). Subdivided into (ascending) Eagle, Beecher, Dora, and Noah members.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 11 (fig. 3), 12, pl. 4. Described in Tintic mining district, where it is 350 to 600 feet thick. Separated into two members of nearly equal thickness by bed of crinkly-laminated medium- and light-gray dolomite about 10 feet thick. Lower member chiefly light- to medium-gray-weathering, thin- to medium-bedded, medium- to fine-banded dolomite; upper member principally medium- to dark-gray, medium- to thick-bedded, medium- to coarse-grained dolomite. Overlies Fish Haven dolomite; underlies Victoria formation. Includes beds that contain fossils of Late Ordovician, Silurian, and Devonian age, but systemic boundaries within formation cannot be recognized by lithologic differences.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 143–144. Because of loose manner in which name Bluebell (or Blue Bell) has been used stratigraphically and because field names Eagle, Beecher, Dora, and Noah dolomites are inappropriate as formal stratigraphic names, it is proposed that name Bluebell (or Blue Bell) be suppressed and that well-defined and time-rock established names as Fish Haven, Laketown, Sevy, and Simonson be applied in area of this report [Fivemile Pass and North Boulter Mountains quadrangles].

Named for Bluebell mine near Eureka, Tintic district.

Blueberry Mountain Argillite[1]

Lower(?) Devonian: Northwestern New Hampshire.

Original reference: C. H. Hitchcock, 1905, Geology of Littleton, N.H., Univ. Press, Cambridge.

Blueberry Mountain is northern part of ridge 2 miles west of Littleton, Grafton County.

Blueberry Mountain Series[1]

Silurian and Devonian: Northwestern New Hampshire.

Original reference: F. H. Lahee, 1913, Am. Jour. Sci., 4th, v. 36, p. 231–250.

Blueberry Mountain is northern part of ridge 2 miles west of Littleton, Grafton County.

†Bluebird Aplite[1]

Eocene: Montana.

Original references: W. H. Weed, 1899, Jour. Geology, v. 7, p. 744–747; 1903, U.S. Geol. Survey Bull. 213, p. 170.

In Butte district.

Bluebird Dolomite[1]

Middle Cambrian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 5 (fig. 2), 7–8. Described in East Tintic Mountains, where it is 150 to 220 feet thick, overlies Herkimer limestone, and underlies Cole Canyon dolomite. Consists of dusky blue-gray medium-grained dolomite studded with short white dolomite rods a centimeter or so long and 1 to 2 centimeters in diameter; white rods are straight, slightly curved, or branched and resemble minute twigs. Middle Cambrian.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 19, 20–21. In Stansbury Mountains, consists of dark-gray medium-crystalline dolomite, 75 to 80 feet thick, at base of Cole Canyon formation; overlies Bowman limestone.

Well exposed along backbone of Bluebird Spur for nearly 1,000 feet, north of Eureka Gulch and west of Cole Canyon, Tintic district.

Bluebonnet Member (of Lake Waco Formation)

Cretaceous (Gulf Series): Central Texas.

W. S. Adkins and F. E. Lozo *in* F. E. Lozo, 1951, Fondren Sci. Ser., no. 4, p. 122–123, 139 (fig. 17), 141 (fig. 18). Consists of limestone flagstones interbedded with calcareous shale and bentonites. Thickness 12 to 18 feet. Underlies Cloice member (new); overlies Pepper formation.

Type area and section: Along Bosque Escarpment from old South Bosque brickyard southwest into Moody Hills, then southward past Moody, McLennan County; type section is opposite Baggetts Station, on east side of McGregor-Moody Road (State Highway 17), about 4½ miles south-southeast of McGregor.

†Blue Canyon Formation[1]

Mississippian: Northern California.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey Geol. Atlas, Folio 66.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 15). Shown on Mississippian correlation chart as underlying Tightner formation in Colfax area.

Named for exposures at village of Blue Canyon, Placer County.

Bluecastle Sandstone Member (of Neslen Formation)

Bluecastle Sandstone Member (of Price River Formation)

Bluecastle Sandstone Bed (in Price River Formation)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: D. J. Fisher, 1936, U.S. Geol. Survey Bull. 852.

D. J. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 11, 14, 17, pls. 10, 11, 12. In western Book Cliffs

(Utah, west of Green River), the Bluecastle is a member at top of Price River formation; in central Book Cliffs (Utah, east of Green River) it is a member in upper part of Neslen formation.

Named for Bluecastle Canyon, Book Cliffs.

Blue Creek Coal Member (of Mansfield Formation)

Pennsylvanian: South-central Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 25, 72. Important marker bed in upper part of Mansfield in Huron area. Thickness 4⅔ feet at type section. Lies approximately 100 feet above base of upper Mansfield in a sequence of sandstones with wavy bedding.

Type section: SW¼NW¼ sec. 10, T. 1 N., R. 3 W., in abanoned strip mine at west end of ridge, Martin County. Named for exposures at headwaters of Blue Creek.

Blue Creek series[1]

Cambrian: Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135, 138–140.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 99. Abandoned by Oklahoma Geological Survey. Unit is Reagan sandstone and lower sandy part of the Honey Creek formation. No series concept is warranted.

Named for Blue Creek, Comanche County.

Blue Creek Canyon Group

Cambrian: Oklahoma.

W. E. Ham, 1949, Oklahoma Geol. Survey Circ. 26, p. 19. Name used to include (ascending) Fort Sill limestone, Royer dolomite, Signal Mountain limestone, and Butterly dolomite. Overlies Timbered Hills group. Name credited to E. A. Frederickson (unpub. thesis).

Derivation of name not stated.

Blue Cut Shale[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 361, 380.

Named for Blue cut, a deep railway cut a few miles south-southwest of Belvidere, Kiowa County.

Blue Earth Siltstone[1]

Ordovician: Southern Minnesota.

Original reference: L. H. Powell, 1935, St. Paul Inst. Sci. Mus., Sci. Bull. 1.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 50 (fig. 13), 54–55. Bed of white to greenish very fine grained silty shale commonly referred to as siltstone. Seldom more than 2 feet thick; 6 inches in section in quarry on Minnesota River, Le Sueur County. Underlies Oneota dolomite; overlies Kasota sandstone, but, where that is lacking, is in direct contact with Jordan sandstone.

Named for exposures along Blue Earth River, near Mankato.

Bluefield Shale[1] or Formation

Bluefield Group

Upper Mississippian: Southern West Virginia, eastern Kentucky, and southwestern Virginia.

Original reference: M. R. Campbell, 1896, U.S. Geol. Survey Geol. Atlas, Folio 26, p. 3.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 255, 262–265. Bluefield group is largest subdivision of Mauch Chunk series in county. Thickness 900 to 1,200 feet. Includes (ascending): Lillydale shale, Webster Springs sandstone, Reynolds limestone, and Droop sandstone members. Overlies Greenbrier; underlies Hinton group.

R. H. Wilpolt and D. W. Marden, 1959, U.S. Geol. Survey Bull. 1072–K, p. 596–597, 598 (fig. 26), geol. section, pls. 28, 29. Referred to as formation because of heterogeneous character of rocks. Thickness 118 to 449 feet. Overlies Greenbrier limestone; underlies Stony Gap sandstone member of Hinton formation. Geographically extended into Kentucky where it is 191 feet thick on Pine Mountain near Whitesburg. Probably early Chester age.

Named for exposures at Bluefield, Mercer County, W. Va.

†Blue Gate Sandstone Member (of Mancos Shale)[1]

Upper Cretaceous: Central southern Utah.

Original reference: G. K. Gilbert, 1877, Geology of the Henry Mountains: U.S. Geog. and Geol. Survey of the Rocky Mountain region, p. 4 [2d ed. 1880].

C. R. Longwell and others, 1923, U.S. Geol. Survey Prof. Paper 132–A, p. 3–4 (table), 15, 21–22. Discussion of rock formations in Colorado Plateau of Utah and Arizona. To rocks above Dakota(?) sandstone in Henry Mountains, Gilbert (1877) applied the local names (ascending) Tununk shale, Tununk sandstone, Blue Gate shale, Blue Gate sandstone, Masuk shale, and Masuk sandstone. Only Gilbert's names for the sandstones have been adopted by U.S. Geological Survey, and in present report his names for the shales are used in quotation marks because of doubt regarding relations of this whole succession of sandstone and shale to named units to north and east. R. C. Moore tentatively correlates "Tununk shale," "Tununk sandstone," and "Blue Gate shale" with Mancos shale of southwestern Colorado and east-central Utah; Blue Gate sandstone he tentatively correlates with Mesaverde formation; "Masuk shale," with the Lewis shale; and Masuk sandstone, with so-called Laramie sandstone of southwestern Colorado. Some geologists, however, believe entire succession corresponds to Mancos shale. Blue Gate sandstone consists of yellow to brown irregularly bedded medium to massive sandstone. Thickness 230 to 1,000 feet.

H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164, p. 108. In Kaiparowits region, Blue Gate sandstone is uppermost member of Mancos. Thickness 276 feet on east side of Circle Cliffs, Garfield County. Overlies "Blue Gate shale" of Gilbert.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 84. Emery sandstone member extended into Henry Mountains; replaces Blue Gate sandstone as used by Gilbert.

Probably named for occurrence on Blue Gate Plateau, Henry Mountains.

Blue Gate Shale Member (of Mancos Shale)

†Blue Gate Shale (in Mancos Shale)[1]

Upper Cretaceous: Central southern Utah.

Original reference: G. K. Gilbert, 1877, Geology of the Henry Mountains: U.S. Geog. and Geol. Survey of the Rocky Mountain region, p. 4 [2d ed. 1880].

C. R. Longwell and others, 1923, U.S. Geol. Survey Prof. Paper 132–A, p. 3–4 (table), 15, 21–22. Discussion of rock formations in Colorado Plateau of Utah and Arizona. To rocks above Dakota(?) sandstone in Henry Mountains, Gilbert (1877) applied the local names (ascending) Tununk shale, Tununk sandstone, Blue Gate shale, Blue Gate sandstone, Masuk shale, and Masuk sandstone. Only Gilbert's names for the sandstones have been adopted by U.S. Geological Survey, and in present report his names for the shales are used in quotation marks because of doubt regarding relations of this whole succession of sandstone and shale to named units to north and east. R. C. Moore tentatively correlates "Tununk shale," "Tununk sandstone," and "Blue Gate shale" with Mancos shale of southwestern Colorado and east-central Utah; Blue Gate sandstone he tentatively correlates with Mesaverde formation; "Masuk shale" with the Lewis shale; and Masuk sandstone, with so-called Laramie sandstone of southwestern Colorado. Some geologists, however, believe entire succession corresponds to Mancos shale. Thickness of "Blue Gate shale" 1,100 to 1,200 feet.

H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164, p. 108. In Kaiparowits region, "Blue Gate shale" of Gilbert overlies Tununk sandstone member of Mancos shale and underlies Blue Gate sandstone member of Mancos. Thickness 1,100 feet on east side of Circle Cliffs, Garfield County.

C. B. Hunt and R. L. Miller, 1946, Utah Geol. Soc. Guidebook 1, p. 8 (table). Generalized section of exposed sedimentary rocks in Henry Mountains structural basin shows Blue Gate shale member of Mancos shale above Ferron sandstone member and below Emery sandstone member. Thickness 1,500 feet.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 37, 83–84, pl. 1. Composed almost wholly of dark-gray finely laminated marine shale. Shale includes some very thin beds of bentonite, shaly sandstone, and sandy or shaly limestone. Thickness about 1,400 feet. Overlies Ferron sandstone member; underlies Emery sandstone member. Ferron sandstone replaces Gilbert's (1877) Tununk sandstone and Emery sandstone replaces Gilbert's, (1877) Bluegate [Blue Gate] sandstone.

In Blue Gate Plateau, Henry Mountains region.

Blue Grass Group[1]

Middle Ordovician: Central Kentucky.

Original reference: S. S. Lyon, 1873, Ohio Geol. Survey, v. 1, pt. 1, p. 119–120.

Named for Blue grass region about Lexington.

Blue Hill Granite Porphyry[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. O. Crosby, 1880, Boston Soc. Nat. History Occ. Papers 3, with map.

W. H. Dennen, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 550, 551. Referred to as Blue Hills porphyry.

Occurs on higher hills of Blue Hills Range.

Blue Hill Shale Member (of Carlile Shale)[1]

Upper Cretaceous: Western Kansas and southeastern Colorado.

Original reference: W. N. Logan, 1897, Kansas Univ. Geol. Survey, v. 2, p. 218, 225, 228, 229.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 24. Clayey gray-black to dark-gray noncalcareous shale; abundant ordinary and septarian concretions and selenite crystals. Contains Codell sandstone zone in upper part. Thickness 75 feet in Hamilton County to 200 feet in Russell County. Overlies Fairport chalky shale member; underlies Fort Hayes limestone member of Niobrara formation.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 121. In Baca County, Colo., member constitutes more than half the formation and consists of dark-gray to black fissile clay shale having a few thin layers of brown platy shale; zone of gray to light-brown septarian concretions about 15 to 20 feet below top of shale. Underlies Codell sandstone member.

Apparently named Blue Hills in Mitchell, Russell, and Republic Counties, Kans.

†Blue Hills Complex[1]

Cambrian and later and older?: Eastern Massachusetts.

Original reference: W. O. Crosby, 1900, Boston Soc. Nat. History Occ. Papers, v. 1, pt. 3.

Includes the Blue Hills proper and extends thence eastward across Quincy and northern parts of Braintree and Weymouth, Suffolk County.

Bluejacket cyclothem

See **Bluejacket Sandstone Member** (of Boggy Shale or Formation).

Bluejacket Sandstone Member (of Boggy Shale or Formation)[1]

Bluejacket Sandstone Member (of Krebs Formation)

Bluejacket Formation (in Cherokee Group or Krebs Group)

Bluejacket Sandstone Member (of Cherokee Shale)

Pennsylvanian (Des Moines Series) : Northeastern Oklahoma, southeastern Kansas, and southwestern Missouri.

Original reference: A. W. McCoy, 1921, Am. Assoc. Petroleum Geologists Bull., v. 5, no. 5, p. 541-550.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 21-22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193. Cherokee group divided into 15 cyclic formational units. Bluejacket formation (cyclothem), fourth in sequence (ascending), overlies the Columbus and underlies the Knifeton. Average thickness 68 feet. Includes Bluejacket sandstone at base. [For complete sequence see Cherokee group.]

W. G. Pierce and W. H. Courtier, 1938, Kansas Geol. Survey Bull. 24, p. 27-30, pl. 1. Bluejacket sandstone has been mapped northward from type locality to Oklahoma-Kansas line. Although Bluejacket cannot be traced with certainty as continuous unit in Kansas, name is applied to prominent sandstone exposed just east and south of Columbus, and that caps the Timbered Hills 2 miles southwest of Columbus. Base of Bluejacket as shown on plate 1 represents base of fairly thick sandstone unit. It was not mapped northeastward beyond sec. 33, T. 32 S., R. 24 E., about 4 miles northeast of Columbus. In places the sandstone is underlain by Rowe coal bed. Term Columbus sandstone was proposed by Haworth and Kirk (1894) for the sandstone exposed southeast of Columbus but was defined rather loosely and would probably include both Little Cabin and Bluejacket sandstone members. Thickness between 20 and 50 feet. Base is 50 to 100 feet below Weir-Pittsburg coal.

W. B. Howe, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2087-2091. Type section revised. As originally defined by Ohern (1914, unpub. ms.), type section of formation includes several sandstone beds, some of which are similar to the Bluejacket, and actual unit called Bluejacket is not clearly differentiated. Trace of base of Bluejacket sandstone, as shown on Ohern's unpublished map and on Geologic map of Oklahoma (1926) in vicinity of Bluejacket, Vinita, and Whiteoak, delineates base of sandstone that occurs 30 to 35 feet below the Bluejacket, as here restricted, in type section. Lower sandstone grades into shale southward, and south of Craig County the Bluejacket line on the "Geologic map of Oklahoma" consistently marks base of Bluejacket sandstone as restricted in this paper. Same conditions obtain northward, and Bluejacket sandstone, restricted, is continuous with Columbus sandstone of Haworth and Crane (1898, Kansas Univ. Geol. Survey, v. 3) as mapped by Pierce and Courtier (1937, Kansas Geol. Survey Bull. 28 [1938, Kansas Geol. Survey Bull. 24]). Bed which apparently should be regarded as Bluejacket sandstone is a well-defined lithologic and mappable unit typically exposed in NE¼NE¼ sec. 25, T. 27 N., R. 20 E., along road from Bluejacket west to Pyramid Corners, in east slope of Timbered Hill, on Oklahoma Highway 25, in Craig County. In Oklahoma, Bluejacket sandstone is member of Cherokee formation and lies above Little Cabin sandstone member and below Broken Arrow coal member; in Kansas, Bluejacket is formation in Cherokee group and lies between Rowe coal below and Weir-Pittsburg coal above.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic column as Bluejacket formation in Krebs group. Overlies Drywood formation; underlies Seville formation.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as sandstone member of Boggy formation.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 39–43, measured sections. Formation includes beds directly above Dry Wood coal and extending to top of Bluejacket coal. Succession includes Bluejacket sandstone (Ohern, 1914; Howe, 1951) from which formation takes its name. Overlies Dry Wood formation; underlies Seville formation. Krebs subgroup of Cherokee group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as Bluejacket sandstone in Krebs formation.

Type locality: NE¼NE¼ sec. 25, T. 27 N., R. 20 E., along road from Bluejacket west to Pyramid Corners, on east slope of Timbered Hill, Craig County. Okla.

Bluelick Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 114.

In Castleman Basin.

Blue Mountain Gravel

Quaternary: Northwestern Arizona.

Donaldson Koons, 1948, Plateau, v. 20, no. 4, p. 54 (fig. 1), 58. Bedded deposits of well-rounded pebbles and cobbles of granite, gneiss, schist, and red and white quartzite, up to 20 inches in the long diameter. Deposits generally deeply weathered. Maximum measured thickness 150 feet, but generally somewhat thinner. Found at elevations ranging from 5,775 feet near Blue Mountain to 7,125 feet near the Pinnacle.

Erich Blissenbach, 1952, Plateau, v. 24, no. 4, p. 121. Underlies Blue Mountain lavas and volcanics.

Named after Blue Mountain, Coconino County, where formation is well exposed.

Blue Mountain Lavas, Volcanics

[Pliocene or later]: Northwestern Arizona.

Erich Blissenbach, 1952, Plateau, v. 24, no. 4, p. 121. Mentioned as overlying Blue Mountain gravels.

Exposed at Blue Mountain, Coconino County.

Bluepoint Limestone[1]

Upper Mississippian: Southeastern Nevada.

Original references: C. R. Longwell, 1921, Am. Jour. Sci., 5th, v. 1, p. 46; 1928, U.S. Geol. Survey Bull. 798.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, no. 5, p. 930 (table 1). Chiefly dark-gray limestone. About 500 feet thick. Overlies Rogers Spring limestone; underlies Callville limestone.

Named for town of Bluepoint, Clark County, Muddy Mountains area.

Blue Rapids Shale (in Council Grove Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 22.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 65. Proposed that Bigelow be dropped as stratigraphic term and that Crouse limestone, Blue Rapids shale, and Funston limestone be recognized as formations.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46. Gray, green, and red shale; contains local limestones and locally a coal bed in Geary County. Thickness 15 to 30 feet. Underlies Funston limestone; overlies Crouse limestone. Wolfcamp series.

Type locality: In cuts of Highway 77, about 1½ miles north of Blue Rapids, Marshall County, Kans.

Blue Ridge Conglomerates[1]

Cambrian: Pennsylvania.

Original reference: F. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. H_2, p. xxiv.

Blue Ridge Member (of Crack Canyon Formation)

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert, Abs., v. 16, no. 10, p. 1885. Listed as lower member of formation. Underlies Grizzly Creek (new); overlies Sulfur Creek formation (new). Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

†Blue Ridge Sandstone[1]

Ordovician and Silurian: Northeastern West Virginia, western Maryland, and northern Virginia.

Original reference: A. Keith and H. R. Geiger, 1891, Geol. Soc. America Bull., v. 2, p. 155–164.

†Blue Ridge Shale[1]

Ordovician: Northeastern West Virginia, western Maryland, and northern Virginia.

Original reference: A. Keith and H. R. Geiger, 1891, Geol. Soc. America Bull., v. 2, p. 155–164.

Blue River Group

Mississippian (Chester Series): South-central Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 48–51, pl. 1. Comprises (ascending) St. Louis limestone, Ste. Genevieve limestone, and Paoli limestone (amended). Only upper 70 feet of group exposed in Huron area; well records show group to be about 400 feet thick. Underlies West Baden group.

Well exposed along banks of Blue River which drains parts of Washington, Harrison, and Crawford Counties.

Blue Springs Muscovite Schist or Formation

Precambrian: Central New Mexico.

J. T. Stark and E. C. Dapples, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1936. Underlies White Ridge quartzite (new); overlies Sais quartzite (new); intruded by Los Pinos granite (new).

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1, p. 1130–1133, pl. 1. Massive and brittle beds of red and gray slates and siltstones characterize basal parts of Blue Springs schist. Central parts largely green, sericitic schists in which some zones are predominently contorted and crenulated. Schistose beds intercalated with more massive slates and arenaceous siltstones. Many beds spotted with biotite and blebs of granulated white quartz. Near top of formation are beds of dense red and gray arenaceous slates, which become increasingly schistose as overlying White Ridge quartzite is approached. Thickness ranges from about 300 feet, between Abo Pass and Highway 60, to nearly 4,000 feet in vicinity of Sierra Montosa.

Named for exposures at Blue Springs, a large seepage area where water issues from Blue Springs schist, north of Highway 60 at western flank of Los Pinos Mountains.

Blue Springs Shale Member (of Matfield Shale)

Blue Springs Shale (in Chase Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 38.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 45. Middle member of Matfield. Shale, chiefly red and gray, and relatively minor amount of limestone, except in southern Kansas where several limestone beds occur in upper part of member; farther north, member is less calcareous and limestone is absent; fossils occur in thin limestones and in gray shale beds in southern part of outcrop area. Thickness about 30 feet. Overlies Kinney limestone member; underlies Florence limestone member of Barneston limestone. Wolfcamp series.

Type locality: In foot of Blue River bluffs southeast of Blue Springs, Gage County, Nebr.

Bluestone facies (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 125–132. Intermediate between Stanton facies (new) to south-southwest and Vanceburg facies to north. Consists of smooth and regular siltstone layers in lower third; remainder composed of undifferentiated silty shale and soft siltstone, shaly to massive. Thickness, as shown by composite sections, about 300 feet. Includes Henley shale member and Farmers siltstone member (new) near base. Underlies Christy Creek siltstone member of Brodhead formation, Morehead facies (all new); overlies Sunbury black shale.

Name derived from village of Bluestone, western Rowan County, where excellent section of lower part of formation is exposed at and adjoining the quarry of Kentucky Bluestone Co. No one locality shows a good continuous exposure of entire formation.

Bluestone Formation[1] (in Pennington Group)

Bluestone Group

Upper Mississippian: Southern West Virginia, eastern Kentucky, and southwestern Virginia.

Original reference: M. R. Campbell, 1896, U.S. Geol. Survey Geol. Atlas, Folio 26.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 259–260. Bluestone group (Mauch Chunk series) overlies Princeton group; from southeast to northwest, successively older horizons are in contact with basal beds of Pottsville series. Thickness 80 to 675 feet.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 181–187, pl. 15. Reger (1926, West Virginia Geol. Survey [County Rept.] Mercer, Monroe, and Summers Counties) named many subdivisions of the Bluestone in West Virginia. In present report (Burkes Garden quadrangle, Virginia), these units are redefined and renamed as members of Bluestone formation (ascending): Pride shale, Pipestem shale, Glady Fork sandstone, Mud Fork, Belcher, Bratton sandstone, and Bent Mountain. Conformable with underlying Pennington; in Tazewell County underlies Pennsylvanian Lee formation in normal sequence; in Burkes Garden quadrangle has been faulted out along southeastern edge of Pennsylvanian belt.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Age of Bluestone formation given as Upper Mississippian.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Assigned to Pennington herein raised to group rank; uppermost formation in group. Overlies Princeton sandstone.

R. H. Wilpolt and D. W. Marden, 1959, U.S. Geol. Survey Bull. 1072–K, p. 598 (fig. 26), 602–603, geol. sections, pls. 28, 29. Interbedded shale, mudstone, siltstone, sandstone, and limestone; impure coal beds. Thickness (measured sections) 228 to 692 feet. Conformable above Princeton sandstone; regionally several hundred feet of beds in upper part may have been truncated before basal sandstone of Pottsville was deposited. Geographically extended into Kentucky.

Well exposed along Bluestone River, Mercer County, W. Va.

Blue Water Basalt Flow[1]

Pleistocene: West-central New Mexico.

Original reference: R. L. Nichols, 1936, Jour. Geology, v. 44, no. 5, p. 628.

In San Jose Valley between Blue Water and the Rio Puerco, Valencia County.

Bluewater Formation

Permian: New Mexico and Arizona.

S. B. Talmage and T. P. Wootton, 1937, New Mexico Bur. Mines Mineral Resources Bull. 12, p. 30. Name applied to so-called Moenkopi of previous reports. Consists largely of red, brown, and purplish shales but includes some beds of sandstone and conglomerate. Thickness about 1,000 feet in Zuni Mountains. Not recognized east of Rio Grande.

Derivation of name not stated.

Bluff Bed[1]
Bluff Formation or Limestone } (in Trinity Group)

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: J. A. Taff, 1891, Texas Geol. Survey 2d Ann. Rept., p. 727, 736.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 1000–1003. Formation described in northern Quitman Mountains, where it is 1,500 to 1,800 feet thick. Underlies Cox formation; overlies Yucca formation. Both Bluff and Finlay formations have been called Finlay by Baker (1927). Taff (1891) divided rocks in Quitman Gap into Mountain bed and Quitman bed. Mountain bed is equivalent to Yucca formation; Quitman bed is equivalent to lower part of Bluff formation.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 16–21. Preoccupied name Bluff replaced by Bluff Mesa formation.

D. L. Amsbury, 1958, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 22. Formation described in Pinto Canyon area, Presidio County, where it consists of 200 feet of very light gray thick-bedded limestone overlain by 450 feet of dark-gray nodular *Orbitolina*-bearing limestone interbedded with light-colored crossbedded sandstone. Overlies Yucca formation; underlies Cox formation.

R. K. DeFord and L. W. Bridges, 1959, Texas Jour. Sci., v. 11, no. 3, p. 291. Bluff limestone underlies Tarantula gravel (new).

Named for Bluff Mesa, El Paso County.

Bluff Bone Bed (in Wichita Group)[1]

Permian: Central northern Texas.

Original reference: J. A. Udden and D. M. Phillips, 1912, Texas Univ. Bull. 246, p. 35–42.

Named for Bluff Creek, south of Electra, Wichita County.

Bluff Sandstone (in San Rafael Group)

Bluff Sandstone Member (of Entrada Sandstone)

Bluff Sandstone Member (of Morrison Formation)[1]

Upper Jurassic: Sotheastern Utah, northeastern Arizona, southwestern Colorado, and northwestern New Mexico.

Original reference: A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U.S. Geol. Survey Prof. Paper 183, p. 21.

H. E. Gregory, 1938, U.S. Geol. Survey Prof. Paper 188, p. 58, pl. 15. In San Juan County, Utah, is basal member of Morrison. Typically one massive bed 200 to 350 feet thick. Underlies Recapture shale member (new); overlies Summerville(?) formation.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 959–960, table 1. As here interpreted, the Bluff is local phase of the Entrada. This correlation is based on regional considerations, tracing of units, and lithologic pecularities. Bluff can be traced southward into Carrizo Mountains, thinning from about 250 to about 15 feet. At Horse Mesa, Ariz., is separated by about 175 feet of sediments from Todilto limestone. Table shows Bluff sandstone in San Rafael group.

W. B. Hoover, 1950, New Mexico Geol. Soc. Guidebook 1st Field Conf., p. 77–80. Entrada, at type locality, is overlain by Curtis and Summerville. Curtis apparently grades into Summerville, and Summerville, in part, grades into Moab tongue of Entrada. Farther south, Entrada divides again into a lower bed, Entrada proper, and Bluff sandstone member. Name Red Mesa is introduced for the crinkly shale and sandstone beds, 100 feet thick, between Entrada and Bluff member. Crinkly beds of Red Mesa are similar in appearance to Carmel at Moab which led Stokes (1944) to conclude that Bluff and Entrada were one and same bed.

J. W. Harshbarger, C. A. Repenning, and R. L. Jackson, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 97. In Navajo country, Summerville formation, Bluff sandstone member, and Recapture shale member of Morrison formation grade laterally southward into a distinct sand facies here named Cow Springs sandstone.

L. C. Craig and others, 1955, U.S. Geol. Survey Bull. 1009–E, p. 133–134. Included in San Rafael group. West of Gallup, N. Mex., the Bluff constitutes an inseparable part of Cow Springs sandstone. It has also been observed to tongue and grade into Summerville formation in southeastern Utah, and part of Bluff tongues with overlying Salt Wash member of Morrison formation in northeastern Arizona. Thus the sandstone unit is related to both Summerville and Morrison formations. Bluff sandstone and correlative Junction Creek sandstone are here arbitrarily assigned to San Rafael group.

V. L. Freeman and L. S. Hilpert, 1956, U.S. Geol. Survey Bull. 1030–J, p. 313, 315 (fig. 60). In Gallup-Albuquerque area, considered of formational rank. Underlies Recapture member of Morrison, and over most of area is conformable with it; near Laguna, interfingers with Recapture.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 42–43. In this report [Navajo country], Bluff sandstone believed to be tongue of Cow Springs sandstone, extending northward from main mass of Cow Springs, but, because of its homogeneous and mappable character and its areal extent, it is considered a separate formation and assigned to upper part of San Rafael group. Ranges in thickness from few feet to about 300 feet.

Named for exposures that form cap rock of cliffs at Bluff, San Juan County, Utah.

Bluff Creek Shale Member (of Graham Formation)[1]

Upper Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 400.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 118–119. Bluff Creek shale member was defined by Drake as including shale interval from top of his Home Creek limestone to base of his *Campophyllum* beds, the name being derived from locality south of Colorado River, where his term "Home Creek limestone" was used consistently. Name was used by Plummer and Moore (1921, Texas Univ. Bull. 2132) to include beds from top of their Home Creek limestone (a higher limestone than Home Creek limestone on Home Creek) to base of Gunsight limestone, and that usage is followed in this report [Brown and Coleman Counties]. Thickness 47 feet. Overlies Home Creek limestone member of Caddo Creek formation.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 50. Shown on columnar section, Brown and Coleman Counties, below Gunsight limestone and above Home Creek limestone member of Caddo Creek formation. Thickness about 90 feet. Consists of shale, limestone and sandstone; shale is gray and very fossiliferous above upper limestone, with ammonoids, gastropods, brachiopods, pelecypods abundant, *Conularia* and shark teeth rare. Upper limestone is gray, oolitic, foraminiferal, and massive and contains fusulinids, "seaweed" structures, and fossil fragments; called Bunger limestone by Bullard and Cuyler (1935, Texas Univ. Bull. 3501). Lower limestone thinner, ferruginous, foraminiferal, and fusulinid-bearing. Sandstones near base lenticular and channel filling near Colorado River.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 69–70, pl. 27. Bluff Creek shale member was first described by Drake (1893) as Bluff Creek bed from exposures along tributary of Colorado River in McCulloch County. Plummer and Moore (1921, Texas Univ. Bull 2132) called the member Bluff Creek shale and stated that a thin yellow limestone in middle of unit may be equivalent to Bunger limestone member in Young and Stephens Counties. Bullard and Cuyler (1935, Texas Univ. Bull. 3501) retained name Bunger for bed in McCulloch County that they said is unlikely to be continuous with one at type locality in Young County but occupies same stratigraphic position. The shale above this Bunger they termed Upper Bluff Creek shale and the shale below, Lower Bluff Creek shale. They named a persistent ferruginous limestone bed lying 15 to 20 feet below their Bunger limestone and 35 feet above base of their Lower Bluff Creek shale the White Ranch limestone. Hudnall and Pirtle (1929, Geologic map of Coleman County) called a limestone unit in this interval in Brown County the North Leon limestone, believing it to be correlative with bed in Eastland County named North Leon by Reeves (1922). Cheney (1950, Abilene Geol. Soc. [Guidebook] Nov. 2–4) and Cheney and Eargle (1951, Geologic map of Brown County) added North Leon and Gonzales to list of limestones in lower part of Graham formation in Brown County. As many as six thin limestone units in lower part of Bluff Creek shale member are traceable for considerable distances across Brown and Coleman Counties [this report], but most of these are discontinuous. Lenticular beds of sandstone are also found in several stratigraphic positions. Exact correlation of the limestones in lower part of Bluff Creek could not be determined because of abrupt changes in intervals of shale between them. Hence formal usage of individual names for these beds whose type localities are chiefly in Brazos River valley is not recommended for Colorado River valley until more definite correlations can be established. Bluff Creek shale of present report ranges in thickness from about 90 feet along Colorado River to about 140 feet in north-central Brown County. Underlies Gunsight limestone member; overlies Home Creek limestone member of Caddo Creek formation.

Named for Bluff Creek, McCulloch County.

Bluff Dale Sand (in Travis Peak Formation)[1]

Lower Cretaceous (Comanche Series): Central northern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 152, 154, 462, 463, 464, 474, 491.

Named for Bluff Dale, Erath County.

Bluff Mesa Formation (in Trinity Group)

Lower Cretaceous: Southwestern Texas.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 12 (table 1), 16–19, 21, pls. 1, 8. Term used to designate unit previously called Bluff beds by Taff (1891) and Bluff formation by Smith (1940). Name Bluff preoccupied. In Eagle Mountains area, consists of black nodular limestone weathering blue gray, limestone pebble conglomerates, brown shales, and some sandstones; limestones contain abundant *Orbitolina*, and some rudistid reef beds. Thickness 147 to a little more than 1,000 feet; greatest thickness is exposed on northeastern front of mountains north of Spar Valley. Conformable upon Yucca formation and unconformable upon Permian(?) beds where Yucca is missing; grades upward into quartzites of Cox sandstone through series of interbedded shales and thin quartzitic sandstones.

Bluff beds named from exposures at Bluff Mesa, El Paso County.

Bluff Point Siltstone Bed (in West River Shale Member of Genesee Formation)

Bluff Point Flagstone[1] Member (of Standish Shale and Flags)

Upper Devonian: Western and west-central New York.

P. D. Torrey and others, 1932, Am. Petroleum Inst. Div. Production Paper 826–4A, p. 16, figs. 6, 7. Thin persistent member of the Standish. Occurs above Crosby sandstone [member].

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2825. Highly cross-laminated ripple-marked layer of siltstone 1 to 2 inches thick is present at base of upper third of West River shale member of Genesee formation in most exposures of member between Lake Erie and Canandaigua Lake. This key bed, which is present in more than 500 square miles in western and west-central New York, was traced eastward to Keuka Lake where it was found to be the 3- to 4-inch Bluff Point flagstone of Torrey and others (1932), the same bed that was named Keuka flagstone by Fox (1932). Torrey's Bluff Point flagstone is present as far east as Plum Point Creek, one-half mile west of village of Himrod, where it is 2½ feet above top of Ithaca member of Genesee. Thick-bedded fossilferous siltstones at top of Ithaca member near Ithaca are at approximately same stratigraphic position as Torrey's Bluff Point flagstone.

U.S. Geological Survey currently classifies the Bluff Point Siltstone as a bed in the West River Shale Member of the Genesee Formation on the basis of a study now in progress.

Type locality not stated.

Bluffport Marl Member (of Demopolis Chalk)

Upper Cretaceous: Western Alabama and eastern Mississippi.

W. H. Monroe, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2740–2742. Bed of calcareous, more or less sandy, silty clay about 65 feet thick, that rests on typical Demopolis chalk and gradationally underlies calcareous clayey sand of Ripley formation; lithology varies from very clayey chalk to compact very chalky clay.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 53–59, pls. 1, 5, 6, 10. Described in Kemper County where it is about 50 feet thick. Underlies Ripley formation.

Type locality: On Bluffport road in NW¼ sec. 27, T. 19 N., R. 1 W., Sumter County, Ala., about 6½ miles due east of Livingston. Crops out in many of raised blocks of Livingston fault zone. Named for Bluffport Bluff along Tombigbee River.

†Bluff Springs Granite[1]

Post-Carboniferous: Eastern Alabama.

Original reference: W. F. Prouty, 1923, Alabama Geol. Survey County Rept. 1, p. 16, 51, 52, 53, 62, 65.

Named for development around Bluff Springs, Clay County.

Blufftown Formation (in Selma Group)

Blufftown Marl[1]

Upper Cretaceous: Western Georgia and eastern Alabama.

Original reference: J. O. Veatch, 1909, Georgia Geol. Survey Bull. 18, p. 86, 88–89.

L. W. Stephenson and W. H. Monroe, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1648–1649. Geographically extended into Alabama. Blufftown formation grades westward into lower part of Selma chalk. As defined here, Blufftown includes additional beds below the marl (as originally defined) that were correlated with upper part of Eutaw formation by Veatch and with "typical beds of Eutaw" by Stephenson (1911 Georgia Geol. Survey Bull. 26). These beds consist of irregularly bedded sands and clays, in part lignitic, and at their base are coarse pebbly sands and sandstones. Unconformably underlies Cusseta formation, which overlaps it toward northeast in Georgia.

D. H. Eargle, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 105. In eastern Alabama, Blufftown grades laterally into Mooreville chalk and basal part of Demopolis chalk. Intertonging relationships discussed in detail. Overlain by Cusseta member of Ripley formation. Included in Salem group.

D. H. Eargle, 1955, U.S. Geol. Survey Bull. 1014, p. 32–43, pls. 1, 2. Described in Georgia where, in Chattahoochee River valley, it consists of basal unit of crossbedded coarse sand, about 150 feet thick, overlain by laminated more or less sandy carbonaceous highly micaceous fossiliferous clay, about 260 feet thick. Toward the east, upper clay member grades rapidly laterally into unfossiliferous coarse sand that is difficult to distinguish either from basal sand member or overlying Cusseta sand. Historical summary of usage of name.

Named for exposures at Blufftown, Stewart County, Ga. In Georgia, crops out in belt from Chattahoochee River valley east-northeastward to Flint River; east of Flint River, becomes indistinguishable from underlying Eutaw formation and overlying Cusseta sand.

Board Cabin Formation

Precambrian: East-central Arizona.

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (table 1), 1502–1504. Quartzose, feldspathic, and volcanic sandstones, tuffaceous wackes, fine and coarse conglomerates, pyroclastic rocks, and thin basaltic lavas, so intimately interbedded and interfingered that accurate mapping is exceedingly difficult. Intraformational unconformaties common, and most conglomerates, sandstones, and wackes contain angular fragments of immediately underlying rock. Rocks of Board Cabin formation, Flying W formation (new), and parts of Haigler formation (new) so similar that the only reliable distinction is their stratigraphic position. Porphyritic lava the most distinctive and abundant rock type. Sedimentary rocks become coarser grained upward in section, and there are none finer than conglomerate in upper half of formation. Typical sedimentary rock is coarse, relatively well sorted, and composed of locally derived materials. Volcanic rock facies more prominent to the west, and there is little sedimentary rock in formation west of Board Cabin Draw. Thickness 250 to 1,820 feet. Conformably overlies Houden formation (new) ; underlies Haigler formation with slight unconformity.

Type section: On Board Cabin Draw between approximate elevations of 4,550 and 4,750 feet, Diamond Butte quadrangle. Another good, but thinner, section on Turkey Creek in southern part of quadrangle. Name derived from Board Cabin Draw, at southeastern foot of Diamond Butte.

Boardman Formation

Lower Ordovician (Canadian): West-central Vermont.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 13, 24–27. Name proposed to include all rocks lying stratigraphically between underlying Clarendon Springs dolomite and overlying Bascom formation. Divided into (ascending) Sutherland Falls marble, Intermediate dolomite, and Columbian marble members. Subdivisions used as defined by Bain (1931), and names retained because of their economic importance in marble belt. Total thickness approximately 900 feet.

Type locality: On southwestern slope of Boardman Hill in Clarendon about 1¼ miles S. 50° W. on top of hill, Rutland County. Formation crops out in band that extends from northern to southern boundary of Castleton quadrangle from Pittsford Township through Proctor and Center Rutland to Clarendon Township.

Boarman Member (of Mifflin Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 10, 16. Limestone or dolomite about 4½ feet thick. Shown on columnar section as underlying Establishment member (new) and overlying Brickeys member (new).

In copy of guidebook used by compiler, a handwritten note states that Brickeys member overlies Boarman member. Thus, Boarman would be basal member of Mifflin formation and would overlie Oglesby member of Pecatonica formation. Since the compiler had no way to determine what changes, if any, had been made in other copies of guidebook, it was impossible to be certain of true stratigraphic relation.

Occurs in Dixon-Oregon area.

Bob Crystalline Limestone Member (of Brownsport Formation)[1]

Bob Formation (in Brownsport Group)

Middle Silurian: Western and central Tennessee.

Original reference: W. F. Pate and R. S. Bassler, 1908, U.S. Natl. Mus. Proc., v. 34, p. 410–432.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, Chart 3. Shown on correlation chart as formation in Brownsport group.

T. W. Amsden, 1949, Yale Univ., Peabody Mus. Nat. History Bull. 5, p. 25. In area of this report [western Tennessee], there does not appear to be any valid basis for subdividing the Brownsport into three members or formations. It is proposed that terms "Beech River," "Bob," and "Lobelville" be abandoned.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 262–264, figs. 2, 81. Bob formation included in Brownsport group. Typically a massive-bedded silt-free medium- to coarse-grained gray crystalline limestone with glassy appearance; locally contains red specks and green grains of gluconite [glauconite]; at some localities entire formation consists of limestone interbedded with shale. Thickness 5 to 30 feet average 25 feet. Throughout most of outcrop belt is a continuous blanket of limestone, but in some areas appears to pinch and swell, possibly to extent of being locally absent or represented only by an alternation of limestone and shale deposited contemporaneously with massive phase elsewhere. Bob limestone is conformable with both Beech

River and Lobelville formations; in several localities, grades into both by progressive interbedding. Where Lobelville is absent, the Bob is unconformably overlain either by Decatur limestone, a Devonian formation, or Chattanooga shale. Pate and Bassler (1908) named Bob limestone for bluff one-half mile below Bobs Landing along west bank of Tennessee River in Decatur County. Type section given by Pate and Bassler (p. 421), however, is composed of 20 feet of Dixon and 40 feet of Beech River, but no Bob limestone as recognized elsewhere by these writers nor as recognized and mapped by Miser, Jewell, and present writer. As shown in this report in section 3, *A'–A''*, figure 81, Bob limestone occurs on hill above the bluff, the Beech River being 80 feet thick and the Bob 5 to 25, increasing in thickness northward; the Bob is overlain by the Lobelville. Foerste (1903) named Gant limestone and Gant bed from exposures in Wayne County. Gant limestone included 30 feet of limestone and is equivalent to Bob limestone as recognized by Miser, Jewell, Wilson. and by Pate and Bassler at some localities. If name Bob had not become so well established, it would be recommended here that Bob limestone be dropped in preference to Gant.

Named for Bob Landing, Decatur County.

Bobcat Hill Conglomerate

Cretaceous or Tertiary: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 55–58, table 1, pl. 1. Interbedded impure volcanic arkose sandstone and conglomerate. Conglomerate characterized by presence of fragments of limestone and volcanic rocks. Sandstones characteristically medium-bedded fine-grained light-grayish-green to yellowish-gray slightly calcareous. A 1-foot bed of limestone, which in places consists entirely of algal remains, occurs near base of formation in eastern part of outcrop area. Thickens from 724 feet in western part of area to 1,138 feet near North Star mines. Unconformably overlies unnamed volcanic rocks.

Named from exposures on north and west sides of Bobcat Hill, near corner common to secs. 25, 26, 35, and 36, T. 24 S., R. 21 W. Better exposed in S½ sec. 27, in vicinity of North Star mines, and extends east and west across southern parts of secs. 26, 27, and 28, T. 24 S., R. 21 W., central Peloncillo Mountains, Hidalgo County.

Bobs Ridge Member (of Huntersville Chert)

Lower Devonian (Onesquethaw): West Virginia.

J. M. Dennison, 1960, Dissert, Abs., v. 21, no. 3, p. 593. Glauconitic quartz sandstone. Accumulated over site of Browns Mountain anticline which was shoal during late Onesquethaw time.

Named for outcrops on Bobs Ridge, Greenbrier County.

Bobtail Quartz Latite Member (of Gem Hill Formation)

Miocene(?): Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 137 (fig. 1), 138 (fig. 2), 140–141. Felsitic to porphyritic rock predominantly cream white in color, but locally tan, pink, brown, or pale green. Latite makes up several large volcanic plugs, a number of small plugs, pods, and dikes intrusive through pre-Tertiary granitic rocks into the Gem Hill; also occurs as several short lentils of flow breccia in the formation. Older than Fiss fanglomerate (new) which it does not intrude.

Type locality: Soledad Mountain, Rosamond quadrangle, secs. 6 and 7, T. 10 N., R. 12 W., San Bernardino Base and Meridian, Kern County. Name derived from Bobtail mines on west slope of Soledad Mountain. Many scattered buttes within 10 miles of Soledad Mountain are remnants of volcanic plugs made up of Bobtail quartz latite.

Bocas [Formation]

Pliocene: Panamá.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (correlation chart). Name appears on correlation chart.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 5–6. Underfined name for strata of Pliocene age.

On Bocas Island.

Bodega Diorite[1]

Pre-Tertiary: Northern California.

Original Reference: V. C. Osmont, 1904, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 43.

C. C. Higgins, 1952, California Univ., Dept. Geol. Sci. Bull., v. 29, no. 5, p. 200, fig. 7. Described with pre-Tertiary rocks of area as being of ancient but unknown age. At Point Reyes, nonconformably overlain sands and shales of Miocene Monterey formation.

Exposures limited to Bodega Head and Point Reyes Peninsula, lower Russian River region.

Bodega Bay deposits[1]

Quaternary: Western California.

Original reference: V. C. Osmont, 1904, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 76.

Bodega Bay, Marin County.

†Bodeville Series[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lvi. 255–267, pl. 3.

Named for Bodeville, Mason County.

Bodine Sandstone

Ordovician: Oklahoma.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 99. Abandoned by Oklahoma Geological Survey. Eldridge (1901, U.S. Geol. Survey 22d Ann. Rept., pt. 1, p. 274) applied name of an asphaltic sandstone pit in Murray County to an asphaltic sandstone in Simpson group. Probably a bed in Bromide formation.

Bogachiel Formation[1]

Cretaceous(?): Northwestern Washington.

Original reference: A. B. Reagan, 1909, Kansas Acad. Sci. Trans., v. 22, p. 160.

Greatest development in Bogachiel Valley, near headwaters of that stream.

Boggs Member (of Pottsville Formation)[1]

Pennsylvanian (Pottsville Series): Southeastern Ohio.

Original reference: W. Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 70.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 31, table 1. Included at top of Lower Mercer cyclothem in Perry County. Thickness about 1 foot. Overlies unnamed shale; underlies Flint Ridge shale and (or) sandstone.

Named because it is correlated with Boggs iron ore of Scioto County.

Boggs Mountain Flows (in Clear Lake Volcanic Series)

Quaternary: Northern California.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), pl. 7. Dark-gray porphyritic andesitic lavas 100 to 500 feet thick. Shown on columnar section above Perini Hill flows (new) and below Cobb Mountain volcanics (new), but age relations of individual units of series are imperfectly known because some units are isolated and contacts of contiguous flows are commonly obscured by sliding.

Vicinity of Boggs Mountain, Lower Lake quadrangle, in Coast Range, about 70 miles north of San Francisco.

Boggy Shale[1] **or Formation** (in Krebs Group)

Pennsylvanian (Des Moines Series): Central southern and eastern Oklahoma and western Arkansas.

Original reference: J. A. Taff, 1889, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 438.

C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 504, 510–511. Includes (ascending) shale, Crekola sandstone member (new), shale, Inola sandstone member, shale, Taft sandstone member (new).

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 51–57. Includes Bluejacket sandstone member near base.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 54–62. Maximum thickness more than 4,000 feet in Le Flore County; top eroded.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1523, 1524. Uppermost formation in Krebs group (new). Overlies Savanna formation; underlies Thurman sandstone.

E. W. Reed, S. L. Schoff, and C. C. Branson, 1955, Oklahoma Geol. Survey Bull. 72, p. 68. Formation, as defined by Oklahoma Geological Survey, comprises strata from base of Bluejacket sandstone member to unconformity at base of Cabaniss group.

J. V. A. Trumbull, 1957, U.S. Geol. Survey Bull. 1042–J, p. 333–335, pl. 16. In Oklahoma, exposed in wide arcuate belt from southeastern Pontotoc County and central and northern Coal County through Pittsburg, Haskell, and McIntosh Counties to northwestern Muskogee County. From there it has been mapped northward to Kansas line. Large outliers remain in Sansbois syncline in Haskell and Latimer Counties, where more than 2,000 feet of formation is present, and in Cavanal syncline in LeFlore County, where as much as 3,000 feet of rocks in formation make up much of Cavanal Mountain. Complete continuous section in Pittsburg County is about 2,850 feet thick. Overlies Savanna formation; underlies Thurman sandstone.

Named for exposures along North Boggy Creek, Pittsburg and Atoka Counties, Okla.

Bogota cyclothem (in McLeansboro Group)

Bogota cyclothem (in Mattoon Formation)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 19–24. Lies above Cohn cyclothem (new) and below Newton cyclothem (new). Contains two cyclothems which are referred to as upper and lower Bogota. Includes Bogota limestone and Bogota shale.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2). Included in Mattoon formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: A few miles southwest of Bogota, Jasper County.

Bogota Limestone Member (of Mattoon Formation)

Bogota Limestone (in McLeansboro Group)

Pennsylvanian: Central and southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 19–24. Limestone in Bogota cyclothem in McLeansboro group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 41, 51 (table 1). Member of Mattoon formation (new). Occurs above Effingham limestone member and below Greenup limestone member. Thickness at type locality about 3½ feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: NE¼NE¼ sec. 17, T. 5 N., R. 8 E., a few miles southwest of Bogota, Jasper County.

†Bogus Tongue (of Cutler Formation)[1]

Permian: Central eastern Utah.

Original reference: A. A. Baker, 1933, U.S. Geol. Survey Bull. 841.

A. A. Baker, 1946, U.S. Geol. Survey Bull. 951, p. 43. Name Bogus abandoned in favor of name Organ Rock tongue; it is evident that red beds formerly included in the Bogus are continuous with Organ Rock tongue at its type locality.

Crops out in Bogus pocket, SW cor. T. 30 S., R. 21 E., San Juan County.

Bohemia Conglomerate (in Portage Lake Lava Series)

Bohemia Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, pt. 2, p. 3, 30, 52, 66, 72, 83, 99, pls. 4, 7.

J. C. Wright and H. R. Cornwall, 1954, Bedrock geology of the Bruneau Creek quadrangle, Michigan: U.S. Geol. Survey Geol. Quad. Map [GQ–35]. Included in Portage Lake lava series.

Named for the fact that it caps Bohemian Range, in Keweenaw County.

Bohemia Porphyrite[1] (in Bohemian Range Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, pt. 2, p. 40, 72.

Named for the fact that it occurs north of Mount Bohemia, Keweenaw County.

Bohemian Range Group[1]

Precambrian (Keweenawan): Northern Michigan and probably northern Wisconsin.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 179–187, pls. 17, 18.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ-27. Name Portage Lake lava series (new) proposed to include Eagle River, Ashbed, Central Mine, and Bohemian Range groups of old reports. These subdivisions are quite arbitrary and depend on continuity of individual flows or conglomerate beds for validity. They are not useful for purpose of this report.

Named for the fact that its rocks compose Bohemian Range, Keweenaw County, Mich.

†Bohicket Marl Sands[1]

Pleistocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 20, 21.

Named for exposures in Bohicket Creek, near Rockville, Charleston County.

Bohío Formation

Bohío Conglomerate[1]

Oligocene, lower and upper: Panamá.

Original references (Bujio Formation): R. T. Hill, 1898, Harvard Coll. Bull. Mus. Comp. Zool., v. 28, no. 5, p. 183; (Bohío Formation): D. F. MacDonald, 1913, Geol. Soc. America Bull., v. 24, p. 708.

H. N. Coryell and J. R. Embich, 1937, Jour. Paleontology, v. 11, no. 4, p. 289–305. Ross and Reeves (1931, U.S. Geol. Survey Prof. Paper 821–B) gave name Bohío to entire group of sediments in Chagres Valley above Madden Dam, and referred them to the Oligocene. Samples of Foraminifera collected from Bohío show that it contains both an Eocene and Oligocene fauna. Bohío formation is restricted to include only Oligocene sediments. Eocene strata are herein named Tranquilla shale.

W. P. Woodring and T. F Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 228–232, 246 (fig. 2). Formation consists of massive or poorly bedded conglomerate, tuffaceous sandstone, and tuffaceous siltstone. Estimated thickness as much as 1,000 feet. Overlies Gatuncillo formation; base of the Bohío not exposed along Panama Canal. Underlies Caimito formation. Grades laterally into Bas Obispo formation. Upper Eocene and lower Oligocene. Bohío was first named by Hill (1898) who used spelling Bujio.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 24–29. Basal part of Bohío in Quebrancha syncline contains smaller Foraminifera of early Oligocene age and upper part of formation in Pacific coastal and Gatún Lake areas, respectively, contains late Oligocene larger Foraminifera and mollusks. Whether formation represents so great a time span in each of areas where it crops out is not known at present. It represents, however, more than the early Oligocene age previously suggested (Woodring and Thompson, 1949). That it does not include all of the Oligocene is shown by late Oligocene age of overlying Caimito formation.

Type region: Bohío Peninsula. Bohío or Bohío Soldado, was a station on original line of Panamá Railroad, near southwest end of ridge forming present Bohío Peninsula. Many localities described by early writers, including French quarries at Bohío and excavation at near-by lock site, are covered by Gatún Lake.

Boice Shale (in Buckner Group)

Mississippian (Kinderhook Series): Subsurface in northeastern Kansas and southwestern Nebraska.

E. C. Reed, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 3, p. 348–349. Name applied to subsurface sequence previously referred to the Hannibal. Consists predominantly of shale with minor amounts of siltstone and sandstone near top; base is marked by zone of hematite concretions or oolites in part embedded in brick-red shale. Occurs between depths of 2,041 and 2,072 in type well and between depths of 2,225 and 2,283 feet in cotype locality. Underlies Chouteau limestone; overlies Fabius group. Placed in lower part of Buckner group of Kinderhook series, according to Marvin Weller's Mississippian correlation chart (Nat. Research Council, Apr. 10, 1945). [Compiler was unable to locate reference to Buckner group.]

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 111. Geographically extended into northeastern Kansas. Strata conformably underlie Compton limestone or occur disconformably beneath upper Sedalia and disconformably overlies deeply eroded Chattanooga. Maximum known thickness 110 feet near Nebraska border in Brown County.

Type locality: Pawnee Royalty Co. Boice well No. 1, located in center of NE¼NE¼ sec. 18, T. 1 N., R. 16 E., Richardson County, Nebr. Cotype locality: Pawnee Royalty Co. Meyers well No. 1, in center of NW¼NW¼ sec. 24, T. 1 N., R. 15 E.

Bois Blanc Formation

Bois Blanc Formation (in Detroit River Group)

Middle Devonian: Michigan.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv., Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 34, 35 (table 1), 80–109. Proposed for a Lower or Middle Devonian formation occupying position between Lower Devonian Garden Island formation (new), or Upper Silurian St. Ignace formation (new) where Garden Island is absent, and the Lower or Middle Devonian Detroit River group. Lower part consists of interbedded chert and dolomite; middle composed of limestone, dolomitic limestones, and a few beds of dolomite; strata range in color from light gray to light buff and contain nodules and irregular masses of chert, which is more abundant in some beds than others; upper part predominantly limestone. Total thickness probably not less than 325 or more than 400 feet. Numerous large blocks of the Bois Blanc occur in Mackinac breccia. Onesquethaw group.

K. K. Landes, 1951, U.S. Geol. Survey Circ. 133, p. 2 (fig. 2), 7. Stratigraphically restricted at top to exclude noncherty limestone and dolomite now included in base of Amherstburg.

W. N. Melhorn, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 819 (fig. 1). Shown on generalized stratigraphic section of Middle Devonian as formation at base of Detroit River group.

Named for exposures on Bois Blanc Island situated in Lake Huron about 2½ miles southeast of Mackinac Island. Present on northern shore of Southern Peninsula between point on Lake Huron about 26 miles southeast of Mackinaw City and Waugoshance or Crane Island, 16 miles west of this city.

Bois d'Arc Limestone[1] (in Hunton Group)

Lower Devonian: Central southern Oklahoma.

Original reference: C. A. Reeds, 1911, Am. Jour. Sci., 4th, v. 32, p. 256–268.

R. A. Maxwell, 1936, Northwestern Univ. Summ. Doctoral Dissert., v. 4, p. 132, 134. Overlies Cravatt formation of Kite group (both new). Reeds considered Cravatt as basal part of Bois d'Arc.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 7, 38–47. Subdivided to include Cravatt member below and Fittstown member (new) above. Thickness 45 to 200 feet with at least part of this variation caused by facies gradation from Bois d'Arc into Haragan formation. Underlies Frisco formation; overlies Haragan. Reeds (1926 Am. Mus. Nat. History Jour., v. 26) designated type locality as along Bois d'Arc Creek, sec. 4, T. 2 N., R. 6 E.; but this must be an error since Bois d'Arc Creek is not present in section 4; however, it is well exposed on north bank of this creek in sec. 11, T. 2 N., R. 6 E., and presumably this was location to which he referred. Type section designated.

T. W. Amsden, 1958, Oklahoma Geol. Survey Bull. 82, 110 p. Bois d'Arc formation consists of two members or lithofacies, lower cherty argillaceous calcilutite (Cravatt member) and upper calcarenite (Fittstown member). Both stratigraphic and faunal evidence indicate that these are facies of one another, and that entire formation is facies of Haragan formation. Brachiopod fauna described.

Type section: Sec. 4, T. 2 N., R. 6 E., starting at top of Cedar Hill and extending north along banks of Chimneyhill Creek. Named for exposures along Bois d'Arc Creek, Pontotoc County.

Boise Granite[1]

Jurassic or Cretaceous: Southwestern Idaho.

Original reference. I. C. Russell, 1902, U.S. Geol. Survey Bull. 199, p. 39.

In rugged mountains which lie to north and east of Boise, extends eastward from this area and occupies an extensive and exceedingly rugged region lying north of Mountain Home.

Boise Sandstone[1]

Pliocene(?): Southwestern Idaho.

Original reference: V. R. D. Kirkham, 1928, Idaho Bur. Mines and Geol. Pamph. 29, p. 1.

Bokchito Formation[1]

Lower Cretaceous (Comanche Series): Southeastern and central Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Overlies Caddo limestone; underlies Bennington limestone.

Named for Bokchito Creek, near Bokchito, Bryan County.

Bolander Group

Pennsylvanian (Des Moines Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Bull. 17, p. 27 (table 2), 51–55. Proposed for group of rocks of upper part of Des Moines series between top of Armendaris group (new) and base of Missouri series (above). At type section, composed largely of gray to light-gray fossiliferous limestone, several beds of fossiliferous gray shale, and one well-developed bed of conglomerate to highly conglomeratic sandstone about 70 feet below top of group. Thickness at type locality about 233 feet.

Type locality: Just west of large box canyon in central part of Whiskey Canyon in north portion of Mud Springs Mountains, in south-central part of sec. 1, T. 13 S., R. 5 W., Sierra County. Name derived from small deserted village of Bolander, about 8 miles northeast of Mud Springs Mountains.

Bolanos Pyroclastic Member (of Umatac Formation)

Bolanos (Balanos) (Baranos) Beds, Andesite, or Formation

Miocene, lower: Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 48, 49 (fig. 37). table 4 [English translation in library of U.S. Geol. Survey, p. 57, 58]; S. Hanzawa in Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 25. At typical outcrop beds consist of (descending) massive, nonstratified agglomerate with some limestone fragments, andesite lava with columnar structure, tuff with abundant limestone fragments, and thick layer of andesite. Conformably underlie Nagas beds. Correlated with Marino agglomerate on Tinian Island, and Manila agglomerate on Rota Island.

U.S. Geological Survey currently classifies the Bolanos as a member of Umatac Formation and designates the age as lower Miocene on the basis of a study now in progress.

Typical outcrop: West side of Mount Bolanos, Guam.

Bolarian Series or Epoch

Middle Ordovician: Eastern North America.

Marshall Kay, 1947, (abs.), Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1198–1199; 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1401, 1402 (fig. 2), 1406–1411. Series comprises rocks younger than Lincolnshire, about late Chazyan, and older than Nealmont, early Trentonian, in the Virginias and Pennsylvania, and time equivalents. Includes Hatterian (lower Bolarian) and Hunterian (upper Bolarian) subseries. Mohawkian series divided into Bolarian and Trentonian series. Term Bolarian used in preference to term Black Riveran.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 77–84, 100. Whether the Bolarian is a series, subseries, or stage depends on conception of each term, as well as on demand for categories in classification. Bolarian epoch has two stages, earlier (Hatterian) marked by relative southeasterly tilting and latter (Bennerian) by gradual northwesterly tilting. Bolarian rocks are in two groups. Lower has three limestone formations: Ward Cove, Peery, and Benbolt. Upper Bolarian has two limestones: McGlone and McGraw (both new).

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 65–96. Discussion of Ordovician Highgate Springs sequence of Vermont and Quebec and its bearing on the classification of stages and series in Ordovician System. "Porterfield" and pre-Trentonian part of "Wilderness" stage constitute type Bolarian. Black Riveran series seems to be contained in Bolarian series of Appalachians, but lowest Bolarian seems older and equivalent to upper Chazyan.

Named for Bolar Cove, Highland and Bath Counties, Va.

Boley Conglomerate Member (of Vamoosa Formation)

Pennsylvanian (Virgil Series): Central Oklahoma.

R. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 82–83, pl. 1. Basal member of Vamoosa formation. Consists mostly of subangular to well-rounded white chert pebbles and cobbles, some which are as large as 6 inches in diameter. Upper limits of member are not always definite and locally grade into sandstone lenses of overlying undifferentiated beds. Overlies units of Tallant and Barnsdall formations. Thickness 50 to 60 feet.

Type locality: Sec. 20, T. 12 N., R. 8 E. Excellent exposure capping promontory in northeastern part of sec. 21, T. 12 N., R. 8 E. Named from town of Boley which is situated on the member in sec. 20.

Bolin Sandstone Member (of Roubidoux Formation)[1]

Lower Ordovician: Central Missouri.

Original reference: S. H. Ball and A. F. Smith, 1903, Missouri Bur. Geology and Mines, v. 1, 2d ser., p. 50.

Named for exposures on Bolin Creek, Miller County.

Bolinas Sandstone[1]

Jurassic(?): Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416 (table).

San Francisco region. Probably named for Bolinas Ridge.

Bolivar cyclothem

Pennsylvanian (Allegheny Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 17. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, ser. 4, Bull. 48, p. 54–55, table 1, geol. map. Includes (ascending) Upper Freeport shale and (or) sandstone, 20 feet; Bolivar clay, 1 to 10 feet; and Bolivar coal. Occurs below Upper Freeport cyclothem and above Lower Freeport cyclothem. In area of this report [Perry County], Allegheny series is described on cyclothemic basis; nine cyclothems are named. [For sequence see Brookville cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 84–88. Bolivar cyclothem in Athens County, includes (ascending) Bolivar shale and (or) sandstone, Shawnee limestone, Bolivar underclay, Bolivar coal members. In sequence, occurs above Lower Freeport cyclothem and below Upper Freeport cyclothem. In area of this report, Allegheny series is described on cyclothemic basis; 13 cyclothems are named. [For complete sequence see Brookville cyclothem.]

Probably named for Bolivar fire clay.

Bolivar Fire Clay (in Allegheny Group)

Bolivar Fire Clay (in Allegheny Formation)[1]

Bolivar underclay or clay member

Pennsylvanian: Western Pennsylvania, Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 159–160.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 75. Fire clay included in Allegheny group in report on Fayette County. In many older reports, name Bolivar fire clay has been so loosely used that much confusion has developed. Going back to original use of name, it becomes evident that Bolivar fire clay lies considerable distance below Upper Freeport coal, whereas clay immediately under coal should be called Upper Freeport fire clay. Bolivar fire clay horizon lies 20 to 50 feet below Upper Freeport coal.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 54–55, table 1. Clay member of Bolivar cyclothem in report on Perry County. Average thickness 5½ feet. Patchy distribution at most exposures; overlain by Upper Freeport limestone; locally sandstone lies above the clay. Bolivar coal not present above clay at any outcrop.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 87. Bolivar underclay member of Bolivar cyclothem, Allegheny series, is about 4 feet thick in Athens County [this report]. In Ohio, the Ortons (1884, Ohio Geol. Survey, v. 5, Economic Geology) seem to have applied name Bolivar to this underclay, but White (1891) is credited later with establishing name in geologic literature. Bolivar underclay and overlying thin and seldom present Bolivar coal have been traced in discontinuous distribution across eastern Ohio. Occurs above Shawnee limestone.

Named for occurrence near Bolivar, Westmoreland County, Pa.

Bolivar Sandstone[1]

Lower Ordovician (Beekmantown): Southwestern Missouri.

Original reference: E. M. Shepard, 1904, Bradley Geol. Field Sta. Drury Coll. Bull. 1, pt. 1, p. 42.

At and around Bolivar, Polk County.

Bolivar Sandstone (in Allegheny Formation)[1]

Bolivar shale and (or) sandstone member

Pennsylvanian: Western Pennsylvania and eastern Ohio.

Original reference: J. J. Stevenson, 1878, Pennsylvania 2d Geol. Survey Rept. K.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 84. In Ohio, shale and sandstone that occur in interval between Lower Freeport coal and Bolivar underclay are called Upper Freeport. However, there are two shale and sandstone members separated by Bolivar cyclothem in interval between Lower and Upper Freeport coals.

Wherever Bolivar members are absent, these two shale and sandstone members coalesce, and it is impossible to distinguish them as separate units. Where it is impossible to separate the two shale and sandstone members, Upper Freeport can and should be applied as a name, but where the two can be recognized the lower shale and sandstone are herein called Bolivar. This lower member may correlate with Butler sandstone in Pennsylvania. Exposures of Bolivar shale and sandstone member of Bolivar cyclothem in Athens County [this report] are confined almost entirely to Waterloo and York Townships. Average thickness of member about 12 feet. Occurs below horizon of Shawnee limestone member.

Probably named for occurrence near Bolivar, Westmoreland County, Pa.

Bollibokka Group

Permian: Northwestern California.

A. H. Coogan, 1960, California Univ. Pubs. Geol. Sci., v. 36, no. 5, p. 243–255. Name proposed to include basic pyroclastic rocks, basic flows, and sparsely fossiliferous interbedded sedimentary rocks which have been referred to separately as Nosoni and Dekkas formations. These names are retained for formational subdivisions of group to be used where recognizable. Where black shale of the Nosoni is not present it is not always possible to separate the two formations and term "Bollibokka group, undivided" is more appropriate than one formation name. Thickness more than 10,000 feet in type section. In Bollibokka area, group is conformable with underlying McCloud limestone and overlying Pit shale. Fossiliferous beds dated as early Guadalupian, middle Permian. Upper unfossiliferous part may be late Permian, Triassic, or both. Smith (1894) included these rocks in the "Carboniferous shales" of his Pitt formation. Diller (1906) who named the Dekkas and Nosoni stated that they were alike and separated the two formations on basis of occurrence of *Fusulina* (now *Parafusulina*) which he considered indicative of Nosoni formation. Occurrence of fossils is unsuitable criterion for recognition of formations and was not reliable even in 1906 because *Parafusulina* does occur near top of Dekkas andesite as mapped by Diller. Lithology is main criterion for subdivision and mapping of Bollibokka group.

Type section: Along Nosoni Creek, Redding quadrangle, Shasta County. Named for Bollibokka Mountain, Bollibokka Mountain quadrangle.

Bolsa Quartzite[1]

Middle Cambrian: Southeastern Arizona and southwestern New Mexico.

Original reference: F. L. Ransome, 1904, U.S. Geol. Survey Prof. Paper 21, p. 28–30.

J. R. Cooper, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 31, fig. 13. Deposited on surface of considerable relief on Apache group (Dripping Spring quartzite). Thickness varies abruptly from 335 to less than 50 feet in Johnson Camp area, Cochise County.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 14–15, pls. 5, 11, 12. In central Cochise County, rocks commonly crossbedded, and beds range from few inches to as much as 10 feet in thickness, average 2 to 4 feet. Rests on smooth surface carved across Precambrian rocks, largely Pinal schist. Underlies Abrigo limestone with transitional contact.

F. F. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 469–472, fig. 4. Transgresses upward through time (Lower Cambrian? to Upper Cambrian) in west to east section through Dos Cabezas and Chiricahua Mountains.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 18–21, tables 1, 2, pl. 1. Described from central Peloncillo Mountains of New Mexico. Arkosic and orthoquartzitic sandstone and conglomerate containing some glauconite and thin shale beds in middle part of unit. Thickness ranges from 60 to 400 feet. Underlies El Paso limestone. Of Middle and Upper Cambrian age.

Well exposed in Bolsa Canyon, on southwest side of Escabrosa Ridge, Bisbee quadrangle, Cochise County, Ariz.

†Bolton Gneiss[1]

Late Carboniferous or post-Carboniferous: Eastern Massachusetts.

Original reference: B. K. Emerson and J. H. Perry, 1903, Geology of Worcester, p. 79, map.

Named for town of Bolton, which it extends through.

Bolton Igneous Series[1] or Group

Upper Ordovician or post-Ordovician: Southeastern Quebec, Canada, and northeastern Vermont.

T. H. Clark, 1934, Geol. Soc. America Bull., v. 45, no. 1, p. 11, 12. Bolton igneous series consists of large masses of gray finely crystalline metabasalt, metagabbro, and metaperidotite. Contains pillow structures and breccias; flow structure identified. Younger than Magog slates; metaperidotite intrudes Sutton schists. Upper Ordovician or post-Ordovician.

C. G. Doll, 1951, Vermont Geol. Survey Bull. 3, p. 38–41, pl. 1. Geographically extended into Vermont where it is referred to as igneous group. Consists of fine- to medium-grained metadiorites and related rocks in area west of Lake Memphremagog. Devonian or younger.

Occurs in vicinity of Bolton, southeastern Quebec.

Bolton Schist[1]

Bolton Formation or Group

Mississippian(?) or older: Central Connecticut.

Original reference: J. G. Percival, 1842, Connecticut Geol. Survey Rept., p. 229–333, map.

H. M. Mikami and R. Digman, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1487. In Branford-Killingworth area, Connecticut, pre-Triassic Bolton formation lies stratigraphically above Middletown gneiss and consists of schist and quartzites. Contact between formations conformable.

E. N. Cameron and others, 1954, U.S. Geol. Survey Prof. Paper 255, p. 20, 21. Age considered probably older than Upper Devonian; designated Paleozoic(?) in geologic map legend.

Frederick Stugard, Jr., 1958, U.S. Geol. Survey Bull. 1042–Q, p. 619, 620–624, pl. 56. Pegmatites in Middletown area cut metasediments of Bolton schist of pre-Mississippian(?) age and, in ascending order of sequence, mafic gneisses, Glastonbury granite gneiss, Maromas granite gneiss, and Monson gneiss. Position of formations in stratigraphic column cannot be determined with accuracy; maximum age is indicated by their relation to the pegmatites, which have been dated by uranium-and thorium-lead ratios as about 260 million years old, presumably Mississippian. Predominantly mica-schist with interbedded layers of quartzite and amphibolite-bearing gneiss. Estimated thickness 1,400 to 4,300 feet. Intruded by Maromas granite gneiss. Crops out as narrow band in northern part of Middletown area, and near the Straits in Connecticut River; divides into two broader bands that enclose northern end of Killingworth dome. West boundary of unit is westward-dipping normal fault of Triassic age. Band of schist extending northward from Collins Hill to village of South Glastonbury is cut on north by a Triassic fault. These two areas of schist are separated by narrow belt of mafic gneiss; easternmost body of schist can be followed northward beyond mapped area to type locality at Bolton Notch.

R. M. Gates and J. L. Rosenfeld, 1959, Connecticut Geol. Nat. History Survey Bull. 84, p. 21–24, fig. 3. Recent study in Middle Haddam quadrangle east of Middletown has resulted in major revision of interpretation of pre-Triassic rocks of area. Some features from maps of Percival (1842) and Westgate (1899, ms.), such as Percival's distinction between schist at and northeast of Great Hill and that to south and west, and Westgate's mapping of Maromas gneiss and its environs. Common mapping practice has been to lump all schist together as Bolton. This was done on Connecticut map of 1956. The Bolton is herein raised to group rank and geographically restricted to schist in Great Hill-Bolton Notch belt. Remaining schist is named Collins Hill formation. Group as herein defined consists of three units. Lower unit, which is Lower or Middle Ordovician, is well-banded quartzite and quartz-sericite above and conglomeratic quartzite below. Middle unit, which is Middle Silurian, is laminated calcareous biotite gneiss, granulite, and schist, showing deep pits and weathered surfaces due to solution of masses of calcite marble. Upper unit, which is Lower Devonian, is gray nonrusty graphitic garnet-staurolite two-mica schist and some platy quartz-serite schist. Unconformably overlies Collins Hill formation.

Named for exposures in western part of town of Bolton, Tolland County.

Bommer Member (of Topanga Formation)

Miocene, middle: Southern California.

J. G. Vedder, R. F. Yerkes, and J. E. Schoellhamer, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–193. Predominantly thick-bedded coarse-grained sandstone and grit which contains thin lenticular pebble beds. Thin beds of fine- to medium-grained sandstone commonly separate coarse-grained sandstone beds in middle and upper parts of member. Maximum thickness about 2,000 feet. Conformably underlies Los Trancos member (new); overlies Vaqueros formation; contact gradational where exposed in Moro Canyon.

Type area: In large fault block extending from upper Moro Canyon to mouth of Bommer Canyon, Orange County. Named for Bommer Canyon, which joins Sand Canyon Wash at north margin of San Joaquin Hills.

Bomoseen Greywacke or Grit Member (of Bull Formation)

Bomoseen Grit[1]

Bomoseen Grit Member (of Schodack Formation)

Lower Cambrian: Southwestern Vermont and eastern New York.

Original reference: R. Ruedemann, 1914, New York State Mus. Bull. 169, p. 67–70, map.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland 1942, New York State Mus. Bull. 331, p. 64–65; Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 65–68. Considered member of Schodack formation.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 46–47, pl. 2. Bomoseen grit crops out along western part of Castleton quadrangle in irregular-shaped pattern from Hampton, N.Y., at south to point of Pines on western shore of Lake Bomoseen. Kaiser (1945, Geol. Soc. America Bull., v. 56, no. 12, pt. 1) mapped Bomoseen in outcrop 1 mile west of West Castleton. This outcrop, which is type locality, extends westward into Whitehall quadrangle. Minimum thickness about 200 feet. Underlies Mettawee slate; in many places, gradational contact between the two requires arbitrary definition. Base not exposed, presumably overlies Nassau formation.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 329–330. First distinguished by Dale (1889, U.S. Geol. Survey Ann. Rept., v. 19, pt. 3B) as "Olive grit," and assigned to base of Cambrian in Washington County, unit was named by Ruedemann (1914) from type exposures near Lake Bomoseen, Vt. Here it consists of medium-grained angular quartz grains, with subordinate amount of feldspar set in sericitic, somewhat calcareous, matrix and characterized by abundant specks of hematite and graphite; locally intercalated green and red slates. There is suggestion of cyclical bedding. Some beds of medium- to coarse-textured calcareous orthoquartzite, flecked with hematite, limonite, and graphite are present. These beds are seldom more than 1 inch thick, but some are as much as 55 feet. Weathers brick red. Thickness probably 500 feet. Here interpreted as facies of Nassau formation farther south. Kaiser (1945) suggested that Bomoseen may be equivalent of Rensselaer grit whose age has long been in dispute.

E–an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 1. Referred to as greywacke member of Bull formation. West of Lake Bomoseen is lowest exposed unit and underlies Mettawee member; east of Lake Bomoseen and north of Pine Pond thrust, it is demonstrably within Mettawee member. Bomoseen graywacke west of Lake Bomoseen conceivably belongs to lower horizon, stratigraphically replacing Biddie Knob formation (new); on other hand, it may merely be part of a thickened section of Bull formation, still underlain by the (unexposed) Mettawee member. Underlies Zion Hill member.

George Theokritoff, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 53–54. Referred to as grit member of Bull formation. Is lowest rock unit exposed in Taconic sequence in Washington County, N.Y.

Type locality: West side of Lake Bomoseen, Castleton quadrangle, Rutland County, Vt.

†Bon Air measures[1]

Pennsylvanian: Southeastern Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 104, 148–151, 167, 168.

Named for mines in White County.

Bonair Sandstone (in Lee Group)[1]

Lower Pennsylvanian: Eastern Tennessee and northern Georgia.

Original reference: M. R. Campbell, 1899, U.S. Geol. Survey Geol. Atlas, Folio 53, p. 3.

V. H. Johnson, 1946, Coal deposits of Sand and Lookout Mountains, Dade and Walker Counties, Georgia: U.S. Survey Prelim. map. Geographically extended into northern Georgia where it is 150 to 200 feet thick. Underlies Vandever shale; overlies Whitwell shale.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4. Sandstone that has been called "Bon Air" at Bon Air, White County, is equivalent to Sewanee conglomerate; because name Sewanee has priority, name Bon Air is discontinued.

Named for Bon Air, White County, Tenn. [Board on Geographic Names gives Bon Air as correct spelling.]

Bonanza Latite[1]

Tertiary: Southern Colorado.

Original reference: H. B. Patton, 1916, Colorado Geol. Survey Bull. 9, p. 21–63.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 195, 196. In Greater Bonanza district, the volcanics in order of succession are Rawley andesite, Bonanza latite, Squirrel Gulch latite, Porphyry Peak rhyolite, and Bremer [Brewer] Creek latite. In South Bonanza district, the volcanic sequence is roughly the same except Porphyry Peak rhyolite is missing and Bonanza atite is replaced by Hayden Peak latite.

Bonanza district, Saguache County.

Bonanza King Formation[1] or **Dolomite**

Middle and Upper Cambrian: Southeastern California and southeastern Nevada.

Original reference: J. C. Hazzard and J. F. Mason, 1936, Geol. Soc. America Bull., v. 47, no. 2, p. 229–240.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 277 (fig. 3c), 316–318. Extended into Nopah and Resting Springs area, Inyo County, Calif. Thickness 1,515 feet. Underlies Cornfield Springs formation: overlies Cadiz formation.

J. C. Hazzard and J. Mason, 1953, Am. Jour. Sci., v. 251, no. 9, p. 643–655. Geographically extended into Goodsprings area, Nevada, where it lies within Goodsprings dolomite of Hewett (1931).

A. R. Palmer and J. C. Hazzard, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 10, p. 2494–2499. On basis of paleontological data, age of Bonanza King formation at its type locality is designated as Middle and Upper Cambrian. On basis of this evidence, names Cornfield Springs and Bonanza King were misapplied in Nopah Range area. Here units so designated should now be considered as unnamed upper and lower divisions, respectively, of Bonanza King formation. Hence, in Nopah area, Bonanza King underlies Nopah formation.

First described in Providence and Marble Mountains, San Bernardino County, Calif. Named for Bonanza King mine, east side of Providence Mountains.

Bonaparte Marble[1]

Mississippian: Southeastern Iowa.

Original reference: C. H. Gordon, 1895, Iowa Geol. Survey, v. 4, p. 211.

Appears at Des Moines River level on south side, about half way between Bentonsport and Bonaparte, Van Buren County.

Bond Formation (in McLeansboro Group)

Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1), 26 (fig. 4), 27, 38–39, 50, pl. 1, geol. sections. Proposed for strata extending from base of Shoal Creek limestone member to top of Millersville limestone member. Characterized in area of typical development by thick limestones. Thickness in type area nearly 300 feet; east of La Salle anticline 75 feet or less. Overlies Modesto formation and underlies Mattoon formation (both new). Members—central and southwestern Illinois (ascending): Shoal Creek limestone, McWain sandstone, Sorento limestone (new) Bunje limestone (new), Flat Creek coal (new), Witt coal (new), Coffeen limestone (new), and Millersville limestone; southeastern and eastern—Shoal Creek limestone, Mount Carmel sandstone, Flannigan coal, Reel limestone, Livingston limestone, and Millersville limestone; northern Illinois—Hall limestone and La Salle limestone. Presentation of new rock-stratigraphic classification for Pennsylvanian of Illinois. Cyclical classification is retained but is independent of rock-stratigraphic classification.

Type section: Composite of seven exposures (geol. section 8) in Bond, Montgomery, and Christian Counties. Named for Bond County. Reference section: Core from drill hole 59, Peabody Coal Co. NW¼NE¼ NW¼ sec. 33, T. 11 N., R. 1 E., Pana quadrangle, Christian County.

†Bone Canyon Member[1] or Limestone[1]

Permian: Western Texas.

Original reference: P. B. King and R. E. King, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 921, 922, 925.

In Bone Canyon, on west side of Guadalupe Mountains.

†Bone Lake Crystalline Schists[1]

Precambrian (middle Huronian): Northwestern Michigan.

Original reference: J. M. Clements, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 60.

Best developed in northern part of Crystal Falls district, in vicinity of Bone Lake.

Bone Spring Limestone[1]

Permian (Leonard Series): Western Texas and southeastern New Mexico.

Original reference: W. G. Blanchard, Jr., and M. J. Davis, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 962, pls. 10, 11.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 566–575, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 13–27, pls. Consists largely of limestones of varied types complexly interbedded and interfingered. Those laid down on shelf area outside Delaware basin, now exposed on Guadalupe Mountains and Sierra Diablo, are of different facies from those laid down within basin, now exposed in Delaware Mountains. Underlies Delaware Mountain group; overlies Hueco limestone and in some areas Wolfcamp series, undifferentiated. In Delaware Mountains, and as far north as Bone Canyon, exposed parts of formation are black cherty limestone in thin beds, with partings and a few members of shaly limestone and silic shale north of Bone Canyon; in Guadalupe Mountains, upper part of black limestone is replaced by thick-bedded gray limestone, Victorio Peak gray member, which forms capping stratum of Sierra Diablo. At top is Cutoff shaly member (new). Thickness several thousand feet.

D. W. Boyd, 1958, New Mexico Bur. Mines Mineral Resources Bull. 49, p. 3 (table 1), 12–14, pl. 1. Victorio Peak and Cutoff members mapped in Otero County, N. Mex.

Named for Bone Springs Canyon, which opens in sec. 2, Block 66, northwestern part of Culberson County, Tex.

Bone Valley Gravel[1] or Formation

Pliocene, middle: Southern central Florida.

Original reference: G. C. Matson and F. G. Clapp, 1909, Florida Geol. Survey 2d Ann. Rept., p. 138–141, table.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 18 (table), 203–208. Gravel makes up only small fraction of deposit; hence unit is here termed formation. Thickness about 50 feet. In type area, Bone Valley lies unconformably on limestone bedrock that is supposed to represent Hawthorn formation; farther north it presumably lies on Tampa and Suwannee limestones. Unconformably overlain by Pleistocene terrace deposits ranging in age from Sunderland to Pamlico. Probably merges southward into Caloosahatchee formation, but there are no known exposures in supposed transition area.

M. H. Bergendahl, 1956, U.S. Geol. Survey Bull. 1030–B, p. 70 (fig. 7), 79–84. Formation described in De Soto and Hardee Counties. Thickness as much as 35 feet. Generally, formation is considered to be Pliocene in age, but, until Miocene-Pliocene boundary is reestablished, age of formation cannot be categorically stated.

K. B. Kitner and L. J. McGreevy, 1959, U.S. Geol. Survey Bull. 1074–C, p. 65. Hawthorn formation of this report [area between Hernando and Hardee Counties, Fla.] includes (1) Hawthorn formation as redefined by Cooke (1945), (2) middle Miocene rocks in hard-rock phosphate belt including those generally assigned to Alachua formation, and (3) middle Miocene rocks in land-pebble phosphate district including noncalcareous rocks which have not always been distinguished from Bone Valley formation.

Named for exposures at town of Bone Valley, west of Bartow, Polk County.

Bonham Marl[1]

Bonham Clay (in Austin Group)

Upper Cretaceous (Gulf Series): Northeastern Texas.

Original reference: L. W. Stephenson, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, p. 8.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Chart shows Bonham marl below the Gober tongue of Austin chalk and above the Ector tongue.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 35. Foraminifera described. Bonham clay listed in Austin group.

Name for exposures a short distance north of town of Bonham, Fannin County, and for fact that town is located on the clay.

Bonita Beds (in Gila Conglomerate)

Pliocene(?) : Southeastern Arizona.

P. A. Wood, 1959, Arizona Geol. Soc. Guidebook 2, p. 60. Massive conglomerate characterized by basaltic and rhyolitic fragments. Range in thickness from about 400 to 800 feet. Disconformably underlie Solomonsville beds. At least pre-Blancan, probably Pliocene age. Name credited to W. L. Van Horn and L. A. Heindl (unpub. theses).

In eastern part of Safford Valley [Graham County].

Bonita Sandstone Member (of Franciscan Formation)

Bonita Sandstone (in Franciscan Group)[1]

Jurassic and Cretaceous: Northern California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416 (table).

U.S. Geological Survey currently classifies the Bonita Sandstone as a member of the Franciscan Formation on the basis of a study now in progress.

Named for exposures at Point Bonita, on north shore of Golden Gate.

Bonita Park Formation.

Cenozoic: Southeastern Arizona.

H. E. Enlows, 1955, Geol. Soc. America Bull., v. 66, no. 10, p. 1216 (table 1), pl. 1. Discussion of sequence of rocks in Chiricahua National Monument. Chiricahua limestone is succeeded by thick section of Lower Cretaceous Bisbee group with recognizable Glance conglomerate at base, and in turn, by section of what appears to be Morita formation. This sequence of Lower Cretaceous rocks is apparently similar to Outlaw formation (Raydon, unpub. thesis) described from area east of Paradise. Above Bisbee group is a 300-foot sequence of red beds and associated tuff named Bonita Park formation (Waller, unpub. thesis). May be equivalent to some of volcanic sediments of Raydon's Blacktail formation. The Bonita Park unconformably underlies Faraway Rock formation in Hands Pass region, just east of the Monument.

Mapped at Bonita Park, Chiricahua National Monument, Cochise County.

Bonnellian series[1]

Lower Cretaceous: Texas.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 64, no. 2, p. 138–139.

Named for Mount Bonnell, near Austin, Travis County.

Bonner Quartzite (in Missoula Group)

Precambrian (Belt Series) : Western Montana.

W. H. Nelson and J. P. Dobell, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–296. Pink crossbedded feldspathic quartzite; forms blocky rubble; outcrops relatively rare. Underlies McNamara argillite; overlies Miller Peak argillite.

Mapped in Bonner quadrangle. Type locality and derivation of name not given.

Bonner Springs Shale[1] or **Formation** (in Kansas City Group)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 111. In Kansas City group. Underlies Merriam limestone member of Plattsburg formation; overlies Farley limestone member of Wyandotte formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 34. Thickness in Nebraska 8 to 10 feet

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. In Schildberg quarry, NW¼SE¼ sec. 5, T. 75 N., R. 29 W., Madison County, consists of 4 feet of olive to dark-gray shale with a thin coallike layer near top; lower 3 feet contains numerous limestone nodules.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 24–25, fig. 5. Uppermost formation in Kansas City group. Consists of gray to black shale overlain by maroon shale that commonly contains limestone nodules Thickness commonly 10 feet. Overlies Wyandotte limestone; underlies Plattsburg limestone.

Type locality: Cement plant northeast of Bonner Springs, Wyandotte County, Kans.

Bonneterre Dolomite[1]

Upper Cambrian: Southeastern Missouri.

Original reference: F. L. Nason, 1901, Am. Jour. Sci., 4th, v. 12, p. 358–361.

Josiah Bridge, 1936, U.S. Geol. Survey Prof. Paper 186–L, p. 234 (table 1). Underlies Davis formation of Elvins group.

G. F. Brightman, 1937, (abs.) Missouri Acad. Sci. Proc., v. 3, no. 4, p. 120; 1938, Jour. Geology, v. 46, no. 3, pt. 1 p. 248–267. Includes Tom Sauk limestone member (new) at base.

Christina Lochman, 1940, Jour. Paleontology, v. 14, no. 1, p. 1–53. Formation varies in thickness throughout area, for it overlaps Lamotte sandstone and is to a certain degree still affected by irregularities in Precambrian surface. Average thickness 375 feet; maximum thickness 448 feet of Delassus on Bonneterre plain. Thickness decreases regularly southward with average of 200 feet in Madison County and minimum of 50 feet where unit lies directly on rhyolite porphyry. Twofold lithic division recognized: basal 50 feet, which is intricate sequence of interbedded and intergrading glauconitic sandstones, fine gray and yellow shales, fossiliferous crystalline limestone, and barren white or pink dolomites; and a 200- to 300-foot upper part, which is essentially a massive-bedded barren crystalline dolomite. Basal 50 feet carries late *Cedaria* fauna of more than 61 species. Upper Cambrian.

Named for exposures at Bonneterre, St. Francois County.

Bonnetian Age and Stage

Middle Cambrian: North America.

B. F. Howell and J. F. Mason, 1938, Jour. Paleontology, v. 12, no. 3, p. 297. Lower *Paradoxides bennetti* fauna, with *Dawsonia* and *Ehmania*, together with faunas which are correlated with them, are assigned a new age and stage name, Bonnetian.

Term taken from original name for Highland Range of Nevada.

†Bonneville Beds[1]

†Bonneville Group[1]

See **Lake Bonneville Beds.**

Bonneville Formation (in Lake Bonneville Group)

Pleistocene: West-central Utah.

C. K. Bullock, 1951, Utah Geol. and Mineralog. Survey Bull. 41, p. 21. Includes those deposits that accumulated in Lake Bonneville at its highest stage. Consists of gravel containing some cobbles and boulders in sandy matrix. Younger than Alpine formation and older than Provo formation (both new). Name credited to H. J. Bissell (unpub. thesis).

C. B. Hunt, H. D. Varnes, and H. E. Thomas, 1953, U.S. Geol. Survey Prof. Paper 257–A, p. 13, 20–21, pl. 1. Includes those deposits that accumulated during what Gilbert (1890, U.S. Geol. Survey Mon. 1) referred to as Bonneville stage. Thickness about 20 feet except at Point of the Mountains where formation was deposited in spit 300 feet high and extending 1 mile west from end of Traverse Mountains. Overlies Alpine or older formations. Included in Lake Bonneville group.

Forms thin and discontinuous beach deposit along old Lake Bonneville shore line. Deposits encircle Lake Mountain.

Bonpas Limestone Member (of Mattoon Formation)

Pennsylvanian: Central and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 41, 51 (table 1), 82, pl. 1. Proposed to replace name Calhoun limestone, in order to restrict name Calhoun to underlying coal. Stratigraphically below Omega limestone member. Medium gray, weathers with reddish cast; dense to finely crystalline, thick bedded; tends to be shaly in lower part. Thickness 3 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NE¼NE¼ sec. 6, T. 2 N., R. 14 W., Richland County. Named from Bonpas Creek, about 1½ miles east of type outcrop.

Bonsall Tonalite

Upper Cretaceous: Southern California.

C. S. Hurlbut, Jr., 1935, Am. Mineralogist, v. 20, no. 9, p. 611–613. Medium-grained plutonic rock presenting in outcrop a color of varying shades of gray which distinguishes it in the field from other intrusives. Characterized by dark inclusions. Shows marginal assimilation at contact with San Marcos Mountain gabbro which it intrudes.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, table facing p. 630. In Late Mesozoic plutonic sequence in central and northwestern San Diego County, Bonsall tonalite is listed as older than Lakeview tonalite and younger than Green Valley tonalite.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 58–62, pl. 1. In this report, name Bonsall tonalite replaces name Perris quartz diorite as used by Dudley (1935) and Val Verde tonalite used by Osborn (1939). Intruded by Woodson Mountain granodiorite and Indian Mountain granodiorite. Considered younger than Lakeview Mountain tonalite. Upper Cretaceous.

Richard Merriam, 1958, California Div. Mines Bull., 177, p. 14, 16 (fig. 2), Described and mapped in Santa Ysabel quadrangle. Younger than Green Valley tonalite. Cretaceous.

Name derived from village of Bonsall located slightly west of central portion of San Luis Rey quadrangle. Tonalite underlies approximately 100 square miles in San Luis Rey quadrangle; also present in Elsinore and Ramona quadrangles.

Bonta Formation

Miocene, upper(?): Northeastern California.

Cordell Durrell, 1957, Pacific Petroleum Geologist, v. 11, no. 3, p. 3. Hornblende and pyroxene andesite, volcanic conglomerate and mudflow breccia. Thickness about 750 feet. Unconformable below Penman formation (new); rests unconformably on Delleker formation (new) and all older rocks; unconformities marked by faulting.

Cordell Durrell, 1959, California Univ. Pub. Geol. Sci., v. 34, no. 3, p. 165 (fig. 1), 172–174. Predominantly andesite mudflow breccia, volcanic conglomerate, and volcanic fanglomerate. Thickness 100 to 750 feet. Underlies Penman formation. Rests in various places on granitic and metamorphic rocks and on Lovejoy, Ingalls (new), and Delleker formations. In many areas, lies across faults between two of older formations; in other areas has been faulted showing renewed movements on the faults. Upper Miocene on basis of fossil flora.

Named for Bonta Creek in south-central part of Blairsden quadrangle, Most representative area is in secs. 28 and 33, T. 23 N., R. 13 E.

Bony Falls Member (of Black River Formation)

Middle Ordovician: Northern Michigan.

R. C. Hussey, 1952, Michigan Dept. Conserv. Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14, 16, 17–22. Section at Bony Falls consists of about 40 feet of limestone, some of which is argillaceous and some finely crystalline dolomitic; a 2-inch layer of bentonite occurs about middle of section, and this may mark top of Black River. Evidence of subaerial erosion appears at several levels throughout section, and a very obvious disconformity near middle of section may represent a time break of considerable duration. Underlies Chandler Falls member (new) of Trenton formation. Separation of Black River rocks from Trenton above presents difficult problem; rocks of the two formations are commonly distinguished on basis of faunal changes that are not always very significant; deposition was practically continuous at some localities from Black River to Trenton time, and dividing line between the two formations becomes an arbitrary one.

Type locality: Sec 1, T. 41 N., R. 24 W., at Bony Falls on Escanaba River, Delta County.

Boone Formation[1]

Boone Limestone[1] or Chert

Lower and Upper Mississippian: Northern Arkansas, southwestern Missouri, and eastern Oklahoma.

Original reference: J. C. Branner and F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. xiii, 27–37.

L. M. Cline, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 9, p. 1132. St. Joe limestone, formerly considered member of Boone, here raised to formation rank. Term Boone should be suppressed as synonym of term Osage.

J. A. Straczek and D. M. Kinney, 1950, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–1. Boone chert mapped in Batesville manganese district. Includes St. Joe limestone member, locally, at base.

E. B. Brewster and N. F. Williams, 1951, Guidebook to the Paleozoic rocks of northwest Arkansas: Arkansas Resources Devel. Comm., p. 13, 14. Formation consists of limestone and chert which vary in relative proportions both horizontally and vertically. Thickness 300 to 350 feet in most of northern Arkansas. Includes Short Creek oolite member in upper part and St. Joe limestone member in basal part. In Yellville quadrangle, basal member of Boone lies at some place on every one of formations preceding it in stratigraphic section except the Joachim, Cotter, and Jefferson City. In northwestern Arkansas overlain by Batesville sandstone, Hindsville limestone, or Fayetteville shale.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Formation mapped in Oklahoma. In Ottawa County, includes at top some beds equivalent in part at least to Moorefield formation of several counties farther south and in northeastern part of state.

E. E. Glick, S. E. Frezon, B. R. Haley, 1956, Kansas Geol. Soc. Guidebook 20th Field Conf., cross section. Lower and Upper Mississippian.

R. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 1, 14 (fig. 2), 40–41. Osagean series, frequently referred to as "Boone chert," includes St. Joe, Reeds Spring, and Keokuk formations.

C. H. Behre, Jr., and A. V. Heyl, Jr., 1959, Deutsche Geol. Gesell. Zeitschr., v. 110, pt. 3, p. 517 (fig. 2). Chart shows Boone formation comprises (ascending) Reeds Spring, Grand Falls, and Short Creek members. Overlies Northview shale; underlies Carterville formation.

Named for extensive development in Boone County, Ark.

Boone Creek Limestone Member (of Palo Pinto Limestone)[1]

Pennsylvanian: Central northern Texas.

Original reference: J. M. Armstrong, 1929, Texas Bur. Econ. Geology, geol. map of Jack County.

Jack and Wise Counties, Brazos River region.

Boone Gap facies (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 119–121. Predominantly shale with minor amounts of limestone, siltstone, and clay. Thickness ranges from about 125 feet in Rockcastle County to nearly 275 feet in northeastern Estill County. Merges with Dicks River facies (new) on west and with Stanton facies (new) on east.

Underlies Conway Cut siltstone member of Brodhead formation, Irvine facies (all new); overlies New Albany shale.

Name derived from Boone Gap, at line between Rockcastle and Madison Counties, where there are excellent exposures in deep cuts on both sides of tunnel of Louisville and Nashville Railroad, and along U.S. Highway 25. Base of formation, in contact with New Albany shale, is exposed less than 1 mile north of tunnel, and top is exposed at roadcut a few feet above highway level at gap.

Booneville Stage[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow and H. M. Chance, 1896, New York Acad. Sci. Trans., v. 15, p. 51–52

Probably named for Booneville, Logan County, Ark.

Bootlegger Member (of Blackleaf Formation)

Lower Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2791–2793; 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 90. Predominantly interbedded medium-gray sandstone, gray siltstone, and dark-gray shale; massive sandstone at base. A few thin layers of chert-pebble conglomerate present. Beds of bentonite common in upper half of member and one bed attains thickness of 10 feet. Widespread thin sandstone at top, in which finely fragmented fish bones are very abundant, is diagnostic feature. Thickness 330 feet in composite type section. Overlies Vaughn bentonitic member (new); underlies Floweree member (new) of Marias River shale (new).

Composite type section: Begins near place where Bootlegger Trail crosses outcrop of member at NE cor. sec. 1, T. 21 N., R. 3 E., Cascade County, and extends westward for about 15 miles toward Muddy Creek along upper part of a south-facing escarpment. Bootlegger Trail, from which member is named, is a secondary road extending from Great Falls north toward Canada.

Bootlegger Cove Clay

Pleistocene: Alaska.

R. D. Miller and Ernest Dobrovolny, 1959, U.S. Geol. Survey Bull. 1093, p. 12 (table 1), 14–15, 35–48, pls. 1, 3, 5, 6, 9. Extensive blue-gray clay of lacustrine or estuarine origin. Thickness 14 to 126 feet. Separates the Knik from overlying Naptowne glacial deposits. Shows interglacial weathering. Pre-Wisconsin.

Typical sections are in SW¼NE¼ sec. 23, T. 14 N., R. 4 W., near Bootlegger Cove, Anchorage area. Exposed almost continuously from point about three-fourths mile southeast of Point Woronzof northward to point about one-half mile southwest of Eagle River Flats; north of the Flats exposed discontinuously in bluffs.

Boott Member (of Littleton Formation)

Lower Devonian: North-central New Hampshire.

M. P. Billings and others, 1945, Geologic map and structure sections of the Mount Washington quadrangle (1:62,500): New Hampshire State Plan. Devel. Comm. and Highway Dept. Consists of diopside granulite, diopside-actinolite granulite, actinolite granulite, actinolite-biotite schist, biotite schist and biotite-pyrite schist. Occurs near middle of Littleton formation.

M. P. Billings and others, 1946, Geol. Soc. America Bull., v. 57, no. 3, p. 264–266. Maximum thickness 65 feet. Type locality cited.

Named from Boott Spur 1.2 miles south-southeast of summit of Mount Washington, Coos County. Exposed in narrow belt extending north-northeast from Boott Spur Trail to within a few hundred feet of Cutler River in Tuckerman ravine.

Bopesta Formation[1]

Miocene, upper: Southern California.

Original reference: J. P. Buwalda, 1934, Pan-Am. Geologist, v. 61, no. 4, p. 310.

J. P. Buwalda and G. E. Lewis, 1955, U.S. Geol. Survey Prof. Paper 264–G, p. 148. Consists of tan and white fine and coarse quartzose sandstones containing some ash and volcanic debris, a few conglomerate beds, and some gray sandy shale beds. Thickness probably not less than 3,500 feet. Beds moderately deformed, with dips as much as 30°. Probably conformable on Kinnick formation; overlain by basic lavas, probably unconformably. Type section designated; derivation of name given.

Type section: From confluence of Cache Creek and its East Fork (which heads on south side of Cache Peak) in NW¼ sec. 1, T. 32 S., R. 34 E., to north side of Cache Peak, which is in sec. 20, T. 31 S., R. 35 E. Named from Bopesta Ridge, southwest of Cache Peak, Kern County.

Boquillas Flags[1]

Boquillas Formation

Upper Cretaceous: Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 29–33.

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1141–1143, pl. 1. Formation described in Buck Hill quadrangle. Overlies Buda limestone; underlies Buck Hill volcanics (Pruett formation). How much of Boquillas is Eagle Ford and how much Austin equivalent not determined.

C. G. Moon, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 157–170, pl. 1. Boquillas-Terlingua problem discussed. A 50-foot rock unit, herein named Fizzle Flat lentil, occurs in middle of Boquillas-Terlingua sequence in Agua Fria quadrangle.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol. Survey Prof. Paper 312, p. 10–12, pl. 1. Boquillas flags described in Terlingua district. Thickness about 1,000 feet. Divided into upper and lower member, plane of division being top of thin sandy limestone bed that represents faunal zone characterized by ammonite (*Crioceras*), found nowhere else in formation. This division of Boquillas into members is not a subdivision of Adkins' (Sellards, Adkins, and Plummer, 1933, Texas Univ. Bull. 3232) Boquillas flags, which includes only lower member; instead it is an extension of his and Udden's definition of formation to include rocks considered by them as more properly belonging to an overlying formation. Beds mapped as Boquillas flags therefore include lower part of what Adkins called Terlingua formation (restricted). Overlies Buda limestone; underlies Terlingua clay.

Named for Boquillas, Brewster County, on Tormillo Creek, Chisos Mountains quadrangle.

Boracho Limestone (in Sixshooter Group)

Cretaceous (Comanche Series): Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Name applied to strata lying between Finlay limestone below and Buda limestone above in Sixshooter group (new). Name credited to J. P. Brand and R. K. DeFord (in press). Described in area of this report (Wylie Mountains and vicinity) as hard pale-yellowish-brown fine-micrograined fossiliferous limestone with thin bands of marl. Approximate thickness 180 to 330 feet.

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 374 (fig. 2), 379-385. Described in Kent quadrangle where it comprises (ascending) Levinson limestone and San Martine members (both new). Middle formation in Sixshooter group. Overlies Finlay limestone; underlies Buda limestone. Deviation of name.

Name derived from Boracho Station on Texas and Pacific Railroad about 10½ miles west of Kent, Culberson County.

Boracho Sandstone

Cretaceous (Comanche Series): Western Texas.

W. E. Tipton, 1951, *in* West Texas Geol. Soc. Guidebook Fall Field Trip, Oct. 26–27, p. 29 (geol. map) Named on map legend.

Culberson County.

Borden Group[1] or Formation

Lower and Upper Mississippian: Indiana and Kentucky.

Original reference: E. R. Cumings, 1922, Handb. Indiana Geology, pt. 4, p. 408, 470 (footnote), 487–490, 492, 531, chart.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 1–248. In Kentucky, comprises (ascending) New Providence formation, Brodhead formation (embracing Locust Point and Carwood divisions of Indiana classification), Floyds Knob formation, and Muldraugh formation (embracing Lower Harrodsburg division and Edwardsville division of Indiana classification). Underlies Harrodsburg (restricted) of Warsaw age, Salem formation, St. Louis limestone, or Ste. Genevieve limestone; overlies Rockford limestone (in Indiana), New Albany shale, Bedford, or Sunbury shale. Age given as Osage. Report deals specifically with 225-mile belt in Kentucky, immediately bordering Lexington Plain and also discusses Lower Mississippian as a whole in east-central interior.

D. J. McGregor, 1958, Indiana Geol. Survey Bull. 15, p. 40 (table 7), 44. In southern Indiana, group comprises five formations (ascending): New Providence shale, Locust Point, Carwood, Floyds Knob, and Edwardsville. Group undifferentiated in northern Indiana. Overlies Rockford limestone: underlies Harrodsburg limestone. Osage series.

Well exposed near village of Borden, Clark County, Ind.

Borden Sandstone (in Monongahela Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, pl. 7.

Lies a short distance above Borden coal in Georges Creek basin.

†Border Conglomerate (in Newark Group)[1]

Upper Triassic: Eastern Virginia.

Original reference: J. K. Roberts, 1923, Pan-Am. Geologist, v. 39, p. 185–200.

Extends in a broken manner from Potomac River at Point of Rocks to Carolina line.

Boring Agglomerate

Pliocene, upper, or Pleistocene, lower: Northwestern Oregon.

R. C. Treasher, 1942, Oregon Dept. Geology and Mineral Industries G. M. I. Short Paper 7, p. 10, geol. map. Structureless mass with tuffaceous matrix containing cobbles and fragments of lava and pieces of wood that are so unaltered that they may be burned.

R. C. Treasher, 1942, Geologic map of the Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. Thickness as much as 100 feet. Lies immediately above Troutdale formation on ridges and hillslopes except where it is intracanyon; lies immediately below Boring lava and represents an opening phase of Boring lava volcanism.

Occurs in Portland area.

Boring Lava

Pliocene, upper, to Pleistocene, lower(?): Northwestern Oregon.

R. C. Treasher, 1942, Oregon Dept. Geology and Mineral Industries G. M. I. Short Paper 7, p. 10, geol. map. Name applied to series of lava flows that spread from number of vents over long period of time.

R. C. Treasher, 1942, Geologic map of the Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. Described as gray basalts containing abundant olivine phenocrysts. Thickness as much as 100 feet. Overlies Troutdale formation and Boring agglomerate; older than terrace gravels and glacial outwash.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 10, 12, pl. 2. Interbedded with Troutdale formation; at its type locality, lava underlies Portland Hills silt member of Troutdale; at Crown Point, a 30-foot flow of Boring lava is referred to as Crown Point member of the Troutdale; in southern part of area, the lava overlies Molalla formation. Age restricted to upper Pliocene.

D. E. Trimble, 1957, U.S. Geol. Survey Geol. Quad. Map GQ-104. Described in Portland quadrangle. Younger than lower Pliocene Troutdale formation; in Sandy River area overlain by deposits thought to be early or middle Pleistocene. Lavas therefore may be wholly Pliocene in age or they may be in part early Pleistocene.

Named for occurrence on Boring Hills southeast of Portland. Caps Troutdale Hills, east of Willamette River; caps Portland Hills and covers Oswego Lake depression; also intracanyon in three canyons in Portland Hills.

Borrego Formation

Pliocene, upper, or (?)Pleistocene, lower: Southern California.

L. A. Tarbet and W. H. Holman, 1944, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1782. Nonmarine mudstone, siltstone, sandstones, and conglomerates probably unconformably overlying all older rocks. Thickness as much as 7,600 feet.

J. W. Durham, 1950, Geol. Soc. America Mem. 43, table facing p. 20. Upper Pliocene.

L. A. Tarbet, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 261 (fig. 40), 262. Lower Pleistocene(?). Thickness 8,600 feet. Shown on columnar section as overlying Palm Spring formation and underlying alluvium lake deposits.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 23 (fig. 2), 24, pl. 2. Mapped as lacustrine facies of Palm Spring formation. In type section, Borrego lake beds grade downward into terrestrial beds of Palm Spring facies and are overlain by Ocotillo conglomerate (new). Formation reaches maximum thickness of 6,000 feet in Borrego Badlands, and thins eastward to 2,000 feet.

Type section: Borrego Badlands, Imperial Valley.

Boscabel Boulder Beds[1]

Upper Triassic: Eastern Virginia.

Original reference: N. S. Shaler and J. B. Woodworth, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 424–425.

Well exposed at Boscabel Ferry, Richmond Basin.

Boskydell Sandstone (in Tradewater Group)

Boskydell marine horizon (in Pottsville Formation)

Pennsylvanian: Southwestern Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 34, 76. Boskydell marine horizon—a calcareous marine sandstone in upper Pottsville, between Finnie sandstone above and Willis coal.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, *in* C. O. Dunbar and L. G. Henbest, Illinois Geol Survey Bull. 67, p. 17 (fig. 3), 20. Listed as sandstone in Tradewater group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31. Name dropped from formal usage.

Exposed 1 mile southwest of Boskydell, Jackson County.

†Bosque division[1]

Lower Cretaceous (Comanche Series): Oklahoma and Texas.

Original reference: J. A. Taff, 1892, Texas Geol. Survey 3d Ann. Rept., p. 272–273, 281–325.

Named for Bosque River.

Bossardville Limestone (in Cayuga Group)[1]

Silurian: Northeastern Pennsylvania and northern New Jersey.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 77, 141–145.

C. K. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1183, measured sections. Keyser limestone and its correlates are underlain in area [southeastern Pennsylvania] in descending order by Bossardville limestone, Poxono Island shale, and Bloomsburg red beds. Where typically developed in vicinity of Delaware Water Gap, the Bossardville consists of three parts. Major (central) beds are blue-black dense limestone. Underlying these beds, at many places, are thin-bedded gray finely straticulate and somewhat shaly limestones. Overlying central beds, locally, is a few feet of thick-bedded impure limestone, weathering yellowish. White (1882) describes green shales, the Deckers Ferry "shale" which present writers have not seen, as lying at top of formation. Poxono Island shale and Bossardville limestone are similar to, and homotaxial with, Wills Creek shale and Tonoloway limestone, respectively, of central Pennsylvania and Maryland but lie in a different province; the corresponding formations differ in their time limits; both are believed to be later than Wills Creek shale.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 253. Bossardville limestone of previous West Virginia reports is replaced by Tonoloway limestone.

Named for Bossardville, Monroe County, Pa.

Bossier Formation (in Cotton Valley Group)

Upper Jurassic: Subsurface in western Louisiana, southern Arkansas, and eastern Texas.

F. M. Swain. 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 582–594. Includes the marine dark-gray to black shale and sandstone and shoreward equivalents of these rocks beneath Schuler formation and above Buckner formation or its basinward equivalent. In type well, occurs between depths of 6,515 and 8,140 feet. Thickness varies from knife edge where it is overlapped by Schuler formation to almost 2,000 feet on flank of North Lisbon field in east-central Claiborne Parish, La. Relationship to underlying Buckner formation not clear; in some areas the Bossier rests directly on Smackover limestone.

Type well: Phillips Petroleum Co. Kendrick No. 1, C., NE¼SW¼ sec. 22, T. 19 N., R. 11 W., Bossier Parish, La., Bellevue Field Deep Test.

†Boston Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 53–57, 61, 81, 84, 86, chart.

Named for occurrence in Albany and Boston mine, Houghton County.

Boston Glacial Substage

Pleistocene (Wisconsin): Northeastern Massachusetts.

S. S. Judson, Jr., 1949, Peabody Foundation for Archeology Papers, v. 4, no. 1, p. 12–23. Name proposed for substage which includes genetically related deposits of till, clay, sand, and gravel. Older than Lexington glacial substage (new). Relation to glacial sequences in other areas of North America unknown.

Named for good exposures in Boston area. No type locality designated because of temporary nature of artificial exposures.

†Boston Group[1]

Mississippian and Pennsylvanian: Northwestern Arkansas and northeastern Oklahoma.

Original reference: J. C. Branner, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. xii.

Named for Boston Mountains, Washington County, Ark.

Boston Basin Series[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. E. Hobbs, 1899, Am. Geologist, v. 23, p. 109–113.

East of west rim of Boston Basin.

Boston Bay Group[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. E. Hobbs, 1899, Am. Geol., v. 23, p. 109–113.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6, column 5a. Age shown as Pennsylvanian but is uncertain; may include Devonian, Mississippian, and Permian.

Occurs in Boston Basin which borders Boston Bay.

Boston Neck Granite[1]

Upper Carboniferous or post-Carboniferous: Southern Rhode Island.

Original reference: F. H. Lahee, 1912, Am. Jour. Sci., 4th, v. 33, p. 365, 449, 454–469.

Occurs at various places along west coast of Narragansett Bay from Watson's pier southward, and inland on Little Neck, Boston Neck, and Tower Hill.

Bostwick Conglomerate or Beds (in Lake Murray Formation)

Bostwick Limestone (in Dornick Hills Group)

Bostwick Member (of Dornick Hills Formation)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 14.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Shown on correlation chart as Bostwick limestone in Dornick Hills group. Lampasas series.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 140, 141 (fig. 3) Rank reduced to member status in Lake Murray formation (new). Underlies Griffin sandstone member (new).

Lynn Jacobsen, 1959, Oklahoma Geol. Survey Bull. 79, p. 32–33. Bostwick conglomerate at base of Lake Murray formation is most prominent exposed unit in Ardmore basin. Consists of limestone and chert conglomerate, sandstone, limestone, and shale. Maximum thickness 500 feet.

Type locality: On Bostwick dairy farm, in W½NE¼ sec. 11, T. 5 S., R. 1 E., Carter County.

Botetourt Formation

Botetourt Limestone Member (of Edinburg Formation)

Middle Ordovician: Western Virginia and eastern Tennessee.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 80, 103, 106. Botetourt limestone member proposed for brown-weathering granular limestone above Lincolnshire formation and below beds of Liberty Hall type. Thickness 15 to 75 feet (type section).

G. A. Cooper, 1956 Smithsonian Misc. Colln., v. 127, pt. 1, p. 49–50. Rank raised to formation. In Catawba Valley northeast of Blacksburg, underlies or interfingers with calcarenites of Effna formation. At Edinburg dam section about 1 mile below Edinburg and at Tumbling Run 1½ miles southwest of Strasburg, Va., dark thin-bedded limestone occurs between granular beds thought to be Botetourt and the cherty Lincolnshire; these beds are here placed in Botetourt formation. Can be recognized in parts of Tennessee as at type section of the Whitesburg of Ulrich; at this place its overlies the Lenoir and occurs at the base of Ulrich's Whitesburg formation.

Type section: In Botetourt County, Va., on deeply gullied hillsides about 0.25 miles south of Dunkard Church and 6.0 miles S. 80° W. of Natural Bridge.

Botijas Limestone Member (of Coamo Formation)

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 149–150. Rudistid-bearing limestone that occurs locally in lower red part of formation in north-central Puerto Rico. Name credited to Briggs and Gelabert (in preparation).

North-central part of island.

Bouchard Formation (in Missoula Group)

Precambrian (Belt Series): Northwestern Montana.

A. B. Campbell, 1960, U.S. Geol. Survey Bull. 1082-I, p. 567–568, pl. 28. Olive-gray, olive-brown thin- to medium-bedded sericitic quartzite and interbedded dark-olive-gray to olive-black argillite more abundant near bottom and top of section. A few beds of vitreous white quartzite and dark-gray fissile shale. Weathers rusty brown to olive drab. Thickness about 4,000 feet. Conformably overlies Sloway formation (new); unconformably underlies vitreous quartzite of Middle Cambrian age.

Type section: In secs. 24 and 25, T. 16 N., R. 26 W. Named for exposures near Bouchard Lake in sec. 23, T. 17 N., R. 27 W., St. Regis-Superior area, Mineral County.

Boucher Formation

Middle Cambrian: Northwestern Vermont.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Name used only on correlation chart. Underlies St. Albans shale; overlies Parker slate. Name credited to Shaw (unpub. thesis).

Boucher Tongue [of Muav Formation]

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 101–102. Composed of thin beds of rusty-brown dolomite. On fresh surface, dolomite appears steely gray and typically even grained, with crystals averaging 0.25 or 0.30 mm. In places, grades into brownish siltstone. Younger than Parashant tongue (new).

Extends southeastward from vicinity of Garnet Canyon at least as far as Cottonwood Canyon, a distance of 25 miles. Grand Canyon area.

Boulder Creek Granite or **Granodiorite**

Boulder Creek Granite (in Pikes Peak Group)

Boulder Creek Granite Gneiss[1]

Precambrian: Central northern Colorado.

Original reference: M. F. Boos and C. M. Boos, 1934, Geol. Soc. America Bull., v. 45, no. 2, p. 305–306.

J. M. Bray, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 768 (fig. 1), 769–770. In this report, Pikes Peak group includes (ascending) Boulder

Creek granite and Overland Mountain granite (new). Younger than Swandyke hornblende gneiss.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 25–27, pl. 1. Commonly dark-gray faintly banded rock that ranges from quartz monzonite to sodic granite. Chiefly coarse-grained primary gneiss, which is locally porphyritic. Near centers of large masses, gneissic structure is not prominent, and rarely color changes to pinkish gray or pink becoming indistinguishable from facies of Pikes Peak granite.

Crops out widely on Boulder Creek, on east flank of Front Range, west and southwest of Boulder, Boulder County.

†Boulder Pass Formation[1]

Precambrian (Belt Series): Northwestern Montana, and southwestern Alberta, Canada.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1900. Term Missoula antedates and reduces to synonymy the Boulder Pass formation.

Section made up from near Boulder Pass, south of Ahern Pass, Glacier National Park, Mont., and in Waterton Lakes National Park, Alberta.

Boulder River Sandstone Member (of Colorado Shale)

Lower Cretaceous: Southwestern Montana.

P. W. Richards, 1957, U.S. Geol. Survey Bull. 1021–L, p. 415–416, pl. 34. Discussion of area east and southeast of Livingston, Mont. Here Colorado shale is divided into 10 units, and these are compared, where possible, with Black Hills and central Montana or Bighorn Basin formations. Unit 7, a thick-bedded or massive sandstone about 100 feet thick, is herein named Boulder River sandstone member. Forms cliffs and ridges between less resistant shale sequence below and thin-bedded sandstone above. On south slope of a hill west of West Boulder River in NE¼ (unsurveyed) sec. 26, T. 3 S., R. 11 E., Park County, member is about 65 feet thick and consists of gray to yellowish-brown mostly fine-grained sandstone. Above it, and below crest of hill, are 145 feet of thin-bedded, in part shaly, sandstone.

Section measured in SE¼ sec. 11, T. 3 S., R. 12 E., in McLeod Basin quadrangle along west side of Boulder River valley. Member forms almost continuous ridge from Boulder River westward to Yellowstone River south of Livingston.

Boulder Wash Group

Precambrian(?) or Tertiary(?): Southeastern Nevada.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, p. 1407–1409. Stratified series, lower part of which is dark-gray compact heavy dolomite that weathers rusty yellow brown, and is interrupted by thin layers of greenish compact shale 3 or 4 feet above base of unit; maximum thickness 200 feet. Above dolomite and separated from it by highly irregular surface of erosion is coarse breccia which fills valleys in the dolomite; thickness several hundred feet and probably exceeds 1,000 feet. Total thickness possibly exceeds 2,000 feet. Unconformably overlies Precambrian schist. Precambrian(?).

F. A. Nickell, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 12, p. 1804 (fig. 2). Breccia, dolomite, andesite, rhyolite, and intrusives. Tertiary(?).

North of Colorado River Canyon and west of Boulder Wash, Clark County.

Bouldin Member (of Lake Waco Formation)

Cretaceous (Gulf Series): Central Texas.

W. S. Adkins and F. E. Lozo *in* F. E. Lozo, 1951, Fondren Sci. Ser., no. 4, p. 120–121, 139 (fig. 17), 141 (fig. 18). Proposed for upper member of formation. Composed of interbedded grayish-white to brownish silty limestone and silty shales with bentonites. Thickness at type locality about 9 feet. Northward from Travis County, a flagstone member near to or identical with stratigraphic position of type Bouldin flags occurs at scattered localities across Williamson, Bell, and McLennan Counties; as exposed in Blue Cut north of Moody, this limestone flag unit is approximately 14 feet thick. Overlies Cloice member (new); underlies emended South Bosque formation.

Type locality and section: Bouldin Creek and diversion cut near the Missouri Pacific-Missouri, Kansas and Texas Railroad, between Milton Street and Barton Springs Road, Austin, Travis County.

Boundary Argillite[1] (in Stevens Series)

Cambrian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 81, map.

C. D. Campbell, 1947, Geol. Soc. America Bull., v. 58, no. 7, p. 611. Remapping of northeastern Stevens County and discovery of Cambrian and Ordovician fossils are thought to justify adoption there of formation names established by Park and Cannon (1943) for Metaline quadrangle. Part of Boundary argillite is considered correlative to Metaline limestone, part correlative to Maitlen phyllite, and part correlative with Gypsum quartzite.

Probably named for its occurrence near international boundary, Stevens County.

Boundary Granodiorite[1] (in Coast Range Intrusives)

Jurassic or Cretaceous: Southeastern Alaska.

Original reference: A. F. Buddington, 1929, U.S. Geol. Survey Bull. 807, p. 32–33, 55–59, maps.

F. M. Byers, Jr., and C. L. Sainsbury, 1956, U.S. Geol. Survey Bull. 1024–F, p. 126. Mentioned in report on tungsten deposits of Hyder district. In upper part of Coast Range intrusives.

Named for exposures along both sides and at head of Boundary Glacier from about 1 mile above its foot; Hyder district.

Boundary Shale

Eocene, upper: Western Washington.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 123, 124, 125, 126. Mentioned in discussion of stratigraphy in Lyre River area. In measured stratigraphic section of Crescent, Lyre, and Lincoln formations in canyon of Lyre River, Clallam County, the Lyre formation is said to rest conformably upon Boundary shale, which forms uppermost part of middle Eocene Crescent formation.

W. S. Drugg, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1682. Boundary shale, in Hoko River area, is in fault contact with Crescent beds. Siltstones of Boundary shale grade upward into Lyre conglomerate.

Derivation of name not stated.

Boundary Peak Granite[1]

Middle or Late Mesozoic: Central eastern California.

Original reference: G. H. Anderson, 1935, Pan-Am. Geologist, v. 64, no. 1, p. 66.

G. H. Anderson, 1937, Geol. Soc. America Bull., v. 48, no. 1, p. 8–11. The granites [Pelliser and Boundary Peak] are probably equivalent in age to the Sierra Batholith—middle or upper Mesozoic. Derivation of name given.

Composes Montgomery Peak and Boundary Peak, at extreme end of Inyo Range.

Bouquet Canon Breccia[1]

Miocene(?) : Southern California

Original reference: A. O. Woodford, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 7, p. 212.

Lower Bouquet Canon, 30 miles north of Los Angeles and 5 miles northeast of Saugus.

Bourbon Group or Formation[1]

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., Guidebook, p. 90, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2028. Suppressed in favor of Pleasonton group.

Named for Bourbon County, Kans.

Bourbon series[1]

Middle Ordovician: Kentucky.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 55, p. 231.

Named for Bourbon County.

Bow Formation or Group[1]

[Upper Cretaceous] : Southern Wyoming.

Original references: A. C. Veatch, 1907, Jour. Geology, v. 15, p. 548; 1907, Am. Jour. Sci., 4th, v. 24, p. 18–22; C. F. Bowen, 1918, U.S. Geol. Survey Prof. Paper 108, p. 229.

Medicine Bow River.

Bowen Formation

Middle Ordovician: Southwestern Virginia and northeastern Tennessee.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 840–841, 876–877, 884 (fig. 3), pl. 5. In Tazewell County, strata embraced by Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Bowen formation is applied to zones 20 and 21; lower zone is brown-weathering calcareous sandstone and upper is red mudrock tongue; these are 14 feet and 60 feet thick, respectively. The sandstone pinches out 8 miles northeast of Russell-Tazewell County line; beyond this point and northeastward to Burkes Garden, Marys Chapel, and Five Oaks, the Bowen is represented only by tongue of red mudrock. Where both zones of the Bowen occur, there is evidence of disconformity between sandstones of Bowen and underlying buff shales of Wardell formation (new); in middle part of Tazewell County, the hiatus between the buff shales and overlying red mudrocks is indicated by absence of zone of brown mudstone; east of meridian of Tazewell, the hiatus includes part of red mudrock which pinches out entirely a few miles northeast; contact with overlying limestones of Witten limestone (new) are conformable. Throughout its extent in Virginia, southwest of Bluefield, beds herein named Bowen formation have been classified by Butts as lower part of the Lowville-Moccasin.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1171–1172. Southwest from Tazewell, Va., the Bowen is traced in both Copper Creek and St. Paul belts into Tennessee. Sandstone, ordinarily less than 15 feet thick in Virginia, thickens gradually into Tennessee. Mudrock phase varies from about 40 to 100 feet in thickness, locally attains thickness of about 175 feet at Thorn Hill. At Heiskell, Tenn., both sandstone and claystone phases are present between underlying Wardell and overlying Witten limestone. In Knoxville belt, allochthonous to Saltville thrust, the Bowen is present in several places between Knoxville and Lenoir City, and thickness may be as much as 200 feet in places. The sandstone occurs at top of the Sevier and is separated from maroon Moccasin claystone by a few feet of limestone probably of Witten age.

Type section: Along State Highway 91, one-half mile south of intersection with County Road 604, Tazewell County, Va. Name derived from Bowen Cove at northwest base of Short Mountain and along County Road 609, west of Maiden Spring.

Bowes Member (of Piper Formation)

Middle Jurassic: Central and eastern Montana (subsurface and surface).

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 97, 102–103. Displays varying lithologies, being represented in Williston basin by red to varicolored shale facies which grade westward into sandstone and sandy oolitic limestone on east flank of Sweetgrass arch. In type section, consists of (descending) 18 feet of light-brown finely crystalline to fragmental limestone, very sandy to argillaceous in part with few thin stringers of light-gray calcareous sandstone; 7 feet of light-gray fine- to coarse-grained very calcareous sandstone; 20 feet of light-gray oolitic to sandy limestone with thin beds of calcareous sandstone; and 12 feet of light-brown fine-grained calcareous sandstone grading downward into light-gray sandy and partly oolitic limestone. Becomes increasingly sandy and somewhat variable in thickness west of type well; eastward becomes interbedded with shale and eventually grades into varicolored shale, thickness uniform. Conformably overlies Firemoon limestone member (new) in Williston basin and most of north-central Montana; southward it overlaps Firemoon member and unconformably overlies Madison limestone. Underlies Rierdon formation.

Type section: The interval 3,360 to 3,417 feet in Northern Ordnance No. 1 Guertzgen well, SW¼NW¼NE¼ sec. 2, T. 31 N., R. 19 E., Blaine County, Montana.

Bowhan Sandstone Member (of Vamoosa Formation)

Bowhan Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Virgil Series) : Northeastern Oklahoma and southeastern Kansas.

Original reference: M. I. Goldman and H. M. Robinson, 1920, U.S. Geol. Survey Bull. 686–Y, p. 361–362, pl. 51.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 12 (fig. 1), 48, pl. 1. Reallocated to Vamoosa formation. Occurs 110 to 140 feet above Cheshewalla sandstone member. Together with overlying Jonesburg sandstone member, the Bowhan extends northward across State line into Kansas.

Named for exposures at Bowhan Point, sec. 16, T. 28 N., R. 11 E., Osage County, Okla.

Bowie Shale Member (of Mesaverde Formation)[1]

Upper Cretaceous: Central western Colorado.

Original reference: W. T. Lee, 1909, U.S. Geol. Survey Bull. 341, p. 320 (table), 322.

E. C. Dapples, 1939, Econ. Geology, v. 34, no. 4, p. 371. Strata near village of Baldwin previously identified as Bowie herein named Baldwin sandstone member of Mesaverde formation.

J. D. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 19. Resting on Rollins sandstone member of Mesaverde of Lee (1912, U.S. Geol. Survey Bull. 510) in Grand Mesa field lie (ascending) Bowie shale member, Paonia shale member, and undifferentiated upper Mesaverde. Lee distinguished Bowie shale as of marine and brackish-water origin and the Paonia as fresh-water origin. Paonia member rests, according to Lee, on Rollins sandstone member in western part of Grand Mesa area, but toward the east, Bowie member appears and gradually thickens eastward. According to Boyer (written commun.) Lee misidentified his units in western part of Grand Mesa area. Upper member of Sego sandstone of present report was mistaken for the Rollins, and strata between upper Sego and Rollins were referred to Bowie shale member.

Typically exposed at Bowie, Delta County.

Bowknot Bed (in Church Rock Member of Chinle Formation)

Upper Triassic: Southeastern Utah.

J. H. Stewart, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 447 (fig. 3), 459; J. H. Stewart and others, 1959, U.S. Geol. Survey Bull. 1046–Q, p. 503 (fig. 73), 518, 519, 520 (fig. 79). Prominent sandstone unit in middle part of Church Rock member.

Present near junction of Green and Colorado Rivers.

Bowler Formation[1]

Permian and Triassic: Central southern Montana.

Original reference: J. P. Rowe, 1906, Montana Univ. Bull. 37, geol. ser. No. 2, p. 81.

Type locality not stated, but judging from list of occurrences on page 16 it is town of Bowler, Carbon County.

Bowling Green Limestone Member (of Edgewood Limestone)[1]

Lower Silurian: Northeastern Missouri and southwestern Illinois.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59, 62.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 16, 19, 20, 21. In Bowling Green quadrangle, typically a brown to dusky-yellow dolomite or dolomitic limestone that is normally gray-blue-green on fresh exposure. Thickness 2 to 40 feet. Underlies Cyrene member; overlies Maquoketa formation; in some areas relationship is uncomformable.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 99. In some areas, underlies Cuivre shale (new).

Named for exposures near Bowling Green, Pike County, Mo.

Bowman Limestone[1]

Middle Cambrian: Central northern Utah.

Original reference: J. Gilluly, 1932, U.S. Survey Prof. Paper 173.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 20. Term Bowman extended into Stansbury Range where it is used to include a series of olive-drab shale and interbedded limestone between Herkimer formation below and Bluebird formation above. Thickness approximately 435 feet; apparently wedges out completely to south. Well exposed in headwaters of Timpie Valley and southward into Muskrat Canyon.

Named for exposures in Bowman Gulch northwest of Ophir, Oquirrh region, Tooele County.

Bowmanstown Chert (in Onondaga Group)

Bowmanstown Chert Member (of Onondaga Formation)

Lower or Middle Devonian: Eastern Pennsylvania.

F. M. Swartz, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 52, fig. 17. Chert about 60 feet thick; underlies Palmerton sandstone; overlies Oriskany conglomerate. Onondaga group. Middle Devonian.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 1145–1146, 1147, 1150, 1151, 1153, 1157. Detailed descriptions of several sections given. Thickness varies from 13 to 111 feet.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart gives age as Lower or Middle Devonian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Onondaga formation as mapped includes Bowmanstown chert member in Lehigh Gap area.

Type locality not stated, but unit described near Bowmanstown, Carbon County.

Bowmanville Interglacial Substage

Pleistocene (Wisconsin): North-central United States.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529, 549, 550. Name introduced for the Cary-Mankato intraglacial substage. Name was used by Baker (1920, Illinois Univ. Bull., v. 17, no. 41) for low-water stage of Lake Chicago which occurred when Cary glacier receded to north and cleared the Straits of Mackinac. Presentation of classification of Wisconsin glacial stage. Report also gives consideration to other classifications, including one proposed by Frye and Willman (1960, Illinois Geol. Survey Circ. 285).

Bowring Limestone Member (of Vamoosa Formation)

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 43–44, pl. 1. Name applied to limestone unit occurring above Cheshewalla sandstone member in Lake Hulah area. Thickness 1 to 2 feet.

Type section: In NE¼ sec. 10, T. 28 N., R. 11 E., Osage County. Named for village of Bowring.

Bowser Formation (in Tuxedni Group)

Bowser Member (of Tuxedni Formation)

Middle(?) and Upper Jurassic: Central southern Alaska.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Consists of thick-bedded to massive sandstone and conglomerate units 100 to 300 feet thick, interbedded with siltstone units 100 to 600 feet thick. Cliff-forming sandstone unit, 500 to 800 feet thick, forms top of member. Siltstone is dark gray, or light gray where calcareous, and weathers light brown. Sandstone partly light gray, partly very dark gray to black. Thickness of member about 2,600 feet. Underlies Tonnie siltstone member; overlies Cynthia Falls sandstone member.

U.S. Geological Survey currently classifies the Bowser as a formation in Tuxedni Group and designates its age as Middle(?) and Upper Jurassic on the basis of a study now in progress.

Crops out over large area of Iniskin Peninsula and is well exposed in valley of Bowser Creek.

Box Member (of Percha Shale)

Upper Devonian or Lower Mississippian: Southwestern New Mexico.

F. V. Stevenson, 1944, Dallas Digest (Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Joint Ann. Mtg.), p. 95. Commonly composed of gray to green calcareous shales with intercalated lenses and nodules of limestone. Upper part of Percha shale. Overlies Ready Pay member (new) with gradational contact.

F. V. Stevenson, 1945, Jour Geology, v. 53, no. 4, p. 241, 243, figs. 2, 13. Upper Devonian age. Becomes progressively more calcareous to the west of Hillsboro; on Bear Mountain, northwest of Silver City, interbedded in shale are many massive beds of limestone, one attaining maximum of 16 feet. Total thickness 46½ feet. Unconformably underlies Lake Valley limestone. Derivation of name given.

M. A. Stainbrook, 1947. Jour. Paleontology, v. 21, no. 4, p. 298. Upper, lighter shales of Percha termed Bella by Keyes (1908). There is little doubt that Bella and Box were proposed for identical division of Percha, and there is little reason to replace earlier name. Percha of early Mississippian age.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 59 (fig. 28), 79 (fig. 39). Underlies Caballero formation and Andrecito member (new) of Lake Valley formation in parts of southwestern New Mexico.

Named for "The Box," the narrow canyon in Mimbres Mountains through which Percha Creek flows eastward into Rio Grande.

Box Butte Member (of Sheep Creek Formation)

Miocene: Northwestern Nebraska.

R. C. Cady, 1940, Am. Jour. Sci., v. 238, no. 9, p. 663–667. Proposed for member in uppermost part of formation. At type section, consists of three parts: lower, 30 to 40 feet, red and green clay with white concretions, limy sandy silt containing thin beds of brown blocky sandstone, and lumpy brown sandstone that weathers into a honeycomb ledge;

middle, 25 feet, lumpy and blocky brown sandstone in beds less than 2 feet thick containing two honeycomb limy ledges; and upper, 40 feet, partly covered, predominantly green clay with limy white concretions. Exposures showing middle sandstone zone are limited to northern part of Box Butte County, where Niobrara Valley cuts it; elsewhere member consists wholly of clay. Sheep Creek formation, exclusive of Box Butte member, fills narrow channels in top of Marsland formation. Top of Marsland is a white limy slabby caprock as much as 5 feet thick; in most exposures the Box Butte rests upon this cap rock. Sheep Creek channel was filled with brick-red silt and sand; at top of channel fill, the silt was cemented with lime; red clay of lower zone of Box Butte member rests upon this cemented zone. Unit occupies position in geologic column of area between earliest recognized Pliocene (Ogallala) beds and latest known Miocene (Sheep Creek) beds.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 131–132. Uppermost member of formation. No direct contact between the Box Butte and the Sand Canyon member (new) was observed. Topographically higher outcrops of Box Butte clays north of outcrops of Sand Canyon member at its type locality are considered as indicating higher stratigraphic position of the former.

Type section: In sec. 27, T. 28 N., R. 49 W., Box Butte County.

Box Canyon Member (of Mutual Quartzite)

Precambrian: Northeastern Utah.

N. C. Williams, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2737 (fig. 2), 2738. Sequence of buff quartzitic sandstones and brown micaceous shales at top of Mutual quartzite. Intertongues in places with purple beds. Thickness 820 feet at Box Canyon. Underlies Red Pine shale (new).

Top of member exposed precisely at mouth of Box Canyon, a tributary to Red Pine Creek near forks in Smith and Morehouse Canyon of western Uinta Mountains. Member exposed upstream from mouth of Box Canyon.

Box Canyon Rhyolite Tuff

Tertiary: Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 29–30, pl. 1. Described as a typical ignimbrite or welded tuff. Structure is massive; color is cream, gray, or pink. Throughout its occurrence, it forms a plate 40 to 75 feet thick. Lies conformably on Mimbres Peak rhyolite, except in its northernmost exposures, where it lies on Kneeling Nun rhyolite.

Found only in upper 4 miles of Box Canyon, Dwyer quadrangle. Largest outcrop is on southeast slope of Mimbres Peak, where its thickness is about 75 feet.

Box Elder Limestone[1]

Lower Ordovician: Northeastern Utah.

Original reference: E. Blackwelder, 1910, Geol. Soc. America Bull., v. 21, p. 519.

Northern Wasatch Mountains.

Box Springs Complex

Precambrian(?): Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 477. Metadiorite-granite complex. The complex dips 50° to 70° into the mountainside so that the exposed thickness is at least 1,500 feet. In northern part of mountains, a granite stock, nearly 2 miles across, cuts the complex, and Perris quartz diorite cuts it on southwest. Tentatively regarded as early Precambrian, but may be much younger.

Well exposed in Perris block in steep southwestern face of Box Springs Mountains, east of Riverside, Riverside County.

Boyer glaciation

Boyer till[1]

Pleistocene: Iowa.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 55, p. 284.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 69, no. 2, p. 129. Referred to as glaciation.

Boyle Limestone[1]

Middle Devonian: Central Kentucky.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 10, 92.

A. C. McFarlan and W. H. White, 1952, Kentucky Geol. Survey, ser. 9, Bull. 10, p. 5–16. Discussion of Doyle-Duffin-Ohio shale relationships. In Kentucky outcrop overlap is by Jeffersonville limestone in west and Boyle limestone in south and east. Locally rests on Waynesville or Estill.

Named for Boyle County.

Boyles Sandstone Member (of Pottsville Formation)[1]

Pennsylvanian: Northern central Alabama.

Original reference: Charles Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 27. In Warrier field, the thick basal sand of the Pottsville is called Boyles sandstone member.

Named for exposure at Boyles Gap, north of Birmingham, Jefferson County.

Boylston Schist[1]

Carboniferous: Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 61, 67–68, map.

Eastern part of Worcester County.

Boysen Formation

Upper Cambrian: North-central and northwestern Wyoming.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1092–1096, 1101 (fig. 3), 1104. Replaces name Gallatin formation. Consists of Upper Cambrian rocks in Wind River Canyon which lie between the Depass (Middle Cambrian) and Big Horn (Ordovician) formations. Rocks are massive limestones, intraformational conglomerates, and shales in basal 182 feet (Maurice member); shales, thin limestones, and thick-bedded intraformational conglomerates in overlying 308 feet (Snowy Range member); maroon and buff dolomitic shales, mudstones, and edgewise conglomerates in upper 40 feet (Grove Creek member).

Helen Foster, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1539 (strat. column), 1541, 1543, 1544, 1546 (fig. 2), 1547. Described in Teton County where it is 102 to 181 feet thick; overlies Gros Ventre formation and underlies Bighorn dolomite. Not subdivided in this area.

Type locality: East of Smith's cabin, approximately 2 miles north of Boysen Dam, Fremont County, Wyo.

Bozeman Lake Beds[1]

Oligocene, lower, to Pleistocene: Central southern and southwestern Montana.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110, pl. 1.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 15. Loose term for entire middle and late Cenozoic section northwest of Yellowstone Park in Gallatin and Broadwater Counties, Mont., including beds ranging in age from early Chadronian to Pleistocene and devoid of lacustrine deposits (except the *Leuciscus turneri* lake beds).

Named for exposures in vicinity of Bozeman, Gallatin County.

Brackett Member (of Stowe Formation)

Lower Cambrian(?): West-central Vermont.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 66, pl. 1. Dark-green albite-epidote-calcite-chlorite schist.

Named for exposures in Brackett Brook. Occurs along eastern border of Rochester-East Middlebury area.

Bracks Rhyolite (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 15 (fig. 3), 25–26. Name proposed for rhyolite overlying Chambers tuff (new). Rhyolite is characteristically light olive gray to greenish black; locally dark reddish brown. Maximum thickness about 300 feet (in vicinity of San Carlos); lenses out on the northwest, north, and south; eastward, dips underground. Underlies Capote Mountain tuff (new).

Type locality: Vicinity of San Carlos, on Vieja Rim east of basin, Presidio County. Name derived from Bracks Canyon which cuts through rhyolite outcrop just west of San Carlos.

Brad Formation (in Canyon Group)[1]

Brad Group

Upper Pennsylvanian: Central and central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24–31, 35.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 108–115. As redefined herein, formation consists only of shale member at base and overlying Ranger limestone member (Drake's Home Creek of the type locality). Cedarton shale and Winchell member (including Clear Creek limestone of Drake and lower or limestone-bearing part of Placid shale member of Plummer and Moore) are included in typical Graford formation of Brazos River basin. Beds included in "shale member" represent upper part of Placid shale of Plummer and Moore, some sandstone, and the Cherty limestone of Drake. Underlies Caddo Creek formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88 Rank raised to group. Includes Ranger limestone and Placid shale. Underlies Caddo Creek group; overlies Graford group.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 51. Shown on composite section of Brown and Coleman Counties as Brad formation in Canyon group. Thickness about 125 feet. Includes Ranger limestone and Placid shale members. Underlies Caddo Creek formation; overlies Winchell limestone.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 66–67, pl. 27. In Brown and Coleman Counties, comprises (ascending) Placid shale member and Ranger limestone member. Overlies Winchell limestone; underlies Caddo Creek formation. Thickness about 130 feet in southwestern Brown County; about 105 feet in central Brown County; not completely exposed northeast of Pecan Bayou.

Named for Brad, Palo Pinto County, Brazos River region.

†Braddyville Limestone (in Shawnee Formation)[1]

Pennsylvanian: Southwestern Iowa and northwestern Missouri.

Original reference: G. L. Smith, 1909, Iowa Geol. Survey, v. 19, p. 617, 618, 623, 629, 632.

Named for exposures at Braddyville, Page County, Iowa.

Bradford Group[1]

Devonian: New York.

Original reference: C. Schuchert and C. O. Dunbar, 1933, A textbook of geology, pt. 2, Historical geology: New York, John Wiley and Sons, Inc., p. 199, 203, 204.

†Bradford Schist[1]

Ordovician: Northeastern Vermont.

Original reference: C. H. Richardson, 1898, Am. Assoc. Adv. Sci. Proc., v. 47, p. 295–296.

Named for Bradford, Orange County.

†Bradfordian[1] Series

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: G. H. Girty, 1904, Science, new ser., v. 19, p. 24.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 12, pt. 1, chart 4. Bradfordian series (part) shown on correlation chart. Includes Conewango stage. Follows Chautauquan series.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 148. Report discusses geology of Coxsackie quadrangle, New York. Above "Portage" (Naples) beds in western New York occur marine Chemung and post-Chemung beds (Chautauquan, Bradfordian) which reach their maximum thickness in Pennsylvania (3,500 feet in central part) and thin greatly westward.

Bradley Granodiorite

Upper Jurassic: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 12, 52–59. Varies in composition from quartz diorite to quartz monzonite; varies in texture and structure from granulated, sheared, and strongly foliated to granitoid and little foliated. Cut by small dikes and sills genetically related to San Jacinto batholith. Cuts Palm Canyon complex (new) usually in form of sills. Probably correlative with Fargo Canyon diorite (new).

Named for exposures in Bradley Canyon, south of Cathedral City, in Palm Springs-Indio area, Riverside County.

†Bradshaw Granite[1]

Precambrian: Central Arizona.

Original reference: T. A. Jagger, Jr., and C. Palache, 1905, U.S. Geol. Survey Geol. Atlas, Folio 126.

U.S. Geological Survey has abandoned the term Bradshaw Granite on the basis of a study now in progress.

Named for Bradshaw Mountains in which it is well displayed, Yavapai County.

Bradshaw Limestone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 397.

Well exposed in Talcott district, Summers County, in bluff south of Greenbrier River, just west of Stony Creek and 0.3 mile southwest of Bargers Springs. Named for association with Bradshaw sandstone.

Bradshaw Sandstone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 394.

Type locality: In vicinity of Indian Mills and along Bradshaw Creek, there being a cliff on the road which ascends the mountain immediately north of Indian Mills and the mouth of Bradshaw Creek, Summers County, W. Va. Also observed in Mercer and Monroe Counties, and in Tazewell County, Va.

Bradshaw Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 398.

Type locality: On mountain road immediately north of Indian Mills, Summers County, W. Va. Also in Mercer, Monroe Counties, and in Tazewell County, Va.

Bradshaw Mountain Complex

Age not given: Southwestern Utah.

K. C. Condie, 1959, The Compass, v. 36, no. 3, p. 185, 186, 191–192. Composed of tonalite, granodiorite, and adamellite; gneisses and schists are also locally abundant. Large limestone and marble inclusions found within the complex. Basic projection of Mineral Range pluton.

Outcrops in Bradshaw mining district immediately southwest of Pass Canyon; in Mineral Range located in Beaver and Millard Counties.

Brady Soil

Pleistocene (Wisconsin): Central Nebraska.

C. B. Schultz and T. M. Stout, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 568 (fig. 2), 570. Proposed for the 1.5-foot buried soil at top of Peorian loess and below Bignell loess.

Type locality: Same as for Bignell loess, that is, Bignell Hill section, southeast of North Platte, 1.7 miles south of Bignell, in E½E½ sec. 3, T. 12 N., R. 29 W., Lincoln County.

Bradyan Interglacial Substage or Subage

Pleistocene (Wisconsin): Midcontinent.

A. B. Leonard, 1951, Jour. Geology, v. 59, no. 4, p. 325. Interval during which Brady soil was formed. This was likely a post-Tazewellian-pre-Caryan (or pre-Mankatoan) interval.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 132–135. Bradyan substage (subage) is interglacial interval of relatively short duration characterized by stable soil-forming conditions. It divides Wisconsinan into two unequal parts.

J. C. Frye and A. B. Leonard, 1955, Am. Jour. Sci., v. 253, no. 6, p. 358–364. Bradyan interglacial interval is most significant break in sedimentation in Midcontinent region during post-Sangamonian time. Provincial classification of post-Sangamonian into Scandian, Bradyan, and Almenan subages is proposed for use in Midcontinent.

Brady soil was named from exposures in loess bluffs south of Platte River valley south of Bignell, sec. 3, T. 12 N. R,. 29 W., Lincoln County, Nebr.

Bragdon Formation[1]

Mississippian: Northwestern California.

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 236, 238.

A. R. Kinkel, Jr., W. E. Hall, and J. P. Albers, 1956, U.S. Geol. Survey Prof. Paper 285, p. 1, 38–41, pl. 1. Composed of interstratified shale, siltstone, sandstone, grit, conglomerate, a small amount of rhyolite tuff, and a small flow of mafic lava. Beds of shale make up more than 75 percent of formation. Thickness 3,500 feet in mapped area; only lower part of formation present. Overlies Kennett formation, but, where Kennett was either not deposited or was locally eroded, the Bragdon rests upon either Balaklala rhyolite or Copley greenstone.

Named from community of Bragdon on Trinity River 8 miles south of Trinity Center, Weaverville quadrangle. Formation occurs as an arcuate band 17 miles long and as much as 4 miles wide at north end of West Shasta district, Shasta County.

Brainard Member (of Maquoketa Shale)

Brainard Shale (in Maquoketa Group)[1]

Upper Ordovician: Northeastern Iowa, northwestern Illinois, and western Wisconsin.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 97.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 50). Shown on correlation chart as member of Maquoketa formation. Underlies Neda shale member; overlies Fort Atkinson limestone member.

C. E. Brown and J. W. Whitlow, 1960, U.S. Geol. Survey Bull. 1123–A, p. 27–28, pl. 3. Described in Dubuque South quadrangle, Iowa-Illinois, where it is rank reduced to member status in Maquoketa shale. Consists of grayish-green and pale-blue soft dolomitic shale. Thickness as much as 135 feet. Underlies Neda member; overlies brown shaly unit in lower part of the Maquoketa.

Named for exposures near Brainard, Fayette County, Iowa.

Brainerd Quartz Monzonite[1]

Eocene: Central northern Colorado.

Original reference: P. G. Worcester, 1921, Colorado Geol. Survey Bull. 21, p. 32.

North side of valley near mouth of Brainerd Tunnel, on Lefthand Creek about a mile east of Ward and farther north in Tuscarora Gulch, Ward district, Boulder County.

Braintree Argillite

Braintree Slate[1]

Middle Cambrian: Eastern Massachusetts.

Original reference: N. S. Shaler, 1871, Boston Soc. Nat. History Proc., v. 13, p. 173, 175.

N. E. Chute, 1950, Bedrock geology of the Brockton quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–5]. Referred to as argillite.

Named for occurrence in Braintree, Norfolk County.

Brallier Shale (in Susquehanna Group)

Brallier Shale (in Portage Group)[1]

Brallier Member (of Fort Littleton Formation)

Upper Devonian: Central Pennsylvania, Virginia and West Virginia.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th ser., v. 46, p. 523, 531, 536.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 210, 216–217. Member of Fort Littleton formation. Overlies Harrell member; underlies Losh Run member.

B. N. Cooper, 1939, Virginia Geol. Survey Bull. 55, p. 44–46, pl. 3. Formation described in Draper Mountain area, where it is 1,500 feet thick and consists of olive-drab siliceous shale and even-bedded siltstone and sandstone. Underlies Chemung; overlies Millboro shale (new).

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 412–445. Geographically extended into West Virginia where it replaces "Portage shales" or "Portage series" of previous reports. Overlies Harrell shale; underlies Chemung. Thickness as much as 2,900 feet (Randolph County).

R. R. Conlin and others, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 274, 276. Includes Stone Creek member (new).

U.S. Geological Survey currently classifies the Brallier as a formation in Susquehanna Group on the basis of a study now in progress.

Named for railway station 6 miles northeast of Everett, Bedford County, Pa.

Branch Canyon Formation

Miocene, middle: Southern California.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2991–2993. On south side of Cuyama Valley and on northeast flank of Caliente Range, Monterey shale grades laterally eastward into marine sandstone which in turn grades eastward into continental Caliente formation; this marine sandstone is herein designated Branch Canyon formation; as transitional facies includes minor fingers of marine shales and continental claystones and sandstones. At type section, comprises units mapped by Eaton and others (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2) as (descending) lower "Neroly," "Cierbo," "Briones," "Temblor," and "Vaqueros;" section is 3,000 feet thick. Southeast of type locality, between Branch and Salisbury Canyons, formation is divisible into two units separated by a 750-foot interval of Monterey shale that contains Relizian microfauna; lower unit (mapped as Vaqueros by English, 1916, U.S. Geol. Survey Bull. 621–M) consists of about 1,200 feet of medium- to coarse-grained thick-bedded sandstone containing a *Turritella ocoyana* fauna and lies directly on Cretaceous sandstone; upper unit consists of about 1,400 feet of medium-grained sandstone that conformably underlies basal shale of Santa Margarita formation; on northeast flank of Caliente Range formation consists of about 1,500 feet of sandstone that contains three amygdaloidal basalt flows up to 50 feet thick (triple basalt flows of Eaton) which serve as key beds. Formation at its type locality is Relizian and possibly Luisian (middle Miocene), and upper 100 feet may be as young as upper Miocene (Eaton's lower "Neroly"). Preoccupied term Bitter Creek has been used for unit herein designated as Branch Canyon.

Type section: Near Branch Canyon on south side of Cuyama Valley near south Cuyama oil field, Cuyama Ranch quadrangle.

Branch Pond Gneiss[1] or Formation

Cambrian: Central southern Maine.

Original reference: E. H. Perkins and E. S. C. Smith, 1925, Am. Jour. Sci., 5th, v. 9, p. 204–228.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 110, 140, table 1. Mentioned in report on Lewiston, Maine, region. Quartz-feldspar-biotite gneiss of Cambrian Pejepscot formation is in part at least equivalent to Branch Pond formation of Perkins.

Named for exposures near Branch Pond in West Palermo, Waldo County.

Branchtown Clay[1]

Pliocene(?): Southeastern Pennsylvania.

Original reference: H. C. Lewis, 1881, Philadelphia Acad. Nat. Sci. Proc., v. 32, p. 258–272, 296–309.

In village of Branchtown [a suburb of Philadelphia].

Brandon Lignite or (residual) Formation[1]

Tertiary, lower: West-central Vermont.

Original reference: Edward Hitchcock, 1861, Rept. Geol. Vermont, v. 1.

Alfred Traverse and E. S. Barghoorn, 1953, Jour. Paleontology, v. 27, no. 2, p. 289–293. Lower Tertiary (probably Oligocene) age assigned to lignite.

Well exposed around town of Brandon, northern Rutland County.

Brandt Sandstone (in Kingsley member of Wellsburg monothem)

Upper Devonian (Chautauquan): Northeastern Pennsylvania.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7), 46–47. Somewhat massive sandstone, which splits along low-angled crossbedding diastems and shale partings into commercial flagstones; marine fauna. Thickness about 30 feet. Occurs in lower part of member above Starrucca sandstone member of Cayuta monothem.

Composite section described is near Lanesboro, Susquehanna County.

Brandy Run Sandstone (in Chester Group)[1]

Mississippian: Southwestern Indiana and northern Kentucky.

Original reference: C. A. Malott, 1919, Indiana Univ. Studies, v. 6, no. 40, p. 7–20.

Well developed in region of Marengo on Brandy Run Creek, Ind.

Brandywine Formation[1] or Gravel

Pliocene(?): Atlantic Coastal Plain from Delaware to Georgia.

Original reference: W. B. Clark, 1915, Am. Jour. Sci., 4th, v. 40, p. 499, 506.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Mineral Resources Bull. 10, p. 39–42. Described in Prince Georges County, Md., and District of Columbia. Gravel is predominant component in this area, therefore term gravel is preferred rather than formation; gravel is commonly overlain by silt. Thickness about 40 feet. Main body lies unconformably on Chesapeake group; outliers in District of Columbia overlap the Miocene and lie on Patuxent formation and crystalline rocks. Because Brandywine lies on Chesapeake group, it must be younger than Miocene, unless, possibly it was deposited during concluding part of that epoch. Because it is highest extensive sheet of river gravel in which present Potomac Valley has been cut, it presumably antedates the Pleistocene era; no fossils have been found to verify age assignment; unit is here referred to as Pliocene.

J. T. Hack, 1955, U.S. Geol. Survey Prof. Paper 267–A, p. 10–17, pl. 1. Described in Brandywine area where it forms surface of the uplands and consists of lower gravel member 10 to 50 feet thick and upper loam member that averages 15 feet in thickness. Overlies North Keys sand (new) which had been mapped as part of the Brandywine by some workers and as part of the Sunderland by others. Base of formation is defined by lowest gravel or coarse sand in the section, even though beds of fine sand identical with the North Keys occur in many places interbedded with the gravel; although formation as here defined may contain a disconformity and hiatus above the base, it is believed that this definition is only one practical for areal mapping and conforms closely to original definition. No basis is found for separating the Brandywine from the Sunderland; both formations at their type localities are underlain by North Keys sand of Miocene(?) age. Age given as Pliocene(?) although field evidence justifies only statement that it may be Miocene, Pliocene, or Pleistocene.

Typically developed in vicinity of Brandywine, Prince Georges County, Md.

Branford Granite Gneiss[1]

Branford Quartz Monzonite

Precambrian: South-central Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 114, 146, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Redescribed as a granitic gneiss. Fine- to medium-grained well-foliated gray gneiss. Part of East Haven granitic body, a structural unit. Pre-Triassic.

H. M. Mikami and R. E. Digman, 1957, Connecticut Geol. Nat. History Survey Bull. 86, p. 13–14, 24–25, 50–51, pl. 1. Discussion of Branford-Stony Creek massif, an igneous body composed of Stony Creek granite and Branford quartz monzonite; a facies of the latter is designated Lighthouse quartz monzonite.

Extensive outcrops in Branford Township, New Haven County.

Brannon Limestone Member (of Cynthiana Formation)

Brannon Cherty Member (of Flanagan Limestone)[1]

Brannon Limestone (in Lexington Limestone)

Middle Ordovician: North-central Kentucky.

Original reference: A. M. Miller, 1913, Kentucky Geol. Survey, 4th ser., v. 1, pt. 1, p. 324.

D. K. Hamilton, 1948, Econ. Geology, v. 43, p. 41 (fig. 2), 42. Referred to as Brannon limestone; consists of finely crystalline siliceous limestone which weathers to very cherty residue. Thickness about 15 feet. Overlies Benson limestone; underlies Woodburn limestone.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1636–1637. Forms middle part of Lexington limestone. Fine-grained siliceous gnarly limestone with much shale in lower part. On weathering, gives rise to conspicuous zone of chert drift and forms greater part of Campbell's (1898) Flanagan chert. Thickness 15 to 20 feet; in some places 30 feet. Includes Woodburn phosphatic member. On the north in Bourbon, Harrison, Franklin, and Fayette Counties, the Brannon fades in a short distance as a useful lithologic unit. Woodburn also thins. Recognition of these beds becomes difficult as Brannon wedges out (lithologic change), but horizon is still well marked wherever *Stromatocerium* and its associates of upper Benson are presented. Pre-Cincinnatian.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 18. All subdivisions of interval between top of Benson limestone and base of Eden formation should be referred to as members of the Cynthiana. This includes lithologic and paleontologic units heretofore defined as Brannon, Woodburn, Greendale, Millersburg, Nicholas, Rogers Gap, Bromley, and Gratz.

Named for exposures at Brannon Station, Jessamine County.

Brannon Limestone Member (in Millsap Lake Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107.

Type locality not stated.

Brannon Bridge Limestone Member (of Lazy Bend Formation)

Brannon Bridge Limestone (in Millsap Lake Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer and J. Hornberger, Jr., 1936, Texas Univ. Bull. 3534, p. 16.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in Lazy Bend formation. Occurs below "Buck Creek sandstone" in Grindstone Creek formation and above Dennis Bridge limestone member of Lazy Bend.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 17–18, fig. 3, pl. 4. Composed of two limestones separated by shale and discontinuous sand bodies. Lower limestone is 15 feet thick and shale is 22 feet thick (measured at Steussy Scarp where ranch road crosses scarp approximately 1½ miles west of Brazos River); a lensing sandstone in upper part of shale has maximum thickness of 4 feet in exposures in drainage immediately south of Meek Bend; upper limestone is 17 feet thick (in quarry on top of cliffs south of Brazos River at Meek Bend). Overlies Steussy shale member; underlies sandstone and shales of Grindstone Creek formation. Type section established.

Type section: Succession of beds exposed in Steussy Scarp, a prominent feature northwest of Rocky Creek west of Brazos River. Name derived from former highway bridge on Brazos River at a point three-fourths mile south of present Highway 80 bridge, Parker County. Outcrop of member extends south of U.S. Highway 80 along west side of meander of Brazos River forming Meek Bend; on west side of Brazos River outcrops are in bluffs along west and south sides of Meek Bend; southeast edge of outcrop forms Steussy Scarp which begins near river and extends southwestward across county line.

Bransford Sandstone Bed (in Gassaway Member of Chattanooga Formation)

Bransford Sandstone Member (of Gassaway Formation)

Upper Devonian: Central Tennessee.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 884, pl. 1. Layer of sandstone 2 to 4 inches thick at base of the Gassaway (new). Overlies Dowelltown shale (new); from Nashville extends southward with the Gassaway but without the underlying Dowelltown.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 11. Name Bransford sandstone not used in present report [Chattanooga shale and Maury formation]; bed so designated by Campbell is not named.

U.S. Geological Survey currently classifies the Bransford Sandstone as a bed in the Gassaway Member of the Chattanooga Formation on the basis of a study now in progress.

Type section: At bridge and along a small stream northwest of bridge, along Highway 31E, 2 miles north of Bransford, Sumner County.

Brassfield Limestone[1] **or Dolomite**

Lower Silurian: Central Kentucky, central northern Arkansas, southern Indiana, southwestern Ohio, and southern Tennessee.

Original references: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 156; 1906, Kentucky Geol. Survey Bull. 7, p. 10, 27.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Albion series.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 116–117, chart facing p. 108. Present at surface in extended area in southwestern Ohio. Trend of outcrop is northeastward from Indiana-Ohio line near Fairhaven across Preble and Montgomery Counties into central Miami County, thence southeastward across Clark, Greene, Clinton, Highland, and Adams Counties to Ohio River near Rome. Thickness 20 to 60 feet; average 20 feet. Underlies Dayton formation, Niagara group.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 34, 35–36. Thickness 20 feet at type section. Thickens northward to 40 or even 50 feet in Adams and Highland Counties, Ohio, and then thins westward into Indiana. In southern Blue Grass, the Brassfield thins westward and is eliminated from sections near Stanford, where the Devonian overlaps on Ordovician. Underlies Plum Creek shale.

E. B. Branson and C. C. Branson, 1947, Jour. Paleontology, v. 21, no. 6, p. 549–556. Brassfield herein considered to consist of lower dolomitic limestone, including *Whitfieldella* bed, and Plum Creek clay member above. Underlies Oldham limestone. Conodonts described. Lower Silurian.

C. W. Wilson, Jr., 1948, Geol. Soc. America Bull., v. 59, no. 8, p. 752, 755, 756. Discussion of channel-filling sediments, south-central Tennessee. Brassfield limestone was deposited as blanket over south-central Tennessee, resting unconformably upon sandstone member of Mannie shale, or where sandstone member is absent, upon underlying Mannie shale. Locally the Brassfield rests on Fernvale limestone in regional stratigraphic succession but not within limits of Pulaski channel. Overlies the Richmond throughout practically entire length of Pulaski channel. Consists of thinly bedded blue-gray finely crystalline limestone containing many species of corals. Maximum thickness 45 feet along Pulaski channel. Underlies Mississippian Medinan series.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 239–244. Northwestward across central Tennessee, the Brassfield becomes dolomitic and in Perry County and vicinity develops basal zone of coarse-grained limestone. Commonly cherty and glauconitic. Lies between overlying Osgood formation or Chattanooga shale, and underlying Mannie or Fernvale formations, or Leipers formation where the Richmond formations are absent as in parts of Columbia quadrangle. Thickness 20 to 50 feet.

H. A. Lowenstam, 1949. Illinois Geol. Survey Rept. Inv. 145, p. 20–21. Niagaran in Illinois is underlain by late Alexandrian formations equivalent to Brassfield limestone of Kentucky and Indiana. These are Sexton Creek limestone in southern half of State and its dolomitic equivalent, Kankakee dolomite in northern part of State.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Feld Conf., Guidebook 6, p. 14, pl. 1. Shown on generalized stratigraphic column of Ordovician and Silurian rocks exposed in Jefferson and Switzerland Counties. Thickness 0 to 11 feet. Underlies Osgood formation; overlies Whitewater formation.

Named for exposures along Louisville and Atlantic Railroad between Brassfield and Panola, Madison County, Ky.

Brasstown Schist[1]

Lower Cambrian: Western North Carolina, central northern Georgia, and eastern Tennessee.

Original reference: A. Keith, 1907, U.S. Geol. Survey Geol. Atlas, Folio 143, p. 4.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 285. Green phyllite, slate, and ottrelite-mica schist overlie Big Butt (Tusquitee) quartzite in Murphy syncline. Keith (1907) separated these rocks into Brasstown schist and Valleytown formation. Only locally is there lithologic criteria for separating these rocks into two formations. The phyllites and schists for the most part are closely folded and have prominently developed schistosity which obscures bedding, so that on stratigraphic evidence available they are not readily divisible. In this report, the two formations are treated as Valleytown formation, the more widely used name.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27. Included in Talladega series believed to be Precambrian.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 48–51. In Mineral Bluff quadrangle, Ga., Keith's (1907) sequence is not entirely applicable. Rocks mapped by LaForge and Phalen (1913, U.S. Geol. Survey Geol. Atlas, Folio 187) as Valleytown formation belong to four formations: Brasstown, Andrews schist, Nottely quartzite, and Mineral Bluff (new). As originally defined, the Valleytown is without definite lower boundary and is lithologically indistinguishable from underlying beds; name Valleytown is not retained. Rocks between Tusquitee quartzite and Murphy marble all conform to Keith's description of the Brasstown, and they are renamed the Brasstown formation.

J. L. Stuckey and S. G. Conrad, 1958, North Carodina Div. Mineral Resources Bull. 71, p. 31–32; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Lower Cambrian(?).

Named for exposures on Brasstown Creek, Clay County, N.C. In Mineral Bluff quadrangle, Ga., crops out in two belts, one on each limb of Murphy syncline.

Brattleboro Phyllite[1]

Ordovician: Southeastern Vermont.

Original reference: C. H: Richardson, 1929, Vermont State Geologist 16th Rept., p. 232.

Named because Brattleboro Township is practically all covered with a fine-grained graphitic phyllite schist.

Bratton Sandstone (in Bluestone Formation)[1]

Bratton Sandstone Member (of Bluestone Formation)

Mississippian (Chesterian): Southeastern West Virginia and southern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 293, 317.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 185, pl. 15. Geographically extended into Virginia and redefined as member of Bluestone formation. Thickness about 10 feet. Overlies Belcher member; underlies Bent Mountain member (new). Consists of greenish-gray micaceous silty sandstone.

Type locality: Near extreme head of Bratton Branch of Brush Creek, Mercer County, W. Va.

Bratton Shale (in Bluestone Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 294, 318.

Type locality: Near extreme head of Bratton Branch of Brush Creek, Mercer County, W. Va.

Brave Boat Harbor Biotite Granite[1]

Carboniferous(?): Southwestern Maine.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 148, 149, 154.

Occurs on northeast side of Brave Boat Harbor, Kittery Township, York County.

Brawley Formation

Pleistocene: Southern California.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, p. 23 (fig. 2), 24, 25, pl. 2. Defined as the lacustrine and continental basinward facies of Ocotillo conglomerate (new); at type section about 2,000 feet of light-gray claystone and thin interbeds of buff sandstone are exposed; in Superstition Hills, composed of lacustrine and terrestrial clays, sands, and pebble gravels, and base is not exposed. Around Superstition Mountain, Brawley formation, basal part of which is Ocotillo conglomerate facies, unconformably overlaps Imperial formation, Alverson lava (new), and Split Mountain formation onto diorite; southeastward and adjacent to Superstition Mountain fault, Ocotillo-Brawley series lies unconformably on Borrego clays, and an angular discordance of as much as 60° is exposed north of fault.

Type section: West of U.S. Highway 99 and west of the south end of the Salton Sea, Imperial County.

Braxton Formation[1]

Pennsylvanian: Northern West Virginia.

Original reference: J. A. Taff and A. H. Brooks, 1896, U.S. Geol. Survey Geol. Atlas, Folio 34.

In greater part of Braxton County.

Brayman Shale[1]

Silurian: Eastern New York.

Original reference: A. W. Grabau, 1906, New York State Mus. Bull. 92, p. 101.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW-20, p. 9 (table 7), 13. Thickness 9 feet in Albany County. Overlies Indian Ladder formation; underlies Cobleskill limestone. Silurian.

J. M. Berdan, 1950, New York State Water Power and Control Comm. Bull. GW-22, p. 10 (table 2), 14-15. In Shoharie County, gradationally overlies Schenectady formation and underlies Cobleskill limestone. Thickness 20 to 40 feet. Upper Ordovician(?).

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 3-14. Brayman is here regarded as eastern extension of Bertie and upper Camillus formations. Discontinuation of name "Brayman" as an Ordovician residual soil is advocated. Proposed here that name Brayman be applied to undifferentiated strata of Camillus and Bertie age in area from Vanhornesville, Herkimer County, to Gallupville, Schoharie County. Brayman lies first upon Ordovician strata in type area and at Sharon Springs. West of Cherry Valley, it lies upon progressively younger strata of Middle and Upper Silurian. At western border of Richfield Springs quadrangle, the Lockport, Vernon, Camillus, and Bertie have all appeared in section beneath the Cobleskill. Thickness about 135 feet at Vanhornesville; 80 feet at Sharon Springs; 17 feet at Gallupville; only a few feet of uppermost Brayman exposed at type section. Thins eastward; diminution due to loss of strata from base so that Brayman includes more time stratigraphically in its western exposures. Everywhere conformably underlies Cobleskill. Upper Silurian.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Shown on correlation chart as Upper Silurian.

Type locality: Along County road one-half mile west of Howes Cave. Named for Braymanville, Cobleskill County.

Brazer Limestone[1] or **Dolomite**

Mississippian: Northeastern Utah. eastern and south-central Idaho, and southwestern Wyoming.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 407, 413.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 22–24, pls. 1, 6. Brazer limestone, in Randolph quadrangle, Utah-Wyoming, consists of massive gray siliceous limestone and sandstone; cherty in places; lower part thin-bedded and shaly, locally phosphatic. Thickness 1,100 feet. Overlies Madison limestone; underlies Wells formation.

J. S. Williams, 1943, Geol. Soc. America Bull., v. 54, no. 4, 610–612, measured sections. Brazer formation at type locality (herein considered to be Brazer Canyon) is 500 feet thick; neither top nor bottom of formation exposed. Overlies Madison formation; underlies Morgan or Wells formation. Traced eastward nearly to Colorado State line; thickness varies greatly over compartively short distances.

J. S. Williams and J. S. Yolton, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 8, p. 1143–1155. Thickness 3,700 feet in section at Dry Lake, Logan quadrangle, Utah. Five units or faunal zones described. Formation at Dry Lake section includes rocks of Iowan and Chesterian age, extending probably from an equivalent of the Warsaw to latest Chester. Underlies Wells formation.

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2161–2162. Beds exposed in southwestern Montana appear to be correlative with those described by Ross (1934, Geol. Soc. America Bull., v. 45, no. 5) in Idaho and are here tentatively assigned to the Brazer. However, neither the southwestern Montana nor the Idaho beds bear much resemblance to type Brazer; a new term seems to be required. Thickness 1,718 feet in Beaverhead County, Mont.

W. L. Stokes, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 16. Westernmost exposures of formation are near Rockland, Idaho. Thickness at least 4,000 feet in east-central Idaho; thinner in Wyoming where the Sacajawea may represent a featheredge. Upper Mississippian.

J. W. Strickland, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 51–57. In southeastern Idaho, the Brazer should be classed as a formation and placed in Madison group containing, in addition to the Brazer, the Mission Canyon and Lodgepole formations. In northern Utah, Upper Mississippian strata formerly included in the Brazer are subdivided into a Chester and a Meramec series on basis of regional correlation and faunal suites. The Brazer should be restricted to rocks of Meramec age and to a facies consisting predominantly of partially dolomitized limestone, siliceous limestone, and calcareous sandstone. Brazer facies is an intermediate stage between dominantly sandstone Humbug formation of north-central Utah and upper Madison limestone of Wyoming. Section of rocks of Chester age formerly included with the Brazer (Williams, 1943; Williams and Yolton, 1945) are raised to group rank, consisting of (ascending) unit 3, Long Trail formation; unit 4, unnamed thin- to medium-bedded cherty limestone sequence; unit 5, Manning Canyon formation. Units 1 and 2 are classed as members of the Brazer as defined in this paper.

W. J. Sando, J. T. Dutro, Jr., and W. C. Gere, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2741–2769. Brazer dolomite in its type area consists of about 850 feet of dolomite with a few beds of quartz sandstone and limestone near top. Divided into three members (unnamed) in Crawford Mountains, Utah. Member 1 consists mainly of thin-bedded cherty fine-grained dolomite weathering dark-yellowish brown; member 2, thick-bedded medium- to coarse-crystalline crinoidal cherty dolomite weathering mostly yellowish gray: member 3 consists of several distinct rock types that are interbedded, most common type being thin-bedded fine-grained dolomite weathering dark yellowish brown. Overlies Lodgepole limestone. Underlies sandstones and carbonate rocks that are referred to Wells formation as used by McKelvey and others (1956). Lower two-thirds of formation has yielded fauna of Early Mississippian age that suggests correlation with Mission Canyon limestone of type Madison group; upper third of formation contains fauna of uncertain affinities, interpreted as Late Mississippian in age. Inasmuch as Brazer cannot be recognized on lithologic or faunal basis outside type area, it is herein recommended that name be restricted to Mississippian dolomite sequence in Crawford Mountains. New nomenclature should be devised for Upper Mississippian limestone-sandstone facies, perviously called Brazer, in northern Cordilleran region. Richardson (1913, 1941) did not indicate precise type locality nor give detailed section in either of his papers on Randolph quadrangle. Recent interpretations of type Brazer have been based on Williams statement (1943) that type section is at mouth of Brazer Canyon where the formation is incomplete because of faulting. Reasons presented for regarding this interpretation as incorrect and site for type section suggested.

M. R. Thomasson, 1959, Dissert, Abs., v. 20, no. 3, p. 999. Discussion of Late Paleozoic stratigraphy and paleotectonics of central and eastern Idaho. Milligen, Muldoon (new), Wood River, and Lemhi (new) formation recognized. Lemhi formation replaces term Brazer.

C. P. Ross, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B232. Discussion of interfingering Carboniferous strata in Mackay quadrangle, Idaho. Rocks commonly called Brazer limestone are widespread from interrupted zone trending nearly north through middle of quadrangle well to north and eastward into Montana. In Mackay quadrangle, their thickness exceeds 8,000 feet. They consist mainly of limestone but include some quartzite and conglomerate of Mississippian age. As originally used in central Idaho (Ross, 1934, Geol. Soc. America Bull., v. 45, no. 5), the Brazer limestone is of Late Mississippian age, but, in localities far to northeast of Mackay quadrangle, limestone that has not yet been mapped separately from the Brazer limestone has yielded fossils of Pennsylvanian and Permian age. In that part of Idaho, the Brazer limestone together with these younger associated beds may have an aggregate thickness of more than 10,000 feet. In Mackay quadrangle, rocks that were mapped as Brazer are now known on basis of paleontologic evidence to be largely of Early to Late Mississippian age, and in several outcrops they even include rocks of Pennsylvanian age; the Pennsylvanian limestone, however, cannot be distinguished in mapping from limestone of Mississippian age without far more refined work than has been practicable so far.

Type section (Sando, Dutro, and Gere): NW¼ sec. 20, T. 11 N., R. 8 E., Rich County, Utah. Named for exposures in Brazer Canyon, Rich County, Utah.

Brazil Formation[1]

Brazil Group

Middle Pennsylvanian: Southwestern Indiana.

Original reference: M. L. Fuller and G. H. Ashley, 1902, U.S. Geol. Survey Geol. Atlas, Folio 84.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 96. Includes Minshall limestone (new).

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (Column 25). Shown on correlation chart as Brazil formation. Includes strata from base of Connellton coal to a little above top of Minshall limestone. Underlies Staunton formation; overlies Mansfield formation.

D. W. Franklin, 1944, Illinois Acad. Sci. Trans., v. 37, p. 89, 90. Referred to as Brazil group. Contains Grandview limestone (new) near top.

F. E. Kottlowski, 1959, U.S. Geol. Survey Coal Inv. Map C–28. As defined by Cumings (1922, Indiana Dept. Conserv. Spec. Pub. 21, pt. 4) formation includes rocks between base of Lower Black coal and unconformity at top of Coal II. In type area, formation is about 75 feet thick and includes four principal named coals (ascending): Lower Block, Upper Block, Minshall, and Coal II. Between Minshall coal and Coal II is Minshall limestone. In strictest sense, unconformity at top of Brazil is not at top of Coal II but at base of prominent sandstone that lies a few feet below Coal III. In Coal City quadrangle, this sandstone, which is basal member of overlying Staunton formation, generally rests on Minshall limestone member, on the gray or black shale beneath the limestone, or on Minshall coal. Hence, thickness of formation in Coal City quadrangle ranges from 35 to 94 feet. Overlies Mansfield formation.

H. C. Hutchinson, 1960, Indiana Geol. Survey Bull. 16, p. 12–21, pl. 1. Formation described in Brazil quadrangle where it ranges from 40 to 90 feet in thickness and includes commercially mined coals, the Minshall and Coal II, and Perth limestone member (new) which closely overlies Minshall coal. Overlies Mansfield formation and underlies Staunton formation.

Named for Brazil, Clay County.

Brazil Limestone[1]

Pennsylvanian: Central western Indiana.

Original reference: F. C. Greene, 1911, Indiana Acad. Sci. Proc. 1910, p. 169–171.

Named for Brazil, Clay County.

Brazil Branch Breccia[1]

Cretaceous: Central northern Arkansas.

Original references: C. Croneis and M. Billings, 1929, Jour. Geology, v. 37, p. 543, 554; 1930, Arkansas Geol. Survey Bull. 3, p. 158–160.

Crops out in W½SE¼ sec. 29, T. 4 N., R. 17 W., about 3 miles south by west of Perryville, in valley of Brazil Branch, a perennial tributary of Fourche la Fave River, on land owned by J. R. Myers, Perry County.

†Brazos Sandstone[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 138.

Named for widely distributed exposures along Brazos River, especially the high cliff at Inspiration Point, 8 miles due south of Mineral Wells.

†Brazos Series[1]

Upper Permian and Triassic: Texas, southern Kansas, eastern New Mexico, and Oklahoma.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 100–103.

Named for Brazos River, central northern Texas.

Brazos River Conglomerate Member (of Garner Formation)[1]

Brazos River Sandstone Member (of Garner Formation)

Middle Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 138.

R. J. Cordell and others, 1954, Abilene Geol. Soc. Guidebook Nov. 19–20, fig. 2. Faunal break occurs in Brazos River sandstone and conglomerate. Part of unit is assigned to East Mountain shale and part retained in Garner formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 21–22, fig. 3, pl. 1. Referred to as sandstone member of Garner in report on Parker County. Essentially massive and crossbedded with lenses and beds of coarse conglomerate and minor shale beds; in some areas, conglomerate is missing. Thickness uniformly 25 to 30 feet. Overlies Mingus shale member; underlies East Mountain formation.

Named for exposures along Brazos River, especially cliff at Inspiration Point, 8 miles south of Mineral Wells, Palo Pinto County.

Breakwater Quartzite[1]

Precambrian (upper Huronian): Northeastern Wisconsin.

Original reference: C. K. Keith, R. J. Lund, and A. Leith, 1935, U.S. Geol. Survey Prof. Paper 184, p. 4.

Named for its location near Breakwater Falls on Pine River, Florence County.

Breathitt Formation or **Group**

Breathitt Formation (in Pottsville Group)[1]

Middle Pennsylvanian: Southeastern Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 47.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 82, 88, 94. Magoffin shale and limestone, Kendrick shale, and Elkins Fork shale are listed in Breathitt formation.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 22). Correlation chart shows Lost Creek limestone and Flint

Ridge flint in upper part of Breathitt formation in Kentucky River valley.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 64, 65, 76, 136, 153. Includes Whetstone Creek shale member (new) in Whitley County area. In Letcher County, includes Bee Tree shale.

R. E. Hauser, 1953, Kentucky Geol. Survey, ser. 9, Bull. 13, p. 11 (fig. 2), 13–28. In Paintsville quadrangle, named units, not including coals are (ascending) Quakertown shale, Campbell Creek limestone, Elkins Fork shale, Kendrick shale, and Magoffin limestone.

J. A. Baker, 1955, U.S. Geol. Survey Water-Supply Paper 1257, p. 32–36. At type locality, the Breathitt includes rocks of Pottsville age only. However, no upper boundary has been defined, and formation includes rocks of Allegheny age in other localities. In Paintsville area, all consolidated rocks above massive sandstones of Lee formation are included in the Breathitt.

Named from exposures in Breathitt County.

†Breckenridge Formation (in Cisco Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. C. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Near east end of Breckenridge oil field.

Breckenridge Limestone Member (of Thrifty Formation)[1]

Breckenridge Formation (in Thrifty Group)

Upper Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 152, 154, 155, 160; 1922, Jour. Geology, v. 30, p. 24.

Wallace Lee, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 54, 61. Upper part of Thrifty formation, in Brazos River area, contains several beds of limestone, including Ivan and Blach Ranch members and, at top. Breckenridge limestone member. Thickness of Breckenridge varies from 5 feet near Crystal Falls to 1½ feet near McCann Bridge. Underlies Harpersville formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 91. Rank raised to formation in Thrifty group. Underlies Chaffin formation; overlies Speck Mountain formation.

D. A. Myers, 1958, Jour. Paleontology, v. 32, no. 4, p. 678 (fig. 1). Shown on stratigraphic column as member of Thrifty formation. Occurs below Chaffin member and above Speck Mountain member.

L. F. Brown, Jr., 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 41, p. 7 (fig. 2), 8 (fig. 3), 18–20, pls. 1, 2. Plummer (1919) applied name "Breckenridge formation" to a section containing three persistent limestone beds and one local limestone, thick shale beds, and lenticular sandstones above his "Gunsight" limestone. The three limestone beds which "form escarpments around east end of Breckenridge oil field" (idem) are the Breckenridge, Blach Ranch, and Ivan limestones of Plummer and Moore's (1921) classification. Breckenridge limestone member was defined by Plummer and Moore as upper limestone of Thrifty formation. It was described as gray, massive, and resistant, from 3 to 4 feet thick, and lying 25 to 45 feet above Blach Ranch member. Plummer and Moore did not include measured section of Breckenridge limestone in its type area, and nearest sections to it were measured at type Blach Ranch area, 10½ miles northeast of Breckenridge and "in escarpment 2 miles northeast of Harpersville" (idem, p. 156), about 8 or 9 miles south of Breckenridge. Line labeled "Breckenridge limestone" on Plummer and Moore's plate 1 is not outcrop of Breckenridge limestone according to their type description but is the outcrop of Blach Ranch limestone. Bradish (1937, Geologic map of Brown County) and Plummer and others (1949, Texas Univ. Bur. Econ. Geology Pub. 4915, pl. 4) traced outcrop of type Breckenridge limestone in type area and Lee (1938) traced Breckenridge limestone in northern Stephens County. Mapping for present report shows that the limestone which Plummer and Moore labeled "Breckenridge" in each of their measured sections in Stephens and Young Counties correlates with their type Breckenridge. Hence, the inconsistency between type description of Breckenridge limestone and outcrop map is interpreted as mislabeling and not an error in type description. Type reference section herein described. Breckenridge outcrop is prominent escarpment throughout most of area. The resistant massive mottled bed of Breckenridge member that caps this escarpment and many outliers is of uniform lithology and thickness. This limestone bed averages 1.8 feet and weathers into angular irregular fragments, usually mottled gray to orange or reddish brown. About 1 foot of nodular or irregularly bedded limestone occurs above and below the massive mottled bed except near Breckenridge, where these limestone units thicken to 3 or 4 feet. Overlies unnamed shale member; underlies Quinn clay member of Harpersville formation.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 72–73, pl. 27. Breckenridge limestone member was named by Plummer and Moore (1921) for a gray massive resistant limestone, 3 or 4 feet thick, forming prominent escarpment in and about Breckenridge in Stephens County. They considered it easily traceable to northeast and south and possibly identifiable with upper Chaffin bed of Drake (1893) in Colorado River valley. Bullard and Cuyler (1935, Texas Univ. Bull. 3501) followed Plummer and Moore's correlations, and the bed they mapped as Breckenridge through northern McCulloch County is the Chaffin limestone of Drake (1893). Cheney and Eargle (1951, Geologic map of Brown County) mapped the Breckenridge and showed it in the interval between their Chaffin and Speck Mountain limestones. Breckenridge was mapped for present report as far southwest as Home Creek and was found to be correlative with the bed Drake considered the lower Chaffin limestone. From vicinity of Home Creek southwest to Colorado River in southeastern Coleman County, this limestone and shale immediately above and below it is removed by channel erosion and channel filled by Parks Mountain sandstone member. Breckenridge not recognized south of Colorado River. Breckenridge is 20 to 40 feet above Speck Mountain limestone member. Beds that intervene between Breckenridge and Chaffin members in Brown County and north of Home Creek in eastern Coleman County are red clay. Plummer and Bradley (1949) named this Quinn clay for exposures in Eastland County.

Type reference section (Brown): On Harris Veale property, near south city limits of Breckenridge, west of U.S. Highway 183, Stephens County. Lower part of section measured from base of Blach Ranch limestone at road level on west side U.S. Highway 183 westward to pond excavated in Breckenridge limestone at top of prominent escarpment (fig. 5, beds

1A–5A). Upper part of section offset westward along outcrop of massive mottled bed of Breckenridge (fig. 5, bed 5A); upper interval measured from base of bioclastic limestone bed of Breckenridge, exposed in gully 1, northwest 20 yards, then southwest to sandstone above Crystal Falls limestone at top of isolated hill (fig. 5, beds 5B–12). All three units of Breckenridge (beds 5A, B, and C) are partly exposed in gullies 2 and 3, beds 5B and 5C are best exposed in gully 1. Makes prominent escarpment in and about town of Breckenridge, Stephens County.

Brecksville Shale (in Orangeville Shale Member of Cuyahoga Formation)

†Brecksville Shale Member (of Orangeville Shale)[1]

Mississippian: Northeastern Ohio.

Original reference: C. S. Prosser, 1912, Ohio Geol. Survey, 4th ser., Bull. 15, p. 69, 98, 127.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 137. Noted as Brecksville shale in Orangeville member of Cuyahoga.

Named for Brecksville, Cuyahoga County.

Breezy Hill cyclothem

See **Breezy Hill Limestone Member** (of Cabaniss Formation)

Breezy Hill Limestone Member (of Cabaniss Formation)

Breezy Hill Limestone Member (of Senora Formation)

Breezy Hill Limestone Member (of Cherokee Shale)

Breezy Hill Limestone Member (of Mulky Formation)

Pennsylvanian (Des Moines Series): Kansas, Missouri, and Oklahoma.

W. G. Pierce and W. H. Courtier, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 17; 1938, Kansas Geol. Survey Bull. 24, p. 33–35. Breezy Hill limestone member is about 5 feet below top of the Cherokee; in most places it consists of 6 inches to 2 feet of gray impure concretionary to nodular limestone but may exhibit considerable variation in thickness and character of material. In most places it is from 1 to 3 feet below Fort Scott coal; where coal is absent, Breezy Hill maintains its same stratigraphic position and is from 4 to 8 feet below top of the Cherokee. Underlain by Squirrel sand of drillers.

W. B. Howe. 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2091–2092. Member of Cherokee formation. Geographically extended into northern Oklahoma where it is essentially a single massive bed about 3 feet thick. Overlies Kinnison shale member (new); underlies covered interval to base of lower limestone member of Fort Scott formation (Blackjack Creek). Has been identified as lower Fort Scott in northern Oklahoma.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 99. Included in Breezy Hill cyclothem.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Shown as Breezy Hill limestone in Mulky coal cycle of Senora formation in Oklahoma. Occurs above Kinnison shale. Mulky coal and underclay not present in Oklahoma.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 84–87, measured sections. Reallocated to member status in Mulky formation. Occurs below underclay of Mulky coal, where latter is present, and above Lagonda ("Squirrel") sandstone in southeastern Kansas or above Kinnison shale in northern Oklahoma. Known in western and northern Missouri only from scattered exposures.

J. V. A. Trumbull, 1957, U.S. Geol. Survey Bull. 1042–J. pl. 16. Member of Senora formation in Oklahoma.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as member of Cabaniss formation.

Named for exposures at Breezy Hill, southwest of Mulberry, Crawford County, Kans.

Breien Member (of Hell Creek Formation)

Upper Cretaceous: Southwestern North Dakota.

W. M. Laird and R. H. Mitchell, 1942, North Dakota Geol. Survey Bull. 14, p. 14–15. Consists of two beds of gray sand separated by gray bentonite. Maximum thickness 31 feet. Interfingers with basal part of formation; base occurs about 20 feet above base of Hell Creek.

Named for occurrence near village of Breien in T. 134, N., R. 82 W., Morton County.

Breitenbush Series or Tuffs

Oligocene to Miocene: Northwestern Oregon.

T. P. Thayer, 1936, Jour. Geology, v. 44, no. 6, p. 704, 705, 709 (fig. 2), 713 (fig. 3). Dominantly tuffaceous; basal exposed part consists of rhyolitic lavas and pyroclastics. Thickness about 7,500 feet. Along Breitenbush River, underlies Sardine series (new); contact gradational. In some areas unconformably underlies Outerson basalts (new).

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 9–10, fig. 1 (geol. map). Referred to as tuffs; about 7,500 feet of water-worked, land-laid tuffs, breccias, and conglomerates, interlayered with lava flows. Although upper beds are Miocene in part, most of tuffs are probably Oligocene, and some may be as old as Eocene. Mapped as Oligocene-Miocene. Type section stated.

Type section: Along Breitenbush River between French and Fox Creeks which are 1 and 5½ miles, respectively, east of Detroit, Marion County.

Bremen Sandstone Member (of Pottsville Formation)[1]

Pennsylvanian: Northern central Alabama.

Original reference: C. Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175.

Named for exposures in Bremen northwest corner of Birmingham quadrangle, Cullman County.

Bremo Quartzite

Silurian or younger: Central Virginia.

G. W. Stose and A. J. Stose, 1948, Am. Jour. Sci., v. 246, no. 7, p. 397–401, 408. Quartzite, about 400 feet thick, that overlies Arvonia slate. Consists of three units: upper and lower, each about 150 feet thick, of thin-bedded quartzite and interbedded knotted slate closely folded and a middle unit of massive quartzite, about 100 feet thick, with a few shale partings; vertical. Structure interpreted as isoclinal syncline.

Named for occurrence at Bremo Bluff, a prominent cliff of quartzite which rises 150 feet above floor of James River at point just east of bridge over river on U.S. Highway 15, Fluvanna County.

Brentwood Limestone Member (of Bloyd Shale)[1]

Lower Pennsylvanian (Morrow Series): Northwestern Arkansas and northeastern Oklahoma.

Original reference: G. I. Adams and E. O. Ulrich, 1904, U.S. Geol. Survey Prof. Paper 24, p. 28, 109.

C. A. Moore, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 3, p. 427–430. Geographically extended into Adair County, Okla., where it is defined to include shale and limestone members of the Bloyd between top of Hale formation and base of Kessler member of the Bloyd. Here consists of blue-black fissile clay shale with thin discontinuous limestone beds. On Bugger Mountain, exposed part of Brentwood is 65 feet thick.

C. A. Moore, 1947, Oklahoma Geol. Survey Bull. 66, p. 39. The Brentwood loses its identity in Oklahoma and becomes indistinguishable in a sequence of alternating, thin, discontinuous limestones and interbedded shale of the lower Bloyd.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1942–1943. Further described in area of type locality where it is recognizable largely by its position between Prairie Grove member (new) of Hale formation below and terrestrial sediments above that comprise newly defined Woolsey member of the Bloyd.

Named from exposures in vicinity of Brentwood Station, Washington County, Ark.

Brereton cyclothem (in Carbondale Formation)

Brereton cyclothem[1] (in Carbondale Group)

Pennsylvanian: Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 182, 192.

J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). In list of Upper Pennsylvanian cyclothems, occurs below Jamestown cyclothem (new).

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 60–61, 103–113, pl. 5. Described in Beardstown, Glasford, Havana, and Vermont quadrangles, where it includes (ascending) Cuba sandstone, Big Creek shale, Herrin (No. 6) coal, Brereton limestone, and Sheffield shale. Underlies Pokeberry cyclothem believed to be equivalent to Jamestown cyclothem. Derivation of name and type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Carbondale formation (redefined). Above St. David cyclothem and below Jamestown cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type section: Along Middle Branch of Copperas Creek, 2 miles northeast of Brereton, in NE¼SE¼NE¼ sec. 1, T. 7 N., R. 4 E., Glasford quadrangle, Fulton County.

Brereton Limestone Member (of Carbondale Formation)

Brereton Limestone (in McLeansboro Formation)[1]

Brereton Limestone (in McLeansboro Group)

Brereton Limestone (in Petersburg Formation)

Pennsylvanian: Central western Illinois and southwestern Indiana.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 25). Shown on correlation chart as limestone in Petersburg formation in Indiana.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 111–112. Included in Brereton cyclothem, McLeansboro group. Overlain and underlain by unnamed shale units. Stratigraphically below Sheffield shale (new).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 48 (table 1), 65, pl. 1. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Carbondale redefined as formation and includes Brereton limestone member. Name Brereton is extended to caprock of No. 6 coal in southern Illinois to replace name Herrin, now restricted to Herrin (No. 6) coal member. Underlies Jamestown coal member in southern Illinois and Lawson shale member (new) in western and northern Illinois. Thickness 3½ feet.

Type locality: East bank Middle Copperas Creek, SE¼NE¼ sec. 1, T. 7 N., R. 4 E., Fulton County, Ill.

Brevard Schist[1]

Brevard Series

Lower Cambrian: Western North Carolina, northwestern Georgia, and northwestern South Carolina.

Original reference: A. Keith, 1905, U.S. Geol. Survey Geol. Atlas, Folio 124, p. 5.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 23–27. Discussion of crystalline rocks of Georgia. Rocks are grouped into 11 belts, in part using names proposed by Adams (1933, Jour. Geology, v. 41, no. 2). Brevard series occupies belt averaging about 2 miles in width and extending from Habersham County southwestward across state into Alabama. Series includes biotite gneiss, mica schist, quartzite, chlorite schist, and marble. Brevard schist was mapped as Cambrian by Keith (1907, U.S. Geol. Survey Geol. Atlas, Folio 147) but is similar to schists in Carolina series. Brevard schist traced southwestward into Alabama where it is included in Ashland and Wedowee formations. Keith believed Brevard schist rested unconformably on Carolina gneiss and old granites, but no evidence of this unconformity is to be found in Georgia. Henderson granite gneiss in North Carolina and Lithonia granite gneiss in Georgia are instrusive into Brevard schist. Name Brevard is retained, but author [Crickmay] believes that Brevard series is essentially part of Carolina series and is Precambrian.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 31; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000); North Carolina Div. Mineral Resources. Fine-grained black and dark schist with lenses of limestone varying from a few hundred feet to more than 1 mile in length and up to 250 feet in thickness. Lower Cambrian(?).

Named for exposures near Brevard, Transylvania County, N.C.

Brewer Phyllite

Brewer Phyllite Member (of Talladega Slate)[1]

Precambrian or Paleozoic: Northeastern Alabama.

Original reference: Charles Butts, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 52, map.

Charles Butts, 1940, U.S. Geol. Survey Geol. Atlas, Folio 226. Rank raised to formation. Overlies Waxahatchee slate; underlies Wash Creek slate (new). Thickness 200 to 500 feet.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 20, 21. Overlies Waxahatchee slate. Underlies Wash Creek slate. Thickness 200 to 500 feet. In Talladega series.

Named for exposures at Brewer School, in Columbiana quadrangle, Chilton County.

Brewer Creek Latite[1]

Tertiary: Southern Colorado.

Original reference: W. S. Burbank, 1932, U.S. Geol. Survey Prof. Paper 169.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 195, 196. In Greater Bonanza district, the volcanics in order of succession are Rawley andesite, Bonanza latite, Squirrel Gulch latite, Porphyry Peak rhyolite, and Bremer [Brewer] Creek latite. In South Bonanza district, volcanic sequence is roughly the same except Porphyry Peak rhyolite is missing and Bonanza latite is replaced by Hayden Peak latite.

Exposed north of and westward along Brewer Creek, Saguache County.

Brewer Dock Limestone (in Clinton Group)

Brewer Dock Member[1] (of Reynales Limestone)

Middle Silurian: West-central New York.

Original reference: H. E. Alling and J. E. Hoffmeister, 1932, 16th Int. Geol. Cong. Guidebook 4, p. 106, 107, 108, chart opposite p. 6.

D. W. Fisher, 1953, Buffalo Soc. Nat. Sci. Bull., v. 21, no. 2, p. 27 (fig. 1), 31–32. Argillaceous limestone with many shale partings. Shale is greenish gray in contrast to bright-green shale of underlying Maplewood. Thickness 3 feet in Genesee Gorge; thins eastward to 2½ feet at Glen Edythe; not identified outside Rochester area. Fauna is similar to the Lower Reynales (Reynales limestone of Niagara Gorge) with which it is correlated as being a more argillaceous near-shore phase. Middle Silurian.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 47. Suggested that Brewer Dock, defined by Sanford (1935, Jour. Geology, v. 43, no. 2) as member of Reynales, be retained for discussing local geology of Rochester and vicinity. In that area, Brewer Dock is separated from rest of Reynales by the Furnaceville. In other parts of western New York where that condition does not exist, use of Brewer Dock is not justified.

D. W. Fisher, 1959, New York State Mus. Sci. Service Map and Chart Ser., no. 1. Included in Clinton group. Middle Silurian.

Typically exposed in Genesee Gorge near Brewer Dock, vicinity of Rochester, Monroe County.

Brewerton Shale[1]

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 28 (table 3). Listed on correlation chart showing development of Niagaran nomenclature.

Exposed at Brewerton, Onondaga County.

†Brewerville Sandstone (in Chester Group)[1]

Mississippian: Southwestern Illinois and southeastern Missouri.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 121.

Named for Brewerville Township, Randolph County, Ill., where it is well exposed in Mississippi River bluffs.

†Brewster Formation[1]

Middle Ordovician: Southwestern Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Bose, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 35, 37.

Named for exposures in Brewster County.

Brezee Phyllite[1]

Lower Cambrian: Southwestern Vermont.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 399.

Named for Brezee Mill Creek, which flows out of northeast end of Taconic Range, 3 miles south-southwest of Brandon, Rutland County.

Brian Head Formation

Miocene(?): Southwestern Utah.

H. E. Gregory, 1944, Am. Jour. Sci., v. 242, no. 11, p. 591–597, 599, 601, 602. Series of white, calcareous, and siliceous shalelike beds overlain by gray igneous agglomerates which in places form surface of plateaus and in other places extend upward to capping sheets of black lava. Thickness about 80 feet in Antimony Canyon; 520 feet in Horse Creek Canyon; 968 feet in North Branch of Limekiln Gulch. Overlies Wasatch formation.

H. E. Gregory, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 983–986, 987–988, 989. Forms almost entire surface of Markagunt Plateau. Along westward-facing cliffs of Sevier Plateau, where entire formation is exposed, stratified calcareous and tuffaceous rocks are separated from overlying dark-gray coarse agglomerate by erosional unconformity believed to be regional in extent. Because of this persistent time break, it has been suggested that Brian Head be restricted to stratified beds and agglomerate correlated with Bullion Canyon volcanics of Tushar and northern Sevier Plateaus.

R. L. Threet, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1386. At type locality, formation includes about 500 feet of interbedded volcanic ash and chalcedony, dacite lava, andesite breccia, and sheeted rhyolitic vitrophyre and tuff. The sheeted vitrophyre at top of type section is a glassy basal zone of the rhyolitic welded tuff caprock of Brian Head Peak. The andesite breccia and dacite lava immediately beneath the sheeted vitrophyre are a local agglomeratic phase of massive andesite lavas which constitute basal formation in group of Tertiary flows and welded tuffs which cap southern High Plateaus. Inasmuch as type Brian Head includes considerable thickness of rocks which are part of overlying group of flows and welded tuffs, it is suggested that term Brian Head formation be restricted, redefined, or abandoned.

Name derived from Brian Head, prominent projection of Markagunt Plateau near Cedar Breaks National Monument.

Briarcliff Dolomite

Upper Cambrian: Southeastern New York.

E. B. Knopf, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1212; 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1817. Dominantly light dolomites with some dark beds. Fossils indicate a horizon not earlier than middle Franconian nor later than middle Trempealeauian state, probably early Trempealeauian. Thickness 700 to 1,000 feet. Occurs below Halcyon Lake calc-dolomite (new) and above White Plains formation (new).

Described in area of Stissing Mountain, Dutchess County.

Briar Hill Coal Member (of Carbondale Formation)

Pennsylvanian: Western Kentucky and southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 47 (table 1), pl. 1. Assigned member status in Carbondale formation (redefined). Occurs above St. David limestone member and below Vermilionville sandstone member. Coal named by Glenn (1912, Kentucky Geol. Survey Bull. 17). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: In mines at DeKoven, Shawneetown quadrangle, Union County, Ky.

Briar Hill cyclothem (in Carbondale Formation)

Pennsylvanian: Southwestern and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 43, 52 (table 2), pl. 1. Proposed for unit formerly termed Crab Orchard cyclothem. Contains Briar Hill (No. 5) coal member. Occurs above St. David cyclothem and below Brereton cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Name derived from Briar Hill near village of DeKoven, Union County, Ky.

Briceville Shale

Briceville Formation

Briceville Shale (in Pottsville Group)[1]

Pennsylvanian: Eastern Tennessee.

Original reference: A. Keith, 1896, U.S. Geol. Survey Geol. Atlas, Folio 25, p. 4.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 58–63. Briceville formation includes 500 to 1,000 feet of strata, predominantly shale. Underlies Jellico formation; overlies Lee group. Term Briceville seems to have been applied to strata down to Corbin sandstone near Oneida and Helenwood, Scott County, but farther south it seems to have been extended down to Rockcastle sandstone. Recommended that term Duskin

Creek be used for strata between the Corbin and Rockcastle where position of Corbin can be determined.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1958, Pennsylvanian Geology of Cumberland Plateau: Tennessee Div. Geology [Folio], p. 1. As result of recent field work, formation names Briceville, Jellico, Scott, and Anderson are discontinued and complete new classification is presented. Strata termed Briceville are included in Slatestone group (new).

U.S. Geological Survey has discontinued the use of the term Pottsville Group in Tennessee.

Named for occurrence at Briceville, Anderson County.

Brickeys Member (of Mifflin Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 10, 16. Limestone or dolomite; thin- to medium-bedded. Thickness about 2 feet. Shown on columnar section as underlying Boarman member (new) of Mifflin formation and overlying Oglesby member (new) of Pecatonica formation.

In copy of guidebook used by compiler, a handwritten note states Brickeys member overlies Boarman member. Since compiler had no way to determine what changes, if any, had been made in other copies of guidebook, it was impossible to be certain of true stratigraphic relation.

Occurs in Dixon-Oregon area.

Brick Yard Limestone[1]

Pennsylvanian: Northern central Texas.

Original reference: W. G. Wender, 1929, Texas Bur. Econ. Geology, geol. map of Eastland County.

Bridalveil Granite[1]

Cretaceous: Northern California.

Original reference: H. W. Turner, 1899, Jour. Geology, v. 7, p. 154.

U.S. Geological Survey currently designates the age of the Bridalveil Granite as Cretaceous on the basis of a study now in progress.

Forms brink of Bridalveil Fall in Yosemite National Park.

Bridgeburg horizon[1]

Silurian: Western New York.

Original reference: G. H. Chadwick, 1917, Geol. Soc. America Bull., v. 28, p. 173–174.

Derivation of name not stated.

Bridge Creek Limestone Member (of Greenhorn Limestone)[1]

Upper Cretaceous: Western Kansas and southeastern Colorado.

Original reference: N. W. Bass, 1926, Kansas Geol. Survey Bull. 11, p. 67.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. In Hamilton County, Kans., Pfeifer shale member and underlying Jetmore chalk member are thicker than farther east; they cannot be distinguished and have been together designated the Bridge Creek limestone member, having a total thickness of 74 feet.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 117–119. In Baca County, Colo., member contains alternating beds of chalky limestone and limy shale with a few thin layers of bentonite;

limestone beds are 3 to 12 inches thick and are separated by 6 inches to 6 feet of shale. Thickness 62 feet along Two Butte Creek; thickens eastward to 74 feet in Hamilton County, Kans.; thins westward to 35 feet in Model anticline in Las Animas County. Overlies Hartland shale member.

Named for exposures in Bridge Creek northwest of Medway, Hamilton County, Kans.

Bridge Creek Shales[1]

Oligocene or Miocene: Central northern Oregon.

Original references: R. W. Chaney, 1927, Carnegie Inst. Washington Pub. 346; 1927, Pub. 349, p. 1–22.

John Day Basin.

Bridgeport Limestone (in Palo Pinto Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: E. Bose, 1918, Texas Univ. Bull. 175, p. 12–13.

Exposed in western part of East Bridgeport, Wise County.

Bridgeport Member (of Bloomsburg Formation)

Bridgeport Sandstone (in Wills Creek Shale)[1]

Silurian: Central Pennsylvania.

Original reference: E. W. Claypole, 1885, Pennsylvania 2d Geol. Survey Rept. F_2, p. 57–58.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 5. Reallocated to member status in Bloomsburg formation. Occurs near middle of formation.

Named for exposures near Bridgeport, Perry County.

Bridger Formation[1]

Eocene, middle and upper(?): Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original references: F. V. Hayden, 1869, U.S. Geol. Survey Terr. 3d Ann. Rept., p. 191 of 1873 ed.; Henry Engelmann, 1876, (Fort Bridger series) *in* Appendix 1 of a report of explorations across the Great Basin of the territory of Utah for a direct wagon route from Camp Floyd to Genoa, in Carson Valley, in 1859, by Capt. James H. Simpson, Engineer Dept., U.S. Army: Washington, U.S. Govt. Printing Office, p. 287–291.

W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168, p. 19–22. In part of Piceance Creek basin, Colorado, rocks of Green River formation are overlain by 400 feet of sandy beds of fluviatile origin that appear to be lithologically and stratigraphically equivalent to basal beds of Bridger formation of Uinta basin. In eastern part of Uinta basin, lower part of Bridger is brown massive sandstone about 800 feet thick. Upper part of formation consists of greenish, drab, red, maroon, ash-gray, and buff sandy mudstone. Locally, contact between Bridger and underlying Green River has been distorted by differential compaction. Underlies Uinta formation.

H. E. Wood 2d, 1934, Am. Mus. Nat. History Bull., v. 67, art. 5, p. 241–242. In southwestern Wyoming, subdivided into Blacks Fork member below and Twin Buttes member above.

R. L. Nace, 1939, Wyoming Geol. Survey Bull. 27, p. 11 (table), 19–21, pl. 1. For purposes of this report [Red Desert], Bridger formation is divided into upper and lower parts, but terms "upper" and "lower" are not intended to indicate time relation to typical Bridger formation in Bridger basin. They are lithologic divisions of formation as it is developed in map area. Lower Bridger is an alternation of somber-colored sandstones, clays, mudstones, shales, and limestones. Upper Bridger is predominantly sandstone and shale. Thickness 670 to 765 feet. Overlies Morrow Creek tongue of Green River; disconformably underlies Continental Peak formation (new). Middle Eocene.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 416. Discussion of Green River and Uinta formations in Duchesne, Uintah, and Wasatch Counties, Utah. Uinta formation comprises thick sequence of chiefly fluviatile beds, but includes varying amount of lacustrine beds. Westward from Colorado State line to the Green River, where formation has been most studied, it contains three recognized vertebrate faunal zones of middle to late Eocene age, and surface exposures indicate thickness of 1,500 to 2,000 feet. This sequence conformably overlies Green River formation as was formerly divided by U.S. Geological Survey into Bridger and Uinta formations. More general recent usage has been to refer entire sequence to Uinta formation, which usage is followed here.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 101, 103. Overlies Morrow Creek member of Green River formation in central part of Great Divide basin, Sweetwater County, Wyo.; underlies Browns Park formation. Thickness 60 to 100 feet.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1074. Overlies Laney shale member of Green River in Bridger basin. Term Morrow Creek abandoned.

C. L. Gazin, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 136. Formation discussed in report on paleontological exploration and dating of early Tertiary deposits in basins adjacent to Uinta Mountains.

Named for exposures in vicinity of Fort Bridger, Uinta County, Wyo.

Bridgerian Age

Eocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 10, pl. 1. Provincial time term, based on the Bridger formation of southwestern Wyoming (of a redefinition of Bridgerian "series" of C. R. Keyes), or more specifically, the time of deposition of Blacks Fork and Twin Buttes members of Bridger formation (Eocene) with enclosed faunas. Covers time interval between Eocene Wasatchian (older) and Uintan ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

†Bridgerian series[1]

[Tertiary]: Colorado, Utah, and Wyoming.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 279, 309.

Bridgetimber Gravel[1]

Pliocene or Pleistocene: Southwestern Colorado.

Original reference: W. W. Atwood and K. F. Mather, 1932, U.S. Geol. Survey Prof. Paper 166.

Harley Barnes, E. H. Baltz, Jr., and P. T. Hayes, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM-149. Mapped as Pliocene or Pleistocene.

Caps Bridge Timber Mountain southwest of Durango.

Bridgeton Formation (in Columbia Group)[1]

Pleistocene: New Jersey.

Original reference: R. D. Salisbury, 1898, New Jersey Geol. Survey Ann. Rept. State Geologist 1897, p. 13-15.

J. H. C. Martens, 1956, Rutgers Univ. Bur. Mineral Research Bull. 6, p. 72-74. Oldest Pleistocene formation in southern New Jersey. Commonly occurs immediately below surface with no younger formations, or only a small amount of windblown sand, overlying it; in Cumberland and Cape May Counties is overlain by Cape May formation; unconformably overlies Cohansey and Kirkwood formations. Composed mostly of coarse sand deposited by rivers. Maximum thickness 60 feet; commonly less than 30 feet. Glassboro phase as described by Salisbury and Knapp (1917, New Jersey Geol. Survey, v. 8) includes greater part of formation.

Named for exposures at Bridgeton, Cumberland County.

Bridgewater Member (of Marcellus Shale)[1]

Middle Devonian: Central eastern New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th ser., v. 19, p. 133, 219.

R. E. Stevenson, 1948, New York State Sci. Service Rept. Inv. 1, p. 2 (table 1). Underlies Solsville member; overlies Chittenango member.

Named for exposures on Seabridge Farm 2¼ miles west of Bridgewater, Oneida County.

Bridle Formation

Precambrian (Yavapai Series): West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 7-10, pl. 3. Metamorphosed series of amygdaloidal and massive flows of andesite and basalt and intercalated sedimentary rocks and rhyolitic tuff. Includes belt of chlorite-biotite schist mapped separately as "spotted schist" (pl. 3). Sedimentary rocks were predominantly deposited in water; they have become schistose rocks in which chlorite and sericite are chief foliated minerals. Thickness 3,000 feet in mapped area; greater thickness exposed in unmapped area south of Bridle Creek. Oldest formation of Yavapai series; underlies Butte Falls tuff (new). Intruded by Dick rhyolite and Lawler Peak granite (both new). Mass of King Peak rhyolite (new) exposed west of Niagara Creek is essentially concordont with southwestern belt of Bridle formation, but evidence proves that rhyolite is intrusive.

Crops out in two belts in southern part of Bagdad area, Yavapai County. Named from Bridle Creek.

Bridport Dolomite Member (of Chipman Formation)

Bridport Dolomite (in Beckmantown Group)

Lower Ordovician: West-central Vermont and northwestern New York.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524, 539, 540, 545-546. Corresponds to Division E of "Calciferous" of Brainerd and Seely (1890, Am. Mus. Nat. History Bull., v. 3). Includes beds of fine-grained dolomite, 1 or 2 feet thick, weathering drab, yellowish, or brown. Occasional fossiliferous pure limestone layers. Rarely thin layers of slate. Maximum thickness 500 feet. Underlies Crown Point limestone; conformably overlies Bascom formation (new). Upper contact of Bridport is in most places a distinct stratigraphic break, above which may be any of the formations of the Chazy or Black River-Trenton that crop out in area occupied by Bridport.

Marshall Kay, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1476. Bridport dolomite formation along Lake Champlain is uppermost part of Beekmantown, Canadian series. Underlies quartz arenites and calcarenites of basal Chazy Day Point within and west of Lake Champlain in Vermont and New York. Beldens calcite marble is a calcitic facies of the Bridport.

W. M. Cady and E-an Zen, 1960, Am. Jour. Sci., v. 258, no. 10, p. 728–739. Rank reduced to member status in the Chipman herein reduced to rank of formation. Consists of massive dolomitic beds, which in Cornwall area interfinger with limestones (Burchards, Weybridge, and Beldens) of Chipman formation. Beekmantown age. [See Chipman formation, this reference.]

Named for wide exposures on hills in southeastern part of town of Bridport, Addison County, Vt.

Bridwell Formation

Pliocene, middle: Western Texas.

G. L. Evans, 1949, West Texas Geol. Soc. Guidebook Field Trip 2, Nov. 6–9, p. 4 (table 1), 6–7. Bedded, unconsolidated sand and clay with thick channel gravel occurring both at base and at higher levels; characteristically reddish brown; locally a few gray highly calcareous members, including caliche cap rock. Thickness at type locality 155 feet; locally pinches out against higher relief features on bed rock surface which extends well above upper level of Couch formation (new). Underlies Blanco formation.

D. C. Van Siclen, 1957, Jour. Geology, v. 65, no. 1, p. 49 (fig. 2), 51, 52. Thickness 75 feet. Stratigraphic section lists formation under heading Pliocene (Miocene?).

Typically exposed on Fowler Ranch, 10 miles north of Crosbyton, Crosby County. Named for Bridwell Ranch in Blanco Canyon.

Brier Slate Member (of Vulcan Iron-Formation)[1]

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1900, U.S. Geol. Survey Geol. Atlas, Folio 62.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. As defined here, Vulcan iron-formation includes (ascending) Traders iron-bearing member, Brier slate member, Curry iron-bearing member, and Loretto slate member.

Named for Brier Hill, Menominee district, [Dickinson County].

†Brier Creek Marl[1]

Oligocene and Miocene: Southeastern Georgia and western South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 18, name only, not defined; 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 435, 464, 465.

Typically exhibited along Brier Creek, near Jacksonboro, Ga.

Brierfield Dolomite[1]

Upper Cambrian: North-central Alabama.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 628, 633, 634, pl. 27.

C. E. Resser, 1938, Geol. Soc. America Spec. Paper 15, p. 17. *Cryptozoon* masses are only indications of organisms present; consequently age determination not possible. Seems Brierfield should be regarded as closely associated with the Ketona and should have stratigraphic position between Nolichucky and Copper Ridge.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart below Ketona dolomite. Middle Cambrian.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 23. Listed with formations of Cambrian or Ordovician age.

Named for exposures on Mahan Creek in Vicinity of Brierfield, Bibb County.

Brier Hill Sandstone (in Washington Group)

Permian (Dunkard): Southwestern Pennsylvania.

W. O. Hickok, 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, ser. 4, Bull. C-26, p. 152. Name proposed for heavy-bedded to massive gray coarse-grained, slightly micaceous sandstone in upper part of Washington group. Thickness 10 to 30 feet; average about 15 feet. Underlies Upper Washington limestone; overlies Jollytown coal. Noted by Stevenson (1876) in his Washington County group but not named.

Well exposed in roadcuts on hilltop northwest of Brier Hill, Fayette County, for which settlement it is named.

Briggs Formation

Lower Permian: Western Texas.

C. C. Albritton, Jr., 1937, Jour. Paleontology, v. 11, no. 1, p. 19. Section in Malone Mountains shows Briggs formation consists of gypsum with interbedded limestones. Thickness more than 300 feet. Separated from Upper Jurassic Malone formation (emended) by unconformity.

C. C. Albritton, Jr., 1938, Geol. Soc. America Bull., v. 49, no. 12, pt. 1, p. 1753–1757. Includes minimum of 630 feet of anhydrite and gypsum with interbedded limestone; base of formation not exposed. Interbedded bodies of limestone range from laminae of microscopic dimensions to lenses more than 100 feet thick and several miles in width. Three lenses of sufficient magnitude to be mapped and considered as members are described (ascending): Black limestone member as much as 150 feet thick; black brecciated limestone member as much as 80 feet thick; and buff limestone member. At least in part equivalent to Leonard formation in Glass Mountains.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 994–995. In northern Quitman Mountains, consists only of medial black brecciated limestone member. Thickness about 200 feet.

Named for Briggs (now Gypsum) Switch on Southern Pacific Railroad, Hudspeth County, Malone Mountains area.

Brigham Quartzite[1]

Lower(?) and Middle Cambrian: Northeastern Utah and southeastern Idaho.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 6, 7.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1115–1116, 1117 (fig. 4), 1118. Walcott's (1908) Blacksmith Fork section restudied. Base of Brigham not exposed. Estimated thickness 1,000 feet. Underlies Langston limestone (emended).

A. J. Eardley and R. A. Hatch, 1940, Geol. Soc. America Bull., v. 51, no. 6, p. 809–812. Described in Bakers Canyon (which may have been Walcott's type locality for Brigham quartzite). Underlies Langston limestone. Total thickness below limestone 1,775 feet.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 7–8, pl. 1. Described in Randolph quadrangle, where it is about 1,600 feet thick, base not exposed. Underlies Langston limestone.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1130 (table). Table of summary formations in Logan quadrangle, Utah, lists Brigham quartzite (Waucobian) above Precambrian Big Cottonwood Canyon series.

W. L. Stokes, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 14. Summary discussion. Although no fossils known, great thickness suggests span of deposition from at least early to middle Cambrian time. Probably passes into Flathead quartzite to north and east. Up to 6,000 feet thick with base not exposed.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 667. In area of this report [northern Utah and southeastern Idaho], all but uppermost shaly units of so-called Brigham quartzite are assigned to Prospect Mountain quartzite.

Type locality: West front of Wasatch Range, northeast of Brigham, Box Elder County, Utah.

Brigham Hill Graywacke

Lower Cambrian: Western Vermont.

E. C. Jacobs, 1935, (abs.) Geol. Soc. America Proc. 1934, p. 85. In Green Mountains, westernmost nappe is made up of Cheshire quartzite, of Lower Cambrian age, infolded with a fine-grained graywacke, which has been traced from Essex Junction into southern Quebec, where it is known as Gilman "quartzite." In Vermont, this rock has been named Brigham Hill graywacke.

E. C. Jacobs, [1937], Vermont State Geologist 20th Rept., p. 100–101. Yellowish to dark-gray very fine-grained graywacke, often with thin bandings of argillaceous material. Phase of Cheshire quartzite, not a formation. Age designated. Exposures described and derivation of name given.

Named for exposure on Brigham Hill, Essex Township, Chittenden County. Crops out intermittently in Green Mountains from Lake Dunmore north to Quebec border. Makes up Arrowhead Mountain as a klippe thrust onto Upper Cambrian slate.

Bright Angel Shale (in Tonto Group)[1]

Bright Angel Group

Middle Cambrian: Northern Arizona, southeastern California, and southern Nevada.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

H. E. Wheeler, 1943, Geol. Soc. America Bull., v. 54, no. 12, pt. 1, p. 1797. Since Lyndon formation does not continue eastward from western Grand Canyon to Granite Gorge region as cartographic unit, underlying and overlying Pioche and Chisholm shales in latter area merge into Bright Angel shale. Thus beyond eastern limit of Lyndon in Grand Canyon, Bright Angel is recognized as corresponding to combined Pioche, Lyndon, and Chisholm formations to the west.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 17, 20–21, 80–84. Thickness varies considerably from place to place owing to lateral changes in lithology along time planes. Both base and top of formation rise stratigraphically, but at irregular rate, from west to east. Thickness 325 feet at type locality. Intertongues with Muav limestone to west. Includes Flour Sack member (new) and Meriwitica and Tincanebits tongues (new).

H. E. Wheeler and E. M. Beesley, 1948, Geol. Soc. America Bull., v. 59, no. 1, p. 75, 77–78. Bright Angel group defined as predominantly argillaceous strata which lie between underlying Prospect Mountain quartzite and overlying Middle Cambrian limestone. This lithogenetic unit ranges in age from partly Precambrian in Nopah Range of southeastern California to entirely Middle Cambrian in Grand Canyon of Arizona.

H. E. Wheeler and V. S. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 10, p. 2413 (fig. 2e), 2414. Includes Chisholm shale member in parts of Grand Canyon.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 32, 34–35, fig. 4, pl. 1. Widely distributed throughout eastern half of Ivanpah quadrangle, California and Nevada, where shale attains maximum thickness of about 420 feet.

Named for Bright Angel Canyon in walls of which formation is well exposed; Arizona.

Bright Diamond Limestone (in Morrison Formation)[1]

Upper Jurassic: Southwestern Colorado.

Original reference: J. D. Irving, 1905, U.S. Geol. Survey Bull. 260, p. 56.

Name probably derived from Bright Diamond mine.

Bright Diamond Quartzite (in Morrison Formation)[1]

Upper Jurassic: Southwestern Colorado.

Original reference: J. D. Irving, 1905, U.S. Geol. Survey Bull. 260, p. 56.

Probably named from Bright Diamond mine.

Brighton Melaphyr (in Boston Bay Group)[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. W. Dodge, 1881, Boston Soc. Nat. History Proc., v. 21, p. 205–208.

Named for occurrence at Brighton.

Brightseat Formation

Paleocene: Eastern Maryland.

R. R. Bennett and G. G. Collins, 1952, Washington Acad. Sci. Jour., v. 42, no. 4, p. 114–116. Dark-gray micaceous sandy clay. Thickness 4 to 8 feet. Unconformably underlies Eocene Aquia greensand; unconformably overlies Upper Cretaceous Monmouth formation.

Type locality: One mile west-southwest of Brightseat, Md., and one-fifth mile south of Sheriff Road.

Brimfield Schist[1]

Pre-Pennsylvanian: Central Massachusetts, northern Connecticut, and southern New Hampshire.

Original reference. B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 17, pl. 24, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 76–80, pl. 1. Believed to be late Precambrian or early Paleozoic.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 20. Proposed that Brimfield schist be restricted to areas where the schist is not known to be equivalent to Worcester formation as redefined in this report [Hudson and Maynard quadrangles, Massachusetts]. Brimfield schist of previous reports dealing with this area are referred to as "mica schist facies" of redefined Worcester. Carboniferous.

M. E. Willard, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–85. Intruded by Belchertown tonalite at type locality of the Belchertown.

Named for occurrence at Brimfield, Mass.

Brindle Pup Andesite (in Ash Creek Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 14, pl. 1. Dark-gray rock which weathers to light-brown surfaces on which cream-colored plagioclase phenocrysts are conspicuous. Groundmass aphanitic to very finely crystalline. Vesicles and quartz amygdules present, increasing in abundance near flow tops. Intercalated Buzzard and Deception rhyolitic flows and basaltic flows similar to Shea basalt. Basaltic flows highly vesicular greenish-black lava containing sparse plagioclase phenocrysts in finely crystalline groundmass. Thickness ranges from about 2,500 feet in widest outcrop to a wedge line. Underlies Deception rhyolite; overlies Buzzard rhyolite (new).

Named and defined from Brindle Pup Gulch, Jerome area, Yavapai County, where it is well exposed. Occurs as thick lense to south of Mingus Mountain.

Brine Creek Formation

Cretaceous: Northern Alaska.

T. C. Hiestand, 1957, Oil and Gas Jour., v. 55, no. 49, p. 194 (table 1). Name appears only on table. Nonmarine. Included with formations assigned Lower and Upper Cretaceous age.

Under heading Arctic foothills and coastal plain.

Briones Sandstone (in San Pablo Group)[1]

Briones Stage or Substage

Miocene, upper: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

J. E. Eaton, U. S. Grant, and H. B. Allen, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 199–200. The Monterey comprises three substages (ascending): Briones, Cierbo, and Neroly. Substages can be recognized strandward by distinctive echinoderm faunas and by a number of more or less distinctive mollusks.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 75–78. Shown on table as underlying Cierbo sandstone and overlying Rodeo shale. Includes Hercules shale member. In San Pablo group.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 22 (fig. 4), 39–41, pl. 1. Described in San Jose-Mount Hamilton area as thick series of massive coarse-grained fossiliferous sandstones and sandy shales. Thickness 3,400 to 5,000 feet. Unit crops out almost without interruption for entire length of Tularcitos syncline; on west limb it rests on Monterey formation; on east limb rests for considerable distances on Cretaceous Berryessa formation (new). Underlies Orinda formation, slight angular unconformity; in some areas underlies Packwood gravels (new).

J. W. Durham, 1954, California Div. Mines Bull. 170, chap, 3, p. 24 (fig. 2), 25 (fig. 3), 26 (fig. 4). Listed as megafaunal stage. Follows Temblor and precedes Cierbo.

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Map GQ–88. Described in Hayward quadrangle as pale-yellow thick-bedded coarse calcareous arkosic sandstone; discontinuous pebble conglomerate. Thickness ranges from 500 to 1,500 feet. Overlies Rodeo shale. In this report, the San Pablo is considered a formation overlying the Briones.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 21–25, fig. 2, geol. map. Formation crops out in northwestern corner and southern half of Pleasanton area. Thickness about 2,000 feet in northern area and 5,000 feet in southern area. Divided into three members: upper, fine-grained sandstone; middle, gray to brown conglomerate fossiliferous calcareous lithic wacke; upper, fine-grained sandstone and interbedded silty claystone. Overlies Hambre sandstone. Near Calaveras Reservoir, transgressively overlaps older Tertiary formations and rests on Niles Canyon formation (new). Underlies Leona rhyolite, Livermore gravels, and in Tularcitos syncline, Orinda formation. Upper Miocene. Term San Pablo group not used in this report.

Named for exposures in Briones Hills, Contra Costa County.

Brisbois Formation

Upper Triassic: Northeastern Oregon.

W. R. Dickinson, 1960, Dissert. Abs., v. 20, no. 11, p. 4367. Upper Triassic sequence includes Begg, Brisbois, and Rail Cabin formations. Thickness of sequence, which is overlain by Lower Jurassic Graylock formation (new), is nearly 15,000 feet.

Type locality and derivation of name not stated. Report discusses Izee area, Grant County.

Briscoe Glacial Substage

Pleistocene (Wisconsin): Central Colorado.

Q. D. Singewald, 1950, U.S. Geol. Survey Bull. 955–D, p. 120, pl. 9 [1951]. Times of maximum ice advance and of two principal ice stands during retreat are called Fairplay, Briscoe, and Alma substages, respectively, of Wisconsin stage of glaciation. The Briscoe represents time covered by deposition of Briscoe moraines.

In northwestern Park County. Moraines present only in Platte, Sacramento, Horseshoe, and Middle Tarryall Valleys.

Brister Limestone Member (of Big Saline Formation)

Lower Pennsylvanian: Central Texas.

F. B. Plummer, 1947, Jour. Paleontology, v. 21, no. 2, p. 142, 143, 144; 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 196 (table 2), 198. Medium- to thick-bedded coarsely crystalline crinoidal limestone made up of conglomeratelike nodules and crinoidal detritus with very irregular bedding planes and other characteristics which suggest reeflike origin. Total thickness 50 to 75 feet. Overlies Lemons Bluff member east of Cavern Ridge; underlies Smithwick formation.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 71–73. Referred to as Brister Bluff lentil. Thickness at designated type locality 20 feet.

Type section: At Rough Creek crossing on Bend-San Saba road, San Saba County.

Brister Bluff Lentil (in Big Saline Formation)

See Brister Limestone Member (of Big Saline Formation).

†Bristol Formation[1]

Pliocene: Northern Florida.

Original reference: E. H. Sellards, 1918, Florida Geol. Survey 10th and 11th Ann. Rept., p. 51.

Typically exposed in vicinity of Bristol, Liberty County.

Bristol Granite Gneiss[1]

Pre-Triassic: Central Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 104–105, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Redescribed as granitoid gneiss with layers and patches of hornblende-plagioclase gneiss occurring locally, especially near borders. Pre-Triassic. Derivation of name.

Named for town of Bristol, Hartford County.

Bristol Limestone (in Washington Formation)[1]

Bristol limestone member

Permian: Northern West Virginia and Eastern Ohio.

Original reference: R. V. Hennen, 1912, West Virginia Geol. Survey Rept. Doddridge and Harrison Counties, p. 168.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 213–215. Member of Washington cyclothem in report on Athens County. Tentatively correlated with Bristol limestone of Hennen.

Thickness about 5½ feet. Occurs above a redbed and shale member and below Washington fire-clay shale member.

Named for Bristol, Harrison County, W. Va.

Bristol Bay Silts and Gravels[1]

Pleistocene: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 177–178.

Extent from Togiak Bay to Bristol Bay.

Bristol Pass Limestone[1]

Lower Mississippian: Eastern Nevada.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171, p. 7, 20, map.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). On correlation chart of recommended revision of stratigraphic units pertaining to the Great Basin, Bristol Pass limestone is shown equivalent to Joana limestone member of White Pine shale. Joana is recommended term. Pioche district as used in this report extends north to Dutch John Mountain, about 40 miles north of Pioche.

Named for occurrence at Bristol Pass, in summit of hill immediately north of bench mark 6149, Pioche district, Lincoln County.

†Bristow Formation[1]

Pennsylvanian: Central Oklahoma.

Original reference: A. E. Fath, 1925, U.S. Geol. Survey Bull. 759, p. 13–15.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 106. Rejected by Oklahoma Geological Survey. Essentially upper part of Vamoosa formation. Name preoccupied by Bristow shale and sandstone of Indiana and Kentucky.

Named for Bristow, Creek County.

Bristow Shale and Sandstone (in Chester Group)[1]

Mississippian: Southwestern Indiana and western central Kentucky.

Original reference: W. N. Logan, 1924, Indiana Dept. Conserv. Pub. 42, p. 11, 125.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 6. Replaced by Palestine sandstone. Local Indiana names of upper Chester are dropped and formations given names of standard Chester column.

Named for exposures near village of Bristow, Perry County, Ind.

Brite Ignimbrite (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 15 (fig. 3), 26, 28. Name proposed for ignimbrite underlying Petan basalt and overlying Capote Mountain tuff (new). Resembles sanidine rhyolite porphyry; in thin section matrix shows glass shards and other pyroclastic material. Thickness about 100 feet. Locally overlain by a post-volcanic gravel.

Type locality: Top of Capote Mountain, Rim Rock country, Presidio County. Name derived from Brite Ranch.

Briton Member (of Mifflin Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 10, 16. Limestone or dolomite. Thickness 10 feet. Shown on columnar section as overlying Hazelwood member (new) and underlying Dement member (new) of Grand Detour formation (new).

Occurs in the Dixon-Oregon area.

Britton Clay[1]

Upper Cretaceous (Gulf Series): Eastern Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 270, 425.

C. C. Albritton, Jr., and others, 1941, Field and Lab., v. 10, no. 1, p. 23. As originally defined, the Arcadia Park included 20 feet of bluish-gray clay at its base; this clay would seem to be more logically grouped with the Britton, from which it cannot be distinguished lithologically. With some adjustment regarding boundary between these two units, the Tarrant, Britton, and Arcadia Park might stand as members of Eagle Ford formation.

W. L. Turner, 1951, Field and Lab., v. 19, no. 2, p. 54. Abandoned in Eagle Ford quadrangle.

Type locality: Britton, northwestern part of Ellis County.

Broadalbin (passage) Beds

Upper Cambrian or Lower Ordovician (Cambrovician): Central New York.

W. J. Miller, 1911, New York State Mus. Bull. 153, p. 29. Incidental mention as transition beds in Theresa formation.

A. W. Grabau, 1936, Paleozoic formations in the light of the pulsation theory, pt. 1, Caledonian and St. Lawrence geosynclines: Peiping, China, Univ. Press, Natl. Univ. Peking, p. 322 (fig. 7), 325–327, 350. The Theresa in Mohawk Valley sections is believed not to be of same age as true Theresa of northern Adirondack Embayment and is referred to as "Theresa" or Broadalbin passage beds. Constitute passage beds from upper Potsdam to Little Falls dolomite. Consist of alternating sandstones and dolomites. Thickness 150 to 250 feet; greatest thickness where Hoyt member of Theresa is not developed.

Occurs in Mohawk Valley, especially in Broadalbin quadrangle.

Broad Branch series[1]

Precambrian: District of Columbia.

Original reference: W. J. McGee, G. H. Williams, and N. H. Daron, 1893, 5th Internat. Geol. Cong., p. 244.

Broad Ford Sandstone

Broad Ford Sandstone (in Pocono Sandstone)[1]

Devonian or Mississippian (Kinderhookian): Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1925, Econ. Geology, v. 20, p. 778–779.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 170, chart 5 (columns 98, 99). Generally included in the Pocono, but its Mississippian age at type locality has been doubted. Shown on correlation chart in Pocono series (Kinderhookian) below Lindside sandstone and above Sunbury shale.

Lynn Glover, 1953, Virginia Jour. Sci., v. 4, new ser., no. 4, p. 259–260. Broadford [Broad Ford] is unfossiliferous at its type locality. By use of stratigraphic position and key beds, the Broadford has been located in six measured sections northeast of Broadford, and in each a Conewango fauna has been found. Generally the real Broadford sandstone in Virginia has been mapped as part of "Chemung formation," and younger Mississippian units have been mistakenly identified as the Broadford.

Type locality: At line between Smyth and Tazewell Counties, Va., about one-half mile north of Broad Ford village where Laurel Creek of Holston River cuts gap through ridge known as Pine Mountain on west and Brushy Mountain on east.

Broad Top series[1]

Carboniferous: Pennsylvania.

Original reference: H. D. Rogers, 1836, Pennsylvania State Geologist 12th Ann. Rept., p. 16–18.

Broadwater Formation

Pleistocene, lower: Western Nebraska.

C. B. Schultz and T. M. Stout, 1945, Am. Jour. Sci., v. 243, no. 5, p. 232–237. Proposed for sediments of early Pleistocene age. Sediments which constitute Broadwater were deposited in following order: basal gravel member, composed of reddish-brown crystalline gravels; Lisco member (new) consisting of diatomaceous marl and peat, with sand and silt lenses; and upper gravel member. Thickness at type locality 65 to 69 feet. Ogallala sediments were deeply eroded before deposition of Broadwater.

C. B. Schultz and T. M. Stout, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 553–588. Discussion of Pleistocene mammals and terraces in Great Plains. Unconformity between Kimball and Broadwater formations is most significant stratigraphic break in upper Tertiary and Pleistocene deposits of western Nebraska and Great Plains in general; likewise faunal break between the two formations is most important one paleontologically in same area. This break is believed to be Pliocene-Pleistocene boundary.

Type locality: At Broadwater locality of University of Nebraska State Museum, quarry 1, in NE¼ sec. 20, T. 19 N., R. 47 W., Morrill County.

Broadway Alluvium

Pleistocene (late Wisconsin): Northeastern Colorado.

G. R. Scott, 1960, Geol. Soc. America Bull., v. 70, no. 10, p. 1543. Consists of 12 to 15 feet of reddish-brown fine- to coarse-grained sand and some pebbles. Younger than Louviers alluvium (new).

Type locality: Gravel pit in SE¼ sec. 30, T. 2 S., R. 67 W. Named from Broadway Avenue on Broadway terrace, which lies 25 feet above South Platte River in Denver.

Brock Shale[1]

Upper Triassic: Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Atlas, Folio 138.

A. F. Sanborn, [1953], Stanford Univ. Abs. Dissert., v. 27, p. 436; 1960, California Div. Mines Spec. Rept. 63, p. 6 (figs. 3, 4), 7–8, pl. 1. Underlies Hawkins Creek member (new) of Modin formation (redefined); overlies Hosselkus limestone. Estimated thickness 400 feet.

Named from Brock Mountain, Redding quadrangle, between Squaw Creek and Pit River.

Brocklebank Granite

Upper Devonian(?): East-central Vermont.

C. G. Doll, [1945], Vermont State Geologist 24th Rept., p. 20–21. Light-gray medium-grained binary granite.

Named from good exposures in several quarries in vicinity of Brocklebank Hill, 4 miles south-southeast of village of Chelsea, Strafford quadrangle.

Brodhead Formation (in Borden Group)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 135–191, pls. 15, 16. Name proposed for a generalized unit in Kentucky which lies between New Providence formation below and Floyds Knob formation above. Falls within Burlington-Keokuk range of general Mississippian column. Comprises rock equivalent to combined Locust Point and Carwood units of Borden group in Indiana, and includes both Rosewood shale and Holtsclaw sandstone of Butts (1915) in Jefferson County and much of New Providence group as described by Butts (1922, Kentucky Geol. Survey, ser. 6, v. 7) for Kentucky. Composed mostly of silty shale, shaly siltstone, massive siltstone, and fine-grained sandstone with many variations from place to place produced by lateral transitions in facies. Thickness ranges from 135 to 270 feet. Unit is thinnest along axis of Cincinnati Arch from where it is progressively thicker both east and west. Includes following members (not in sequence): Caney Creek, Christy Creek siltstone, Clementsville limestone, Combs Mountain siltstone, Conway Cut siltstone, Culver Springs shale, Frenchburg siltstone, Ginseng siltstone, Haldeman siltstone, Indian Fort shale, Lebanon Junction siltstone, McKinney Knob, Perry Branch siltstone, and Rolling Fork limestone. Differentiated into six facies (in order of occurrence along outcrop belt around Lexington Plain from Indiana to Ohio): Holtsclaw Hill, Pilot Knob, Athertonville, Liberty, Irvine, and Morehead.

Type section: Starting at sandstone quarry just east of bridge over Dicks River, at Louisville and Nashville Railroad Station, Brodhead, Rockcastle County, and along road up hill east-southeast. Name derived from town of Brodhead.

Brodhead Member (of Marcellus Formation)

Middle Devonian: East-central Pennsylvania.

Bradford Willard, 1938, Pennsylvania Geol. Survey, ser. 4, Bull. G–11, p. 17. Name proposed for very finely arenaceous dark-gray nonfissile phase of formation. Bedding generally obscured. Exhibits subconchoidal fracture. May carry bands of small concretions. Devonian. Also referred to as Brodhead Creek member.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 139, 170–171. Thickness 20 to 30 feet. Middle Devonian.

Well exposed in quarry on north side of Stroudsburg and beyond, up Highway 90 along west bank of Brodhead Creek, Monroe County. Named for Brodhead Creek valley.

Brodhead Creek Member (of Marcellus Formation)

See Brodhead Member (of Marcellus Formation).

Brodhead Creek Member (of Tully Formation)

Upper Devonian: East-central Pennsylvania.

R. E. Stevenson and W. S. Skinner, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 30, 31, 32. Middle member of formation. Variable lithology; consists of shales and sandy shales changing eastward to fine sandstone at East Stroudsburg. Contains lense of dense hard limestone. Thickness about 75 feet at type section where appears to include whole of Tully. Overlies Weissport member (new) on Pohopoco Creek east of Lehighton. Grades into Trimmers Rock sandstone east of Stroudsburg.

Type section: On Brodhead Creek 3 miles northwest of East Stroudsburg, Monroe County.

†Broken Arrow Formation[1]

Pennsylvania (Des Moines Series): Northeastern Oklahoma.

Original reference: R. H. Wood, 1925, Oklahoma Geol. Survey Bull. 35, p. 71.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 99. Abandoned by Oklahoma Geological Survey. Name was given to facies of Labette shale and Nowata shale in area where Oologah and Lenapah were not recognized. Term is not useful, and name is one of those applied to Croweburg coal bed.

Named for Broken Arrow, Tulsa County.

Broken Jug Limestone (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 531, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 16–18, pl. 1. In general, consists of limestone, pure, shaly, and sandy, interbedded with sandstone, shale, and conglomerate. Coarse limestone conglomerate prominent locally. Red to green shale and sandstone present at three horizons in Eureka district. Thickness approximately 3,400 feet in Sylvanite district and perhaps more than 5,000 feet in Eureka district. Overlain by Howells Ridge formation (new) in Sylvanite district and by Ringbone shale (new) and Hidalgo volcanics (new) in Eureka district. Trinity age.

Named from Broken Jug Pass in Sylvanite part of Little Hatchet Mountains, where formation occupies several square miles on east side of the crest. Makes up dissected chain of hills and ridges that front northeast corner of range, in Eureka district.

Brokeoff Andesite[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 5, p. 71 (map).

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 674. Cenozoic.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta, v. 8, p. 77 (table 2), 78 (table 3), 79, 80 (table 4). Listed on tables and mentioned in text in report on uranium geochemistry of Lassen volcanic rocks.

Brokeoff Mountain is in Lassen Volcanic National Park.

Bromide Formation[1] (in Simpson Group)

Middle Ordovician: Central southern and southwestern Oklahoma.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 27.

C. E. Decker, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 4, p. 655–656, measured sections. Outcrops are more widespread than those of any other formation of Simpson group. Measured sections show thickness varies from 87½ feet to 674½ feet. Uppermost formation of group; overlies Tulip Creek formation.

A. R. Loeblich, 1942, Jour. Paleontology, v. 16, no. 4, p. 413–436. Formation, as used in this report, is same as that defined and mapped by Decker and Merritt (1931, Oklahoma Geol. Survey Bull. 55) and thus includes typical Bromide, Criner, and Cool Creek formations of Ulrich. At type section, herein described for first time, formation includes 15 beds with total thickness of 127½ feet; underlies Viola limestone; base of section covered. Evidence presetned by bryozoa suggests lower Trenton age, and fauna is closely allied to Decorah of Minnesota. Review of previous stratigraphic work.

R. S. Bassler, 1943, Am. Jour. Sci., v. 241, no. 11, p. 694–695. Black River age on basis of cystids.

C. E. Decker, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 1, p. 100, 135 (table 5). Discussion of Athens graptolites in Bromide formation. Trenton in age.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 120–123, chart 1. Consists of sandstone. shale, and limestone, latter predominating at least in upper part. Thickest at west end of Arbuckle Mountains where it measures 647 feet. Subdivided into two members: Mountain Lake below and Pooleville above (both new). Overlies Tulip Creek formation; underlies Viola formation. Bromide has been variously placed from Chazyan to Trenton. Brachiopod evidence does not support Loeblich's (1942) conclusion of a lower Trenton age. Chart shows Bromide spans interval from upper part of Chazyan to upper part of Bolarian.

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, p. 84–94, fig. 1, charts 1, 2. Loeblich (1942) measured and described type section. Topmost 10 to 18 feet of dense, thin-bedded limestone of Loeblich's beds 2 and 3 are quite probably Corbin Ranch formation (new) of this report. Also, it is quite possible that lower part of section (plus covered section at base) involves some normal or faulted Tulip Creek strata. U.S. Highway 77 Bromide section is 427 feet thick and subdivisible into a 55- to 60-foot basal sandstone and a 370-foot section of overlying shales and limestones; West Spring Creek section is 420 feet thick and subdivisible into same basal sandstone 60 to 75 feet thick, and overlying shale and limestone section 355 feet thick. Disconformable contact with both underlying Tulip Creek and overlying Corbin Ranch. Ostracoda discussed. Fossils indicate an age essentially Blackriverian.

Type section: Along old road on hill northwest of old Galbraith Hotel in town of Bromide, in sec. 32, T. 1 S., R. 8 E., Johnston County. Section is exposed as faulted inlier in upper Simpson.

Bromley Shale (in Cynthiana Formation)[1]

Bromley Shale Member (of Cynthiana Formation)

Middle Ordovician: Northern Kentucky and southwestern Ohio.

Original reference: R. S. Bassler, 1906, U.S. Nat. Mus. Proc., v. 30, p. 9.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1642–1643. Division of the Cynthiana. Consists of 30 feet of drab and blue shales in lower part of bank of Ohio River at Cincinnati. Some of the shales and fine-grained siliceous, earthy and commonly gnarly limestones of lower Cynthiana in northern Bluegrass and also in northern Madison County have been regarded as Bromley, perhaps not too accurately. The Bromley is a facies of lower Greendale and has its own distinctive fauna. Pre-Cincinnatian.

D. K. Hamilton, 1950. Kentucky Geol. Survey, ser. 9, Bull. 5, p. 18. All subdivisions of interval between top of Benson limestone and base of Eden formation should be referred to as members of the Cynthiana. This includes lithologic and paleontologic units heretofore defined as Brannon, Woodburn, Greendale, Millersburg, Nicholas, Bromley, Gratz, and Rogers Gap.

L. H. Lattman, 1954, Am. Jour. Sci., v. 252, no. 5, p. 265, 267. Bromley shale appears to be local facies which crosses major faunal zone boundary and may well be discarded as formational name. Cincinnatian series should be extended downward to embrace Cynthiana formation.

Well exposed along river just below Bromley, Kenton County, Ky.

Broncho Mountain Granite[1]

Precambrian: Colorado.

Original reference: R. D. Crawford and P. G. Worcester, 1916, Colorado Geol. Survey Bull. 10.

Exposed on Broncho Mountain, Gold Brick district, Gunnison County.

Bronco Volcanics

Cretaceous or lower Tertiary: Southeastern Arizona.

James Gilluly, 1945, Am. Jour. Sci., v. 243, no. 12, p. 643, 645, 648. Consists dominantly of andesite flow breccias and flows in lower part and of quartz latite flows and tuffs in upper part. These is interfingering of the two varieties of rock; andesitic rocks constitute about two-thirds of the formation. Thickness 5,000 to 6,000 feet. Unconformably overlies Bisbee formation. Intruded by Uncle Sam porphyry.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 87–90, pl. 5. At the base, formation locally has a conglomerate composed mainly of volcanic material. Invaded, deformed, and altered by Uncle Sam porphyry, Schieffelin granodiorite, and andesite porphyry east-northeast of Bronco Hill. Typical exposure designated.

Typically exposed northeast and north of Bronco Hill, Tombstone area, central Cochise County. Outcrop of formation in this area covers about 3½ square miles. Smaller bodies found in other parts of central Cochise County.

Bronson Formation or Group[1]

Bronson Subgroup (in Kansas City Group)

Pennsylvanian (Missouri Series): Eastern Kansas, southern Iowa, western Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Bull. 238, p. 1, 17, 21.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2029, 2031 (fig. 4). Strata included in Kansas City group as now defined are divisible into three main parts of subequal thickness, which are treated as subgroups (ascending): Bronson, Linn (new), and Zarah (new). Bronson extends from base of Hertha formation to top of Dennis formation and includes (ascending) Hertha, Ladore, Swope, Galesburg, and Dennis formations. Uppermost Bronson unit (Winterset limestone) extends as far southward as T. 8 N. in Oklahoma, but Hertha disappears before Kansas-Oklahoma State line is reached. South of point where Hertha disappears, lower Missourian deposits are referred to Skiatook group and are named (ascending) Seminole formation, Checkerboard limestone, Coffeyville formation, Dennis formation, Cherryvale shale, and Drum limestone. Oklahoma Geological Survey uses Hogshooter (instead of Dennis) and Dewey as a formation name, rather than member of Drum limestone.

Type region: Vicinity of Bronson, Bourbon County, Kans.

Brook Lentil (in Big Saline Formation)

See Brook Ranch Member (of Big Saline Formation).

†Brooke Formation[1]

Lower Cretaceous: Northeastern Virginia.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 321.

Vicinity of Brooke Station, 9 miles north of Fredericksburg, Spotsylvania County.

Brookfield Diorite[1]

Brookfield Diorite Gneiss

Brookfield Plutonic Series

Pre-Triassic: Western Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 107, map.

E. N. Cameron, 1951, Connecticut Geol. Nat. History Survey Bull. 76, p. 13. Included in Mount Prospect complex and not mapped by name.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Redescribed as diorite gneiss. Generally dark or speckled fine- to medium-grained gneiss, mostly layered, locally schistose. Interlayered with and cut by bodies of light rock of similar composition but with more potash feldspar, especially as large porphyroblasts. Associated with small bodies of biotite hornblendite and pyroxenite in Mount Prospect and West Torrington areas. Pre-Triassic. Derivation of name stated.

J. W. Clarke, 1958, Connecticut Geol. Nat. History Survey Quad. Rept. 7, p. 31–38, map. Redefined as Brookfield plutonic series. Occurs in well-defined plutons, four of which crop out in Danbury quadrangle [this report].

Named for town of Brookfield, Fairfield County.

Brookline Conglomerate Member (of Roxbury Conglomerate)[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 56–57.

Extensively exposed at Brookline, Suffolk County.

Brooklyn Gneiss[1]

Precambrian or early Paleozoic: Southern New York.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 7.

T. W. Fluhr, 1057, Geol. Soc. America Eng. Geology Case Histories No. 1, p. 2, 7 (fig. 1). Bedrock formations in Queens midtown tunnel, New York, include Fordham gneiss, Hell-Gate dolomite, Brooklyn injection gneiss, Inwood limestone, and Manhattan schist. All formations are highly folded, faulted, and metamorphosed. There is disagreement regarding age of formations, but they are here considered to be early Paleozoic. Brooklyn injection gneiss is mixed rock produced from the Fordham by intrusion and injection of Ravenswood granodiorite.

Occurs in New York City.

Brook Ranch Member (of Big Saline Formation)

Pennsylvanian: Central Texas.

F. B. Plummer, 1947, Jour. Paleontology, v. 21, no. 2, p. 142, 143 (table), 144–145; 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 196 (table 2), 197 (fig. 2), 198. Typically very hard subcrystalline dark-gray, nearly black cherty limestone. Total thickness 15 to 25 feet. Overlies Gibbons conglomerate member, west side of Cavern Ridge; underlies Lemons Bluff member.

F. B. Plummer, 1950, Texas Uni. Bur. Econ. Geology Pub. 4239, p. 64. Brook lentil makes up basal layers of Big Saline in Kimble, Mason, and McCulloch Counties. Occurs between Gibbons conglomerate lentil and Lemons Bluff member, where it is present, and otherwise between Gibbons conglomerate or older rocks and Soldiers Hole limestone beds. Member extends from mouth of Big Saline Creek in Kimble County to Little Brady Creek south of Rochelle in McCulloch County where it pinches out against Ellenburger uplift. Thickness at designated type locality 22 to 25 feet.

Type locality: Along abandoned highway 3½ miles south and 1 mile east of Brady and ¾ mile northwest of Brook Ranch headquarters, McCulloch County.

Brooks Bed[1]

Mississippian: Northwestern Kentucky.

Original reference: A. F. Foerste, 1910, Kentucky Geol. Survey Rept. Prog. 1908, 1909, p. 83.

Derivation of name not explained; may be from Brooks, Bullitt County.

Brooks Lake Glaciation

Pleistocene (late Wisconsin): Southwestern Alaska.

E. H. Muller *in* T. L. Pewé and others, 1953, U.S. Geol. Survey Circ. 289, p. 2-3, 13 (table 1). Four major glaciations tentatively recognized in northern part of Alaska Peninsula. Brooks Lake, last major glaciation of Aleutian Range, succeeded Mak Hill glaciation (new). In lowlands moraine front rises prominently from well-developed outwash plain. Morainic system controls drainage in eastern part of lowlands and encloses basins of Brooks, Naknek, and other large piedmont lakes. Moraines of this glaciation are the most prominent and least modified in lowland. Boulders abundantly exposed on surface of moraine and drainage of moraine belt completely unintegrated, indicating relatively short interval since recession of glaciers.

Named for large lake 36 miles east-southeast of Naknek, northern Alaska Peninsula.

Brookville Clay (in Allegheny Formation)[1]

Brookville Clay (in Pottsville Formation)

Brookville clay or underclay member

Pennsylvanian: Eastern Ohio and western Pennsylvania.

[Original reference]: Wilber Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 125–128.

G. W. White, 1949, Ohio Geol. Survey, 4th ser., Bull. 47, p. 160–169, geol. map. In Holmes County is uppermost member of Pottsville formation. Average thickness 6 feet 5 inches. Lies immediately below Brookville coal which in turn underlies Putnam Hill limestone; typically rests on white thin-bedded micaceous clay-bonded sandstone; at some localities rests immediately upon Tionesta coal.

N. K. Flint, 1951, Ohio Geol. Survey, ser. 4, Bull. 48, p. 40, 41, table 1. Included in Brookville cyclothem, Allegheny series, in Perry County. Lies stratigraphically above Homewood sandstone, base of which is considered boundary between the Pottsville and Allegheny series.

R. E. Lamborn, 1956, Ohio Geol. Survey Bull. 55, p. 54–66, geol. map. Termed Brookville clay member of Pottsville series. Thickness in Tuscarawas County 2 to 12 feet. Lies about 74 feet above Lower Mercer limestone, 45 feet below Upper Mercer limestone, and about 55 feet below Lower Kittanning coal.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 51. Underclay member of Brookville cyclothem in report on Athens County. Thickness 2½ feet. Overlies Homewood sandstone member; underlies Brookville (No. 4) coal or Putnam Hill limestone member. Allegheny series.

Described by Stout in Muskingum County, Ohio.

Brookville cyclothem

Pennsylvanian (Allegheny Series): Southeastern Ohio

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 6. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 40–42, table 1, geol. map. Includes (ascending) Homewood shale and (or) sandstone, 15 feet; Brookville clay, 4 feet; Brookville coal; Putnam Hill limestone, 1 to 6 feet. Occurs above Tionesta cyclothem of Pottsville series and below Clarion cyclothem. In area of report, Allegheny series is described on a cyclothemic basis; nine cyclothems are named (ascending):

Brookville, Clarion, Scrubgrass, Lower Kittanning, Strasburg, Middle Kittanning, Lower Freeport, Bolivar, and Upper Freeport.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 50–53. In Athens County, includes (ascending) Homewood sandstone, Brookville underclay, Brookville (No. 4) coal, Putnam Hill limestone member. Occurs above Tionesta cyclothem of Pottsville series. In area of this report, Allegheny series is described on a cyclothemic basis; 13 cyclothems are named (ascending): Brookville, Ogan, Winters(?), Clarion, Scrubgrass, Lawrence, Lower Kittanning, Strasburg, Middle Kittanning, Upper Kittanning, Lower Freeport, Bolivar, and Upper Freeport.

Name derived from Brookville, Jefferson County, Pa. Rogers (1858, Geology of Pennsylvania, v. 3, pt. 1) used name Brookville for the coal.

Brookville terrane[1]

Cretaceous: Kansas.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 255.

Derivation of name not stated but probably Brookville, Saline County.

Broom Creek Group

Permian: Eastern Wyoming, northeastern Colorado, and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 5, 18, 19 (fig. 6), 21, 37, 45. Consists of interbedded limestones and sandstones. Comprises interval from base of Cassa group to top of Wendover group (both new). Age uncertain (Pennsylvanian or Permian). Thickness 14 to 75 feet.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull, 14, p. 37, 38 (fig. 15). Stratigraphically expanded to include a few higher beds than included in original definition, placing top at an unconformity located in the overlying Cassa group. Thickness exposed on Broom Creek 85 to 101 feet. Permian.

Type locality: In Broom Creek valley, sec. 10, T. 28 N., R. 66 W., Platte County, Wyo.

Broomhill facies[1] (of New Providence Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 100–103.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. Correlation chart lists Broom Hill [Broomhill] facies of New Providence formation.

Name derived from village of Broomhill, SW cor. sec. 5, T. 1 S., R. 6 E., Clark County.

Brophy Canyon Formation

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Shown in list as underlying Fiske Creek formation and overlying Davis Creek formation (both new). Upper Jurassic and Cretaceous section about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Brougher Dacite[1]

Miocene, upper(?): Central Nevada.

Original reference: J. E. Spurr, 1905, U.S. Geol. Survey Prof. Paper 42, p. 44, 50, map.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1953, Geology of Coaldale quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-23]. Oddie rhyolite, as described in this report, includes Brougher dacite of Spurr.

Composes Butler, Brougher, Siebert, and Golden Mountains, Tonopah district.

Brown Bear Leader Sandstone (in Frontier Formation)

Upper Cretaceous: Southern Idaho.

T. K. Kiilsgaard, 1951, Idaho Bur. Mines and Geology Pamph. 92, p. 17, 32. Massive resistant sandstone about 80 feet thick. First massive sandstone underlying the important coal beds in Frontier formation.

Crops out as ribs, crossing ridge crests on western side of Horseshoe Creek Basin, and extends north of Superior Creek to southern side of Packsaddle Creek near Pintar mine. In vicinity of Brown Bear mine and Brown Bear Creek, Horseshoe Creek district, Teton County.

Brown County Bed (in Valentine Formation)

Pliocene: Northwestern Nebraska.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 137. Name applied to a 2-foot bed of diatomaceous marl from arboreous flora was collected by Chaney and Elias (1936, Carnegie Inst. Washington Pub. 487). A slightly lower horizon than Niobrara River channel sand in the Valentine.

Brown Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 381.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 71. Predominantly white sandstone 240 feet thick. Overlies Big Valley bed; underlies Spring Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315-D, p. 27, pl. 58. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Brown Creek, Mills County.

Browne Glaciation

Pleistocene: Central southern Alaska.

Clyde Wahrhaftig, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 7, 13 (table 1); Clyde Wahrhaftig, 1958, U.S. Geol. Survey Prof. Paper 293-A, p. 16-17, 22-26, pls. 2, 3, 5. Four distinct glacial advances separated by marked ice withdrawals recognized along Nenana River. Browne, the earliest recognized, preceded Dry Creek glaciation (new). Deposits are granite blocks, largest of which are 40 feet in length.

Blocks rest on terraces 500 feet above Nenana River at Browne, 1,000 feet above river near Ferry, and 2,500 feet above river at Lignite Creek, 6 miles north of Healy.

Browning Sandstone Member (of Spoon Formation)

Browning Sandstone (in Carbondale Formation)

Pennsylvanian: Western Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 26, 78. Eastward-trending channel sandstone in lower Carbondale, about 5 feet below Colchester (No. 2) coal. Deposits locally truncate lower Carbondale and Pottsville strata and rest on pre-Pennsylvanian.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 10. Type locality stated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), 62, pl. 1. Reallocated to member status in Spoon formation (new). Stratigraphically above Abingdon coal member. Thickness 8⅔ feet.

Type locality: Sec. 18, T. 2 N., R. 1 E., Browning Township, Schuyler County.

Brown Mountain Sandstone (in Panoche Formation or Group)

Brown Mountain Sandstone Member (of Moreno Grande Formation)

Upper Cretaceous: Central California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2). Listed as uppermost of 10 subdivisions of Panoche formation (or group). Underlies Dosados member of Moreno formation; overlies Ragged Valley shale. Name credited to J. Q. Anderson.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 31. Southward from Pacheco Pass to Coalinga region, Moreno Grande formation (new) includes restricted Moreno, Brown Mountain sandstone, and *Pachydiscus* silt (also called Ragged Valley shale) as members.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 31. Brown Mountain sandstone, a poorly defined stratigraphic unit of late Upper Cretaceous, is included in uppermost part of Panoche formation of this report [Ortigalita Peak quadrangle].

Occurs in Coalinga-Ortigalito area, San Joaquin Valley.

Browns Mills Limestone Member (of Row Park Limestone)

Middle Ordovician: Central southern Pennsylvania.

F. M. Swartz and R. R. Thompson, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 4, 5. Dark-gray limestone. Overlies Social Island limestone member (new); underlies New Market limestone. Name credited to J. G. Palacas (unpub. thesis).

In Franklin County.

Browns Park Formation[1]

Miocene(?): Northeastern Utah, northwestern Colorado, and southern Wyoming.

Original reference: J. W. Powell, 1876, Geology of eastern part of Uinta Mountains, p. 40, 44, 168.

W. H. Bradley, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 32. Mapped in Carbon and Sweetwater Counties, Wyo. Formation was laid down on eroded surface that cuts older slightly deformed Eocene rocks, but was deformed by subsequent movements that affected both Browns Park and older rocks. Miocene(?).

G. E. Untermann and B. R. Untermann, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 5, p. 685, 686 (table). In Dinosaur National Monument, consists of friable chalk-white to grayish crossbedded sandstones, in part tuffaceous; lake, fluviatile, and some eolian deposits; cherty sandstones and chert beds and concretions; basal conglomerate composed of conglomeratic sandstone and quartzite from Uinta Mountain group. Unconformably overlies Bishop(?) conglomerate; unconformably underlies Quaternary alluvium. In northeast corner of Monument, Browns Park lies on Precambrian Uinta Mountain group with angular discordance. Thickness 1,200 feet. Pliocene.

B. D. Carey, Jr., 1955, Intermountain Assoc. Petroleum Geologists Guidebook 6th Field Conf., p. 47–49. Commonly two units: lower, conglomerate of variable thickness which consists primarily of Precambrian cobbles; upper, composed of beds of chalky-white and grayish-white sandstone, tuffaceous sandstone, thin beds of chert and occasional beds of vitric tuff and fresh-water limestone. Thickness of basal conglomerate 0 to 300 feet; aggregate thickness of upper unit 1,200 feet. Powell estimated 1,800 feet, and this appears to be fairly representative for northwestern Colorado. Unconformably overlies all formations from Precambrian through middle Eocene Bridger formation. Suggestion before Society of Vertebrate Paleontologists to consider formation as middle Miocene (Hemingfordian) and perhaps, partly lower Miocene (Arikareean) in age.

Well developed in Browns Park, northwestern Colorado and northeastern Utah.

Browns Point Formation

Miocene: Northwestern Washington.

S. L. Glover, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2022–2023. Name applied to marine sedimentary series in strata designated by earlier workers as part of Hoh formation. At type section, comprises about 5,000 feet of moderately cemented buff to gray arkosic sandstones and thin-bedded dark-gray mudstones. Here strata are on south flank of northwesterly trending anticline; some beds are vertical or overturned; formation includes similar rocks, not before described, that form Destruction Island, and also 1,500 feet of exposures at Grenville Bay. Comparative studies indicate the Browns Point is younger than Hoh formation, older than immediately overlying early Pleistocene Taholah or late Pleistocene Queets beds, and older than Pliocene Quinault formation.

Type section: Olympic Peninsula along 3 miles of coast from NE¼ sec. 33 to SW cor. sec. 16, T. 25 N., R. 13 W., Jefferson County.

Brownsport Formation[1]

Brownsport Group

Middle Silurian: West-central Tennessee and northeastern Mississippi.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 566–583, 681–708.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Brownsport group shown on correlation chart as comprising (ascending)

Beech River formation, Bob formation, Lobelville formation, and Decatur limestone.

T. W. Amsden, 1949, Yale Univ., Peabody Mus. Nat. History Bull. 5, p. 138. Described in Decatur, Perry, Wayne, and Hardin Counties, Tenn., as Brownsport formation. Consists of about 100 feet of thin-bedded argillaceous limestones and calcareous and shales with lenses of thick-bedded nonargillaceous limestone. Overlies Dixon formation with apparent conformity; underlies Decatur limestone with apparent conformity. Present investigation does not reveal any satisfactory lithologic or faunal basis for division of Brownsport into formations or members, and it is proposed that terms "Beech River," "Bob", and "Lobelville" be abandoned.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 257–270, fig. 2 From a study of Foerste's descriptions of his Brownsport bed, it is apparent that he included all the beds that today comprise the Beech River Bob, Lobelville, and Decatur formations. Brownsport group as used in this report includes these four units as formations. Overlain by formations of the Devonian or by Chattanooga shale; overlies Wayne group.

Named for exposures in vicinity of Brownsport Furnace, Perryville quadrangle, Decatur County, Tenn.

Brownstown Marl[1] **or Formation**

Brownstown Marl (in Austin Group)

Upper Cretaceous (Gulf Series): Southwestern Arkansas, northwestern Louisiana, southwestern Oklahoma, and northeastern Texas.

Original references: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72, 86–87, 188; 1894, Geol. Soc. America Bull., v. 5, p. 302, pl. 12; 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 340.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Correlation chart does not show Brownstown marl as outcropping in Louisiana.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 36. Brownstown marl included in Austin group. Foraminifera described.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Brownstown and Ozan formations mapped undifferentiated.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 46–48, pl. 1. Brownstown and Ozan formations undifferentiated in McCurtain County. In Arkansas, Brownstown rests unconformably on Tokio formation; this unconformity not recognized in McCurtain County.

First described in vicinity of Brownstown, Sevier County, Ark.

Brownstown Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian: Central-western West Virginia.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 586.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 78, pl. 7. In Kanawha group a little below Campbell Creek coal. Derivation of name given.

Named from Brownstown (now called Marmet), Kanawha County.

Brownstown Hills Sandstone Member[1] (of Edwardsville Formation)

Mississippian (Osagean): Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 172, 174, 175, 237, 240, 245.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 74. Brownstown Hills sandstone and Dry Creek sandstone members included in Medora Knob facies of formation.

Named for fact it caps Brownstown Hills of south-central Jackson County.

†Browntown Sandstone (in Monongahela Formation)[1]

Pennsylvanian: Northern West Virginia, eastern Ohio, and southwestern Pennsylvania.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 58.

Exposed along bed and bluffs of Ten Mile Creek, at and below Brownstown, Harrison County, W. Va.

Brownville Limestone Member (of Wood Siding Formation)

Brownville Limestone (in Wabaunsee Group)[1]

Brownville Limestone Member (of Konawa Formation)

Pennsylvanian (Virgil Series) : Southeastern Nebraska, southwestern Iowa, eastern Kansas, and north-central Oklahoma.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 17, 29.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 43. Overlies Wood Siding formation (new).

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273–2275. Rank reduced to member status in Wood Siding formation (redefined). Overlies Pony Creek shale member; underlies Towle shale member of Onaga formation (new).

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 67–71. Member described in Pawnee County where it is a single limestone unit. Thickness less than 1 foot to as much as 15 feet. Overlies Pony Creek shale member; underlies Permian Admire shale. Continuous from southeastern Nebraska to north-central Oklahoma, where it has been traced as far south as North Canadian River; south of river, the "Prague" of Seminole County is probably continuation of Brownville.

A. E. West, 1960, Shale Shaker, v. 11, no. 3, p. 4–6. Basal member of Konawa formation in report on Lincoln County, Okla. Underlies Americus(?) limestone. Stratigraphically above Grayhorse limestone. Thickness less than 1 foot to more than 3 feet.

Type locality: In Missouri River bluffs southwest of railway station at Brownville, Nemaha County, Nebr.

Brownville Slate[1]

Age(?) : Maine.

Original reference: C. T. Jackson, 1837, Geol. rept. public lands of Maine, v. 1, p. 37.

†Brownwood division[1]

Pennsylvanian: Central Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept. p. lxvii, pl. 3.

Named for Brownwood, Brown County.

Brownwood Shale Member (of Graford Formation)[1]

Brownwood Shale (in Canyon Group)

Upper Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 389.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 94–95. Referred to as Brownwood shale member in Canyon group. Shale is quite sandy throughout, contains at least a dozen sandstone lentils and layers and one conglomerate bed designated as Rough Mountain conglomerate. Thickness measured 3½ miles north of Rochelle, 325 feet. Overlies Rochelle conglomerate; underlies Adams Branch limestone.

R. J. Cordell and D. A. Zimmerman, 1954, Abilene Geol. Soc. Guidebook. Nov. 19–20, p. 47–49. On basis of faunal studies in Brown County, the lower Brownwood is probably late Strawn and upper Brownwood early Canyon. Base of conglomerate separating the two parts of the Brownwood should apparently be regarded as Strawn-Canyon contact.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook Apr. 17–19, p. 51. Shown on composite section of Brown and Coleman Counties as member of Graford formation. Underlies Adams Branch limestone member; is base of section here described. Thickness about 200 feet. Consists of silty gray to red fissile shale; contains sandstone beds locally, and coquinas of crinoid columnals, brachiopods, and pelecypods. Fusulinid-bearing limestone about 60 feet below top, 1.2 miles east of Winchell.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58 (table 1), 63–64, pl. 27. Drake (1893) placed Brownwood bed in Canyon division of Cummins (1891). He included in it shale and some sandstone which overlie both the Rochelle conglomerate and his Coral limestone bed (Capps limestone lentil of Plummer and Moore, 1921). Drake's Brownwood bed is practically identical with unit that has been considered by later geologists as Brownwood shale member. Plummer and Moore used term Brownwood shale in sense that Drake used it but considered the Rochelle conglomerate to underlie their Capps limestone lentil. Some geologists [see the bibliography of this report] have considered base of Brownwood shale to be top of Capps limestone lentil. Most geologists have considered base farther south, where the Capps is absent, to be the base of Rochelle conglomerate. Name Brownwood shale member is proposed for formal adoption in area of present report [Brown and Coleman Counties] because of lateral continuity of the member, its conspicuous topographic expression, its consistent relationship to other traceable units, and also because of wide usage of name at present time. Recommended that base of member be drawn at top of Capps limestone lentil of Plummer and Moore (1921). Also proposed that top of Brownwood be drawn at base of Adams Branch limestone member. In Brown County, basal beds of Brownwood member are gray shale containing marine fossils. They grade upward into red shale containing several beds of impure limestone and beds of sandstone. About 50 feet above base are additional beds of gray shale containing marine fauna, including brachiopod genus *Chonetina*. This shale is overlain alternately by lenticular beds of sandstone and a calcareous bed that appears in different places to be a desiccation breccia of limestone fragments, a cemented mass of algal(?) limestone pebbles, an impure clastic limestone, a sandy limestone, or (as in Winchell area) a bed of gray limestone 2 feet thick containing fusulinids. This is the limestone considered to be the Palo Pinto equivalent by Nickell (1938, Texas Univ. Bur. Econ, Geology Pub. 3801) and by Cheney and Eargle (1951, West Texas Geol. Soc. Guidebook Spring Field Trip, June 1–2). Above this carbonate bed, and in many places cutting into it, is conglomeratic sandstone. Mostly gray silty shale and some lenticular beds of sandstone occupy interval from the conglomeratic sandstone, near middle part of the Brownwood, to base of Adams Branch member. This part of the Brownwood was called lower member of Graford formation by Nickell (1938). Thickness about 225 feet along Colorado River; about 300 feet in central part of Brown County where entire unit is exposed.

Named for Brownwood, Brown County.

Brownwood Canyon[1]

Carboniferous: Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxvii, pl. 3.

In vicinity of Brownwood, Brown County.

Bruja Island Diorite or Dolerite

Oligocene or Miocene: Panamá.

[T. F. Thompson], 1943, Panama Canal Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 26. Diorite represents massive dike that has cut through and distorted lower beds of Gatún sandstone.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 898 (table 2), 901. Referred to as dolerite. Lower Miocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 326. Oligocene or Miocene.

Quarried on Bruja Grande Island, in Gatún Lake, C.Z.

Brujo Limestone (in Mayagüez Group)

Cretaceous: Southwestern Puerto Rico.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 197; 1960, Geol. Soc. America Bull. 71, no. 3, p. 337, pl. 1. Contains massive- to thick-bedded microcoquina, pellet limestone, some calcilutite, and minor wacke and mudstone. Lithologically the Brujo is identical with Cotui limestone member (new) of San Germán formation; the two are differentiated only by structural or age relationships. At type section, limestone probably dips northwest beneath a series containing conglomerate, limestone, breccia, and volcanic rock, part of San Germán formation. Southeast of El Brujo ridge the El Brujo fault separates the limestone from another area of San Germán formation to the south. Turonian to Campanian.

Type section: Near El Brujo where the microcoquina forms ridge trending northeast.

Brule Formation[1] or **Clay**[1] (in White River Group)

Oligocene, middle and upper: South Dakota, northeastern Colorado, western Nebraska, and eastern Wyoming.

Original reference: N. H. Darton, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 4, p. 736, 755–759.

A. L. Lugn, 1938, Am. Jour. Sci., v. 36, 5th ser., no. 213, p. 227. Upper formation of White River group. Thickness 500 to 600 feet. Contains *Leptauchenia* and *Oreodon* beds. Overlies Chadron formation. Underlies Gering formation of Arikaree group.

C. B. Schultz and T. M. Stout, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1921; 1941, Guide for a field conference on the Tertiary and Pleistocene of Nebraska: Nebraska Univ. State Mus. Spec. Rept., p. 4 (table 1), 37. Formation, in Nebraska, subdivided into Orella member below and Whitney member above (both new). Overlies Chadron formation; contact between the two formations provisionally drawn at base of certain continuous purple-tinted white, sometimes silicified, limestone layers, which is upper of several such limestone beds in lower part of local section.

C. B. Schultz and T. M. Stout, 1955, Nebraska Univ. State Mus. Bull., v. 4, no. 2, p. 38–46. Darton did not specify type locality. For practical purposes, Darton's (1899) "Round Top to Adelia Station" section, near Crawford, Sioux County, Nebr., should be considered type locality. Brule formation, in this typical area, approximately 480 feet thick. This same area was used for type definitions of Brule subdivisions. Orella and Whitney members overlie Chadron formation. Writers depart from their 1938 action in defining base of Brule as base of "purplish white layers" and suggest top of "purplish white layer" as redefined plane of division between Chadron and Brule. Locally Whitney member is capped by unit herein named Bayard paleosol complex. Middle and Upper Oligocene.

J. C. Harksen, 1960, Geology of the Sharps Corner quadrangle (1:62,500): South Dakota Geol. Survey. Underlies Sharps formation (new). Consists of at least 200 feet of interbedded pinkish to greenish clays and sands. In White River group.

Named for Brule Indians who once roamed over Pine Ridge Indian Reservation in southern South Dakota.

Brule Schists[1]

Brule Volcanics[1]

Precambrian: Northwestern Michigan.

Original reference: R. C. Allen, 1910, Michigan Geol. and Biol. Survey Pub. 3, geol. ser. 2, p. 34.

Named for exposures north and south of Brule River. Iron River district.

Bruno Limestone (in Chase Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 38, 40.

Named from exposures on Bruno Creek, a few miles northeast of Florence, Kans.

Brunswick Conglomerate (in Newark Group)[1]

Upper Triassic: Eastern Pennsylvania.

Original reference: E. T. Wherry, 1914, B. L. Miller, Anniversary history of Lehigh County, v. 1, chap. 1, p. 8.

Crops out in region adjoining Boyertown Hills, Berks County.

Brunswick Formation (in Newark Group)

Brunswick Shale[1] or lithofacies (of Newark Group)

Upper Triassic: New Jersey and southeastern Pennsylvania.

Original references: H. B. Kummel, 1897, New Jersey Geol. Survey Ann. Rept. State Geologist 1896, p. 47–55; 1897, Jour. Geology, v. 5, p. 547–549.

D. B. McLaughlin and Bradford Willard, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 43. Interpretation of Newark group implies: (1) Brunswick and Lockatong were largely formed contemporaneously as red torrential and nonred paludal facies respectively; (2) Stockton and early Brunswick sedimentations were also to a degree contemporaneous; and (3) Newark is not a group of three distinct formations successively deposited, but a series of interfingering, in part contemporaneously formed, continental facies.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook for Field Trips Atlantic City Mtg., p. 44–46, 50–51, pl. 1. Formation includes Perkasie member near top and Graters member near middle. Much of formation is soft bright-red argillaceous shale with interbeds of thin- to medium-bedded siltstone; lower part of section contains large amount of thick-bedded tough red argillite with several dark-gray interbedded members; some gray, greenish, and bluish shale occurs high in section. Distribution noted.

D. B. McLaughlin, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. C–9, p. 90–108, pls. Brunswick lithofacies discussed in detail in Bucks County, Pa.

Named for exposures in valley of Raritan, near New Brunswick, Middlesex County, N.J. In New Jersey, occurs in three belts separated by faults and by outcrop of Stockton and Lockatong in respective fault blocks. Owing to dying out of Hopewell fault in both directions, two southern belts merge in Pennsylvania and at northeast end of Sourland Mountain in New Jersey. Southern belt crosses Delaware near Washington Crossing. Middle belt extends northward from Hopewell fault to 1½ miles north of Lambertville where it is cut off by Flemington fault; west of the Delaware, shale of this band is bordered on northwest side by Paleozoic rocks of the floor, brought up by the fault. Northern band crosses Delaware north of Point Pleasant, Pa., and has width of about 10 miles north to Triassic border north of Milford, N.J. In Pennsylvania, continues as wide unbroken band through Bucks, Montgomery, into Berks County.

Brush Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 45 (table 1), 63, pl. 1. Name applied to thin unit formerly designated as Middle DeLong coal. Stratigraphically above Hermon coal member (new), formerly designated as Lower DeLong coal, and below DeLong coal member, formerly designated as Upper DeLong coal. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Along Brush Creek, secs. 6 and 8, T. 9 N., R. 2 E., Knox County.

Brush cyclothem (in Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 52 (table 2), pl. 1. Name applied to cyclothem formerly called Middle DeLong. Above Hermon cyclothem (new) and below DeLong cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification independent of rock-stratigraphic classification.

Type locality: Along Brush Creek, secs. 6 and 8, T. 9 N., R. 2 E., Knox County.

Brush formation[1]

Upper Jurassic: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 301.

Derivation of name not stated.

Brush Creek Clay (in Conemaugh Formation)[1]

Brush Creek Fire Clay (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania and eastern Ohio.

Original reference: J. P. Lesley, 1879, Pennsylvania 2d Geol. Survey Rept. Q_2.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 62–65, table 1. Brush Creek clay listed as member of Brush Creek cyclothem in report on Perry County.

Brush Creek limestone was named for occurrence along Brush Creek, Cranberry Township, Butler County, Pa.

Brush Creek cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 11, 15. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 62–65, table 1, geol. map. Includes (ascending) Brush Creek shale, 17 feet; Brush Creek clay and Brush Creek coal (both absent in Perry County); and Brush Creek limestone, 3 inches to 10 feet. Occurs above Mason cyclothem and below Wilgus cyclothem. In area of this report, Conemaugh series is described on cyclothemic basis; seven cyclothems are named. [For sequence see Mahoning cyclothem.]

Exposed in Perry County.

Brush Creek Fire Clay Shale (in Conemaugh Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 315.

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. Survey Rept. Inv. 17, p. 14. Brush Creek clay is light gray and varies from plastic to hard. Underlies Brush Creek coal. Conemaugh series.

Brush Creek Limestone Member (of Conemaugh Formation)[1]

Brush Creek limestone member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 34.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 62, table 1. Limestone member of Brush Creek cyclothem in report on Perry County. Average thickness about 2 feet. Marine fauna. Conemaugh series.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 32–37. Discussed as Brush Creek limestone member, Conemaugh series, in report on Morgan County. Commonly consists of two limestones, each from 6 inches to 1½ feet thick, separated by 4 to 8 feet of shale, clay shale, or sandstone. Locally some exposures have only lower bed from 1 to 1½ feet thick. Occurs above Brush Creek coal and below Buffalo sandstone and shale. In earlier years of geological work in tracing strata from Maryland, Pennsylvania, and West Virginia into Ohio, there was much difference of opinion as to correlation of lower Conemaugh beds. Term Brush Creek was applied variously to Cambridge limestone, to the true Brush Creek limestone, and to Mahoning limestone. Much of this miscorrelation resulted from lack of knowledge that the well-established Cambridge limestone changed in character and became discontinuous westward in Ohio. As a result, the true Brush Creek was called Cambridge, and term Brush Creek was applied to the still lower Mahoning limestone. Coals were involved also in changes in terminology over the years. Regional changes in lithology of Brush Creek limestone member added further difficulty to the correlations. Condit (1912, Ohio Geol. Survey, 4th ser., Bull. 17) discussed some of these difficulties in correlation.

See Lower Brush Creek Limestone and Upper Brush Creek Limestone.

Named for exposures along Brush Creek, Cranberry Township, Butler County, Pa.

Brush Creek Red Bed (in Conemaugh Formation)[1]

Pennsylvanian: Southern Pennsylvania.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 58, pls. 6, 7.

See Lower Brush Creek redbed member.

Somerset, Somerset County.

Brush Creek Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 305–308.

Allegheny County.

Brush Creek Shale (in Conemaugh Formation)[1]

Brush Creek shale and sandstone member

Brush Creek shale member

Pennsylvanian: Northern West Virginia, western Maryland, and eastern Ohio.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 309.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 62. Basal member of Brush Creek cyclothem in report on Perry County. Average thickness 17 feet. Typically buff to greenish sandy or clayey shale. Lies between Mason coal and Brush Creek limestone.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 31. Brush Creek shale and sandstone member occupies interval between base of Brush Creek limestone and top of Mason coal. In early geological reports on Ohio, Mason coal was one of the beds to which name Brush Creek coal was applied, as in original description. Thickness of Brush Creek shale and sandstone varies from 6 to 14 feet in eastern York Township, Morgan County [this report], where Mason coal is best developed. In some exposures, member consists of gray to dark-gray shales. In most of the area, the lithology varies from sandy shale with siderite nodules to shaly thin-bedded sandstone or to more massive sandstone phase. Changes from shale to sandstone are rapid. Above Mason coal and below Brush Creek coal. Conemaugh series.

Named for association with Brush Creek limestone and coal.

Brush Hollow Limestone

Cenozoic (probably Quaternary): Southwestern Colorado.

W. F. Tanner, 1954, Oklahoma Acad. Sci. Proc., v. 35, p. 95 [1955]. Limestone of continental origin. Unconformably overlies sandstones and conglomerates of Cretaceous and Pennsylvanian age. Thickness varies from a few inches to approximately 25 feet. Formation includes three facies: conglomerate, travertine, and medium- to fine-crystalline limestone. Color is buff to tan. Locally the surface has appearance of caliche.

Crops out in Canon City area in T. 18 S., Rs. 69 and 70 W. Named after Brush Hollow Reservoir in T. 18 S., R. 69 W.

Brushy Basin Shale Member (of Morrison Formation)[1]

Upper Jurassic: Southeastern Utah, northeastern Arizona, southwestern Colorado, and northwestern New Mexico.

Original reference: H. E. Gregory, 1938, U.S. Geol. Survey Prof. Paper 188, p. 59, pl. 15, strat. sections.

W. L. Stokes and D. A. Phoenix, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 93. In San Miguel and Montrose Counties, Colo., overlies Salt Wash member and underlies Burro Canyon formation (new). Average thickness about 400 feet.

C. T. Smith, 1951, *in* New Mexico Geol. Soc. Guidebook 2d Field Conf. p. 13 (chart), 38; 1954, New Mexico Bur. Mines Mineral Resources Bull. 31, p. 17–18, pl 1. Described in Thoreau quadrangle, New Mexico, where average thickness is about 100 feet. Grades laterally into thin-bedded sandstone to west and south, and into siltstone and mudstone to east and north. Overlies Prewitt sandstone member (new); underlies Dakota(?) sandstone.

W. L. Stokes, 1952, Utah Geol. and Mineralog. Survey Bull. 46, p. 9 (table 1), 11–12, pl. 1. In Thompsons area, overlies Salt Wash sandstone member and underlies Cedar Mountain formation. Consists of mudstone, varicolored, bentonitic, with few lenses of siltstone, sandstone, and conglomerate. Thickness 306 feet.

L. C. Craig and others, 1955, U.S. Geol. Survey Bull. 1009–E, p. 155–156. Constitutes upper part of Morrison in region of this study [Colorado Plateau], where it is present in western Colorado, eastern Utah, northern New Mexico, and part of northeastern Arizona. To southwest, has been removed by post-Morrison erosion. Eastern and northeastern boundary is arbitrary line drawn where Salt Wash member loses its identity and cannot be distinguished from upper part of Morrison. Member is predominantly variegated claystone containing varying amounts of silt and sand. Thickness varies over the Plateau—more than 600 feet at Vernal, Utah, and 450 feet in southwestern Colorado.

V. L. Freeman and L. S. Hilpert, 1956, U.S. Geol. Survey Bull. 1030–J, p. 314, 315 (fig. 60), 320–321, 323–324, 326, 329, 332–333. In Laguna,

N. Mex., area, Recapture, Westwater Canyon, and most of Brushy Basin members are present in stratigraphic interval previously considered as Recapture. Sandstone previously considered as Westwater Canyon is at top of Brushy Basin and is known locally as Jackpile ore-bearing bed. Thickness ranges from 0 to about 370 feet; thickness largely determined by amount of deformation and erosion before deposition of Dakota sandstone.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 55, strat. sections. Present in northeastern and eastern parts of Navajo country. Intertongues with Westwater Canyon member; underlies Burro Canyon formation and where that is absent Dakota sandstone. Thicknesses: 194 feet at McElmo Creek; 156 feet in Carrizo Mountains area; 148 feet at Toadlena; 51 feet at Thoreau.

E. B. Ekren and F. N. Houser, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–221. In Moqui SE quadrangle, Montezuma County, Colo., member is 150 to 300 feet thick and consists of varicolored bentonitic mudstone with a few conglomeratic sandstone lenses. Overlies Westwater Canyon sandstone member. Intertongues with overlying Burro Canyon formation.

Named for exposures in Brushy Basin, near Blanding, San Juan County, Utah.

Brushy Canyon Formation (in Delaware Mountain Group)

Lower Permian (Guadalupe Series): Western Texas.

P. B. King *in* R. K. DeFord and E. R. Russell, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 4 (fig. 2), 8. Delaware Mountain group divided into (ascending) Brushy Canyon, Cherry Canyon, and Bell Canyon formations (all new).

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 577–579, 585 (fig. 7), 586–588, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215 p. 28–30, pl. 3 [1949]. Characterized by many sandstone beds that are coarser grained than those elsewhere in group; individual beds are lenticular and pinch out within short distances; many sections include as many as dozen beds of sandstone of various thicknesses, but others contain only a few; sandstones extend to top of a formation. Thickness 1,000 feet. Conformably overlies Bone Spring formation with Cutoff shaly member (new) forming transition zone between: overlaps northwestward on to Bone Spring.

Named for Brushy Canyon, 6 miles south-southeast of Guadalupe Peak, Culberson County; canyon drains westward down Delaware Mountains escarpment and crosses whole thickness of formation.

†Brushy Creek Chert[1]

Middle Devonian: Southeastern Oklahoma.

Original reference: E. O. Ulrich, 1927, Oklahoma Geol. Survey Bull. 45, p. 30.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 106. Abandoned by Oklahoma Geological Survey. Name preoccupied by Pennsylvanian sandstone in Illinois. Unit now called Pinetop chert.

Named for exposures on Brushy Creek, Pittsburg County.

Brushy Creek Sandstone (in McLeansboro Formation)[1]

Pennsylvanian: Southeastern Illinois.

Original reference: G. H. Cady, 1926, Illinois State Acad. Sci. Trans., v. 19, p. 256–258.

Exposed on north flank of ridge along Brushy Creek at Town Hall near center of Brushy Township, and at other places.

†Brushy Mountain measures (in Pottsville Group)[1]

Pennsylvanian: Southeastern Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 104, 149–153, 167, 169.

Named for Brushy Mountain, Morgan County.

Brussels Formation

Pleistocene (Sangamon? and Illinoian): West-central Illinois and east-central Missouri.

W. W. Rubey, 1952, U.S. Geol. Survey Prof. Paper 218, p. 82–87, pl. 1. Proposed for thick series of well-laminated silts which locally contains much sand and gravel. Lithology varies but in general has fairly characteristic development in each of four regions. Most typical and most widespread facies is developed near Brussels. Here, lower third or fourth of formation is massive calcareous clay, and upper part an alternating series of laminated and massive beds of silt, clay, and fine sand. Maximum thickness 75 feet. Formation is younger than parts of Illinoian till and as old or older than Sangamon(?) loess.

Named for exposures near Brussels, Calhoun County, Ill. Widespread throughout Hardin and Brussels quadrangles. Deposits recognized in Lincoln and St. Charles Counties, Mo., and downstream to St. Louis.

Bruton Formation (in Fresnal Group)

Pennsylvanian (Virgil Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 79–82. Term introduced for the red shales, arkosic sandstones and conglomerates, with interbedded nodular to irregularly bedded limestones, which occur between top of the Moya formation (new) below and base of the Permian Wolfcamp above. In eastern part of Oscura Mountains, grades southward laterally into limestones, sandstones, and shales of lower part of Fresnal group. Locally underlies Abo formation. Thickness at type locality 113 feet; in Abo Canyon about 120 feet.

M. L. Thompson, 1954, Kansas Univ. Paleont. Contr. 14, Protozoa, art. 5, p. 17–18. Upper 40 feet of Bruton as defined by Thompson (1942) is transferred to Bursum formation. A lower part of the Bursum as defined by Wilpolt and others is here retained in the Bruton.

Type locality: Northeast side of Oscura Mountains in SE¼ sec. 32, T. 5 S., R. 6 E., Socorro County. Name derived from Bruton Tank on northeast side of Oscura Mountains.

Bryan Sand (in Yegua Formation)

Bryan Sandstone (in Yegua Group)

Eocene (Claiborne): Eastern Texas.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3945, pt. 2, p. 853 (fig. 131), 856. Lenticular body of sand at base of Yegua formation. Overlies Mount Tabor member (new) of Crockett formation.

Discussion of Yegua problem; author favors placing Crockett-Yegua boundary at base of Bryan sand.

A. A. Matthews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 3, geol. map. Rank raised to formation in Yegua group. At type locality, medium- to coarse-grained, well-sorted, irregularly bedded, coarsely laminated, uniformly crossbedded nearly white sandstone of characteristic deltaic origin. Locally, includes an 8-inch red iron sandstone bed. Contains petrified wood. Estimated thickness 553 feet. Lenticular along strike but not absent except where cut out by faulting. Overlies Smetana sandstone (new); underlies Easterwood shales (new).

Type locality: Along State Highway 21 from 2.1 to 3.75 miles west of court house, Brazos County.

†Bryant limestone[1]

Middle Ordovician: Central eastern Missouri.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59, 61.

Named for exposures along Bryant Creek, Lincoln County.

Bryant Lake Limestone[1]

Precambrian: New York.

Original reference: H. L. Alling, 1927, Geol. Soc. America Bull. v. 38, p. 798, 800.

Derivation of name not stated and not indicated on map.

Bryantsville Breccia or Bed (in Levias Member of Ste. Genevieve Limestone)

Mississippian (Meramec): Southern Indiana.,

J. B. Patton, 1949, Indiana Div. Geology Prog. Rept. 3, p. 9–10. Uppermost bed of Levias is brown rubbly brecciated dense limestone termed Bryantsville bed by C. A. Malott (unpub. ms.) and marks Meramec-Chester contact where Aux Vases is absent.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 9, 95, 96. Bryantsville breccia applied to persistent bed that is characteristically present at top of Levias member. Commonly 4 feet thick and has uneven base above a thin shale break; usually highly brecciated at top and has loose shaly and nodular facies a few inches thick at very top; frequently quite cherty, chert being flintlike, and the masses partly brecciated and arranged more or less obliquely with the bedding; lower part usually less brecciated than top and well cemented into hard limestone. Contains *Platycrinus penicillus* columnals and colonies of *Lithostrotion harmodites*. This latter fossil has been listed by Butts and Ulrich in Fredonia limestone, but it seems probable that these authors confused the sandstones in many of their sections and that their described occurrence of this fossil actually is in top of Levias instead of top of Fredonia; it has not been observed below Bryantsville in southern Indiana. Butts, Ulrich, and Weller recognized a limestone breccia in the interval in Indiana and Kentucky but did not apply name to it It is quite probable that Bryantsville breccia may extend continuously southward from Ohio River and westward about the whole of eastern and southern outcrop about Illinois basin. Type exposures noted.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 21, 30–36, pl. 1. Field separation of the Levias member of the Ste. Genevieve limestone from younger Paoli limestone is dependent upon recognition of Aux Vases formation, if it is present, or of the Bryantsville breccia. Where Bryantsville is exposed, it is best stratigraphic marker in locating Meramec-Chester boundary as currently defined. Detailed description of unit; thickness as much as 12 feet.

Type exposures: NW¼NW¼ sec. 25, T. 4 N., R. 2 W., north side of U.S. Highway 50, about 1 mile southwest of Bryantsville, Lawrence County, Ind.; Richard Burton quarry section SW¼NW¼ sec. 20, T. 4 N., R. 1 W., north of road, 1¼ miles east of Bryantsville; Hixon quarry, SE¼NE¼ sec. 20, T. 4 N., R. 1 W., 2 miles east of Bryantsville.

Bryn Mawr Gravel[1]

Pliocene (?): Southeastern Pennsylvania, northern Delaware, and northeastern Maryland.

Original reference: H. C. Lewis, 1881, Philadelphia Acad. Nat. Sci. Proc., v. 32, p. 258–272, 277–278, 288, 296–309.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 37–39. Described in Prince Georges County, Md., and District of Columbia where it consists of coarse poorly sorted pebbles in red sand and silt; bright-red color distinguishes it from pink or yellow Brandywine formation with which it is nowhere in contact. The farther inland parts lie unconformably on crystalline rocks of the Piedmont; extends eastward onto eroded surface of Patuxent formation; forms surface of ground wherever it occurs. Formation may be Miocene or older but is here assigned to Pliocene(?)

R. M. Overbeck and T. H. Slaughter, 1958, Maryland Dept. Geology, Mines and Water Resources Bull. 21, p. 84–85. In Cecil County, rests unconformably on Patuxent, Patapsco, and Raritan formations; locally, as at Bay View, lies on schists and intrusive rocks.

First described in vicinity of Bryn Mawr, Pa.

Bryson Formation

Bryson Formation (in Pottsville Group)[1]

Middle Pennsylvanian: Northeastern Tennessee and southeastern Kentucky.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 33, 44, 208, pl. 40–A.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 111–114, 138. Highest Pennsylvanian subdivision in Cumberland Gap coal field. Overlies Hignite formation. Partially equivalent to Anderson formation of Tennessee.

Named for Bryson Peak, Claiborne County, Tenn.

Búcaro Formation

Eocene: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg v. 8, Abt. 4a, no. 29, p. 134 (correlation chart). Name Búcaro appears in correlation chart. Underlies Tonosi formation.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 235–236. Referred to as Bucarú formation. Exposed thickness of Eocene rocks north of Guanico Point is about 2,000 feet. Lower beds are coarse dark-gray sandstones, conglomerates, and sandy shales. These beds are followed by about 1,500 feet of blue-green or black shales with thin gritty sandstones; in their lower part are several fossil zones, the lower about 50 feet above base of section. Underlies David formation.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 327. On north side of Point near Bucarú, is in fault contact with volcanics; to south grades downward into volcanics. Lexicon uses Búcaro as preferred spelling.

Near village of Búcaro, Los Santos Province.

Bucarú Formation

See Búcaro Formation.

Bucatunna Clay Member (of Byram Formation)[1]

Bucatunna Formation or Clay

Oligocene, middle: Southeastern Mississippi and southwestern Alabama.

Original reference: B. W. Blanpied and others, 1934, Shreveport Geol. Soc. Guidebook 11th Ann. Field Trip, p. 3, 4, 12–16, charts.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1315 (fig. 1), 1316, 1332–1341. Uppermost member of Byram formation. Unconformably overlies and in some areas grades into unnamed marl member; underlies Chickasawhay limestone. Near Leaf River, Miss., cuts out or overlapped by Catahoula sandstone. Thickness 11 to 55 feet.

G. E. Murray, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 700, 702 (fig. 1). Referred to as Bucatunna clay. Overlies Byram formation. Included in Vicksburg stage.

E. C. Tonti, 1955, Dissert. Abs., v. 15, no. 8, p. 1372. Name Hennessey Bayou member proposed for lower Bucatunna transgressive unit heretofore included in Byram formation.

Type locality: Along Bucatunna Creek, north of Denham post office, which is located in sec. 19, T. 8 N., R. 5 W., Wayne County, Miss.

Buchanan Gravel[1]

Pleistocene (Kansan): Eastern and central Iowa.

Original reference: S. Calvin, 1896, Iowa Acad. Sci. Proc., v. 3, p. 58–60.

A. E. Flint *in* A. V. Heyl, Jr., and others, 1959, U.S. Geol. Survey Prof. Paper 309, p. 25. Buchanan gravels considered to be of Kansan age.

Named for Buchanan County.

Buchanan Hill Conglomerate[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: J. P. Lesley, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 2, p. 1489–1536.

Caps Buchanan Hill, just south of New York line.

Buck Tongue (of Mancos Shale)[1]

Buck Formation

Buck Shale Member (of Price River Formation)

Upper Cretaceous: Central eastern Utah and central western Colorado.

Original reference: C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851, p. 23, 32.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, p. 1 (facing p. 1011). Shown on correlation chart as formation.

H. E. Wheeler and V. S. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 10, p. 2413 (fig. 2), 2417. Member of Price River formation. Stated that term "tongue" is misleading when used in formal designation and that there should be no implication that the Buck shale is part of Mancos as lithostratigraphic or map unit. Montana age.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 180 (fig. 2), 182. Buck tongue of Mancos occurs above Castlegate member and below Sego member of Blackhawk formation. From its western edge near Woodside, Utah, the tongue thickens eastward to maximum of 380 feet at West Salt Creek, Colo., where it passes into main body of the Mancos.

Named for Buck Canyon, T. 19 S., R. 23 E., Utah.

†Buck Creek Formation[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: C. N. Gould, 1925, Oklahoma Geol. Survey Bull. 35, p. 78.

U.S. Geological Survey has abandoned the name Buck Creek formation.

Named for exposures along Buck Creek in northeastern part of Osage County.

Buck Creek Sandstone[1]

Buck Creek Sandstone Member (of Grindstone Creek Formation)

Pennsylvanian (Strawn Series): Central northern Texas.

Original reference: F. B. Plummer and J. Hornberger, Jr., 1936, Texas Univ. Bull. 3534, p. 162.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on chart as basal member of Grindstone Creek formation. Occurs below Santos limestone member and above Brannon Bridge limestone member of Lazy Bend formation.

Crops out on Buck Creek in southwestern part of Parker County.

Buckeye Shale (in Sumner Group)[1]

Buckeye Shale Member (of Wellington Shale)

Permian: Southeastern Kansas.

Original reference: R. C. Moore, 1936, Kansas Geol. Soc. Guidebook 10th Ann. Field Conf., p. 12 (fig. 4).

J. L. Garlough and G. L. Taylor, 1941, *in* Stratigraphic type oil fields; Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 87 (table 2). Table lists rocks of Sumner group at their outcrop, 200 miles east of Hugoton gas field; Wellington shale is divided into (ascending) Buckeye shale, Carlton limestone, shale, and Geuda salt.

Buck Hill Volcanic Series

Eocene, upper, Oligocene and younger(?): Western Texas.

S. S. Goldich and C. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Oct. 29–31, p. 13–22. Name applied to Tertiary volcanic succession unconformably overlying Boquillas formation. Includes (ascending) Pruett formation with its intercalated flows (Crossen trachyte, Sheep Canyon basalt, and Potato Hill andesite), Cottonwood Spring basalt, Duff formation, Mitchell Mesa rhyolite, Tascotal formation, and Rawls basalt. Eocene to Miocene(?). [See Green Valley volcanic series.]

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1143–1145, 1170, pl. 1. Described in Buck Hill quadrangle where Mitchell Mesa rhyolite is uppermost unit. Thickness 2,000 feet or more. Flows came into region from north, and thus mapped boundaries probably represent their original southern limits closely; flows were eroded in part and weathered before being covered with ash. In Buck Hill and Jordan Gap quadrangles, series has been folded into broad northwest-plunging nose. Lower Tertiary. Pruett is tentatively assigned to Eocene and the Duff to Oligocene. Derivation of name.

R. L. Erickson, 1953, Geol. Soc. America Bull., v. 64, no. 12, pt. 1, p. 1358 (table), 1361–1371, pl. 1. Series described in Tascotal Mesa quadrangle where it includes (ascending) Pruett tuff (formation), Duff tuff (formation), Mitchell Mesa tuff-flow, Tascotal tuff (formation), and Rawls basalt. Thickness about 3,900 feet. Overlies Boquillas formation; angular unconformity. Underlies Quaternary gravels. Eocene(?), Oligocene, Miocene(?).

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 542–543, pl. 1. Described in Cathedral Mountain quadrangle where Rawls basalt is uppermost unit. Crossen trachyte, Sheep Canyon basalt, and Potato Hill andesite, considered intercalated flows in Pruett formation by Goldich and Elms, are here given formational status, and name Pruett is restricted to the tuff, sandstone, conglomerate, and limestone below Crossen trachyte. Aggregate thickness more than 4,600 feet. Overlies Boquillas formation; angular unconformity. Top of Eocene is placed at disconformity between Crossen trachyte and Sheep Canyon basalt. Suggested that overlying lava and tuff layers are Oligocene and younger(?).

Named for outcrops in Buck Hill quadrangle, Brewster County, Tex.

Buckhorn Asphalt

Pennsylvanian: Southern Oklahoma.

H. J. Smith, 1938, The cephalopod fauna of the Buckhorn asphalt: Dept. Geology and Paleontology, Chicago Univ., p. 1, 3. Asphalt deposit containing cephalopod fauna; main fossil-bearing bed is shaly limestone; thin veneer of calcium carbonate gives rocks a white appearance, but on fresh exposure rocks are black.

A. G. Fisher and Robert Finley, Jr., 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1887. Buckhorn sediment of Oklan age was laid down as shell breccia in argillaceous and sandy matrix, grading upward into gravel; faulting of Arbuckle orogeny permitted Ordovician oil to saturate the sediment.

Occurs in abandoned quarry in sec. 2, T. 1 S., R. 3 E., about 3 miles south of Sulphur, Murray County. Region is on northern flank of Ardmore basin.

Buckhorn Conglomerate (in Cedar Mountain Group)

Buckhorn Conglomerate Member (of Cedar Mountain Formation)

Lower Cretaceous(?): Central eastern Utah.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 958, 965–966, pl. 4. At type locality, unit is 20 to 30 feet thick, irregularly bedded with minor sandy lentils, but generally present as single massive stratum. Underlies Cedar Mountain shale (new); overlies Brushy Basin shale member of Morrison. Together with Cedar Mountain shale comprises Cedar Mountain group (new).

W. L. Stokes, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1773, 1774. Rank reduced to member status in Cedar Mountain formation.

Type locality: Buckhorn Flat at southwest flank of Cedar Mountain, Emery County. Prominent in northern part of San Rafael area where it caps Cedar Mountain, a tabular mass of Jurassic sediments about 75 square miles in extent.

†Buckhorn Limestone[1]

Lower Mississippian: Central northern Utah.

Original reference: F. M. Wichman, 1920, Eng. and Mining Jour. v. 110, no. 12, p. 563.

Ophir mining district.

Buckhorn Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9. Dolomite, argillaceous, with green shale partings; contains bentonite zone. About 6 feet thick. Shown on columnar section (fig. 3) as underlying St. James member (new) and overlying Glenhaven member (new) of Guttenberg formation.

In the copy of the guidebook used by the compiler, in figure 3 the name Buckhorn had been crossed out and the name Red Oak written in. Likewise, the name Glenhaven had been crossed out and the name Garnet written in. Thus, the sequence would read (descending) St. James, Red Oak, Garnet. However, in figure 9, the name Glenhaven had not been changed. Since the compiler had no way to determine what changes, if any, had been made in other copies of the guidebook, it was impossible to be certain which names were to be retained.

Occurs in Dixon-Oregon area.

†Buckingham Marl or Limestone

Miocene, upper: Florida.

W. C. Mansfield, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1916; 1939, Florida Geol. Survey Bull. 18, p. 11–16. Proposed for limestone cropping out in Lee County. Believed to be uppermost Miocene. Underlies Tamiami limestone. Fossils listed.

G. G. Parker, 1951, Am. Water Works Assoc. Jour., v. 43, no. 10, p. 823. Tamiami formation as herein defined includes Buckingham limestone of Mansfield.

Type locality: Quarry near State Highway 25, one-half mile west of Orange River, sec. 5, T. 44 S., R. 26 E., Lee County.

Buck Island Member (of Davis Creek Formation)

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Upper member of formation. Overlies Baldy Mountain member (new); underlies Brophy Canyon formation (new). The Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Buck Lodge diabase[1]

Upper Triassic: Central northern Maryland.

Original reference: C. R. Keyes, 1891, Geol. Soc. America Bull., v. 2, p. 320.

East of Sugarloaf Mountain, Frederick County.

Buck Mountain Granite

Precambrian(?): Northwestern Wyoming.

C. C. Bradley, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 36–37. Name applied to granite in Buck Mountain stock. A pink or white granite resembling alaskite.

Named for Buck Mountain in Grand Teton National Park.

Buckner Formation

Buckner Member (of Haynesville Formation)

Upper Jurassic: Subsurface in Arkansas, Louisiana, Mississippi, and Texas.

H. K. Shearer, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 6, p. 724. Formation, approximately 200 feet thick, is characterized by anhydrite with shale and dolomitic limestone. Overlies Smackover limestone; underlies Cotton Valley formation.

W. B. Weeks, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 8, p. 959 (fig. 2), 960 (fig. 3), 966. Maximum thickness penetrated in Arkansas 270 feet. Pre-Comanche.

R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 158. Jurassic(?).

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 21–25, cross sections. Presumably Upper Jurassic.

R. W. Imlay, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 11, p. 1437 (table 1), 1451–1458. Detailed discussion with Jurassic formations of Gulf Coast region. Upper Jurassic (Kimmeridgian).

F. M. Swain, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 578 (table 1), 592, strat. sections, chart. Underlies Bossier formation (new) of Cotton Valley group. Upper Jurassic.

T. H. Philpott and R. T. Hazzard, 1949, Shreveport Geol. Soc. Guidebook 17th Ann. Field Trip, fig. 5 (correlation shart). Chart shows Buckner as basal member of Haynesville formation (new).

Named after Buckner field, Columbia County, Ark.

Buckner Group

See Boice Formation.

†Buck Point Sandstone Member (of Nelagoney Formation)

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: F. R. Clark, 1918, U.S. Geol. Survey Bull. 686–I, p. 94.

Buck Point Sandstone is considered the equivalent of Okesa Sandstone, and name is abandoned.

Well exposed at Buck Point and elsewhere around edges of main divide between Sand and Buck Creeks in T. 26 N., 11 E., Osage County.

Buckrange Sand Lentil (of Ozan Formation)[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: C. H. Dane, 1926, U.S. Geol. Survey Press Bull. 8823, Sept. 10.

Crops out short distance north of village of Buckrange, Howard County; also 1 mile northeast of village, on road to Nashville.

†Buck Ridge Gneiss[1]

Precambrian: Southeastern Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 1, p. 80–91, 118.

Forms Buck Ridge.

Buck Ridge Schist

Precambrian (Archean?): Western North Carolina.

C. E. Hunter and P. W. Mattocks, 1936, Tennessee Valley Auth. Div. Geology Bull. 4, p. 12, 14. Rather variable both in composition and texture, but usually is fine textured and composed of secondary micas, chlorites, and feldspars. Includes Bearwallow schist (new).

Named from Buck Ridge in Spruce Pine quadrangle, where it has its largest outcrops.

Bucks Granodiorite

Late Jurassic(?): Northern California.

Anna Hietanen, 1951, Geol. Soc. America Bull., v. 62, no. 6, pl. 1. Shown on map as Bucks granodiorite.

Occurs on Feather River in Merrimac area, Plumas National Forest, Butte and Plumas Counties.

Bucks Bridge Member (of Tribes Hill Formation)

Bucks Bridge (mixed) Beds[1]

Lower Ordovician (Beekmantown): Northern New York.

Original reference: G. H. Chadwick, 1915, Geol. Soc. America Bull., v. 26, p. 289–291.

R. R. Wheeler, 1946, Harvard Univ. Summ. of Theses 1942, p. 144. Middle member of Tribes Hill formation in St. Lawrence Valley. Underlies Ogdensburg member; overlies Heuvelton member.

Apparently named for Bucks Bridge on Nettle Creek in St. Lawrence Valley.

Buckshot Ignimbrite (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 15 (fig. 3), 20. Name proposed for rhyolite porphyry, 40 to 75 feet thick, that caps Buckshot Rim. Fresh rock is grayish red to moderate yellowish brown; weathered surface, pale to dark reddish brown; locally a dusky green layer of brittle glassy rock is present at base. In thin section, matrix shows glass shards and other pyroclastic material. Overlies Colmena tuff (new); underlies Chambers tuff (new).

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Quad. Map 23. Described in Van Horn Mountains area where it forms a resistant cap rock from 3 to 20 feet thick. Overlies Colmena formation. Crops out only on southern flanks of Colquitt syncline in the Sierra Vieja.

Type locality: Four miles east of Candelaria, Rim Rock country, Presidio County.

Buckskin Schist

Pre-Ordovician(?): North-central Washington.

E. A. Youngberg and T. L. Wilson, 1952, Econ. Geology, v. 47, no. 1, p. 2–4, 12. Name applied to series of quartz-amphibole schists containing two horizons of intermittent marble beds and calcareous schist. Mapping indicates beds may be 3,000 to 3,500 feet thick. Age sequence not clear; it would appear that Fernow unit (new) is older than less metamorphosed Buckskin and Martin Ridge schists; this would require that beds be overturned as Fernow gneisses lie stratigraphically above the schists.

Named for occurrence in vicinity of Buckskin Mountain, near Holden, Chelan County.

Buckskinian series

Cretaceous (Mid-Cretacic): Northwestern Kansas, and eastern Colorado.

[C. R.] Keyes, 1941, Pan-Am. Geologist, v. 76, no. 4, p. 304 (chart). Includes Gove chalk below and Wallace shales above; thickness about 700 feet. Occurs above Pueblan series and unconformably below Rawlinsian series.

Charles Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 207. Includes a great section of dark shales, exposed in eastern Colorado and northwestern Kansas, usually called vaguely and erroneously the Pierre formation. Section covers a large but indefinite part of the median part of Asiniboine centrum shales. There is doubtless another series between the Buckskinian and the top of Apishapa shale member of Pueblan series.

Name derived from a way station in Wallace County, Kans.

Buckskin Mountain Formation

Permian (Wolfcampian): Northeastern Nevada.

T. G. Fails, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no 10, p. 1693–1697. Proposed for a 1,200-foot uniform sequence of yellow-tan quartzose calcisiltites and minor gray calcarenite beds of Wolfcampian age conformably overlying Pennsylvanian-Permian Strathearn formation and conformably overlain by Permian Beacon Flat formation (new).

Type section: On north side of Humboldt River at Carlin Canyon loop area; base in NW¼NW¼SW¼ sec. 22, T. 33 N., R. 53 E., and top in NW¼SE¼NW¼ sec. 22, Elko County. Crops out prominently on Buckskin Mountain, 3 miles south of type locality.

Bucksport Formation

Age not stated: Eastern Maine.

L. A. Wing, 1957, Maine Geol. Survey GP. and G. Survey 1, sheet 1. Thin-banded limey quartzite-uniform bands of light-greenish and dark-gray to purple bands. Lighter bands are quartz rich, and original calcareous minerals have been recrystallized to form lime silicates, mostly diopside; darker bands are quartz and biotite rich, and purple tints are due to finely divided biotite. Overlies Penobscot formation; appears to be overlain and interbedded with unit referred to as Veazie formation (new). Name credited to J. M. Trefethen (1950, Preliminary map of Bucksport area, Maine: Maine Univ.). [Compiler was unable to locate this reference.]

Report covers portions of Hancock and Penobscot Counties.

Buck Spring Formation

Cambrian: South-central Wyoming.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Soc. Guidebook 9th Ann. Field Conf., chart 2; A. B. Shaw and C. R. DeLand, 1955, Wyoming Geol. Soc. Guidebook 10th Ann Field Conf., p. 38. Name applied to facies equivalents of Gros Ventre group in south-central Wyoming. Contains brown to red sandstone, siltstone with minor amounts of glauconite, and no limestone; by comparison Gros Ventre group contains green fissile highly glauconitic shales and much limestone. Where Death Canyon limestone is missing, entire shale sequence may be called Gros Ventre formation, but where these rocks are in brown to red sand and siltstone facies name Buck Spring is applied. Thickness at type locality 106 feet.

Type locality: Near Buck Spring in SE¼ sec. 4, T. 22 N., R. 88 W., in northwestern part of Rawlins uplift.

Buda Limestone (in Washita Group)[1]

Buda Limestone (in Sixshooter Group)

Upper Cretaceous (Comanche Series): Southeastern Texas, and northern Mexico.

Original reference: T. W. Vaughan, 1900, U.S. Geol. Survey Bull. 164, p. 18.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Correlation chart shows Buda limestone in Washita group, Upper Cretaceous (lower Cenomanian). Overlies Grayson shale. Present in Chihuahua, Mex.

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1140–1141, pl. 1. Described in Buck Hill quadrangle, Texas, where it is 65 to 68 feet thick. Disconformably overlies Grayson clay; disconformably underlies Boquillas formation. Lower Cretaceous.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 10 (table 1), 13, 31, pl. 1. Described in Eagle Mountains, Hudspeth County, where it underlies Eagle Ford formation and overlies Eagle Mountains sandstone member (new) of Grayson formation. Maximum thickness 225 feet. Upper Cretaceous.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology, Geol. Quad. Map 21. In Wylie Mountains and vicinity, uppermost formation in Sixshooter group (new). Overlies Boracho formation (new); overlain with angular discordance by Tertiary volcanic strata. Thickness 40 to 150 feet.

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 374 (fig. 2), 385–386. Described in Kent quadrangle where it is uppermost formation in Sixshooter group. Unconformably overlies San Martine member (new) of Boracho formation; unconformably underlies Boquillas flags. Thickness 160 feet. Cenomanian.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol. Survey Prof. Paper 312, p. 10, pl. 1. Described in Terlingua district, Texas, where it is commonly 90 feet thick, overlies Grayson formation and underlies Boquillas flags. Comanche series, Upper Cretaceous.

A. P. Noyes, Jr., and Keith Young, 1960, Texas Jour. Sci., v. 12, nos. 1–2, p. 70 (fig. 3), 74 (fig. 5), 90–92. Described in Purgatory Creek area, Texas, where it is 40 feet thick, overlies Del Rio clay and unconformably underlies Eagle Ford formation.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 41–42, pl. 2. At Grayson Bluff, southern Denton County, Tex., the Buda consists of clastic coquinitic buff to yellow limestone about 18 inches thick. Unconformable with underlying Denison formation; contact with overlying Woodbine is irregular surface of erosion. Washita group. Upper Cretaceous.

Named for Buda, Hays County, Tex.

Buell Limestone

Eocene, upper: Eastern Oregon.

J. E. Allen, 1946, Oregon Dept. Geology and Mineral Industries G.M.I. Short Paper 15, p. 8 (pl. 4), 9–11. Dense gray rock with both carbonaceous and clastic fragments. Weathers brown near surface. Estimated thickness 20 feet. Deposit is similar in appearance and composition to Dallas limestone (new) 10½ miles to southwest. Both appear to lie disconformably on older basalt. Fossils occur in Buell limestone but have not been identified. If Buell does occupy stratigraphic position similar to Dallas limestone, it would be of upper Eocene age.

Occurs about 2 miles west of Buell and 3½ miles southeast of Willamina, Polk County, a short distance south of State Highway 22. Extensively quarried.

Buena Vista Sandstone Member (of Cuyahoga Formation)[1]

Buena Vista Sandstone Member (of Logan Formation)

Buena Vista Siltstone Member (of New Providence Formation)

Mississippian: Southern Ohio and north-central Kentucky.

Original reference: E. Orton, 1874, Ohio Geol. Survey, v. 2, pt. 1, p. 615, 618, 626.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 78, 133, pl. 6. Buena Vista siltstone considered member of New Providence formation in area of Vanceburg facies in Kentucky. Overlies Henley member; underlies Rarden member; [Stockdale] cannot clearly justify Hyde's recognition of the Buena Vista in Lewis County; this is partly because of difficulty in distinguishing overlying "Rarden shale member" of Hyde in Kentucky. Considered Lower Mississippian.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 60–61, 62. Buena Vista sandstone considered basal member of Logan formation. In area of Vanceburg facies, underlies Rarden shale member; in area of Scioto Valley facies, underlies Portsmouth shale member.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 3 (table 1), 24, 25. Here considered member of Cuyahoga formation in areas of Scioto Valley and Vanceburg facies where it overlies Henley shale member; in Scioto Valley facies, underlies Portsmouth shale member; in Vanceburg facies, underlies Rarden shale member. Editor's note states that Hyde (1921, Ohio Geol. Survey Bull. 23) correlated Buena Vista sandstone with Berne and lower part of Byer in discussion geology of Camp Sherman quadrangle; such a correlation would necessitate placing Rarden, Vanceburg, Churn Creek, and most of Portsmouth shale in Logan formation.

Named for Buena Vista, Scioto County, Ohio.

†Buena Vista Shale[1]

Lower and Middle Cambrian: Central western Virginia.

Original reference: H. D. Campbell, 1905, Am. Jour. Sci., 4th, v. 20, p. 445–447.

Named for Buena Vista, Rockbridge County.

†Buffalo Cement Bed[1]

Silurian: Western New York.

Original reference: G. H. Chadwick, 1917, Geol. Soc. America Bull., v. 28, p. 173–174.

Buffalo, Erie County.

Buffalo Formation (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: G. H. Ashley, 1926, Pennsylvania Topog. and Geol. Atlas 65, p. 24–25, pl. 4.

Punxsutawney quadrangle.

†Buffalo Glaciation, Drift, or Till

Buffalo Glacial Stage[1]

Pleistocene: Rocky Mountain region.

Original reference: E. Blackwelder, 1915, Jour. Geology, v. 23, p. 310, 328–336.

John de la Montagne, 1956, Wyoming Geol. Soc. Guidebook 11th Ann. Field Conf., p. 29–30. Glacial sequence in Jackson Hole area (ascending): Buffalo, Bull Lake, and Pinedale.

G. M. Richmond, 1957, Internat. Assoc. for Quarternary Research, 5th Cong., Madrid, p. 157; 1960, Geol. Soc. America Bull., v. 71, no. 9, p. 1371–1382. Pleistocene deposits in Rocky Mountain region are grouped into three stages: Buffalo (oldest), Bull Lake, and Pinedale, each with characteristic topographic expression and soil development. Buffalo stage includes till sheets of three ancient glaciations. Lower and middle sheets are precanyon and the upper is of intracanyon or postcanyon age. Where stratigraphically superimposed, each of these tills is overlain by thick strongly developed reddish clay soil.

Named for occurrence of drift along Buffalo Fork or Snake River in Wyoming.

Buffalo Granite[1]

Precambrian: Central southern Virginia.

Original reference: F. B. Laney, 1917, Virginia Geol. Survey Bull. 14, p. 36, map.

In vicinity of Buffalo Lithia Springs, Mecklenburg County, Va.

Buffalo Sandstone Member (of Conemaugh Formation)[1]

Buffalo shale and (or) sandstone member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 33.

M. T. Sturgeon and others, 1958, Ohio Div. Geology Bull. 57, p. 95 (table 11), 114. Referred to as Buffalo shale and (or) sandstone member of Wilgus cyclothem in report on Athens County. White (1878) used name Buffalo for thick sandstone between Brush Creek and Cambridge (Pine Creek in Pennsylvania) limestones. Adams (1903) called shale between Cambridge limestone and Brush Creek coal Buffalo shale. In Ohio, both the sandstone and shale between the Brush Creek and Cambridge limestones are called Buffalo although name is commonly considered as applied to sandstone. Flint's (1951) description of Buffalo shale in Perry County fits that of Meyersdale redbed rather than that of Buffalo member. Term Buffalo is used in this report for both shale and sandstone. Thickness of member varies from 7 to 8 feet to almost 43 feet. Meyersdale redbed member, which overlies Buffalo sandstone in Pennsylvania, is not present in Athens County. Conemaugh series.

Attains maximum development along Buffalo Creek, in Buffalo Township, Butler County, Pa.

Buffalo shale[1]

Upper Ordovician and lower Silurian: Northeastern Missouri and southwestern Illinois.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59, 61.

Named for Buffalo Creek, Pike County, Mo.

Buffalo Shales (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: T. K. Adams, 1903, Mines and Minerals, v. 23, p. 360.

N. K. Flint, 1951, Ohio Div. Geology, ser. 4, Bull. 48, p. 65, Table 1. Buffalo shale member included in Wilgus cyclothem in Perry County. Term Buffalo has previously been restricted to massive cliff-forming sandstone, but in this report shale occurring in the same interval is also called Buffalo. Thickness 23 to 52 feet. Consists of shale or clay shale of various gray, green, purple, and red shades. Contains numerous hematite, siderite, and limonite nodules some of which are calcareous. Conemaugh series.

M. T. Sturgeon and others, 1958, Ohio Div. Geology Bull. 57, p. 114. Flint's (1951) description of Buffalo shale in Perry County fits the Meyersdale redbed rather than that of Buffalo member.

Exposed near Pittsburgh, Allegheny County.

Buffalo Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 384.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec. [Guidebook] Spring Mtg., p. 71. Clay, 125 feet thick. Underlies Wilbarger Creek bed; overlies Rough Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Buffalo Creek, Mills County.

Buffalo Creek Limestone (in Kanawha Formation[1] or Group)

Pennsylvanian (Pottsville Series): Southwestern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 143.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 78. Marine limestone here considered to be of lower Allegheny age.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 12). In this report, the Kanawha is considered a group in Pottsville series.

Named for association with Buffalo coal, Lee district, Mingo County.

†Buffalo Creek Sandstone Member (of Conemaugh Formation)[1]

Pennsylvanian: Pennsylvania.

Original reference: G. H. Ashley, 1908, Pennsylvania Topog. and Geol. Survey Comm. Rept. 1906–1908, p. 161.

In region of Buffalo Creek, Butler County.

Buffalo Hart Substage

Buffalo Hart Till

Pleistocene (Illinoian): Illinois.

M. M. Leighton and H. B. Willman, 1949, *in* Itinerary State Geologists Field Conference on late Cenozoic Geology of Mississippi Valley, p. 7 (table 1); 1950, Jour. Geology, v. 58, no. 6, p. 602 (fig. 2). Illinoian stage is divided into (ascending) Loveland, Payson, Jacksonville, and Buffalo Hart substages.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 125 (fig. 50), 139, geol. sections 50–52, 58, 61, 64, 66, 69. Buffalo Hart moraine extends through northeast part of Beardstown quadrangle and northward through west part of Vermont quadrangle. Buffalo Hart deposits also form surface drift through all upland areas of Havana and Glasford quadrangles. Outwash deposits scarce, but some gravel and sand occurs over older Illinoian till and under Farmdale or Peorian loess in small ravines north and south of Vermont. Buffalo Hart till cannot be differentiated from older Illinoian tills, except locally where intra-Illinoian gravel, sand, and silt deposits are deposited. Derivation of name given.

Named for Buffalo Hart in northern Sangamon County.

Buffalo Hill Sandstone (in Clear Fork Group)[1]

Permian: Central and central northern Texas.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull., v. 1, opposite p. 96.

Named for Buffalo Hills, Taylor County.

Buffalo Hump Formation (in Deer Trail Group)

Precambrian (Belt Series): Northeastern Washington.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Named as uppermost of five formations in group. Overlies Stensgar dolomite.

Report discusses magnesite belt of Stevens County.

Buffalo Peaks Andesite[1]

Oligocene, lower(?): Central Colorado.

Original reference: D. B. Gould, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 7, p. 900, 990, 999, 1000.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 103–105, pl. 1. On Hall Buttes, andesite varies from gray to black, with phenocrysts of hornblende and pryoxene. Flow structure common, and platy jointing often well developed. Small amounts of agglomeratic material at base of volcanics. Thickness between 500 and 600 feet at westernmost end of West Hall Butte and decreases to between 200 and 300 feet at east end of East Hall Butte; much thicker on Buffalo Peaks. An early Oligocene age is suggested.

Lies on truncated surface of Paleozoic strata affected by syncline extending northerly from valley of Trout Creek in sec. 3, T. 14 S., R. 77 W., past Pony Spring, to northeast spur of Buffalo Peaks in Salt Creek area, Park and Chaffee Counties.

Buffalo River Series[1] or Group

Ordovician: Northern Arkansas.

Originial reference (Big Buffalo Series): R. S. Bassler, 1915, U.S. Natl. Mus. Bull. 92, v. 2, pls. 1, 2.

J. S. Cullison, 1938, Jour. Paleontology, v. 12, no. 3, p. 219–228. Buffalo River group as originally defined by Ulrich (1911) included Joachim dolomite at top, St. Peter sandstone, and Everton sandstone and dolmite. McQueen (1937) has described Dutchtown formation, which lies unconformably between the Joachim and the St. Peter and Everton of Ulrich's section. The Dutchtown is only formation of Buffalo River group that contains fossils in abundance.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 113–114. Buffalo River series consists of (ascending) Everton, St. Peter, Dutchtown, and Joachim formations. Originally Big Buffalo series, but name of Big Buffalo River, after which group is named, was changed to Buffalo River.

Ulrich (1911, Geol. Soc. America Bull. v. 22, pl. 27) did not use term Big Buffalo Series. He showed an unnamed epoch preceding the Chazyan and succeeding the Canadian. This unnamed epoch comprised (ascending) Everton, St. Peter, and Joachim Formations. Bassler's Big Buffalo Series comprises (ascending) Sneeds, Everton, St. Peter, and Jasper Formation.

Named for exposures on Buffalo River in Newton County. River was formerly called Big Buffalo.

†Buffalo Run Limestone[1]

Upper Cambrian: Central Pennsylvania.

Original reference: C. D. Walcott, 1916, Smithsonian Misc. Colln. v. 64, no. 3, Pub. 2370, p. 165.

Two miles north of Benore post office, Center County.

Buffalo Springs Formation (in Conococheague Group)

Buffalo Springs Member (of Conococheague Formation)

Upper Cambrian: Southeastern Pennsylvania.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Geologic map of the Richland quadrangle, Pennsylvania (1:24,000): Pennsylvania Geol.

Survey, 4th ser., Atlas 167–D. Consists of dirty-white or pinkish-gray to medium-gray crystalline limestone, commonly with laminae, alternating with yellowish-gray to light-olive-gray weathered dolomite and magnesian limestone; dolomite is fine to medium crystalline and commonly light gray on fresh surface; thin sandy limestone or silty limestone beds occur locally. Light-olive-gray weathering shaly limestone interbeds present in many outcrops. The white to pinkish-gray limestones commonly grade laterally into very light-gray limestone. Light-blue-gray limestone common near top of member. Estimated thickness more than 700 feet; base of member not exposed in quadrangle; partial section (type section) 247 feet. Underlies Snitz Creek member (new); oldest exposed Cambrian limestone in quadrangle.

Carlyle Gray and D. M. Lapham, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 148–150. Upper Cambrian.

Carlyle Gray and others, 1960. Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Conococheague group.

Type section: Partial section measured along old trolley line about 0.7 mile southeast of Buffalo Springs, Lebanon County. No satisfactory type section available in Lebanon County, but best partial section has been measured and used as type section.

Buffalo Wallow Formation[1]

Upper Mississippian: Western central Kentucky and southern Indiana.

Original reference: Charles Butts, 1917, Mississippian formations of western Kentucky: Kentucky Geol. Survey, p. 112.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 840. Name Buffalo Wallow has been used for all of the Chester above Tar Springs sandstone in southeastern part of Eastern Interior basin, but as all of the formations of the Elvira group with the possible exception of the Vienna and Waltersburg can be identified at type locality of the Buffalo Wallow, the name has little value.

Preston McGrain and F. H. Walker, 1954, Kentucky Geol. Soc. Field Trip, April 1954, p. 28. Leitchfield formation differs from Buffalo Wallow (Butts, 1917) in that it includes the Tar Springs as basal member.

Named for Buffalo Wallow, a circquelike excavation in the shales of the formation on highway, 2 miles west of Cloverport, Breckenridge County, Ky.

Buffkin Formation[1]

Buffkin Limestone (in Wabash Formation)

Pennsylvanian: Southwestern Indiana.

Original reference: Marshall Harrell, 1935, Indiana Div. Geology Pub. 133, p. 73 (chart).

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 78. Gives derivation of name.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 25). Correlation chart shows Buffkin limestone in Wabash formation; occurs above Parker limestone and below Grayville limestone.

F. D. Spencer, 1953, U.S. Geol. Survey Circ. 266, p. 14 (fig. 4). Column credited to C. E. Wier (1944–51) shows Buffkin formation at top of section above New Haven formation.

Named for Buffkin, Posey County.

Bufkin Limestone

See Buffkin Formation.

Bug Scuffle Limestone Member (of Gobbler Formation)

Pennsylvanian: Southeastern New Mexico.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93. Appears only on columnar section. Consists of massive gray cherty limestone which grades laterally into sandstone and shale.

In Sacramento Mountains, Otero County.

Bujio Formation

See **Bohío Formation.**

Buldir Volcanics

Quaternary(?): Southwestern Alaska.

R. R. Coats, 1953, U.S. Geol. Survey Bull. 989–A, p. 8, 13–14, fig. 2. In general, rocks are pale-gray dense holocrystalline olivine basalts and olivine-hypersthene basalts. Flows generally thin, averaging less than 10 feet. Interstratified with lava flows on sea cliffs northeast of Kittiwake Pond, at an altitude of 760 feet, are layers of essential basaltic lapilli, consisting of hyalophyric olivine basalt.

Associated with Buldir Volcano and parasitic cone (Hill 1350) to northeast of main cone, which contributed largely to construction of southwestern part of Buldir Island, in western Aleutian Islands.

†Bulger Limestone (in Monongahela Formation)[1]

Upper Pennsylvanian: Southwestern Pennsylvania and eastern Ohio.

Original reference: W. T. Griswold and M. J. Munn, 1907, U.S. Geol. Survey Bull. 318, p. 38–39, 70.

Named for exposures at Bulger, Washington County, Pa.

Bulitan Stage

See Bulitian Stage.

Bulitian Stage

Paleocene: California.

V. S. Mallory, 1953, (abs.) Jour. Paleontology, v. 27, no. 6, p. 903; 1954, Pacific Petroleum Geologist, v. 8, no. 11, p. 1. Named as one of six stages, based on foraminiferal assemblages, in the lower Tertiary of California. Includes interval between Eocene Juniperan [Juniperian] stage above and Paleocene Ynezian stage. Also spelled Bulitan.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 29–32, 75, 92, fig. 7, tables. Bulitian stage follows Ynezian. Includes two zones, *Bulimina bradburyi* below, and *Valvulineria wilcoxensis* above. Stage generally correlates with Laiming's (1939, 6th Pacific Sci. Cong. Proc., v. 2) "D-Zone." Strata of type Bulitian include Anita shale superjacent to strata of topmost Ynezian and subjacent to the 20 feet of siltstone

774–954—vol. 1—66——34

immediately underlying Sierra Blanca limestone. Followed by Penutian stage (name proposed to replace Juniperian stage).

Type area: In Canada el Bulito, Santa Barbara County.

Bull Slate[1]

Bull Formation or Group

Lower Cambrian: West-central Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 401.

E-an Zen, 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1829–1830. Revised stratigraphic sequence proposed for north end of slate belt in Taconic Range consists of three major units: Biddie Knob formation (base), Bull formation, and Hooker black slate.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 1–2. Formation includes (ascending) Castleton conglomerate (new), Mudd Pond (new), Zion Hill, Bomoseen graywacke, and Mettawee members. Overlies Biddie Knob formation; underlies West Castleton formation (new).

J. G. Elam, 1960, Dissert. Abs., v. 21, no. 6, p. 1523–1524. Discussion of Troy South and East Greenbush quadrangles, New York. Stratigraphic section divided into four groups and previously described dominant formational names have been elevated to group status. Groups are Bull (Lower Cambrian), West Castleton (Lower Cambrian-Upper Cambrian), Poultney (Lower Ordovician), and Normanskill (Middle Ordovician).

Named for quarry on Bull Hill, 2 miles north of Castleton, Castleton quadrangle.

Bullard Limestone[1]

Pennsylvanian: Utah.

Original reference: O. P. Peterson, 1924, Am. Inst. Min. and Met. Engrs. Trans., v. 70, p. 915.

Bingham district.

Bullard Peak Series

Precambrian: Southwestern New Mexico.

C. H. Hewitt, 1959, New Mexico Bur. Mines Mineral Resources Bull. 60, p. 12–35, 104–105, pl. 1. Rock types that make up Bullard Peak series grouped into five mappable units: (1) quartz-feldspar gneiss, biotite gneiss, quartzite, muscovite schist, and biotite schist; (2) sillimanite gneiss; (3) hornblende gneiss and amphibolite gneiss; (4) granite gneiss; and (5) migmatite and undifferentiated metamorphic rocks. Rocks of series have been intruded and are bounded by granite and related rocks of Burro Mountains granite batholith. Older than Ash Creek series (new).

Crops out along crest, west flank, and north end of Big Burro Mountains in parts of T. 18 S., R. 17 W.; T. 18 S., R. 16 W.; T. 19 S., R. 17 W.; and T. 19 S., R. 16 W., Grant County. Named from exposures in general area of Bullard Peak.

Bull Creek Limestone[1]

Pennsylvanian: Central northern Oklahoma.

Original reference: F. C. Greene, 1918, Am. Assoc. Petroleum Geologists Bull., v. 2, p. 121.

C. C. Branson, 1955, The Hopper, v. 15, nos. 10–11, p. 129. Abandoned. Name is preoccupied by Bull Creek sandstone of Drake (1893) in the Strawn of Texas. Bull Creek is a small tributary of Bird Creek. The bed is Birch Creek limestone of Bowen (1918), the valid name for the member.

Well exposed on Bull Creek, in northwestern part of T. 23 N., R. 11 E., Osage County.

Bull Creek Sand (in Hell Creek Member of Lance Formation)

Cretaceous: Northwestern South Dakota.

E. P. Rothrock, 1937, South Dakota Geol. Survey Rept. Inv. 28, p. 10. Uniform medium-grained golden-yellow sand in upper part of Hell Creek member.

Area of report is Harding County.

Bull Creek Sandstone (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 3, p. 374, 379.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec. [Guidebook] Spring Mtg., p. 72. Largely floggy layers. Thickness 50 to 75 feet. Overlies Horse Creek clays and shales; underlies Bill Valley bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Bull Creek, Mills County.

Bull Creek Sandy Limestone (in Greenhorn Formation)

Upper Cretaceous: Southeastern Montana and northeastern Wyoming.

M. N. Bramlette and W. W. Rubey *in* R. C. Moore, 1949, Geol. Soc. America Mem. 39, p. 27 (fig. 18). In lower chalk marl facies of formation. Older than Stoneville Flats limestone (new).

Carter County, Mont., and Crook County, Wyo.

Bull-Domingo Agglomerate or Breccia

Age not stated: South-central Colorado.

W. C. Peters, 1953, Econ. Geology, v. 48, no. 7, p. 599–600. Agglomerate composed of boulders of gneiss, syenite, and pegmatite held in a solid and impermeable matrix of finer material all derived from Precambrian rocks cut by the pipe. Pipe is which agglomerate accumulated interpreted as the site of a boiling spring which formed in an area of intersecting faults and enlarged to present size by churning rock debris.

D. L. Reynolds, 1954, Am. Jour. Sci., v. 252, no. 10, p. 587. Referred to as breccia.

Limited to an irregular and relatively narrow pipe (1,000 feet of known depth and 100 to 200 feet in diameter) in Silver Cliff mining district, Custer County.

Bullhead Member (of Fox Hills Formation)

Upper Cretaceous: South Dakota.

R. E. Stevenson, 1957, Areal geology of the McIntosh quadrangle (1:62,500): South Dakota Geol. Survey. Consists of thin beds of buff bentonitic silty clay and clayey silts alternating with thin beds of buff, fine, subgraywacke sands. Thickness 400 feet. Overlies Timber Lake member; underlies Colgate member.

Bull Hill Gneiss[1]

Bull Hill Member (of Hoosac Formation)

Cambrian or Lower Ordovician: Southern Vermont.

Original reference: C. H. Richardson, 1931, Vermont State Geologist 17th Rept., p. 221.

J. B. Thompson, Jr., 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for field trips in New England, p. 41. Rank reduced. Described as microcline augen gneiss believed to be metamorphosed rhyolite and rhyolite tuff. Maximum thickness 1,000 feet. Occurs near base of Hoosac formation. Cambrian or Lower Ordovician.

Type locality: On Bull Hill east of northeast of village of Grafton and north of village of Cambridgeport, Saxtons River quadrangle.

Bullington Member (of Magdalena Formation)

Bullington facies (of Morrison Formation)

Pennsylvanian: Central northern New Mexico.

L. L. Ray and J. F. Smith, Jr., 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 184–185. Limestone conglomerate composed of subrounded prismatic fragments of limestone, some almost lithographic in character, embedded in a light-gray to buff matrix of compact limestone. Fragments have maximum length of about 3 inches and breadth of 1 inch. In places, pebbles are smaller shapeless masses of light-buff limestone. Occasionally conglomerate is slightly reddish. Lies stratigraphically above all, or near top of, the "red beds" of the formation and below a sugary yellow sandstone which is presumably near top of formation.

J. F. Smith, Jr., and L. L. Ray, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 898. Along North Fork of Cimarroncito Creek in Cimarron Range, Bullington member of Magdalena crops out approximately 100 feet below Magdalena-Dakota contact.

K. G. Brill, 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 828. On Cimarroncito Creek, Dakota sandstone is in contact with Morrison formation, and Bullington conglomerate here, as in type locality, is a coarse-grained facies of Morrison formation.

First described from exposures in southern part of Moreno Valley and along western valley wall to a point about 1½ miles north of Comanche Creek, Colfax and Taos Counties.

Bullion Dolomite Member (of Monte Cristo Limestone)[1]

Bullion Member (of Monte Cristo Dolomite)

Bullion Limestone Member (of Monte Cristo Limestone)

Lower Mississippian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 18.

J. C. Hazzard, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1503; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881, 883 (fig. 2). Geographically extended into Nopah Range, Inyo County, Calif., where it is described as limestone 515 feet thick; overlies Anchor limestone member and underlies Yellowpine limestone member (Arrowhead limestone member not recognized in area).

Charles Deiss, 1952, U.S. Geol. Survey Bull. 973–C, p. 116-117, pl. 13. Member described in Sloan district, Nevada, where it is 445 feet thick, overlies Anchor member; uppermost unit of formation; underlies Bird Spring formation. Consists essentially of dolomite.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 42. Described in Ivanpah quadrangle (California-Nevada) where it is nearly pure dolomite. Overlies Anchor limestone member; underlies Arrowhead limestone member.

Named for Bullion mine, sec. 23, T. 25 S., R. 58 E., Goodsprings quadrangle, Clark County, Nev.

Bullion Butte Bed (in Sentinel Butte Shale Member of Fort Union Formation)

Paleocene: Southwestern North Dakota.

E. P. Beroni and H. L. Bauer, Jr., 1952, U.S. Atomic Energy Comm. TEI Rept. 123, p. 6, figs. 2, 4. Thickness about 15 feet at Bullion Butte. Contains uraniferous lignite.

Named for occurrence on Bullion Butte, Golden Valley County.

Bullion Canyon Volcanics

Bullion Canyon Series

Miocene(?): Central Utah.

Eugene Callaghan, 1939, Am. Geophys. Union Trans. 20th Ann. Mtg., pt. 3, p. 439 (fig. 2), 440 (fig. 3), 441–446. Volcanics vary greatly from place to place in proportion of flows to pyroclastics. Total thickness at least 5,000 feet. In eastern part of Tushar Mountains, three distinct parts distinguished, and here includes Delano Peak latite member (new). Overlies Carmel shale and limestone, Navajo sandstone, and Wasatch formation. Underlies (in central part) Mount Belknap rhyolite (new); on west in contact with Roger Peak basaltic breccia and Joe Lott tuff (both new); on east in contact with Dry Hollow latite (new). Tertiary.

P. F. Kerr and others, 1957, Geol. Soc. America Spec. Paper 65, p. 14-22, pl. 1. For purpose of this report, to follow variations in alterations, Bullion Canyon series is divided into 12 members. Rock Candy latite and agglomerate applied to one member, others unnamed.

D. P. McGookey, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 5, p. 595, 605–607, 609–615. Gray Gulch formation as designated by Spieker (1949) includes strata equivalent to Bald Knoll formation of Gilliland (1951), part of Bullion Canyon volcanics of Callaghan (1939) and a previously unnamed interval mapped as Gray Gulch(?) by Lautenschlager (1952, unpub. thesis). Proposed that (1) term Gray Gulch be abandoned; (2) term Bald Knoll formation be used for lower part of interval formerly assigned to Gray Gulch; (3) name Dipping Vat formation (new) be applied to upper coarse interval of lacustrine beds formerly included in Gray Gulch formation; and (4) fluvial beds equivalent to Bullion Cayon volcanics be included in Bullion Canyon volcanics, clastics. Term Bullion Canyon volcanics, clastics is used herein for the sequence of mudflows, conglomerate tuffaceous sandstone, and tuff that disconformably overlies Dipping Vat formation. Section that crops out along Little Lost Creek and Lost Creek is divisible into three distinct units. Thickness about 2,510 feet. Term Bullion Canyon volcanics, lava flows, is used herein for a sequence of igneous rock that appears to have been extruded as lava flows. This sequence lies disconformably on the Bullion Canyon volcanics, clastics. These extrusive rocks are designated as upper member of a sequence that is believed equivalent to Bullion Canyon volcanics as defined in type area near Marysvale. Based on stratigraphic position, Bullion Canyon volcanics, clastics are believed early middle Tertiary. Relations suggest that the lava flows are middle Tertiary, probably Oligocene.

U.S. Geological Survey currently classifies the Bullion Canyon Volcanics as Miocene(?) on the basis of restudy of the area.

Named for Bullion Canyon, west of Marysvale, Piute County.

Bull Lake Glaciation or **Drift**

Bull Lake glacial stage[1]

Pleistocene: Rocky Mountain region.

Original reference: E. Blackwelder, 1915, Jour. Geology, v. 23, p. 310, 325–340.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Sec. [Guidebook] 2d Ann. Field Trip Oct. 4–5, correlation chart. Bull Lake stage comprises an early Bull Lake substage, Porcupine Ranch substage (new), and late Bull Lake substage. Bull Lake stage is preceded by Buffalo stage and followed by Lackey Creek stage (new).

John de la Montagne, 1956, Wyoming Geol. Soc. Guidebook 11th Ann. Field Conf., p. 30. Glacial sequence in Jackson Hole area (ascending) Buffalo, Bull Lake, and Pinedale.

G. M. Richmond, 1957, Internat. Assoc. for Quaternary Research, 5th Cong., Madrid, p. 175; 1960, Geol. Soc. America Bull., v. 71, no. 9, p. 1371–1382. Pleistocene deposits in Rocky Mountain region are grouped into three stages: Buffalo (oldest), Bull Lake, and Pinedale, each with characteristic topographic expression and soil development. Bull Lake stage comprises well-developed mature moraines that are commonly the outermost on the canyon floors. Deposits are separable into two substages, which, where superimposed, are each overlain by mature zonal soils.

G. M. Richmond, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B223–B224. Discussion of correlation of alpine and continental glacial deposits of Glacier National Park and adjacent high plains, Montana. Deposits of two late Pleistocene alpine glaciations are correlated with Bull Lake and Pinedale glaciations of Wyoming. The older, Bull Lake, consists of two distinct advances separated by a major recession. Its two sets of moraines can be traced northeast from mountain front for 18 miles to point where the younger overlaps the older and merges with continental drift of same age. Drift is probably older than Farmdale loess of Illinois, dated as between 22,900 ± 900 years to 26,100 ± 600 years.

Moraines of stage well exposed in vicinity of Bull Lake, on northern slope of Wind River Range.

Bull Lake Creek Shales[1]

Cambrian: Western Wyoming.

Original reference: E. B. Branson, 1917, Geol. Soc. America Bull., v. 28, p. 347–350.

In Wind River Mountains. Probably named from Bull Lake Creek.

Bull Mountain Andesitic Series

Tertiary: Northwestern Arizona.

B. E. Thomas, 1949, Econ. Geology, v. 44, no. 8, p. 667. Comprises oldest Tertiary eruptive rocks in area. Consists of flows, tuffs, and breccias predominantly andesitic in composition. Rests upon surface cut on Cerbat complex (new); disconformably underlies Kingman series (new).

B. E. Thomas, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 407, pl. 1. Consists mostly of flows of medium-gray to grayish-red purple andesite, with some dark-gray basalt members. Intercalated with flows and especially abundant in basal section are beds of pink and red scoriaceous breccia and yellow to red tuff and lapilli. Strata reach thickness of almost 1,000 feet in northernmost extension of Kingman Mesa. Farther north, series occurs as isolated small cappings of ridges and buttes with maximum thickness of 350 feet. Geographic distribution discussed.

Named after Bull Mountain, which is capped by rocks of the series. Occurs along east side of Cerbat Mountains, Mohave County.

†Bull Mountain Series[1]

Eocene: Central southern Montana.

Original reference: W. Lindgren, 1886, U.S. Tenth Census, v. 15, p. 745, pl. 60.

In Bull Mountains and adjacent territory, Yellowstone County.

Bull Pond Limestone[1]

Age(?): New York.

Original reference: W. W. Mather, 1843, Geology New York, v. 1, pl. 45.

From Monticello, Sullivan County, to Croton River near Bulls Bridge, Westchester County.

Bull Run Glacial Epoch

Pleistocene: Central northern Oregon.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 835, 841 (table 1). Second of five glacial epochs. Occurs in interval between Cascadian and Willamettian epochs. During Bull Run epoch, erupted lavas were mostly andesitic; they are named Cascan volcanics.

Bull Run Shales (in Newark Group)[1]

Upper Triassic: Northeastern Virginia.

Original reference: J. K. Roberts, 1923, Pan-Am. Geologist, v. 39, p. 185–200.

Crops out over Bull Run Battlefield, Prince William County.

Bull Shoals Mountain Chert Bed (in Powell Dolomite)

Lower Ordovician: Central northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 39, pls. 2, 12 (fig. 2). Delicately banded chert nodule bed occurring above base of Powell dolomite.

Well exposed on road over Bull Shoals Mountain, in SE¼ sec. 19, T. 20 N., R. 15 W., Marion County.

Bullwagon Dolomite Member (of Vale Formation)

Bullwagon Dolomite (in Clear Fork Group)[1]

Permian (Leonard Series): North-central Texas.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull., v. 1, p. 96–97, pl.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank reduced to member status in Vale formation.

Named for Bullwagon Creek, Taylor County.

Bullwhacker Member (of Windfall Formation)

Upper Cambrian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 20, 21, 22, pl. 2. Composed of a rather uniform sequence of thin-bedded platy or shaly limestone, some of which is slightly silty; on fresh fracture, color ranges from medium light to medium dark gray. Shaly or sandy partings and thin interbeds weather to buff or pinkish, and whole member has a collective yellowish-tan color that is distinctive. Limestone beds are from ¼ to 1 inch thick and are fine grained to subporcellaneous in texture. Commonly 400 feet thick throughout area. At Eureka it appears to be conformable with both Catlin member (new) below and Pogonip group above.

Named from exposures in vicinity of Bullwhacker mine, Eureka mining district, Eureka County.

Bully Hill Rhyolite[1]

Middle and Late Triassic: Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Survey Geol. Atlas, Folio 138.

J. P. Albers, 1953, California Div. Mines Spec. Rept. 29, p. 5–7, pls. 1, 5. Name Bully Hill rhyolite restored as formal stratigraphic unit. Formation considered largely extrusive soda rhyolite and soda rhyolite porphyry rather than intrusive alaskite and alaskite porphyry (as it was considered by Graton who abandoned the name in 1910). Thickness (in Afterthought mine) about 1,100 feet. Lies with apparent conformity between older Dekkas andesite and younger Pit formation.

M. A. Murphy, W. P. Popenoe, and J. P. Albers, 1957, Sacramento Geol. Soc. Ann. Field Trip May 25–26, p. 12. Noted as being in fault contact with Pit formation near Afterthought mine.

Occurs in Bully Hill region, Shasta County.

†Bully Hill Volcanics[1]

Age(?): Northern California.

Original reference: J. S. Diller, 1905, Am. Jour. Sci., 4th, v. 19, p. 380–385. Redding quadrangle.

Bumpnose Limestone Member (of Crystal River Formation)

Eocene, upper: Northwestern Florida.

W. E. Moore, 1955, Florida Geol. Survey Bull. 37, p. 19 (fig. 4), 21 (table 1), 30, 36–42. Beds younger than the Crystal River of Puri occur in Jackson County at top of Ocala group. These beds are here named Bumpnose limestone and constitute uppermost member of formation. Contains *Lepidocyclina (Nephrolepidina) chaperi* Lemoine and R. Douville. Occurs above *Asterocyclina* zone of Crystal River and below Marianna limestone which contains *Lepidocyclina (Lepidocyclina) mantelli* (Morton). Soft easily crumbled white limestone generally more granular than typical Marianna. Thickness ranges from 0 to 15 feet; appranently thins to southeast where it is replaced in subsurface by Gadsden limestone southeast of Cypress fault.

H. S. Puri, 1957, Florida Geol. Survey Bull. 38, p. 33–34. Moore's Bumpnose member is not stratigraphically valid because beds for which name was proposed are not younger than the Crystal River of Puri since they underlie Marianna limestone of Oligocene age. The interval is a faunizone, and exactly the same beds are defined by MacNeil (1944, Am. Assoc. Petroleum Geologists Bull., v. 28, p. 1313) as *Lepidocyclina fragilis* faunizone at same outcrop.

Type locality: Quarry near center of W½ sec. 23, T. 5 N., R. 11 W., Jackson County. Named for exposures along and near Bumpnose Road north and west of Marianna.

†Buncombe Group[1]

Precambrian and Cambrian(?): Western North Carolina.

Original reference: W. C. Kerr, 1869, North Carolina Geol. Survey Rept. 2, p. 13–35.

Occupies larger part of great transmontane plateau between Blue Ridge and Smoky Mountains.

†Bunger Formation (in Cisco Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Named for Bunger, Young County.

Bunger Limestone Member (of Graham Formation)[1]

Bunger Formation (in Graham Group)

Upper Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Graham group. Overlies North Leon formation; underlies post-Bunger cycles 1 to 7.

E. L. Thackery, 1951, West Texas Geol. Soc. Guidebook, June 1–2, p. 14–15, chart. Chart shows Bunger limestone in Graham group above Gonzales limestone and below Gunsight limestone in Brazos River outcrop section; thins toward Colorado River section.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook May 25–26, fig. 4. Generalized columnar section shows Bunger limestone in Graham group stratigraphically above Salem School limestone and below unit termed Number 3 limestone.

Named for Bunger, Young County.

Bunje cyclothem (in Bond Formation)

Bunje cyclothem (in McLeansboro Group)

Pennsylvanian: Southwestern Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). Name appears in list of cyclothems in McLeansboro group. Occurs below Flat Creek cyclothem and above Sorento cyclothem (new).

H. R. Wanless, 1956, Illinois Geol. Survey Circ. 217, p. 6, 7, 11, pl. 1. Simon (1946, unpub. thesis) worked out sequence above Shoal Creek limestone in Bond County and proposed terms (ascending) Sorento, Bunje, and Flat Creek for cyclothemic units in lower half of interval. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 43, 52 (table 2), pl. 1. In Bond formation (new). Above Sorento cyclothem and below Flat Creek cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: S½ sec. 7, T. 6 N., R. 4 W., Bond County. Named for village of Bunje.

Bunje Limestone Member (of Bond Formation)

Pennsylvanian: Central and southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), 72, pl. 1. Name applied to limestone member that lies stratigraphically above Sorento limestone member (new) and below Flat Creek coal member (new). Olive gray or bluish gray; cone-in-cone structure throughout. Thickness as much as 18 inches. Name credited to J. A. Simon (unpub. ms.). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: SE¼SW¼ sec. 7, T. 6 N., R. 4 W., Bond County. Named for exposures about 1 mile south of village of Bunje.

Bunker Andesite[1]

Eocene: Central southern Colorado.

Original references: W. Cross, 1890, Colorado Sci. Soc. Proc., v. 3, pt. 3, p. 272; 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 289.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 197. In Silver Cliff-Rosita region, the volcanics, in order of decreasing age, consist of Rosita fragmental andesite, Bunker massive andesite, Fairview diorite in dikes cutting earlier andesite, Bald Mountain dacite flows, rhyolite in dikes, eruptive channels and flows, Pringle andesite, trachyte flows, and Bassick agglomerate.

Forms greater part of Rosita Hills, Silver Cliff-Rosita region.

Bunker Hill Volcanics

See Jonestown Volcanics.

Burbank Member (of Cuyahoga Formation)[1]

Mississippian: North-central Ohio.

Original reference: G. W. Conrey, 1921, Ohio Geol. Survey, 4th ser., Bull. 24, p. 50.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 49. Included in Killbuck shale facies (new) of the Cuyahoga. Consists of series of alternating gray arenaceous shales and buff-gray fine-grained sandstones and siltstones with maximum exposed thickness of 150 feet. Base not exposed. Underlies Armstrong sandstone member.

E. J. Szmuc, 1958, Dissert. Abs., v. 18, no. 6, p. 2109. Discussion of stratigraphy and paleontology of Cuyahoga formation. Term Burbank not used since it refers to strata lithically and faunally idential with upper part of Meadville member.

Named for Burbank in northern part of Wayne County.

Burchards Member (of Chipman Formation)

Burchards Limestone (in Chipman Group)

Lower Ordovician: West-central Vermont.

Marshall Kay and W. M. Cady, 1947, Science, v. 105, no. 2736, p. 601. Middle Ordovician limestones of west-central Vermont have been described and mapped by Cady (1945, Geol. Soc. America Bull., v. 56, no. 5), who included Crown Point, Beldens, and Middlebury formations in Chazy "group." Inasmuch as first-named formation is structurally separated from Crown Point limestone of type locality and other outcrops in New York and is succeeded by Beldens formation rather than by Valcour limestone, it is here proposed that "Crown Point" formation east of Champlain thrust in west-central Vermont be designated Burchards limestone. Consists of about 150 feet of somewhat magnesian limestone that has species of *Maclurites*. Underlies Beldens formation. Basal formation of Chipman group (new).

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 28–29. Dark-gray and white finely banded marble with few thin brown-weathering dolomite beds. Questionably overlies Bascom formation disconformably. Only surface exposure on eastern edge of West Rutland athletic field.

Marshall Kay *in* W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, p. 263, chart 2 (column 15). Lower Ordovician (Canadian).

W. M. Cady and E-an Zen, 1960, Am. Jour. Sci., v. 258, no. 10, p. 728–739. Rank reduced to member status in the Chipman herein reduced to rank of formation. Characterized by limestone with dolomitic markings. Mapping in Sudbury-Brandon area shows that sequence of the Burchards, Weybridge, and Beldens members, though generally about that order, is locally much varied. Bridport dolomite member interfingers with the limestone members. Beekmantown age.

Named from stream that enters Lemon Fair River, 3 miles west of type locality in belt of outcrop between Cornwall village and The Ledges, Addison County.

†Burches Ferry Marl[1]

Upper Cretaceous: Northeastern South Carolina and eastern North Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 14.

Named for exposures at Burches Ferry, on west side of Peedee River, in Florence County, S.C.

Burden Conglomerate[1]

Lower Cambrian: Eastern New York.

Original reference: A. W. Grabau, 1903, New York State Mus. Bull. 69, p. 1034.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland, 1942, New York State Mus. Bull. 221, p. 43–62. In Catskill quadrangle, following sequence distinguished (ascending): Nassau beds, Burden iron ore, Bomoseen grit, Burden conglomerate (Grabau), Schodack shale and limestone, and Zion Hill quartzite. Zion Hill quartzite, Schodack shale and limestone, Burden conglomerate, and Bomoseen grit are intimately connected and interfolded. Seems practicable to extend term Schodack formation to include as members the beds that occur associated or interbedded with it. Burden iron ore formation consists of limonite and siderite iron ore between Nassau and Schodack beds. Occurs in belt extending from southern base of Mount Tom to Church Hill, about 4 miles in all. Grabau united under name Burden conglomerate the beds at Burden iron mine of earliest Schodack age with those of later Schodack age found at Claverack Creek and north of Becraft Mountain. All are of Schodack age and not of Normanskill age.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 330–331. Name Burden originally given by Grabau (1903) to a conglomerate of limestone pebbles in calcite matrix with imbedded rounded quartz sand grains. Grabau was uncertain of age but asserted it to be Ordovician and possible correlate of Rysedorph conglomerate. Ruedemann (1942) used name Burden for an iron ore of local stratigraphic significance in Columbia County. Questionable whether the two workers were speaking of same unit. Type area reexamined and modifications of previous interpretations presented. An excellent section reveals sideritic and limonitic rock with imbedded subangular fragments of limestone, shale, and grit occupying position between interbedded sandy shales and thin quartzites below (Nassau) and a calcitic ferruginous orthoquartzite with abundant quartz crystals above (Zion Hill). In opposition to Ruedemann's views, the writer [Fisher] found no evidence of Schodack formation. It is here suggested that the Burden iron ore denotes a residual soil which accumulated on a Lower Cambrian erosional surface; the hiatus represents Middle and Upper Cambrian times. Ferruginous nature of the Zion Hill explained as iron oxide incorporated in an initial transgressive clastic deposit. Overyling Zion Hill, in turn, are bonafide graptolite-bearing strata of Schaghticoke and Deepkill age.

Named for occurrence at Burden iron mines, 5 miles south of Hudson. Columbia County.

Burditt Marl[1]

Burditt Marl (in Austin Group)

Upper Cretaceous (Gulf Series): Central Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 270, 407, 441, 442, 449.

Keith Young and Edward Marks, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 3, p. 477, 480 (fig. 2), 486–487. Report is biostratigraphic study of Austin group in Williamson County. Chart shows group comprises Austin chalk and Burditt marl. Thickness of Burditt 45 feet. Faunal change from Austin chalk to Burditt marl abrupt.

C. L. Durham, Jr., 1955, Corpus Christi Geol. Soc. [Guidebook] Ann. Field Trip, March 11–12, [p. 57], pl. 16. In Travis County, overlies Dessau formation (new).

D. L. Frizzell, 1956, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 38. Foraminifera described. Burditt marl listed in Austin group.

Type locality: Along Little Walnut Creek downstream from Austin-Cameron Road, Travis County. Named from Burditt School.

Burge Sands Member (of Ogallala Formation)[1]

Burge Channel Member (of Valentine Formation)

Pliocene: Northern Nebraska.

Original reference: F. W. Johnson, 1936, Am. Jour. Sci., 5th, v. 31, p. 467–473.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, p. 223, 227; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1260, 1264 (table 1). Referred to as Burge channel member of Valentine formation redefined and assigned to Ogallala group (redefined). Occurs at top of formation.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 137–138. Highest known fauna from the Valentine comes from Burge channel quarries. It seems best not to consider the Burge a channel member but merely a channel within the undivided Valentine.

Type locality: Burge quarry, on Snake River, southwest of Valentine, Cherry County.

Burgen Limestone[1]

Lower Ordovician: Central Oklahoma.

Original reference: J. P. Boyle, 1939, Oklahoma Geol. Survey Bull. 40KK.

Present over entire area of Okfuskee County.

Burgen Sandstone[1]

Lower or Middle Ordovician: Northeastern Oklahoma.

Original reference: J. A. Taff, 1905, U.S. Geol. Survey Geol. Atlas, Folio 122.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 16 (fig. 3), 20–22, pls. 2, 3, 4. Described on southwestern flank of Ozark uplift. Predominantly sandstone with minor amounts of shale and thin dolomitic limestone; thin beds of green fissile shale and sandy dolomite present in upper parts. Thickness 72 feet near Qualls where entire thickness is exposed; 26 feet along Spring Creek in sec. 12, T. 19 N., R. 20 E.; outside mapped area thickness of 100 feet reported. Unconformably overlies Cotter dolomite; conformably succeeded by Tyner shale in southern exposures; truncated by pre-Chattanooga erosion north of T. 19 N., where it is succeeded by Sylamore sandstone member of Chattanooga. Age assignment and correlation not certain; precise dating is dependent upon correct correlation of overlying Tyner; if Tyner is equivalent of Bromide, then Burgen is probably equivalent to lower Bromide sand (Tulip Creek). Chart shows Champlainian series.

Named for exposures in Burgen Hollow, 6 miles northeast of Talequah, northern Cherokee County.

Burgess Oolite Member (of Bangor Limestone)[1]

Mississippian: Northwestern Alabama.

Original reference: W. B. Jones, 1928, Alabama Geol. Survey Circ. 8, p. 13–15.

W. B. Jones, 1939, Econ. Geology, v. 34, no. 5, p. 575, 576. Thickness 0 to 40 feet. Underlies unnamed blue fossilferous limestone; separated from underlying Rockwood oolite by unnamed blue fossiliferous limestone 100 feet thick.

Type locality: Burgess quarry, on hill about 3 miles east of Russellville, Franklin County.

Burgner Formation

Pennsylvanian (Atoka): Southwestern Missouri.

W. V. Searight and E. J. Palmer, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2127–2131. Section from cuttings and cores shows formation to consist of black shale, black siltstone, coal, limestone, and clay. Thickness as much as 67 feet. Occurs as sink fillings in Mississippian formation. Megafauna related to both Morrowan and Desmoinesian but cannot be certainly correlated with either; microfauna includes specimens of *Millerella* and primitive *Fusulinella*; considered post-Morrowan pre-Desmoinesian or Atokan.

Named for occurrence on the Burgner land, Jasper County.

Burgoon Group[1]

Mississippian: Pennsylvania.

Original reference: J. D. Sisler and others, 1933, Pennsylvania Geol. Survey, 4th, Bull. M–19, p. 8.

Named because it is cut through by valley of Burgoon Run above Kittanning Point, Blair County.

Burgoon Sandstone (in Pocono Group)

Burgoon Formation (in Pocono Group)

Burgoon Group

Burgoon Sandstone Member (of Pocono Formation)[1]

Mississippian: Western Pennsylvania, southeastern Ohio, and northern West Virginia.

Original reference: C. Butts, 1904, U.S. Geol. Survey Geol. Atlas, Folio 115.

R. M. Leggette, 1936, Pennsylvania Geol. Survey, 4th ser., Bull. W–3, p. 38–39. In many parts of area [northwestern Pennsylvania], Burgoon sandstone is top formation of Pocono group. As much as 450 feet thick in places. Overlies Cuyahoga formation. In Crawford and adjoining counties, Shenango sandstone of I. C. White marks top of Ponoco and is probably equivalent to part of Burgoon sandstone.

R. E. Sherrill and L. S. Matteson, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. 122, p. 7–8. Referred to as Burgoon group in Pocono series. Thickness 250 to 270 feet in area of this report [Hillards quadrangle]. Upper 75 to 100 feet of group is Burgoon sandstone member. Below this sandstone is Hempfield (Shenango) shale member, 75 to 100 feet thick. Lower 75 to 90 feet of group is Shenango sandstone member. Overlies Cuyahoga group; underlies Lower Connoquenessing sandstone of Pottsville series.

R. C. Bolger and C. E. Prouty, 1953, Pennsylvania Acad. Sci. Proc., v. 27, p. 125. In Cameron County, Burgoon sandstone is topmost unit of Pocono group. Thickness 90 to 100 feet in south; 25 to 30 feet in north. Directly overlies Patton formation.

J. L. Dally, 1956, Dissert. Abs., v. 16, no. 12, p. 2425. Pocono group discussed in West Virginia. In northern part of State, group is represented by Manheim formation (new) and Burgoon formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania ,1: 250,000) : Pennsylvania Geol. Survey, 4th ser. Map legend shows Burgoon formation in Pocono group.

Named for exposures in valley of Burgoon Run, above Kittanning Point, Blair County, Pa.

Burica Sandstones

Miocene, upper, or Pliocene, lower: Panamá.

R. A. Terry, 1941, Geog. Rev., v. 31, no. 3, p. 381 (fig. 5). Name Burica listed on map explanation. Upper Miocene.

A. A. Olsson, 1942, Bulls. Am. Paleontology, v. 27, no. 106, p. 173–175 (21–23). Sandstone transitional with overlying Charco Azul shales. Base of sandstones and basement on which they rest not exposed. Age tentatively considered as lower Pliocene or uppermost Miocene.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, Geol. Sci., p. 234 (chart). Lower part sandstones and conglomerate; upper part tuffaceous shale.

Crop out on Burica Peninsula, Panamá, at or near Burica Point and Burica Island.

Burke Formation (in Ravalli Group)[1]

Precambrian (Belt Series) : Northeastern Idaho and northwestern Montana.

Original reference: F. L. Ransome, 1905, U.S. Geol. Survey Bull. 260, p. 277–285.

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 62, p. 32–34, pl. 11. Light-gray flaggy fine-grained sandstones and shales, mostly greenish, with variable amount of purple quartzitic sandstone and white quartzite. Shallow water features throughout. Thickness about 2,000 feet. Overlies Prichard slate; underlies Revett quartzite.

C. F. Calkins, 1908, U.S. Geol. Survey Bull. 384, p. 38. Lowermost formation in Ravalli group.

J. W. Hosterman, 1956, U.S. Geol. Survey Bull. 1027–P, p. 728–729, pl. 57. Described in Shoshone County, Idaho, where is is between 2,220 and 2,500 feet thick. Chiefly thin-bedded light- to greenish-gray fine-grained argillaceous quartzite and some white to light-purple thick-bedded quartzite. Contacts with underlying Prichard formation and overlying Revett quartzite transitional.

Typically developed along Canyon Creek from Burke to Gem, Idaho.

Burkes Garden Limestone Member (of Benbolt Formation)

Middle Ordovician: Southwestern Virginia.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 835, 836, 869, 871, 879, 884 (fig. 3). In Tazewell County, strata embraced by the Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Burkes Garden limestone member is applied to zones 12 and 13. At type locality, these zones, the *Chasmatopora*, and the crossbedded limestone, are 47 and 63 feet, respectively. In Burkes Garden and Thompson Valley, member is 100 to 200 feet thick; in median belts, thins from about 100 feet near Russell-Tazewell county line to 60 feet at Tazewell; thin or absent on northwest side of Clear Fork Valley east of Gratton. Overlies

Shannondale limestone member (new); underlies Gratton limestone (new).

Type locality: Along County Road 637 and Pounding Mill Branch, immediately south of U.S. Route 19, Tazewell County. Named from Burkes Garden Creek about 1½ miles south of Gose Mill.

Burkesville Limestone Lentil (in Cumberland Sandstone)

Upper Ordovician: South-central Kentucky.

W. R. Jillson, 1951, The Burkesville limestone: Frankfort, Ky., Roberts Printing Co., p. 5–15. Upper 3 feet of lentil consist of gray compact dolomitic bouldery fossiliferous limestone; lower 3 feet consist of grayish to reddish soft limy shale with a 1-inch layer of chert.

W. R. Jillson, 1953, The Haggard limestone: Frankfort, Ky., Roberts Printing Co., [p. 2]. About 70 feet below top of Cumberland and about 40 feet below Haggard limestone (new).

Exposed on P. A. Davis property within southern limits of Burkesville, Cumberland County.

Burket Black Shale Member (of Harrell Shale)[1]

Burket Shale Member (of Rush Formation)

Upper Devonian: Central Pennsylvania.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 523, 536.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 201, 218–219. Member of Rush formation. Intergrades with Tully member. Underlies Harrell member of Fort Littleton formation.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3. Rush formation includes Burket shale member and Tully limestone member.

Named for exposures at Burket, a suburb of Altoona, Blair County.

Burkeville Beds[1]

Miocene, upper, and Pliocene(?): Eastern Texas and western Louisiana.

Original reference: A. C. Veatch, 1902, Louisiana Geol. Survey, pt. 6, Rept. for 1902, p. 136, pl. 37.

A. C. Ellisor, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 4, p. 494-495. This [Burkville] horizon has been traced in subsurface from Terry Field in Orange County, south of Burkville to Calhoun County. Name *Potamides matsoni* zone suggested for this horizon in subsurface where it is 400 or more feet thick. Since Veatch and others have recognized Burkville beds as mappable unit and have described sections and fauna, it is no doubt worthy of rank of formation. However, it seems inadvisable to introduce a new formation without further fieldwork.

Named for Burkeville [correct spelling], Newton County, Tex.

Burley Lake Beds[1]

Pleistocene: Southern Idaho.

Original reference: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; H. T. Stearns, 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

E. G. Crosthwaite, 1956, Ground-water possibilities south of the Snake River between Twin Falls and Pocatello, Idaho: U.S. Geol. Survey Circ. 371, p. 6, 7. Described as unconsolidated to well-compacted clay, silt, sand

and fine gravel. Intercalated basalt layers occur 150 to 325 feet below surface and at bottom of sequence. Geographic area noted.

Known only from drill holes in vicinity of Burley (Cassia County) and Rupert and Paul (Minidoka County).

Burlingame Limestone Member (of Bern Limestone)

Burlingame Limestone (in Shawnee Group)

Burlingame Limestone (in Wabaunsee Group)

Burlingame Limestone Member (of Wabaunsee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: J. G. Hall, 1896, Kansas Univ. Geol. Survey, v. 1, p. 105.

G. E. Condra, 1933, Nebraska Geol. Survey Paper 8, p. 5, 10; G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 45–46. In Nebraska, comprises (ascending) Taylor Branch limestone, Winnebago shale, and South Fork limestone.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 309 (fig. 14). Graphic section of Pennsylvanian in Adams County shows Burlingame limestone occurring below Soldier Creek shale and above Silver Lake shale.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 32). Correlation chart shows Burlingame limestone in Shawnee group in Missouri.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 20. Assigned to Wabaunsee group when that group was redefined for Missouri.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 18. Three limestones and two shales now included in Soldier Creek shale were formerly included in the Burlingame.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276–2277. Rank reduced to member status in Bern limestone (new). Underlies Soldier Creek shale member; overlies Silver Lake shale member of Scranton shale (reintroduced as a formation).

H. G. Hershey and others, 1960, Iowa State Highway Research Board Bull. 15, p. 13, fig. 5. Consists of three limestone beds separated by shale. Upper limestone, about 6 inches thick, is dark gray and finely crystalline, contains fossil fragments, and is underlain by dark-gray clayey shale about 1½ feet thick. The lower two limestones are separated by calcareous laminated gray shale about 5 feet thick. Upper of the two limestones is gray, argillaceous, and blocky; lower is concretionary, sandy, and fragmental. Total thickness 12 feet. Underlies Soldier Creek shale; overlies Silver Lake shale. Wabaunsee group.

Type locality: Burlingame, Osage County, Kans. Limestone makes a prominent escarpment that crosses west part of Burlingame.

†Burlingame Shale[1]

Pennsylvanian: Eastern Kansas and northwestern Missouri.

Original references: E. Haworth, 1895, Kansas Univ. Quart., v. 3, p. 278, pl. 20; 1895, Am. Jour. Sci., 3d, v. 50, p. 461, pl. opposite p. 466.

Named for Burlingame, Osage County, Kans.

Burlington Limestone

Burlington Limestone (in Osage Group)[1]

Lower Mississippian (Osage Series): Iowa, Illinois, Kentucky, and Missouri.

Original reference: D. D. Owen, 1852, Rept. Geol. Survey Wisconsin, Iowa, and Minnesota, p. 90–140.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 132–133. Included in Osage group, Valmeyer series.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5. In Mississippian standard section, Burlington limestone is included in Osagean series. Occurs above the Fern Glen formation and below Keokuk limestone.

C. P. Kaiser, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2163–2168. Discussion of stratigraphy of Lower Mississippian rocks in southwestern Missouri. Burlington limestone ranges in thickness from a trace to 145 feet; thickest in Springfield area. Thins southward from Springfield and disappears from section between Mount Vernon, Lawrence County. and the Tri-State mining district. Divided into six faunal zones that are correlated with equivalent zones in northeastern Missouri. Rests unconformably on Reeds Spring formation in southern part of area. Reeds Spring and St. Joe formations pinch out a short distance north of Springfield, Greene Conuty, and north of here the formation rests unconformably on Northview or Sedalia formations. Keokuk limestone rests with apparent conformity on Burlington limestone in southwestern part of area. Elsewhere the Burlington is either surface formation or is covered by thin veneer of Pennsylvanian sediments. Osagean.

T. R. Beveridge and E. L. Clark, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 71–80. Presentation of revision of early Mississippian nomenclature in western Missouri. Kaiser (1950) proposed that name Pierson be dropped, assigning the more dolomitic lower beds to the Sedalia and the upper beds to the St. Joe. Kaiser considered the entire St. Joe to be Osagean and the Sedalia to be Kinderhookian. Thus he placed a series line in the middle of the Pierson of Weller. In present report, the Pierson is accepted as defined by Weller and base of Osagean is placed at Pierson-Northview contact. The Pierson is extended northward to include the silty dolomitic limestone unit which lies between the Northview and the Burlington in west-central Missouri. This unit was included in upper Sedalia of west-central Missouri by Moore (1928, Missouri Bur. Geology and Mines, 2d ser., v. 21) and Kaiser (1950). Hence, Burlington directly overlies Pierson.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 9 (fig. 2), 42–47. Formation described in Bowling Green quadrangle where it is 53 to 61 feet thick. Consists of thin- to massive-bedded coarsely crystalline brown to light-gray limestone with chert nodules and lenses. In most of quadrangle, covered by glacial drift, loess, and its own chert residuum. Lies upon undulatory surface of Hannibal formation in that part of quadrangle north of southern boundary of T. 53 N., south of this area overlies Chouteau formation with gradational contact. Osagean series.

Named for exposures at Burlington, Des Moines County, Iowa.

†Burlington Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ., Quart., v. 2, p. 110, 120–121, 125.

Named for Burlington, Coffey County.

†Burlington Limestone (in Chemung Formation)[1]

Upper Devonian: Central northern Pennsylvania.

Original reference: A. Sherwood, 1878, Pennsylvania 2d Geol. Survey Rept. G, p. 37.

Occurs about 1 mile east of Burlington on farms of W. B. Kline, J. Morley, and C. E. Campbell and at other places in Bradford County.

Burls Creek Shale Member[1] (of Katalla Formation)

Oligocene: Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 772–775, 779.

D. J. Miller, D. L. Rossman, and C. A. Hickcox, 1945, Preliminary report on petroleum possibilities in the Katalla area, Alaska: U.S. Geol. Survey, p. 7 (table), 10–11; 1945, Geologic and topographic map and sections of the Katalla area, Alaska: U.S. Geol. Survey War-Minerals Inv. Prelim. Map. Restricted to massive gray shale and associated glauconitic sandstone that lie conformably between the Basin Creek (new) and organic shale members. Lower contact drawn at base of lowest bed of massive glauconitic sandstone or at top of highest bed of gray sandstone of Basin Creek type. Partly sandy shale forms major part of member except near head of east fork of Burls Creek and along Burls Creek-Chilkat Creek ridge, where total thickness of glauconitic sandstone beds nearly equals thickness of shale. Lens-shaped calcareous concretions, averaging more than 2 feet across, abundant in shale. Lithology and thickness range widely in Katalla area. Thickness between 160 and 260 feet near head of west fork of Burls Creek; increases to maximum of perhaps 1,000 feet in western part of area. Oil company geologists (unpub. mss.) have used term Burls Creek formation to include Basin Creek sandstone and shale below and Cannon-ball shale above.

Best exposed on Burls Creek, Controller Bay region.

Burnam Limestone

Upper Ordovician: Central Texas.

V. E. Barnes, P. E. Cloud, Jr., and Helen Duncan, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 1030–1043. Coarse-grained and yellowish to light-brownish-gray or almost white; contains pale yellowish-orange stylolites and angular to rounded pebbles and blebs of fine-grained yellowish-gray to pearl-gray limestone; fossiliferous. Thickness unknown; outcrops are collapsed into older rocks. Directly underlies Stribling formation; bedding is approximately parallel between the two units, and both formations dip steeply southward; relations at base of Burnam are uncertain; may rest directly on Honeycut formation or other rocks may intervene between the two units.

Type locality: (Only known occurrence) is midway between Austin and Llano, along Burnam Branch of Doublehorn Creek, southern Burnet County, 4.7 miles airline south-southeast of Marble Falls.

Burned Mountain Metarhyolite

Precambrian: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 14, 54–56, pl. 1. Ranges from brick red to light pink but generally is reddish orange; relict, commonly drag-folded flow bands clearly visible in most outcrops. Intruded older Moppin metavolcanics (new) as sills and dikes; possibly some small flows. The layers of metarhyolite almost everywhere concordant with underlying and overlying strata. Previously called Vallecitos rhyolite, but here renamed because the earlier name was preempted.

Exposed on La Jarita Mesa, in Canada del Oso, in La Jara Canyon, along Vallecitos Canyon near Escondida Creek, and in areas immediately south of Jawbone Mountain near head of Buckhorn Gulch in Las Tablas quadrangle and in area immediately to the south. Named after exposures on northwest side of Burned Mountain, in sec. 8, T. 28 N., R. 7 E., Las Tablas quadrangle.

Burnet Marble[1]

Cambrian and Ordovician: Central Texas.

Original reference: B. F. Shumard, 1861, Am. Jour. Sci., 2d, v. 32, p. 214.

Named for exposures at Burnet and neighboring parts of Burnet County.

†Burnetan System[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lv, 255–267, pl. 3.

Named for Burnet County.

Burnett Formation (in Puget Group)[1]

Eocene: Western Washington.

Original reference: Bailey Willis and G. O. Smith, 1899, U.S. Geol. Survey Geol. Atlas, Folio 54.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 63–64. Youngest formation of group in Carbon River area. Composed of shales and sandstones approximately 5,000 feet thick. Underlies lavas and Pleistocene glacial deposits; overlies Wilkeson sandstone. Formations in Carbon Canyon have been folded into anticlines and synclines with a general northwesterly trend.

Named for exposures on South Prairie Creek, near Burnett, Tacoma quadrangle.

Burns Formation (in Silverton Group)

Burns Quartz Latite or Latite Tuff[1] (in Silverton Volcanic Series)

Tertiary, middle or upper: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 120.

E. S. Larsen, Jr., 1949, Am. Geophys. Union Trans., v. 30, no. 6, p. 863. Burns quartz latite listed in Silverton volcanic series in report on San Juan Mountains, Colo. Overlies Eureka rhyolite; underlies unnamed pyroxene quartz latite.

U.S. Geological Survey currently classifies the Burns as a formation in Silverton Group and designates the age as middle or late Tertiary on the basis of a study now in progress.

Named for exposures in Burns Gulch, Silverton quadrangle.

Burnt Lava Flow

Recent: Northern California.

M. A. Peabody, 1931, Geog. Rev., v. 21, no. 2, p. 269–270. Recent flow in the Modoc Lava field.

H. A. Powers, 1932, Am. Mineralogist, v. 17, no. 7, p. 272, 275, pl. 1. Mentioned as the most recent of a group of basalt eruptions or flows for which term Modoc basalt is proposed.

C. A. Anderson, 1941, California Univ., Dept. Geol. Sci. Bull., v. 25, no. 7, p. 371, geol. map. Covers an area of about 14 square miles.

Occurs in Modoc Lava field.

Burnt Limestone

Lower Cretaceous (Comanchean): Southern Texas.

Charles Schuchert, [1943], Stratigraphy of the eastern and central United States: New York, John Wiley and Sons, p. 957. Incidental mention in short discussion of Buda limestone. Suggests name be abandoned. [Compiler was unable to locate an earlier reference to the name.]

Burnt Bluff Formation[1]

Burnt Bluff Group

Middle Silurian (Niagaran Series): Northern Michigan and Wisconsin.

Original reference: G. M. Ehlers, 1921, Geol. Soc. America Bull., v. 32, p. 129.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Burnt Bluff group (Wisconsin and Michigan) includes Byron dolomite below and Hendricks dolomite above.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Field Excursion, p. 2 (table), 7–19, 31 (fig. 2). Group includes (ascending) Lime Island dolomite (new), Byron dolomite, and Hendricks dolomite. Thickness about 310 feet. Underlies Manistique group; overlies Cataract group.

Named for exposures in high cliff called Burnt Bluff, on east shore of Big Bay de Noc, Delta County, Mich.

Burnt Branch Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. P. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 375.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec. [Guidebook] Spring Mtg., p. 72. Flaggy sandstones 125 feet thick; about 25 feet of clay at base. Overlies Lynch Creek bed, where present; underlies Elliott Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Burnt Branch, in Lampasas County, or vicinity.

Burnt Canyon Breccia

Quaternary: Southern California.

C. R. Allen, 1954, California Div. Mines Bull. 170, map sheet 20. Shown on map legend as a landslide deposit.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 325 (table 1), 332, pls. 1, 3. Described in San Gorgonio Pass area as a dissected landslide deposit. Maximum thickness about 100 feet. Rests partly on crystalline complex and partly on Heights fanglomerate.

Report covers San Andreas fault zone in San Gorgonio Pass, Riverside County.

Burnt Canyon Member (of Highland Peak Formation)

Burnt Canyon Formation (in Ophir Group)

Burnt Canyon Limestone

Middle Cambrian: Southeastern Nevada and western Utah.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 36–38, fig. 5. Dark-gray to black, thin- to medium-bedded limestone. Previously termed basal or "C" unit of Highland Peak limestone as restricted by Wheeler (1940). Recognition of overlying Dome and Swasey limestones in the Highland Peak requires that unit be given formational rank. Thickness 225 to 420 feet. Overlies Burrows limestone; conformably underlies Dome limestone. In House Range, Utah, formation consists of uppermost 225 feet of Howell limestone as emended by Deiss (1938).

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 35, 45–46, pl. 1, measured sections. Formation included in Ophir group in Sheeprock Mountains where it overlies Millard formation and underlies Dome limestone. Thickness 178 to 221 feet. Basal 21 feet may represent Burrows limestone.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 49, 50 (fig. 4). Proposed that name Chisholm be applied to unit in House Range that Wheeler (1948) designated as Burnt Canyon limestone. Correlation chart (fig. 4) shows Wheeler's Burnt Canyon in Wah Wah Range replaced by Whirlwind (new) and Swasey formations; in Pioche district, Wheeler's Burnt Canyon is replaced by part of Burrows formation, Whirlwind formation, and lower part of Highland Peak formation.

U.S. Geological Survey currently classifies the Burnt Canyon as a member of Highland Peak Limestone on the basis of a study now in progress.

Named for typical exposures in Burnt Canyon on west slope of Highland Range, Pioche district, Nevada.

Burnt Gulch Conglomerate

Miocene or Pliocene: Northwestern Wyoming.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 124 (table 1), 143, fig. 2. Alluvial fan remnants.

Made up in the main of boulders, gravel, and sand almost without stratification. Boulders more than 20 feet in diameter have been measured, but they decrease in size away from mountains. Thickness on Dinwoody Creek 300 feet.

Type locality: At west end of Table Mountain on Burnt Gulch, after which deposits are named. Present along east slope of Wind River Mountains, Fremont County. Best exposures on Dinwoody Creek.

Burnt Meadow Syenite[1]

Post-Carboniferous: Maine.

Original reference: F. W. Toppan, 1932, Geology of Maine, Dept. Geology, Union Coll., Schenectady, p. 26.

Burnt Mill Shale (in Crooked Fork Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Includes beds between top of Crossville sandstone and base of Coalfield sandstone (new). Thickness 35 to 130 feet. Hooper coal occurs near base of shale. In northern part of Barthell Southwest quadrangle, overlying Coalfield sandstone is missing and Burnt Mill and Glenmary shale (new) form a single unit; this composite unit in turn is truncated by overlying Wartburg sandstone which locally rests on the Crossville.

Named from exposures near Burnt Mill Bridge in Robbins and Oneida South quadrangles, Scott County.

Burnt Ridge Sandstone Member (of Rose Hill Formation)

Silurian: Central Pennsylvania.

H. H. Arndt, 1959, Geol Soc. America Guidebook Pittsburgh Mtg., p. 28, 29, 30. Name applied to sandstone in middle part of Rose Hill. Unit previously called Center iron sandstone (Swartz, 1931). Thickness 90 feet in Burnt Ridge section. Thins to 10 feet in Mifflintown quadrangle, and is poorly represented, if at all, to west in section at Mount Union. Name credited to J. T. Miller.

Reference section: Burnt Ridge.

Burnt River Schist[1]

Pre-Carboniferous(?): Northeastern Oregon.

Original reference: James Gilluly, 1937, U.S. Geol. Survey Bull. 879.

C. W. Merriam and S. A. Berthiaume, 1943, Geol. Soc. America, v. 54, no. 2, p. 162–163. Discussion of late Paleozoic formations of central Oregon. Burnt River schist in eastern Oregon shows very little similarity to any of the formations under discussion (Coffee Creek, Spotted Ridge, and Coyote Butte) beyond occurrence of limestone and conglomerates. Indefinite age.

Named for exposures in Burnt River Canyon, T. 11 and 12 S., R. 41 E., Baker quadrangle, Baker County.

Burntside Granite Gneiss[1]

Precambrian (Huronian): Northeastern Minnesota.

Original reference: F. F. Grout, 1926, Minnesota Geol. Survey Bull. 21, p. 29.

Burntside Lake, Vermilion district.

†Burpee Formation[1]

Eocene, middle: Northwestern Oregon.

Original reference: H. G. Schenck, 1927, California Univ. Pub. Dept. Geol. Sci. Bull., v. 16, no. 12, p. 455, 456.

P. D. Snavely, Jr., and H. E. Vokes, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 97. Described in coastal area between Cape Foulweather and Cape Kiwanda as about 5,000 feet thick and consisting of rhythmically bedded arkosic sandstone and intercalated siltstone and, locally, interbedded volcanic material. Conformably overlies Siletz River volcanic series; underlies Nestucca formation (new), angular unconformity.

H. E. Vokes, Hans Norbisrath, and P. D. Snavely, Jr., 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 88. Described in Newport-Waldport area, where it is oldest strata exposed and covers more than one-half of area mapped and greater part of Toledo and Tidewater quadrangles. Thickness 6,000 to 7,000 feet; base not exposed. Overlies Moody shale member of Toledo. Eocene.

U.S. Geological Survey has abandoned the term Burpee on the basis of a study now in progress.

Type locality: Rock quarry on Southern Pacific Railroad at Burpee Station, on east bank of Yaquina River, Lincoln County, midway between Toledo and Elk City.

Burr Limestone Member[1] (of Grenola Limestone)

Permian: Southeastern Nebraska, eastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Underlies Salem Point shale member; overlies Legion shale member. Thickness 8 to 15 feet. Wolfcamp series.

Type locality: Bluffs and ravines west of South Fork of Little Nemaha River, in sec. 20, at point one-fourth mile west of north-south road. 2½ miles northwest of Burr, Otoe County, Nebr.

Burrego Formation (in Hansonburg Group)

Pennsylvanian (Missouri Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 64, 65. Term proposed for the massive to massively bedded and nodular limestones that overlie the Council Spring limestone (new) and underlie the red shales and arkosic red sandstones at base of Story formation (new). At type locality, formation is almost entirely limestone; in Mocking Bird Gap area, contains several thick sandstones and, on Cadronito Hill, contains several thick shale strata. Thickness about 52 feet.

Type locality: North of Burrego Spring on northeast side of Oscura Mountains, in SE¼ sec. 31, T. 5 S., R. 6 E., Socorro County.

Burro Gravel and Tuff[1]

Tertiary(?): Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 67.

Named for Burro Mesa, Brewster County.

Burro quartzite[1]

Cambrian(?): Southwestern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State printer, p. 4, 5.

Derivation of name not given.

Burroak Shale[1] **Member** (of Deer Creek Limestone)

Pennsylvanian (Virgil Series): Southwestern Iowa, eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 8, 20, 53–54, figs. 1, 2.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 48. Burroak shale member of Deer Creek limestone underlies Ervine Creek limestone member and overlies Haynies limestone member. Burroak pinches out in southeastern Nebraska where Haynies limestone unites with the Ervine Creek.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035. Member of Deer Creek formation; overlies Haynies limestone member; underlies Larsh shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947. Kansas uses Larsh-Burroak shale member for interval.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17. In Missouri, interval between Rock Bluff limestone member and uppermost limestone of the Deer Creek is occupied by shale. This shale has been treated by Missouri Geological Survey as the Rock Bluff-Ervine Creek interval with implication that intervening Haynies limestone is absent in Missouri. The shale is now called Larsh-Burroak, but the Missouri Survey recognizes possibility that the Burroak shale member may be absent in Missouri and that the uppermost limestone of the Deer Creek may include both the Haynies and Ervine Creek members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 17, fig. 5. Burroak shale not everywhere differentiated in southwestern Iowa because of absence in some areas of Haynies limestone, which results in the coalescing of Burroak and Larsh shales. Where Haynies is present, as near Thurman, Burroak shale is bluish gray, argillaceous, and fossiliferous. Thickness about 1 foot near Thurman.

Type locality: Roadcuts and ravines near Burr Oak School, E½ sec. 21, T. 71 N., R. 43 W., Fremont County, Iowa, about 6 miles south of Pacific Junction, and about 3½ miles north of Bartlett, Mills County.

Burro Canyon Formation

Lower Cretaceous: Southwestern Colorado, northeastern Arizona, northwestern New Mexico, and southeastern Utah.

W. L. Stokes and D. A. Phoenix, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 93. Proposed to designate relatively thin sequence of rocks of probable Lower Cretaceous age lying between Morrison formation (Brushy Basin member) and Dakota sandstone. Includes essentially the same rocks as those designated post-McElmo by Coffin (1921, Colorado

Geol. Survey Bull. 16). Consists of alternating conglomerate, sandstone, shale, limestone, and chert. Thickness 150 to 260 feet. Sandstones and conglomerates are gray, yellow, and brown; shales faintly varicolored, mainly purple and green.

E. B. Ekren and F. N. Houser, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 192–201. Described in Four Corners area where it is present in all four States. Thickness 140 to 206 feet. Intertongues with Brushy Basin member of Morrison. In Utah and Colorado, includes Karla Kay member (new) at base.

R. G. Young, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 157–158. This study indicates that two names, Cedar Mountain formation and Burro Canyon formation, have been applied to same physically continuous unit, which can be traced over wide areas of Colorado Plateau with no significant change in character. Proposed here to drop name Burro Canyon and retain older name Cedar Mountain for these noncarbonaceous deposits.

Type locality: Burro Canyon, sec. 29, T. 44 N., R. 18 W., San Miguel County, Colo.

Burro Mesa Riebeckite

Tertiary: Southwestern Texas.

J. D. Martinez, E. H. Statham, and L. G. Howell, 1960, Texas Univ. Bur. Econ. Geology Pub. 6017, p. 38–39, 44 (fig. 38). Incidental mention in paleomagnetic study of Tertiary volcanics in Big Bend National Park.

Burro Mountains granite

Precambrian: Southwestern New Mexico.

Term used many times in discussion of Bullard Peak Series and Ash Creek Series. Probably refers to granite in Burro Mountains granite batholite.

Burroughs Dolomite[1]

Lower Silurian: Northwestern Illinois and western Wisconsin.

Original reference: F. T. Thwaites, 1923, Jour. Geology, v. 31, no. 7, p. 533.

Near top of Burrough's Bluff, at north end of Savannah, Carroll County, Ill. Also in and above Charles Miles' quarry near southeast edge of same city.

Burroughs Limestone Member (of Modesto Formation)

Burroughs Beds (in McLeansboro Group)

Pennsylvanian: Southwestern Illinois.

J. M. Weller, 1946, *in* C. L. Cooper, Illinois Geol. Survey Bull. 70, p. 13. Name appears in a list of beds above the Shoal Creek limestone in Macoupin County. Name credited to J. R. Ball.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 29, 37–38, 85. Succession of beds between the Carlinville and Macoupin cyclothems; beds do not seem to belong to either cyclothem, nor do they comprise enough conventional units to be classed as a cyclothem. Beds consist regularly of three members: a basal sandstone or sandy shale, a middle limestone, and a top shale. Thickness about 6 feet.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 38, 45 (table 1), 68, pl. 1. Name Burroughs limestone member of Modesto formation (new) restricted to middle sandy unit of strata formerly called Burroughs beds. Occurs above Carlinville limestone member and below Womac coal member (new). Thickness as much as 3 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: NW¼SW¼ sec. 27, T. 10 N., R. 7 W., Carlinville quadrangle, Macoupin County.

Burrows Member (of Highland Peak Formation)

Burrows Dolomite

Burrows Limestone (in Ophir Group)

Middle Cambrian: Southeastern Nevada and northwestern Utah.

H. E. Wheeler, 1940, Nevada Univ. Bull., Geology and Mining Ser., no. 34, p. 12, 27–29. Name applied to variable thickness of strata between Peasley limestone (new) and Highland Peak unit "C" of Wheeler and Lemmon (1939, Nevada Univ. Bull., Geology and Mining Ser., no. 31); both contacts unconformable. Consists mainly of a white and light, medium, to dark-gray, coarse-grained (sugary textured) massively bedded dolomite. Basal 29 feet (at type locality) are thinly and distinctly bedded, medium- and dark-gray, fine-grained limestone; beds vary in thickness from about 29 to 33 feet throughout district. Thickness ranges from 130 feet in Panaca Hills to about 400 feet at type section; 230 feet on southwest slope of Ely Range.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 36–38. Originally termed dolomite; studies now indicate unit is thickly to massively bedded light-colored limestone which has locally been subjected to epigenetic dolomitization. Underlies Burnt Canyon limestone (new). Geographically extended into House and Wah Wah Ranges, Utah, where it consists of the light-gray zone, 340 [335] feet thick in middle part of the "Howell limestone" (Deiss, 1938, Geol. Soc. America Bull., v. 49, p. 1145).

H. E. Wheeler and Grant Steele, 1951, Utah Geol. Soc. Guidebook 6, p. 32 (fig. 5), 35. In House Range, underlies Burnt Canyon limestone and overlies Millard limestone.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 35, 44. Burrows limestone included in Ophir group in Sheeprock Mountains although not clearly recognized in area. On basis of grain size, basal 21 feet of Burnt Canyon limestone may represent the Burrows. No unconformity was noted at or near base of Burnt Canyon lithology, but it is possible one may be present which could account for absence of Burrows lithology.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 50. Wheeler's correlation of middle unit of Howell limestone with Burrows limestone of Pioche district is here considered to be incorrect because "Burrows limestone" in House Range underlies Chisholm formation, whereas in Pioche district, the Burrows limestone overlies both Chisholm and Peasley formations. Consequently, because the two units are not correlative, the "Burrows limestone" of House Range is without valid name. Proposed here that definition of Howell limestone be further restricted to include only carbonate sequence of western Utah that underlies Chisholm formation and overlies Busby and Tatow formations, or their equivalents, and that Millard limestone be rank reduced to member of Howell. In Pioche district, the Burrows underlies Whirlwind formation (new) and overlies Peasley. Wheeler's (1948) Burnt Canyon limestone discontinued.

U.S. Geological Survey currently classifies the Burrows as a member of the Highland Peak Limestone on the basis of a study now in progress.

Type section: On northwest spur of Comet Peak, immediately south of Peasley Canyon, on west slope of Highland Range, Pioche district, Nevada. Name derived from canyon east of Comet mine, about 1 mile south of type section.

Burrows Shale

Middle Cambrian: Southeastern Nevada.

Charles Deiss, (abs.), 1937, Geol. Soc. America Proc. 1936, p. 274. Mentioned in discussion of succession of Middle Cambrian faunas in southern half of Cordilleran trough.

Present in Highland Range, Lincoln County.

Bursum Formation (in Magdalena Group)

Permian (Wolfcamp): Central and southeastern New Mexico.

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 61. In mapped area, about 30 miles north of type section, formation consists of dark-purplish-red and green shale in beds up to 40 feet thick, separated by thinner beds of arkose, arkosic conglomerate, and gray limestone. A thin rubbly nodular purplish-gray limestone occurs locally at base. Thickness ranges from 28 to 234 feet. Underlies Abo formation; overlies upper member of Madera limestone. Age given as (Wolfcamp) Permian(?).

R. L. Bates and others, 1947, New Mexico Bur. Mines Mineral Resources Bull. 26, p. 23, pl. 1. At type locality, formation is 250 feet thick and consists of shale, conglomerate, and arkosic sandstone in lower part, and marine limestone and shale in upper part.

E. R. Lloyd, 1949, New Mexico Bur. Mines Mineral Resources Bull. 29, p. 32–33. In discussing Pennsylvanian-Permian contact, Thompson (1942, New Mexico Bur. Mines Mineral Resources Bull. 17) mentioned presence of fusulinid-bearing marine sediments of lower Wolfcamp age unconformably overlying Pennsylvanian rocks [Fresnal group] in a number of localities in south-central New Mexico. These lower Wolfcampian limestones received three different names in 1946. Kelley and Wood introduced name Red Tanks member of Madera limestone in Lucero uplift; Wilpolt and others introduced name Bursum for beds exposed in Los Pinos Mountains and vicinity of Abo Canyon; Stark and Dapples described same section and named it Aqua Torres formation. Name Bursum is preferred by New Mexico Bureau of Mines and Mineral Resources. Bruton formation (Thompson, 1942), of Pennsylvanian age, is very similar in lithology to Bursum, and it is possible that all or part of the Bruton has been included in descriptions of the Bursum. Similar section, now included in Bursum, was found by Thompson (1942) in Fresnal Canyon in northern Sacramento Mountains where it is 250 feet thick and overlies beds of upper Virgil age. It is overlain with angular unconformity by Abo formation.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93. Shown on composite columnar section, Sacramento Mountains, Otero County, as underlying Abo formation and overlying Holder formation (new). Consists of shale, gray and red sandstone, limestone, and limestone conglomerate. Thickness as much as 350 feet.

M. L. Thompson, 1954, Kansas Univ. Paleont. Contr. 14, Protozoa, art. 5, p. 17–18. Redefined to apply only to pre-Abo (Wolfcampian) Permian rocks of New Mexico. As thus redefined, it takes in uppermost 40 feet of Bruton formation of Thompson (1942). A lower part of Bursum, as defined by Wilpolt and others, is retained in Bruton formation.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 47–49. As redefined by Thompson (1954), formation at its type locality consists of a lower 48 to 65 feet of red beds and limestones and upper massive to nodular limestones about 70 feet thick. Overlies Panther Seep formation (new).

Carel Otte, Jr., 1959, New Mexico Bur. Mines Mineral Resources Bull. 50, p. 25–26. In northern Sacramento Mountains, Thompson's sequence of "transition beds" consists largely of marine sequences of fossiliferous gray shale, limestone, and sandstone, whereas in central New Mexico the Bursum is predominantly red beds that occur interbedded with a few thin fusulinid-bearing limestones. In addition, upper part of "transition beds" occurring north of Tularosa are younger than "Bursum" age. Name Laborcita formation is therefore proposed for strata between top of Holder formation and top of highest marine limestone underlying main mass of Abo red beds.

Type section: Exposures just west of Bursum triangulation point, in SE¼ sec. 1, T. 6 S., R. 4 E., Oscura Mountains, Socorro County.

Burton Sandstone (in Greene Formation)[1]

Permian: Northern West Virginia.

Original reference: R. V. Hennen, 1909, West Virginia Geol. Survey Rept. Marshall, Wetzel, and Tyler Counties, p. 182.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. and Econ. Survey Bull. 14, p. 17. Shown on table of summary of stratigraphic sections of Dunkard group, Harrison County. Underlies unnamed shale below Ninevah limestone; overlies Hostetter coal and (or) fire clay.

Named for Burton, Wetzel County.

Busby Quartzite[1]

Busby Quartzite or Formation (in Ophir Group)

Lower Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 28–32, fig. 5. Geographically extended into House Range area where it includes Tatow limestone (Deiss, 1938); in Wah Wah Range includes uppermost 70 feet of beds assigned to Pioche shale by Wheeler (1943, Geol. Soc. America Bull., v. 54, no. 12, pt. 1). Thickness 165 feet in House Range; 450 feet in Deep Creek Range. Overlies Pioche shale; underlies Millard limestone (new). Busby may be tongue extending southward from Prospect Mountain quartzite. Middle Cambrian.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 35, 39–41, pl. 1, measured sections. In Sheeprock Mountains, Busby quartzite or formation included in Ophir group. Comprises 146 feet of beds, mainly quartzites, sandstones, and sandy limestones. Age is lower Middle Cambrian with strong indications that it was deposited only slightly after early Cambrian time.

U.S. Geological Survey currently considers the Busby quartzite to be Lower Cambrian in age. This designation is based on the discovery of *Olenellus* near top of quartzite in Deep Creek Range.

Named for exposures in Busby Canyon, on northeastern slope of Dutch Mountain, Gold Hill district.

Busby Quartzite Member (of Langston Formation)

Middle Cambrian: Southeastern Idaho and northern Utah.

G. B. Maxey, 1955, Dissert. Abs., v. 15, no. 4, p. 558. Incidental mention.

Bushberg Sandstone Member (of Sulphur Springs Formation)[1]

Bushberg Formation (in Sulphur Springs Group)

Lower Mississippian: Central eastern Missouri.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, 2d ser., v. 2, p. 110.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 43–46. Prior to 1933, beds here described [Boone County] as Bushberg were called Sylamore and were believed to be equivalent to Sylamore sandstone of Arkansas. Ulrich considered Bushberg to be top member of Sulphur Springs formation. In this report, the Sulphur Springs is classed as a group. In its areal extent, the Bushberg is known to lie upon the Jefferson City, Powell, Joachim, St. Peter, Plattin, Kimmswick, and Callaway formations. In Boone County, overlies Callaway limestone; underlies Chouteau formation. Estimated thickness 2 feet.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 69–71. Ulrich described Bushberg as uppermost of three members of Sulphur Springs formation. Term Sulphur Springs is herein abandoned and the Bushberg referred to as formation. Name indicates that vicinity of Bushberg was meant to be type locality, although it is reasonably certain that Ulrich was describing outcrops at Goetz Quarry near Glen Park. Type locality herein designated. Geographically restricted to outcrops in Jefferson County and closely adjacent parts of Franklin and St. Louis Counties. Bushberg provides little useful data by means of which it may be correlated with isolated, widely separated exposures. Early Mississippian age of conodont fauna described as from the "Bushberg" by Branson and Mehl (1933, Missouri Univ. Studies, v. 8, no. 4) is not questioned, but its identification as a Bushberg fauna is not supported by evidence at hand. Fauna from the "Bushberg" described by Branson (1938, Missouri Univ. Studies, v. 13, no. 4) should not be considered valid evidence of age of the Bushberg; sandstone from which fauna came is isolated and far removed from Bushberg as herein restricted, and its relationships are not clear. Average thickness about 10 feet. Unconformable upon Maquoketa, Kimmswick or "Fernvale," Grassy Creek, and Glen Park. Underlies Bachelor formation (new). Tentatively placed in Upper Devonian.

Type locality (Mehl, 1960): Outcrops at head of ravine draining into Mississippi River at Bushberg, formerly station on St. Louis, Iron Monutain, and Southern Railroad, NW¼NE¼NW¼ sec. 8, T. 41 N., R. 6 W., Jefferson County, Mo.

Busseron Sandstone Member[1] (of Shelburn Formation)

Upper Pennsylvanian: Southwestern Indiana.

Original reference: E. R. Cumings, 1922, Handb. Indiana Geology, pt. 4, Sep. Pub. 21, p. 524, 529, chart.

F. E. Kottlowski, 1954, U.S. Geol. Survey Coal Inv. Map C-11. Composed of gray to brown massive sandstone, sandy shale, and shale about 50 to 65 feet thick. Underlies a coal which in turn underlies Maria Creek limestone member; basal member of formation; overlies Coal VII at top of Dugger formation.

Probably named for village of Busseron, Knox County.

Butano Sandstone[1]

Eocene or Oligocene: Southern California.

Original reference: J. C. Branner, J. F. Newsom, and R. Arnold, 1909, U.S. Geol. Survey Geol. Atlas, Folio 163.

E. E. Brabb, 1960, Dissert. Abs., v. 21, no. 5, p. 1163. In Big Basin area, Butano sandstone of late Eocene (Narizian) age is divided into six informal units, which may prove to be members. Thickness about 9,000 feet. Overlies Locatelli formation (new) ; underlies San Lorenzo formation (subdivided).

Named for exposures on Butano Ridge, San Mateo County.

Butcherknife Basalt

Tertiary or younger: Southwestern Texas.

S. S. Goldich and M. A. Elms, 1949. Geol. Soc. America Bull., v. 60, no. 7, p. 1165–1168, pl. 1. Fresh, black, very fine-grained rock with conchoidal fracture. Younger than lowermost Pruett. Although cannot be correlated definitely with either Sheep Canyon basalt or the younger Cottonwood Spring basalt, it is much like them in composition.

Occurs on Butcherknife Hill, Buck Hill quadrangle, west-central Brewster County.

†Butler amygdaloid[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for a Captain Butler, discover of the lode.

Butler Clay Member (of Calvert Bluff Formation)

Butler Clay Member (of Rockdale Formation)[1]

Eocene, lower: Central and southern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 587.

H. B. Stenzel, 1953, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists, Mineralogists, and Soc. Econ. Geologists Joint Mtg. Guidebook, p. 52, 54. Reallocated to member status in Calvert Bluff formation. Forms basal part of formation, but top boundary indistinguishable from remainder of Calvert Bluff. Overlies Simsboro formation.

Typically exposed at town of Butler, Freestone County.

†Butler flow[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart complied by M. G. Wilmarth).

Copper district of Keweenaw Point.

†Butler Limestone (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 49.

Present at Butler, Butler County in cut near railroad station, hence name.

Butler Sandstone Member (of Allegheny Formation)[1]

Butler Sandstone (in Allegheny Formation)

Butler Sandstone Member (of Freeport Formation)

Middle Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 40–71, 130.

G. H. Ashley, 1926, Pennsylvania Topog. and Geol. Atlas 65, p. 28, pl. 4; M. N. Shaffner, 1946, Pennsylvania Topog. and Geol. Atlas 55, p. 51–65; E. G. Williams, 1960, Jour. Pateontology, v. no. 5, p. 910 (fig. 2). Member of Freeport formation.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 60, 75, fig. 21. Lies about 35 feet below Upper Freeport coal which is considered top of Allegheny group. Thickness 5 to 15 feet. In Fayette County, commonly replaced by sandy shale. Sandstone may lie above or below Bolivar fire clay.

Type locality: Town of Butler, Butler County, Pa., just below Mr. Muntz's, opposite mills of Woldo & Bros., where it has been quarried.

Butlerville quartzites[1]

Cambrian: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 38.

Derivation of name not stated.

Buttahatchie Gravel[1]

Quaternary(?): Alabama.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann, Rept. 1888, v. 2, p. 189.

Butte Formation

Permian (Wolfcampian): Eastern Nevada.

J. S. Berge, April 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 5, p. 11 (fig. 3). Butte formation, as shown on correlation chart, underlies Robbers Roost formation (new) and unconformably overlies Ely limestone. Permian (Wolfcampian). Column on chart credited to G. P. Lloyd (1959, unpub. thesis).

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). Name appears on correlation chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. Underlies Murry [formation] (new); stratigraphically above Ely limestone.

Present in White River valley and Moorman Ranch areas.

Butte Gravel Member (of Sutter Formation)

Butte Gravels[1]

Tertiary, upper: Northern California.

Original reference: Howel Williams, 1929, California Univ. Pub., Dept. Geol. Sci. Bull., v. 18, p. 112–129.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34, sheet 2. Used in a restricted sense. Top 150 feet of gravels are considered a sporadic basal member of Sutter formation. Upper Tertiary.

Present at Marysville Buttes, Sutter County.

Butte Quartz Monzonite[1]

Upper Cretaceous or Paleocene: Central western Montana.

Original reference: W. H. Weed, 1899, Jour. Geology, v. 7, p. 740–750.

G. E. Becraft, 1960, U.S. Geol. Survey Mineral Inv. Field Studies Maps MF–171 and MF–172. Upper Cretaceous or Paleocene.

Prevailing rock of Butte district.

Butte Creek Basalt

Late Pleistocene and Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 45–46. Narrow flow of black vesicular olivine basalt. Thickness 10 to 150 feet. Covered by Alder Creek basalt (new).

Issued from fissure at elevation of approximately 6,000 feet on east wall of Butte Canyon, Macdoel quadrangle. Extends for about 10 miles and ends near Soule Ranch at elevation of about 4,800 feet.

Butte Creek Beds

Oligocene, upper, or Miocene, lower: Northwestern Oregon.

J. E. Allen, 1946, Oregon Dept. Geology and Mineral Industries G.M.I. Short Paper 15, p. 5. Name credited to Harper (1941, unpub. map of Molalla quadrangle). Fossils, both foraminifera and megafossils in Marquam limestone (deposit) indicate Vaqueros age, correlative with Illahe-Mehama formation of Thayer (1939) and Butte Creek beds.

W. D. Lowry, 1947, Geol. Soc. Oregon Country News Letter, v. 13, no. 1, p. 5. Mentioned as containing the Wilhoit coal.

Occurs along Butte Creek about 3 miles east of Scotts Mills, Marion County.

Butte Falls Tuff

Precambrian (Yavapai Series): West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 7, 10–11, pl. 3. Largely massive- to well-bedded metamorphosed water-deposited tuff and possibility includes some flows. Several kinds of rocks have been grouped under the tuff, including quartz-sericite schist, quartz-feldspar-biotite schist, and grayish-white, gray, and purple slate. Thickness more than 2,500 feet. Younger than Bridle formation (new); underlies Hillside mica schist (new) with gradational contact. Intruded by Dick rhyolite and Lawler Peak granite (both new).

Exposed for more than 1 mile along Boulder Creek in vicinity of Butte Falls, for which these rocks have been named; Bagdad area, Yavapai County.

Butte Mountain Formation

Permian: Eastern Nevada and western Utah.

Grant Steele, 1960, Dissert, Abs., v. 20, no. 12, p. 4635. Incidental mention in stratigraphic interpretation of Pennsylvanian-Permian systems of eastern Great Basin. Subsidence continued, accompanied by deposition of

Kaibab, Butte Mountain, Phosphoria, and Gerster formations, until latest Guadalupian times, when westerly positives once again fed minor amounts of chert clastics east and south into western part of Phosphoria-Gerster deposition basin in Nevada.

Type locality and derivation of name not stated.

Butterfield Andesite Flows

Oligocene: Northern Utah.

R. E. Marsell and R. L. Threet, 1960, Geologic map of Salt Lake County, Utah (1:62,500); supp. to Bull. 69 [not yet published]: Utah Geol. and Mineralog. Survey. Named on map legend. Occurs above Knight conglomerate and below Rose Canyon latite-andesite flows.

Mapped in southern part of Salt Lake County. Largest exposure in south of Butterfield Canyon.

Butterfield Limestone Member (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 37, map, sections.

Exposed in Butterfield Canyon, Bingham district.

Butterly Dolomite (in Arbuckle Group)

Upper Cambrian: Southwestern Oklahoma.

C. E. Decker, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1317–1318, table 1; 1939, Oklahoma Geol. Survey Circ. 22, p. 15, 16 (table 1), 22–23. Mostly coarse dolomite with large quartz grains and thin quartz conglomerate in upper part. Color ranges from pink to yellow and gray. Thickness at type locality 286 feet; on west side of East Timbered Hills 374 feet. Overlies Signal Mountain formation: underlies Chapman Ranch member of McKenzie Hill formation. Name Butterly is substituted for Chapman Ranch, and name Chapman Ranch is used for the limestone at the base of the McKenzie because it appears that Ulrich intended the name Chapman Ranch to apply to the limestone rather than the dolomite.

W. E. Ham, 1949, Oklahoma Geol. Survey Circ. 26, p. 58–62. Butterly dolomite in Mill Creek-Ravia area, Johnston County, includes strata 333 to 435 feet thick that lie conformably on Royer dolomite and grade upward into limestone beds of McKenzie Hill formation.

Type section: On east side of U.S. Highway 77 in sec. 18, T. 2 S., R. 2 E., southeast of Chapman Ranch buildings, [Murray County]. Named for ranches owned by John Butterly and Butterly brothers at southeast end of West Timbered Hills, secs. 28 and 29, T. 1 S., R. 1 E.

Buttermilk Falls Limestone (in Onondaga Group)

Buttermilk Falls Limestone Member (of Onondaga Formation)

Lower or Middle Devonian: Northeastern Pennsylvania.

Bradford Willard, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–11, p. 5, 6 (fig. 3), 14, 16; 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 144–145. Because of elevation of term Onondaga to group rank, name Buttermilk Falls is introduced for those beds formerly designated as the Onondaga limestone. In Monroe County, consists of heavily bedded dark- or blue-gray limestone; contains nodules and lenses of dark chert, most abundant in middle of formation, but decreasing in upper and lower beds as these pass over respectively in the Marcellus formation and

Esopus shale. Thickness about 200 feet; thins westward to 5 feet in Lehigh River above Palmerton. Middle Devonian.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12 pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Onondaga formation as mapped includes Buttermilk Falls limestone member in easternmost part of State.

Crops out low on north side of Godfrey Ridge, at various places in vicinity of the Stroudsburgs, along railroads south of these boroughs, and in nearby quarries. Named for Buttermilk Falls on Marshall Creek, Monroe County. Continues east into Pike County but west only into Carbon County.

Butternut Shale Member (of Skaneateles Formation)

Middle Devonian: Central New York.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 181–182. Proposed to replace Berwyn of Cooper, 1930 (not Richards and Birk, 1925).

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart shows Butternut shale below Chenango sandstone and above Pompey shale and sandstone. Middle Devonian.

[G. A. Cooper], 1955, *in* New York State Geol. Assoc. [Guidebook] 27th Ann. Mtg., p. 10, 11. Dark-gray shale grading upward into Chenango sandstone member. Overlies Pompey member. Thickness 220 to 235 feet.

Type section: In the Cascades formed by branch of Butternut Creek, southeast of Syracuse, Tully quadrangle, Onondaga County.

Butte Valley Basalt

Late Pleistocene and Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 44–45. Black vesicular olivine basalt dotted with schollendomes. Thickness 80 feet at Juniper Lodge at bottom of Mount Hebron grade on U.S. Highway 97, where it overlies dark volcanic sand.

P. R. Wood, 1960, U.S. Geol. Survey Water-Supply Paper 1491, p. 19 (table 4), 29–31, pl. 1. Late Pleistocene and Recent.

Occurs at southern end of Butte Valley, around Jerome, Macdoel quadrangle.

Butte Valley Formation

Lower(?) Triassic: Southeastern California.

B. K. Johnson, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p. 384–385, figs. 1, 3. Consists of impure carbonates and limy argillaceous rocks thermally metamorphosed to very fine grained calc-silicate hornfelses; mostly banded rock of alternating laminae of light- and dark-gray hornfels, but locally includes massive units a few feet thick. About 4,000 feet thick. Contact between Permian Anvil Spring formation (new) and Butte Valley not exposed; east of Striped Butte, underlies Warm Spring formation (new), contact between the two gradational through as much as several hundred feet.

Exposed along east side of Butte Valley, Manly Peak quadrangle in southern Panamint Range, Inyo County.

Butting Ram Sandstone Member (of Talledega Slate)[1]

Pre-Devonian (probably Paleozoic): Eastern Alabama.

Original reference: Charles Butts, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 54, 58, map.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 20. Mentioned in discussion of Talledega series.

Named for fact it is believed to form Butting Ram shoals on Coosa River, on border between Chilton and Coosa Counties, about 10 miles northeast of Clanton.

Buttle Diatomite Member (of Monterey Formation)

Miocene-Pliocene: Central western California.

Y. T. Mandra, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 6, p. 78, 79-81, 88. Proposed for diatomite, about 500 feet thick, in Monterey formation. Overlies typical Monterey cherts, shales, and thinner interbeds of diatomite. Unconformably underlies sandy conglomerate that grades upward into gray-white sandstone that has been mapped as Santa Margarita by some workers and Pancho Rico by other workers. Name Pancho Rico is preferred in this report. Delmontian.

Type locality: Buttle Canyon, in NE¼ sec., 15, T. 24 S., R. 10 E., Mount Diablo base and meridian, approximately 4 miles west southwest of Bradley, Monterey County. Locality is on southwest limb of Hames Valley syncline.

Button Mold Knob Member (of new Providence Formation)

Lower Mississippian: Northern Kentucky and southern Indiana.

J. E. Conkin, 1957, Bulls. Am. Paleontology, v. 38, no. 168, p. 114–116, 120–121. Middle member of New Providence formation, Silver Hill facies. Divisible into lower, middle, and upper parts. Consists largely of green-gray shale with ironstone lenses and concretions, some limestones; crinoidal bioherms. Thickness about 145 feet. Underlies Kenwood sandstone member; overlies Coral Ridge member (new).

Type locality: Button Mold Knob, Bullitt County, Ky. Only lower and middle parts are well exposed here.

Buttrill Ranch Member (of Dagger Flat Formation)

Upper Cambrian: Southwestern Texas.

J. L. Wilson, 1954, Jour. Paleontology, v. 28, no. 3, p. 251, 252; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 12, p. 2465. Typically a graywacke sandstone and shale sequence with a few thin sandy chocolate-weathering flags. Thickness at type locality 370 feet. Underlies Roberts Ranch member (new).

Type locality: Dagger Flat, Brewster County. Exposed along Dagger Flat anticlinorium approximately 1½ miles southeast of Buttrill's ranch.

Buttsgin Formation[1]

Eocene: Southern Texas.

Original reference: R. A. Liddle, 1921, Texas Univ. Bull. 1860, p. 82, map, and columnar section.

Typically exposed in Butts Gin, approximately 6 miles northwest from Yancey, Medina County, in bed and tributaries of branches of Seco Creek.

Butts Ranch Shale Member (of Panoche Group)

Upper Cretaceous: Northern California.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 203, 226 (fig. 5), pl. 3. Consists of purplish or brownish calcareous and clay shales, thinly bedded and cut at various angles by sandstone dikes 2 or 3 feet wide; abundantly foraminiferal. Thickness at type locality 200 feet. Underlies Big Oak Flat shale member (new); overlies Call sandstone member (new).

Type locality: Along Paynes Creek 1 mile north of Butts Ranch, San Benito County. Member is exposed only along northeast limb of Butts Ranch syncline.

†Buxton Formation[1]

Pennsylvanian: Southeastern Kansas.

Original reference: F. C. Schrader and E. Haworth, 1905, U.S. Geol. Survey Bull. 260, p. 447.

Named for Buxton, Wilson County.

Buzzard Rhyolite (in Ash Creek Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 11–12, pl. 1. Outcrops in lower reaches of Black Canyon tinted in shades of red, whereas those in the headwaters are buff to cream. Contorted flow banding and amygdaloidal and vesicular structures common in flows. Fragmental structures common; some represent flow breccia. Thin sandy interbeds in breccia exposed near base of rhyolite west of Ward Pocket and three-fourths of a mile southeast of Allen Spring. Similar interbeds of sedimentary rock exposed near top of rhyolite north of Oak Wash. Megascopically rhyolitic rocks commonly porphyritic. Thickness of complete section in lower part of Black Canyon, where it overlies Gaddes basalt (new) and underlies Shea basalt, estimated at 3,500 feet.

Good exposures in Buzzard Canyon, a tributary to Black Canyon, southeast of Mingus Mountain. Excellent outcrops in Black Canyon, Jerome area, Yavapai County.

Buzzard Peak Conglomerate Member (of Topanga Formation)

Miocene, middle: Southern California.

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 515–519. Sandy conglomerate and coarse-grained pebbly sandstone with a few thin beds of white siliceous siltstone. Thickness about 2,000 feet; base not exposed. Overlain with apparent conformity by either the lower member of Puente formation or by a few feet of andesite breccia or massive calcic andesite which in turn is overlain by the Puente.

Crops out in core of Buzzard Peak anticline in San Jose Hills, 5 miles west of Pomona, Los Angeles County.

Byer Member[1] (of Logan Formation)

Mississippian: Central and southern Ohio.

Original reference: J. E. Hyde, 1912, History of Fairfield County, p. 211; 1915, Jour. Geology, v. 23, p. 656, 657, 659, 678, 764–765, 771–775.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172–173; 1942. Jour. Geology, v. 50, no. 1, p. 55, 56–58. Included in Pretty Run sandstone facies (new) of formation. Underlies Allensville conglomerate member; overlies Berne conglomerate member.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 3 (table 1), 26–27. Overlies the Berne here included in Cuyahoga formation.

Named for Byer, Jackson County.

Byham limestone member[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, table opposite p. 61, p. 134.

In Buchanan's Ravine, north of Shaws School (Buchanan Station) and about 1½ miles north-northwest of Byham School, south of Meadville, Crawford County.

Byram Formation (in Vicksburg Group)

Byram Marl (in Vicksburg Group)[1]

Byram Member (of Vicksburg Formation)

Oligocene: Mississippi, southwestern Alabama, northwestern Florida, and Louisiana.

Original reference: T. L. Casey, 1902, Philadelphia Acad. Nat. Sci. Proc., v. 53, p. 517–518.

F. F. Mellen, 1939, Mississippi Acad. Sci. Jour., v. 1, p. 18. Member at top of Vicksburg formation.

R. O. Vernon, 1942, Florida Geol. Survey Bull. 21, p. 56. Limestone mapped as Suwannee in this report [Holmes and Washington Counties] may represent time interval equivalent to that required for deposition of Glendon limestone, Byram marl, and lower Chickasawhay marl of western Alabama and eastern Mississippi. Not possible to establish mappable units within the Suwannee.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Byram limestone, as shown on correlation chart, comprises (ascending) Glendon limestone, Byram marl, and Bucatunna clay members. Vicksburg group.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1315 (fig. 1), 1329–1344. Byram formation as herein treated includes, in addition to marl to which name Byram was applied originally, the Glendon limestone member at base and Bucatunna clay member at top. Overlies Marianna limestone; underlies Chickasawhay limestone and Flint River formation.

W. H. Monroe, 1954, U.S. Geol. Survey Bull. 986, p. 80–98, pls. 1, 3, 4, 5. Byram formation including Glendon and Bucatunna member is present in belt across Mississippi from Warren County and southern part of Yazoo County on west to Wayne County on east. Present in western and central Alabama and has been doubtfully identified in Florida. Thickness about 110 feet. Entire section not exposed at any one place. Overlies Marianna limestone; disconformably(?) underlies Catahoula sandstone.

E. C. Tonti, 1955, Dissert. Abs., v. 15, no. 8, p. 1372. In stratigraphic investigation of Vicksburgian deposits in Mississippi, Alabama, and

Florida, two sedimentary cycles were identified. District disconformity marks upper and lower boundary of each unit. Lowermost cycle extends from disconformity at base of Mint Springs-Mariana formation to similar break at top of Byram formation (this report). Uppermost cycle contains Bucatunna marl and clay facies extending to disconformity at base of overlying Catahoula and Chickasawhay formations. Name Vicksburg stage suggested to include these deposits. Name Hennessey Bayou member proposed for lower Bucatunna transgressive unit heretofore included in Byram formation.

Type locality: On right bank of Pearl River, in S½NW¼NW¼ sec. 19, T. 4 N., R. 1 E., Hinds County, Miss. Named for Byram.

Byram Gneiss

Byram Granite Gneiss[1]

Precambrian: Northern New Jersey and eastern Pennsylvania.

Original reference: A. C. Spencer, 1908, U.S. Geol. Survey Geol. Atlas, Folio 161.

D. M. Fraser *in* B. L. Miller, D. M. Fraser, and R. L. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C-48, p. 163 (fig. 30), 187–193. Described in Northampton County, Pa., where it intrudes Franklin formation, Moravian Heights formation (new), and Pochuck gneiss.

W. S. Bayley, 1941, U.S. Geol. Survey Bull. 920, p. 18, 46, 50–51, pl. 5. Gray granitoid gneiss composed of microcline, microperthite, quartz and hornblende, with some pyroxene and biotite. Byram granite gneiss, Losee diorite gneiss, and Pochuck gabbro gneiss grade into one another through intermediate forms which as a rule can be recognized easily in thin sections, although they may not be distinguishable everywhere in the field. With decrease in oligoclase, the Losee phases pass into the Byram phases. Intrudes Franklin limestone and Pickering gneiss.

Bradford Willard *in* Bradford Willard and others, 1959 Pennsylvania Topog. and Geol. Survey Bull. C9, p. 219. Byram gneiss may be upper part of batholith which engulfed all but remnants of Franklin limestone and Pochuck gneiss.

Named for Byram Township, Sussex County, N.J., where good exposures occur in hills northeast of Roseville.

Byron Beds[1]

Byron Dolomite (in Burnt Bluff Group)

Middle Silurian (Niagaran): Southeastern Wisconsin and northern Michigan.

Original reference: T. C. Chamberlin, 1877, Geol. Wisconsin, v. 2, p. 345–348.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Byron dolomite included in Burnt Bluff group.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 9, 13–14. Overlies Lime Island dolomite (new); underlies Hendricks dolomite. Thickness 80 to 155 feet.

Named for Byron Township, Wis.

Byron Schist

Age not stated: West-central Maine.

Kern Jackson, 1953, Maine State Geologist Rept. 1951–1952, p. 53, 64–60. Consists of alternate layers of dark staurolitic schist and light fine-grained quartzite. Contacts between layers are alternately sharp and gradational. Schist lamellae are more readily weathered, creating a "washboard" effect. Thickness about 5,000 feet.

Named for excellent exposures in bed of Swift River in vicinity of Byron, Oxford County.

Caballero Formation

Mississippian (Kinderhook): Central southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1941, (abs.) Tulsa Geol. Soc. Digest, v. 9, p. 73–75; 1941, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 25, no. 5, p. 935; no. 12, p. 2116–2117, 2122–2125, fig. 4. Soft, gray, silty, marly limestone beds which weather to rounded, nodular, rubbly chunks on fresh exposures. Interbedded soft gray shales curve around nodular limestone lumps. Upper portion of section more shaly. Maximum thickness of 60 feet developed in area between Mule and San Andres Canyons in Sacramento Mountains. Thins to about 40 feet in northern part of range and to 28 feet in southernmost part of area. Unconformably underlies Alamogordo member (new) of Lake Valley formation; unconformably overlies various members of Percha formation. Heretofore considered a part of Lake Valley formation.

F. V. Stevenson, 1944, Dallas Digest (Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Joint Ann. Mtg.), p. 94–95; 1945, Jour. Geology, v. 53, no. 4, p. 239. Overlies Contadero formation (new).

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 9–10, fig. 5. Thickness varies from featheredge to 60 feet in central southern New Mexico. Basal part in many places contains thin layer of fissile black shale. Georgraphic distribution given.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 32. Summary paper. Extended to southern part of San Andres Mountains.

Type section: In Deadman Canyon, Sacramento Mountains, sec. 3, T. 17 S., R. 10 E., Otero County. Best developed in Sacramento Mountains, occurs in central and southern portion of San Andres Mountains, and locally in Lake Valley area. Missing elsewhere in New Mexico.

Caballo Blanco Rhyolite Tuff

Tertiary: Southwestern New Mexico.

F. J. Kuellmer and others, 1953, *in* New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 50 (map). Name appears on legend for map of Mimbres Valley.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 30–31, 32, pl. 1. Described as white, cream, or light-gray porphyritic rhyolite tuff interpreted as an ignimbrite. Matrix partly pumiceous. Reaches maximum thickness of 325 feet at Caballo Blanco in Dwyer quadrangle; thins to the west and pinches out toward the south near Box Well. According to generalized stratigraphic section Caballo Blanco rhyolite tuff is uppermost unit of eruptive suite termed Lower Volcanic series. Occurs above Rustler Canyon basalt (new). Unconformably underlies Razorback andesite and rhyolite of Upper Volcanic series. Derivation of name.

Name is taken from a mountain in secs. 25 and 36, T. 18 S., R. 11 W. (as shown on pl. 1), Dwyer quadrangle.

Caballos Novaculite[1]

Devonian and Mississippian: Southwestern Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 39.

P. B. King, 1937, U.S. Geol. Survey Prof. Paper 187, p. 47–55, pls. 23, 24. Subdivided into five members (ascending): lower chert; lower novaculite; middle chert; upper novaculite; upper chert. Name Santiago chert, which had been applied to three upper members, abandoned. Thickness 200 to 600 feet. Overlies Maravillas chert; underlies Tesnus formation.

B. N. Berry and H. M. Nielson, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2254–2259. King's (1937) lower two members of Caballos form one genetic unit and upper three members from another genetic unit; proposed here to revive original terminology of Udden, Baker, and Böse and recognize two distinct formations. Name Caballos is restricted to lower formation which includes lower chert member and lower novaculite member as described by King, and term Santiago chert revived and applied to upper three members.

The U.S. Geological Survey currently designates the age of the Caballos Novaculite as Devonian and Mississippian.

Named for exposures on Horse (Caballos) Mountain, Brewster County.

Cabaniss Formation (in Cherokee Group)

Cabaniss Group

Cabaniss Subgroup (of Cherokee Group)

Pennsylvanian (Des Moines Series): Central and northeastern Oklahoma, southeastern Kansas, and western Missouri.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1524 (fig. 1), 1526. Defined to include all rocks that crop out above Krebs group (new) and below base of Marmaton group. Extends from northeast flank of Arbuckle Mountains northeastward to Kansas-Oklahoma line and comprises (ascending) Thurman sandstone, Stuart shale, and Senora formation. In northern Oklahoma, top of group is base of Fort Scott limestone; between Arkansas River and Arbuckle Mountains base is Calvin limestone. Thickness 1,000 feet in latitude of Cabaniss; thins southwestward and northeastward due to overlap of lower units by higher as well as thinning within units; about 200 feet along Arbuckle Mountains; 350 feet at Arkansas River; 160 feet at Kansas-Oklahoma line. Krebs and Cabaniss groups together are nearly but not quite the same stratigraphically as Cherokee rocks of southeastern Kansas.

W. V. Searight, 1953, *in* W. B. Howe and M. V. Searight, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. Geographically extended into Carroll and Livingston Counties, Mo., where it comprises (ascending) Croweburg, Verdigris, Wheeler, Bevier, Lagonda, and Excello formations.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as comprising following formations (ascending):

Weir, Tebo, Scammon, Mineral, Robinson Branch (new), Fleming, Croweburg, Verdigris, Bevier, Lagonda, Mulky, and Excello formations. Overlies Krebs group; underlies Marmaton group. Cygnian substage.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 44–46. Term Cherokee group readopted, and Cabaniss reduced to rank of subgroup. In southeastern Kansas, Cabaniss succession extended from top of Seville limestone in Krebs subgroup to base of Blackjack Creek limestone, which is lower Marmaton. Thickness about 200 feet.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as formation in Cherokee group. Includes Tiawah limestone, Chelsea sandstone, Verdigris limestone, and Breezy Hill limestone together with several coals. Overlies Krebs formation; underlies Fort Scott limestone of Marmaton group.

Named from village of Cabaniss, in T. 6 N., R. 12 E., northwestern Pittsburg County, Okla.

Cabes Point Conglomerate lithofacies (of Louisenhoj Formation)

Upper Cretaceous: Virgin Islands.

T. W. Donnelley, 1960, Dissert. Abs., v. 20, no. 7, p. 2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. Intercalated conglomerates containing pebbles and cobbles of Water Island formation (new). Louisenhoj formation considered of Cenomanian age.

Report discusses geology of St. Thomas and St. John Islands.

Cabezon Fanglomerate[1]

Quaternary: Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 387–392, map.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 324 (fig. 2), 325 (table 1), 331, pls. 1, 3. Described in San Gorgonio Pass area as a gray to tan ill-sorted conglomerate rich in clasts of pegmatitic and granitic rocks. Maximum thickness about 1,500 feet. Unconformably underlies Heights fanglomerate; unconformably overlies Painted Hill formation, angular unconformity on wall of Stubby Canyon is tentatively regarded as the contact, although it may be a local angular unconformity within the Cabezon section. Type area suggested.

Type area apparently in foothills north of Cabazon, Riverside County. Fanglomerate appears to be continuous from Millard Canyon east to Whitewater and thence northward around flank of range. Post office is now spelled Cabazon, but Vaughan used the Indian spelling Cabezon and this is retained as formational name.

Cabin Shale[1]

Lower Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

K. F. Bick, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1066. In Deep Creek Mountains area, name Cabin shale dropped in favor of Pioche, which has priority.

Named for exposures in Cabin Gulch, south of North Pass Canyon, Gold Hill quadrangle.

Cabin Creek Sandstone[1]

[Pennsylvanian]: Oklahoma.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 99. Abandoned by Oklahoma Geological Survey. Name used in error by Weidman (1932, Oklahoma Geol. Survey Bull. 56, p. 23) for Little Cabin sandstone. Croneis had used name in 1930 for sursurface sandstone in Arkansas.

Cabin Hill Member (of Rose Hill Formation)

Silurian: Central Pennsylvania.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 28. In lower part of Rose Hill formation. Name credited to Miller (unpub. ms.).

Type locality and derivation of name not stated.

Cable Formation (or lake beds)[1]

Quaternary(?): Southern California.

Original reference: A. C. Lawson, 1906, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 431–462.

Named for town of Cable, Kern County.

Cable Canyon Sandstone Member (of Montoya Dolomite)

Cable Canyon Member (of Second Value Formation)

Cable Canyon Sandstone (in Montoya Group)

Upper Ordovician: Southwestern New Mexico.

V. C. Kelley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2201 (table). On table only. Thickness from fraction of a foot to 50 feet. Underlies Jornada limestone (new); overlies Bat Cave limestone (new). Montoya group.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 57–59, fig. 4. Coarse-grained granulitic sandstone, medium gray on fresh exposure and contains grains of white, gray, pale-rose, smoky, and blue-gray quartz, gray chert, and dolomite. Texture ranges from well-sorted medium-grained sand to unsorted small-pebble and granule conglomerate. Latter texture more characteristic. It is everywhere one single bed, 17 to 35 feet in thickness. Its appearance at a distance is always as a dark band above the light-colored cliffs of Bat Cave formation. Conformably underlies Upham dolomite (new). Type locality and derivation of name given.

R. H. Flower, 1958, Roswell Geol. Soc. Guidebook 11th Field Conf., p. 70. Rank reduced to member of Second Value formation.

H. J. Howe, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 10, p. 2287–2296. Disconformably overlies El Paso dolomite and underlies Upham dolomite in Sacramento Mountains. Montoya group.

Type locality: Cable Canyon section from which it takes its name, opposite Sierrite mine in NW¼ sec. 10, T. 16 S., R. 4 W., Caballo Mountains.

Cabo Rojo Agglomerate Member (of San Germán Formation)

Upper Cretaceous: Southwestern Puerto Rico.

R. C. Mitchell, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2972. Incidental mention.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 340–341. Agglomerate member of San Germán formation. Thickness about 50 meters. Stratigraphically below Cotui member. Upper Cretaceous. Mitchell (1954) tentatively considered member Upper Jurassic(?) because of erroneous correlation of two different outcrops of Cotui limestone with entire Cretaceous of Puerto Rico.

Type locality: In steep-walled, narrow roadcut at km. 10.1 on Route 4, 3.5 km. south of Cabo Rojo.

Cabo Rojo Stage[1]

Pleistocene: Puerto Rico.

Original reference: B. Hubbard, 1923, New York Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 1, p. 96.

J. D. Weaver, 1956, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 318. Term introduced for late Pleistocene deposits of western Puerto Rico.

Lares district.

Cabot Head Shale Member (of Cataract Formation)[1]

Cabot Head Shale (in Cataract Group)

Cabot Head Shale (in Medina Group)

Lower Silurian: Ontario, Canada, and northern Michigan and western New York.

Original reference: A. W. Grabau, 1913, Geol. Soc. America Bull., v. 24, p. 438, 460.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1981 (fig. 2), 1982 (fig. 3), 1990–1991. Discussion of stratigraphy of Medinan group in New York and Ontario. Cabot Head shale, overlies Manitoulin dolomite and underlies Grimsby sandstone. Although name Cataract holds priority, Cabot Head has become firmly entrenched in Canadian literature, and it seems unwise to attempt to replace the name. Unit is about 75 feet at type locality; 60 feet in vicinity of Hamilton; about 50 feet at Stoney Creek. Upper 27 feet of Power Glen formation (Bolton, 1953, Canada Geol. Survey Paper 52–23) at DeCew Falls is interpreted as Cabot Head shale and 8 to 10 feet of Cabot Head shale crops out in Niagara Gorge. This is most eastward exposure of unit, for isochronous Grimsby sandstone beds replace Cabot Head east of Niagara River. In restored stratigraphic cross section (fig. 2) of Medinan group datum is Manitoulin-Cabot Head contact, the line along which dominant transgression changed to dominant regression; hence this contact most closely approaches a true time-line.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 4 (fig. 1), 6. Formation in Cataract group. Cabot Head in Northern Peninsula is recognized almost entirely from well samples. Only two outcrops are known; both occur in eastern Delta County. Thickness 13 to 18 feet near Isabella. Overlies Manitoulin dolomite; underlies Moss Lake formation (new). Alexandrian series.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Included in Medina group. Overlies Rumsey Ridge shale herein given formational rank.

Named for exposures at Cabots Head on Manitoulin Islands, Ontario.

Cabotian[1] [Lavas, Red Rock, and Gabbro]

Precambrian: Eastern Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. Nat. History Survey Final Rept., v. 4, p. xiv-xx, 215, 295–298.

Named for mountain range that appears at Duluth and eastward.

Cabresto Metaquartzite

Precambrian: Central northern New Mexico.

P. F. McKinlay, [1955?], New Mexico Bur. Mines Mineral Resources Bull. 42, p. 8–10, pl. 1. Gray to cream-colored massive quartzite; in places layers of mica gneiss and graphite mica gneiss. Quartzite usually composed of 2- to 10-foot layers of coarsely crystalline glassy to milky quartz. Thickness ranges from 200 to over 1,000 feet.

Named from exposures along Cabresto Canyon, along south edge of Costilla quadrangle, Taos County.

Cacapon Sandstone Member (of Clinton Formation)[1]

Middle Silurian: Western Virginia and northern West Virginia.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

Charles Butts, 1940, Virginia Geol. Survey Bull., 52, pt. 1, p. 238, 242, 243, 246. Referred to as Cacapon division of the Clinton. Included in lower part of Iron Gate facies (new). In colloquial use, term Cacapon for the part of the Clinton carrying red or iron sandstone is permissible. Thickness of division about 157 feet.

Named for exposures on slopes of Cacapon Mountain, Winchester quadrangle, Virginia and West Virginia.

†Cacaquabic granite[1]

Precambrian: Minnesota

Original reference: J. M. Clements, 1903, U.S. Geol. Survey Mon. 45.

Exposed on shores and islands of Kekekabic Lake.

Cache Formation[1]

Pliocene or Pleistocene: Northern California.

Original reference: G. F. Becker, 1888. U.S. Geol. Survey Mon. 13, p. 219.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), 30–34, pls. 1, 2, 7. Described in Lower Lake quadrangle. Fresh-water deposits of gravel, silt, and clay, except near top of section where tuffaceous sediments, marl, limestone, and diatomite predominate. Thickness 300 to 6,500 feet. In some areas, overlies serpentine and sediments of Knoxville group. Shown on columnar section as underlying Clear Lake volcanic series and unconformably overlying Tejon formation.

Occurs east of Clear Lake, about North Fork of Cache Creek, Lake County.

Cachenian Stage

Late Cretaceous: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 991–993, 1006. One of six stages, based on foraminiferal assemblages, in Upper Cretaceous column between top of Moreno and base of Panoche, as defined by Anderson and Pack (1915). Includes interval between Weldonian stage (new) above and Delevanian stage (new) below.

Occurs in the Great Valley in both surface and subsurface. Well developed in surface section of Cache Creek, T. 12 N., R. 4 W., Yolo County.

Cache Valley Formation (in Salt Lake Group)

Cache Valley Group[1]

Miocene and Pliocene: Southeastern Idaho and northeastern Utah.

Original reference: A. C. Peale, 1879, U.S. Geol. and Geog. Survey Terr. 11th Ann. Rept. p. 603–606, 634, 635, 640, 641.

Neal Smith, 1953, Intermountain Assoc. Petroleum Geologists Guidebook 4th Ann. Field Conf., p. 73, 75 (fig. 2). Formation at top of Salt Lake group. Overlies West Spring formation (new). Thickness 1,000 to 2,000 feet. Middle and upper Pliocene.

R. D. Adamson, C. T. Hardy, and J. S. Williams, 1955, Utah Geol. Soc. Guidebook 10, p. 1, 2, 6–7. Redefined to include West Spring formation. Thickness 7,674 feet. Overlies Collinston conglomerate; underlies Mink Creek conglomerate (new). Miocene and Pliocene.

Well exposed on north side Cache Valley, northeastern Utah and southeastern Idaho, and on Bear River below middle canyon.

Cactus Granite[1]

Cactus Quartz Monzonite

Jurassic or Cretaceous: Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub. Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 364–365.

R. B. Guillou, 1953, California Div. Mines Spec. Rept. 31, p. 5 (fig. 2), 12–13, pl. 1. Redescribed as Cactus quartz monzonite. Differentiated into three facies (in order of age of emplacement from oldest to youngest): aplite, quartz diorite, and quartz monzonite. Intrudes Baldwin gneiss and truncates the Chicopee formation (new) and Furnace limestone.

Named for Cactus Flat, San Bernardino Mountains, San Bernardino County.

Cactus Point Granite

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 14, pl. 1. Commonly light gray on fresh exposures; weathered rock commonly has yellow tint. May be correlative with Big Baldy granite (new).

Crops out in area of about 5 square miles around Cactus Point, a small knob northeast of Ash Mountain Park headquarters, Sequoia National Park.

Caddell Formation (in Jackson Group)

Caddell Clay[1]

Eocene, upper: South-central Texas.

Original reference: E. T. Dumble, 1915, Geol. Soc. America Bull., v. 26, p. 462.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626–2627. Formation at base of Jackson group. Consists of glauconitic very fine sand, silt, and clay; calcareous and ferruginous concretions near base; marine beds locally interbedded with chocolate lignitic clays and sands. Underlies Wellborn sandstone. Type locality designated. Dumble's locality not located with certainty.

Type locality: Cuts along Highway 147 just west of relocated bridge, 4 miles west of site of Caddell, San Augustine County.

Caddo Limestone[1]

Lower Cretaceous (Comanche Series): Southeastern and central southern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Correlation chart shows Caddo limestone above Kiamichi formation and below Bokchito formation.

Named for Caddo, Bryan County.

†Caddo Shale[1]

Lower and Middle Ordovician: Southwestern Arkansas.

Original reference: A. H. Purdue, 1909, Geol. Soc. America Bull., v. 19, p. 557.

Caddo Creek Formation (in Canyon Group)[1]

Caddo Creek Group

Upper Pennsylvanian: Central and central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31, 35.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geol. Pub. 3801, p. 108, 115. Formation consists of Hog Creek shale member, whose type locality is in northern Brown County, and overlying Home Creek limestone of northern Brown County, which has been correlated with limestone also called "Home Creek" occurring at same horizon in Brazos River basin in Palo Pinto County. Although these members are distinguishable in northern Brown County and in area along river, it is not practicable to separate them in much of intermediate area, for the reason that the Home Creek is broken into a number of relatively thin limestone beds interbedded with shale with no obvious dividing line between them. Thickness 69 feet. Overlies Brad formation (redefined); underlies Graham formation of Cisco group (restricted).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to group. Includes Hog Creek shale below and Home Creek limestone. Underlies Graham group; overlies Brad group.

Robert Roth, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, fig. 2. Generalized columnar section shows group including Hog Creek shales and sandstone, Home Creek limestone, and lower part of Gonzales shale.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, fig. 4. Generalized columnar section shows group including unnamed strata below Ranger limestone up to base of Salem School limestone.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–18, p. 51. Shown on columnar section of Brown and Coleman Counties as Caddo Creek formation. Includes Colony Creek shale member below and Home Creek limestone member above. Thickness about 50 feet. Underlies Graham formation; overlies Brad formation.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 67. As originally defined, formation included Drake's Hog Creek shale below Home Creek limestone member above. Because of miscorrelations in past, name Hog Creek shale should be replaced. As redefined here, formation includes (ascending) Home Creek limestone member and Colony Creek shale member. Thickness about 55 feet along Colorado River; about 75 feet in central Brown County.

Named for tributary of Brazos River in Stephens County, Brazos River region.

Caddo Gap Novaculite[1] (in Arkansas Novaculite)

Devonian(?): Southwestern Arkansas.

Original reference: C. L. Cooper, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 211.

W. H. Hass, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 12, p. 2532. Incidental mention in discussion of age of Arkansas novaculite.

Named for Caddo Gap, Montgomery County.

Caddo Pool Formation (in Kickapoo Creek Group)

Caddo Pool Formation (in Smithwick Group)

Pennsylvanian (Lampasas): North-central Texas (subsurface).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 84 (fig. 5), 86. Proposed for middle formation of Smithwick group. Consists principally of about 200 feet of dense black spicular limestone with some thin sandstones in lower part. Occurs between depths of 3,820 and 3,960 feet in type well. Overlies Eastland Lake formation (new); underlies Parks formation (new).

M. G. Cheney, 1947, Jour. Geology, v. 55, pt. 2, no. 3, p. 209. Stratigraphic section assigned to Kickapoo Creek group (new) includes the Rayville (new), Parks and Caddo Pool formations.

Some reports place the Kickapoo Creek Group in the Strawn Series.

Type well: Anzac Oil Corp. *et al.* E. S. Graham No. 1, in Allen Hines Survey, Abstract 135, central Young County. Discovery well of Caddo Pool of eastern Stephens County was completed in this black limestone which is colloquially known as the "Caddo lime"; hence the name.

Cades Sandstone

Cades Conglomerate (in Chilhowee Group)[1]

Precambrian (Ocoee Series): Eastern Tennessee and western North Carolina.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 2.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 960–961. Cades sandstone is adapted from Cades conglomerate of Keith (1895) who mapped the Cades north and south of Cades Cove and widely elsewhere in mountains. Term is here restricted to rocks mainly north and west of the cove and beneath Green-briar fault. Sandstone lies in a similar position to rocks of Webb Mountain and Big Ridge. Around most of its periphery, the Cades is thrust over adjacent rocks but may lie with sedimentary contact on Metcalf phyllite (new) to south; its strata are inverted over wide areas. Total thickness unknown; as much as 4,000 feet exposed in some sections. Predominantly a coarse-grained feldspathic sandstone, in graded beds as much as 3 feet thick, commonly containing chips of dark fine-grained rock and pebbles of leucogranite but no grains of blue quartz; dark-gray argillaceous and silty rocks form partings between sandstone beds as well as a few units nearly 1,000 feet thick; also contains beds 10 to 50 feet thick of conglomerate characterized by well-rounded cobbles of quartzite, granite, and gneiss.

Named for exposures near Cades Cove, Blount County, Tenn.

Cadillac Granite

Mississippian: Southeastern Maine.

G. H. Chadwick, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 73. Coarse-grained red granite; lighter in color and finer grained at contacts with country rocks.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1796, 1797. Name is synonymous with undefined Cadillac Mountain granite. Younger than Prettymarsh diorite (new) which is post-Lower Devonian in age.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 175, 176–177. Age tentatively considered Mississippian.

Composes central massif of Mount Desert Island, Hancock County.

Cadiz Beds[1]

Upper Devonian: Western New York.

Original reference: G. H. Chadwick, 1934, Geol. Soc. America, Prelim. list of titles and abstracts of papers to be offered at 47th Ann. Mtg., Rochester, N.Y., Dec. 27–29, 1934, p. 12.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 2, chart 4. Shown on correlation chart between Cuba sandstone below and Hinsdale sandstone above.

Occurs on Genesee-Olean meridian in Genesee River region.

Cadiz Formation[1]

Lower and Middle Cambrian: Southeastern California.

Original reference: J. C. Hazzard and J. F. Mason, 1936, Geol. Soc America Bull., v. 47, no. 2, p. 229–240.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 31, 32, 35. Lyndon limestone geographically extended into California where it consists of member 5E of Cadiz formation (Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4); Chisholm shale also extended into area where it includes member 5F and 5G of the Cadiz (Hazzard, 1937).

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, table 1. Redefined to include all beds between top of Lower Cambrian Chambless limestone and base of Middle Cambrian Bonanza King formation. This redefinition made because, as originally defined, lower limit of formation had been established on faunal basis and not on lithology.

As redefined, formation is mappable lithologic unit in both Marble and Providence Mountains. Thickness about 690 feet.

Type section: Measured in west-east direction up west front of high limestone ridge about 2 miles north of National Old Trails Highway where it crosses Marble Mountains about 3 miles north of Cadiz, San Bernardino County.

Caesar Canyon Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 2), 98 (fig. 3). In central Nevada. Overlies Antelope Valley formation; underlies Gatecliff formation (new).

Toquima Range, Nye County.

Cagle Silt

Pleistocene (Kansan): Southwestern Indiana.

W. J. Wayne, 1958, Jour. Geology, v. 66, no. 1, p. 8, 9 (fig. 1), 10. Proglacial loess; conformably underlies Kansas stage till; overlies Pennsylvanian Mansfield formation. Consists of silt, grayish-brown, mottled locally; calcareous and abundantly fossiliferous, becoming less so in lower 1.0 foot; wood, peat, and humus common at upper contact; lenticular, pinching out toward west. Thickness 3 feet.

Type locality: Emergency spillway Cagles' Mill Reservoir, SE¼NE¼ sec. 13, T. 12 N., R. 5 W., Putnam County.

Cahil Sandstone Member (of Franciscan Formation)

Cahil Sandstone (in Franciscan Group)[1]

Jurassic and Cretaceous: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

U.S. Geological Survey currently classifies the Cahil Sandstone as a member of the Franciscan Formation on the basis of a study now in progress.

Named for exposures on Cahil Ridge, San Mateo County.

Cahuenga Beds

Cretaceous(?): Southern California.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 6 (table 1), 19–20, 21 (fig. 11), pl. 1. Consists of five unnamed units: basal sedimentary breccia, coarse sandy boulder conglomerate, lens of conglomeratic sandstone, sandy pebble conglomerate, and well-bedded conglomeratic sandstone. Thickness about 5,300 feet. Except for boulder conglomerate, beds are confined to Cahuenga Peak fault block; some boulder conglomerate is exposed in southwestern part of Griffith block and in Ferndell block. A thick section of Cahuenga beds is missing at base of Topanga formation, which rests unconformably on the conglomerate in Cahuenga Peak and Ferndell blocks. Overlies Griffith beds (new); contact not exposed. Cahuenga beds are folded into broad anticline in Cahuenga Peak fault block.

Occurs in Griffith Park area, city of Los Angeles. Area is bounded on west by Cahuenga Pass and Dark Canyon. Cahuenga Peak is near western end of Santa Monica Mountains.

Caimito Formation[1]

Oligocene and Miocene: Panamá

Original reference: D. F. MacDonald, 1913, Geol. Soc. America Bull., v. 24, p. 709.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 14, Geol. Sci., p. 234 (chart). As shown on correlation chart, comprises (ascending) Chilibrillo, Caimito, and Alajuela.

[T. F. Thompson], 1943, Panama Canal Spec. Eng. Div. 3d Locks Proj., pt. 2, chap. 3, p. 18–19, fig. 3–2. MacDonald (1913) considered the Caimito to overlie immediately the Emperador formation. Recent studies have indicated that this is incorrect and that the formation bears closer affinity to the Panamá tuff. These two formations overlap many of the Oligocene beds within the Pacific area of the Canal Zone, locally lying upon the Emperador and thin only because of transgressive overlap. Gradational with overlying Panamá tuff.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 232–236, 246 (fig. 2). Formation name was introduced by MacDonald (1913) but was not properly defined then or later (MacDonald, 1919, U.S. Natl. Mus. Bull. 103). Type region was not specified. Most of MacDonald's brief description of formation is description of strata on Pacific side of Canal Zone now assigned to La Boca formation. MacDonald's statement that the Caimito overlies Emperador limestone—now assigned to member rank in Culebra formation—was based on misidentification of limestone in the La Boca formation and in the Caimito itself. Caimito formation and Emperador limestone member of Culebra are nowhere in contact. On account of these confusing formation assignments, published data on fossils of Caimito and Culebra formations and Emperador limestone member are misleading or erroneous. In Madden basin, formation comprises (ascending) unnamed calcareous sandstone-siltstone, unnamed pyroclastic clay, Chilibrillo limestone, unnamed calcareous sandstone, and Alhajuela sandstone members. In Quebrancha syncline, comprises (ascending) Quebrancha limestone member and calcareous siltstone member. In Gatún Lake area and Caribbean coast, Canal Zone, comprises three unnamed members. Thickness as much as 1,000 feet. Overlies Bohío formation. Formation in Madden basin includes considerable time span—late Oligocene to late early Miocene, or possibly early middle Miocene.

Type region (Woodring and Thompson): Assumed to be region that furnished the name. Caimito, or Caimito Junction, was located on the present alignment of Panamá Railroad and Darién.

Cairo glaciation

Cairo till[1]

Pleistocene (pre-Nebraskan): North America.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 69, no. 2, p. 129. Referred to as glaciation.

Cajalco Quartz Monzonite[1]

Late Mesozoic: Southern California.

Original reference: P. H. Dudley, 1935, California Jour. Mines and Geology, v. 31, no. 4, p. 491, 502, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 481, table 4. Late Mesozoic. In plutonic series of area, the Cajalco is considered younger than the La Posta quartz diorite and older than Lakeview quartz monzonite.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 76. Rocks called Cajalco quartz monzonite by Dudley (1935) belong to Woodson Mountain granodiorite, which is considered Cretaceous.

Covers large areas in Riverside County between Monument Peak and Arlington Mountain, including Cajalco Canyon.

Cajon Formation

Age not stated: Southern California.

R. E. Wallace, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 790. Incidental mention.

Mapped area is approximately 20 miles long and 5 miles wide along San Andreas rift between Palmdale and Elizabeth Lake, Los Angeles County.

Calais Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Quarried at Calais, Calais Township, Washington County, in quadrangle adjoining Montpelier quadrangle on east.

Calamity Formation

Pleistocene, upper: Southwestern Texas.

C. C. Albritton, Jr., and Kirk Bryan, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1863. On basis of disconformities in valley-fill complex, the Quaternary (late Pleistocene) has been divided into (ascending) Neville, Calamity, and Kokernot formations.

C. C. Albritton, Jr., and Kirk Bryan, 1939, Geol. Soc. America Bull., v. 50, no. 9, p. 1434–1441, 1443–1445, 1449–1450, 1453, strat. section. At type locality, consists of silt and sand with interbedded gravel and subordinate amounts of silty, humic clay. A foot of pebble and cobble gravel composed of fragments of Cretaceous limestone and Tertiary volcanic rocks marks base of section. This grades upward into 4 feet of pebbly, clayey silt and sand whose upper half is dark with humus. Upper part of section is essentially a duplication of this sequence with a second, somewhat darker, humic zone at top. Contains artifacts, buried hearths, and human skeletons. Of several cultures represented, one is Pecos River Cave dweller. Thickness at type locality 11½ feet; elsewhere along Sheep Creek and upper segment of Calamity Creek, thickness ranges from 12 to 16 feet; maximum thickness 30 feet along intermediate segment of Calamity Creek. Disconformably overlies Neville formation; disconformably underlies Kokernot formation.

C. B. Hunt, 1952, U.S. Geol. Survey Bull. 996–A, p. 6. Proposed Pleistocene-Recent boundary would be at unconformity between Neville and Calamity formations.

Type locality: Along bank of Sheep Creek, directly south of Terlingua-Alpine road crossing, Brewster County. Well exposed along banks of Sheep Creek, along Calamity Creek from Neville's House to southern end of Elephant Mountain, and along intermediate segment of Calamity Creek.

Calapooya Formation[1]

Eocene, upper, and Oligocene: Southwestern Oregon.

Original reference. F. G. Wells and A. C. Waters, 1934, U.S. Geol. Survey Bull. 850.

V. T. Allen, J. S. Loofbourow, Jr., and R. L. Nichols, 1951, U.S. Geol. Survey Circ. 143, p. 2, 3 (fig. 2). Uncomformably overlies Umpqua formation. Consists of lava flows, tuffs, breccias, mud flows, and water-laid clays, shales, sandstones, and conglomerates. Contains silicified wood, charcoal, and leaves. Thickness several thousand feet. Deposited in continental environment probably during late Eocene time.

U.S. Geological Survey currently considers the Calapooya Formation to be late Eocene and Oligocene in age.

Named for occurrence along crest of Calapooya Mountain.

Calaveras Formation[1]

Calaveras Group[1]

Upper Paleozoic (Permian in places): Northern California.

Original reference: H. W. Turner, 1893, Am. Geologist, v. 11, p. 307–324, 425.

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 280–282, 283. Calaveras is name given to pre-Mesozoic bedrock of the Sierra Nevada, south of Taylorsville region. Name is catchall for Paleozoic rocks of Sierra Nevada and, hence, has no stratigraphic significance. In central part of Sierra Nevada, most of the Calaveras lies to east of the Mother Lode, which represents a late Jurrasic thrust fault which brought Calaveras westward over Jurassic rocks. West of Mother Lode country, Calaveras is brought up in the midst of Jurassic along a large compound, often highly faulted, anticline. In places, as along Cosumnes River, there is a single belt of Calaveras flanked by Amador [group], but in other places, as on Calaveras River, there are several narrow belts of Calaveras repeated by faulting. The complex anticline that exposes the Calaveras west of the Mother Lode, plunges southward from Calaveras River. On Stanislaus River, there is only a narrow faulted belt of Calaveras in the midst of the Amador and Mariposa. South of Stanislaus River, the western belt of Calaveras plunges beneath Jurassic rocks and is not again exposed. Amador group is younger than Calaveras and older than Mariposa. Uncomformably underlies Cosumnes formation (new) of Amador group.

J. H. Eric, A. A. Stromquist, and C. M. Swinney, 1955, California Div. Mines Spec. Rept. 41, p. 7–9, pls. 1–4. The wide age span for the so-called catchall Calaveras is a result of the fact that no description exists for a type section of the formation. As a result, many different types of rocks have been mapped as Calaveras by various geologists. Term Calaveras formation is used in this report [Angels Camp and Sonora quadrangles] as it was originally defined by Turner; that is, it includes all rocks that are shown to be Paleozoic in age on basis of paleontologic or geologic evidence. In mapped area, some rocks previously assigned to Calaveras are excluded from that formation because no valid evidence of Paleozoic age has been found. Some of the rocks previously mapped as Calaveras are assigned to Cosumnes formation of Amador group.

Cordell Durrell, 1959, California Univ. Pubs. Geol. Sci., v. 34, no. 3, p. 177. Underlies Penman formation in Blairsden quadrangle.

Named for prominent development in Calaveras County.

†Calciferous Formation[1]

Lower Ordovician: Northwestern Michigan.

Original reference: A. C. Lane, 1907, Michigan Miner, v. 9, no. 2, p. 9.

Named for Calciferous Creek, a branch of Au Train River, Marquette region.

†Calciferous mica schist[1]

Ordovician and Silurian: Western New Hampshire and Vermont.

Original references: C. H. Hitchcock, 1870, Geol. and Min. New Hampshire 2d Ann. Rept., geol. map; 1873, Am. Assoc. Adv. Sci. Proc., v. 21, p. 134–135; 1877, Geology New Hampshire, pt. 2, p. 658–675; 1896, Jour. Geology, v. 1, p. 44–62; 1896, Geol. Soc. America Bull., v. 7, p. 510–512; 1906, Vermont Geol. Survey 5th Rept., p. 86, 115.

Southwestern New Hampshire.

Calder Creek Member (of Wells Formation)

Pennsylvanian (Springeran-Morrowan): Idaho.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). Name appears on chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. Underlies Heglar Canyon member (new); overlies Milligen formation.

Present in Sublett Mountain area.

Calderwood Formation[1]

Cambrian(?): Central southern Maine.

Original reference: G. O. Smith, 1896, Geology Fox Island, Maine, p. 12, 28–29.

Vinalhaven Island, Knox County.

Caldwell sediments

Pleistocene, upper: Southwestern Idaho.

C. N. Savage, 1958, Idaho Bur. Mines and Geology County Rept. 3, p. 20 (table 1), 27, 41, 42, 48, figs. 3, 4. Clay, silt, sand, and fine gravel, chiefly nonconsolidated. Some caliche. Thickness as much as 50 feet. Underlies Recent Snake River eruptives; overlies Nampa sediments (new).

In Boise Valley, generally below 2,500 feet elevation, Ada and Canyon Counties.

Caldwell Canyon Volcanics

Tertiary (post-Oligocene?): Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 85–86, pl. 17. Consists, for most part, of glassy laminated white, red, orange, pink, yellow, gray, and black flows. In lower part of sequence are soft buff flow breccias or lithic tuffs. Upper part consists of very fine grained laminated flows of latite or possibly rhyolite. Maximum thickness of sequence about 300 feet. Uncomformably overlies Wiggins formation (new). Youngest extrusives in region.

Name derived from Caldwell Canyon, just southwest of Wiggins Peak in southern end of Absaroka Range. Caldwell Canyon volcanic rocks of this area confined to Wiggins Peak and vicinity. Other occurrences may be present north of mapped area.

Caldwell Knob Member (of Rockdale Formation)

Caldwell Knob Member (of Seguin Formation)[1]

Eocene, lower (Wilcox): Southeastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 575, 576, 577.

M. W. Beckman and F. E. Turner, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 608–621. Redefined and reallocated to member status in Rockdale formation. As originally defined, Seguin formation straddles Midway-Wilcox boundary; a disconformity occurs within Solomon Creek member, which is here restricted to beds below the disconformity; Caldwell Knob is extended below to include all oyster and sand beds down to the disconformity. Where it is possible to recognize divisions as redefined, Caldwell Knob beds should be regarded as basal member of Rockdale formation. Where divisions cannot be differentiated, it may be necessary to continue use of Seguin formation, recognizing that it contains the break between the Midway and the Wilcox.

Type locality: Caldwell Knob 10 miles north of Bastrop and about 2 miles south of Colorado River in Bastrop County.

Caledonia Conglomerate[1] (in Bohemian Range Group)

Precambrian: Northern Michigan.

Original reference: A. C. Lane, 1911, Michigan Geol. and Biol. Survey Pub. 6, geol. ser. 4, p. 576, 580, 588, 593, 612, 957.

Probably named for occurrence near old Caledonia mine, Ontonagon County.

Calef Member (of Eliot Formation)

Probably Ordovician and Silurian: Southeastern New Hampshire.

Jacob Freedman, 1950, Geol. Soc. America Bull., v. 61, no. 5, p. 453 (fig. 2), 456, pl. 1. Chiefly black phyllite with some green quartz-chlorite phyllite. Maximum thickness 800 feet. Occurs at top of Eliot formation of Silurian(?) age. Underliies Berwick formation.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Probably Ordovician and Silurian.

Exposed in narrow belt in Mount Pawtuckaway quadrangle between villages of Epping, Rockingham County, and Lee, Stafford County. Named from Calef Road.

Calera Limestone Member (of Franciscan Formation)

Calera Limestone Member (of Cahil Sandstone)[1]

Jurassic and Cretaceous: Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 5, p. 416 (table).

H. E. Thalman, 1943, (abs.) Geol. Soc. America Bull., v. 45, no. 12, pt. 2, p. 1827. Paleontological evidénce indicates Upper Cretaceous age.

U.S. Geological Survey currently classifies the Calera Limestone as a member of the Franciscan Formation on the basis of a study now in progress.

Named for exposures in sea cliffs at lower end of Calera Valley, San Mateo County.

Calhoun Coal Member (of Mattoon Formation)

Pennsylvanian: Central and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 51 (table 1), 82, pl. 1. Name applied to coal immediately below Bonpas limestone member (new), Stratigraphically above Trowbridge coal member (new). Thickness 16 inches. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NE¼NE¼ sec. 6, T. 2 N., R. 14 W., Richland County. Name derived from village of Calhoun, 2 miles west of type exposure.

†Calhoun Limestone[1]

Pennsylvanian: Eastern Kansas and northwestern Missouri.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 28.

Name for Calhoun Bluffs, about 3 miles northeast of Topeka, Kans.

Calhoun Limestone

Pennsylvanian: Southeastern Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, Illinois Geol. Survey Bull. 67, p. 27 [1943]. Lenticular bed with maximum thickness of about 3 feet which overlies persistent coal in Richland and Lawrence Counties. Light gray, more or less argillaceous, and locally grades laterally into calcareous sandy shale. Provisionally correlated with Omega limestone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 41. Replaced by Bonpas limestone member of Mattoon formation (both new). Name Calhoun restricted to underlying coal.

Named from Calhoun, Richland County.

Calhoun Shale (in Shawnee Group)

Calhoun Shale Member (of Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci Trans., v. 15, p. 29.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 22. Formation is 2 to 3 feet thick in Weeping Water Valley; about 10 feet at Kansas line. Overlies Deer Creek formation; underlies Hartford limestone (Wolf River) member of Topeka formation.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Calhoun formation is a succession of shale beds which separates Deer Creek formation from overlying Topeka formation. Jones Point shale, Sheldon limestone, and Iowa Point shale members, previously included in the Calhoun, have been found to lie above rather than below the Hartford ("Wolf River") limestone and are included in Topeka formation. Shawnee group.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 65. Included in Shawnee group. Clayey and sandy shale with minor amount of limestone and one or more coal beds. In northern Kansas a thin coal bed and much sandstone, a part of which fills channels, occur near top of formation. Dark-gray silty fossiliferous shale comprises lower part, and plant remains occur in sandy part. In southern Kansas, shale diminishes in thickness and is locally absent near Oklahoma line. Maximum thickness about 45 feet, near Kansas River. Overlies Deer Creek formation; underlies Topeka limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 17, fig. 5. Dark-gray to bluish-green shale; fossiliferous. Thickness 1½ to about 3 feet. Overlies Ervine Creek limestone member of Deer Creek formation; underlies Hartford limestone member of Topeka formation. Shawnee group.

Named for Calhoun Bluffs, about 3 miles northeast of Topeka, Shawnee County, Kans.

Calico Amygdaloid[1] (in Central Mine Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Calico Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Calico Formation

Miocene: Southern California.

C. W. Chesterman, 1956, California Div. Mines Bull. 174, p. 85. Pumice deposits northwest of Barstow occur in a thick series of volcanic rocks of Calico (Miocene) formation. The volcanic rocks consist mostly of tuffs and rhyolite flows; strike northwest and dip moderately to the southwest. Thickness about 270 feet (at Williams Brothers quarry). Name credited to T. W. Dibblee, Jr. (unpub. map).

Typical section exposed on steep hillside a few hundred feet east of Williams Brothers pumice quarry, 18 miles northeast of Barstow, San Bernardino County.

Calico phase (of Amargosa chaos)

Post-Miocene(?): Southern California.

L. F. Noble, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1936. Listed as a phase of Amargosa chaos, as assemblage of blocks on overthrust plate of Amargosa thrust.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 965, 968–972, pl. 3. Mosaic of fault blocks composed mostly of rhyolitic lava and tuff; a kaleidoscopic mixture of light and dark—the light shades yellowish white to buff, and dark shades dull pinkish to red; rocks are almost wholly Tertiary in age. Exposed thickness a little more than 1,000 feet. Overlies Virgin Spring phase except at two places where it forms the sole of the thrust. Contact with the Virgin Spring is sinuous and roughly parallel with outcropt of Amargosa thrust; Calico phase is folded with the Virgin Spring just as if the two units were beds in a sedimentary series. Calico and Jubilee phases are not in contact in the area, and their relative position is not known.

Occurs in Virgin Spring area near Death Valley. Name is derived from Calico Peaks in northeastern part of area. Calico phase covers about 10 square miles in area mapped.

Calico Bluff Formation[1]

Upper Mississippian: Central eastern Alaska.

Original reference: A. H. Brooks and E. M. Kindle, 1908, Geol. Soc. America Bull., v. 19, p. 292.

Helmuth Wedow, Jr., 1954, U.S. Geol. Survey Circ. 316, p. 3, pl. 1. Consists of about 1,500 feet of alternating beds of shale and limestone in Eagle-Nation area. Underlies unnamed shale, argillite, slate, and chert unit intermediate between Calico Bluff and Nation River formation.

Exposed at Calico Bluff and other points on Upper Yukon River, also on Porcupine River, Nation River region.

Calico Peak Porphyry[1]

Tertiary: Southwestern Colorado.

Original reference: W. Cross and A. C. Spencer, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, pl. 22, map.

Occurs on north slope and elsewhere in vicinity of Calico Peak, about 4 miles northwest of Rico, Dolores County.

Calico Rock Sandstone Member (of Everton Formation)[1]

Middle Ordovician: Central northern Arkansas.

Original reference: G. C. Branner, 1929, Geologic map of Arkansas: Arkansas Geol. Survey.

U.S. Geological Survey currently designates the age of the Everton Formation and its members as Middle Ordovician.

Named for outcrops in river bluffs east and west of town of Calico Rock, on White River, in western part of Izard County.

Caliente Formation

Caliente Red Beds

Miocene, lower and middle: Southern California.

T. W. Dibblee, Jr., *in* Chester Stock, 1948, Southern California Acad. Sci. Bull., v. 46, pt. 2, p. 84. Coarse gray conglomerate, gray sands, and red clays; continental. Underlie Apache formation (new).

W. E. Ver Planck, 1952, California Div. Mines Bull. 163, p. 35, 36 (fig. 7), 37. Described in connection with gypsum deposits in Ventura County as Caliente red beds.

I. T. Schwade, 1954, California Div. Mines Bull. 170, map sheet 1. Formation noted as occurring on eastern margin of Cuyama Valley where it overlies lower Miocene marine beds [Painted Rock formation] and in southeastern part of the valley in proximity to upper(?) Miocene nonmarine strata.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2978 (fig. 3), 2993–2995. On northeast flank of southeastern Caliente Range, Branch Canyon sandstone (new) and upper part of Painted Rock sandstone member of Vaqueros grade laterally eastward into continental redbeds; these continental beds of middle and lower Miocene are here designated as Caliente formation. At type locality, consists predominantly of claystone, sandstone, and conglomerate, with some basalt flows; thickness about 4,200 feet; lower 1,000 feet grades abruptly westward into Painted Rock sandstone; overlying 1,100 feet grades laterally northwest into Branch Canyon sandstone; underlies Quatal formation with accordant contact. In northern Cuyama Badlands area, about 3,000 feet thick and rests on beds of the Vaqueros or on Simmler redbeds; farther southeast, lies on granitic rocks. In Cuyama Badlands, formation made up of brilliantly varicolored red and green claystone, arkosic sandstone, and incoherent conglomerates of terrestrial deposition; they form the picturesque badland topography. West of Cuyama River, beds apparently grade westward into Branch Canyon and Vaqueros formations, although relationships are obscured by structural complexities; here the redbeds were mapped by English (1916) as Pato red member of Vaqueros formation.

Type locality: Caliente Range, in Midway Peak Southwest and Elkhorn quadrangles.

California Granite[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1929, New York State Mus. Bull. 281, p. 52, 61–65.

Forms California phacolith, Lake Bonaparte quadrangle and extends into Antwerp quadrangle. Derivation of name not stated.

Call Sandstone Member (of Panoche Group)

Upper Cretaceous: Northern California.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2. p. 200, 202–203, 226 (fig. 5), pl. 3. Mainly massive brownish concretionary sandstone and some interbedded siltstones and gray clay-shale. Fairly persistent conglomerate, about 100 feet thick, occurs at base of member on northeast side of Butts Ranch syncline. Thickness 2,600 to 2,900 feet on northeast side of Butts Ranch syncline; 1,200 feet thick on southwest side of syncline. Overlies Paynes shale and sandstone member (new); underlies Butts Ranch shale member (new) on northeast side of syncline; unconformably underlies Big Oak Flat shale and sandstone member (new) on southwest limb of syncline; the unconformity cuts out about 1,200 feet of the Call within a horizontal distance of 1½ miles.

Type locality: Section exposed through Call Mountains on Paynes Creek 2 miles north of Butts Ranch, San Benito County.

Callahan Flow

Recent: Northern California.

M. A. Peacock, 1931, Geog. Review, v. 21, no. 2, p. 269–270. Recent flow in Modoc Lava field.

C. A. Anderson, 1941, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 7, p. 370. Discussed as one of three flows grouped under term Modoc basalt. Covers area of about 10 square miles.

Occurs in Modoc Lava field.

Callaway Limestone[1]

Middle Devonian: East-central Missouri.

Original reference: C. R. Keyes, 1894, Missouri Geol. Survey, v. 4, p. 30, 43.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 30–39. Formation described in Boone County, where it consists of three limestone facies: Cooper, Callaway, and Ashland. Underlies Bushberg formation of Sulphur Springs group; overlies Jefferson City formation.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 100 (fig. 3). Underlies Turpin sandstone member (new) of Grassy Creek formation.

Named for development in Callaway County.

Calliham Sandstone Member (of Whitsett Formation)

Calliham Sand[1]

Eocene, upper: South-central Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1315.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626 (table 1), 2633. Termed sandstone member of Whitsett. At type locality, about 22 feet of medium-grained irregularly cross-bedded sandstone is exposed in south bank of river; upper 10 feet shows concretionary induration; about 2 feet from top is fossiliferous lens containing *Corbula*-type pelecypods. Elsewhere sand is coarse grained and conglomeratic; southwest of Fashing, consists of two layers of fossiliferous very fine grained sandstone separated by 10 feet or more of silty clay; in gently sloping area around Fashing, becomes indistinguishable from Dubose member below and Fashing clay member above.

Type locality: About 0.6 mile north-northeast of village of Calliham where old Whitsett-Calliham Road crosses Frio River. Named for village of Calliham, which is near Frio River in McMullen County about 1 mile west of Live Oak County line on Farm Road 63 from Three Rivers to Tilden.

Call Mill Slate[1]

Precambrian(?) or Lower Cambrian: Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 225–226.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137, 138–140. Fine-grained argillaceous dark-purple or nearly black usually fissile slate. Maximum thickness about 100 feet. Underlies Pinnacle graywacke; overlies Tibbit Hill schist.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Geographically extended to northwestern Vermont. Precambrian(?).

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1135–1136. If present in Vermont, beds are included in Pinnacle formation.

Best exposed in gorge below Call Mill, Sutton quadrangle, Quebec.

Calloway Limestone

See **Callaway Limestone,** correct spelling.

Calls Fort Shale Member (of Bloomington Formation)

Middle Cambrian: Northwestern Utah.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 649, 651–652, 659–660, 672. Occurs at or near top of formation. High Creek section, Bear River Range, shows unit consists of limestone and shale 180 feet thick; 200 feet in Calls Fort section, Wasatch Range. Name credited to Norman Denson. (unpub. thesis).

Type locality: West side of Wellsville Mountain, near Calls Fort Monument, about 7 miles north of Brigham City, Box Elder County.

Callville Limestone[1]

Upper Mississippian, Pennsylvanian, and Lower Permian: Southeastern Nevada and northwestern Arizona.

Original references: C. R. Longwell, 1921, Am. Jour. Sci., 5th, v. 1, p. 47; 1928, U.S. Geol. Survey Bull. 798.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, no. 5, p. 930. Gray limestone, commonly thin bedded, with interbedded shale in upper part. Thickness about 2,000 feet. Underlies unnamed Permian red beds; overlies Bluepoint limestone. Pennsylvanian and Permian(?).

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 520–523. Restricted to Pennsylvanian limestones below Permian dolomitic beds. Where exposed in boundary area between Nevada and Arizona, contains two members: lower consists of thick-bedded cliff-forming commonly oolitic limestones which terminate by wedging beneath Shivwits Plateau; upper consists of silty, in many places crossbedded limestones that weather into subdued slopes. These limestones grade laterally and intertongue with lower Supai formation of Grand Canyon area. Thickness 277 to 673 feet. Sections show Callville overlies Rogers Spring limestone and Redwall limestone; underlies Pakoon limestone (new) in Grand Wash Cliffs.

Ben Bowyer, E. H. Pampeyan, and C. R. Longwell, 1958, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–138. As mapped in Clark County, Nev., includes Pakoon limestone of McNair (1951). Pennsylvanian and Permian.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). In Virgin Mountains, Nev., overlies Illipah formation.

U.S. Geological Survey currently designates the age of the Callville Limestone as Late Mississippian, Pennsylvanian, and Early Permian on the basis of a study now in progress.

Named for exposures in Callville Mountain, Clark County, Nev.

Caloosahatchee Marl[1] **or Formation**

Pliocene, middle: Southern and northern Florida.

Original reference: W. H. Dall, 1887, Am. Jour. Sci., 3d, v. 34, p. 161–170.

W. C. Mansfield, 1939, Florida Geol. Survey Bull. 18, p. 8, 10 (fig. 2). Overlies Tamiami formation (new). Pliocene.

R. O. Vernon, 1952, *in* A summary of the geology of Florida and a guidebook to the Cenozoic exposures of a portion of the state: Florida Geol. Survey, p. 58, 59. Prior to 1942, Pliocene series in Florida was composed of Citronelle formation, Tamiami limestone, Buckingham marl, Bone Valley gravel, Alachua formation, Charlton formation, and Caloosahtchee marl. Vernon (1942, Florida Geol. Survey Bull. 21) dated part of Citronelle as possibly early Nebraskan and the rest as Pleistocene alluvium. This fieldwork cast some doubt on dating of the "Pliocene" beds in south peninsula. Cooke (1945, Florida Geol. Survey Bull. 29) continued to recognize Alachua formation, Bone Valley formation, Buckingham marl, Caloosahatchee formation, Citronelle formation, and Tamiami as Pliocene. Presence of fresh-water mollusks in top of Caloosahatchee (as presently defined by U.S. Geological Survey) casts doubt on its present age assignment.

Recognition of upper Miocene beds in the peninsula eliminated all Pliocene beds in southern Florida except Caloosahatchee marl and Bone Valley formation. It is hoped that future fieldwork will definitely place these beds into Miocene or Pleistocene, or definitely prove them to be Pliocene in age.

J. R. DuBar, 1957, Illinois Acad. Sci. Trans., v. 50, p. 187–193; 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 133–135, 139–144. Subdivided to include (ascending) Fort Denaud, Bee Branch, and Ayers Landing members (all new). Unconformably overlies Tamiami formation; unformably underlies Fort Thompson formation (Okaldakoochee member, new). Thickness of exposed deposits commonly less than 10 feet, but base of formation visible in only a few places; test holes show thickness of 50 to 60 feet or more east of La Belle. Pleistocene (Sangamonian). Age determination based on vertebrate fossils.

J. R. DuBar, 1958, Florida Geol. Survey Bull. 40, p. 34–37, 41 (fig. 7), 49–64, 76–82, pls. Marl is exposed almost continuously in banks of Caloosahatchee River between Fort Denaud and Fort Thompson. Thickness commonly less than 10 feet. Base exposed only in few places. Exposed beds divided into (ascending) lower marine marl, *Cyrtopleura costata* zone, oyster biostrome, brackish-water marl, Bee Branch member, and upper shell bed. Unconformably overlies Tamiami formation; unconformably underlies Fort Thompson formation. Pleistocene, primarily on basis of vertebrate fauna and to lesser degree on molluscan fauna and stratigraphic relationships.

Named for exposures on Caloosahatchee River, Lee County, especially between Labelle and Olga.

Caloso Formation

Mississippian (Kinderhook): Northern and central New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 83, 86–87. Limestone unit with maximum thickness of 86 feet. Name credited to Noble (unpub. thesis).

A. K. Armstrong, 1955, New Mexico Bur. Mines Mineral Resources Circ. 39, p. 3, 32. Term Caloso formation, as used in this paper, restricted to lower 28 feet of sandstone, shales, and dense gray limestones which contain a small Kinderhook fauna. Disconformably underlies Kelly formation; unconformably overlies Precambrian gneiss and schist.

Louise Fillman, chm., Lexicon Committee, 1958, Lexicon of pre-Pennsylvanian stratigraphic names of West Texas and southeastern New Mexico: Midland, West Texas Geol. Soc., p. 30. As defined by Noble (unpub. thesis), comprises lower member chiefly of arkose and locally conglomeratic basal sandstone or shale, and shaly limestone beds; middle member of massive or thick-bedded resistant limestone with brown-weathering cherty gray limestone bed at top; and upper member, which thins northward, generally a medium-gray medium-bedded limestone containing many nodules and lenses of white and gray chert, and in certain zones is made up largely of white coquina.

A. K. Armstrong, 1958, New Mexico Bur. Mines Mineral Resources Mem. 5, p. 3, 5–7, 9, 11–12, 14–15. Age discussion and regional correlations.

Type locality: Along Caloso Arroyo in T. 2 N., R. 2 W., Ladron Mountains.

Calumet Amygdaloid[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane, 1907, Lake Superior Min. Inst. Proc., v. 12, p. 89–92.

E. S. Davidson and others, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–54. Included in Portage Lake lava series.

Named for occurrence at Calumet mine, Houghton County.

†Calumet Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane, 1907, Lake Superior Min. Inst. Proc., v. 12, p. 89–92.

T. M. Broderick, C. D. Hohl, and H. N. Eidemiller, 1946, Econ. Geology, v. 41, no. 7, p. 678 (fig. 1). Name used on geologic section of Michigan copper district.

Named for occurrence in Calumet mine, Houghton County.

Calumet Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Calumet Granodiorite

Eocene, lower: Colorado.

C. H. Behre, Jr., E. F. Osborn, and E. H. Rainwater, 1936, Econ. Geology, v. 31, no. 8, p. 786–792. Irregular mass of granodiorite with local differentiates that intrudes Paleozoic rocks in vicinity of Calumet mine. Hand specimens show a gray medium-grained crystalline rock generally equigranular with crystals unoriented but locally trachitoid to gneissic.

Occurs at abandoned iron mine at Calumet, Chaffee County.

Calumet and Hecla Conglomerate[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1895, Michigan Geol. Survey, v. 5, pt. 1, p. 117, footnote.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

Named for occurrence in Calumet & Hecla mine, Houghton County.

Calvert Ash Bed (in Ash Hollow Member of Ogallala Formation)

Calvert Ash Bed (in Valentine Member of Ogallala Formation)

Pliocene: Northwestern Kansas.

J. S. Carey and others, 1952, Kansas Geol. Survey Bull. 96, pt. 1, p. 9–11, 24–27. Name applied to volcanic ash bed. Thickness about 22 feet. Lies in lower half of Ash Hollow member and stratigraphically lower than Reager ash bed (new).

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 251. Reallocated to Valentine member of Ogallala formation.

Name derived from pit of Wyandotte Chemicals Corp., at Calvert, northeastern Norton County.

Calvert Formation[1] (in Chesapeake Group)

Miocene, middle: Eastern Maryland, Delaware, and Virginia.

Original reference: G. B. Shattuck, 1902, Science, new ser., v. 15, p. 906.

Lincoln Dryden and R. M. Overbeck, 1948, Maryland Dept. Geology, Mines and Water Resources [Rept.] Charles County, p. 53–61. Described in Charles County, where it includes Fairhaven diatomaceous earth member and Plum Point marls member. Overlies Nanjemoy formation; underlies Pleistocene deposits.

H. F. Ferguson, 1953, Maryland Dept. Geology, Mines and Water Resources Bull. 11, p. 35. In St. Marys County, formation is silty to sandy diatomaceous clay containing some thin shell beds in upper part. Basal part, Fairhaven diatomaceous earth member, consists of thick bed of yellowish-gray clay containing many diatoms. Thickness (in wells) 110 to 140 feet. Overlain by Pleistocene sediments in northern and western parts of county and by lithologically similar Choptank formation in central and southern parts. Chesapeake group.

Named for exposures in Calvert County, Md., especially in Calvert Cliffs, bordering Chesapeake Bay.

Calvert Bluff Clay Beds (of Rockdale Formation)[1]

Calvert Bluff Formation (in Wilcox group)

Eocene, lower: Central and southern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 585, 586, etc.

H. B. Stenzel, 1953, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists Mineralogists, and Soc. Econ. Geologists Joint Mtg. Guidebook, p. 53 (geol. map), 54. Rank raised to formation. Includes Butler clay member (reallocated). Overlies Simsboro formation.

Type locality: Calvert Bluff on Brazos River, Jesse Webb League, Robertson County.

Calvertian Substage

Miocene, middle: Maryland, New Jersey, and Virginia.

D. S. Malkin, 1953, Jour. Paleontology, v. 27, no. 6, p. 767, 768. Substage based on microfaunal assemblages; includes all sediments deposited in central Atlantic Coastal Plain province during time of accumulation of Calvert formation, type exposure of which is considered exemplary of the substage. In sequence, the Calvertian is followed by Choptankian substage.

†Calvin Sand Series[1]

Pennsylvanian: Central Oklahoma (subsurface and surface).

Original reference: A. I. Levorsen, 1927, Am. Assoc. Petroleum Geologists Bull., v. 1, no. 7, p. 658–682.

Seminole County.

Calvin Sandstone[1] (in Marmaton Group)

Pennsylvanian (Des Moines Series): Central and southern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas Folio 74.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 26–30. In Okfuskee County, divided into three unnamed members: basal sandstone, thick, middle shale, and upper sandstone. Thickness about 245 feet. Underlies Wetumka shale; overlies Senora formation. Marmaton group.

Type locality: Town of Calvin, Hughes County.

Camargo Formation

Ordovician (Richmond): South-central Tennessee.

C. W. Wilson, 1948, Geol. Soc. America Bull., v. 59, no. 8, p. 742–743. Proposed by M. G. Mehl (1928, unpub. ms.) for channel-filling sediments which he considered to be Silurian. Consists predominantly of greenish-blue to olive or light-brown arenaceous shales and shaly sandstones. Locally basal members consist of considerable thickness of limestone conglomerate and heavy-bedded coarse brown sandstone; lower members are distinctly valley fills. Coarse limestone blocks of talus along valleys of pre-Camargo surface now constitute Camargo conglomerates that are plastered across eroded edges of Fernvale, Leipers, and Catheys; this conglomerate grades laterally toward center of old valleys into coarse sandstones and even shales; succeeding the fills proper is a considerable thickness of light-brown to olive or green arenaceous shale that is widespread; locally this part of formation rests directly on the Fernvale or older rocks, but, in regions where lower fill is present, there is no evident break between the two parts of the formation. Thicknesses vary between 30 feet and something more than 100 feet and are measured from lowest exposure to highest adjacent Fernvale outcrop. Ordovician (Richmond).

Well exposed in Good Hollow and branches, about 2 miles southwest of Camargo, Lincoln County. Also about one-half mile west of Coldwater on Coldwater-Blanche Road.

†Camargo Schist[1]

Precambrian and Lower Cambrian: Southeastern Pennsylvania.

Original reference: A. I. Jonas and E. B. Knopf, 1921, Washington Acad. Sci. Jour., v. 11, p. 447.

Named for village of Camargo, near Quarryville, Lancaster County.

Camas Basalt[1]

Tertiary: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 99, map.

South side of Camas Prairie, Stevens County.

Cambridge Limestone Member (of Conemaugh Formation)[1]

Pennsylvanian: Eastern Ohio, western Pennsylvania, and West Virginia.

Original reference: E. B. Andrews, 1873, Ohio Geol. Survey, v. 1, p. 262.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 116–118. Included in Wilgus cyclothem, Conemaugh series. Occurs above Wilgus coal and underclay member and below Bakerstown shale and sandstone member of Anderson cyclothem. Member has also been called Upper Cambridge limestone and Pine Creek limestone, the latter a name which is still used in Pennsylvania.

Named for exposures near Cambridge, Guernsey County, Ohio.

Cambridge Red Bed (in Conemaugh Formation[1] or Group)

Pennsylvanian: Northwestern West Virginia and southwestern Pennsylvania.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 61, pl. 6.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C-26, p. 78, fig. 21. In Fayette County, occurs 230 to 250 feet above top of Upper Freeport coal, which is base of Conemaugh group. Lies below Upper Bakerstown coal and above Woods Run limestone. Thickness as much as 12 feet.

First described near Wheeling, Ohio County, W. Va.

Cambridge Slate[1] (in Boston Bay Group)

Cambridge Argillite

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: N. S. Shaler, 1871, Boston Soc. Nat. History Proc., v. 13, p. 173-175.

M. P. Billings, F. B. Loomis, Jr., and G. W. Stewart, 1939, Geol. Soc. America Bull., v. 50, no. 12, p. 1875, 1876, 1882. Referred to as argillite. Described as gray somewhat arenaceous argillite and slate. Carboniferous. Overlies Roxbury conglomerate, but latter is thrust over Cambridge in northern part of Hingham area.

Best exposed at Cambridge. Other occurrences also in Boston basin area.

Camden Chert[1]

Camden Formation

Lower or Middle Devonian: Western Kentucky and western Tennessee.

Original reference: J. M. Safford and C. Schuchert, 1899, Am. Jour. Sci., 4th, v. 7, p. 429-430.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 310-312. Camden formation consists of two contemporaneous phases of limestone and chert. Thickness 14 to 164 feet. Unconformably overlies Harriman formation; unconformably underlies Pegram formation at exposure near mouth of Standing Rock Creek and at the Whirl of Buffalo River; elsewhere underlies Chattanooga shale or Eutaw sand.

E. M. Luttrell and Ann Livesay, 1952, Kentucky Geol. Survey, ser. 9, Bull. 11, p. 5. Only known exposure of Camden chert in Kentucky is in narrow northeastward trending fault block one-fourth mile long, 0.4 mile south of Little Bear Creek on west side of Kentucky Lake, and 4½ miles above Kentucky Dam, near Aurora.

Named for exposures along Cypress Creek, southeast of Camden, Benton County, Ky.

†Camden series[1]

Upper Cretaceous and Eocene: Arkansas, Louisiana, southeastern Oklahoma, and eastern Texas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. for 1888, v. 2, p. 49-65, 177, 188.

Named for exposures in bluffs at Camden, Ouachita County, Ark.

Camelback Formation

Tertiary(?): South-central Arizona.

D. A. Holm, 1938, Oil possibilities of Arizona: Arizona State Land Dept., p. 32-33. Series of red arkosic conglomerates and sandstones. Consists of three members on Camelback Mountain (ascending): dark-maroon arkose, lying unconformably on older granite, about 100 feet thick; middle member of lighter color, composed of coarser material, with great angular boulders, about 200 to 300 feet thick; and dark-red arkose, in part conglomeratic, with sand matrix, well-defined bedding and ripple marks, at least 200 feet thick.

Occurs on west end of Camelback Mountain in Phoenix region, Maricopa County.

Camels Hump Group

Lower Cambrian and Cambrian(?): North-central Vermont.

W. M. Cady, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–79. Composed chiefly of schist, quartzite, and gneiss. Intergrades with overlying Ottauquechee formation. Overlies Precambrian interbedded gneiss, quartzite, and greenstone unconformably.

A. L. Albee, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–102. Described in Hyde Park quadrangle. Belvidere Mountain amphibolite is considered upper formation of group in northern part of quadrangle.

R. A. Christman, 1959, Vermont Geol. Survey Bull. 12, p. 23–37, geol. map. In Mount Mansfield quadrangle, occurs above Tibbet Hill schist and below Ottauquechee formation.

Typical section exposed in gorge of Winooski River west of and downstream from Waterbury. Named for wide occurrence on and near Camels Hump, a peak about 7 miles west of village of Waterbury in adjacent Camels Hump quadrangle. Traced about 30 miles southwestward from exposures in northwest part of Montpelier quadrangle.

Cameo Member (of Price River Formation)

Upper Cretaceous (Montana): Central western Colorado.

R. G. Young 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 188, 191, fig. 2. In Neslen facies. Uppermost coal-bearing rocks of formation; upper limit placed at boundary between coal-bearing rocks of this member and non-coal-bearing rocks of Farrer facies. The massive white-capped medium-grained cliff-forming basal littoral marine sandstone caps Mount Garfield near Palisade, first appearing near Hunter Canyon and continuing south beyond Grand Mesa; grades downward into tongue of Mancos shale, which lies disconformably on coal measures of Cozzette member (new). Above basal sandstone, near Mount Garfield, lies about 250 feet of coal-bearing rocks consisting of sandstone, sandy shale, carbonaceous shale, and coal at base of which is Cameo coal zone (C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851). About 60 feet above base of Cameo coal zone is Carbonera coal zone.

Named for exposures near town of Cameo, Mesa County.

Cameron Beds (of Tolchaco Gravels)

Quaternary: Central northern Arizona.

Parry Reiche, 1937, Am. Jour. Sci., 5th ser., v. 34, no. 200, p. 131–133, pl. 1. Medium member of Tolchaco gravels (new). Dominantly argillaceous. Partial section of upper-middle part of member, three-eights of a mile southeast of Graben Wash, is representative of bulk of beds there and to the northwest. Consists of red clays with occasional fine sand laminae; interbedded red and gray clays and buff loose massive silty very fine sands; and gray and pink bedded clays with silt partings. Individual beds range from 1 to 10 inches in thickness. Ranges in thickness up to as much as 65 feet.

In Cameron district of the Plateau Province. Lies at elevations about 170 feet above Little Colorado River profile.

Cameron Red Shale Member (of Greenbrier Series)[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 142.

Exposed in Cameron County.

Cameron Sandstone Member (of McAlester Formation)[1]

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. C. Branson, 1957, Geology Notes, v. 17, no. 11, p. 106. Abandoned by Oklahoma Geological Survey on the basis of the fact that name is preoccupied by Mississippian Cameron red shale in Pennsylvania. No replacement of Oklahoma name has been made.

Named for exposures west and northwest of Cameron, T. 8 N., R. 26 E., LeFlore County.

Cameron Creek Formation (in Big Snowy Group)

Cameron Creek Member (of Tyler Formation)

Mississippian or Pennsylvanian: Central Montana.

H. D. Hadley and P. J. Lewis, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 142. Varicolored shale with occasional thin limestones and irregular white to ferruginous sandstones. Thickness 50 to 300 feet. Overlies Heath shale and underlies Alaska Bench limestone. Name credited to L. S. Gardner.

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 233 (fig. 2), 334 (fig. 3), 335, 336 (fig. 4), 339, 343, 347. Included in Big Snowy group. Thickness at type locality herein designated 222 feet. Underlies Alaska Bench limestone; overlies Heath formation. Reasons for using Cameron Creek in preference to Tyler formation presented.

R. P. Willis, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1942 (fig. 2), 1952–1953. Rank reduced to member status in Tyler formation; overlies unnamed lower member; includes Bear Gulch tongue.

Type locality: Canyon of one of tributaries of south-draining Cameron Creek, a few hundred feet north of Stonehouse Ranch headquarters in sec. 31, T. 11 N., R. 21 E., Golden Valley, Mont., on southeast side of Big Snowy Mountains.

Camillus Shale (in Salina Group)

Camillus Shale Member (of Salina Formation)[1]

Upper Silurian: Western to east-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 18–19, chart.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Formation in Salina group. Occurs above Syracuse salt and below Bertie waterline. Cayugan series.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 7, fig. 1. Discussion of age of Brayman shale. Proposed that name Brayman be applied to undifferentiated strata of Camillus and Bertie age in area from Vanhornesville, Herkimer County, to Gallupville, Schoharie County. Term Camillus as used herein is restricted to strata lying beneath Fiddlers Green dolomite and above Vernon shale.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Field Conf., p. 7. Upper Silurian Cayugan series (revised) contains two formations, the Salina and Bertie. Salina consists of two facies: Vernon red shales near base and the Camillus gray calcareous shales and dolomites with salt and gypsum beds above.

W. P. Leutze, 1956, Am. Assoc. Petroleum Geolgists Bull., v. 40, no. 7, p. 1694 (fig. 1). Stratigraphic column of middle Salina group in Onondaga County shows Camillus shale, 160 to 190 feet, above Syracuse formation (where recognized in outcrop). Underlies Bertie waterline. Prior to this study, most publications listed fossils from Syracuse formation as coming from Camillus shale.

W. L. Kreidler, 1957, New York State Mus. Bull. 361, p. 5. Formation contains Syracuse salt member at base.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. In Salina group. At top of Canastotan stage (new).

Named for exposures at Camillus, Onondaga County.

Camino Cielo Sandstone Member (of Juncal Formation)

Eocene, middle: Southern California.

B. M. Page, J. G. Marks, and G. W. Walker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1730 (fig. 2), 1733 (fig. 3), 1734 (fig. 4), 1751–1752. Light-gray massive arkosic lenticular sandstone. Thickness at type locality 2,300 feet; 2 miles distant, at western boundary of map area, thickness is 300 feet; and at eastern boundary, 5½ miles distant, thickness is 1,700 feet. Occurs about middle of formation; present only on southside of Santa Ynez fault.

Type section: In roadcuts of Camino Cielo and Romero Canyon Roads, from 2,900 feet N. 21° W. to 1,400 feet S. 47° W. of Romero Saddle Guard Station on crest of Santa Ynez Range, Santa Barbara County. Extends westward parallel with crest of range, past western limit of map area; north and east of type locality is interrupted by Romero Saddle fault and the Franciscan "intrusive" mass, but continues again and extends past eastern limit of map area.

Camp Member (of Denmark Formation)

Middle Ordovician (Trentonian): Northwestern New York.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p 530, 531. Name given to basal member of Denmark formation. At type locality, consists of thick hummocky beds of rubbly weathering blue-gray nodular argillaceous calcilutite and shale with thinner intercalated beds of hard pure calcilutite, calcisiltite, and a few calcarentites. Maximum thickness 12 feet. Underlies Glendale member (new); overlies Shoreham formation.

Type section: Exposures extending for more than 1 mile on banks of Mill Creek, 1 mile east of Sackets Harbor, between New York State Highway 3 and New York Central Railroad bridge. Named for Camp Mills 2 miles east of Sackets Harbor, Jefferson County.

Campagrande Limestone

Campagrande Formation (in Trinity Group)[1]

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 47.

P. B. King, 1953, *in* P. B. King and P. T. Flawn, Texas Univ. Bur. Econ. Geology Pub. 5301, p. 99–100, pls. 1, 3. Referred to as Campagrande limestone. In Van Horn area, made up of several beds of massive ledge-making light-gray limestone, in part sandy or conglomeratic, and of nodular limestone and marl; at base is conglomerate containing chert and limestone fragments largely derived from the Hueco limestone. Thickness in Streeruwitz Hills 100 to 140 feet; in other areas 30 to 60 feet. Underlies Cox sandstone.

Named for Campagrande Draw, in Finlay Mountains, El Paso County.

Campbell Creek (Lower) Sandstone (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western Mercer and Summers Counties, p. 327.

Campbell Creek Limestone (in Breathitt Formation)

Campbell Creek Limestone (in Kanawha Formation[1] or Group)

Pennsylvanian: West Virginia and southeastern Kentucky.

Original reference: I. C. White, 1885, The Virginias, v. 6, p. 7–16.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 42, 60, 79, pl. 6. Slightly fossiliferous limestone 30 to 40 feet thick above Campbell Creek coal. In Kanawha group.

R. E. Hauser, 1953, Kentucky Geol. Survey, ser. 9, Bull. 13, p. 11 (fig. 2), 14–16. Zone of doorknob-shaped dense blue limestone concretions; individual concretions average 18 inches in thickness and 4½ feet in diameter. Zone occupies position near middle of a 35-foot brown shaly siltstone which locally contains lenses of sandstone. Occurs about 20 feet below Campbell Creek coal and 35 to 40 feet above Howard coal. Occurs in Paintsville quadrangle.

Named for exposures along Campbell Creek, Kanawha County, W. Va.

Campbell Mountain Rhyolite[1] (in Alboroto Group)

Miocene: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull. 718.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 93 (table 18). Alboroto rhyolite described in San Juan district. Lower part consists of tridymite rhyolite which includes Campbell Mountain and Willow Creek rhyolites and probably Outlet Tunnel quartz latite [all included in Alboroto group] of Creede district.

Named for Campbell Mountain, Creede district.

Campbells Ledge Black Slate (in Pottsville Formation)[1]

Pennsylvanian: Northeastern Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. G_7, p. 37–42.

At Campbell's Ledge, near Coxton, Lackawanna County.

Camp Branch Sandstone Member (of Pottsville Formation)[1]

Lower Pennsylvanian: Northern central Alabama.

Original reference: C. Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175.

Named for exposures along south bluff of Camp Branch, Birmingham district.

Camp Colorado Limestone Member (of Pueblo Formation)[1]

Camp Colorado Formation (in Pueblo Group)

Permian: Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 418.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in the Pueblo here given group status. Overlies Stockwether formation; underlies "Dothan" formation of Moran group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as limestone member of Pueblo formation. Consists of irregularly bedded fine- to medium-grained gray limestone, which commonly weathers brownish, and intervening thin beds of shale; at type locality and farther south, basal beds consist of fossiliferous shale interbedded with earthy discontinuous limestone layers; dark-blue to nearly black chert occurs commonly as nodules in upper limestone beds. Thickness 5 to 25 feet. Overlies Salt Creek Bend shale member; underlies Watts Creek shale member of Moran formation.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 269–270, pl. 11. Extended into Brazos River valley. Thickness 10 to 25 feet. Overlies Salt Creek Bend shale member; top of member not easily distinguished from overlying Watts Creek shale member of Moran formation.

Named for Camp Colorado, northeast of Coleman, Coleman County.

Camp Creek Group[1]

Camp Creek Series

Precambrian (Belt Series): Central western Montana.

C. D. Walcott, 1906, Geol. Soc. America Bull., v. 17, p. 3–6, 18 (table). Upper subdivision of Algonkian in Camp Creek, Mission Range section. Series consists of (descending) gray sandstones, 1,762 feet; reddish sandstones, 1,560 feet; greenish sandstones and shales and reddish sandstones 4,491 feet; gray sandstone, 700 feet; siliceous limestone, 198 feet; gray and reddish sandstones, 975 feet; and interbedded gray and reddish sandstones, 2,041 feet. Overlies Blackfoot series (new).

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 62, p. 27 (chart). Thickness over 5,000 feet in Phillipsburg district.

As group in Belt series: See Idaho correlation chart complied by M. G. Wilwarth, 1932.

Described from Mission Range.

Camp Creek Shale Member (of Pueblo Formation)[1]

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept. pt. 1, p. 387, 416.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Consists of red and gray shale, a little sandstone and several thin beds of gray limestones; species of *Schwagerina* occur in zones from base to top. Average thickness about 80 feet. Lowermost subdivision is shale which attains thickness of 8 to 12 feet in McCulloch County, but thins to 1 or 2 feet north of Colorado River, so as to bring overlying limestone beds of Camp Creek shale member close to Saddle Creek limestone; these limestone beds of the Camp Creek have been included with the Saddle Creek in eastern Coleman County and northward. Underlies Stockwether member. *Artinskia lilianae* Miller and Unklesbay, collected in northwestern McCulloch County, 20 feet above base of member, represents stratigraphically lowest known occurrences of this genus in North America. *Artinskia* is judged to indicate post-Pennsylvanian age of beds in which it occurs.

Named for Camp Creek, Coleman County.

Camp Davis Formation

Camp Davis Conglomerate

Pliocene, lower: Western Wyoming and southeastern Idaho.

A. J. Eardley and others, 1944, Hoback—Gros Ventre-Teton Field Conf., [geologic map]. Privately printed. Consists of conglomerates, fanglomerates, rhyolitic and andesitic flows, breccia and tuffs, and fresh-water limestone. Overlies Pass Peak conglomerate (new). Uppermost Miocene or lowermost Pliocene.

J. C. Bayless, 1950, Michigan Acad. Sci., Arts, and Letters, Papers, v. 34, p. 211 (fig. 1), 212 (table 1), 213–215. Formation geographically extended into Snake River Plains, Idaho. Includes several thousand feet of calcareous conglomerates, fanglomerates, sandstones, and fresh-water limestones. Near Alpine, contains beds of tuff, and in Calamity Point area is cut by two andesite sills 1,200 and 300 to 1,000 feet thick. Unconformably overlies Paleozoic and Mesozoic formations. At north end of Caribou Range, interbedded with or overlain by rhyolitic flows. Term Camp Davis replaces name Salt Lake formation as previously used in area. Conglomerates of map area probably correlate in age with Payette formation, and this name for the formation has priority over name Camp Davis. However, the conglomerates are lithologically similar to Camp Davis formation of western Wyoming, and name Camp Davis is herein retained. Miocene and Pliocene(?).

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 75–76, pls. In lower Hoback Valley, formation consists of (ascending) gray conglomerate which forms bold escarpments much of way from mouth of Camp Creek north to beyond Game Creek in southern Jackson Hole; interval of poorly indurated tuffaceous sand; white-weathering fresh-water limestone about 50 feet thick; upper red conglomerate at least 2,000 feet thick, best displayed on north side of lower Horse Creek about 1½ miles above Snake River. Thickness several thousand feet. Term has been extended to similar conglomerates and associated tuffs in Star, Grand, and Swan Valleys, Idaho. Late Miocene or early Pliocene. Type exposure noted.

J. D. Love, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 89–90. At type section, only basal 450 feet of several thousand is adequately exposed. In Horse Creek section, formation is more than 5,600 feet thick. Formation rests with slight angular unconformity on Lower Cretaceous rocks. Two thrust sheets composed of Triassic, Jurassic, and Cretaceous rocks involve conglomerate of Camp Davis formation. Lower thrust sheet attains maximum development between forks of Horse Creek and thins northward, wedging out in cliff face on north side of Horse Creek. Both bottom and top contacts are exposed. Upper thrust sheet thickens northward and cuts across upper half of formation. Hoback normal fault, part of which is of Pleistocene or Recent age, has downdropped the Camp Davis between 6,000 and 10,000 feet, thereby giving the rocks a strong northeast dip. Believed to be early Pliocene; age assignment based partly on fossils and partly on structural relations.

Type section (Love, 1956): Along east side of U.S. Highway 187 in sec. 29, T. 39 N., R. 115 W., Teton County. Named after Camp Davis, University of Michigan camp along Hoback River.

Camp Ground Member (of Deese Group)

Pennsylvanian (Desmoinesian): Central southern Oklahoma.

C. L. Ramay, 1957, (abs.) Ardmore Geol. Soc. Criner Hills Field Conf., p. 45. Member mentioned in discussion of Desmoinesian stratigraphy in Pleasant Hill syncline of Criner Hills.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc. Petroleum Geology of southern Oklahoma a symposium, v. 2, Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 33. Named credited to I. C. Hicks (oral commun., 1953), who applied it primarily to uppermost of major ridge-making sandstones of Deese group in Lake Murray State Park below Williams member—about 500 feet below that member and 1,600 feet or more above Rocky Point conglomerate. Fusulinid limestone a few inches thick present locally near base. Type locality stated.

Type locality: On east line NE¼SE¼ sec. 20, T. 5 S., R. 2 E., at east end of principal tent camp in park, Murray County.

Campito Formation

Campito Sandstone[1]

Precambrian(?) and Lower Cambrian: Eastern California.

Original reference: E. Kirk, 1918, U.S. Geol. Survey Prof. Paper 110.

C. R. Longwell, 1950, Geol. Soc. America Bull., v. 61, no. 5, pl. 1. Overlies Deep Spring formation; underlies Silver Peak group.

U.S. Geological Survey currently designates the age of the Campito Formation as Precambrian(?) and Lower Cambrian on the basis of a study now in progress.

Named for prominent exposures on Campito Mountain, Inyo Range.

Campitoan series

Precambrian (Protozoic): Eastern California.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 4, p. 307 (chart). Series, consisting of 3,600 feet of sandstones. Unconformable below Barrelian series and above Deepian series.

Occurs in Death Valley region.

Camp Jenkins Schist or Formation

Lower Devonian: Central Connecticut.

G. P. Eaton and J. L. Rosenfeld, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 2, p. 170 (fig. 1), 181 (table 1). Lead gray staurolite-garnet, biotit-muscovite schist with thin interbedded "sugary" micaceous quartzites. Overlies Mine Brook formation (new). Previous workers with the exception of Percival (1842, Report on the Geology of the State of Connecticut: New Haven), grouped the sequence of rocks from Collins Hill schist through Camp Jenkins schist as a single formation, and believed it to be intruded by Glastonbury, Maromas, and Haddom gneisses. Present work shows that these rocks represent four distinct formations, with unconformity separating Collins Hill from the others.

Camp Jenkins [now Ranger Headquarters of Meshomasic State Forest] is in Middle Haddam quadrangle, Middlesex County.

Camp Nelson Limestone[1] (in High Bridge Group)

Camp Nelson Member (of High Bridge Limestone)

Middle Ordovician: Central Kentucky.

Original reference: A. M. Miller, 1905, Kentucky Geol. Survey Bull. 2, p. 9, 12.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 12; D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 40–41. Lowermost formation in High Bridge (Highbridge) group. Underlies Oregon limestone. Essentially a lithographic type limestone, but contains recognizable masses of magnesian limestone. Thickness about 300 feet.

J. L. Rich, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 18. Referred to as member of High Bridge limestone.

Named for Camp Nelson, Jessamine County.

†Campobello Group[1]

Silurian: Southeastern Maine.

Original reference: N. S. Shaler, 1886, Am. Jour. Sci., 3d. v. 32, p. 47–60.

Named for development on Campobello Island, off southwest coast of New Brunswick, adjacent to southeastern part of Washington County.

Camp Springs Conglomerate[1]

Triassic: Northwestern Texas.

Original reference: D. D. Christner, 1926, Texas Univ. Bull. 2607, p. 16–17.

Well exposed at Camp Springs, near center of east line of Scurry County.

Camp Supply Beds[1]

Lower Cretaceous: Western Oklahoma.

Original reference: R. T. Hill, 1895, Am. Jour. Sci., 3d, v. 50, p. 227.

Near Camp Supply, G (now Custer) County.

Campus Formation[1]

Pleistocene: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pub., Dept. Geol. Bull., v. 2, p. 398, map.

Named because of its occurrence within limits of University Campus, Berkeley [on a hill behind the area now covered with buildings].

Camp Williams unit (in Salt Lake Group)

Post-early Oligocene and pre-late Pliocene: North-central Utah.

L. W. Slentz, 1955, Utah Geol. Soc. Guidebook 10, p. 23, 24 (fig. 6), 26–27. Salt Lake group, in Lower Jordan Valley, is divided into (ascending) Traverse volcanics, Jordan Narrows unit, Camp Williams unit, Harkers fanglomerate, and Travertine unit. Camp Williams is mostly mudstones and siltstones that are poorly consolidated and lesser amounts of impure sandstone; basal conglomerate, primarily of igneous detritus, also present. Characteristically red to tan. Thickness at least 100 feet; not completely exposed in most places.

Name derived from Camp Williams military reservation. Areal extent limited and confined to Jordan Narrows and immediate vicinity. Lower Jordan Valley defined as that part of Jordan Valley northward from Traverse Mountains to Great Salt Lake. Travertine unit, as much as 20 feet thick in places; overlies both Camp Williams and Jordan Narrows units.

Camulos formation[1]

Pliocene, middle or upper: Southern California.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 43, p. 316.

Named for railway hamlet of Camulos, a few miles directly west of Saugus Junction, Santa Clara Valley, Los Angeles and Ventura Counties.

†Canaan Formation[1]

Mississippian: West Virginia and western Maryland.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

Named for exposures in Canaan Mountain, Tucker and Grant Counties, W. Va.

†Canaan Limestone or Dolomite[1]

Cambrian and Ordovician: Connecticut.

Original references: J. D. Dana, 1872, Am. Jour. Sci., 3d, v. 4, p. 370; 1874, Am. Assoc. Adv. Sci. Proc; W. H. Hobbs, 1893, Jour. Geology, v. 1, p. 717–736, 780–802.

Canaan Mountain Fire Clay[1]

Pennsylvanian: Northeastern West Virginia.

Original reference: D. B. Reger, 1923, West Virginia Geol. Survey Rept. Tucker County, p. 190, 191, 444.

Top of Canaan Mountain, Tucker County.

Canaan Mountain Schist

Pre-Triassic: Northwestern Connecticut.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as predominantly schist; composed of quartz, oligoclase or andesine, biotite, garnet and sillimanite.

Named for Canaan Mountain in town of Canaan, Litchfield County.

Canada Hill Granite[1]

Canada Hill granite phase (of Hudson Highlands Complex)

Precambrian: Southeastern New York.

Original reference: C. P. Berkey and Marion Rice, 1919, New York State Mus. Bulls. 225–226, maps and passim.

K. E. Lowe, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 143–144. In place of Canada Hill, Reservoir, and Mahopac granites described by Berkey and Rice (1919), term Canada Hill granite phase of Hudson Highlands complex is used to include all rocks representative of granitic igneous activity in Hudson Highlands after Pochuck diorite phase and earlier than Storm King granite intrusion. Such generalization is necessary because of difficulty of distinguishing the three similar granite types in the field. Typical representative of Canada Hill phase is medium-gray medium-grained biotite granite.

Type locality: Kings quarry, south of Garrison, Canada Hill, Putnam County, is in midst of granite area.

Canadaway Formation (in Arkwright Group or Chautauqua Group)

Canadaway Group[1]

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1933, Geol. Soc. America, Preliminary list of titles and abstracts of papers to be offered at 46th annual meeting, Chicago, Ill., Dec. 28–30, p. 19, 82, 83, 84.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1748–1749, chart 4. Chadwick suggests limiting Canadaway group to Dunkirk and Gowanda formations and introducing a new group name for the beds—Laona, Westfield, Shumla, and Northeast—between the Canadaway and Conneaut.

I. H. Tesmer, 1954, Dissert. Abs., v. 14, p. 2317–2318. Discussion of stratigraphy of Cherry Creek quadrangle, New York. Canadaway group is reduced to formational status in Chautauqua group. Formation comprises (ascending) Dunkirk, South Wales, Forestville (new name to replace Gowanda), Laona, Westfield, Shumla, and Northeast members. Underlies Chadakoin formation.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 31–32. Basal formation in Arkwright group (new). Underlies Chadakoin formation. Average thickness about 1,050 feet in Chautauqua County. Chautauquan series.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 9, 10 (fig. 1). Formation, at type locality, consists of strata which lie between base of Dunkirk shale and base of Dexterville member of Chadakoin formation. Here the Canadaway consists of about 1,000 feet of strata, the lower part of which contains interbedded black and gray shale with limy concretions while upper part is composed of interbedded gray shale and siltstone. In Chautauqua County, contact between Canadaway and Chadakoin is marked by first appearance of brachiopod *Pugnoides duplicatus* in basal Dexterville. As this form does not continue eastward into Cattaraugus County, the Canadaway-Chadakoin contact is placed there at the last appearance of *Tylothyris mesacostalis* which occurs in "Machias" and Cuba members of Canadaway but which does not continue into younger Chadakoin. In type area, comprises (ascending) Dunkirk, South Wales, Gowanda, Laona, Westfield, Shumla, and Northeast members. Overlies Chemung. Perrysburg formation of Pepper and de Witt (1951) is not used in this paper because upper boundary of unit is indeterminable east of Perrysburg.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook 29th Ann. Mtg., p. 15–18. Group, in Wellsville area, comprises (ascending) Dunkirk shale, South Wales shale, Canaserage sandstone, Hume shale, Caneadea shale, Rushford sandstone, "Machias" shale, and Cuba sandstone. Underlies Chadakoin group. Chautauquan series. Term Perrysburg not used because the Laona or its correlate has not been traced into Wellsville region.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation, as mapped in western

Pennsylvania, includes "Portage" formation of northwestern Pennsylvania.

Type section: Along Canadaway Creek, near Dunkirk, Chautauqua County, N.Y.

†Canadian Series[1]

†Canadian Period[1] or System[1]

Lower Ordovician: North America.

Original references (Period or System): J. D. Dana, 1874, Am. Jour. Sci., 3d, v. 8, p. 214; 1875, Manual of geology, 2d ed., p. 142, 163, 182; E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 647–679, pl. 27.

E. O. Ulrich and G. A. Cooper, 1938, Geol. Soc. America Spec. Paper 13, p. 1–321. Canadian [system] zoned for brachiopods. Canadian consists of lower, middle, and upper divisions. The Canadian follows the Ozarkian and precedes the Ordovician.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2. As shown on correlation chart, the Canadian is lowermost series of Ordovician system. It is succeeded by Champlainian series. Stages have not yet been established in the Canadian. Generalized standard section includes (ascending) Gasconade, Roubidoux, Jefferson City, Cotter-Smithville, and Black Rock formations.

R. H. Flower, 1957, New Mexico Bur. Mines Mineral Resources Mem. 2, p. 17–18. Believed that recognition of Canadian as distinct system would simplify problem of early Paleozoic stratigraphy. The Canadian would be a four part system, and this would leave remainder of Ordovician to be resolved in terms of Chazyan, Mohawkian, and Cincinnatian. Ordovician as thus restricted would begin with Cooper's Whiterock stage. Tentative classification of units in Canadian suggested: Gasconadian, Demingian, Jeffersonian, and Cassinian. Classification based principally on cephalopod distribution.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–32. Canadian series includes Gasconadian, Demingian, Jeffersonian, and Cassinian stages.

Named from development in Canada.

Canajoharie Shale[1] (in Trenton Group)

Middle Ordovician: Eastern New York.

Original reference: J. M. Clarke, 1911, New York State Mus. Bull. 149, p. 10–12.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 267 (fig. 11), 268–271. Formation comprises the older shales of Mohawk Valley; these overlie the lowest Sherman Fall Shoreham limestone, are of about Denmark (Sherman Fall) age, and are overlain by similar shales of Utica formations. At type section, formation includes Minaville member (new) and Fairfield member. Overlies Glens Falls formation. The Canajoharie thickens eastward, and it is believed that the Snake Hill represents an eastern more sandy facies of the Canajoharie and consists of the initial deposits of clastic rocks resulting from Vermontian (middle Trenton) orogeny; upper part of Schenectady formation contains characteristic upper Canajoharie (Fairfield) graptolites. Southward and eastward from upper West Canada Creek valley, the Denmark member (new) of Sherman Fall formation passes through the Dolgeville interbedded facies into the Canajoharie shale.

Named for outcrop at Canajoharie, Montgomery County.

Canal Limestone[1]

Pennsylvanian: Northeastern Pennsylvania.

Original reference: C. A. Ashburner, 1886, Pennsylvania 2d Geol. Survey Ann. Rept 1885, p. 445.

Crops out on southeastern band of the canal, 800 feet southwest of mouth of Mill Creek, Luzerne County.

†Canandaigua Shale[1]

Middle Devonian: Central and western New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 22 [p. 67, 1912 ed.].

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 364, 369. Incidental mention in discussion of Ledyard and Tichenor members of Ludlowville formation.

Canary Ironstone

Pennsylvanian (Allegheny Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 58. Typically calcareous concretionary ironstone. Included in Clarion cyclothem and lies below Clarion underclay member and above Clarion shale and (or) sandstone member.

Present in Athens County.

Canas Gypsum Member (of Yeso Formation)

Permian: Central New Mexico.

C. E. Needham and R. L. Bates, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1660. Commonly pure white gypsum; locally, thin silt partings and thin limestone beds. Thickness 96 feet at Lomo des las Canas, 52 feet in Yeso type section, 80 feet in southern Chupadera Mesa, and 115 feet at Bent, Otero County. Disappears a short distance north of Yeso type section. Occurs above middle evaporite unit of Yeso; underlies Joyita sandstone member (new).

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 61. Overlies Torres member (new).

Name taken from the Loma de las Canas, a range of hills 9 miles due east of Socorro, Otero County.

Cañas Arriba Formation

Oligocene, lower: Puerto Rico.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 54. Name adopted to replace Río Descalabrados series (Hodge, 1920) for the following reasons: Hodge's term referred to Eocene, not Oligocene; name not well chosen as no outcrops occur along river in question; and strata are distinctive enough from those of Rio Jueyes and Coamo Springs to merit separate name. Estimated thickness 2,000 feet. Locally underlies Juana Díaz formation; near town of Juana Díaz, lower Oligocene is in contact with middle Oligocene Juana Díaz formation; towards southwest, the Cañas Arriba is overlain by Quaternary deposits.

Named for occurrence in Barrio Cañas Arriba, north of Cuarto Calles Coamo-Guayama district.

Canaseraga Sandstone[1] Member (of Perrysburg Formation)

Canaseraga Member (of Canadaway Formation)

Canaseraga Sandstone (in Canadaway Group)

Upper Devonian: West-central New York.

Original reference: G. H. Chadwick, 1923, Geol. Soc. America Bull., v. 34, p. 69.

W. H. Bradley, J. F. Pepper, and G. B. Richardson, 1938, U.S. Geol. Survey Bull. 899–A, p. 17, pl. 3. Unit termed Dunkirk sandstone in this report was named Canaseraga by Chadwick. Later he found the Canaseraga to be a sandy phase of the Dunkirk. He now recommends dropping term Canaseraga; this recommendation is herein followed.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Revived and redefined as sandstone member of Perrysburg formation (new). These siltstones and sandstones are a definite unit around Canaseraga in central part of State and are not represented in rock sequence in vicinity of Dunkirk in western New York. At type exposure, member consists mainly of thin-bedded to massively bedded siltstones and some interbedded silty gray shale containing a few thin layers of black shale near base; top not exposed. Toward the west in Genesee River valley, upper siltstone of Canaseraga thins and grades laterally into black, dark-gray, and blackish-gray shale of Hume member (new). East of Dalton, upper part of member becomes more massive as siltstone increases in thickness and interbedded shale decreases. In Bath and Woodhull quadrangles, underlies Canisteo member (new); underlies and interfingers with South Wales member (new) to west. Thickness 163 to about 308 feet.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 12. Member of Canadaway. Overlies South Wales member; underlies Hume member.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17 (table 2), 18. Formation in Canadaway group.

Type exposure: On Slader Creek, south of Canaseraga, Allegany County.

Canastotan Stage

Upper Silurian (Cayugan): North America.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser., no. 1. Cayugan series is divided into Canastota(n) and Murder(ian) stages. Canastota stage contains all of Salina group from base of Vernon shale to top of Camillus—Lower Cayugan of previous usage. About 850 feet of Canastotan rocks present in type area.

Type area: Sullivan, Lincoln, Oneida, and Vernon Townships near Canastota. Chittenango and Oneida quadrangles, New York.

Cañazas Formation[1]

Miocene(?): Panamá.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 247.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 328–329.

Occurs near Cañazas, Veraguas Province.

Canby Latite[1]

Oligocene(?) or Miocene(?): Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 120.

Named for prominence in Canby Mountain, Silverton quadrangle.

Candelaria Formation[1]

Lower Triassic: Southwestern Nevada.

Original reference: S. W. Miller and H. G. Ferguson, 1936, Geol. Soc. America Bull., v. 47, p. 241–252.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1953, Geology of the Coaldale quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–23]. Described in Coaldale quadrangle where it consists largely of dark tuffaceous sandstone with thin conglomerate lenses and some shale; locally as much as 2 feet of basal conglomerate with fragments from Palmetto formation. Unconformable above Diablo formation (new); not in contact with Middle Triassic(?) Excelsior formation, and it is presumed that the two are present on different plates of major thrust. Thickness 3,225 feet at type locality.

Type locality: About 2 miles southeast of Candelaria, Mineral County.

Candler Formation (in Evington Group)

Candler Phyllite and Schist

Paleozoic(?): South-central Virginia.

W. R. Brown, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1547. Incidental mention of phyllite and schist.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1), 93. Formation described as lustrous gray-green phyllite and fine- to coarse-grained schists. Some quartzites and greenstone volcanics(?). Garnet- staurolite- and chloritoid-bearing facies widespread in eastern areas. Thickness 1,500 to about 4,000 feet. Underlies Joshua schist (new); both in Evington group (new) of Paleozoic(?) age. Overlies Catoctin greenstone. Type locality designated.

G. H. Espenshade, 1954, U.S. Geol. Survey Bull. 1008, p. 14–16, pl. 1. Thin lenses of white quartzite and white marble and lenses of blue marble locally interbedded with phyllite.

W. R. Brown and H. C. Sunderman, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1356. Includes Esmont slate facies (new).

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2), 31–33, 48, pl. 1. Age shown on columnar section as Lower Paleozoic(?).

Type locality: Candler Mountain 2 miles south of Lynchburg, Campbell County, Lynchburg quadrangle.

Caneadea Member (of Perrysburg Formation)

Caneadea Member (of Canadaway Formation)

Caneadea Shale[1] (in Canadaway Group)

Upper Devonian: Southwestern New York.

Original reference: G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, no. 3, p. 200.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Rank reduced to member status in Perrysburg formation (new). Restricted to all rocks between top of Hume shale member (new) and base of Luther's Rushford sandstone which is exposed in Caneadea Gorge 3.3 miles east of Rushford. Lower part of member consists of gray siltstone ranging in thickness from 1 to 20 inches, which is interbedded with gray silty shale. Middle part is largely shale containing some siltstone. Upper part, which is exposed along Caneadea Creek below Rushford Dam, is shale containing many thin beds of siltstone. No complete exposure present. Estimated thickness 280 feet. Figure 4 shows that Caneadea, Canisteo (new), and Gowanda members, although closely related in time of deposition, are not strictly correlative throughout.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 12. Member of Canadaway formation. Overlies Hume member; underlies Rushford member.

L. V. Rickard, 1957, New York State Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17 (table 2), 18. Formation in Canadaway group. Overlies Hume shale; underlies Rushford sandstone.

Well exposed in Caneadea Gorge, west of town of Caneadea in Angelica quadrangle, Allegany County. This is same locality as that given by Chadwick "on Caneadea Creek, just below the power dam."

Canebrake Conglomerate

Pliocene: Southern California.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 22 (fig. 1), 23, pl. 2. Defined as the coarse marginal conglomerate facies of Palm Spring and Imperial formations. Thickness at type section about 7,000 feet. Most westerly exposures are fanglomerate that laps onto and against crystalline "basement" rocks. Southeastward along strike, lower 4,000 feet of conglomerate grades into Imperial and Palm Spring formations; upper 3,700 feet persists basinward into Carrizo Valley as a gray pebble and cobble conglomerate that rests on Palm Springs formation; this conglomerate thins to about 2,500 feet on south side of Coyote Mountains. In Indio Hills, Canebrake is difficult to distinguish from overlying Ocotillo conglomerate (new). In Mecca Hills, overlaps onto Orocopia schist; southeast of Box Canyon, overlies Dos Palmas rhyolite (new); southward from Salton Sea, Truckhaven rhyolite (new) wedges into the Canebrake.

Type section: At southeastern base of Vallecito Mountain, 3 miles west of Fish Creek Wash, Imperial County. Name derived from Canebrake Wash.

Cane Creek Formation

Middle Ordovician (Mohawkian): Southwestern Virginia and northeastern Tennessee

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 51, chart 1 (facing p. 130). Mostly thin-bedded gray to dove limestone weathering to light gray; limestone layers often separated by thin shale partings. Sequence contains several bentonites; two thick ones near top. Greenish mudstone bed 30 feet thick near base. Total thickness 150 feet. Overlies Hardy Creek formation. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: Along L. and N. Railroad east of Cane Creek and approximately one-half mile west along railroad from Ben Hur Station, Ben Hur quadrangle, Lee County, Va.

Cane Hill Member (of Hale Formation)

Pennsylvanian (Morrow Series): Northwestern Arkansas and northeastern Oklahoma.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1938–1939, 1948 (fig. 2). Name applied to lower member of Hale formation. Composed of silt, silty sandstone, and fine-grained sandstone; locally calcareous. Bedding is generally shaly or thin and sheety, or consists of shaly siltstone alternating with thin hard beds of sandstone. Thickness ranges from thin edge to 65 feet. Unconformably underlies Prairie Grove member (new); overlies Pitkin limestone or, where the Pitkin has been removed by erosion, the Fayetteville shale.

Typically exposed in southern part of Washington County, Ark., in vicinity of Cane Hill. Well exposed beside Arkansas State Highway 59 for 3 miles along the road south of Evansville in SE¼ sec. 35, T. 13 N., R. 33 W. Extends westward a short distance into Oklahoma.

Canelo Redbeds

Cretaceous(?): Southeastern Arizona.

J. H. Feth, 1948, Am. Assoc. Petroleum Geologists Bull. v. 32, no. 1, p. 83, figs. 1, 2. Post-Permian, probably Cretaceous, sandstones, shales, conglomerates, quartzites, and thin-bedded limestones. Thickness of 1,360 feet in northern Canelo Hills. Underlie unnamed fanglomerate of Tertiary(?) age; overlie unnamed sandstones and conglomerates of Cretaceous(?) age.

Named for their characteristic occurrence in canyons of the northern Canelo Hills, approximately 25 miles northeast of Nogales and 60 miles by road southeast of Tucson.

Cane River Formation (in Claiborne Group)[1]

Eocene, middle: Western Louisiana, southern Arkansas, and eastern Texas.

Original reference: W. C. Spooner, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, no. 1, p. 7; no. 3, p. 220, 224, 227, 235–236.

D. B. Tait, R. C. Baker, and G. A. Billingsley, 1953, U.S. Geol. Survey Circ. 241, p. 7. Geographically extended into southern Arkansas where it crops out about 5 miles north of Columbia County line.

R. F. Dinnean, 1958, Louisiana Geol. Survey Geol. Summ. no. 1, p. 5, pl. 1. Formation crops out in southwestern part of Chestnut salt dome area, Natchitoches Parish. Composite section obtained partially from auger holes on south side of dome is 107½ feet thick. Includes a lower 13-foot noncalcareous sequence of sandy blue-green and brown clay, a middle 27-foot calcareous fossiliferous member of blue-gray, green, and dark-brown glauconitic marl, and an upper 67-foot noncalcareous sequence with few glauconite beds. Overlies Carrizo formation; underlies Sparta formation. Claiborne group.

Type locality: Baden Hill on Cane River, one-half mile north of Natchitoches, Natchitoches Parish, La.

Cane Spring Formation

Upper Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]. Massive dolomite and limestone, with thin-bedded impure limestone and shale in lower part. Thin lava flow near base and 20-foot lens of dark-brown siliceous conglomerate 100 feet above base. Total thickness more than 1,000 feet. Conformably underlies Osobb formation (new); conformably overlies Augusta Mountain formation (new).

Type locality: Summit and southeast slope of Augusta Mountain in vicinity of Cane Spring, 2 miles south of quadrangle boundary.

Caney Shale[1]

Mississippian: Central southern and southeastern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

J. C. Barker, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 173–178. Formation in Lawrence uplift area has two facies, a lower calcareous siltstone phase and an upper black shale unit. Subsurface stratigraphers have referred to calcareous phase as "Mayes." This phase is exposed in only three localities, and it was not feasible to map it as separate unit; it is here referred to as "Ada Mayes." Thickness 350 to 720 feet. Unconformably overlies Welden limestone; underlies "Springer" shale.

M. K. Elias, 1956, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma, a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 57–75. Mississippian Caney shale, in northern Arbuckle Mountains, is divided into (ascending) Ahlosa (Ahloso), Delaware Creek, and Sand Branch members (new). Term Ahlosa (Ahloso) is introduced for unit commonly referred to as "Mayes" or "Ada Mayes." Overlies Welden limestone; underlies Rhoda Creek formation (new). In this area is Meramec and Chester. In southern Arbuckle Mountains, Caney shale (previous usage) contains Delaware Creek and possibly upper part of Ahloso; underlies Goddard shale.

Jerome Westheimer, 1956, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma, a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 392–393. Proposed that term Caney be restricted to those Mississippian sediments around Arbuckle Mountains overlying Sycamore limestone and that a new name be assigned to post-Caney, pre-Springer sediments. Goddard shale is now known to be time equivalent of upper part of Caney shale as developed on northeast flank of Arbuckles and is of essentially same age as Elias' lower and upper Sand Branch members of the Caney.

M. K. Elias and C. C. Branson, 1959, Oklahoma Geol. Survey Circ. 52, p. 3–24. Caney shale is established in region in which it was originally described by designating a type section in Arbuckle Mountain area. Five measured sections in adjacent ravines west of Viola townsite are so designated, and type sections of three members are likewise established there. Original type locality is abandoned except as source of name, and the shales which there contain exotic boulders are left under name of Johns Valley shale. Thickness at type locality about 381 feet; top of shale not preserved in type section. Shale is Mississippian consisting of Meramecian Ahloso member, Delaware Creek member (later Meramecian and early Chesterian), and late Chesterian Sand Branch member. Sycamore sandstone exposed below Caney type section is unlike Sycamore of its type area and may be facies of grading into Ahloso member, Summary of history relative to confusion in use of term Caney.

J. D. Prestridge, 1959, *in* Ardmore Geol. Soc., Petroleum Geology of southern Oklahoma, a symposium, v. 2; Tulsa, Am. Assoc. Petroleum Geologists. p. 158 (fig. 2), 161. Overlies Worthey member (new) of Sycamore formation.

Type section (Elias and Branson): Sec. 14, T. 2 S., R. 7 E., Johnston County.

Caney Creek Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. Spec. Paper 22, p. 76, 157, 159–160, 202, pls. 6, 15. Predominantly siltstone and shale. As much as 72 feet thick. Underlies Clementsville member (new); overlies unnamed shaly member. Included in Liberty facies (new) of formation.

Type locality: A prominent knob, at head of Caney Creek, 2 miles east of Lebanon, Marion County.

Caney Point Marl Member (of White Bluff Formation)

Eocene (Jacksonian): Southeastern Arkansas.

H. S. Puri, 1952, Jour. Paleontology, v. 26, no. 2, p. 202, 209. Mentioned in a list of fossil localities.

L. J. Wilbert, Jr., 1953, Arkansas Div. Geology Bull. 19, p. 39, 56–70. One of three marine facies of formation. Typically calcareous glauconitic clay containing a varied invertebrate fauna; includes the more calcareous elements of the formation. Thickness 11 to 20 feet. Occurs in basal part of formation; stratigraphically equivalent with Pastoria sand member; underlies Rison clay member in Drew and Lincoln Counties, contact gradational; sharply separated from underlying Claiborne beds by a contact that shows evidence of disconformity. Type locality designated.

Type locality: Caney Point, on Saline River, approximately 5½ miles northwest of crossroads at Rye, Cleveland County. Outcrops are largely restricted to the upland which parallels the Saline River on the west, extending from east-central Bradley County to northwestern Cleveland County.

Caneyville Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southeastern Nebraska, and northeastern Oklahoma.

Original references: R. C. Moore, M. K. Elias, and N. D. Newell, 1934, Stratigraphic section of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc. [Am. Assoc. Petroleum Geologists 20th Ann. Mtg.]. Mar. 21–23, Wichita; R. C. Moore, 1935, Kansas Geol. Survey Bull. 20, table facing p. 14.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 172; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 58. Consists of three limestones and separating shales in southern part of outcrop area; two limestones and a shale elsewhere. In northern Kansas where no discernible boundary between Caneyville and Pony Creek is found, strata from base of Nebraska City limestone to base of Brownville limestone are designated Caneyville-Pony Creek, or may be called Wood Siding formation, which is defined by Nebraska Geological Survey to have limits that correspond exactly to Caneyville-Pony Creek. Thickness about 21 feet. Comprises (ascending) Nebraska City limestone member, unnamed shale, limestone, shale sequence, and Grayhorse limestone member. Underlies Pony Creek shale; overlies French Creek shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 13. In Nebraska Caneyville shale is a poorly defined member of Wood Siding formation;

thickness 6 to 10 feet. Underlies Pony Creek shale member with boundary indefinite; overlies Nebraska City limestone member.

Type locality: Sec. 11, T. 32 S., R. 8 E., Chautauqua County, Kans. Name derived from Caneyville Township.

Caneyville Shale [1] Member (of Wood Siding Formation)

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 9.

See Caneyville Limestone (in Wabaunsee Group).

Type locality: Sec. 11, T. 32 S., R. 8 E., Caneyville Township, Chautauqua County, Kans.

Canisteo Shale Member (of Perrysburg Formation)

Upper Devonian: Western and west-central New York.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Proposed for 190 feet of soft bluish-gray to olive-drab shale that overlies Canaseraga sandstone member in Greenwood, Hornell and Woodhull quadrangles. This is basal part of sequence which according to Bradley (Bradley and Pepper, 1938, U.S. Geol. Survey Bull. 899–A) was named Gowanda by Chadwick and traced by him from vicinity of Gowanda to vicinity of Canisteo. Absence of definite top to Gowanda member east of Gowanda and presence of thin layers of siltstone and shale at base of Canisteo member and top of Canaseraga between Wiscoy and Hornell indicate that the Canisteo, Caneada, and Gowanda members, although closely related in time of deposition, are not strictly correlative throughout. Above Canisteo is thick unnamed sequence of silty shale, siltstone, and sandstone; the Canisteo grades upward into this unit, which probably contains upper part of Caneadea member.

Named for occurrence in vicinity of Canisteo, Steuben County.

Canjilon Till

Quaternary: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103; 1938, Jour Geology, v. 46, no. 7, p. 937 (fig. 4), 959. Named as oldest of seven Quaternary formations in area. Underlies Canones andesite (new); Quaternary formations overlie pre-Quaternary rocks with angular unconformity.

Occurs in Abiquiu quadrangle, Rio Arriba County.

Cannelton Limestone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: I. C. White, 1885, The Virginias, v. 6, p. 8, 15.

H. R. Wanless, 1939, Geol. Soc. America Special Paper 17, p. 79. Slightly fossiliferous marine limestone; occurs near middle of Kanawha group, between Brownstown sandstone (above) and Matewan coal.

Occurs in vicinity of Cannelton, Fayette County.

Cannelton Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southwestern Indiana.

Original reference: T. C. Hopkins, 1896, Indiana Dept. Geology and Nat. Resources 20th Ann. Rept. p. 314.

Quarried at Cannelton, Perry County.

Cannelton Shale (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 151–152, 170.

Canning Ridge Quartz Monzonite

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Name applied to quartz monzonite occurring in stock on Canning Ridge.

Occurs at south end of Wylie Mountains, Culberson County.

Canning Ridge Trachyte

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Name applied to trachyte occurring in stock on Channing Ridge.

Occurs at south end of Wylie Mountains, Culberson County.

Cannon Limestone[1]

Cannon facies (of Bigby-Cannon Limestone)

Middle Ordovician: Central and eastern Tennessee and southwestern Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 417, 418, 429, pl. 27.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 2 (fig. 1), 80, 126–134. Bigby limestone grades laterally into Cannon limestone; the two are contemporary facies of unit here termed Bigby-Cannon limestone which overlies Hermitage formation and underlies Catheys formation. All included in Nashville group.

Well exposed southwest of Kettle Creek pool, Cannon County, Tenn.

Cannonball Member (of Fort Union Formation)

Cannonball Formation (in Fort Union Group)

Cannonball Marine Member (of Lance Formation)[1]

Paleocene: Southwestern North Dakota and northwestern South Dakota.

Original reference: E. R. Lloyd, 1914, U.S. Geol. Survey Bull. 541, p. 248, 249.

W. M. Laird and R. H. Mitchell, 1942, North Dakota Geol. Survey Bull. 14, p. 18–20. Formation in Fort Union group. Comprises upper 250 to 300 feet of old Lance formation. Typically exposed along Cannonball River. To west, intergrades with underlying Ludlow formation; in mapped area [southern Morton County], overlies and is gradational with the Ludlow. Conformably underlies Tongue River formation.

S. K. Fox, Jr., and R. J. Ross, Jr., 1942, Jour. Paleontology, v. 16, no. 5, p. 660–673. Analysis of 64 species of foraminifera from Cannonball beds of North Dakota indicates their Midway (Paleocene) age. This supports recent evidence from paleobotany and from vertebrate paleontology, but is contrary to former belief, based on Cannonball mollusks and corals, that the Cannonball is of late Cretaceous age.

O. A. Seager and others, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1414, 1415, 1417. Fort Union in North Dakota represented by three members: Tongue River, Cannonball, and Ludlow. The Cannonball and Ludlow are interfingering contemporaneous sediments of early Paleocene age.

R. E. Stevenson, 1954, Areal geology of the Morristown quadrangle (1:62,500); 1957, Geology of Ralph quadrangle (1:62,500); 1957, Geology of the McIntosh quadrangle (1:62,500); South Dakota Geol. Survey. Formation mapped in Morristown, Ralph, and McIntosh quadrangles. Thicknesses: 60 to 75 feet, 95 feet, and 170 feet in respective quadrangles. In Morristown quadrangle is top of section; interfingers with underlying Ludlow formation; in Ralph quadrangle, includes Giannonatti facies at top, interfingers with underlying Ludlow formation, and underlies Tongue River formation; top of section in McIntosh quadrangle and interfingers with underlying Ludlow.

N. H. Darton, 1951, Geologic map of South Dakota (1:500,000): Mapped as Cannonball formation.

Typically exposed in bluffs of Cannonball River, Tps. 132 and 133 N., R. 8 W., Morton County, N. Dak.

Cano Member (of Mesaverde Formation)

Upper Cretaceous: North-central New Mexico.

C. E. Stearns, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 463 (fig. 2), 466, pl. 1. Massive sandstone interbedded in Mancos shale. First massive sandstone characteristic of Mesaverde in area. Thickness increases southward from 25 feet in Arroyo Pinovetito to at least 225 feet southeast of Hogan.

H. E. Wheeler and V. S. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 10, p. 2415–2416. By use of map patterns and symbols, Stearns (1953) implies that an unexposed cutoff separates Cano member from undifferentiated Mesaverde. Yet this so-called Mesaverde member occurs only as part of Mancos shale, with no indication that it occurs anywhere in vertical sequence as recognized part of formation of which it is a designated member.

Present only in Tongue Valley.

Canoas Siltstone Member (of Kreyenhagen Shale)

Canoas Silt

Eocene: Central California.

B. L. Clark, 1943, California Div. Mines Bull. 118, pt. 2, p. 189 (fig. 72) [preprint 1941]. Shown on correlation chart as Canoas silt underlying "Kreyenhagen" proper and overlying the Domengine.

J. A. Cushman and S. S. Siegfus, 1942, San Diego Soc. Nat. History Trans., v. 9, no. 34, p. 390–391. Consists of greenish-gray soft crumbly clayey siltstone, with a few thin beds of light-gray fine sand. Thickness 110 feet. Basal member of Kreyenhagen; conformably overlies Avenal sandstone.

Type locality: In Garza Creek, Kings County.

Canon (Canyon) Rhyolite[1]

Miocene (Barstovian): Northwestern Nevada and southeastern Oregon.

Original reference: J. C. Merriam, 1910, California Univ. Dept. Geology Bull., v. 6, no. 2, p. 29, 30, 31–33.

D. O. Cochran, 1959, Oregon Dept. Geology and Mineral Industries Bull. 50, p. 10 (chart), 11. Canyon rhyolite listed with Cenozoic formations of Oregon. A highly silicic dense rhyolite with characteristics suggesting welding in some areas and with flow structures present elsewhere. Thickness about 400 feet. Overlies Steens basalt; underlies Virgin Valley formation.

Type area: Virgin Valley, Nev. Name derived from Thousand Creek Canon (Canyon), Humboldt County, Nev.

Canones Andesite

Quaternary: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103. Named as second of seven Quaternary formations in area. Younger than Canjilon till (new); older than Vallecito basalt (new).

H. T. U. Smith, 1938, Jour. Geology, v. 46, p. 937 (fig. 4), 959. In sequence listed, Canones andesite is younger than Canjilon till and older than Hinsdale(?) and Lobato basaltic lavas (new).

Occurs in Abiquiu quadrangle, Rio Arriba County.

Canter Limestone[1]

Mississippian: Southern Ohio.

Original reference: E. B. Andrews, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 158, 163.

In Hamilton Township, Jackson County.

Canterbury Gneiss

Canterbury Granite Gneiss[1]

Pre-Pennsylvanian: Eastern Connecticut and southern Massachusetts.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 136, 142, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 54–55. Referred to as an orthogneiss. Same as Ayer granite of Thompson Township, Windham County, Conn., which extends into Massachusetts. Age considered Upper Carboniferous.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Outcrop in Thompson Township here mapped as Canterbury granitic gneiss. Pre-Triassic. Derivation of name given.

U.S. Geological Survey currently designates the age of the Canterbury Gneiss as pre-Pennsylvanian on the basis of a study now in progress.

Named for town of Canterbury, Windham County, Conn.

Cantinas Sandstone (in Asuncion Group)

Upper Cretaceous: West-central California.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 132 [preprint 1941]. Forms upper part of Asuncion group (new) in southern Santa Lucia Range. Overlies Godfrey shales (new).

Santa Lucia Range is mountainous area, between Salinas Valley and the coast, which extends from Monterey Bay to central part of San Luis Obispo County.

Canton Phacolithic Complex[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1929, New York State Mus. Bull. 281, p. 65–76.

Occurs in Canton, Gouverneur, and Ogdensburg quadrangles.

Canton Schist[1] or Formation

Precambrian: Northwestern Georgia.

Original reference: W. S. Bayley, 1928, Georgia Geol. Survey Bull. 43, p. 43–46, map.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, p. 1379. Canton formation is here regarded as part of the Carolina gneiss or series, which is considered Precambrian.

Well exposed in vicinity of Canton, southwestern part of Tate quadrangle, Cherokee County.

Canton Shale Member (of Carbondale Formation)[1]

Canton Shale (in Carbondale Group)

Pennsylvanian: Central and western Illinois.

Original reference: T. E. Savage, 1921, Illinois Geol. Survey Extr. from Bull. 38.

Leland Horberg, 1950, Illinois Acad. Sci. Trans., v. 43, p. 171, 174. In Henry County, underlies Tertiary gravels which generally have been referred to Lafayette formation.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 106–107, 190, 195, 196, 197. Consists of upper and lower part separated by limestone bed 4 inches to 1 foot thick. Total thickness as much as 35 feet. Underlies Cuba sandstone; overlies St. David limestone. Included in St. David cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), 66, pl. 1. Carbondale redefined as formation. Canton shale member underlies Vermilionville limestone member which replaces preoccupied name Cuba sandstone.

Type locality: Center sec. 9, T. 6 N., R. 4 E., Fulton County. Named from exposures near Canton.

Cantua Sandstone Member (of Lodo Formation)

Cantua Sandstone Member (of Arroyo Hondo Formation)

Cantau Sandstone Member[1] (of Martinez? Formation)

Eocene: Southern California.

Original reference: R. Anderson and R. W. Pack, 1915, U.S. Geol. Survey Bull. 603, p. 33, 59–63, map.

R. T. White, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 256–257. Assigned to member status in Lodo formation (new). Overlies Cerros member (new); underlies Arroyo Hondo member.

H. E. Vokes, 1939, New York Acad. Sci. Annals, v. 38, p. 27, 28. Assigned to member status in Arroyo Hondo formation. Lies entirely within Ragged Valley shale member; a basal portion of Ragged Valley shale, approximately 100 feet thick, appears to underlie the Cantua throughout area.

M. C. Israelsky, 1951, U.S. Geol. Survey Prof. Paper 240–A, p. 1–2. Restricted to the sandstone unit, thus excluding about 100 feet of fine-grained strata underlying the sandstone and originally included in the Cantua.

Named for fact it reaches greatest development at head of west branches of Cantua Creek, Fresno County.

†Cantua Shale[1]

Eocene or Oligocene: Southern California.

Original reference: C. C. Church, 1930, Pan-Am. Geologist, v. 54, no. 1, p. 79.

Phoenix Canyon, near Coalinga, Coalinga region.

Cantwell Formation[1]

Lower Cretaceous: Southern Alaska.

Original reference: G. H. Eldridge, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 16, map.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, p. 235, chart 10d (column 23). Consists of several thousand feet of continental deposits and some interbedded lavas and graywacke.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Name appears on map legend under Cretaceous and Jurassic rocks undifferentiated.

Clyde Wahrhaftig, 1958, U.S. Geol. Survey Prof. Paper 293–A, p. 8–9, pls. 1, 3, 9. Formation occupies large synclinorium in center of Alaska Range. On the north, it is bounded by vertical fault which forms its contact with Birch Creek schist. Eldridge designated locality on Nenana River then known as Cantwell River as type locality.

Type locality: On Nenana River (formerly Cantwell River) about 3 or 4 miles above its junction with the Yanert Fork.

Canutillo Formation.

Middle Devonian: Texas.

L. A. Nelson, 1937, Colorado Univ. Studies, v. 25, no. 1, p. 89. Stratigraphic section in Franklin Mountains includes Devonian Canutillo formation which lies between Mississippian Helms formation and Silurian Fusselman limestone.

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 163 (fig. 3), 164, 170 (fig. 5). About 175 feet of sediments consisting of cherty limestone, light brown in color, immediately overlying Fusselman; thin beds of fossiliferous gray limestone; thin bed of dense, almost black sandstone, which weathers brown; and about 40 feet of black shale, fissile shale at top of formation. Middle Devonian.

F. V. Stevenson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 18, p. 22–23. Most limited in areal extent of all Devonian formations in New Mexico. Basal part consists chiefly of massive calcareous siltstone that is overlain by thin beds of varicolored shale interbedded with massive thick beds of calcareous brown siltstone. Average thickness 25 to 30 feet. Most complete exposure, 88 feet thick, is in San Andres Canyon, San Andres Mountains. Overlies Fusselman limestone; underlies Sly Gap formation. Fauna and geologic history of southwest indicate that formation is probably early Late Devonian.

F. V. Stevenson, 1945, Jour. Geology, v. 53, no. 4, p. 221–222. Sediments below Sly Gap in Sacramento and San Andres Mountains, hitherto called Canutillo from supposed correlation with Canutillo formation in Franklin Mountains of Texas, are herein named Onate formation.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 36, 37 (fig. 17). In Franklin Mountains, Tex., formation consists of approximately 15 feet of soft thin-bedded gray siltstone. Separated from underlying Fusselman by 42 feet of cherty limestone, probably Devonian; overlain by 57 feet of soft flaky gray-black shale identical in character with part of Percha shale of Lake Valley area.

Named from town of Canutillo, Tex., on Santa Fe Railroad about 13 miles north of El Paso.

Canville Limestone[1] Member (of Dennis Limestone)

Canville Limestone Member (of Hogshooter Formation)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and northeastern Oklahoma.

Original reference: R. C. Moore, 1932, Kansas Geol. Guidebook 6th Ann. Field Conf., p. 91, 97.

R. C. Moore, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40, 42. Rank reduced to member status in Dennis limestone.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 90–91. Canville limestone member of Dennis formation; underlies Stark shale member; overlies Galesburg formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma. In Kansas, locally, a single layer about 1 foot thick; where thickness is greater, up to maximum of 3 feet, two or three beds may occur; member thins southward from type region.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11–12. Galesburg formation redefined to exclude Canville limestone and Stark shale formerly included in it by Missouri Geological Survey.

M. C. Oakes, 1940, (abs.) Tulsa Geol. Soc. Digest, v. 9, 51; 1952, Oklahoma Geol. Survey Bull. 69, p. 59, 60, 61. Present locally in northeastern Oklahoma where it is basal member of Hogshooter formation.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 421. In measured section near Winterset, Madison County, Canville member of Dennis formation is a bluish-gray discontinuous nodular band about 8 inches thick.

Named from exposures on Canville Creek, Neosho County, Kans.

Canyon Conglomerate[1]

Pliocene: Yellowstone National Park.

Original reference: W. H. Weed, 1896, U.S. Geol. Survey Geol. Atlas, Folio 30.

Named for occurrence in Grand Canyon of Yellowstone River.

Canyon Group[1]

Canyon Formation[1]

Canyon Series

Upper Pennsylvanian: Central northern and central Texas.

Original reference: W. F. Cummins, 1891, Texas Geol. Survey 2d Ann. Rept., p. 361–374.

N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387–402 (repr. 1917 as Texas Univ. Bull, 1755). Canyon division comprises (ascending) Coral limestone, Rochelle conglomerate, Brownwood, Adams Branch limestone, Cedarton, Clear Creek, bed no. 7, cherty bed, Hog Creek, Home Creek, Bluff Creek, and *Campophyllum* beds. Overlies

Strawn division, with Ricker bed at top; underlies Cisco division, with Trickham bed at base.

F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull, 2132, p. 87–120; 1922, Jour. Geology, v. 30. Canyon group comprises (ascending) Graford formation (with Rochelle conglomerate, at base, Capps limestone lentil, Brownwood shale, and Adams Branch limestone); Brad formation (with Cedarton shale at base, Clear Creek limestone, Placid shale, and Ranger limestone); and Caddo Creek (with Hog Creek shale, below, and Home Creek limestone, above). Overlies Strawn group (Ricker bed at top), underlies Cisco group.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 94–118. Group includes (ascending) Palo Pinto, Graford, Brad, and Caddo Creek formations.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 87–90. Rank raised to series. Comprises (ascending) Whitt (new), Graford, Brad, and Caddo Creek groups. Includes sediments above disconformity (unconformity in more positive areas) at top of Strawn series (base of Lake Pinto sandstone at Mineral Wells) and below disconformity marked by Kisinger channel (base of Cisco series) of southeast Young County. Village Bend limestone is top member of East Mountain shale of Lone Camp group (new) in Strawn series. Subdivision is thought to be approximately equivalent to Missouri series of Kansas.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 288 (fig. 1), 299. Rocks of Kawvian series (new) are widespread in North America. In north-central Texas, include the Canyon and Cisco.

R. J. Cordell and D. A. Zimmerman, 1954, Abilene Geol. Soc. Guidebook Field Trip Nov. 19–20, p. 46 (fig. 38), 47–49. In Palo Pinto County, Canyon-Strawn contact has for several years been placed at base of Lake Pinto sandstone (top of East Mountain shale). Position and correlation of Village Bend limestone (within East Mountain shale) has been used as evidence for unconformity at base of Lake Pinto sandstone. In general area of its type locality, the Village Bend occurs at variable intervals below beds identified as Lake Pinto. This variability of interval provided some postulation of erosional surface at top of East Mountain shale. Also inferring from statements by Cheney and Goss (1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 12) typical Strawn fossils, such as *Fusulina*, *Prismopora*, and *Mesolobus*, were not known above base of Lake Pinto at time of their publication. Believed from data available that logical Canyon-Strawn contact should be at base of Turkey Creek sandstone in Palo Pinto County. Turkey Creek sandstone is immediately overlain by Keechi Creek shale near top of which *Triticites* (post-Strawn age) has been found. Also concluded that lower Brownwood of Brown County is probably late Strawn age and that the upper Brownwood is early Canyon. Hence, base of conglomerate separating these two parts of Brownwood shale should be regarded as Canyon-Strawn contact. This would increase Strawn interval in Brown County about 125 feet, at expense of Canyon.

J. W. Shelton, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1515, 1524, pl. 1. Strawn-Canyon boundary in north-central Texas is evaluated from surface studies in Colorado River and Brazos River valleys. Zonation based on fusulinids is best criterion for defining boundary. Strawn series is characterized by genus *Fusulina* and Canyon series by *Triticites*. Brachiopod *Mesolobus* and bryozoan *Prismopora* are not persistent in outcrop area; boundary is placed at three different stratigraphic positions so that locally prominent surfaces, which agree with paleontological evidence, may be used as the contact. In Colorado River valley, boundary is considered to be top of Capps limestone, which is continuous to north through Comanche County and most of Eastland County. In southern part of Brazos River valley, boundary is placed at top of "boulder" bed (of other investigators). This bed, which is present in northeastern Eastland County and southwestern Palo Pinto County, lies about 20 feet above Capps limestone. It is correlated with, and designated as, Village Bend limestone of central Palo Pinto County. In eastern Palo Pinto County, boundary is placed at base of Lake Pinto sandstone, which overlies Village Bend limestone.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58 (table 1), 62–68, pl. 27. Sequence of rocks now assigned to Canyon group includes most of the rocks assigned to Milburn shales and Brownwood division by Tarr (1890, Texas Geol. Survey 1st Ann. Rept.) and to Brownwood-Ranger series by Dumble (1890, Texas Geol. Survey 1st Ann. Rept.). Tarr's Brownwood division and Dumble's Brownwood-Ranger series were described as overlying their Milburn shales (later called Brownwood shale) and as including rocks that are barren of coal and that consist chiefly of limestone. Upper limit of this sequence was not definitely identified but appears to have been top of Gunsight limestone member of Graham formation, Cisco group, of presesnt classification. Drake (1893), adopting Cummins' (1891) divisions of rocks in Brazos River valley, applied term Canyon to prominent beds of limestone and intervening beds of shale of Colorado River valley, to which he gave local names and which he classified as beds. He considered base of Canyon to be top of his Coral limestone bed (Capps limestone lentil of Plummer and Moore) and top of Canyon to be his *Campophyllum* bed (Gunsight limestone member of present usage). Plummer and Moore (1921) raised Canyon to group rank, divided it into formations named for Brazos River valley localities, and further divided these into members bearing nomenclature of Drake's beds. This terminology is still widely used, though some renaming, reorganization, and redefining of units has been accomplished. Following nomenclature is recommended for formations and members (ascending): Graford formation, with Brownwood shale, Adams Branch limestone, and Cedarton shale members; Winchell limestone with lower and upper unnamed limestone members: Brad formation with Placid shale and Ranger limestone members; and Caddo Creek formation with Colony Creek shale and Homewood limestone members. Thickness about 600 feet in area of this report [Brown and Coleman Counties].

Named for Canyon, Palo Pinto County.

Canyon City Group[1]

Upper Cretaceous (Montana): Southeastern Colorado.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Colorado and New Mexico 3d Ann. Rept. p. 89–91.

Near Hardscrabble Creek, a small branch running into Arkansas River just below Canyon City, Canyon City region.

Canyon Creek Member (of San Juan Tuff)[1]

Miocene(?): Southwestern Colorado.

Original reference: W. S. Burbank, 1930, Colorado Sci. Soc. Proc., v. 12, p. 186.

Along Canyon Creek just below Camp Bird mill, Ouray district.

†Canyon Largo Group[1]

Eocene and older(?): Northwestern New Mexico and southwestern Colorado.

Original reference: W. H. Holmes, 1877, U.S. Geol. and Geog. Survey Terr. 9th Ann. Rept. for 1875, pls. 35, 38.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 16, pl. 1. Term resurrected to replace San Juan "Wasatch." Tiffanian, Clarkforkian(?), and Wasatchian, of San Juan Basin, northwestern New Mexico and narrow fringe of southwestern Colorado.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 276–282. Discussion of proposal by Wood and others to reinstate term Canyon Largo and also discussion of conflicts in usage of term by early workers, Newberry, Holmes, and Keyes. It is concluded that no acceptable name for formation generally known as San Juan Basin "Wasatch" is available in previous literature. Hence, name San Jose formation is proposed.

Named for Canyon Largo, in northeastern part San Juan County and west part of Rio Arriba County, N. Mex.

Canyon Largo Sandstone[1]

Eocene: Northwestern New Mexico.

Original reference: C. R. Keyes, 1906, Geol. Soc. America Bull., v. 17, p. 725.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 273–280. Discussion of conflicts in usage of term Canyon Largo by early workers, Newberry, Holmes, and Keyes, Keyes proposed use of Canyon Largo for a part, only, of the New Mexico "Wasatch" of most other writers. He credited term to Newberry and not to Holmes. Keyes' proposal is a definitely published proposal which is valid as far as priority has any bearing. Keyes used name repeatedly in publications over a span of years, and his is most nearly continued and established use in literature. Import of Keyes' publications depends on whether Newberry or Holmes is considered as having originally established the name. Because of this confusion, no acceptable name for formation generally known as San Juan basin "Wasatch" is available in previous literature and San Jose is proposed.

Derivation of name not given.

Canyon Springs Sandstone Member (of Sundance Formation)

Canyon Springs Sandstone Member (of Rierdon Formation)

Upper Jurassic: Northwestern Wyoming and southwestern South Dakota.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 247–251, geol. sections. At type section, consists of about 26 feet of soft fine-grained calcareous fossiliferous white sandstone that underlies Stockdale Beaver member (new) and overlies Gypsum Spring formation. Thickness ranges from featheredge to about 45 feet; thickens and thins considerably in short distances, and is recognizable as a member only along southern and western margins of Black Hills.

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 466 (table 2), 475. Reallocated to member status in Rierdon formation herein assigned to Sundance group.

Type locality: Conical butte about 4 miles west of Horton, Weston County, Wyo., one-fourth mile north of road from Horton to Upton, and near center sec. 23, T. 48 N., R. 62 W. Named for Canyon Springs Prairie immediately east of type locality.

†Cap au Gres standstone[1]

Lower Ordovician: Western Illinois, southeastern Iowa, and northeastern Missouri.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59, 60.

Typically developed at Cap au Gres, a headland on Illinois side of Mississippi River in Calhoun County, Ill.

Capay Formation[1]

Capay Stage

Eocene, lower: Northern California.

Original reference: T. H. Crook and J. M. Kirby, 1935, Geol. Soc. America Proc. 1934, p. 334–335.

B. L. Clark and H. E. Vokes, 1936, Geol. Soc. America Bull., v. 47, no. 6, p. 853 (fig. 1), 858–861. Referred to as stage based on faunal assemblages. Spans interval between Meganos stage below and Domengine stage above. Strata referable to this stage have been incorrectly correlated by Clark (1921, Jour. Geology, v. 29, no. 2) with those containing fauna of division D of Meganos group.

C. W. Merriam and F. E. Turner, 1937, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 24, no. 6, p. 91–113. Discussion of middle Eocene Capay stage of northern California. Check list of species of stage in Capay Valley and Vacaville areas is given. Deposits of stage represent in several areas a discrete transgressive overlapping of marine conditions as shown by fact that beds rest both upon the Meganos and upon earlier formations. At type section of Meganos, on north side of Mount Diablo, Capay stage is either missing or represented by coal beds which have offered little or no fossil evidence of their immediate age. Locality which had yielded most of the fossils lies on west side of Capay Valley, Yolo County, and west of Tancred Station, in south-central part of sec. 28, T. 11 N., R. 3 W., Mount Diablo base and meridian.

Boris Laiming, 1940, 6th Pacific Sci. Cong., v. 2, p. 535–568. Discussion of character and distribution of smaller foraminifera in marine Eocene deposits of California. Correlation of foraminiferal zones is shown with faunal "stages" already established by paleontologists on basis of mollusca. Correlation chart shows 12 foraminiferal zones in Eocene as compared to 6 stages on basis of mollusca. Foraminiferal zones (ascending) C, B–4, B–3, and B–2 correlate with Capay stage of Clark and Vokes (1936).

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Chart shows age of Capay formation as lower Eocene.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 52–56, pls. Eocene sedimentary rocks of California have been separated faunally and stratigraphically into six units (Clark and Vokes, 1936). By local geologists these units are referred to (ascending) as Meganos, Capay, Domengine, Transition, Tejon, and Gaviota stages. Three of these are recognized in area mapped [Coast Ranges immediately north of San Francisco Bay region]. U.S. Geological Survey recognizes, for this paper, Tejon, Domengine, and Meganos formations and Capay shale. Name Capay shale, already in literature, was recommended for adoption in this paper with reservation that it should be pointed out that this unit may be facies of the Meganos. Name Capay formation was used by Crook and Kirby (1935) for marine sediments exposed on west side of Capay Valley, Yolo County, and near Tancred Station in sec. 28, T. 11 N., R. 3 W. The section is over 600 feet thick and rests upon Upper Cretaceous beds. It is composed of invertebrate shales, sandstone, and conglomerates, and about 500 feet above base contains invertebrate fauna distinct from Domengine and Meganos formations as recognized on north side of Mount Diablo. In area of present report, Capay shale is exposed in banks of Ulatis Creek in Vaca Valley, Potrero Hills, and in Browns Valley on west side of Napa Valley. Probably middle shale member at Martinez now mapped as part of Martinez formation may be in part equivalent of the Capay. Thickness in some areas as much as 1,000 feet. Overlies Martinez formation; underlies Domengine sandstone.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Capay formation was proposed for conglomerate and estuarine deposits. possibly 2,400 feet thick, in Capay Valley, Cache Creek. Lower 600 feet contains at least four conglomerates, and near top is a 10-foot gritty mudstone with many pebbles and small gastropods. The mudstone rests upon sandstone that contains a few poorly preserved Eocene fossils and is overlain by coarse conglomerate with micaceous quartz sand matrix. *Turritella merriami* has been found only in the conglomerate with other forms, many of which are worn and generally larger than those in the mudstone. Occurrence of *T. merriami* above the mudstone is similar to that in sequence at Marysville Buttes. It is reasonably certain that the mudstone was deposited contemporaneously with at least some part of Marysville claystone member of the Meganos, and that at least lower part of Capay formation is equivalent to at least the upper part of Meganos formation (unit "E" of Clark and Woodford, 1927). Lower Eocene.

Named for occurrence in Capay Valley, west of Rumsey Hills, west of town of Winters, Yolo County.

Cape Limestone (in Maquoketa Group)

Upper Ordovician: Southeastern Missouri and southwestern Illinois.

A. M. Gutstadt, 1954, Dissert. Abs., v. 14, no. 10, p. 1683. Maquoketa group is divided into (ascending) Orchard Creek shale, Cape limestone, and Eden shale.

A. M. Gutstadt, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 3, pt. 1, p. 523–524. Shideler (1937) applied the name Ada limestone to the Missouri "Fernvale." Templeton and Willman (1953, unpub.) reported that name Ada was preempted and proposed name Cape limestone, from Cape Girardeau, Mo. At this locality, where it is in contact with underlying Orchard Creek shale, the Cape is gray and medium crystalline and contains shale partings and abundant fossil fragments (mostly crinoid segments). Thickness 8 feet.

Well exposed at North Main and Broadway Streets, Cape Girardeau, Mo.

Cape Ann Granite[1]

Late(?) Paleozoic: Northeastern Massachusetts.

Original references: C. H. Clapp, 1910, Igneous rocks of Essex County, Mass; B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 188–189, map.

U.S. Geological Survey currently designates the age of the Cape Ann Granite as late(?) Paleozoic on the basis of a study now in progress.

Named for occurrence at Cape Ann, Essex County.

†Cape Beauford coal measures[1]

Cretaceous: Alaska.

Original references: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 249; W. H. Dall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 819–820.

†Cape Blanco Beds[1]

Miocene: Southwestern Oregon.

Original reference: J. S. Diller, 1902, U.S. Geol. Survey Bull. 196, p. 30–31.

At Cape Blanco, Port Orford quadrangle.

Cape Cod series[1]

Tertiary and Quaternary: Massachusetts.

Original reference: N. S. Shaler, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 535.

Cape Elizabeth Formation (in Casco Bay Group)[1]

Pennsylvanian (?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

Named for development at Cape Elizabeth, Cumberland County.

Cape Fear Coquina

Pleistocene: Eastern North Carolina.

W. B. Wells, 1944, Elisha Mitchell Sci. Soc. Jour., v. 60, no. 2, p. 130, 132, pls. 63, 64. Rather heavily sanded shell rock known to underlie Kure sandstone (new) or the deeper consolidated phase of this stratum; contact unconformable. Throughout most of its area, its surface is only a few feet above mean sea level, but where Inland Canal cuts across it, top attains an altitude of 22 feet above mean sea level.

Crops out on sea front between Fort Fisher and Kure's Beach fishing pier, on lower Cape Fear Peninsula.

†Cape Fear Formation[1]

Lower Cretaceous: Coastal Plain of North Carolina.

Original reference: L. W. Stephenson, 1907, Johns Hopkins Univ. Circ. 71, p. 93–99.

S. D. Heron, Jr., 1958, South Carolina Div. Geology Bull., v. 2, no. 11–12, chart 1. Age shown on correlation chart as Lower Cretaceous.

S. D. Heron, Jr., 1959, Geol. Soc. America, Southeastern Sec., Guidebook for Coastal Plain Field Trip, p. 1–2, 5–6, 16–18. Outcrop relationships of Cape Fear, Middendorf, and Bladen units are open to several interpretations. View that Middendorf represents an updip portion of Bladen member of Black Creek seems preferable. Bladen rests on Cape Fear formation in downdip exposures, and Middendorf rests on Cape Fear in updip exposures in Fort Bragg. Lower (?) Cretaceous.

Named for exposures on Cape Fear River.

†Cape Girardeau Marble[1]

Middle Ordovician: Southeastern Missouri.

Original reference: B. F. Shumard, 1855, Missouri Geol. Survey 2d Ann. Rept., pt. 2, p. 155.

Named for Cape Girardeau, Cape Girardeau County.

†Cape Girardeau Sandstone[1]

Upper Ordovician (Richmond): Southeastern Missouri.

Original reference: B. F. Shumard, 1868, St. Louis Acad. Sci. Trans., v. 2, p. 156.

Named for Cape Girardeau, Cape Girardeau County.

Cape Horn Slate[1]

Mississippian: Northern California.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey Geol. Atlas, Folio 66.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 15). Shown on correlation chart above Relief quartzite and below Delhi formation. Chesterian.

Named for occurrence at Cape Horn, overlooking North Fork of American River, Placer County.

Cape May Formation (in Columbia group)[1]

Pleistocene (Sangamon and Wisconsin): New Jersey and southeastern Pennsylvania.

Original reference: R. D. Salisbury, 1898, New Jersey Geol. Survey Ann. Rept. State Geologist 1897, p. 19–20.

Paul MacClintock, 1943, Jour. Geology, v. 51, no. 7, p. 458–472. From evidence in New Jersey, the Cape May seems best referred to Sangamon interglacial stage.

H. G. Richards, 1944, Acad. Nat. Sci., Philadelphia Notulae Naturae, no. 134, p. 5. Formation apparently represents entire duration of the Pleistocene between last major interglacial and the Recent. At present, formation is divided into following zones or phases: (1) interglacial marine, sand and clay with warm water fauna, last major interglacial; (2) glacial marine, sand with cold-water fauna, early Wisconsin; (3) transitional, fine sand; and (4) fluvial, sand and gravel, Wisconsin and post-Wisconsin. Future work will probably show that term Cape May formation should not be used for all these phases. Studies made in excavations of Cape May Canal.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation mapped in eastern Pennsylvania. Sands and gravels with clay and silt at base locally; includes areas of Recent alluvium and swamp deposits. Younger than Pensauken formation (Illinoian). Wisconsin stage. [Term Columbia group not used].

Named for fact it covers the whole of Cape May County, N.J.

Cape Neddick Gabbro[1]

Devonian (?): Southwestern Maine.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 151.

Occurs at Cape Neddick, York County.

Cape San Juan Limestone

Upper Cretaceous: Puerto Rico.

C. J. Maury, 1929, Science, new ser., v. 70, no. 1825, p. 609. Sequence of Upper Cretaceous sedimentaries includes San Germán deposits, Ensenada shale, Fajardo, and Cape San Juan limestones.

C. L. McGuinness, 1948, Ground-water resources of Puerto Rico: [San Juan?] Puerto Rico Aqueduct and Sewer Service, p. 174 (table). Synonym of San Diego formation.

Capetí Limestones

Oligocene, middle: Panamá.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (correlation chart). Name appears on correlation chart. Occurs below Arusa formation [or member of Tapaliza formation]. Middle Oligocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 329. Undefined name applied to limestones in Darien area. Oligocene.

Darién area.

Capistrano Formation[1]

Miocene, upper, and Pliocene, lower: Southern California.

Original reference: A. O. Woodford, 1935, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 15, no. 7, p. 169, 184, 216–217.

J. G. Vedder, R. F. Yerkes, and J. E. Schoellhamer, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–193. Subdivided to include Osa member (new). Unconformably underlies Niguel formation (new).

Named for development around Capistrano, Orange County.

Capita Shale Member (of Domengine Formation)

Eocene: Central California.

M. B. Payne, 1951, California Div. Mines. Spec. Rept. 9, p. 3, 13, 21, 22, pls. 1, 4. At type locality, comprises 50 feet of homogeneous gray shale which is firm, massive, micaceous, and in places carbonaceous. In Gres Canyon, Capita member is represented by a sand facies. Overlies Nonada sandstone member (new); underlies Chaney Ranch sandstone (new); lower and upper contacts gradational.

Type locality: In Chaney Ranch Canyon, Panoche quadrangle, Fresno County. Name taken from Capita Canyon just south of Chaney Ranch Canyon.

Capitan Limestone[1]

Permian (Guadalupe Series): Western Texas and southeastern New Mexico.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull., v. 9, p. 41.

R. K. DeFord and E. R. Lloyd, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 11. Capitan and Carlsbad are names of different facies of equivalent beds. Capitan is massive reef limestone, which grades basinward into upper Delaware Mountain sandstone (Bell Canyon, new) and lagoonward into Carlsbad limestone.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 589–592, 654–656, 661–662, pl. 2. Classification of higher Guadalupe beds used in this paper differs from that used in previous reports. All beds of upper Guadalupe age were placed in Capitan limestone, a chronologic unit that included Altuda, Vidrio, and Gilliam members. Name Capitan is herein restricted to that part of former Vidrio member, or reef facies, that is upper Guadalupe (post-Word) in age, and both it and the Altuda and Gilliam are given rank of formation. This change brings usage in Glass Mountains into harmony with that of type area of Capitan in

Guadalupe Mountains, where name is restricted to a lithologic unit, the reef facies. This classification is also adopted by Lewis (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1). Where traced westward from Delaware Mountains into Guadalupe Mountains, or from Delaware basin toward its margins, sandstones and limestones of Bell Canyon formation (new) of Delaware Mountain group are replaced by light-gray thick-bedded or massive limestone of Capitan; in higher beds of Bell Canyon, the change takes place along edge of Reef escarpment.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 59–64, 75–79, pl. 3, strat. sections. Detailed discussion of geology of southern Guadalupe Mountains, Tex. Thickness 1,000 to 2,000 feet. Consists in part of compact light-gray, cream-colored, or white calcitic limestone associated with dolomitic limestones.

Named for El Capitan Peak, El Paso County, Tex.

Capitol terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703 (fig. 8), 1707–1709, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Capitol is applied to a terrace deposit younger than the Asylum (new) and older than Beaumont (Sixth Street). Thickness about 40 feet east of Austin. Traced coastward surface of terrace appears to coincide with surface of Lissie formation in Wharton County. Since term Capitol was used as a terrace by Hill and Vaughan (1898, U.S. Geol. Survey 18th Ann. Rept.), it has priority over Lissie (Deussen, 1914).

Named for occurrence near State Capitol at Austin, Travis County. Also well exposed east of Capitol, and from there eastward to Chicon Street.

Capitol Creek Shale[1]

Middle Cambrian: Montana.

Original references: A. Rothpletz, 1915, Die fauna der Belt formation bei Helena in Montana: Munich; C. D. Walcott, 1916, Smithsonian Misc. Coll. v. 64, p. 291.

Cap Mountain Limestone Member (of Riley Formation)

Cap Mountain Formation[1] (in Timbered Hills Group)

Upper Cambrian: Central Texas.

Original reference: S. Paige, 1911, U.S. Geol. Survey Bull. 450, p. 23.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 18–19. Formation included in Timbered Hills group in Oklahoma. Occurs below the Honey Creek and above the Reagan. Ulrich (1932, Geol. Soc. America Bull., v. 43, p. 742) considered this an extension of the formation by same name in Llano-Burnet area, Texas. Present only in secs. 23 and 26, T. 2 S., R. 4 E., in eastern part of Arbuckle Mountains southwest of village of Mill Creek.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ Geology Pub. 4301, p. 154 [1945]; P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 27, 29, 253, 309–310 [1946]. Redefined and reduced to member status in Riley formation (new). As redefined, includes some quite sandy beds formerly included in Hickory sandstone. Consists of lower part made up of alternating impure dark-brown limestone and calcareous sandstone becoming more calcareous upward, and an upper part of mostly brownish-gray thick-bedded to massive limestone. Thickness 400 feet or more in Blanco County. Overlies Hickory sandstone member; underlies Lion Mountain sandstone member. Lower boundary, based on lithology, rises westward, crossing faunal zones until only about one-quarter as much of limestone is present in northwestern Gillespie County as in Blanco County; top boundary gradational but much more nearly at same time-horizon.

E. A. Frederickson, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 7, p. 1349, 1350–1351. Term Cap Mountain discarded in Oklahoma. Beds are considered to be dolomitic Honey Creek equivalents.

Named for Cap Mountain, Llano County.

Capote Mountain Tuff (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 15 (fig. 3), 26–28. Name proposed for the section of tuff overlying Bracks rhyolite (new) and underlying Brite ignimbrite (new). Outcrop characteristically threefold; upper white- to pinkish-gray member nearly 1,300 feet thick; middle red siltstone layer 10 to 40 feet thick; and lower variegated tuff member, predominantly dusky brown to grayish red purple, more than 300 feet thick. Difficult to differentiate from underlying Chambers tuff (new) on the north and south where the Bracks rhyolite is absent.

R. K. DeFord and L. W. Bridges, 1959, Texas Jour. Sci., v. 11, no. 3, p. 289–291. Underlies Tarantula gravel (new).

Type section: On west face of Capote Mountain, Rim Rock country, Presidio County.

Capps Limestone Member (of Mineral Wells Formation)[1]

Capps Limestone (in Lone Camp Group)

Middle Pennsylvanian: Central Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 96, 97; 1922, Jour. Geology, v. 30, p. 24, 35.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 91, 92, 94, 95.

Member of Mineral Wells formation in report on Brazos River valley area. Member is lenticular deposit of small area and considerable variation in thickness. Overlies Ricker sandstone member.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 90–91. Rochelle conglomerate and Capps and Adams Branch limestones have been miscorrelated in their type localities in Colorado River district and Brazos River district; this fact should be borne in mind in using early literature. Rochelle conglomerate may be traced northward below Capps limestone.

M. G. Cheney and D. H. Eargle, 1951, Geologic map of Brown County, Texas (1:62,500): Texas Univ. Bur. Econ. Geology. Mapped as Capps limestone at top of Lone Camp group.

J. W. Shelton, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1524. Strawn-Canyon boundary is drawn at top of Capps limestone in Colorado River valley.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 62, pl. 27. Capps limestone lentil, as used by Plummer and Moore (1921), extends across Brown County north of Colorado River, except where removed locally by channel erosion. Community of Early encompasses type locality. Unit has been classified as member of Mineral Wells formation, but for purposes of this report [Brown and Coleman Counties] term Mineral Wells formation is not used. In present report, Capps limestone lentil is at top of Strawn group, undifferentiated.

Named for Capps Farm, 3 miles east of Brownwood, Brown County.

Captain Creek Limestone Member[1] (of Stanton Limestone)

Pennsylvanian (Missouri Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: N. D. Newell, 1935, Kansas Geol. Survey Bull. 21, pt. 1, p. 76–79.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32–33. Thickness about 2 feet in Nebraska; 4½ feet in northwestern Missouri.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 80. Dark to bluish-gray granular or dense brittle limestone; massive or even bedded; locally upper few inches is a brecciated silicified mottled pink and gray bed. Thickness along Kansas River 4½ to 5½ feet; locally in Miami County, a little more than 10 feet; near Independence, Montgomery County, a limestone 55 feet thick has been assigned to this member. Underlies Eudora shale member; overlies Vilas shale.

Type locality: On Captain Creek 2 miles east of Eudora, in roadcut near SE cor. sec. 3, T. 13 S., R. 21 E., Douglas County, Kans.

Capulin Basalts

Recent: Northeastern New Mexico.

Helen Stobbe, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1354. Incidental mention only.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1021 (table 2), 1023, 1031, pl. 1; H. R. Stobbe, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1057. Dark-gray to black vesicular to scoriaceous olivine basalts containing plagioclase, olivine, and magnetite, often with small plagioclase phenocrysts. Outcrops relatively fresh and unweathered, rarely etched into relief, and usually preserve the disorganized surface of flowing lava. Derivation of name and geographic distribution given.

Named after the cone and flows of Mount Capulin. Found in five localities within 25 miles of Mount Capulin, which are either at or near to Horseshoe Crater, Mount Marcy, Twin Craters (south cone), and Van Cleve, Union, and Colfax Counties.

Capulin Mountain Basalt

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 118 (fig. 18), 129, 136 (table 4). Medium dark gray to dark gray, porphyritic, and vesicular, with phenocrysts totaling about 10 percent of rock. Mentioned in discussion of Capulin basalts in Des Moines quadrangle [most of discussion refers to basalts from Capulin Mountain].

Capulin Mountain is in southwestern corner of Des Moines quadrangle, Union County.

Caraba facies (of Caimito Formation)

Oligocene, upper, to Miocene, lower: Panamá Canal Zone.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 901. Facies presumably of parts of the middle and upper members of the Caimito. Where exposed at Río Caraba consists of a thick massive very sparsely jointed sandstone-conglomerate-breccia overlain by a thick section of thin-bedded limestone and limy fine-grained sandstone. The limestone overlying the facies has fossil assemblage characteristic of the Caimito formation. If facies is later demonstrated to be a mappable unit, it should be given formational status, although it is included in Caimito formation on plate 2 (geol. map).

Typically exposed along the Río Caraba southwest of Gamboa and in gullies along south bank of Chagres Crossing Reach due south of Canal Beacons 29 and 30.

†Carbon Group[1]

Tertiary: Wyoming.

Original reference: L. Lesquereux, 1876, U.S. Geol. Survey Terr. Bull. 5, 2d ser., p. 244–248.

Carbonado Formation (in Puget Group)[1]

Eocene: Western Washington.

Original reference: Bailey Willis, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 400–436.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 55, 63, 65, 67. Lowest formation of group in Carbon River area. Underlies Wilkeson formation. Thickness in Carbonado River Canyon 1,328 feet. Formations in Carbon Canyon have been folded into anticlines and synclines with a general northwesterly trend.

Name derived from town of Carbonado, Pierce County.

Carbonate Hill Limestone (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 47–50, table 1, pl. 1. Consists largely of thin-bedded coarse- to medium-grained dark-gray sandy calcarenite which weathers brown or gray. Thin conglomeratic beds of small subangular mostly limestone pebbles occur in lower part of formation. In most areas, base of formation marked by prominent bed of brown-weathering limestone containing abundance of large oyster shells. Similar beds, 8 feet to 10 feet thick, are found throughout formation. Thickness 113 feet on northeast side of McGhee Peak; elsewhere a close approximation to average thickness is 200 feet. Conformable with both the underlying McGhee Peak formation (new) and the overlying Still Ridge formation (new).

Named from exposures in vicinity of the Carbonate Hill (McGhee) mine, on east side of Peloncillo Range in sec. 34, T. 24 S., R. 21 W. No complete section could be measured around mine. Section studies and measured in detail west of mine on upper slopes of McGhee Peak. Four other exposures in the range. Peloncillo Mountains, Hidalgo County.

Carbon Butte shales (in Kwaguntan series)

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan.-Am. Geologist, v. 70, no. 2, p. 107 (chart), 113. Comprises black shales 1,000 feet thick. Underlie Echo limestone (new); overlie Solitude limestone (new).

Forms most of the height of Carbon Butte, a prominent remnantal butte, on east side of Chuar Valley; Grand Canyon region.

Carbondale Formation[1] (in Kewanee Group)

Carbondale Group

Middle Pennsylvanian: Illinois and western Kentucky.

Original reference: E. F. Lines, 1912, Illinois Geol. Survey Bull. 17, p. 74.

J. A. Culbertson, 1932, The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 5–6. Formation, in Pike County, Ind., includes Arthur limestone (new).

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 22, 26. In Illinois, includes Browning sandstone and Hanover limestone (both new).

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 36 (footnote). Principal divisions of Pennsylvanian system in Illinois (Caseyville, Tradewater, Carbondale, and McLeansboro) considered formations in previous publications are, according to present usage of Illinois Geological Survey, groups.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1), 34–36, 46–48 (table 1), 65–66, pl. 1. Redefined as formation to include strata between base of Colchester (No. 2) coal and top of Danville (No. 7) coal. As originally defined Carbondale included strata from bottom of Murphysboro coal to top of Herrin (No. 6) coal. Murphysboro coal was then considered equivalent to No. 2 coal of western Illinois. Intent was to use No. 2 coal as base of Carbondale, and except at Murphysboro, it was so used. Dominantly gray shale with sandstone prominent locally. Commonly 225 to 300 feet thick; in parts of northern, western, and southwestern Illinois, thins to about 125 feet, locally even less; about 400 feet thick in part of southeastern Illinois. Overlies Spoon formation (new); underlies Modesto formation (new). Members in southern Illinois (ascending): Colchester (No. 2) coal, Shawneetown coal (new), Roodhouse coal, Summum (No. 4) coal, Hanover limestone, Harrisburg (No. 5) coal, St. David limestone, Briar Hill (No. 5A) coal, Vermilionville sandstone, Herrin (No. 6) coal, Brereton limestone, Jamestown coal, Conant limestone (new), Anvil Rock sandstone, Bankston Fork limestone, Allenby coal (new), Galum limestone, and Danville (No. 7) coal. In northern and western Illinois (ascending); Colchester (No. 2) coal, Francis Creek shale, Jake Creek sandstone, Lowell coal, Oak Grove limestone, Purington shale, Pleasantview sandstone, Kerton Creek coal, Summum (No. 4) coal, Hanover limestone, Covel conglomerate, Springfield (No. 5) coal, St. David limestone, Canton shale, Vermilionville sandstone, Big Creek shale, Herrin (No. 6) coal, Brereton limestone, Lawson shale (new), Pokeberry limestone, Copperas Creek sandstone, and Danville (No. 7) coal members. In eastern Illinois (ascending): Colchester (No. 2) coal, Shawneetown coal, Summum (No. 4) coal, Harrisburg (No. 5) coal, Herrin (No. 6) coal, and Danville (No. 7) coal members. Presentation of new rock-stratigraphic classification of Pennsylvanian in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification. Type section designated.

Type locality: Compiled from exposures in SE¼NE¼ sec. 1, T. 7 N., R. 4 E., Glasford quadrangle, and secs. 20 and 21, T. 8 N., R. 3 E., Canton quadrangle, Fulton County, Ill. Named for Carbondale, Jackson County.

Carbon Ridge Formation

Carbon Ridge Group

Permian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 2, 64–66. Proposed for rocks of Permian(?) age that occur south and east of Eureka. Probably included in "Upper Coal Measures" of Hague (1883, U.S. Geol. Survey 3d Ann. Rept.; 1892, U.S. Geol. Survey Mon. 20). Two facies distinguished: eastern, in Diamond Mountains; and western, which includes type area, south of Eureka. Both facies are unconformably overlain by Newark Canyon formation (new). In western facies, overlies Diamond Peak formation; in eastern facies, overlies Ely limestone. Composed largely of sandy or silty limestones that weather to shades of brown; dominantly thin bedded. Maximum thickness of 1,750 feet.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 91, 93 (chart 1), 102. Rank raised to group. In Carbon Ridge area, comprises (ascending) unnamed limy shales, argillaceous limestones, silts and mudstones, Riepe Spring limestone (new), Riepetown sandstone (new), and Pequop formation. Group retains same limits as recognized by Nolan and others (1956). Pennsylvanian-Permian (Missourian, Virgilian, Wolfcampian, Leonardian).

Grant Steele, 1960, Dissert. Abs., v. 20, no. 12, p. 4635. Discussion of stratigraphic interpretation of Pennsylvanian-Permian systems of eastern Great Basin. During Virgilian to earliest Wolfcampian time, following units were deposited: Strathearn, Jakes Creek (new), Carbon Ridge, Oquirrh, Ferguson Springs (new), and Pakoon.

W. B. Douglass, Jr., 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 181–183. Discussion of southern Butte Mountains area, White Pine County. Basal Permian rocks overlying disconformity at top of Ely limestone include some rocks which are Wolfcampian. These rocks, together with Leonardian and lower Wordian rocks constitute unit mapped as Carbon Ridge formation. Rocks of unit consist of monotonous alternating sequence of buff fine- to medium-grained limestones and a lesser amount of white to buff calcareous fine- to medium-grained sandstones. Thickness 997 feet. Conformably overlies Arcturus formation. On basis of fusulinid fauna, Knight (1956, Jour Paleontology, v. 30, no. 4) suggested that unit was equivalent to Arcturus formation as defined by Spencer (1917). Field evidence indicates that this is incorrect and that these rocks are more likely equivalent to "Rib Hill" formation of Ely district and also correlatable to west with Carbon Ridge formation at Eureka and Havallah formation at Battle Mountain.

Type area: On Carbon Ridge lying just north of mouth of Secret Canyon, vicinity of Eureka, Eureka County.

Carbon River [coal] Series[1]

Eocene: Western central Washington.

Original reference: B. Willis, 1886, U.S. 10th Census, v. 15, pls. 81, 84.

Puget Sound region.

Carcass Creek Glaciation or Drift

Pleistocene, upper: South-central Utah.

R. F. Flint and C. S. Denny, 1958, U.S. Geol. Survey Bull. 1061–D, p. 117 (fig. 25), 122–125, pl. 6. Distal half of Fish Creek-Grover drift lobe. Composed chiefly of till with morainal topography. Commonly has subparallel series of looped boulder-covered end moraines consisting of long laterals curving into incomplete nested terminals. Laterals approximate 50 feet in height in upstream segments and gradually become lower in downstream direction, curving into terminal ridges no more than 10 or 15 feet high. Successive moraine ridges separated by narrow swales floored with sandy alluvium and colluvium. Drift contains little outwash. Drift of Carcass Creek glaciation constitutes parent material of soils and caliche. This fact is compatible with but does not support hypothesis that this glaciation is probable correlative of Bull Lake stage in Rocky Mountains.

Mapped on flanks of Boulder Mountain, including the upper course of Carcass Creek on northeast flank of Boulder Mountain, near Grover, Wayne, and Garfield Counties.

Cardenas lava series

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 109, 110–111. Sequence of eight lava-flows, being 100 to 250 feet thick, and separated from one another by a few feet of sandstone, 1 to 15 feet, in most instances. Total thickness 1,000 feet. Between sandstone sections of Grand Canyon series below and Chuaran series above. Marked erosional unconformities at top and bottom. Limited areal extent; lavas laterally dwindle away in all directions allowing the two unconformity planes to merge into one.

Name taken from Cardenas Butte at the base of which the full sequence is well exposed, in westward bend of Colorado River below mouth of Little Colorado River, Grand Canyon region.

Cardens Bluff Shale Member (of Hampton Formation)

Lower Cambrian: Northeastern Tennessee.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28 (table), 41, pls. 1, 18. Dominantly clay shale, darker than usual shale of formation; on divides, weathers to bright orange-rusty chips. In gorges of Doe and Watauga Rivers through Iron Mountains, bedding in shale is crossed by well-marked slaty cleavage. Thickness 100 to 200 feet. Basal shale of formation. Member loses characteristic features northeastward, either by pinching out between sandstone layers or by passing into interbedded sandstone and shale.

Named for Cardens Bluff on Watauga River below Watauga Dam, Carter County. Along crest of Iron Mountains, member forms well-defined strike valley that continues northeastward as far as U.S. Highway 21, between Shady Valley and Mountain City.

Cardiff Conglomerate[1]

Ordovician(?): Maryland, Pennsylvania, and Virginia.

Original reference: E. B. Mathers, Am. Jour. Sci., 4th ser., v. 17, p. 143.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 95–96, 106; A. J. Stose and G. W. Stose, 1944, U.S. Geol.

Survey Prof. Paper 204, p. 50. Described in York County, Pa., where it underlies Peach Bottom slate and forms a narrow band between the slate and the Peters Creek schist on the flanks of a hill area of slate locally called Slate Ridge that extends from Susquehanna River southwestward 4 miles to Maryland line. Unit is closely folded. Ordovician(?). Removed from Glenarm series.

Norman Herz, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 980. In discussion of Baltimore gabbro complex, Cardiff conglomerate is included in Glenarm series, age of which is considered as probably early Paleozoic.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Probably Lower Paleozoic.

Present in strongly marked synclinal basin with its greatest development near Cardiff, Harford County, Md.

Cardiff Shale[1]

Cardiff Shale Member (of Marcellus Shale)

Middle Devonian: Western to east-central New York and eastern Pennsylvania.

Original reference: J. M. Clarke and D. D. Luther, 1904, New York State Mus. Bull. 63, p. 16.

Bradford Willard, 1937, Am. Jour. Sci., 5th, v. 33, no. 196, p. 276 (table 2). Table of Hamilton correlations in Maryland, Pennsylvania, and New York shows Cardiff shale member of Marcellus formation present in eastern Pennsylvania and central New York. At top of formation; overlies Chittenango member.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 104 [1946]. Discussion of Catskill and Kaaterskill quadrangles. Mount Marion beds are the Hamilton beds of former writers, but they are now known to represent but a part of Hamilton group and to belong to its lowest or Marcellus division. They seem to correspond roughly with Cardiff or upper Marcellus of central New York.

Well exposed in vicinity of village of Cardiff, Onondaga County.

Cardigan Gneiss

Precambrian(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 14–20; 1946, U.S. Geol. Survey Prof. Paper 209, p. 9, 10–15 [1947]. Includes rocks of many varieties, ranging in color from dark brownish gray through greenish gray to very light silvery gray and in texture from almost massive or crudely gneissic to thoroughly schistose. Commonest variety is banded, irregularly foliated rock, dark- to medium-gray on fresh fracture, with commonly a slight greenish cast caused by chlorite. On weathering, rocks become brown or dark brownish gray. Oldest formation in Ajo quadrangle, and serves as basement upon which the lavas and sedimentary rocks were deposited and as country rock for the intrusive masses. Intruded by Chico Shunie quartz monzonite and Cornelia quartz monzonite (both new); separated by faults from Concentrator volcanics (new).

Principal area of outcrop extends from Gibson Arroyo and the Cardigan prospect, from which formation is named, westward along lower southern slopes of Cardigan Peak and occupies most of the range of hills between Copper Canyon and Chico Shunie Arroyo. Exposed over about 8 square miles of quadrangle.

Careaga Sand or Sandstone

Careaga Formation

Pliocene, upper: Southern California.

C. R. Canfield, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 1, p. 54, Careaga formation, an unpublished name proposed by some field geologists for a mappable yellow sand unit which occurs in Santa Maria district, section exposed at Schumann Cut in Casmalia Hills. Correlates with an upper sand unit in the Foxen called the fine sand member.

S. G. Wissler and F. E. Dreyer, 1943, California Div. Mines Bull. 118, pt. 2, p. 235 [preprint 1941]. Careaga formation (Canfield's Foxen gravel and Foxen fine sand member) consists of upper member of from 20 to 70 feet of unfossiliferous bluish-gray gravels and lower member of from 110 to 500 feet of fine-grained fossiliferous sand. In type area, separated from underlying Foxen by slight angular unconformity.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1340 (table 10), 1355–1358. Described as Careaga sandstone. Subdivided into lower fine-grained sandstone unit, designated Cebada fine-grained member, and upper coarse-grained sand and conglomerate unit, the Graciosa coarse-grained member. Thickness 50 to 1,425 feet; greatest range is in Cebada member, which is absent in places and has a maximum thickness of 1,000 feet. Conformably underlies Paso Robles formation; gradationally overlies Foxen mudstone; in some areas, discordantly overlies lower part of Sisquoc or upper member of Monterey. Type region designated.

G. F. Worts, 1951, U.S. Geol. Survey Water-Supply Paper 1000, p. 27. Discussed as Careaga sand. In most water wells, the Careaga is logged as sand—rarely as sandstone; induration is apparently a surface feature and does not extend to any appreciable depth; therefore, Careaga sand is used here rather than sandstone.

Type region: North flank of Purisima Hills south of Careaga Station on the now abandoned Pacific Coast Railroad, Santa Barbara County.

Caribbean Limestone[1]

Pliocene: Panamá.

Original reference: D. F. MacDonald, 1913, Geol. Soc. America Bull., v. 24, p. 710.

[T. F. Thompson], 1943, Panama Canal Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 21. Names Toro limestone and Caribbean limestone have been used to describe deposits of shell breccia or cemented coquina that overlies Gatun sandstone in region between Limon Bay and Chagres River. Formation [Toro] has been assigned to upper Miocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 329. Informal name for limestone in Canal Zone later named Toro limestone.

Between Limon Bay and Chagres River, C.Z.

Cariblanco Formation

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover, 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 147–149. Predominantly thick coarse conglomerates separated by sandstones and siltstones. Limestone present at three horizons: lenticular limestone containing volcanic rock fragments is interbedded with coarse sandstone near top of the lower massive conglomerate; petroliferous limestone concretions lie in volcanic sandstone in upper part of formation; and thick lenses of silty limestone are interbedded with volcanic sandstone and siltstone near top of formation. Layer of tuff composed largely of pink plagioclase crystals lies near middle of formation. Thickness in type area about 3,000 feet. In northeastern Puerto Rico, strata here correlated with the Cariblanco may be as thick as 8,000 feet. Increase in thickness toward northeast appears to be largely result of lateral interfingering of the Cariblanco with strata believed to be equivalent to Coamo formation (new). Unconformably(?) overlies Robles formation (new); conformably underlies Coamo formation. Name credited to Lynn Glover (in press).

H. L. Berryhill, Jr., and Lynn Glover 3d, U.S. Geol. Survey Misc. Geol. Inv. Map I–319. Basal 495 feet of formation extends eastward from Coamo quadrangle into westernmost part of Cayey quadrangle and crops out as massive, stratified conglomerate along upper part of steep ridge west of Vertedero where it is in a downfaulted block. Northwest of Vertedero, the conglomerate is truncated by a fault and lies in juxtaposition with Las Tetas lava member of Robles formation. Along east side of ridge west of Vertedero, conglomerate is in deposition contact with underlying siltstone of Colloa member (new) of Robles formation.

Named for outcrops along northeast-trending ridge which contains prominent peak known as Cariblanco, Coamo quadrangle.

†Caribou Formation[1]

Mississippian: Northern California.

Original reference: J. S. Diller, 1892, U.S. Geol. Survey Geol. Atlas, Folio 15 (prelim. proof sheet ed.).

Northwest of Caribou Bridge, Plumas County, in southeast part of Lassen Peak quadrangle.

Caribou Hills Glaciation

Pleistocene: Central southern Alaska.

D. B. Krinsley *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 5, 13 (table 1). Southwest part of Kenai Peninsula was glaciated three or more times during Quaternary period. Caribou Hills, the oldest recognized glaciation, preceded Swan Lake glaciation. Till exposed near heads of gullies in high ridges of the Caribou Hills. Series of successively lower marginal channels with linear lakes, lateral moraines, kame terraces on the Hills above altitude of 2,000 feet is record of several retreatal phases of this glaciation.

Found in highest parts and on slopes of Caribou Hills, southwest of Kenai Peninsula, Cook Inlet area.

Carimona Member (of Decorah Formation)

Carimona Member (of Platteville Formation)

Middle Ordovician: Southeastern Minnesota.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 759–763. Proposed for the few feet of limestone and interbedded limestone and shale at top of the Platteville and underlying green shales of Decorah formation. Limestone beds are pale yellowish brown, very fine and fine grained, and medium bedded and have smooth to broadly rippled surfaces. Limestones are separated by beds of shale that increase in thickness from bottom to top of unit. Shales are yellowish brown to olive, calcareous, fissile, and poorly fossiliferous. Near base of member, a thin unfossiliferous chocolate-colored shale is overlain by a bed of bentonite 2 to 4 inches thick. Across Fillmore County, Minn., member thickens regularly northwestward from 3 to 6 feet and extends without much increase to the Twin Cities; thins to a few inches in southwestern Wisconsin where it underlies Spechts Ferry member of the Decorah. Where typically developed, overlies McGregor member; contact is placed below a thin yellowish-brown or chocolate-colored calcareous unfossiliferous fucoidal shale. Toward the southeast, this thin shale is separated from the bentonite by less than an inch of limestone, but, in type area and toward the northwest, two medium beds of limestone, separated by thin shale, intervene between the fucoidal shale, and the bentonite member extends upward to include highest bed of Carimona-type limestone and includes a few thin beds of greenish Decorah-type shale. The Carimona occupies same stratigraphic interval as Quimbys Mill member, but the two are lithologically distinct and not known to overlap.

A. F. Agnew, 1956. Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 49–50. Reallocated to member status in Decorah formation for following reasons: Carimona lithology is similar to that of limestone bands in Spechts Ferry member of Decorah; Carimona and Spechts Ferry wedge out eastward, and Guttenberg member thins eastward, whereas Quimbys Mill member of Platteville wedges out to west and McGregor member of Platteville thins westward; and there is a disconformity at top of Quimbys Mill member.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1032–1033. Carimona member of Platteville thins southeastward into Iowa, and at McGregor is only a few inches thick, including bentonitic limy shale that represents the Carimona bentonite; in this area, where the Spechts Ferry is a recognizable rock unit, the Carimona directly underlies it. A bentonite seam lies wholly within or underneath the Carimona member and about 4½ feet (in Fillmore County) below a bentonite in shale at base of Decorah. These bentonite beds converge southeastward and diverge northwestward; the bed in the Carimona is that one in Minnesota that has been mistakenly correlated with the Spechts Ferry bentonite in Iowa.

Typically developed in central Fillmore County, Minn. Name derived from hamlet of Carimona, 4½ miles west of Preston and in the S½ sec. 4, T. 102 N., R. 11 W.

Carl Sandstone Member (of Shenango Formation)

Mississippian (middle Meramec or younger): Northwestern Pennsylvania.

P. A. Dickey, R. E. Sherrill, and L. S. Matteson, 1943, Pennsylvania Geol. Survey, 4th ser., Bull. M–25, p. 15–16. Shenango formation in Oil City quadrangle contains three sandstones (descending): "C", or Carl; medial, or "B"; and lower, or "A". Thickness 51 feet near Carl; basal 6 feet is yellowish gray, coarse grained, and very massive, with lenticular clay nodules, and apparently disconformable with underlying shale; upper 45 feet is gray to greenish-gray and golden-brown medium- to coarse-grained sandstone with local crossbedding. Along Allegheny River in northern part of quadrangle, sandstone becomes progressively less massive, more shaly, and more poorly bedded eastward across quadrangle. Red and green shale and sandstone invade horizon of upper part of Carl at Oil City and eastward along river; at Smoky Hill, 2½ miles east of quadrangle, these continental red and green beds are prominently developed throughout sandstone. Thickness in Franklin quadrangle 30 to 50 feet; top lies about 300 feet above Corry sandstone. A disconformity may separate the Carl from underlying shale; if this is definitely established, the Carl should probably be included with overlying Patton formation.

Named for exposures at Carl, Venango County.

Carlile Shale (in Colorado Group)[1]

Carlile Shale Member (of Cody Shale, Colorado Shale, or Mancos Shale)

Carlile Formation (in Benton Group)

Upper Cretaceous: Eastern Colorado, northwestern Iowa, western Kansas, southeastern Montana, western Nebraska, northeastern New Mexico, South Dakota, and eastern Wyoming.

Original reference: G. K. Gilbert, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 565.

W. W. Rubey and N. W. Bass, 1925, Kansas Geol. Survey Bull. 10, p. 16, 40. Carlile shale, in north-central Kansas, comprises Fairport chalky member (new) in basal part and Blue Hill shale member above. Overlies Greenhorn limestone.

W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A, p. 4 (table). Carlile shale, in Black Hills region, comprises unnamed lower member, 75 to 125 feet thick, and Turner sandy member (new), 150 to 200 feet thick. Overlies Greenhorn formation; underlies Sage Breaks shale member (new) of Niobrara formation.

H. D. Thomas, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 9, p. 1189–1197. Upper Cretaceous shale which has been called Carlile in Laramie basin, Wyoming, overlies Frontier formation and is, in turn, overlain by beds of the Niobrara. Fauna of upper part of Frontier is of same age as that of upper type Carlile of Colorado, whereas fauna of the "Carlile" of Laramie basin is of Niobrara age. Believed that use of name Carlile should be discontinued in Laramie basin and that name Niobrara should be extended downward to embrace beds erroneously called Carlile. This basal Niobrara shale is correlated with Sage Breaks shale member of the Niobrara of the Black Hills, and name Sage Breaks is here substituted for abandoned name Carlile.

C. H. Dane, W. G. Pierce, and J. B. Reeside, Jr., 1937, U.S. Geol. Survey Prof. Paper 186–K, p. 214–220. Carlile shale in eastern Colorado comprises (ascending) Fairport chalky shale, Blue Hill shale, and Codell sandstone members. Overlies Greenhorn limestone; underlies Niobrara formation.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7), 17. Formation comprises (ascending) Fairport shale, Blue Hill shale, and Codell sandstone members. Combined thickness of Carlile in Nebraska is about 150 feet in the east, 250 feet in the southwest, and 400 to 500 feet in the northwest. Overlies Greenhorn limestone; underlies Niobrara chalk. Colorado group.

C. H. Rankin, 1944, New Mexico Bur. Mines Mineral Resources Bull. 20, p. 7, 12, measured sections. Contains Juana Lopez sandstone member (new) near top in northern New Mexico.

P. C. Petsch, 1946, South Dakota Geol. Survey Rept. Inv. 53, p. 17 (fig. 5), 43–47. Discussion of geology of Missouri Valley in South Dakota. Text refers to Benton group as comprising Graneros shale, Greenhorn limestone, and Carlile shale. Outcrop of Carlile present between Westfield and

Sioux City along east bluffs of Big Sioux River in Plymouth and Woodbury Counties, Iowa.

C. H. Dane, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 78. Classed as member of Mancos shale in Rio Arriba County, N. Mex. Contains two subdivisions in this area. Lower, about 200 feet thick, consists largely of dark to black shale containing in basal 50 to 60 feet a group of six bentonitic clay beds. Upper, chiefly dark to black shale, weathering light brownish gray with numerous beds of hard dark-colored platy sandy limestone or calcareous sandstone. Estimated thickness about 600 feet in vicinity of El Vado. Overlies Greenhorn limestone member; underlies Niobrara calcareous shale member. Upper Cretaceous.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–111. Report discusses Hardin area, Big Horn and Yellowstone Counties, Mont. Carlile classified as member of Cody shale. Underlies Niobrara shale member; overlies Greenhorn calcareous member. Thickness 280 feet.

Keith Young, 1951, Jour. Paleontology, v. 25, no. 1, p. 35–68. Suggested that term Carlile shale be discontinued in southern Montana and term Frontier formation be redefined to include all rocks between top of Mowry shale and base of Niobrara formation.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2187–2192, 2197 (fig. 2). Discussion of Colorado shale of central and northwestern Montana and equivalent rocks on north flank of Black Hills. Carlile shale in Black Hills region is 550 to 650 feet thick. Divisible into a basal unnamed dark-gray shale member 75 to 155 feet thick; Turner sandy member, 185 to 260 feet thick; and Sage Breaks member, 195 to 305 feet thick. Overlies Greenhorn formation; underlies Niobrara formation.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. Benton formation in northwestern Mora County, N. Mex., is represented by equivalents of Graneros shale, Greenhorn limestone, and Carlile shale.

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–146. Report covers La Veta area, Huerfano County, Colo. Carlile shale of Colorado group, consists of a shale unit, about 225 feet thick, and overlying Codell sandstone member, 5 to 10 feet thick. Overlies Greenhorn limestone; underlies Fort Hays limestone member of Niobrara formation.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Carlile shale of Colorado group, comprises (ascending) Fairport chalk, Blue Hill shale, and Codell sandstone members. Overlies Greenhorn limestone; underlies Fort Hays limestone member of Niobrara chalk. Upper Cretaceous.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 48, 55, pls. Described in Buffalo-Lake De Smet area, Wyoming, where it is classified as member of Cody shale. Thickness about 156 feet. Overlies Greenhorn calcareous member; underlies Niobrara shale member.

U.S. Geological Survey currently classifies the Carlile as a member of the Colorado Shale in Winnett-Mosby area, Montana.

Named for Carlile Spring and Carlile Station, 21 miles west of Pueblo, Colo.

Carlim Limestone[1]

Middle Ordovician: Central Pennsylvania.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 526, 533, 537.

R. M. Field, 1919, Am. Jour. Sci., 4th, v. 48, p. 414–417. Underlies Valentine formation (new).

Charles Butts, F. M. Swartz, and Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 96, p. 18–20, pl. 1. Underlies Bellefonte dolomite; overlies Lowville limestone. Chazy group.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. "Carlim group" includes Hatter limestone (new) above and Loysburg formation, with Clover member, below. Chazyan (?) series.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 195. Terms Carlim, Lemont, and "Lowville" have been applied to different units at various localities. Carlim limestone included Clover limestone and Hatter formation in Tyrone district, the overlying Benner and much of the Nealmont being referred to the "Lowville"; in Bellefonte district, the "Carlim" included beds from the Clover to the lower Valley View, the upper part of that member and the Valentine being classed as "Lowville" and the latter included much of the Nealmont in other sections. The Lemont member of the "Carlim" in the Tyrone district is Hostler member of Hatter formation; it is the part of Valley View limestone between metabentonites E and D at Bellefonte and a part of the Nealmont at type locality at Lemont. Confusion developed principally from misidentification of, and misunderstanding of, ranges of species of *Maclurites*, *Tetradium*, and *Cryptophragmus*.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 20. Carlim limestone is the upper Loysburg plus the Hatter in its type locality is older than the Brenner formation that underlies Valley View member of Curtin limestone. Type Lemont limestone is equivalent to most of Nealmont limestone that overlies Valentine member of Curtin limestone. Type section of Lowville is in New York; it is preferable that a local name be applied in Pennsylvania, inasmuch as precise correlation is uncertain.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Described in Huntingdon and Hollidaysburg quadrangles where it is 100 to 200 feet thick. Comprises lower unnamed member and Lemont limestone member. Overlies Bellefonte dolomite; hiatus. Underlies Lowville limestone; hiatus. Lower Ordovician.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 51. Published lists of fossils from Carlim limestone and Butts' collection in National Museum indicate that the Carlim is not Chazyan. In view of confusion, it seems best to drop Carlim in favor of Kay's terms Loysburg and Hatter.

Named for Carlim, 18 miles northeast of Williamstown, Blair County.

Carlin Formation

Pliocene, lower: Northeastern Nevada.

Jerome Regnier, 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1191, 1198, 1201, pl. 1. At least 600 feet of tuffaceous conglomerate and sandstone, rhyolitic and basaltic tuffs, diatomite shale, and limestone. Vertebrate fossils (late Clarendonian). Overlies Palisade Canyon rhyolite (new); sedimentary contact and angular unconformity. Also overlies Raine Ranch formation (new); underlies Hay Ranch formation (new).

Beds of formation fill Carlin basin. Good exposures are present 5 miles southwest of Carlin and in area along Susie Creek. Beds in most places show small faults and gentle folds.

Carlin Canyon Formation

Permian (Leonardian and Guadalupian?) : Northeastern Nevada.

T. G. Fails, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 10, p. 1693, 1695 (fig. 1), 1699–1702. Proposed for 1,225-foot sequence of tan quartzose calcisiltites and massive brown cherts of Leonardian and possibly Guadalupian age. Conformably overlies Beacon Flat formation (new) ; unconformably underlies Miocene-Pliocene Humboldt formation.

Type section: North side of Humboldt River at Carlin Canyon; top of section in NE¼NW¼NW¼ sec. 13, from which place section runs west along side of canyon for about 2,000 feet; jumps south along chert outcrop for about 3,400 feet to another westerly trending canyon, where section runs again west for about 1,200 feet at its base in prominent north-south valley in SE¼NW¼SE¼ sec. 14, T. 33 N., R. 53 E., Elko County.

Carlinville cyclothem[1] (in McLeansboro Group)

Carlinville cyclothem (in Modesto Formation)

Pennsylvanian: Southwestern Illinois.

Original reference: H. R. Wanless, 1931, Geol. Soc. America Bull., v. 42, p. 801–812.

J. R. Bell, 1952, Illinois Geol. Survey Bull. 77, p. 34–37. Maximum exposed thickness in Carlinville quadrangle 37 feet. Includes Carlinville limestone. In sequence, Carlinville cyclothem overlies Trivoli cyclothem and underlies Burroughs beds. Name Shoal Creek has been used for the cyclothem in belief that Carlinville limestone was correlative of Shoal Creek limestone. However, recent studies have shown that Carlinville limestone is not correlative of Shoal Creek.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). Table shows Carlinville cyclothem between the Macoupin above and the Trivoli below.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11. Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 54 (table 3), pl. 1. In Modesto formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: SW¼SW¼ sec. 35, T. 10 N., R. 7 W., Macoupin County.

Carlinville Limestone (in McLeansboro Group)

Carlinville Limestone Member (of McLeansboro Formation)[1]

Carlinville Limestone Member (of Modesto Formation)

Middle and Upper Pennsylvanian: Southwestern and central western Illinois.

Original reference: A. H. Worthen, 1873, Illinois Geol. Survey, v. 5, p. 287, 290–301, 309.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 35–37. Carlinville limestone in McLeansboro group. In Carlinville quadrangle, generally consists of an upper massive limestone bed separated from a thinner lower one by dark shale. Locally there are three or four beds of limestone with intervening shale and then two or three of the limestone beds with intervening shale. Average total thickness 4½ feet. Included in Carlinville cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1), 69, pl. 1. Reallocated to member status in Modesto formation (new). Stratigraphically below Burroughs limestone member and above Chapel (No. 8) coal member (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: SW¼SW¼ sec. 35, T. 10 N., R. 7 W., Macoupin County. Named for outcrops in vicinity of Carlinville.

Carlisle Center Formation

Carlisle Center facies (of Schoharie Formation)

Lower or Middle Devonian: East-central New York.

Winifred Goldring and R. H. Flower, 1944, Am. Jour. Sci., v. 242, no. 6, p. 340. Name proposed to replace preoccupied Sharon Springs formation of Goldring and Flower (1942).

R. E. Stevenson, 1949, New York State Sci. Service Rept. Inv. 3, p. 6. Buff to brown sandy shale, with top 6 inches being a greenish glauconitic sandy shale. Locally base is marked by glauconite bed. Thickness 5 to 45 feet. Overlies Esopus formation; underlies Springfield Center member (new) of Onondaga formation.

J. M. Berdan, 1950, New York State Water Power and Control Comm. Bull. GW–22, p. 10 (table 2). Overlies Esopus siltstone; underlies Schoharie grit. Thickness about 20 feet. Lower or Middle Devonian.

J. H. Johnsen, 1957, Dissert, Abs., v. 17, no. 10, p. 2247. Facies of Schoharie formation (redefined). Underlies Rickard facies (new). Exposed in road southwest of Little York and in cut on U.S. Route 20 about 2 miles west of Sharon Springs, just a little east of Schoharie County.

Carlos Sandstone Member[1] (of Wellborn Formation)

Eocene, upper: Southeastern Texas.

Original reference: B. C. Renick, 1936, Texas Univ. Bull. 3619, p. 31–32, table opposite p. 17.

W. L. Russell, 1955, Gulf Coast Assoc. Geol. Soc. Trans., v. 5, p. 168. Renick mapped Carlos sandstone extending west from Carlos about 3 miles. Fieldwork in this area shows that the sandstone extending west from Carlos is in the Manning at a stratigraphic position about 100 to 150 feet above top of Carlos. This sandstone is here named Goodbread. Type locality discussed.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2626 (table 1), 2628. Mentioned in discussion of Wellborn sandstone, but in this report the Wellborn is considered a formation, undivided.

Type locality: About one-half mile north of road intersection at Carlos, Grimes County.

Carlotta Formation (in Wildcat Group)

Pliocene to Pleistocene: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 35–39, 113–115, pls. 1, 2. Predominantly massive nonmarine conglomerate, sandstone, and carbonaceous claystone; some marine lenses; locally contains white volcanic ash beds. Thickness 500 to 3,000 feet. Uppermost formation of group; unconformably underlies Hookton formation (new); overlies Scotia Bluffs sandstone (new) with contact gradational.

Type section: Near town of Carlotta, Humboldt County. No complete well-exposed section exists. Principal distribution is in trough of major Eel River syncline and in western part of Fortuna quadrangle. Westward plunge of Cenozoic structures and the Little Salmon Creek fault limit eastward extent.

†Carlsbad Limestone[1] or Group

Permian (Guadalupe Series): Southeastern New Mexico and western Texas.

Original references: O. E. Meinzer, B. C. Renick, and Kirk Bryan, 1926, U.S. Geol. Survey Water-Supply Paper 580–A, p. 12–13, map; N. H. Darton, 1926, Geol. Soc. America Bull., v. 37, p. 419.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 64–69, pls. 2, 3. Limestone described and mapped in southern Guadalupe Mountains, Tex.

N. D. Newell and others, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 46. Group includes Seven Rivers, Yates, and Tansill formations.

P. T. Hayes, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–98. Group described in Carlsbad Caverns East quadrangle where it comprises (ascending) Seven Rivers, Yates, and Tansill formations. Overlies Queen sandstone in northwest and toward southeast Goat Seep limestone. Underlies Salado formation; toward southeast interfingers with Capitan limestone.

Term Carlsbad Group abandoned; replaced by Artesia group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4).

Named for exposures in vicinity of Carlsbad, N. Mex.

Carlton Granophyre[1] or Porphyry

Precambrian: Southwestern Oklahoma.

Original reference: M. G. Hoffman, 1930, Oklahoma Geol. Survey Bull. 52, p. 39–48. [Hoffman also used term Carlton porphyry.]

Composes nearly all of Carlton Mountains, Wichita Mountains area.

Carlton Limestone (in Sumner Group)[1]

Carlton Limestone Member (of Wellington Formation)

Permian: Southeastern Kansas.

Original reference: R. C. Moore, 1936, Kansas Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 6–8. Wellington formation is subdivided into 10 members. The Carlton is the fifth in the sequence (descending). Younger than Highland shale member (new); older than Chisholm Creek shale member (new).

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41. Occurs a short distance below Hutchinson salt member. Contains fossil insects. Leonard series.

Identified southward from Walton, Harvey County, to Wichita, Sedgwick County.

Carlton Porphyry[1] or Rhyolite

Carlton Mountain Porphyry

Precambrian: Southwestern Oklahoma.

Original reference (Carlton porphyry): C. N. Gould, 1904, Oklahoma Geol. Survey Dept. Geology and Nat. History 3d Bienn. Rept., p. 18, 20.

J. A. Taff, 1904, U.S. Geol. Survey Prof. Paper 31, p. 64. Carlton Mountain porphyry mentioned in discussion of igneous rocks of Wichita Mountains. Plate 2 shows granite-porphyry mapped in vicinity of Carlton Mountains, Comanche County. [May be same as Carrollton Mountain porphyry, the geographic feature now being Carlton Mountains.]

R. E. Denison, 1959, (abs.) Oklahoma Acad. Sci. Proc. 1958, p. 124–125. The Carlton is a typically porphyritic and locally perlitic rhyolite with major phenocrysts of microperthite and minor phenocrysts of quartz, orthoclase, sodic plagioclase, and magnetite. Groundmass is micro- to cryptocrystalline and occasionally a micrographic intergrowth of quartz and feldspar. Believed to be surface equivalent of one of Wichita granites.

Occurs in area of Carlton Mountain[s], Comanche County.

Carlton Slate

Precambrian: Northeastern Minnesota.

A. E. Sandberg, 1938, Geol. Soc. America Bull., v. 49, no. 5, p. 797 (fig. 2), 798, 810. The Keweenawan at Duluth rests unconformably on Carlton slate.

G. M. Schwartz, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1002–1003. Thomson formation has been referred to as Thomson slate, St. Louis slates, Cloquet slates, and Carlton slate, but Thomson slate has priority. It is here suggested that term Thomson formation replace Thomson slate.

Occurs in vicinity of Duluth.

Carltonian Formation[1]

Precambrian (Keweenawan): Northeastern Minnesota.

Original reference: A. C. Lawson, 1893, Minnesota Geol. Nat. History Survey Bull. 8, p. xxi, 22, 23.

Named for extensive exposures in Carlton Peak, northeast Minnesota.

†Carlyle Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 119.

Named for Carlyle, Allen County.

Carmack Limestone[1]

Lower Mississippian: Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 37.

W. C. Morse, 1930, Mississippi Geol. Survey Bull. 23, passim. Term Camack Creek used interchangeably with Carmack limestone.

W. C. Morse, 1936, Mississippi Geol. Survey Bull. 32, p. 16 (pl. 1). Generalized section of Paleozoic rocks shows Carmack limestone underlying Iuka formation and overlying Devonian Whetstone Branch formation.

Named for Carmack Creek, a tributary of Tennessee River north of Whetstone Branch, Tishomingo County.

Carmack Creek Limestone

See Carmack Limestone.

Carman Quartzite (in Maquam Group)

Middle Ordovician (Chazyan): Northwestern Vermont and southeastern Quebec, Canada.

Marshall Kay, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1172. Fine-sand quartzite and argillaceous fine sandstone with some limestones toward top. Thickness 60 to 135 feet. Underlies Youngman formation (new); overlies Beldens formation.

Marshall Kay and W. M. Cady, 1947, Science, v. 105, no. 2736, p. 601. Basal formation of Maquam group (new).

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 81. Has type section at head of Shipyard Bay in Highgate Springs area; it contains about 120 feet of thin- to medium-bedded quartz sandstone having a few argillaceous partings and includes some calcarenite beds in upper part. Section exposes contact with underlying Beldens calcitite but top is cut off by fault.

Type locality: Shipyard Bay, Highgate Springs, Franklin County, Vt.

Carmel Formation (in San Rafael Group)[1]

Middle and Upper Jurassic: Southern, central, southeastern and northeastern Utah, northeastern Arizona, western Colorado, and northwestern New Mexico.

Original references: J. Gilluly and J. B. Reeside, Jr., 1926, U.S. Geol. Survey Press Bull. 6064, March 30; 1928, U.S. Geol. Survey Prof. Paper 150–D, p. 73–76.

E. T. McKnight, 1940, U.S. Geol. Survey Bull. 908, p. 86–89, pls. In area between Green and Colorado Rivers, the Carmel is exposed in irregular belt from Green River near mouth of the San Rafael roughly eastward to Moab fault at the Dugway northeastward across Moab anticline and Courthouse syncline. Thickness 125 feet at north end of Tenmile Butte and 152 feet near Courthouse Spring. In contrast to its lithology in San Rafael Swell and other parts of southern Utah, the Carmel contains no limestone in area of this report. It is composed chiefly of pink to red to reddish-brown muddy sandstone with, locally, considerable gray to reddish sandy mudstone. The mudstone occurs in upper part of formation near the Green River, but eastward grades into reddish-brown muddy sandstone that forms top of Carmel at Courthouse Rock. In eastern part of area, light-colored beds are subordinate to red facies and appear chiefly in basal part of formation, which toward the Green River is entirely red. These light-colored beds toward the east are largely sandstone, in part limy, and are white, yellowish white, and dirty grayish. They are interbedded with red muddy sandstones, are discontinuous along outcrop, and commonly show lenslike thickening and thinning. Overlies Navajo sandstone; underlies Entrada sandstone, apparent conformity. Upper Jurassic.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51 (table), 89, 92–94, strat. sections. Described in Zion Park region where it is 200 to 300 feet thick; underlies Entrada sandstone and unconformably overlies Navajo sandstone (Temple Cap member) of Glen Canyon group. Consists of bluish-gray limestone in resistant massive beds and soft shaly beds; some argillaceous and gypsiferous shale; marine fossils. A series of fluvial and eolian beds formerly included in the Carmel are here treated as Temple Cap member of Navajo.

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 597. In Strawberry Valley quadrangle, Utah, grades into Twin Creek limestone.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 963–964, chart 8C (columns 2–9). Formation not been accurately dated but probably corresponds to most of Middle and the earliest Upper Jurassic.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 38 (table), 68–70, strat sections. Described in Henry Mountains region where it is 100 to 626 feet thick. Consists of thin-bedded red sandstone, shaly sandstone and shale, thin limestone, and, in northwestern part of area, thick beds of gypsum. Unconformably overlies Navajo sandstone; underlies Entrada sandstone.

J. H. Mackin, 1954, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–14. Extended into Iron Springs district, Utah, where it includes all the strata previously called Homestake limestone. Overlies Navajo sandstone; underlies Entrada sandstone.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 33–35. Over most of Navajo country, Carmel consists of typically silty strata, but, in southwestern part of area, has different lithologic characteristics owing to introduction of locally derived sand. This variation of deposition continued during deposition of Entrada sandstone; hence, the two units are difficult to differentiate in this area. Thickness between 100 and 200 feet.

F. W. Cater, Jr., 1955, U.S. Geol. Survey Geol. Quad. Map GQ–64. Mapped in Horse Range Mesa quadrangle, Colorado, where it consists largely of red to buff nonresistant horizontally bedded siltstone, mudstone, and sandstone. Thickness 20 to 50 feet. Grades upward into Entrada sandstone; overlies Navajo sandstone.

Named for occurrence at Mount Carmel, Kane County, Utah.

Carmelo Series[1]

Upper Cretaceous: Western California.

Original reference: A. C. Lawson, 1893, California Univ. Pubs., Dept. Geol. Bull., v. 1, p. 1–59.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Mapped with Upper Cretaceous marine sediments.

Carmelo Bay region, southwest coast of San Mateo County.

†Carmen Formation

Miocene, lower: Eastern central Idaho.

A. L. Anderson, 1956, Idaho Bur. Mines and Geology Pamph. 106, p. 1, 16, 28–31, pl. 1. Consists for most part of moderately well-indurated thin-bedded fine-grained clastic rocks, mostly shales with considerable amount of intercalated sandstone and locally some conglomerate and lignite. Except for lignitic beds, rocks are light colored, mostly white or light gray. One conglomerate bed near base is some tens of feet thick. Distinguished from underlying Challis volcanics by absence of lava flows, ignimbrites, and other products of direct volcanic origin.

A. L. Anderson, 1959, Idaho Bur. Mines and Geology Pamph. 118, p. 21, 27. Preoccupied name Carmen replaced by Kirtley formation.

Named after settlement of Carmen. Excellent exposures above and below settlement and along Carmen Creek to east. Contained wholly within and forms floor and flanks of broad intermontane Salmon Basin, Lemhi County.

Carmichaels Formation[1]

Pleistocene (Illinoian) : Western Pennsylvania.

Original reference: M. R. Campbell, 1902, U.S. Geol. Survey Geol. Atlas, Folio 82.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C-26, p. 153-154, pl. 1. In Fayette County, deposits occur in abandoned meanders of Monongahela and Youghiogheny Rivers. Thickness 60 to 80 feet locally but more commonly thinner.

Named for exposures at Carmichaels, Green County.

Carnahan Bayou Member (of Fleming Formation)

Miocene: Central Louisiana.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 118 (fig. 26), 154-158, geol. map. Group of siltstones with intercalated sand lenses, local brackish-water clays, and thin tuffaceous beds. Thickness more than 125 feet. Underlies Dough Hills member (new) ; overlies Lena member (new).

Basal beds are typically exposed in roadcuts along U.S. Highway 71W, south of Lena, Rapides Parish. Name derived from Carnahan Bayou.

Carnahan Run Shale (in Conemaugh Formation)

Pennsylvanian: Western Pennsylvania.

J. J. Burke, 1958, Science, v. 128, no. 3319, p. 302. Calcareous marine shale, 1½ to 7 feet thick (5 feet at type locality) ; occurs 126 feet below Ames limestone, 13½ to 23½ feet above Woods Run limestone, and approximately 216 to 226 feet above Upper Freeport coal.

Type locality: About 0.7 mile north of North Vandergrift, Parks Township, Armstrong County.

Carnerada Conglomerate Member (of Marlife Shale)

Upper Cretaceous: Central California.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec. Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Red cobble conglomerate 0 to 2,200 feet thick. At base of Marlife shale (new). Overlies Ciervo shale (new). Name credited to D. W. Sutton (unpub. thesis).

Type locality: South Branch of Moreno Gulch, Fresno County. Name derived from Carnerada Canyon.

Carneros Sandstone Member[1] (of Temblor Formation)

Miocene, or Miocene, lower: Southern California.

Original reference: G. M. Cunningham and W. F. Barbat, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 4, p. 419-421.

H. H. Heikkila and G. M. MacLeod, 1951, California Div. Mines Spec. Rept. 6, p. 4 (table 1), 5 (table 2), 9, pl. 1. Described in Bitterwater Creek area as commonly a hard medium- to fine-grained calcarenite tan to gray sandstone. Along axial trace of McDonald anticline, minimum exposed thickness is 1,250 feet; thickness at mouth of Cedar Canyon 123 feet; change in thickness probably due to rapid change in facies; sandstone pinches out as it crosses Bitterwater Creek northwestward. Conformably overlies Santos shale member; conformably underlies Media shale member.

Named for Carneros Creek, Kern County.

Carney Lake Complex

Precambrian: Northern Michigan.

S. B. Treves, 1960, Dissert. Abs., v. 20, no. 10, p. 4080. Chiefly lower Precambrian gneisses that contain inclusions of older rocks, and minor syenite, granodiorite dikes, and pegmatites, numerous middle Precambrian metadiabase dikes and some quartz-rich pegmatite veins; a few upper Precambrian diabase dikes.

Present in Dickinson County.

†Carolina Gneiss[1] or Series

Precambrian: Northwestern North Carolina, South Carolina, northern Georgia, eastern Tennessee, and western Virginia.

Original reference: A. Keith, 1901, U.S. Geol. Survey Geol. Atlas, Folio 70, p. 2.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1379. Carolina gneiss, or Carolina series, is made up largely of biotite gneiss and mica schist, with beds of kyanite schist, quartzite, and rarely marble. Ashland, Wedowee, and Canton formations of Alabama and Georgia are here regarded as part of Carolina series.

T. L. Kesler, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 756, 775–781. Near Kings Mountain, mica schists and gneisses, previously mapped as Carolina gneiss, and hornblende gneisses previously mapped as Roan gneiss, actually constitute metamorphosed upper part of the Gaffney. Similar rocks in Beaver Creek area are apparently stratigraphically higher. Evidence in other parts of Carolina Piedmont, indicates that intrusive diorite and possibly recrystallized mafic volcanic rocks have been included in the Roan and possibly recrystallized felsic volcanic rocks in the Carolina. Names Carolina and Roan have lithologic but not stratigraphic value.

F. D. Eckelmann and J. L. Kulp, 1956, Am. Jour. Sci., v. 254, no. 5, p. 291, 314. Carolina gneiss includes all the various mica gneisses and mica schists in Spruce Pine district. Rocks are interlayered with those of the Roan gneiss, and the two types grade into each other along and across the strike. Roan-Carolina sequence (or complex) appears to be a single sedimentary unit with varying lithology, complicated by intense isoclinal folding and plastic deformation. Crosscutting relationship between the Cranberry gneiss or Henderson gneiss and the Roan-Carolina complex are entirely absent; the Cranberry and Henderson formations are in a consistent and conformable stratigraphic position below the Carolina-Roan complex as seen in Cranberry, Roan Mountain, and Mount Mitchell quadrangles.

Named for its occurrence on Piedmont Plateau in North and South Carolina.

Carolinas Limestone

Pliocene or Pleistocene: Mariana Islands (Tinian)

Risaburo Tayama, 1936, Geomorphology, geology, and coral reefs of Tinian Island together with Aguijan and Naftan Islands: Tohoku Univ., Inst. Geology and Paleontology Contr. in Japanese Language, no. 21, p. 21–26, 31 [English translation in library of U.S. Geol. Survey, p. 20–25, 31–32]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, table 3. *Halimeda* and coralline limestone. Beds dip seaward at angle of about 20°. Underlies Mariana limestone. May be Plio-Pleistocene.

Occurs on southeast coast of Tinian Island.

Caroline Limestone

Pleistocene or early Holocene: Caroline Islands (Fais).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 347 (correlation chart) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 68, table 5 [English translation in library of U.S. Geol. Survey, p. 82]. Named on correlation chart. Coral reef limestone. Older than Fais limestone. Consists chiefly of Halimeda limestone, with lesser amounts of coral limestone. Plio-Pleistocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 26. About 3 meters thick. Twenty meters above sea level. Early Holocene.

Fais (Feys) Island, west Caroline Islands.

†Carolinian Bed[1]

Eocene: Eastern South Carolina and North Carolina.

Original reference: E. Ruffin, 1843, South Carolina Agric. Survey 1st Rept., p. 6–24.

Exposed on Ashley and Cooper Rivers and their branches, also on Santee River and its branches, and on the Savannah and its branches. Named for extensive development in Coastal Plain of South Carolina.

Carpenter Bed[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: J. A. Taff, 1891, Texas Geol. Survey 2d Ann. Rept., p. 733, 735.

Probably named for Carpenter Spring, east side of Eagle Mountain, El Paso County.

Carpenter Limestone Member (of Grayson Formation)

Upper Cretaceous: Southwestern Texas.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 11 (table 1), 27, 28, pls. 1, 8, 16. Consists of about 90 feet of nodular thin-bedded black limestone weathering blue gray and interbedded gray shales; fossiliferous. Underlies a 60-foot middle member informally referred to as the reef-limestone; conformably overlies Georgetown limestone, to which it is very similar in appearance.

Type locality: Carpenter Canyon at a point about 1 mile above Carpenter Wells, Hudspeth County.

Carpenter Creek Porphyry[1]

Post-Cretaceous(?) : Central Montana.

Original reference: L. V. Pirsson, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 501.

U.S. Geological Survey currently designates the age of Carpenter Creek Porphyry as post-Cretaceous(?) on basis of study now in progress.

Named for occurrence above Carpenter Creek, Little Belt Mountains.

Carpinteria Formation[1]

Pleistocene, upper: Southern California.

Original reference: R. W. Chaney and H. L. Mason, 1934, Carnegie Inst. Washington Pub. 415, p. 48–52 [preprint 1932].

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 38, pl. 1. Late Pleistocene.

Probably named for Carpinteria, Santa Barbara County.

†Carquinez Series[1]

Eocene: Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416.

Carrasco limestone[1]

Upper Cambrian(?) : Southwestern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 5.

Well displayed back of Carrasco smelter property, near Silver City, Silver City region.

Carrigan black lands[1]

Pleistocene: Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey, v. 2, Ann. Rept. 1888.

Carrizo Flow or Tongue (of Clayton Basalt)

Late Cenozoic: Northeastern New Mexico

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 112, 133, 134, 143 (fig. 20). East of type locality, Clayton basalt consists of many long tongues. For purposes of this report, these tongues have been named, from south to north, Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that gave rise to these basalts are unknown.

Present in eastern Union County.

†Carrizo Formation[1]

Miocene: Southern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, no. 3, chart opposite p. 226.

Named for exposures in broad valley of Carrizo Creek, immediately north of Coyote Mountain, Imperial County.

Carrizo Sand (in Claiborne Group)[1]

Carrizo Formation (in Wilcox Group)

Eocene, middle: Southern and eastern Texas and western Louisiana.

Original reference: J. Owen, 1889, Texas Geol. and Min. Survey 1st Rept. Prog., p. 70, 73–74.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 60–65 [1938]. Sand (formation) described in Leon County, Tex., where it is about 60 feet thick. Underlies Newby glauconitic sand member (new) of Reklaw formation; overlies Sabinetown formation of Wilcox group.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 47 (fig. 1), 65–68, geol. map. In this report, Carrizo formation is considered uppermost formation in Wilcox group. Overlies Sabinetown formation; underlies Reklaw formation.

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 243–C, p. 37. Because of similarity of their stratigraphic position above Carrizo sand and similarity of the ferruginous beds partly composing them, Reklaw and Bigford members of Mount Selman formation have been regarded as contemporaneous. Geographic and stratigraphic positions of fossiliferous, ferruginous sandstones north of Leming, Atascosa County, suggest they represent eastward extension of the Bigford from Frio County. If the Leming and Scruggs Creek localities should prove to represent the same zone, then, on assumption that the conglomerate is basal part of Reklaw, it would appear that the Bigford is not exact equivalent of the Reklaw, but is older and intervenes between the Carrizo and the Reklaw.

H. B. Stenzel, 1953, Texas Univ. Bur. Econ. Geology Pub. 5305, p. 10 (fig. 3), 14 (fig. 5), 19–34. Formation (sand) described in Henrys Chapel quadrangle where it is 27 to 104 feet thick and consists of lower cross-bedded part and upper shaly level-bedded part. Overlies Wilcox group, locally, Henrys Chapel ball clay lentil (new); underlies Newby glauconitic sand member of Reklaw formation.

Type exposure: In quarries about one-half mile west of Carrizo Springs, Dimmit County, Tex.

†Carrizo Creek Beds[1]

Miocene: Southern California.

Original reference: C. R. Orcutt, 1890, California State Mining Bur. 10th Ann. Rept., p. 915.

Crops out on Carrizo Creek, but can also be seen along west side of valley around Coyote Mountains at Yuba Buttes and at Superstition Mountain as well as at San Felipe Valley, west of Salton Sea, Imperial County, and at places north of San Gorgonio Pass, in Riverside County.

Carrizo Mountain Formation

Carrizo Mountain Group

Carrizo Mountain Schist[1]

Precambrian: Western Texas.

Original reference: W. H. von Streeruwitz, 1891, Texas Geol. Survey 2d Ann. Rept. 1890, p. 681–683.

P. B. King, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 144 (fig. 1), 145–147. Carrizo Mountain schist described in Van Horn region where it consists of a number of contrasting types of metamorphic rocks which can be mapped separately over wide areas. These rocks fall into two main groups, one of which appears to lie stratigraphically below the other; lower group is largely of igneous origin and upper group largely sedimentary origin. Schist is overthrust northward on succeeding Allamoore limestone (new).

P. B. King and P. T. Flawn, 1953, Texas Univ. Bur. Econ. Geology Pub. 5301, p. 20–24, pl. 2. Carrizo Mountain group used in this report. Described as a body of metamorphic rocks of great thickness which in individual areas can be subdivided into a variety of rock types, most of which are mappable as separate entities. Many of these entities are well defined sedimentary units a thousand or more feet thick, which would be formations in their own right in sequence less disturbed and more widely exposed. Unit does not correspond with other formations as these are commonly differentiated in Texas. Although it is impracticable to subdivide unit into named divisions, it deserves informal designation as a group in much same manner as metamorphic units in Alaska and Canada. U.S. Geological Survey prefers term formation. Term group is used in this report without prejudice as to whatever usage may be adopted in subsequent reports of U.S. Geological Survey.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. All Precambrian rocks in Wylie Mountains and vicinity are referred to Carrizo Mountain group. Unconformably underlies Powwow conglomerate.

Named for Carrizo Mountains, El Paso County.

Carrizozo Lava Flow

Recent: South-central New Mexico.

J. E. Allen, 1951, *in* Roswell Geol. Soc. Guidebook 5th Field Trip, p. [7, 9–11]. Lava flow or malpais in all probability was extruded within last 1,000 years from base of single crater near northern end of flow. Exhibits all features commonly associated with recent flows of basaltic composition, such as flow units, pressure ridges, collapsed lava tunnels, and kipukas or steptoes of older rocks surrounded as islands by lava. Other minor surface features are ropy lava (pahoehoe), spatter cones, grooved lava, squeezeups, vesicular lava, and banded lava. Flow is approximately 44 miles long, in places up to 5 miles wide, and has average thickness of about 70 feet. Very close to 1 cubic mile in volume.

Eastern edge of flow is encountered along U.S. Highway 380, 4.2 miles west of Carrizozo.

†Carrollton Limestone[1]

Mississippian: Northwestern Arkansas.

Original reference: H. S. Williams, 1900, Arkansas Geol. Survey Ann. Rept. 1892, v. 5, p. 334–337.

Exposed in cliff in ravine in Carrollton, Carroll County.

Carrollton Mountain Porphyry[1]

Precambrian: Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135 (table), 136–137.

Bain's map shows Carrollton Mountains in eastern part of Wichita Mountains, Comanche County.

Carson Conglomerate

Tertiary, lower or middle: Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 31, 48–49, pls. 1, 3. Characteristically coarse, containing many boulders over a foot in diameter. Usually well cemented and quite resistant to processes of denudation. Matrix is light gray and resembles concrete; cement is silica. Boulders, cobbles, and pebbles consist of rhyolite, trachyte, andesite, black chert, and quartzite. Overlaps Precambrian rocks of area.

R. H. Jahns, 1946, New Mexico Bur. Mines Mineral Resources Bull. 25, p. 25. Early or middle Tertiary. Best exposures cited.

Overlaps rocks of Precambrian age along western, northern, and northeastern borders of Petaca area, Rio Arriba County. Best exposed in vicinity of Las Tablas where beds form bold cliffs and benches along lower slopes of Tusas River valley.

Carson Lava[1]

Pleistocene: Southwestern Washington.

Original reference: I. A. Williams, 1916, Oregon Bur. Mines and Geol., Min. Res. Oregon, v. 2, no. 3, p. 95–96.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, pl. 2. Age shown on chart as Pleistocene.

Extends from Carson Station to Wind River Canyon, Skamania County.

Carson Creek Formation[1]

Paleozoic or Mesozoic: Northern California.

Original reference: F. A. Moss, 1927, Eng. and Mining Jour., v. 124, p. 1010–1011.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, pt. 4, p. 675. Local name for bedrock series. Paleozoic or Mesozoic.

Exposed west of Carson Hill, Calaveras County.

Carsonian series[1]

Quaternary: Nevada.

Original reference: C. R. Keyes, 1923, Pan.-Am. Geologist, v. 40, p. 52, 78.

Well exposed in the valleys of the Carson and Truckee Rivers in western Nevada.

Carsonville Granite

Precambrian: Southwestern Virginia.

A. J. Stose, 1942, (abs.) Am. Geophys. Union Trans., 23d Ann. Mtg., pt. 2, p. 342. Injection complex of early Precambrian age is exposed in Elk Creek anticline in Grayson County. There, sedimentary rocks and diorite have been intruded by the Striped Rock and Carsonville granites.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 34–37, pl. 1. Narrow belt of fine-grained pink felsitic granite that intrudes the Striped Rock granite along its northern and western borders; it is interbanded with a porphyritic biotite granite which has pink microcline phenocrysts and contains xenoliths of Saddle gneiss.

Named from village of Carsonville, 2 miles north of Baxter Ferry on New River. Well exposed on road near Carsonville, near Mountain View School to west, on Rock Creek, on Roaring Branch, on a tributary to Saddle Creek, and near head of Little Peach Bottom Creek. Occurs within areas of Comers granite gneiss and Grayson granodiorite gneiss.

Carters Limestone (in Stones River Group)

Carters Limestone Member (of Lowville Limestone)[1]

Middle Ordovician: Central Tennessee.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 258–268.

Ray Bentall and J. B. Collins, 1945, Tennessee Div. Geology Oil and Gas Inv. Prelim. Chart 4, sheet 1. Rank raised to formation in Stones River group.

C. W. Wilson, 1949, Tennessee Div. Geology Bull. 56, p. 44–45. Names Tyrone and Lowville should not be used in central Tennessee; name Carters has priority over New York name, Lowville, and Kentucky name, Tyrone; name Carters limestone should be restored to formational rank and used as originally defined by Safford, that is, to include strata between overlying Hermitage formation and underlying Lebanon limestone. In central Tennessee, Carters limestone consists of upper thin-bedded unit and lower massive-bedded unit, which are referred to as Upper member and Lower member. The two members are separated by a bentonite bed, and Lower member contains two bentonite beds. Thickness of Lower member averages 50 feet; maximum thickness of Upper member 28 feet. Safford's "type locality" discussed in detail.

Named for exposures on Carters Creek, Maury County. Carters Creek arises from many several tributaries about 8 miles north of Columbia, Maury County, flows essentially southward, joining Rutherford Creek about 3½ miles north of Columbia.

†Carters Creek Limestone[1]

Middle Ordovician: Central Tennessee.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 258–268.

Named for exposures on Carters Creek, Maury County.

†Cartersville Formation[1]

Lower Cambrian: Northwestern Georgia.

Original reference: H. K. Shearer, 1918, Georgia Geol. Survey Bull. 34, p. 48–49, 128–163.

T. L. Kesler, 1950, U.S. Geol. Survey Prof. Paper 224, p. 19. Abandoned. Shearer grouped together some parts of Conasauga and Rome formations in which metasiltstone is common and designated them Cartersville formation. It has been impossible to adhere to this grouping, because Shearer's contacts transgress the strike of the rocks and his formation includes carbonate rocks, calcareous metashale, and noncalcareous metashale which, as shown herein, are stratigraphically distinct.

Named for exposures in vicinity of Cartersville, Bartow County.

Cartersville Granite[1]

Precambrian: Central Virginia.

Original reference: A. I. Jonas, 1928, Virginia Geol. Survey, prelim. ed. of geol. map of Virginia.

Mapped at and around Cartersville, Cumberland County.

Carterville Formation[1]

Upper Mississippian: Southwestern Missouri.

Original reference: C. E. Siebenthal, 1907, U.S. Geol. Survey Geol. Atlas, Folio 148.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 268–270. Consists of shaly lumpy somewhat conglomeratic and in most places oolitic limestone, calcareous shale, light to dark argillaceous arenaceous shale. and shaly sandstone, massive unindurated sandstone, massive hard sandstone, and quartzite. Thickness ranges from a few inches up to 50 feet. Occupies depressions (apparently old sink holes) in Boone formation; in all occurrences surrounded by a rim of Boone limestone.

C. H. Behre, Jr., and A. V. Heyl, Jr., 1959, Deutsche Geol. Gesell. Zeitschr., v. 110, pt. 3, p. 517 (fig. 2). Chart shows formation, about 16 feet thick, overlying Short Creek member of Boone formation and underlying Cherokee shale.

Named for exposures west of Carterville, Jasper County.

Carthage Limestone[1]

Mississippian (Warsaw): Southwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Geol. Survey Bien. Rept., p. 30, 37, 38.

Named for exposures at Carthage, Jasper County.

Carthage Limestone (in Lisman Formation)

Carthage Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Western Kentucky and southern Illinois.

Original references: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, p. 60, 61; 1857, Kentucky Geol. Survey, v. 3, p. 18.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 26). Shown on correlation chart as limestone in Lisman formation.

Named for Carthage Settlement (no longer in existence) on Ohio River, just above mouth of Wabash River, Union County, Ky.

Carthew Member (of Altyn Formation)

Precambrian (Belt Series): Southern Alberta, Canada, and western Montana.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1883–1884, fig. 2. Magnesian limestones, dolomites, quartzites, and intermediate rocks which grade upward into basal Appekunny formation. Colors range from blue gray through buff to brown and dark brownish red; bedding thin to thick. Red beds, especially, show thin laminae. Thickness estimated at 700 to 900 feet. Overlies Hell Roaring member (new).

Type locality: Eastern cliffs of Cameronian Mountain above Cameron Creek, Waterton Lakes Park, Alberta. Well exposed on eastern face of Bertha Mountain, on slopes between Vimy Peak and the Narrows of Waterton Lake, and on northern cliffs of Gable Mountain, Glacier National Park.

Cartwright Gravel

Pleistocene (pre-Wisconsin): Northwestern North Dakota and northeastern Montana.

A. D. Howard, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 578, pl. 1. Gravel which marks paths of streams across Missouri Plateau peneplain. Caps Cartwright bench along parts of major valleys characterized by distinctive brown, water-worn pebbles.

A. D. Howard, 1960, U.S. Geol. Survey Prof. Paper 326, p. 19–21, pl. 1. Gravel and interbedded sand on Missouri Plateau peneplain. Thickness 35 to 40 feet at Cartwright locality; regional average thickness about 30 feet. Older than Crane Creek gravel; younger than Flaxville gravel. Pre-Wisconsin, Aftonian(?).

Well exposed along road that descends into Yellowstone Valley, 5 to 6 miles north of town of Cartwright in northwestern McKenzie County, N. Dak., not far from Yellowstone-Missouri confluence.

Carwood Formation[1] (in Borden Group)

Lower Mississippian: Southeastern Indiana.

Original reference: P. B. Stockdale, 1929, Ohio Jour. Sci., v. 29, no. 4, p. 170.

P. B. Stockdale, 1931, Indiana Div. Geology Pub. 98, p. 76–77, 147–192. Includes following facies (herein named): Bennettsville, Knob Creek, Evans Landing, Delaneys Creek, Sparksville, Gent, Fleener, and Kelly Hill.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 76). Shown on correlation chart in Borden group, Osage series. Underlies Floyds Knob formation; overlies Locust Point formation.

Named from village of Carwood (Bridgeport), 4¾ miles southeast of Borden, NW¼NW¼ sec. 9, and SW¼SW¼ sec. 4, T. 1 S., R. 6 E., Clark County. Any one of numerous exposures in Clark County might serve as a "type" section; best is along Borden-Martinsburg Road, one-half mile southwest of Borden.

Cary Stade

Cary (Caryan) Substage[1] or Subage

Pleistocene (Wisconsin): Mississippi Valley.

Original reference: M. M. Leighton, 1933, Science, v. 77, p. 168.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 132. Bradyan subage (new) occurs between Tazewellian Caryan sub-ages. It divides Wisconsinian into two unequal parts. Report also mentions Cary till and Cary loess.

R. V. Ruhe, Meyer Rubin, and W. H. Scholtes, 1957, Am. Jour. Sci., v. 255, no. 10, p. 671–689. New radiocarbon dates in Iowa permit a grouping of age values and raise new problems in stratigraphic correlation of late Pleistocene deposits in Iowa and adjacent regions. An older group of ages greater than 29,000 years dates Iowan substage and pre-Iowan deposits. An old group of ages of 22,900 to 25,100 years dates the Farmdale substage. An intermediate group of ages ranges 14,000 to 17,000 years. Minimum date of Tazewell-Cary interstadial is 14,000 years. Cary maximum in southern extremity of Des Moines lobe in Iowa was 14,000 years ago. A young group of ages ranges from 11,900 to 14,000 years and record Cary glaciation in southern extremity of Des Moines lobe.

V. C. Shepps, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 167–187; V. C. Shepps and others, 1959, Pennsylvania Geol. Survey, 4th ser., Bull G–32, p. 2–59. Deposits of Cary substage in northwestern Pennsylvania include Kent, Lavery, Hiram, and Ashtabula tills.

Meyer Rubin, 1960, Am. Geophys. Union Trans., v. 41, no. 2, p. 288–289. Discussion of changes in Wisconsin glacial stage chronology by C^{14} dating. Type Mankato till dates at about 12,000 years, making it older than Valders till of Thwaites at Two Creeks, and actually placing it into Cary substage range of ages. Because of difficulty in finding any type of break between Cary-age and Tazewell-age deposits in many places, some workers have abandoned division of the two entirely, grouping them together.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 1, 3–4, 7. Presentation of new classification of Wisconsinan stage of Lake Michigan glacial lobe. Consists of following substages (descending): Valderan, Twocreekan, Woodfordian, Farmdalian, and Altonian. The Woodfordian includes Iowan substage of Illinois usage (but not of the type), the type Tazewell and Cary substages. Includes that part of the Cary that has recently been assigned to the Mankato (Leighton, 1957; Wright, 1957, Science, v. 125, no. 3256).

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529–552. Presentation of new classification of Wisconsin glacial stage of north-central United States. Cary glacial substage by St. Charles intraglacial substage and from younger Mankato glacial substage by Bowmanville intraglacial substage. Author [Leighton] does not agree with classification proposed by Frye and Willman (1960) in which they placed all three substages, Tazewell, Cary, and Mankato in the Woodfordian.

Name amended to Cary Stade to comply with Stratigraphic Code adopted 1961.

Name derived from town of Cary, McHenry County, Ill.

Caryville Sandstone (in Redoak Mountain Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau; Tennessee Div. Geology [folio], p. 11, 19, pls. 2, 3, 4. Thickness 60 feet near Caryville; 10 feet in Cross Mountain section; 20 feet in Walnut Mountain section. Overlies a shale unit 80 to 190 feet thick at base of group; separated from overlying Fodderstack sandstone (new) by a shale interval 50 to 150 feet thick.

Named from exposures in section above Caryville, Jacksboro quadrangle, Campbell County. A northwest-southeast belt of massive Caryville crosses Windrock, Duncan Flats, Fork Mountain, Block, and Jacksboro quadrangle.

Casadepaga Schist[1]

Pre-Paleozoic or Lower Paleozoic: Northwestern Alaska.

Original reference: P. S. Smith, 1910, U.S. Geol. Survey Bull. 433, p. 70–75, map.

Covers 100 square miles in Solomon and Casadepaga quadrangles, one belt along east part of quadrangles and another along west part of quadrangles, Seward Peninsula.

Casa Larga Marls

Eocene, upper: Panamá Canal Zone.

[T. F. Thompson] 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 8. Oldest known sedimentary formations known to rest upon the Basement Complex occur within the vicinity of the Tranquilla shales, which formerly cropped out at a point in the Chagres River Valley now inundated by the waters of Madden Lake, and in so-called Casa Larga marls to the southeast of Tranquilla shale locality. On basis of their fossil content, the marls are considered to be upper Eocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 329. Expression used by Thompson was "so-called Casa Larga marls." An undefined name for calcareous strata in Gatuncillo formations.

Madden basin.

†Cascade Formation[1]

Precambrian : Northwestern Michigan.

Original reference: M. E. Wadsworth, 1890, Lake Superior along the south shore, by Julian Ralph, p. 77–99 ; 1st ed., 1890 ; 2d ed. 1891.

Well exposed at Cascade Range, Marquette district.

†Cascade Formation[1]

Lower Cretaceous : Central Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

Kiril Spiroff, 1938, Econ. Geology, v. 33, no. 5, p. 558 (fig. 2). Mapped as Cretaceous in Barker mining district, Hughesville, Montana.

Named for development in Cascade County ; Little Belt Mountains and Fort Benton region.

†Cascade Sandstone (in Chemung Formation)[1]

Cascade sandstone member (of Cayuta monothem)

Upper Devonian : Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G–5, p. 74–79, 82, 98.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7), 47. Reallocated to base of Cayuta monothem. Described near Lanesboro as usually massive coarse gray to olive-green sandstone; highly micaceous and usually stained with iron oxide. Made up of several lenses not individually traceable for great distance, yet unit as whole is very persistent. Layers of coarse flat pebbles and conglomeratic layers locally developed. Underlies Owego shale member (new). [Shown as equivalent to lower part of Owego in fig. 7.] Also termed Cascade Creek sandstone member.

Forms cliffs which wall in Cascade Creek at Erie Railroad crossing, Susquehanna County.

Cascade Creek Sandstone (in Chemung Formation)[1]

Upper Devonian : Northeastern Pennsylvania.

Original references: J. J. Stevenson, 1892, Am. Geologist, v. 9, p. 22 ; 1892, Am. Assoc. Adv. Sci. Proc., v. 40, p. 235.

Susquehanna and Wayne Counties.

Cascades Formation[1] or Andesite

Pleistocene : Central northern Oregon and southwestern Washington.

Original reference: I. A. Williams, 1916, Oregon Bur. Mines and Geology, Mineral Resources Oregon, v. 2, no. 3.

1959, Dept. Geology and Mineral Resources Bull. 50, p. 9, 11. Cascade andesite (Cascan) listed in Cenozoic formations of Oregon.

Occurs in Cascade Mountains.

Cascadia Formation[1]

Oligocene and Miocene (?) : Central northern Oregon.

Original reference: E. T. Hodge, 1928, Pan-Am. Geologist, v. 49, p. 341–356.

Exposed near Cascadia, Linn County.

Cascadian Stage[1] or Glacial Epoch

Pleistocene: Central northern Oregon.

Original reference: E. T. Hodge, 1930, Monthly Weather Rev., v. 58, p. 405–411.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 834–835, 841 (table 1). Oldest of five glacial epochs; followed by Bull Run glacial epoch.

Cascadilla Shale Member (of Ithaca Formation)

Cascadilla Shale Member[1] (of Ithaca facies subgroup)

Upper Devonian: South-central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 202.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4. Member of Ithaca formation. Underlies Williams Brook member; overlies Six Mile shale member. Thickness 150 feet.

Occurs in Ithaca region. Probably named for Cascadilla Gorge at Ithaca, Tompkins County.

Cascajo Conglomerate Member (of San Joaquin Formation)

Pliocene, upper: Southern California.

W. P. Woodring, Ralph Stewart, and R. W. Richards, 1940, U.S. Geol. Survey Prof. Paper 195, p. 49–54, pl. 3 [1941]. Unit of conglomerate and sandstone, generally blue, lying at base of San Joaquin formation. Average thickness 50 feet, but at places considerably greater. Overlies Etchegoin formation.

Type locality: Cascajo Hill, on west flank of South Dome, Kettleman Hills. South Dome is the northern part of the anticline that is overlapped by the alluvium of San Joaquin Valley.

Cascan Formation

Pliocene or Pleistocene: Central northern Oregon.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 841 (table 1), 842 (fig. 4), 879–886. Mnemonic name proposed for formation composed chiefly of andesitic lava flows that lie on top of Dalles and Troutdale formations and are older than Mount Hood formation.

E. T. Hodge, 1940, Oregon State Coll. Studies in Geology Mon. 1 [map with text]. Described in Madras quadrangle where it lies conformably upon Madras formation and unconformably upon all older formations. Older than a Recent unit termed the Intracanyon formation.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 7, pl. 2. Pliocene.

Type locality: Cascade Mountains of northern Oregon.

Casco Bay Group[1]

Pennsylvanian (?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

Includes (ascending) Cape Elizabeth Formation, Spring Point Greenstone, Diamond Island Slate, Scarboro Phyllite, Spurwink Limestone, Jewell Phyllite, and Mackworth Slate.

Named for development in and around Casco Bay, Cumberland County.

Casey Limestone[1]

Middle Devonian: Southern central Kentucky.

Original reference: T. E. Savage, 1930, Kentucky Geol. Survey, ser. 6, v. 33, p. 12, 143–144.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, chart 4. Shown on correlation chart below Duffin limestone and above Boyle limestone.

J. M. Weller, 1944, Illinois Geol. Survey Bull. 68, p. 211. Southward in Kentucky it [Sellersburg limestone] loses its typical lithologic and faunal characters and may be overlapped by the Casey limestone.

Well exposed in southwestern part of Casey County.

Caseyville Formation (in McCormick Group)

Caseyville Sandstone (in Pottsville Group)[1]

Caseyville Group

Lower Pennsylvanian: Southeastern Illinois and western Kentucky.

Original reference: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, p. 48, 49, 62, pl.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 36–39. Group includes (ascending) Lusk, Battery Rock, and Pounds formations. Maximum thickness more than 400 feet in parts of Pope and Hardin Counties; thins irregularly westward to not more than 200 feet in northern Union County. Underlies Tradewater group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1), 28–30, 44 (table 1), 61–62, pl. 1. Defined as formation in McCormick group (new). Includes strata from base of Pennsylvanian to top of Pounds sandstone member. Corresponds to Caseyville formation as defined by Lee (1916, Geology of the Shawneetown quadrangle in Kentucky; Kentucky Geol. Survey) and probably to strata referred to as Caseyville conglomerate by Owen (1856). Caseyville as previously used in Illinois (Weller, 1940) is thus redefined to exclude 40 to 60 feet of strata (including Reynoldsburg coal) above Pounds sandstone and below Grindstaff sandstone that are here included in overlying Abbott formation (new). Characterized by dominance of sandstone and prominent development of sandy shale and siltstone. Thickness commonly 350 feet. In southeastern area, includes (ascending) Lusk shale, Battery Rock sandstone. Sellers limestone, Gentry coal (new), and Pounds sandstone members; in southwestern area includes (ascending) Wayside sandstone, Battery Rock sandstone, Drury shale, and Pounds sandstone members. Type area defined by Lee (1916). Supplementary section given.

U.S. Geological Survey has abandoned use of the term Pottsville in Kentucky and Illinois.

Type area (Lee, 1916): Measured from outcrops on Illinois shore of Ohio River between mouth of Saline River and Gentry's Landing below Battery Rock, T. 11 S., R. 10 E., Shawneetown quadrangle, Hardin County. Reference section: Along railroad cut of Illinois Central Railroad from tunnel, NW¼SW¼SE¼ sec. 31, T. 11 S., R. 5 E., southward to

NE¼SE¼NE¼ sec. 18, T. 12 S., R. 5 E., Brownfield and Harrisburg quadrangles, Pope County, Ill.

Cashaqua Shale Member (of Sonyea Formation)

Cashaqua Formation (in Naples Group)

Cashaqua Shale[1]

Upper Devonian : Western and central New York.

Original reference: J. Hall, 1840, New York Geol. Survey 4th Rept., p. 390–391, 409, 423, 452–455.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 12. Cashaqua shale includes (ascending) unnamed shale member, Rock Stream flagstone member (new), and Parrish limestone lentil.

G. W. Colton and Wallace de Witt, Jr., 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–54. Rank reduced to member status in Sonyea formation. Hall (1840) gave formational name Cashaqua to soft gray mudrock and shale that crops out along lower part of Cashaqua Creek (spelled Keshequa on recent topographic maps) near Sonyea in west-central Livingston County. As originally defined by Hall and as subsequently used by other geologists in western two-thirds of area covered by present report, Cashaqua shale included, in terms of nomenclature of this report, all rocks between Middlesex shale member of Sonyea formation and base of Rhinestreet shale member of West Falls formation. In Livingston and Ontario Counties and west half of Yates County, Hall's Cashaqua shale included in ascending order units herein assigned to Pulteney shale (new), Rock Stream siltstone, and Cashaqua shale members of Sonyea formation. In eastern half of Yates County, Hall's Cashaqua included parts of West River shale and underlying Geneseo shale. Hall's Cashaqua is redesignated Cashaqua shale member of Sonyea. Name is herein restricted to the medium-gray to medium-greenish-gray mudrock and shale facies that crop out at type exposure of Hall's Cashaqua near Sonyea. In Erie County, directly overlies Middlesex shale member; between southwestern Genesee County and eastern Livingston County, overlies Pulteney shale member; from eastern Livingston County to Keuka Lake, overlies Rock Stream siltstone member. Thickness 35 to 159 feet. Reference section designated.

R. G. Sutton, 1960, New York State Mus. Bull. 380, p. 13–18. Formation included in Naples group. Overlies Middlesex shale; underlies Rhinestreet black shale. Subdivided to include Sawmill Creek (new), Rock Stream, and Rye Point (new) members. Thickness 28 to 480 feet; thickens from shore of Lake Erie to Seneca Lake.

Named for exposures on Cashaqua Creek, Livingston County, above junction of Genesee Valley Canal. Reference section: Buck Creek in Morris Township, 3 miles southwest of Sonyea, Livingston County.

Casitas Formation

Pleistocene : Southern California.

J. E. Upson, 1951, U.S. Geol. Survey Water-Supply Paper 1108, p. 21–23, table facing p. 12, pl. 1. Body of considerably deformed red continental deposits consisting of clay, silt, sand and gravel. Thickness in measured sections 188 to 401 feet; about 1,000 feet thick beneath Shepard Mesa and may be more than 3,000 feet thick beneath alluvial plain farther south. Underlies older alluvium, terrace deposits, and younger alluvium; overlies Santa Barbara formation; east of Rincon Creek, overlaps and cuts out Santa Barbara and rests on Rincon shale and older formations at least at margins of Santa Barbara basin.

Extensively exposed in valley of Rincon, Carpinteria, and Gobernador Creeks, Santa Barbara County.

Casmalia Gypsiferous Shale or Redbeds[1]

Miocene: Southern California.

Original reference: H. W. Hoots and S. C. Herold, 1935, Geology of natural gas: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 156.

Occurs in Casmalia Hills, Santa Maria district.

†Cason Limestone[1]

Silurian: Northern Arkansas.

Original reference: H. S. Williams, 1894, Am. Jour. Sci., 3d, v. 48, p. 325–331.

Named for Cason tract, near Batesville, Independence County.

Cason Shale[1]

Upper Ordovician: Northern Arkansas.

Original reference: H. S. Williams, 1894, Am. Jour. Sci., 3d, v. 48, p. 325–331.

E. B. Brewster and N. F. Williams, 1951, Guidebook to the Paleozoic rocks of northwest Arkansas [Shreveport Geol. Soc. 19th Ann. Field Trip]: Arkansas Resources Devel. Comm., Div. Geology, p. 13. Black and blue-gray shale and thin argillaceous platy limestone. Thickness as much as 23 feet. Unconformable on the Fernvale limestone, and in most places in this area unconformably overlain by St. Joe limestone.

Named for Cason tract, near Batesville, Independence County.

Casper Formation[1]

Pennsylvanian and Permian: Southeastern Wyoming.

Original reference: N. H. Darton, 1908, Geol. Soc. America Bull., v. 19, p. 407, 413, 414, 416, 418–430.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 10–11; 1950, Bull. 13–A, p. 11. Section measured in Laramie Range, Wyo., south of Union Pacific Railroad, 18 miles west of Cheyenne. According to Colorado terminology, upper formations of section would be classed under Ingleside formation, but in Wyoming this part of section plus equivalent of the Fountain is called Casper as revised by Knight (1929, Wyoming Univ. Pub. Sci. Geology, v. 1, no. 1). Hence, name Casper is used for Pennsylvanian in Laramie Range to include Ingleside and Fountain formations.

H. D. Thomas, 1948, Wyoming Geol. Assoc. Guidebook 3d Ann. Field Conf., p. 88–89. in Casper Mountain-Alcova area, the Casper is 400 to 500 feet thick; this is comparable to combined thickness of Amsden and Tensleep to the west. Many geologists have divided section in this area into Amsden and Tensleep. Basal bed, commonly sandstone, rests on eroded surface of Madison. Lower part of Casper comprises thin interbedded limestones and sandstones resembling Amsden; upper part is thick tan cross-bedded sandstone which seems lithologically identical to Tensleep of areas to west. Entire Casper of this area seems to be completely younger than any part of Tensleep. Fusulinids (*Triticites*) have been collected from Casper.

M. L. Thompson, H. D. Thomas, and J. W. Harrison, 1953, Wyoming Geol. Survey Bull. 46, p. 5–55. Formation comprises alternating succession of beds made up principally of crossbedded sandstones and fossiliferous limestones. Thickness 500 to over 1,000 feet. Rests unconformably on Mississippian limestone (Madison) along northern part of Laramie Range. Mississippian rocks thin southward, and south of Little Medicine section the Casper everywhere rests on Precambrian rocks. In northern part of range, overlain unconformably by Opeche shale, but evidence of such break becomes less clear in southern part of range. Fusulinid faunas indicate formation ranges from Middle Pennsylvanian (Desmoinesian) to Lower Permian (Wolfcampian).

R. S. Agatston, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 535–549. Formation includes all beds from top of Madison limestone to base of Permian (Opeche) red shales. Fusulinid data, correlated with midcontinent fauna, suggest that formation spans Middle and Upper Pennsylvanian and part of Lower Permian. Subdivided into lower, middle, and upper divisions. Lower division present throughout most of southeastern Wyoming and exposed along flanks of Laramie Range throughout Laramie and Shirley basin regions. Composed of four major rock types (in order of importance); arkose, sandstone, shale, and limestone, Middle division represented throughout Laramie Mountain and Basin region, Shirley basin, and southeastern part of Wind River basin. Where definable, thickness 100 to 300 feet, and strata consist mainly of carbonates separated by thin sandstone interbeds which underlie upper Casper interbedded cherty dolomite and sandstone with local disconformity. Age thought to be Upper Pennsylvanian. Upper division exposed throughout Laramie Mountains and adjacent basins. The section, 230 to 500 feet thick, is sandstone, limestone, and dolomite. Red sandstone, shaly sandstone, and shale (200 to 400 feet thick) overlie presently recognized upper limit of the Casper along east flank of Laramie Mountains, but underlie Opeche shale and Minnekahta limestone. They have been included in Broom Creek and Cassa groups by Condra and others (1940).

C. A. Burk and H. D. Thomas, 1956, Wyoming Geol. Survey Rept. Inv. 6, p. 3–11. Underlies Goose Egg formation (new).

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Discussion of stratigraphy of Pennsylvanian system in northeastern Utah, western Wyoming, northwestern Colorado, and southeastern Idaho. Suggested that Quadrant and Casper formational names be abandoned and Tensleep-Amsden-Sacajawea terminology extended to include strata formerly referred to by these names.

E. K. Maughan and R. F. Wilson, 1960, *in* Guide to the geology of Colorado: Rocky Mountain Assoc. Geologists, p. 36 (fig. 2), 38–39 (fig. 3). 40 (table 1), 41. Mississippian, Pennsylvanian, and Permian.

Named for occurrence in Casper Range.

Cass Limestone[1] (in Douglas Group)

Pennsylvanian (Virgil Series): Southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 41, 58.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 29–30. When named in 1927, exact age relation of the Cass was not known, but since that time it has been found that this subdivision is cyclothemal formation composed of three members (ascending): Shoemaker limestone (redefined), Little Pawnee shale (new), and Haskell limestone. Thickness 17 feet or more. Underlies Robbins shale; overlies Plattford formation.

Type locality: Platte River bluffs and Burlington quarries located 1½ to 2 miles northwest of South Bend, Cass County.

Cassa Group

Permian: Eastern Wyoming, northeastern Colorado, and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 5, 19, 45. Comprises upper 180 feet of Division I of Hartville "formation" (Condra and Reed, 1935). Thickness ranges from 175 to 328 feet. Underlies Phosphoria group; overlies Broom Creek group (new). Consists of Owl Canyon formation (new) below, Lyons sandstone above.

Type locality: Buckshot Canyon (also called Ragan Canyon), T. 29 N., R. 67 W., 3 miles northeast of Cassa, Platte County, Wyo.

Cassadaga Group

Cassadaga Stage

Upper Devonian (Chautauquan): North America.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1734, chart 4. Devonian subdivided into 10 stages of which the Cassadaga is ninth in sequence (ascending). [For complete sequence see Helderberg stage, this reference.] Follows Chemung stage and is succeeded by Conewango. Embraces sequence from Dunkirk shale to Wolf Creek-Panama conglomerate. Includes Canadaway and Conneaut groups.

A. T. Cross and J. H. Hoskins, 1951, Jour. Paleontology, v. 25, no. 6, p. 718 (fig. 3). Shown on composite stratigraphic column of western New York and northwestern Pennsylvania as Cassadaga group. Includes Canadaway and Conneaut formations. Overlies Chemung group; underlies Conewango group.

Type section (stage): Headwaters and valley of Cassadaga Creek in Dunkirk, Chautauqua, and Jamestown quadrangles, New York.

Cassel Hill Member (of Catahoula Formation)

Miocene: East-central Louisiana.

W. D. Chawner, 1936, Louisiana Dept. Conserv. Geol. Bull. 9, p. 121–122. Loose, noncalcareous sands and sandy clays which commonly contain considerable silicified wood; occurs at base of the Catahoula. Thickness as much as 45 feet; near Cassel Hill 15 to 25 feet thick. Unconformably overlies Vicksburg formation. Separated from overlying Chalk Hills member (new) by an interval of massive sandstone and gray tuff.

Well developed in vicinity of Cassel Hill, NE¼ sec. 9, T. 10 N., R. 5 E., Catahoula Parish.

Cassin Formation[1]

Lower Ordovician: West-central Vermont and northeastern New York.

Original reference: H. P. Cushing, 1905, New York State Mus. Bull. 95, p. 362.

R. R. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939. Geographically extended to northeastern New York.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, p. 266. Usage of name summarized.

Typically exposed at old Fort Cassin, Addison County, Vt.

Cassinian Series or Stage

Ordovician (Canadian) : North America.

R. H. Flower, 1957, New Mexico Bur. Mines Mineral Resources Mem. 2, p. 18. Divisions within Canadian system favor natural division into four major units: Gasconadian, Demingian, Jeffersonian, and Cassinian. The Cassinian include the Fort Cassin and Providence Island beds of Champlain Valley and Smithville and Black Rock of northern Arkansas. Classification based principally on cephalopod distribution.

Canadian series includes Gasconadian, Demingian, Jeffersonian, and Cassinian stages. Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–32.

Cassville Shale Member (of Washington Formation)[1]

Cassville Shale (in Washington Group)

Cassville shale member

Pennsylvanian: Northern West Virginia, eastern Ohio, and southwestern Pennsylvania.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 41.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. 26–C, p. 135, 145. Basal unit of Washington group. Overlies Waynesburg coal; underlies Waynesburg sandstone from which it is separated locally by Elm Grove limestone. Thickness as much as 25 feet.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 89–90. Cassville shale member is basal unit of Washington series of the Permian in Ohio. Conformably overlies Waynesburg (No. 11) coal; underlies Elm Grove limestone member. Thickness in Morgan County 3 to 6 feet.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 18 (table 2), Cassville shale in Washington formation listed in stratigraphic summary of Dunkard group in Harrison County. At base of formation. Thickness 0 to 15 feet.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg. p. 118 (table 2). Cassville shale listed in Washington series. Permian.

U.S. Geological Survey currently designates the age of the Cassville Shale Member of Washington Formation as Pennsylvanian on the basis of a study now in progress.

Named for exposures in vicinity of Cassville, Monongalia County, W. Va.

Castaic Formation

Miocene, upper: Southern California.

Peter Dehlinger, 1952, California Div. Mines Spec. Rept. 26, p. 5 (footnote). Incidental mention.

J. C. Crowell, 1954, California Div. Mines Bull. 170, map sheet 7. Consists of shale with interbedded sandstone and minor beds of pebble conglomerate. Thickness at least 7,000 feet. Conformably underlies Ridge Basin group (new) with an interfingering contact that is marked by an abrupt upward increase in the proportion of sandstone beds; unconformably overlies Mint Canyon formation. Previous investigators have included the Castaic in the Modelo, but it differs lithologically from Modelo of Ventura and thus can be differentiated.

Type locality: Along lower reaches of Castaic Canyon north of Castaic, Ridge basin area. Los Angeles and Ventura Counties. Crops out only northeast of San Gabriel fault.

Castalia Sand

Pleistocene, upper: Eastern North Carolina.

W. B. Wells, 1944, Elisha Mitchell Sci. Soc. Jour., v. 60, no. 2, p. 130–131, pls. 63, 64. Vertical cliff exposes four layers (or horizons) which show progressively decreasing consolidation upward; each lies unconformably on the preceding. Maximum thickness of exposure a little more than 9 feet. Castalia sand is a stratum exhibiting marked variations in thickness, consolidation, and color. A large part of layer is poorly consolidated and consists of gray dark mottled medium sand. Underlies Pine sand (new); overlies Kure sandstone (new).

Exposed between Kure's Beach fishing pier and Ethyl Dow Bromine Plant on lower Cape Fear Peninsula.

Castanea Sandstone[1]

Lower Silurian (Albion Series): Central Pennsylvania.

Original reference: F. M. Swartz, 1934, Geol. Soc. America Bull., v. 45, p. 83, 91, 102, 109.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart at top of Albion series; underlies Rose Hill shale at base of Clinton group; lies above Tuscarora (Clinch) sandstone.

Named for Castanea, a suburb of Lock Haven, Clinton County.

Castile Gypsum[1] or Formation

Castile Anhydrite[1]

Permian (Ochoa Series): Western Texas and southeastern New Mexico.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 43.

W. B. Lang, 1949, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 10, p. 1569-1572. Base of Salado formation redefined. Anhydrite included in top of Castile (Lang, 1937) is included in base of Salado. This redefinition of Salado confines Castile to Delaware basin.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 586, 609, 611, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 68–69, 89–91, pl. 3. Formation, as now defined, includes beds in lower part of Ochoa series that are confined in extent to Delaware basin and overlap sloping surface of Capitan limestone along its margins. Also overlies Bell Canyon formation (new) of Delaware group. Salado includes higher beds, which occur both in the basin and beyond its margins. As thus defined, Castile is dominantly anhydrite-bearing and Salado dominantly salt-bearing but these distinctions are not absolute. Drill records indicate that formation has maximum thickness of between 1,500 to 2,000 feet near center of basin.

Named for Castile Spring, El Paso County, Tex.

Castine Volcanics[1]

Castine Formation

Cambrian(?): South-central Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 5.

P. S. Wingard, 1958, Kansas Acad. Sci. Trans., v. 61, no. 3, p. 330–333. Castine formation, previously designated as Cambrian, now tentatively designated as either Middle or Upper Silurian. Overlies Ellsworth formation.

Named for exposures on Castine Peninsula, Hancock County.

Castiyo Limestone

Aquitanian: Mariana Islands (Tinian).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 52, table 4 [English translation in library of U.S. Geol. Survey, p. 62].

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 25. Castiyo is coralliferous, foraminiferal, and algal limestone. *Miogypsina* limestone and Tinian formation of Tayama (1936) and Lasso limestone of Tayama (1952) should be included in this formation. Aquitanian. Type locality stated. Refer to K. Asano (1939, Jubil. Pub. Yabe's 60th Birthday).

Type locality: Puntan Casityo, Tinian Island.

Castle Granite[1]

Miocene or Pliocene: Central southern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 56.

F. C. Armstrong, 1957, Econ. Geology, v. 52, no. 3, p. 221. In Castle Mountains, Flathead quartzite occurs near Castle granite and locally has been thermally metamorphosed by it.

Forms central core of Castle Mountain, Little Belt Mountains.

†Castle Limestone Member (of Madison Limestone)[1]

Lower Mississippian: Central northern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

L. L. Sloss and R. H. Hamblin, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 3, p. 314–315. Strata called Mission Canyon are lithologically and faunally identical with Weed's Castle limestone; because latter term has been discarded, it is proposed that term Mission Canyon be applied throughout Montana and northern Wyoming.

Named for town of Castle, Little Belt Mountains quadrangle, where it is well developed.

Castle Rhyolite

Tertiary: Northwestern Wyoming.

R. E. Wilcox, 1944, Geol. Soc. America Bull., v. 55, no. 9, p. 1053, 1059, pl. 1. Compact rhyolite, the ground mass of which ranges in texture from glassy to micrographic or diffuse spherulitic. Underlies Meadow rhyolitic tuff (new). Elkhorn basalt (new) is probably intermediate in age between Castle rhyolite and Cataract basalt (new).

Exposed in cliffs below Third Cataract in Gardiner River, Yellowstone Park.

Castle Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat, Internat., v. 6, Océanie, fasc. 2, p. 79. Bedded cinders, bombs and spatter composing a partly eroded cinder cone from which lava flow of nepheline basalt, more than 100 feet thick, extends for half a mile. Unconformably overlies rocks of Kailua volcanic series. Distribution noted.

Named for occurrence on Castle Ranch. Covers area of about one-half square mile north of Ulumawao Peak, on northeast side of Koolau Range about 10 miles northwest of Makapuu Head.

Castle Creek Flows

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942. Carnegie Inst. Washington Pub. 540, p. 92–93. Castle Creek flows (pumice flows) were products of glowing avalanches that descended southwest flank of Mount Mazama into valley of Castle Creek. The flows traveled 18 miles before they joined flows of Rogue River valley. They were prevented from spreading northward by high ridge of lava, but southward they overflowed gorge of Castle Creek and spilled into valley of Union Creek, which they filled to maximum depth of 250 feet. Pumice flows spread all the way down Castle Creek, but later scoria flows did not extend beyond park boundary, a distance of about 7 miles. Glowing avalanches of pumice and scoria were part of final activity of Mount Mazama and followed what is termed the main pumice fall.

Castle Creek flows westward from Crater Lake.

†Castlegate coal group (in Blackhawk Formation)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: F. R. Clark, 1928, U.S. Geol. Survey Bull. 793.

In Book Cliffs.

Castlegate Sandstone (in Mesaverde Group)

Castlegate Member (of Price River Formation)

Castlegate Sandstone Member (of Price River Formation)[1]

Upper Cretaceous: Eastern central Utah and western central Colorado.

Original reference: J. B. Forrester, 1918, Utah Acad. Sci. Trans., v. 1, p. 24.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 130–131. Age definitely fixed as Montana and probably late Montana.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 187, 188–189, figs. 2, 3, pl. 3. Referred to as member instead of sandstone member because it includes coal-bearing rocks throughout considerable part of its outcrop. Primarily a massive crossbedded white or pink sandstone which changes from coarse to fine grained as traced eastward. This part of member belonging to Farrer facies (new), represents inland flood-plain deposits and is replaced for a few miles east of Green River by lagoonal deposits which contain a few thin coals. These, in turn, are replaced eastward in vicinity of Thompsons by littoral marine bar sandstones. This part of Castlegate, as well as thin topmost lagoonal deposit present from Desert east to Cottonwood Canyon, is placed in Neslen facies (new). Member separated from remainder of formation in Beckwith Plateau by Buck tongue of Mancos shale, which thickens eastward. Member thins eastward and disappears in Mancos near West Salt Creek, Colo. From western end of Book Cliffs to Green River, composed mainly of nonmarine sandstone. Near Green River, it passed into lagoonal deposits. Three littoral marine bar sandstones interfinger eastward into Mancos, as far as Salt Creek, Colo. Thickness of member ranges from about 500 feet at Castlegate to featheredge near West Salt Creek.

J. D. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 11 (table), 13–14, pls. Price River formation restricted by removal of Castlegate sandstone, which is raised to formational rank. Thickness at type locality about 400 feet. In area of this report [Book Cliffs], its thickness ranges up to 190 feet. Eastward from Westwater Wash, where it is about 70 feet thick, formation thins rapidly, and at Utah-Colorado State line it is 30 feet thick; at mouth of West Salt Creek, it is discontinuous. Ranges from massive conglomeratic sandstone at Castlegate to fine-grained siltstone at east boundary of Utah and passes into entirely shaly beds in Colorado. Underlies Buck tongue of Mancos shale in Beckwith Plateau to Colorado line.

Named from Castlegate, Carbon County, Utah, where it forms gatelike passage in Price River Canyon about 2 miles above the town.

Castle Hayne Limestone

Castle Hayne Marl[1]

Eocene, middle and upper: Coastal Plain of North Carolina and South Carolina.

Original reference: B. L. Miller, 1910, Geol. Soc. America Bull., v. 20, p. 674–675.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 20 (fig. 2), 25–26. Geographically extended into South Carolina, where it is recognized only in artificial exposures. At pit of Carolina Cement & Lime Company, Harleyville, Dorchester County, unconformably underlies Cooper marl, is 46 feet thick, and consists of buff-gray tough to hard crumbly fossiliferous limestone overlying a gray soft fine-grained granular limestone. Considered upper Claiborne.

H. E. LeGrand and P. M. Brown, 1955, Carolina Geol. Soc. Guidebook of Excursion in Coastal Plain of North Carolina, Oct. 8–9, p. 9, 28, 30, 36. Described in coastal plain of North Carolina where it underlies Yorktown formation near Pollicksville. Includes shell bed composed of valves and fragments of *Ostrea georgiana* Conrad in a reddish sandy matrix. This is section from which Miller (Clark and others, 1912, North Carolina Geol. and Econ. Survey, v. 3) designated Trent marl as middle Eocene. Kellum (1926, U.S. Geol. Survey Prof. Paper 143) concluded that the Trent was early Miocene, separated from underlying Castle Hayne of Jackson age by erosional unconformity. Kellum's Trent species came from vicinity of Silverdale, a locality not mentioned by Miller and which is about 17 miles from type locality along Trent River. Recent work has shown that Kellum's Trent (lower Miocene) is nonexistent and that unit designated by Kellum as lower Miocene is in part of Castle Hayne age and in part of

Yorktown age. Original Trent of Miller is here moved from middle Eocene to upper Eocene and included in Castle Hayne although considered a distinctive facies of it.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 44–45; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500.000) : North Carolina Div. Mineral Resources. Mapped as middle and upper Eocene. As mapped, included Castle Hayne and Trent formations of older maps.

Named for exposures at Castle Hayne, New Hanover County, N.C.

Castle Hill Andesite[1]

Devonian (?) : Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 114, 169, 174.

Lies between Aroostook River and the State road from Ashland to Presque Isle, partly in Castle Hill Township and partly in Wade Plantation, Aroostook County.

Castle Hill Tuff[1]

Devonian (?) : Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 119, 120–121, 122–125.

Exposed in open fields and along roadside about 1 mile west of Castle Hill Hotel, on Castle Hill Ridge, Aroostook County.

Castle Rock Conglomerate[1]

Oligocene, lower : Eastern Colorado.

Original reference : W. T. Lee, 1902, Am. Geologist, v. 29, p. 96–109.

H. E. Woods 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 16, pl. 1. Oligocene, Chadronian.

Named for typical development on Castle Rock Butte, Douglas County.

Castleton Conglomerate Member (of Bull Formation)

Lower Cambrian : Western Vermont and eastern New York.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 2. Limestone-pebble, slate-matrix, intraformational conglomerate. Pebbles carry early Cambrian *Elliptocephala* fauna. Thickness probably not more than 20 feet. Overlies Mudd Pond member (new) ; occurs near top of formation below West Castleton formation (new).

Probably named for Castleton River, Vt.

Castle Valley Stage

Recent : Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Sec. [Guidebook] 2d Ann. Field Trip, Oct. 4–5, correlation chart. In proposed time-stratigraphic standard for Rocky Mountains, the Recent epoch includes (ascending) Castle Valley, Temple Lake, Spanish Valley, and Gannett Peak stages.

Twin Lakes area.

Castner Limestone

Precambrian : Southwestern Texas.

R. L. Harbour, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1786 (fig. 1), 1787–1788, 1789. Oldest rocks exposed in Franklin Mountains. Includes limestone, hornfels, and chert, as well as diabase sills; contains moundlike algal structures near base. Thickness about 1,112 feet. Underlies Mundy breccia (new). Rests on intrusive granite. Term limestone considered preferable to formation despite the fact that limestone comprises little more than half the thickness of unit at type locality.

Type locality: One and one-half miles southeast of North Franklin Mountain and one-half mile northwest of point at which Fusselman Canyon issues from mountains. Named from exposures in Castner Range on Fort Bliss Military Reservation. Outcrops limited to northern half of Franklin Mountain by faults and intrusive granite. South of Castner Range, fault in Fusselman Canyon drops Castner below level of Quaternary deposits.

Casto Volcanics[1]

Permian (?): Central Idaho.

Original reference: C. P. Ross, 1927, Idaho Bur. Mines and Geology Pamph. 25.

C. P. Ross, 1934, U.S. Geol. Survey Bull. 854, p. 28–35, pl. 1. Coarse conglomerate present in a few places in Casto quadrangle. One bed of limestone noted. Underlie Challis volcanics; unconformable above old sedimentary rocks; cut by Idaho batholith. Thickness 2,000 to 5,000 feet.

Covers large area in Casto quadrangle.

Castor Creek Member (of Fleming Formation)

Miocene: Central Louisiana.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 118 (fig. 26), 164–168, 174, geol. map. Brackish-water calcareous clays and noncalcareous silts. Thickness at least 200 feet. Underlies Blounts Creek member (new); overlies Williamson Creek member (new).

Well exposed in southern valley wall of Castor Creek in Tps. 3 and 4, R. 2 W., Rapides Parish.

Castro Shale Member (of Alhambra Formation)

Eocene, upper: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 53–54, pl. 4–A. Brownish-gray silty shale becoming somewhat arenaceous toward top. Thickness at type section 145 feet. Underlies Roop sandstone member (new) with contact gradational; overlies Escobar sandstone (new).

Type section: West limb of Pacheco syncline, short distance east of the east portal or Muir Tunnel, near Martinez, Contra Costa County.

Catahoula Group[1]

Oligocene and Miocene (?): Southeastern Mississippi.

Original reference: B. W. Blanpied and others, 1934, Shreveport Geol. Soc. 11th Ann. Field Trip. p. 4.

Catahoula Sandstone,[1] Tuff,[1] or **Formation**

Miocene, Miocene (?), and Oligocene (?): Louisiana, southern Alabama, Mississippi, and eastern Texas.

Original reference: A. C. Veatch, 1905, Louisiana Geol. Survey Bull. 1, Rept. 1905, p. 84, 85, 90.

F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 715–720. Formation, in eastern Texas, divided into two members Chita (new) and Onalaska. In south Texas, divided into three members (ascending): Gant, Soledad, and Chusa.

B. W. Blanpied, chm., 1934, Shreveport Geol. Soc. [Guidebook] 11th Ann. Field Trip p. 12–22. Catahoula group, Clarke and Wayne Counties, Miss., comprises (ascending) Bucatunna member, Lower Chickasawhay member, Upper Chickasawhay member, and "Catahoula." Overlies Vicksburg group; underlies Citronelle.

B. C. Renick, 1936, Texas Univ. Bull. 3619, p. 67, table facing p. 17. In southeastern Texas, includes Dunlap Quarry sandstone member.

W. D. Chawner, 1936, Louisiana Dept. Conserv., Geol. Bull. 9, p. 110–134. In Catahoula Parish, formation is composed largely of tuffaceous sandstones, sands, and clays, with some loose sands and hard silicified sandstones. Maximum thickness 350 feet. Includes Cassel Hill member (new) in lower part and Chalk Hills member (new) above. Unconformably underlies Citronelle(?) formation.

H. N. Fisk, 1938, Louisiana Dept. Conserv., Geol. Bull. 10, p. 142–149. In Grant and La Salle Parishes, Catahoula formation comprises two mappable units, lower tuffaceous siltstone member and an upper thicker member composed of lenticular sands, clays, and silts. Grades downward into sands and clays of Vicksburg group. Underlies Montgomery member (new) of Pleistocene.

H. N. Fisk, 1940, Louisiana Dept. Conserv., Geol. Bull. 18, p. 143–147. Lower formation in Grand Gulf group in report on Avoyelles and Rapides Parishes. Underlies Fleming formation. Name Catahoula became widely used and has appeared in literature of adjacent coastwise States. Its usage can be justly criticized because lower limit of formation has never been accurately defined and upper limit was not and cannot be established from type locality where beds pass beneath Mississippi River flood plain. No section published permits a lithologic correlation to be established, yet usage of name has been extended into subsurface on lithology. Only part of Catahoula formation found at surface in Rapides Parish is upper 100 feet of siltstones and intercalated sand lentils exposed in northwestern top of parish. Catahoula-Vicksburg contact not exposed in Rapides Parish and lower limit of Catahoula in subsurface is arbitrarily placed on first appearance of Vicksburg fossils.

F. W. Bates and J. B. Wharton, Jr., 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 8, p. 1136–1138. Term Catahoula group should be dropped, leaving Gulf Coast Miocene composed of three formations: Fleming, Catahoula, and Chickasawhay. Believed that there is not sufficient evidence of sufficient lithologic or paleontologic change to warrant placing division between Miocene and Oligocene strata at base of Fleming; hence, entire Catahoula should be considered Miocene in age. Subsurface data.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1315 (fig. 1). 1344–1354, "Upper Chickasawhay" of Shreveport Geological Soc. Guidebook 11th Ann. Field Trip is herein named Paynes Hammock sand. This sand intertongues at west with nonfossiliferous beds referred to Catahoula sandstone and with the Paynes Hammock tongue below Catahoula tongue. Paynes Hammock sand and equivalent beds on west referred to Catahoula sandstone are correlated with Tampa limestone. Upper part of Catahoula may be Alum Bluff in age. Miocene.

W. L. Russell, 1957, Gulf Coast Assoc., Geol. Soc. Trans., v. 7, p. 65–72. Formation described in Grimes, Brazos, and Burleson Counties, Tex. Thickness about 350 feet in Grimes County. Basil member is Chita, 10 to 50 feet thick. About 70 to 100 feet above Chita in south-central Brazos County is Dunlap sandstone, 0 to 40 feet thick. About 175 feet above base of Catahoula is Corough sandstone (new), 0 to 40 feet thick. Overlies Whitsett formation; underlies Oakville formation.

D. H. Eargle and J. L. Snider, 1957, Texas Univ. Bur. Econ. Geology Rept. Inv. 30, p. 14. Catahoula tuff described in Karnes County. Thickness about 480 feet. Unconformably overlies and progressively overlaps underlying Frio clay and upper part of Jackson formation. Underlies Oakville sandstone. Because of stratigraphic relations, believed to be early Miocene.

G. R. Pinkley, 1958, South Texas Geol. Soc. [Guidebook] Fall Field Trip, p. 35, 37. Formation, in Fashing field, Atascosa County, includes Gueydan ash member at base.

U.S. Geological Survey currently designates the age of the Catahoula as Miocene(?) and Oligocene(?) in some areas on the basis of a study now in progress.

Named for typical development in Catahoula Parish, La.

Cataldo Quartzite[1]

Precambrian (Belt Series): Northern Idaho and central eastern Washington.

Original references: O. H. Hershey, 1912, Geol. Soc. America Bull., v. 23, p. 526; 1912, Am. Jour. Sci., 4th, v. 34, p. 264–267.

Exposed over a great area, beginning a little above mouth of Pine Creek, and thence nearly to station of Rose Lake; also occurs near town of Tekoa, Wash. Probably named for town of Cataldo, Kootenai County, Idaho.

Catalina Gneiss

Precambrian: Southeastern Arizona.

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 110–113. Term Catalina gneiss describes the gneissic rocks that make up the core of Santa Catalina Mountains and extend southeastward from Mount Lemmon into Tanque Verde and Rincon Mountains. Divided into three general types: banded augen gneiss, augen gneiss, and granitic gneiss-gneissic granite.

Area: Santa Catalina Mountains.

Catalina Granite

Post-Cretaceous: Southeastern Arizona.

F. L. Peirce, 1958, Dissert. Abs., v. 19, no. 2, p. 300. Orogeny which apparently took place during Laramide time was accompanied by emplacement of Leatherwood quartz diorite (new) which was followed by emplacement of Catalina granite. Some border phases of the granite apparently represent replacement of sediments, and some of the granite was igneous as shown by the chilled borders of dikes of the granite that cut the Leatherwood quartz diorite (new).

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 114. Characterized by two different facies: northern exposures, according to Peirce, are hypidiomorphic granular granodiorite, containing mainly quartz, orthoclase, and oligoclase; outcrops on the south are of crystalloblastic granite, composed of abundant quartz and orthoclase.

In Santa Catalina Mountains [Pima County].

Catalina Schist

Catalina metamorphic facies (of Franciscan Series)[1]

Mesozoic or older: Southern California.

Original reference: A. O. Woodford, 1924, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 3.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 13, Woodford (1924) designated the metamorphic rocks of Palos Verdes Hills and the more extensive rocks of Santa Catalina Island the Catalina metamorphic facies of the Franciscan. Absence of unaltered sedimentary rocks indicates that metamorphics are older than Franciscan. Name Catalina schist considered more appropriate term.

J. E. Schoellhamer and A. O. Woodford, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–117. Mesozoic or older.

Occurs on Catalina Island, off coast of southern California, and in San Pedro Hill and Palos Verdes Hills on adjacent mainland.

Catalina Schist Breccia[1]

Miocene, lower (?): Southern California.

Original reference: A. O. Woodford, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 7, p. 211–212.

Southeast end of Catalina Island.

Catamount Schist[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Swede Pond quartzite and below Bear Pond schist.

Type locality: Catamount Mountain, west of Pettersville, Warren County.

Cataract Basalt (in Gardiner River Rhyolite-Basalt Complex)

Tertiary: Northwestern Wyoming.

R. E. Wilcox, 1944, Geol. Soc. America Bull., v. 55, no. 9, p. 1050, 1055–1056, pls. 1, 2. Name applied to basalt of Gardiner River rhyolite-basalt complex (new). Normal facies is massive medium-grained basalt, carrying abundant phenocrysts of plagioclase and ferromagnesian minerals. Younger than Meadow rhyolitic tuff (new) and older than Sheepeaters basalt (new). Contemporaneous with Lodgepole rhyolite (new); overlies Elkhorn basalt (new).

Present on Gardiner River, Yellowstone Park. Uncontaminated phase occurs at Second Cataract, about 700 feet downstream from complex at First Cataract. Crops out at frequent intervals several miles southward upgrade of wide tributary valley.

Cataract Formation[1]

Cataract Group

Lower Silurian: Ontario, Canada, and northern Michigan and western New York.

Original reference: C. Schuchert, 1913, Geol. Soc. America Bull., v. 24, p. 107.

G. V. Cohee, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 33, sheet 2. In Michigan, formation crops out in extreme eastward extension of Northern Peninsula on east side of Drummond Island, Chippewa County, and in a few places to west in Delta and Luce Counties. Rocks are light-brown to brownish-gray dense to finely crystalline dolomite that is cherty in part.

G. M. Ehlers, 1948, Michigan Geol Soc. [Guidebook] Ann. Field Trip, June 18, 19, 20, 21. Cataract group listed on Silurian chart of Northern Peninsula, Mich. Includes Mayville dolomite. Mayville comprises (ascending) Manitoulin dolomite, Cabot Head shale, and Dyer Bay dolomite; thicknesses of these units are given from subsurface data. Underlies Burnt Bluff group. Alexandrian series.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1984. Discussion of stratigraphy of Medinan group in New York and Ontario. Recommended that names Albion, Alexandrian, Anticostian, Cataract, and Power Glen be suppressed.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 4 (fig. 1), 5–7. Group in northern Michigan comprises (ascending) Manitoulin dolomite, Cabot Head shale, and Moss Lake formation (new). Thickness 110 to 200 feet. Underlies Burnt Bluff group with Lime Island dolomite (new) at base. Term Mayville not used in this classification. Alexandrian series.

Well exposed at Cataract, Ontario.

†Cataract Falls Sandstone (in Ste. Genevieve Formation)

Mississippian: Southwestern Indiana.

C. A. Malott, 1945, (abs.) Indiana Acad. Sci. Trans., v. 55, p. 77 [1946]. Proposed for a persistent sandstone, ranging from 1 foot to more than 30 feet in thickness, that occupies nearly the middle one-third of the formation.

C. A. Malott, 1946, Jour. Geology, v. 54, no. 5, p. 323. Unit referred to as "Cataract Falls sandstone" is directly correlated with Rosiclare sandstone of southern Illinois.

Occurs at double falls of Mill Creek near Cataract, Owen County.

Catawissa Reds[1] or Red Beds

Upper Devonian: Northeastern Pennsylvania and eastern New York.

Original reference: G. H. Chadwick, 1932, Eastern States Oil and Gas Weekly, v. 1, no. 17, p. 7.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Catawissa red beds; occur below Montrose red beds and above Katsberg red beds; equivalent to Cayuta shale and sandstone.

Crops out at Catawissa, Columbia County, Pa., south of Susquehanna River. Also present in western Catskills along Delaware River.

Cathedral Granite[1]

Tertiary: Central northern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 7, p. 329–376.

Cathedral Bluffs Tongue (of Wasatch Formation)[1]

Cathedral Bluffs Tongue (of Knight Formation)

Eocene, lower and middle: Southwestern Wyoming and northwestern Colorado.

Original reference: A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

W. J. Morris, 1955, Dissert. Abs., v. 15, no. 3, p. 394. Name Knight formation extended from Bridger basin to include dominantly fluviatile Wasatchian deposits of Washakie basin. Hence Cathedral Bluffs is considered tongue of Knight formation.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 101, 102. Overlies Tipton tongue of Green River formation; underlies and interfingers with Laney shale member and Morrow Creek member of Green River; intertongues laterally with Battle Spring formation (new). Thickness as much as 900 feet. Has yielded some fossils thought by some to be early Eocene and by others to be middle Eocene.

Forms highly colored escarpment of Laney Rim and Cathedral Bluffs, Sweetwater County, Wyo.

Cathedral Peak Granite[1] (in Tuolumne Intrusive Series)

Cretaceous: East-central California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 126–127, map.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2121, 2122, 2123 (fig. 1). Discussed in paper dealing with potassium-argon dating of igneous rocks. Age given as 83.7 millions of years. Younger than Half Dome quartz monzonite and older than Johnson granite porphyry and Hoffman quartz monzonite (new).

Named for fact it composes Cathedral Peak and adjoining parts of Cathedral Range in Yosemite National Park.

Cathedral Valley Agglomerate

Tertiary, upper: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, p. 12, pl. 2. Thick sequence of agglomerate beds with subordinate tuff beds and lava flows; rocks are predominantly basalt and basaltic andesite. Beds dip north toward Bering Sea at angles of a few degrees. Probably comparable in age to Belkofski tuff (new) but direct evidence is lacking.

Type region: Cathedral Valley in vicinity of Pavlof Volcano, Alaska Peninsula.

Catheys Limestone[1]

Catheys Limestone (in Nashville Group)

Middle Ordovician : West-central Tennessee.

Original reference: C. W. Hayes and E. O. Ulrich, 1903, U.S. Geol. Survey Geol. Atlas, Folio 95.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 136–157. Six major facies recognized: shaly, laminated siltstone, granular, clayey, dove-colored, nodular, and pale-colored. Facies do not occur as stratigraphic units in chronological order but rather are interbedded with each other and may recur in both vertical and lateral distribution. In general, the Catheys thickens eastward from featheredge covered by younger sediments somewhere between Perry-Wayne-Hardin Counties and Maury-Giles Counties to as much as 250 feet in Sequatchie Valley. Overlies Bigby-Cannon limestone, being in contact with Bigby facies in western part and with Cannon facies in eastern part. Underlies Leipers formation. In Nashville group, Hayes and Ulrich did not specify type section. Bassler (1932, Tennessee Div. Geology Bull. 38) suggested section at Columbia. In present study, two sections are measured along Catheys Creek, each of which would serve as type section. Section along Dry Fork 65 feet; section along north slope of spur overlooking Catheys Creek 69 feet.

Suggested type sections (Wilson) : Along road up Dry Fork Creek and up hill to east, beginning about 500 feet south of intersection of Dry Fork and Catheys Creek 1 mile west of Isom, Maury County. On slope of spur overlooking Catheys Creek between Ivory Hollow and Shannon Branch about one-fourth mile southeast of Taylorsville, and about 2 miles east of Isom. Named for Catheys Creek, Lewis and Maury Counties.

Cat Hill Gneissoid Granite[1]

Precambrian : Southeastern New York.

Original reference: C. P. Berkey, 1911, New York State Mus. Bull. 146, p. 52, 57.

Occurs in Garrison district, Putnam County. Probably named for occurrence at Cat Hill.

Cativa Marl (in Gatún Formation)

Miocene, middle : Panamá.

H. N. Coryell and Suzanne Fields, 1937, Am. Mus. Novitates no. 956, p. 1. Fossiliferous marl in lower part of Gatún formation.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 330–331. Undefined name for calcareous siltstone in Gatún formation.

Catlin Member (of Windfall Formation)

Upper Cambrian : Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 20–21, 22, pl. 2. Composed of interbedded massive limestone, in part cherty, and thin-bedded shaly and sandy limestone. The massive limestone beds are for the most part fine grained although some are coarser grained; some of the coarser beds are crowded with trilobite fragments. The thinner bedded limestones are light to medium gray and have sandy interbeds that weather to brown or pinkish brown. Thickness 250 feet throughout the area around Eureka. Member is in sharp though normal contact with Dunderberg shale below and is conformable with Bullwhacker member (new) above.

Named from exposures near the Catlin shaft of the Croesus mine in New York Canyon, Eureka mining district, Eureka County.

Cat Mountain Rhyolite

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 710 (fig. 2), 729–731, pl. 1. Cliff forming series of rhyolite flows and mud flows. When fresh, rhyolites are red, and the mud flows or breccias are red or buff. Weathers dark reddish brown on steep slopes and many shades of purple, brown, buff, red, blue, and even white on more subdued slopes. Breccia at the base and tuff at the top. Thickness in Cat Mountain-Golden Gate Mountain area at least 700 to 800 feet; farther south, thickness between 200 and 300 feet. Usually rests either on overthrust mass of Cretaceous sedimentary and volcanic rocks or, where thrust has been removed by erosion, directly on truncated edges of sedimentary rock. Underlies Safford tuff (new); unconformably overlies Amole arkose (new).

Well exposed on Cat Mountain and Golden Gate Mountain. Most conspicuous and one of the most widespread formations in Tucson Mountains, Pima County.

Catoctin Greenstone, Formation, or **Metabasalt**

Catoctin Schist[1]

Catoctin Series

Precambrian: Western Maryland, northern Virginia, and northeastern West Virginia.

Original reference: A. Keith and H. R. Geiger, 1891, Geol. Soc. America Bull., v. 2, p. 155–164.

A. S. Furcron, 1939, Virginia Geol. Survey Bull. 54, p. 19–28. Catoctin series, in Warrenton quadrangle, divided into Warrenton agglomerate member (new) at base and basalt flows now altered to metabasalt or "greenstone" schist. Underlies Loudoun formation; overlies Fauquier formation (new).

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12], Carroll and Frederick Counties, p. 20–22. Catoctin metabasalt described in Frederick County where it is exposed in area between South and Catoctin Mountains. Underlies Loudoun formation. Overlies Swift Run tuff. The volcanic series, comprising Catoctin basalt, aporhyolite, and Swift Run tuff, overlies granitic injection complex of early Precambrian age.

R. O. Bloomer and R. D. Bloomer, 1947, Jour. Geology, v. 55, no. 2, p. 94–106. Formation in central Virginia consists of undetermined thickness of hydrothermally altered andesite classed as propylite. Underlain by variable thickness of both metamorphosed and unmetamorphosed conglomerate, sandstone, tuff, and andesite to which name Oronoco formation is assigned. In northern Virginia, the Catoctin is overlain by Loudoun formation. In central Virginia, the Unicoi, which is at least partly equivalent to the Loudoun, crops out along western flanks of Blue Ridge but is not exposed in Catoctin outcrop belt. In western part of Piedmont province, the Catoctin overlies the Lynchburg. Catoctin may be Cambrian in age.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 12–14, 15 (fig. 5), pl. 1. Described in Elkton area, Virginia, as Catoctin greenstone. Consists of altered lava, largely basaltic in composition, and associated pyroclastic sediments. Thickness 0 to 1,000 feet; maximum thickness on slopes of Blue Ridge in southeast part of area. Underlies Loudoun formation of Chilhowee group; overlies Swift Run formation.

R. O. Bloomer, 1950, Am. Jour. Sci., v. 248, no. 11, p. 753–783. The Catoctin is exposed in two parallel belts that extend into central Virginia. One belt caps main mass of the Blue Ridge, and the other occurs in an alignment of ridges about 20 miles to the southeast. In central Virginia, northwestern belt of Catoctin is thrust upon Chilhowee group, but farther northeast it underlies the Loudoun. In some places, the Catoctin in northwestern belt overlies the Swift Run or granitized complex. Elsewhere, the granitized complex has been thrust upon the Catoctin and base is unexposed. Catoctin in central Virginia is exposed on both limbs of major anticlinal fold that has been truncated by erosion, at least, to combined thickness of Catoctin and Lynchburg formations. Generally believed that there is significant hiatus between Catoctin formation and Chilhowee series. The Catoctin and concordantly underlying Lynchburg and Swift Run formations are defined as late Precambrian and the Chilhowee as Lower Cambrian. Although age classification may be correct, there is evidence of continuous sequence from base of Lynchburg into Chilhowee. This relationship may appear to be refuted where Chilhowee rests with conspicuous unconformity upon granitized complex definitely older than late Precambrian. However, this unconformity is an inclined surface that cuts across formation boundaries. Lynchburg and Catoctin overlap this surface from east to west. Hence, absence or restricted thickness of Catoctin beneath the Chilhowee in certain sections is not due to interval of erosion between the two formations, but to location of sections with respect to margin of overlap. In places, there appears to be complete section between Catoctin in the Blue Ridge and the Wissahickon in the Piedmont of central Virginia. No continuous faults, including Martic overthrust have been identified. The Catoctin is not everywhere separated from the Wissahickon or the Lynchburg from the Wissahickon by faults. In this report, term Oronoco is abandoned in favor of Swift Run formation. Not certain whether Catoctin is late Precambrian or Cambrian.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1). In James River synclinorium, Catoctin greenstone underlies Candler formation of Evington group (both new); overlies Lynchburg gneiss.

J. C. Reed, Jr., 1955, Geol. Soc. America Bull., v. 66, no. 7, p. 871–896, pl. 1. Formation described near Luray, Va., where it unconformably overlies granitic rocks and is not intruded by them, as has been suggested by some earlier workers. No important time break is indicated between deposition of Catoctin formation and overlying Cambrian sediments (Chilhowee group). Catoctin may be early Cambrian.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2), 22–28, pl. 1. Catoctin greenstone described in Lynchburg quadrangle. Catoctin is at top of Lynchburg formation but intertongues, in part, with upper Lynchburg and overlying Candler formation. Lynchburg and Catoctin are referred to as "Late Precambrian" group which overlies Virginia Blue Ridge complex (new) and underlies Lower Paleozoic(?) Evington group.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 12 (table 1), 14, 16. Catoctin greenstone described in Rockingham County. Overlies Swift Run formation; underlies Loudoun formation of Chilhowee group. Cambrian or Precambrian.

Named for Catoctin Mountain, Loudoun County, Va., and Frederick County, Md.

Catron Formation (in Breathitt Group)

Catron Formation (in Pottsville Group)[1]

Middle Pennsylvanian: Southeastern Kentucky.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 33, 41, 207, pl. XLA.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 96–99, 138. Underlies Hignite formation; overlies Mingo formation. Report contains measured sections, correlation charts, and plates.

U. S. Geological Survey currently classifies the Catron as a formation in Breathitt Group on the basis of a study now in progress.

Named for exposures on Coon Branch of Catron Creek in Black Mountains, Harlan County.

Catskill Formation[1] **or Redbeds** (in Susquehanna Group)

Middle and Upper Devonian and Lower Mississippian: New York, Maryland, New Jersey, and Pennsylvania.

Original reference: W. W. Mather, 1840, New York Geol. Survey 4th Rept., p. 212, 213, 227–233.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19. Catskill, as used in this report, is defined broadly as the continental magnafacies of the Devonian. In Pennsylvania, it is divisible into several clearly separable and distinct units. These are all well exposed and typically developed. Their relative ages are fixed through the fact that in practically all cases they are traceable into fossiliferous marine beds. Many of these divisions, known and named by I. C. White, are of long standing, have a well-established place in the literature, and take precedence over any other system of Catskill terminology previously misapplied to Pennsylvania. No doubt some of Chadwick's divisions are valid and may even be close correlates with terms used in this report. However, names drawn from the section in Catskill Mountains have no place in the nomenclature in Pennsylvania's continental Devonian sequence. Thickness varies through process of progressive off-lap. Featheredge is encountered in traversing west from Potter into McKean and Warren Counties; pinching out is observed in Conemaugh gorge west of Johnstown; similar conditions are also reported in Fayette County. Thickest section, about 6,200 feet, is along Lehigh River, Carbon County. Limits of Catskill vary radically. Top is drawn where red or green Catskill sandstones and shales yield to gray, usually conglomeratic Pocono. At base, continental beds intertongue with marine, neritic facies of the Devonian which changes progressively from early Middle Devonian in New Jersey to Portage in upper Delaware Valley, earliest Chemung in Susquehanna Valley above Harrisburg, very late Chemung on Allegheny Front and progressively later Chautauquan from north-central to northwestern Pennsylvania. Some units included in Catskill facies are the Mount Pleasant red shale, Honesdale sandstone, Cherry Ridge red beds, Damascus red shale, Shohola formation, Delaware River flags. Analomink red shale, and New Milford formation.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 333. Discussion of geology of Appalachian Valley in Virginia. Term Hampshire formation is used in preference to term Catskill. Chadwick (1933, Am. Jour. Sci., 5th, v. 36; 1936, New York State Mus. Bull. 307) demonstrated that Catskill formation of type locality corresponds mainly to Hamilton and Portage formations and that Chemung and Hampshire are younger than true Catskill. Thus, if they [Chemung and Hampshire] were ever present in eastern New York, they would have overlain the Catskill and extended above top of present Catskill Mountains. Hence, name Catskill cannot be properly applied to red rocks described in this report under restored name Hampshire formation.

P. H. Price and H. P. Woodward, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 11, p. 1993–1994; H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 528. Darton's (1892) term Hampshire formation is herein revived for rocks previously called Catskill formation in West Virginia. It is appropriate to refer to post-Chemung red beds of West Virginia as the Catskill facies, but, because term facies refers to an equivalent of some other formations, there must be some definite post-Chemung horizon of which the local "Catskill" beds can be regarded as the nonmarine equivalent.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. In this report [Hollidaysburg and Huntingdon quadrangles, Pennsylvania], term Hampshire formation is used in preference to term Catskill. Use of Hampshire conforms with present usage of Virginia Geological Survey.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept.] Washington County, p. 92. Thickness about 3,800 feet in Washington County. Lower Catskill rocks consist of brownish-red in part arkosic sandstones alternating with red argillaceous shale including occasional bands of greenish shale; upper part of formation contains more greenish-gray sandstone and shale alternating with red rocks. Catskill continental beds seem to be nonmarine equivalent of the upper Devonian contemporaneous and intertonguing with marine sediments ranging from Hamilton to Chemung and in part post-Chemung. Underlies Pocono group.

T. W. Amsden, 1954, Maryland Dept. Geology, Mines and Water Resources Bull. 13, p. 16. In Maryland, only the post-Chemung part of the Devonian remains in the red-bed facies. As there is no unanimity of opinion as to how name Catskill should be applied in New York area, it seems preferable to use name Hampshire in Garrett County, which is only a few miles from type area of Hampshire.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., Field Trip 1, p. 3. Included in Susquehanna group. Pennsylvania Geological Survey currently limits use of term Catskill to the thick brownish- and grayish-red units which characterize middle and upper parts of the Middle and Upper Devonian red-bed sequence. Light-colored sandstone, such as Honesdale and Elk Mountain members, known in the east are included in the Catskill only in those areas where they are underlain by a thick all-red unit. Correlation of members in eastern part of the State with those in central part is complicated and is reserved for future detailed mapping. Overlies transition beds in group; underlies Pocono formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation mapped in central and eastern Pennsylvania. Chiefly red to brownish shales and sandstones; includes gray and greenish sandstone tongues named Elk Mountain, Honesdale, Shohola, and Delaware River in east. Included in Susquehanna group; map bracket shows Catskill above unnamed marine beds and below Oswayo formation. As mapped, marine beds, which consist of gray to olive-brown shales, graywackes, and sandstones, contain "Chemung" beds and "Portage" beds including Burket, Brallier, Harrell, and Trimmers Rock with Tully limestone at base, Upper Devonian.

Named for development in Catskill Mountains, Greene County, N.Y.

†Catskill (Delthyris) Shaly Limestone[1]

Catskill Shaly Limestone Member (of New Scotland Formation)

Lower Devonian: Eastern New York.

Original reference: L. Vanuxem, 1842, Geology of New York, pt. 3, p. 120–122.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 71–75. Name Catskill shaly limestone member applied to upper member of New Scotland. Overlies Kalkberg limestone member. Thickness about 120 feet.

Type exposure: On the Catskill at mouth of main gorge of Austin's glen, Catskill. Named for occurrence on Catskill Creek, near Madison, Greene County.

Cattaraugus Formation[1]

Cattaraugus Shale or Formation (in Conewango Group)

Devonian: Southwestern New York and northern Pennsylvania.

Original reference: J. M. Clarke, 1902, New York State Mus. Bull. 52, p. 524–528.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 53–63, charts, geol. map. Formation in Conewangan series. Computed thickness about 370 feet in Wellsville area, though no outcrop shows more than 10 feet of rock. Comprises three principal rock types: (1) flat pebble conglomerates of Upper Devonian age, (2) crossbedded thinly laminated green sandstones, and (3) red shale. Includes Wolf Creek conglomerate member at base and Salamanca conglomerate member in upper part. Overlies Germania formation; underlies Oswayo formation.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30 (table), 33. Basal formation in Conewango group, Chautauquan series. Comprises (ascending) Panama conglomerate, Amity, Salamanca conglomerate, and Saegerstown members. Thickness about 300 feet. Underlies Oswayo formation; overlies Chadakoin formation of Arkwright group (new). Upper Devonian. Area of report, Chautauqua County.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17 (table 2), 19. In Wellsville area, considered middle formation in Conewango group. Overlies Wolf Creek conglomerate; underlies Oswayo shale. Thickness about 375 feet in Genesee River valley. Westward in Salamanca and Olean quadrangles, the Cattaraugus has been subdivided into (ascending) Amity shale, Saegerstown shale, and Salamanca conglomerate.

I. H. Tesmer, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1651. Series of structure-contour maps drawn on base of each of several successive conglomerates in southwestern New York and northwestern Pennsylvania suggests following stratigraphic sequence (ascending) for Cattaraugus formation: Le Boeuf conglomerate, unnamed member (mostly shale and siltstone), Woodcock-Bimber Run-Dutchmans conglomerate, unnamed member (mostly shale and siltstone), Panama conglomerate, unnamed member (mostly shale and siltstone), Wrightsville-Wolf Creek conglomerate, unnamed member (mostly shale and siltstone), Riceville shale, Corry-Pope Hollow conglomerate, Orangeville shale, Sharpsville sandstone, unnamed member (mostly shale and siltstone), Salamanca conglomerate, unnamed member (mostly shale and siltstone) Killbuck conglomerate, and unnamed member (mostly shale and siltstone). Overlies Chadakoin formation; underlies Oswayo formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. In western Pennsylvania, consists of red, gray, and brown shale and sandstone with proportion of red decreasing westward. Includes Venango sands of drillers and Salamanca sandstone and conglomerate; some limestone in Crawford and Erie Counties. Upper Devonian.

Named for development in Cattaraugus County, N.Y.

Cattaraugus parafacies[1]

Devonian or Carboniferous: Southwestern New York and northern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, table opposite p. 61.

Named for development in Cattaraugus County, N.Y.

Cattasauqua Limestone[1]

Ordovician: Southeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey G_6, p. 153.

The name of the town is spelled Catasauqua, Lehigh County.

Cattron Diorite

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose. 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties Rept., p. 17, 18. Altered to hornblende diorite in most of its extent. Intruded Saddle gneiss (new). Injected, intruded, and replaced by series of granitic intrusions. In places, pink pegmatite cuts across unit that contains intrusions of white aplite. By metasomatic replacement, diorite has become hypersthene granodiorite with microcline metacrysts which contain inclusions of andesine, hypersthene, and other primary minerals of the diorite.

A. J. Stose and G. W. Stose, 1957, Virginia Geol. Survey Bull. 72, p. 25–26, pl. 1. Fine-grained grayish-green gneissic rock in which milky-gray feldspar and green hornblende are only minerals discernible to unaided eye. Diorite contains injection of both white and pink aplite which is composed of microcline and quartz. This resulted in two varieties of injection gneiss that have been mapped separately.

Named from Cattrons Mill on Elk Creek, where one of larger outcrops occurs. Injection gneiss formed by intrusion of white aplite in diorite exposed in vicinity of Salem Church, Cattrons Mill, on northwest side of Brierpatch Mountain, and east of Fallville. Migmatite formed by pink aplite injection seen near Bennington Mill, south of Elk Creek village, and southwest of Fallville.

†Cavanal Group[1]

Cavaniol Group[1]

Pennsylvanian : Central eastern Oklahoma and western Arkansas.

Original reference: N. F. Drake, 1897, Am. Phil. Soc. Proc., v. 36, p. 371, 388.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey. Group concept is not useful and has not been employed.

Named for Cavanal Mountains, northern part of Le Flore County, Okla.

†Cave Limestone[1]

Pennsylvanian : Eastern Kansas.

Original reference: G. C. Swallow and F. Hawn, 1865, Kansas Geol. Survey Rept. on Miami County, p. 7.

Apparently named for occurrence in it of many caves and crevices from which bold springs usually flow.

Cave Creek Formation

Cenozoic (?) : Southeastern Arizona.

H. E. Enlows, 1955, Geol. Soc. America Bull., v. 66, no. 10, p. 1217. Rhyolitic tuffs and welded tuffs 4,500 feet thick. Probably correlative with Rhyolite Canyon formation in Chiricahua National Monument. Name credited to Raydon (unpub. thesis).

In Cave Creek area, Cochise County.

Cave Creek Formation (in Cimarron Group)[1]

Permian : Central southern Kansas and northwestern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 27.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1751, 1793. Cragin's "Cave Creek formation" is identical with Blaine formation of Oklahoma. It is here divided into (ascending) Medicine Lodge, Nescatunga, Shimer, and Haskew gypsums. Cave Creek has priority, but the Blaine has wider accepted usage.

Named for Cave Creek, Comanche County, Kans.

Cavendish Schist[1]

Upper Cambrian : Southeastern Vermont.

Original reference: C. H. Richardson, 1929, Vermont State Geologist 16th Rept., p. 210, 223.

In roadcut a few rods north of Gassetts Station, Windsor County.

Cave Springs Sandstone[1]

Pennsylvanian : Southern Kansas.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 66.

In vicinity of Cave Springs, Elk County.

†Caw Caw Formation[1] or Sands[1]

Eocene, middle : Central South Carolina.

Original reference: E. Sloan, 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 449.

Named for exposures at Caw Caw Swamp, Orangeburg County.

Cawker terrane[1]

Cretaceous: Kansas.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 255.

Derivation of name not stated, but probably Cawker City, Mitchell County.

Cawood Sandstone Member (of Hance Formation)[1]

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 37, 120, 158.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 65, 66, 67, 69, 77, 138. Massive sandstone about 200 feet above base of formation.

Forms massive bluffs along Martins Fork of Cumberland River at Cawood, Harlan County, Ky.

Cayey Siltstone Member (of Robles Formation)

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., and Lynn Glover 3d, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I-319. Thick sequence of rocks consisting principally of siltstone. About 300 to 350 meters thick in north-central part of quadrangle but thins toward southwest where it intertongues with Lapa lava member and consists of three tongues: one beneath the lava, another separates the two flows making up the lava, and a third overlies the lava. Lower and middle tongues pinch out southwestward within the quadrangle. Also includes layers of sandstone and volcanic breccia and locally a conglomerate at top. Overlies Río Matón formation.

Named for exposures along Highway 1, southwest of Cayey, beginning at Quebrada Santo Domingo and ending at the Río Matón, Cayey quadrangle.

Cayey Tuffs

Cretaceous: Puerto Rico.

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 319. Berkey (1915, New York Acad. Sci. Annals, v. 26, p. 29) suggested name for an extensive development of tuffs in vicinity of Cayey, but term has not been used since. [Term Sierra de Cayey tuffs is used on page 61.]

Cayuga Group[1] or **Dolomite**

Cayuga Series

Upper Silurian and Lower Devonian: New York, western Maryland, Pennsylvania, and Virginia.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874-878.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 145-257. Cayugan formations of West Virginia are Williamsport sandstone (redefined), Bloomsburg red-bed facies, and Wills Creek and Tonoloway limestones. Total thickness varies from 170 to more than 1,250 feet. Upper Silurian.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Cayugan series used for uppermost division of Silurian system. Includes interval above Niagaran series.

R. L. Miller and J. O. Fuller, 1954, Virginia Geol. Survey Bull. 71, p. 154–159, pls. In this report [Rose Hill district, Lee County], upper part of Cayuga is missing owing to faulting, and subdivision of beds of Cayuga age is not practical. Because of dominance of dolomite in sequence, unit is called Cayuga dolomite. Consists in general of basal sandstone several feet thick overlain by about 20 feet of blue-weathering limestone and then by thick-bedded dolomite that varies in thickness because it lies directly beneath overthrust fault plane. Not possible to determine true stratigraphic thickness in mapped area; where present, ranges from thin film to possible 90 feet. Thickness outside mapped area indicates that formation thins from northeast to southwest in Wise and Lee Counties. Unconformably overlies Clinton shale. Cayuga is youngest Silurian formation in region. In northeastern Lee County, underlies Lower Devonian Helderberg limestone; farther northeast in Virginia other Devonian formations are present in section. Despite length of hiatus contact of Brallier shale and Cayuga dolomite at Hagan is seemingly conformable.

L. V. Rickard, 1955, New York State Geol. Assoc. 27th Ann. Mtg., p. 7. In central New York, Upper Silurian Cayugan series (revised) contains Salina and Bertie formations. Underlies Helderbergian series (revised) of Lower Devonian.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. New York Silurian, standard reference section for United States, is divided into two series, an older, Niagaran, and a younger, Cayugan. This is departure from earlier usages involving three series. Cayugan series divided into two stages: Canastota(n) and Murder(ian) (both new). Rondout and Manlius formations, formerly included in Silurian are now placed in Early Devonian.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 11 (table 1), 47. In Rockingham County, group comprises Bloomsburg formation and overlying Tonoloway limestone. Thickness 220 to 600 feet. Overlies Clinton formation.

U. S. Geological Survey currently designates the age of the Cayuga Series as Late Silurian and Early Devonian on the basis of a study now in progress.

Typically exposed at north end of Cayuga Lake, N.Y.

Cayuse Flow

Recent: Southwestern Oregon.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, p. 50 (fig. 4), 54. Discussion of volcanoes of Three Sisters region. Name applied to flow from Cayuse Cone.

Cayuse Cone is southeast of South Sister Mountain.

Cayuse Limestone

Precambrian (Belt Series): Northwestern Montana.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 211, 213 (table 1), 215–216. Dull-gray crystalline buff-tan-weathering dolomite interbedded with pale-maroon and green-gray fissile argillite which grades upward into alternating zones of shaly bedded calcareous argillite and finally passes into sideritic and dolomitic hard marble; upper part blue- and dull-gray thick-bedded finely oolitic, coarsely crystalline algal limestone which shows typical bioherm structure. Thickness 1,000 to 2,100 feet; entire thickness exposed throughout distance of only 4 miles on upper part of hills west of South Fork and south of West Fork of Sun River. Unconformably overlies Miller Peak argillite north and south of Deer Creek; north of West Fork of Sun River, Cayuse is thrust upon Mississippian Hannan limestone and shale of Lower Cretaceous Kootenai along Lewis overthrust. Underlies Hoadley formation (new) with contact probably gradational. Miller Peak argillite, Cayuse limestone, Hoadley formation, and Ahorn quartzite (new) are equivalent in age to lower and middle part of Missoula group of Clapp and Deiss (1931) in Sapphire and Garnett Ranges. Report covers southwestern Saypo quadrangle.

Name derived from Cayuse Creek, tributary of South Fork of Flathead River in northern part of Ovando quadrangle, where formation is thickest.

Cayuta Shale Member (of Chemung Formation)[1]

Cayuta Formation (in Chemung Group)

Cayuta monothem

Upper Devonian: Western New York and northern Pennsylvania.

Original reference: H. S. Williams, 1906, Science, new ser., v. 24, p. 365–372.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32, 33. Rank raised to formation in Chemung group. Geographically extended to Pennsylvania.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7), 47. Termed a monothem. Includes Starrucca shale member at top, Owego shale member below, and Cascade [also called Cascade Creek] sandstone member at base. Underlies Wellsburg monothem.

Exposed along Cayuta Creek from Cayuta Lake, Schuyler County, N.Y., to creek's discharge into Susquehanna River.

Cazenovia Group[1]

Cazenovia Stage

Middle Devonian (Erian): Eastern North America.

Original references: T. A. Conrad, 1841, New York Geol. Survey 5th Rept., p. 31; L. Vanuxem, 1842, Geology of New York, pt. 3, p. 150–160.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1733, chart 4. Cazenovia group of Conrad (1841) and Vanuxem (1842) revived and used as a stage term. As used here, includes strata from top of Onondaga to base of Centerfield, or the Marcellus and Skaneateles formations. In this report, the Devonian is subdivided into 10 stages of which the Cazenovia is fourth in sequence (ascending). Follows the Onesquethaw (new) and is succeeded by the Tioughnioga (new). [For complete sequence see Helderberg stage this reference.]

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv. Geol. Survey Div. 44, Geol. Ser. 37, p. 35 (table 1). In Mackinac Straits region, Michigan, Cazenovia group includes Dundee limestone. Overlies Detroit River group.

A. T. Cross and J. H. Hoskins, 1951, Jour. Paleontology, v. 25, no. 6, p. 718 (fig. 3). Shown on composite stratigraphic column of western New York and northwestern Pennsylvania as Cazenovia group including Marcellus and Skaneateles formations. Underlies the Tioughnioga group.

Type sction (stage) : In township of Cazenovia, N.Y., where entire sequence occurs. Group named for exposures at town of Cazenovia.

Cebada Fine-Grained Member (of Careaga Sandstone)

Pliocene, upper : Southern California.

W. P. Woodring, W. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1356–1358; W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 10, 32, 42–47, pl. 1. Consists of fine-grained generally massive soft sandstone; lower part typically very fine grained and light gray, but most of sandstone is light yellowish brown. Maximum thickness 1,000 feet. Lower member of Careaga. Gradationally overlies Foxen mudstone, and on north flank of eastern Purisima Hills overlaps part of Sisquoc formation; underlies Graciosa member of Careaga.

Type region : On north flank of Purisima Hills south of Careaga Station on the now abandoned Pacific Coast Railroad, Santa Maria district.

Cedar Formation[1]

Upper Triassic : Northern California.

Original references : J. S. Diller, 1892, Prelim. proof-sheet ed. of U.S. Geol. Survey Lassen Peak folio; 1895, pub. as U.S. Geol. Survey Geol. Atlas, Folio 15.

Named for exposures on Cedar Creek, along toll road between Redding and Round Mountain, Lassen Peak region.

†Cedar Limestone[1]

Middle and Upper Devonian : Eastern Iowa.

Original reference : D. D. Owen, 1852, Rept. Geol. Survey Wisconsin, Iowa, and Minnesota. p. xix.

Named for valley of Cedar River, eastern Iowa.

Cedar Bay Granite[1]

Mesozoic (?) : Southeastern Alaska.

Original reference : U. S. Grant and D. F. Higgins, 1910, U.S. Geol. Survey Bull. 443, p. 41–43, 46.

Surrounds two-thirds of Cedar Bay and forms core of neck of land between Wells Bay and passage northwest of Glacier Island, Prince William Sound region.

Cedar Butte Basalt[1]

Pleistocene : Southern Idaho.

Original references : H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 30 (table), 69, pl. 6. Aphanitic blue pahoehoe basalt with fresh green olivine phenocrysts. Thickness about 200 feet.

Type locality : Cedar Butte, T. 8 S., R. 29 E., Power County.

Cedar City Tongue (of Kayenta Formation)

Upper Triassic(?): Southwestern Utah.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2521–2522. Largely nonresistant mudstone and siltstone. Mudstone and silty mudstone, which make up major part of total thickness, are reddish brown locally streaked and spotted light gray; siltstone, which forms beds 1 to 5 feet thick, is moderate reddish orange to light gray and is mottled with white in some places. In Chinle section along Coal Creek, measured by Thomas and Taylor (1946) and redescribed by Gregory (1950, Utah Geol. and Mineralog. Survey Bull. 37), rocks here assigned to Cedar City tongue are designated as units 28, 29, and 30; and units 23, 24, and 25, respectively. Thickness 425 feet along Coal Creek but 720 feet in Shurtz Creek, 5 miles south; this increase in thickness accompanies decrease in thickness of underlying Shurtz sandstone tongue (new) of Navajo sandstone.

U. S. Geological Survey currently considers the Cedar City tongue to be Upper Triassic(?). This age designation is made on basis of recent studies of the Kayenta.

Type locality: About 2 miles east of Cedar City, Iron County, directly east of the Red Hill. State Highway 14 crosses type locality a few hundred feet below power plant of Southern Utah Power Co.

Cedar Cliff Limestone Lens (in Wills Creek Shale)[1]

Cedar Cliff Limestone Member (of Williamsport Sandstone)

Upper Silurian: Western Maryland and northern West Virginia.

Original reference: C. K. Swartz, 1923, Maryland Geol. Survey, Silurian Volume, p. 41.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 152, 162, 192. Reallocated to member status in Williamsport sandstone (redefined). Present in middle part of formation in area near Cumberland, Md.

Well exposed at Cedar Cliff, southwest of Cumberland, Allegany County, Md.

Cedar Creek Argillite[1] (in Stevens Series)

Cambrian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 80, map.

C. D. Campbell, 1947, Geol. Soc. America Bull., v. 58, no. 7, p. 602 (table 4), 609–611, pl. 1. Remapping of northeastern Stevens County and discovery of Cambrian and Ordovician fossils are thought to justify adoption there of formation names established by Parker and Cannon (1943) for Metaline quadrangle. Correlative with Maitlen phyllite are parts of Weaver's Northport limestone, Boundary argillite, Deep Lake argillite, and all of Cedar Creek argillite.

Exposed along road up Cedar Creek to Frisco-Standard mine and on north slopes of Red Top Mountain, Stevens County.

†Cedar Creek Beds[1]

Cedar Creek facies (of Brule Formation)

Cedar Creek Member (of White River Formation)

Oligocene, middle: Northeastern Colorado.

Original reference: W. D. Matthew, 1901, Am. Mus. Nat. History Mem., v. 1, pt. 7, p. 355–374, 444.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 16, pl. 1. Referred to as Cedar Creek facies of lower Brule formation. Apparently higher in volcanic ash than typical Orella member of Brule in Nebraska-South Dakota area. If considered valid and appropriate member name, it would have priority over Orella.

E. C. Galbreath, 1953, Kansas Univ. Paleont. Contr. 13, Vertebrata, art. 4, p. 14–16. Proposed here to use term Cedar Creek member of White River formation for the beds of Orellan age, composed of pink and tan sandstones and silts, that lie above disconformity separating Horsetail Creek member from this member or above the grayish-white silts where no disconformity is evident and that lie below a "white marker" which is lowest bed of Vista member (new). These deposits are, seemingly, Matthews's (1901) Cedar Creek beds, which Woods and others (1941) called Cedar Creek facies of Brule formation. Data on typical exposures. Location of Cedar Creek beds described by Matthew not definitely known.

Typically exposed in secs. 29 and 21, T. 11 N., R. 53 W., Logan County. Named for Cedar Creek, Logan County.

Cedar Creek Limestone[1]

Pennsylvanian: Southeastern Nebraska.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 7, 12, 21, 36.

Best developed at type locality on Cedar Creek 1½ miles southwest of town of Cedar Creek, Cass County.

Cedar Fort Member (of Oquirrh Formation)

Pennsylvanian (Desmoinesian): Northwestern Utah.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 108–115, pls. 1, 2. Predominantly orthoquartzites, with subordinate amounts of cherty and argillaceous limestones, and some crystalline limestones and bioclastic limestones. Thickness 1,371 feet at type locality. Overlies Meadow Canyon member and underlies Lewiston Peak member (both new).

Type locality: On east limb of Pole Canyon syncline (west limb of West Canyon anticline) in sec. 36, T. 5 S., R. 3 W., Utah County. Section measured on spur south of small east-trending canyon bearing local name of Spring Creek. Named for exposures northwest of town of Cedar Fort.

Cedar Grove Sandstones (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 169–178.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 91, 95, 104. Cedar Grove sandstones included in Kanawha group.

Named for its association with Cedar Grove coal, Cedar Grove, Kanawha County.

Cedar Hill Serpentinite

Lower Paleozoic: Northern Maryland and southeastern Pennsylvania.

D. M. Lapham, 1960, Pennsylvania Geologists Guidebook 25th Ann. Field Conf., p. 35–38. Cedar Hill serpentinite is within easternmost serpentinite belt of two such belts which trend northeast from Maryland into

Pennsylvania. Western belt trends approximately N. 30° E., is about 4 miles long and composed of small serpentine lenses separated by Peters Creek formation. Eastern serpentinite is essentially continuous, extending northeastward from Susquehanna River for about 15 miles and trending about N. 80° E. At Cedar Hill, contact with Peters Creek schist lies just north of Cedar Hill quarry. Further to the east, the serpentinite is in contact with Wissahickon schist. Both schist formations are believed to be lower Paleozoic in age.

Named for occurrence at Cedar Hill, Cecil County, Md.

Cedar Hills Anhydrite[1]

Permian: Central Kansas.

Original reference: R. G. Moss, 1932, Kansas Geol. Survey Bull. 19.

In Ness and Hodgeman Counties.

Cedar Hills Sandstone Member (of Hennessey Shale)

Cedar Hills Sandstone (in Cimarron Group)[1]

Cedar Hills Sandstone (in Nippewalla Group)

Permian: Southern Kansas and northern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p 3, 24.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1782, 1789–1791. Assigned to Nippewalla group (new).

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 39. Consists of feldspathic sandstone, siltstone, and silty shale, chiefly red, containing beds of white sandstone in upper and lower parts; upper part contains "snow balls" of white gypsum; shaly siltstone separates the more resistant and more massive coarse siltstone and very fine sandstone. Thickness about 180 feet. Underlies Flowerpot shale; overlies Salt Plain formation. Nippewalla group, Leonard series.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as sandstone member of Hennessey shale.

Named for Cedar Hills, Barber County, Kans.

Cedar Keys Limestone

Cedar Keys Formation

Paleocene: Northern and central Florida (subsurface).

W. S. Cole, 1944, Florida Geol. Survey Bull. 26, p. 27–28. Term Cedar Keys formation is designed to cover rocks encountered in wells in peninsular and northern Florida from first appearance of *Borelis* fauna to top of Upper Cretaceous. Thickness 570 feet in Hilliard Turpentine Company No. (W–336) and 566 feet in Cedar Keys No. 2 (W–355).

P. L. Applin and E. R. Applin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1699, 1704, 1708. Cedar Keys limestone overlies Lawson limestone (new) and underlies Oldsmar limestone (new).

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 84–86. Cedar Keys formation, as used in this report, covers interval extending from top of *Borelis* fauna, or top of a characteristic lithology, to top of the Cretaceous, which, in Levy County, is upper Lawson limestone. Cole's Cedar Keys is thus expanded by inclusion of an indefinite thickness of beds at top and contracted by exclusion of upper Lawson. Applin (1944) applied name Cedar Keys to a similar interval and with this usage formation is much more uniform in its occurrence and thickness. Florida Geological Survey has accepted new definition but retains original name. Paleocene.

Type well and derivation of name not given.

Cedar Mesa Sandstone Member (of Cutler Formation)[1]

Cedar Mesa Formation (in Cutler Group)

Permian: Southeastern Utah.

Original reference: A. A. Baker and J. B. Reeside, Jr., 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 11, p. 1420, 1421, 1423, 1441, 1445, 1446.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2054, 2055. In revised terminology in Four Corners region, Cedar Mesa is raised to formation in Cutler group. Occurs above Halgaito formation.

J. H. Stewart, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1855. Thickness of member about 800 feet in Monument Valley. Underlies Organ Rock tongue and overlies Halgaito tongue; in some areas overlies Rico formation.

Well exposed on Cedar Mesa, Utah, on San Juan River, west of Mexican Hat (Bluff post office).

†Cedar Mountain Beds[1]

Miocene, upper: Central Nevada.

Original references: J. C. Merriam, 1914, California Univ. Pub., Bull. Dept. Geol., v. 8, no. 12, p. 277; 1916, v. 9, p. 163–172.

Cedar Mountains.

Cedar Mountain Complex

Precambrian: Southwestern Minnesota.

E. H. Lund, 1956, Geol. Soc. America Bull., v. 67, no. 11, p. 1487–1489, pl. 1. Name applied to youngest of three groups of Precambrian igneous and metamorphic rocks exposed in Minnesota River valley. Consists of several small roughly circular intrusives; largest forms prominent knob called Cedar Mountain. Gabbro-diorite makes up bulk of rock in Cedar Mountain and forms outer shell 500 feet thick surrounding a granite core. Well-developed banding or primary flow structure is characteristic of Cedar Mountain gabbro and related types in other localities. Complex considered younger than rock types grouped in Minnesota Valley granite series.

Crops out in area south and southeast of Franklin, in Renville, Redwood, and Brown Counties.

Cedar Mountain Formation

Cedar Mountain Shale or Formation (in Dakota Group or Cedar Mountain Group)

Lower Cretaceous: Central Utah and northwestern Colorado.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 966–967, 989, table 1. Term Cedar Mountain shale proposed to include variegated beds between Buckhorn conglomerate (new) below and Dakota(?). Predominantly shale. Thins eastward: 272 feet at type locality: 100 feet, Cisco, Utah; 25 feet, Blue Mountain, Colo. Shale-conglomerate contact sharp though position of boundary depends on local position of conglomerates and may vary within vertical interval of 100 feet or more. Upper contact variable; in places is gradational into Dakota(?) beds; elsewhere is sharp but irregular. Together with Buckhorn conglomerate comprises Cedar Mountain group (new).

W. L. Stokes, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1774. Formation redefined to include Buckhorn conglomerate reduced to member status. Name applicable to Lower Cretaceous sediments of Utah west of Colorado River. For region east of Colorado River to an undetermined position in central Colorado, name Burro Canyon formation is applicable.

W. L. Stokes, 1952, Utah Geol. and Mineralog. Survey Bull. 46, p. 9 (table 1), 19–20, pl. 1. Described in Thompsons area where it is 110 feet thick; overlies Brushy Basin shale member of Morrison and underlies Dakota sandstone. Buckhorn conglomerate not represented in this area.

R. G. Young, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 17–21. Formation described in Grand Junction area, Colorado, where it disconformably underlies Naturita formation (new). Consists of basal conglomeratic sandstone unit and overlying variegated mudstone unit. In most localities, basal sandstone is massive cliff-forming unit with undulatory base and sharply defined upper surface. Farther west in Utah, three such sandstones, separated by mudstone units, are present in formation. These sandstones are termed Lower, Middle, and Upper Cedar Mountain sandstones. Lower, which is probably equivalent to Stokes' Buckhorn is present in deeper scours in Grand Junction area and is directly overlain in these scours by Middle sandstone. Where Lower sandstone is absent, the Middle sandstone constitutes the basal sandstone. Where only Middle sandstone is present basal unit averages about 25 feet thick, but where both sandstones are present it may be as much as 80 feet thick. Mudstone unit averages about 35 feet in Grand Junction area but slightly thicker along western edge. Included in Dakota group.

R. G. Young, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 157–171, 180–181, 183, 188. Considered facies of Dakota group. Upper part of formation passes laterally into lower part of Naturita formation herein also considered facies of Dakota group. Proposed also to drop name Burro Canyon formation and retain older name Cedar Mountain formation for noncarbonaceous deposits of Dakota group throughout Colorado Plateau.

Type section: Southwest flank of Cedar Mountain, Emery County, Utah, just north of Buckhorn Reservoir.

Cedar Mountain Group

Lower Cretaceous(?): Colorado and Utah.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 987–989. Recommended that Buckhorn conglomerate and Cedar Mountain shales (both new) be called Cedar Mountain group and tentatively classed as Lower Cretaceous. On generalized section, group is above Morrison formation and below Dakota(?) sandstone.

Type area not stated. Cedar Mountain shale has its greatest development in central Utah and northwestern Colorado.

Cedar Park Member[1] (of Walnut Clay)

Lower Cretaceous (Comanche Series) : Eastern Texas.

Original reference : W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 331.

V. E. Barnes, 1958, Texas Univ. Bur. Econ. Geology Guidebook 1, p. 24. Thickness commonly 10 feet or less.

Type locality : Quarries about 2 miles northwest of Cedar Park, Williamson County.

†Cedar Point Shales and Shaly Limestones[1]

Permian : Central Kansas.

Original reference : L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Probably named for Cedar Point, Chase County.

Cedar Rapids phase (of Otis Limestone)[1]

Middle Devonian : Central eastern Iowa.

Original reference : W. H. Norton, 1921, Iowa Geol. Survey, v. 27, p. 378.

In quarries at Cedar Rapids and at numerous other exposures.

Cedar Spring Member (of Cove Mountain Formation)

Tertiary : Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1). White and pink airfall tuff, sediments, and green-tan-purple rhyolite vitric tuff. Thickness 300 feet. Upper part of formation; overlies Pilot Creek basalt member (new).

Occurs in Washington County. Type locality and derivation of name not stated.

Cedarton Shale Member (of Graford Formation)[1]

Cedarton Shale (in Graford Group)

Upper Pennsylvanian : Central Texas.

Original reference : N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 391.

C. O. Nickell *in* Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 104–105. Underlies Winchell shale member (new).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Graford group. Overlies Adams Branch formation ; underlies Winchell formation.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 51. In Brown and Coleman Counties, member consists of shale, red in upper part and gray in lower part. Upper part locally contains fern leaf prints; lower part contains crinoid debris and a few fusulinids. Thickness about 70 feet. Overlies Adams Branch limestone member; underlies unnamed limestone at base of Winchell limestone.

Named for Cedarton, Brown County.

Cedartop Gypsum Member (of Blaine Gypsum)[1]

Permian : Southwestern Oklahoma and western Texas.

Original reference : C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 56.

R. L. Clifton, 1942, Jour. Paleontology, v. 16, no. 6, p. 686 (table 1). Table of upper Leonard series in Kansas, Oklahoma, and Texas shows Cedartop member above Medicine Lodge member and below Acme member.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 30. Shown on correlation chart of West Texas.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 22–23, pl. 1. New type locality designated. Present study shows that Haystack gypsum caps Cedartop Butte and since all rocks younger than Haystack have been eroded away, this butte cannot be type locality for what is here called Cedartop gypsum. At newly selected type locality, member is 10½ feet thick, separated from underlying Haystack gypsum member by 12½ feet of red and gray-green shale and from overlying Collingsworth gypsum member by 13½ feet of shale.

Type locality (redesignated): In bluffs about 250 yards north of Cedartop Butte, in the SE¼SE¼ sec. 35, T. 8 N., R. 21 W., Beckham County, Okla.

Cedar Vale Shale[1] Member (of Scranton Shale)

Cedar Vale Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, p. 53.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 49 (fig. 11), 212. Rank raised to formation in Wabaunsee group. Term Scranton abandoned. Overlies Happy Hollow limestone; underlies Rulo limestone. Average thickness 25 feet.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p 309 (fig. 14). Stratigraphic section shows occurrence in Adams County, Iowa.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 2274 (fig. 1), 2277. Rank reduced to member status in Scranton shale here reintroduced as a formation with stratigraphic span as assigned to it by Haworth and Bennett (1908). Underlies Rulo limestone member: overlies Happy Hollow limestone member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 14, fig. 5. Cedar Vale shale, Wabaunsee group, is marked by Elmo coal at top. Shale is gray and blocky and contains nodular limestone near top and center. Thickness 18 feet in drill hole near Coin. Overlies Happy Hollow limestone; underlies Silver Lake shale. Rulo limestone, which underlies Silver Lake in some areas has not been identified in Iowa.

Type locality: East of Cedar Vale, Chautauqua County, Kans.

Cedar Valley Limestone[1]

Cedar Valley Formation

Middle Devonian: Eastern Iowa, southwestern Illinois, and southeastern Minnesota.

Original reference: W. J. McGee, 1891, U.S. Geol. Survey 11th Ann. Rept., pt. 1, p. 314.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9 (geol. column), 94–97. Geographically extended into southeastern Minnesota where it covers southwestern corner of Fillmore County, about three-quarters of Mower County, and part of southeastern Freeborn County. Thickness generalized section about 100 feet. Senecan series.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1750–1751, chart 4. Shown on correlation chart as Middle Devonian. However, age of Cedar Valley has long been a moot question. Known fauna of Cedar Valley contains no fossils of unequivocal late Devonian age. Evidence for age based on position of Independence shale leads to difficulties. Independence shale contains Chemung fauna, but Stainbrook (1935) believes that the Independence is stratigraphically below the Cedar Valley. Others believe that the Independence represents fillings of caverns in the Cedar Valley and that it is therefore younger than formation it seemingly underlies.

M. A. Stainbrook, 1944, Illinois Geol. Survey Bull. 68, p. 185–187. Formation includes (ascending) Linwood, Littleton, and Coralville members. Overlies Independence shale, probably unconformably; in some areas, overlies Davenport member of Wapsipinicon; in some areas, overlies Spring Grove member where Davenport has been eroded; in northern and western Iowa, may rest on Maquoketa or even Galena where it overlaps the Wapsipinicon. Stratigraphically below Shellrock formation. Upper Devonian.

D. L. Dunn, 1959, Jour. Paleontology, v. 33, no. 6, p. 1001–1017. Discussion of Devonian chitinozoans from Cedar Valley formation in Iowa. In this area, formation includes (ascending) Solon, Rapid, and Coralville members. Investigators are not in agreement concerning age of the Cedar Valley. Correlations discussed. Investigators who support cave-filling origin of underlying Independence shale, hold the Cedar Valley to lie conformably upon Davenport member of Wapsipinicon. The Cedar Valley overlaps the Silurian and Ordovician to north.

Named for exposures in valley of Cedar River, Iowa.

Cedarville Andesite[1]

Miocene: Northeastern California.

Original reference: H. A. Powers, 1932, Am. Min., v. 17, no. 7, p. 253–282.

In Modoc lava-bed quadrangle.

Cedarville Dolomite

Cedarville Dolomite (in Durbin Group)

Cedarville Limestone[1]

Middle Silurian: Southwestern Ohio and southeastern Indiana.

Original reference: E. Orton, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 271, 277–278, 301, 304–306.

D. A. Busch, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1976. Stratigraphically expanded below to include 43 feet of dolomite formerly included in the Huntington dolomite, as exposed at Ridgeville, Randolph County, Ind. As redefined, total thickness of Cedarville formation is 95 feet.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as uppermost unit in Durbin group. Underlies Peebles dolomite.

Edwin Kirk, 1946, Washington Acad. Sci. Jour., v. 35, no. 2, p. 34. Referred to as Cedarville dolomite and noted as occurring in Indiana.

R. J. Bernhagen, chm., 1960, Ohio Acad. Sci. Geology Sec. Guidebook 35th Ann. Field Conf., p. 13, 17–19, 21. Silurian section in Yellow Springs region shows Cedarville dolomite, as much as 50 feet thick, above Springfield dolomite. Top of section. Niagaran.

Well exposed at Cedarville, Greene County, Ohio.

Cedarville Sandstone (in Monongahela Formation)[1]

Pennsylvanian : Northern West Virginia and western Maryland.

Original reference: D. B. Reger, 1916, West Virginia Geol. Survey Rept. Lewis and Gilmer Counties, p. 124.

Forms cliff at east end of Cedarville, Gilmer County, W. Va.

Cedarville Series[1]

Oligocene, middle, or Miocene : Northeastern California.

Original reference: R. J. Russell, 1928, California Univ. Pub., Dept. Geol. Sci. Bull., v. 17, no. 11, p. 402–416, map.

C. A. Anderson, 1941, California Univ. Pub., Dept. Geol. Sci. Bull., v. 25, no. 7, p. 352–353. Described in discussion of basement rocks of Medicine Lake Highland area. Exposures outside mapped area indicate Cedarville series probably underlie the highland. Character of underlying rocks unknown. Older than Warner basalt.

D. I. Axelrod, 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1936. Lower Cedarville contains flora that is apparently mid-Oligocene in age.

Mapped over a large part of Warner Range, west of Cedarville, Modoc County.

Ceja Glorieta sandstone[1]

Permian : New Mexico.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 64, no. 4, p. 263.

†Cement shale[1]

Upper Devonian : Western Colorado.

Original reference : C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 281, 289.

Takes title from [exposures on?] Cement Mountain, a few miles from Crested Butte, Gunnison County.

Cement City Limestone Member (of Drum Limestone)

Cement City Limestone Bed (in Kansas City Formation)[1]

Pennsylvanian (Missouri Series) : Northwestern Missouri, southwestern Iowa, eastern Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: H. Hinds and F. C. Greene, 1915, Missouri Bur. Geology and Mines, v. 13, 2d ser., p. 7, 27–28, 118.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030, 2031 (fig. 4). Member of Drum limestone. Underlies Corbin City limestone member; overlies Quivira shale member of Cherryvale formation. Northeastward tracing proves that Dewey member of the Drum is the same as limestone called Cement City in Kansas City area. Dewey has priority over Cement City (Hinds and Greene, 1915) and is recognized as a formational unit by Oklahoma Geological Survey. Kansas Geological Survey has used Cement City for lower member of Drum limestone and Cement City was recognized by the inter-state conference

(May, 1947). Kansas proposes to deviate from the interstate classification by adopting Dewey instead of Cement City. Other State surveys will continue to recognize Cement City until question of stratigraphic identity of the type of this unit (near Kansas City) and the Dewey is removed.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37. Thickness near Winterset, Iowa, 6 feet; Sarpy County, Nebr., 11 feet. Persists southward into Oklahoma. Type locality stated.

Type locality: In cement plant quarry at Cement City, Jackson County, Mo.

Cemetery Limestone[1]

Upper Cambrian: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, 437.

Named for occurrence at Elkhorn cemetery, Elkhorn region.

Centennial Limestone[1]

Middle and Upper Cambrian and Lower Ordovician: Central northern Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

Probably named for Centennial mine, Tintic district.

Centennial Series

Precambrian: Southeastern Wyoming.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Name proposed for metalimestone schist series intruded by older gray granites and lying stratigraphically below Deep Lake metaquartzite. Occurs below Snowy Range series (new).

Area is west, northwest, and north of Centennial, Medicine Bow Mountains, Albany County.

Centennial School Sandstone and Shale Member (of Bald Eagle Sandstone)

Upper Ordovician: Central Pennsylvania.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geology Contr. 3, 58p. Lower member of Bald Eagle in vicinity of Tyrone Gap. Underlies Spring Mount sandstone member (new). Overlies Reedsville shale. [Swartz refers to his 1955 report *in* Pennsylvania Geologists guidebook 21st Ann. Field Conf. Compiler was unable to locate this reference.]

Type locality and derivation of name not given.

Centerfield Coral Bed

See **Mahantango Formation** (in Hamilton Group).

Centerfield Limestone Member (of Ludlowville Shale)[1]

Centerfield Formation

Middle Devonian: Central and western New York and eastern Pennsylvania.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 22.

G. A. Cooper and A. S. Warthin, 1942, Geol. Soc. America Bull., v. 53, no. 6, p. 876 (fig. 2), 877–878. Formation, at type section, consists of 5 feet of alternating shale and limestone bands, the latter as much as 4 inches thick. This is overlain by about 6 feet of sandy limestone abounding in corals. Formation thins westward to 4½ feet at Blossom in Erie County where it is mostly limestone. West of Blossom on Lake Erie shore, approximate position of the Centerfield is marked by a thin layer of limestone containing abundant *Styliolina*. East of type section, sand content increases, and differentiation into alternate bands of shale and limestone disappears. On Seneca and Cayuga Lakes, formation is fairly homogeneous sandy limestone about 30 feet thick. In Erie County, N.Y., overlies Levanna shale and underlies Ledyard shale; at Skaneateles Lake, overlies Butternut shale and underlies a coral bed. Where exposed in eastern Pennsylvania near Stroudsburg, consists of 23 feet of bluish calcareous sandstone containing corals.

T. B. Coley, 1954, Jour. Paleontology, v. 28, no. 4, p. 453, 454, 455. Referred to as formation. Underlies Ledyard formation; overlies Levanna formation. Ostracodes discussed.

R. S. Boardman, 1960, U.S. Geol. Survey Prof. Paper 340, p. 3–4. Member occurs at base of Ludlowville shale. Thickness at type locality 20 feet. Underlies Ledyard member. Contains lowest occurrence of trepostomatous Bryozoa known in Hamilton group.

Type section: On Schaffer Creek, about 1 mile north of Centerfield, Canandaigua quadrangle, New York.

Center Hall Formation[1]

See Centre Hall Member (of Nealmont Limestone).

Center Iron Sandstone (in Clinton Formation)[1]

Center Iron Sandstone (in Rose Hill Shale)

Middle Silurian: Central southern Pennsylvania.

Original reference: C. K. Swartz and F. M. Swartz, 1931, Geol. Soc. America Bull., v. 42, p. 625, 628, 629, 634, 638.

F. M. Swartz and H. J. Hambleton, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 19, 21–22, 27. At Center, about 36 feet of Center iron sandstones are exposed along road where Center member was originally measured; 2 miles south of New Germantown where road crosses plunging nose of anticlinal Rising Mountain, the sandstone is more than 60 feet thick and occurs in upper part of Rose Hill shale about 150 to 210 feet below Keefer sandstone; thickens eastward to 210 feet at Susquehanna Gap; thins and gradually disappears northwest of Center and New Germantown.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 29. Unit renamed Burnt Ridge sandstone member of Rose Hill.

Named from exposures south of Center village, Perry County.

Center Peak Conglomerate Member (of Panoche Formation)

Lower Cretaceous: Southern California.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull., v. 71, no. 10, chart 10e (column 15). Shown on correlation chart at base of Panoche formation. Underlies Curry Mountain shale member.

Centerpoint volcanic facies (of Eagleford Formation)

Upper Cretaceous: Southwestern Arkansas.

R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 143, 147–148. Red and gray clays with interbedded pebbly tuffaceous sandstones. Overlies the Trinity; underlies Tokio formation. Name implies that this group of rocks is a volcanic facies of the Eagleford formation of northeast Texas. Unit has commonly been referred to as the volcanic "Woodbine."

Settlement of Centerpoint in Howard County is located within the area of the outcrops and within relatively short distances of the upper and lower contacts of the formation.

Centerville Clay

Centerville Formation[1]

Lower Silurian (Albion Series): Southwestern Ohio and southeastern Indiana.

Original reference: A. F. Foerste, 1931, Kentucky Geol. Survey, ser. 6, v. 36, p. 173, 184–185.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as Centerville clay; stratigraphically below Brassfield limestone. Included in Albion series.

Named from exposures east of Centerville, Montgomery County, Ohio.

Centerville Limestone[1]

Silurian (Niagaran): Western Tennessee.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 397, 402, 407.

Named for exposures at Centerville, Hickman County.

Centinela Gravels[1]

Pleistocene: Southern California.

Original reference: A. J. Tieje, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, no. 5, p. 510.

Exposed south of Centinela Creek, Los Angeles County.

†Central Limestone and Shale Group[1]

Lower, Middle, and Upper Ordovician: Central and eastern Tennessee.

Original reference: J. M. Safford, 1856, Geology Reconn. Tennessee 1st Rept., p. 149, 154–156.

Named for central basin of middle Tennessee.

Central City Granite[1]

Central City Quartz Bostonite

Precambrian(?): Central northern Colorado.

Original references: J. Underhill, 1906, Univ. Colorado Studies, v. 3, no. 4, p. 272; 1906, Colorado Sci. Soc. Proc., v. 8, p. 103–122.

George Phair, 1952, U.S. Geological Survey Trace Elements Inv. Rept. TEI–247, p. 26. Referred to as quartz bostonite.

Occurs only on each side and a little south of head of Spring Gulch, just south of Central City Railroad station, Gilpin County.

Central Fee sandstone unit (in Sycamore Canyon Member of Puente Formation)

Miocene, upper: Southern California.

C. J. Kundert, 1952, California Div. Mines Spec. Rept. 18, p. 6 (fig. 2), 7, pl. 2. Series of sandstone and sandy siltstone beds in upper part of

Sycamore Canyon member. Thickness approximately 1,050 feet. Underlies Hoover conglomerate unit (new) of Sycamore Canyon member.

Occurs in Whittier-La Habra area, south of Whittier fault, Los Angeles County.

Centralia cyclothem (in McLeansboro Group)

Pennsylvanian: Southwestern Illinois.

J. R. Ball, 1943, Illinois Acad. Sci. Trans., v. 36, no. 2, p. 147, 148. In sequence in Carlinville quadrangle. Centralia cyclothem occurs below Macoupin cyclothem and above Shoal Creek cyclothem. Thickness about 5 feet; cyclothem not fully developed in quadrangle. The included fossiliferous limestone [probably Centralia limestone] is about 17 feet above the Shoal Creek limestone.

Type locality and derivation of name not given.

Centralia Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Southwestern Illinois.

Original reference: J. R. Ball, 1934, Illinois Acad. Sci. Trans., v. 26, no. 3, p. 97.

Derivation of name not stated, but probably is Centralia, southwest corner of Marion County.

Centralian Epoch or Series[1]

Pleistocene (Illinoian and Sangamonian): Illinois and Iowa.

Original reference: G. F. Kay, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 449–452.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 38. In Iowa and Illinois, the Pleistocene is classed as a period (system) and four epochs (series) are used to include a glacial-interglacial pair each. These are Grandian (Nebraskan and Aftonian), Ottumwan (Kansan and Yarmouthian). Centralian (Illinoian and Sangamonian), and Eldoran (Wisconsinan and Recent). Of these units, each of the first three essentially coincides with a glacial cycle; present data indicate that the youngest (Eldoran) includes two distinct cycles, each of which is complex within itself. These terms have not been adopted for official use in Kansas partly because of this inconsistency and partly because retention of Quaternary as the System-Period with Pleistocene as its contained Series-Epoch would necessitate erection of new category of names to include these terms and thus produce further complication of classification system.

Named for Centralia, Marion County, Ill.

†Central Mine Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 80–81, chart.

Houghton County.

Central Mine Group[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane and A. E. Seaman, 1907, Jour. Geology, v. 15, p. 680, 689.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Name Portage Lake lava series (new) proposed to include Eagle River, Ashbed, Central Mine, and Bohemian Range groups of old reports. These older subdivisions are quite arbitrary and depend on continuity of individual flows or conglomerate beds for validity. They are not useful for purpose of this report.

Well exposed in workings of Central mine on a cross-fissure, exposing a good section (secs. 24, 25, 36, T. 58 N., R. 31 W.).

Central Valley Beds[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 187.

Derivation of name not stated.

Central Valley Sandstone

Lower Devonian : Southeastern New York.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 728–730, 731 (fig. 2). Consists of white-weathering, mottled violet sandstone with a 1-foot bed of white-weathering chert at top of unit. Fossiliferous. Thickness about 25 feet. Lower contact covered; sandstone may rest on beds of New Scotland age or may rest on strata of pre-New Scotland, Upper Silurian age. Underlies Connelly conglomerate, contact abrupt.

Type section: In Thruway cut at Highland Mills, Orange County. This is only known exposure of unit. Name derived from Central Valley. Section is located on eastern side of Green Pond-Schunemunk Mountain outlier.

Centre Hall Member (of Nealmont Limestone)

Middle Ordovician : Central and central southern Pennsylvania.

Original reference (Center Hall) : R. M. Field, 1919, Am. Jour. Sci., 4th, v. 48, p. 404, 417–419, 422.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 3; no. 2, p. 97–101, 103. Rank reduced to member of Nealmont limestone. Overlies Oak Hall member (new) ; underlies Rodman member. Thickness about 45 feet.

Named for village of Centre [Center] Hall, Centre County.

Centre Point division[1]

Pleistocene : Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 29, 35–42, 188.

Named for exposures at Centre Point, Howard County.

Cerbat Complex

Precambrian : Northwestern Arizona.

B. E. Thomas, 1949, Economic Geology, v. 44, no. 8, p. 666, fig. 2; 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 393–403, pl. 1. Basement assemblage of metamorphic and igneous rocks. Oldest-rocks of vertical to steeply dipping layers of hornblende-diopside schist and amphibolite, biotite schist, quartzite, and lit-par-lit gneiss. These rocks typically occur together but in no particular sequence. Layered rocks are intruded by granite magma, and granite gneiss is predominant rock type in complex. Perhaps fifty percent of gneiss is migmatite, whereas balance is believed to be orthogneiss. Thick sheets of pegmatite injected between layers of metamorphic rocks in many places. Aplite or aplitic granite commonly associated with pegmatite dikes. Diabase dikes, ranging in width from few feet to 150 feet, also common. Narrow zones of mylonite scattered throughout complex. The coarsely porphyritic Diana granite (new), which is preserved in the schists in western half of Chloride district, is only unit of complex that was mapped separately. Capped along extreme eastern and southern borders of range by isolated Tertiary volcanic rocks including Bull Mountain series (new). Intruded by Ithaca Peak granite porphyry (new).

Forms bulk of Cerbat Mountain, Mohave County.

Cerro Glaciation

Cerro Till[1]

Cerro glacial stage[1]

Pleistocene (pre-Wisconsin): Southwestern Colorado.

Original references: W. W. Atwood and K. F. Mather, 1915, U.S. Geol. Survey Prof. Paper 95, p. 14, pl. 1; 1924, Geol. Soc. America Bull., v. 35, p. 122; 1932, U.S. Geol. Survey Prof. Paper 166.

K. F. Mather, 1957, New Mexico Geol. Soc. Guidebook 8th Field Conf., p. 106. Cerro glacial stage mentioned in report on geomorphology of San Juan Mountains. First of three Pleistocene glaciations identified in area. Older than Durango glacial stage.

Named for Cerro Summit, about 12 miles east of Montrose, Montrose County.

Cerro Gigante Basalt

Oligocene or Miocene: Panamá.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 898 (table 2), 901–902. Unit is discussed under general heading "Bruja Island dolerite, Cerro Gigante basalt, and related igneous rocks." These include lower Miocene flows, plugs, and dikes of basic rock, hard and generally moderately joined; unconformable below Gatun formation and above upper Caimito member. "Basalt" is used in this paper as a field term applied to basic fine-grained igneous rocks including "andesite" and "basalt."

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 330. Oligocene or Miocene. Derivation of name.

In Gatún Lake area. Cerro Gigante is name of peak about 8 kilometers southwest of Barro Colorado Island.

Cerro Gordo Clay[1]

Lower Cretaceous (Comanche Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 111, 188.

Underlies the poor lands from Cerro Gordo, Little River County, to within 6 miles of Rocky Comfort, extending east to Cane Creek.

Cerro Gordo Substage[1]

Cerro Gordo Member (of Lime Creek Formation)

Upper Devonian: Central northern Iowa.

Original reference: C. L. Fenton, 1919, Am. Jour. Sci., 4th, v. 48, p. 355–376.

M. A. Stainbrook, 1944, Illinois Geol. Survey Bull. 68, p. 182 (fig. 1), 187. Middle member of Lime Creek formation. Overlies Juniper Hill member; underlies Owen limestone member. Consists of fossiliferous shale.

Named for exposures in Cerro Gordo County.

Cerros Shale Member (of Lodo Formation)

Paleocene and Eocene: Southern California.

R. T. White, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 256–257. Named as basal member of newly defined Lodo formation. Underlies Cantua sandstone member.

R. T. White, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 10, p. 1722–1727, 1734, 1738. Described as lithologically identical with the Lodo and recognizable as a distinct cartographic unit only where it is overlain by the Cantua sandstone. Anderson and Pack (1915) mapped the unit as basal part of the Cantua. Thickness at type locality about 630 feet. Overlies Moreno shale.

J. E. Schoellhamer and D. M. Kinney, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–128. Described at type section as consisting of about 50 feet of massive highly glauconitic siltstone and sandy siltstone overlain by 523 feet of gray claystone; a 4-foot medium-grained arkosic sandstone is present 194 feet above base. Paleocene and Eocene.

Type locality: Cerros Hill on west side of Tumey Gulch at the west corner sec. 14, T. 16 S., R. 12 E., M. D. B. and M., Fresno County. No geographic names were available, so the conspicuous hill where the member is exposed was named Cerros Hill.

Cerrotejonian Stage

Pliocene, early: California.

D. E. Savage, 1955, California Univ. Pubs. Geol. Sci., v. 31, no. 1, p. 11–19. Stage based on mammalian faunal assemblage. Subjacent to Montediablan stage (new). Contemporaneous with earlier part of North America Clarendonian age of Wood and others (1941).

Type section: In nonmarine and marine deposits mapped as Santa Margarita by Hoots (1930) in Tejon Hills, Kern County. This is 100 miles from type exposure of Santa Margarita formation.

Chacha Limestone

Pleistocene or early Holocene: Mariana Islands (Saipan).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]. Chatcha limestone named on correlation chart. Pleistocene.

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 57–58, table 4 [English translation in library of U.S. Geol. Survey, p. 68–69]. Raised coral reef limestone. Consists primarily of corals and lesser amounts of *Halimeda* on Saipan but on other islands consists primarily of *Halimeda* and secondarily of corals. Correlated with Rota limestone on Rota, Sonson limestone on Tinian, and Barrigada limestone on Guam. Younger than Mariana limestone.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 26. Early Holocene.

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 88. Tanapag limestone as used in this report includes rocks which Tayama called Chacha limestone.

Type locality: Chacha, Saipan.

Chaco marl[1]

Eocene: Northwestern New Mexico.

Original reference: C. R. Keyes, 1906, Geol. Soc. America Bull., v. 17, p. 725.

Derivation of name not given.

†Chacra Sandstone Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: C. H. Dane, 1936, U.S. Geol. Survey Bull. 860-C.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2158–2159. Beds that were included in Chacra sandstone member by Dane (1936) appear to be about equivalent to combined upper two southward-extending tongues of Cliff House sandstone northeast of Newcomb. Cliff House sandstone of Mesaverde group, therefore, will replace Chacra sandstone member throughout the former extent of that unit.

In Chacra Mesa coal field.

Chacra[1] terrane

Cretaceous: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geological formations of New Mexico; Des Moines, Robert Henderson, State Printer.

San Juan region.

Chadakoin Beds[1]

Chadakoin Formation (in Arkwright Group)

Chadakoin Group

Upper Devonian: Western New York and northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1923, Geol. Soc. America Bull., v. 34, p. 69.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 32–33; 1955, New York State Mus. Sci. Service Circ. 42, p. 11, 12. Upper formation in Arkwright group (new). Composed of approximately 420 feet of gray siltstone beds with some interbedded gray shale, especially near top of formation. Comprises Dexterville member below and Ellicott member above. Overlies Canadaway formation; underlies Cattaraugus formation of Conewango group. Chautauquan series.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17 (table 2), 18–19. Rank raised to group. Includes beds between base of Wellsville formation and Germania formation. Approximately same as Conneaut group (Chadwick, 1934, Bulls. Am. Paleontology, v. 21, no. 71). Comprises (ascending) Wellsville formation, Hinsdale sandstone, Whitesville formation, and Germania formation. Thickness about 585 feet. Overlies Canadaway group; underlies Conewango group. Chautauquan series.

Named for exposures in quarries at Dexterville (Jamestown) on Chadakoin River, Chautauqua County, N.Y.

Chadron Formation[1] (in White River Group)

Oligocene, lower: Western Nebraska, northeastern Colorado, Montana, South Dakota, North Dakota, and eastern Wyoming.

Original reference: N. H. Darton, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 4, p. 736, 759, pl. 82.

C. B. Schultz and T. M. Stout, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1921. In northwestern Nebraska, contact between Chadron and overlying Brule is provisionally drawn at base of a certain continuous purple-tinted white sometimes silicified limestone layer, which is the upper of several such limestone beds in lower part of the local section.

R. L. Nace, 1939, Wyoming Geol. Survey Bull. 27, p. 31–35, 43. Described in Red Desert area, Wyoming, where it is about 218 feet thick and includes Beaver Divide conglomerate member (new) in basal part. Disconformable above Continental Peak formation.

John Clark, 1954, Carnegie Mus. Annals, v. 33, art. 11, p. 197. In Big Badlands area, South Dakota, subdivided into (ascending) Ahearn, Crazy Johnson, and Peanut Peak members, standard section designated for South Dakota.

N. M. Denson and others, 1955, U.S. Geol. Survey Coal Inv. Map C–33. Mapped in Billings and Golden Valley Counties, N. Dak.

C. B. Schultz and T. M. Stout, 1955, Nebraska Univ. State Mus. Bull., v. 4, no. 2, p. 25–38, figs. 3, 10, tables 1, 2. Darton did not specify type locality for Chadron. He stated in 1931 (Wilmarth, 1938, p. 393) that the formation was named for exposures at Chadron, Nebr. However his 1899 illustration of section at Chadron does not show exposure of this formation and his text references show no familiarity with the outcrops shown on his map near there. For all practical purposes his knowledge of the Chadron seems to have been derived in northwestern Nebraska from his "Adelia" section, northwest of Crawford, Sioux County, Nebr. "Adelia" section is section used for discussion in present report. Detailed description in western Nebraska. Three divisions, lower, middle, and upper, recognized. Lower is essentially Yoder of Schlaikjer (1935) and Ahearn of Clark (1954); middle is probably only in part equivalent to Crazy Johnson of Clark (1954); upper corresponds closely to Peanut Peak of Clark. Thickness 143 to 209 feet. Underlies Brule formation. Writers depart from their 1938 action in defining base of Brule as base of upper purplish-white layer and top of upper purplish-white layer is herein suggested as redefined plane of division between Chadron and Brule. In Crawford, Nebraska area, overlies Cretaceous Pierre shale; in Torrington area, Wyoming, underlies Cretaceous Lance formation.

L. J. Bjorklund and R. F. Brown, 1957, U.S. Geol. Survey Water-Supply Paper 1378, p. 26. Underlies flood plain of South Platte River from near Proctor, Colo., eastward to Sedgwick, Colo. Exposures are abundant north of river from Sterling to Proctor.

W. T. Thom, Jr., 1957, Billings Geol. Soc. Guidebook 8th Ann. Field Conf., p. 11 (table 1). Geographically extended into Crazy Mountain Basin, Mont., where it consists chiefly of volcanic ash, silt, and sand.

Standard section: In Big Badlands on south fork of Indian Creek, from sec. 34, T. 3 S., R. 12 E., to sec. 10, T. 4 S., R. 12 E., Pennington County, S. Dak. Named for exposures at Chadron, Dawes County, Nebr.

Chadronian Age

Oligocene: North America.
