H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 11, pl. 1. Provincial time term, based on the Chadron formation, type locality near Chadron, Nebraska. Includes the old term "*Titanotherium* *beds*," used in its more extended sense. Covers the interval between the Duchesnean (Eocene) and Orellan (Oligocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for the North American continental Tertiary. [For sequence see under Puercan.]

Type area: Northwestern Nebraska and southwestern South Dakota.

Chaffee Formation[1]

Upper Devonian: Central Colorado.

Original reference: E. Kirk, 1931, Am. Jour. Sci., 5th, v. 22, p. 229–230.

Ogden Tweto and T. S. Lovering, 1947, Colorado Mining Resources Board [Bull.], p. 380 (chart). In Gilman district, includes Parting quartzite member below and Dyer dolomite member above. Thickness about 120 feet. Overlies Harding sandstone; underlies Gilman sandstone member (new) of Leadville limestone.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 169–177. Described in Pando area where it unconformably overlies Harding quartzite or Peerless formation and unconformably underlies Gilman sandstone member of Leadville dolomite. Comprises two members. Parting quartzite below and Dyer dolomite above. Thickness 118 to 137 feet.

I. N. Mackay, 1953, Colorado School Mines Quart., v. 48, no. 4, p. 21–28, pls. Described in Eagle and Pitkin Counties, where it disconformably overlies Manitou dolomite and is in contact with overlying Leadville limestone along an erosional surface. Includes Parting and Dyer members. Thickness 216 to 233 feet.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 13–15. Described in Garfield quadrangle where it is 150 to 250 feet thick and includes both Parting quartzite and Dyer dolomite members. Erosional unconformities of low relief separate it from underlying Fremont dolomite and overlying Leadville limestone.

Named for Chaffee County where it is well exposed south of Arkansas River about 5 miles southeast of Salida, and on western slope of Monarch Mountain, at Monarch, about 15 miles southwest of Salida.

Chaffin Limestone Member (of Thrifty Formation)[1]

Chaffin Formation (in Thrifty Group)

Upper Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 410–412.

C. O. Nickell, 1938, *in* Wallace Lee and others, Texas Univ. Bur. Econ Geology Pub. 3801, p. 127–128. Chaffin limestone member, at type locality, crops out above Chaffin coal and is 20 feet thick, Within 200 yards to the north, it is cut out by unconformity and replaced by sandstone of later age. Where Chaffin limestone reappears east of Rockwood, two limestones are present, separated by 12 feet of shale. Some observers have considered these two beds to represent bifurcation of the Chaffin as it appears south of Colorado River, but presence of carbonaceous shale in position of Chaffin coal below the thick upper limestone near Rockwood suggests that lower bed there may be a separate limestone bed in Lohn shale member. Plummer and Moore (1921, Texas Univ. Bull. 2132) correlated upper and lower limestone beds of split Chaffin limestone with Breckenridge limestone and Blach Ranch limestone, respectively, of Brazos River basin, where the Blach Ranch, like the Chaffin, has a thin coaly bed below it. Top member of Thrifty formation. Overlies Parks Mountain sandstone member; underlies Harpersville formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 91. Rank raised to formation in Thrifty group. Underlies Obregon formation (new); overlies Breckenridge formation. Consists of an upper thin limestone member about 20 feet above a thicker limestone member, both fusulinid-bearing; these are separated from basal Parks Mountain sandstone member by shale.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 50. Shown on composite stratigraphic section of Brown and Coleman Counties as limestone member at top of Thrifty formation. Consists of gray, slabby limestone, commonly purple blotched; fusulinids and "seaweed" structures abundant. Overlies Parks Mountain sandstone member; underlies Waldrip shale member of Permian Pueblo formation.

D. A. Meyers, 1958, Jour. Paleontology, v. 32, no. 4, p. 678 (fig. 1). Member shown on stratigraphic column as occurring above Breckenridge member.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 215–D, p. 74, pl. 27. Drake (1893) traced the Chaffin limestone across Coleman and Brown Counties. From vicinity of Home Creek northward, he found two limestones and called the lower one the lower Chaffin limestone. The lower Chaffin is here correlated with Breckenridge limestone member. The generally persistent upper part of Chaffin limestone member has been variously called Breckenridge limestone (Plummer and Moore), Upper Crystal Falls limestone (Hudnall and Pirtle, 1929, Geologic map of Coleman County; 1931, Geologic map of Brown County), Chaffin limestone (Sellards, 1933, Texas Univ. Bull. 3232), Breckenridge limestone (Bullard and Cuyler, 1935, Texas Univ. Bull. 3501), and Crystal Falls limestone (Chaney, 1950, Abilene Geol. Soc. Guidebook Nov. 2–4). Chaffin limestone member immediately south of Colorado River ranges from about 15 feet in thickness at Chaffin mines to about 7 feet at Waldrip. At this locality, it is a slabby irregularly bedded gray limestone, stained purplish red. Contains abundant fusulinids and thin wavy structures of clear calcite. These structures characterize bed over most of Coleman County. Thins northward. Average thickness 1 to 2 feet in Brown County. Overlies Parks Mountain sandstone member; underlies Waldrip shale member of Pueblo formation.

Named for Chaffin coal mine, 2 miles east of Waldrip, McCulloch County.

Chagres Alluvium

Pleistocene and Recent: Panamá.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 898 (table 2), 904. Alluvial deposits of interbedded clays, silts, sands, and gravels, variably loose to well compacted. Intergrades locally with Atlantic muck. Table 2 shows thickness of Chagres alluvium, Chagres gravel, Atlantic muck, and Pacific muck 300 feet. Pleistocene and Recent.

Present along Chagres River valley and its tributaries, the Río Gatún, and Río Trinidad, and other principal valleys, vicinity of Lake Gatún.

Chagres Sandstone[1]

Pliocene, lower: Panamá.

Original reference: D. F. MacDonald, 1919, U.S. Nat. Mus. Bull. 103, p. 532.

W. P. Woodring, and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 244, 246 (fig. 2). Includes Toro limestone member at base. Chagres proper above Toro member consists of very massive mostly fine-grained sandstone and some siltstone. Thickness difficult to determine; MacDonald considered it to be 1,000 feet or more. Overlies and partly overlaps Gatún formation; base sharply defined. Fossil evidence indicates late Miocene age; however, it may be early Pliocene if the coastal Gatún west of Canal Zone is late Miocene.

W. P. Woodring, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–1; 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 12, 47–50, pl. 1. Lower Pliocene.

Named for exposures that overlook coast from Toro Point to mouth of Río Chagres. Outcrop area lies west of Canal, and extends from Canal Zone southwestward along Caribbean coast to between Río Indio and Río Miguel.

Chagrin magnafacies[1]

Upper Devonian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 28.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 46. An attempt to apply Caster's (1934) system of facies classification to Genesee rocks of New York was not wholly successful. The Chagrin magnafacies not recognized.

Chagrin Shale[1]

Chagrin Shale Member (of Ohio Formation)

Upper Devonian: Northern Ohio and western Pennsylvania.

Original reference: C. S. Prosser, 1903, Jour. Geology, v. 11, p. 521.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 37–42; Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 131, chart facing p. 108. Member of Ohio formation. Overlies Huron member; underlies Cleveland member.

Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 17; K. V. Hoover, 1960, Ohio Geol. Survey Inf. Circ. 27, p. 19–22. In vicinity of Cleveland, the Chagrin is composed largely of soft gray shale and mudstone containing small limy nodules and some gray siltstones that range in thickness from ½ to 3 inches. Although well records show the Chagrin to be about 500 feet thick in eastern Cuyahoga County, only 200 feet of the shale is exposed above level of Lake Erie. In Ashtabula and Trumbull Counties adjacent to Ohio-Pennsylvania State line, about 1,200 feet of Chagrin is exposed. Massively bedded white or gray siltstones and silty mudrock in upper part of Chagrin have been traced eastward into Crawford County, Pa., into rocks that were named Riceville by White (1881). Underlies Cleveland member of Ohio shale; base of Chagrin not exposed in Ohio.

Named for exposures on Chagrin River, Cuyahoga County, Ohio.

Chainman Shale[1]

Chainman Shale (in White Pine Group)

Chainman Shale Member (of White Pine Shale)

Upper Mississippian: Eastern Nevada, eastern California, and western Utah.

Original reference: A. C. Spencer, 1917, U.S. Geol. Survey Prof. Paper 96, p. 24, 26, map.

G. S. Campbell, 1951, Utah Geol. Soc. Guidebook 6, p. 21 (fig. 4), 23. Geographically extended into House and Confusion Ranges, Utah, where it is about 1,200 feet thick, overlies Joanna (Joana) limestone and underlies Bird Spring limestone.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v 37, no. 1, p. 147 (fig. 2). Shown as member of White Pine shale on correlation chart of recommended revision of stratigraphic units in Great Basin.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 69–70. Term Chainman shale extended into Eureka district, Nevada, and applied to basal black shale of Upper Mississippian sequence where this unit can be mapped separately (mapped in two areas only). Elsewhere equivalent beds are included in Chainman and Diamond Peak formations undifferentiated. Predominantly black shale with thin interbeds of brown sandstone. Apparent thickness at mouth of Secret Canyon about 5,000 feet. Base not exposed in this western belt, western limit being marked either by igneous rocks or by fault contact with lower Paleozoic rocks. In Windfall Canyon, Permian(?) rocks rest directly on Chainman shale or Diamond Peak formation.

C. W. Merriam and W. E. Hall, 1957, U.S. Geol. Survey Bull. 1061–A, p. 4 (table 1), 5. Geographically extended into Inyo Mountains, Calif., where it is more than 1,000 feet thick; underlies Pennsylvanian Keeler Canyon formation (new) and overlies Perdido formation. Consists of dark-gray silty shale and phyllite with limestone interbeds. Late Mississippian.

W. M. Winfrey, Jr., 1958, Am. Assoc. Petroleum Geologists Rocky Mountain Sec. 8th Ann. Mtg., p. 77, 78 (fig. 2). Uncomformably underlies Sheep Pass formation (new).

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2172 (fig. 2), 2173. In Confusion Range, underlies Ely limestone, used in this report to replace Bird Spring formation.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). Illipah formation overlies Chainman in Gold Hill district and Confusion Range, Utah, and Moorman Ranch area, Nevada.

Walter Sadlick, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 81–90. Discussion of following aspects of Chainman stratigraphy: history and problems of stratigraphic nomenclature, paleotectonic setting, and geosynclinal concepts, regional distribution and sediments, and paleontologic correlations. The Chainman is recognized as a valid stratigraphic unit. Diamond Peak and Scotty Wash are referred to as facies within the Chainman. White Pine shale seems to be correlative to Pilot shale, Joana limestone, and Chainman formation; if so, White Pine should be suppressed. Any combination of names for mutually intercalated units within the Chainman may be used, for instance: (1) refer to Chainman-Diamond Peak formations undifferentiated; (2) refer to Chainman with Diamond Peak facies, and so on; (3) refer to Chainman with molasse facies, meiorogenic facies, dark euxinic shale facies, and so on, or (4) as the least favorable combination, consider Chainman, Diamond Peak, Scotty Wash as distinct formations.

The author [Sadlick] prefers a combination of procedures 2 and 3. There are lithologic units in the Chainman as thin as 5 feet and others as thick as 120 feet that persist for as much as 150 miles laterally. These units have not been mapped in all instances. One of these units is referred to as "Skunk Springs limestone band" becauses, in Confusion Mountains, the Skunk Springs water tank is on this unit which is about 15 feet at that locality.

R. L. Langenheim, Jr., and Herbert Tischler, 1960, California Univ. Pubs. Geol. Sci., v. 38, no. 2, p. 89–150. Discussion of Quartz Spring area, Inyo County, Calif. Formations, Tin Mountain limestone, Perdido formation, and Rest Spring shale as defined by McAllister (1952), are utilized in discussion and description of rocks in the area. On the other hand, Joana limestone, Peers Spring formation, and Chainman shale, with somewhat different limits, are the formations to which these same rocks would be assigned in a regional discussion of Mississippian stratigraphy in the Great Basin. For purposes of expressing regional stratigraphic relationships, many already proposed stratigraphic names are redundant. Figure 5 presents condensed set of already proposed names as restricted and applied to units of regional significance. Names Peers Spring formation and Chainman shale are retained for formational units within a White Pine group, although these three names have frequently been employed in a synonymous sense.

Named for Chainman mine, near Lane, Ely quadrangle, Nevada. South of Eureka, occurs in discontinuous band from Windfall Canyon to mouth of Secret Canyon, and in Tollhouse Canyon east of Newark Mountain.

Chalfin Member (of Salem Limestone)

Mississippian (Valmeyer Series): Southwestern Illinois.

J. W. Baxter, 1959, Dissert. Abs., v. 19, no. 11, p. 2910. Salem limestone is subdivided into four members [sequence not indicated] to which names Kidd, Fults, Chalfin, and Rocher are assigned. Chalfin member is composed of calcilutites, calcisiltites, and calcarenites containing a predominence of microcrystalline, nonskeletal grains, believed to have been formed by the progressive cementation of chemically precipitated carbonate.

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 2–3, 7, 10, 24–27, pl. 1. Consists of varying thicknesses of fine-grained limestone; fine- to medium-grained, fossiliferous, locally oolitic limestone, and semilithographic limestone some of it brecciated. Thickness 30 to 57 feet. Conformably overlies Fults member; conformably underlies Rocher member.

Type section: In Mississippi Bluffs, 1 mile southeast of Chalfin Bridge in NE¼SW¼ sec. 7, T. 4 S., R. 10 W., Monroe County.

†Chalk Bluff Formation[1]

Permian (Wolfcampian Series): Southeastern New Mexico.

Original reference: W. B. Lang, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7. [As defined in this reference includes (ascending) Queen sandstone, Seven Rivers, and Three Twins (new) members.]

R. K. DeFord and E. R. Lloyd, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 9. Lang's term Chalk Bluff is a suitable synonym for Whitehorse if one is needed. In this symposium, Whitehorse group of West Texas and New Mexico is divided into (ascending) Grayburg, Queen, Seven Rivers, Yates, and Tansill formations.

R. K. DeFord and G. D. Riggs, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1713. Lang's Three Twins member of Chalk Bluff seems to include both Tansill and Yates sand, but if so, the two units are described as intergradational, and superposition of Tansill on Yates is not clearly recognized. Lang's Chalk Bluff is essentially the Whitehorse group of subsurface geologists.

N. D. Newell, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 43–45; P. T. Hayes and R. L. Koogle, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–112, Queen sandstone considered of formational rank.

N. D. Newell, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 46; P. T. Hayes, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–98. Seven Rivers raised to formational rank in Carlsbad group.

Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4) proposed to replace terms Whitehorse, Chalk Bluff, and Bernal in Guadalupe Mountains of New Mexico and West Texas.

Well exposed in Chalk Bluff, on eastern bank of Pecos River southeast of Artesia, Eddy County.

Chalk Creek Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 138, 139 (fig. 1), 140, 143 (fig. 2), 145 (fig. 3). Sequence of gray to tan, medium-grained to conglomeratic sandstone alternating with claystone varying in shades of gray, pink, maroon, and green. Sequence has been considered by some workers as belonging to Kelvin formation. Thickness 3,150 feet; entire member is present on east (upthrown) side of "Great" fault. Only 800 to 900 feet present on overturned east flank of anticline. Remainder of section, approximately 2,300 feet, has been omitted by a thrust fault. Wegemann (1915, U.S. Geol. Survey Bull. 581–E) concluded that only 850 feet of strata separated the basal sand (Longwall) from the "Wasatch" coal bed, and later writers followed his thinking. Well data, heretofore unavailable, has made clarification possible. Overlies Spring Canyon member (new); underlies Coalville member (new) with transitional contact.

Named for typical exposures on north side of Chalk Valley between Spring Hollow fault and the "Great" fault, Coalville anticline, Summit County.

Chalk Hills Member (of Catahoula Formation)

Miocene: East-central Louisiana.

W. D. Chawner, 1936, Louisiana Dept. Conserv. Geol. Bull. 9, p. 122–124. Name given to bed of white or cream-colored volcanic ash or tuff about 8 feet thick that occurs near the top of formation. Separated from underlying Cassel Hill member (new) by an interval of gray tuff or tuffaceous siltstone, and massive medium- to coarse-grained sandstone.

Prominently exposed in the Chalk Hills through secs. 7, 16, 17, 18 and 21, T. 10 N., R. 5 E., Catahoula Parish. Extends westward into La Salle Parish and then thins out.

Chalk Mountain Dacite[1]

Recent(?): Northern California.

Original reference: C. A. Anderson, 1936, Geol. Soc. America Bull., v. 47, no. 5, p. 656–657.

Composes most of Chalk Mountain, a small conical hill rising 400 feet east of North Fork of the Cache Creek, Lake County.

Chalk Mountain Nevadite[1]

Eocene: Colorado.

Original reference: W. Cross, 1886, U.S. Geol. Survey Mon. 12, p. 345–349.

Forms mass of Chalk Mountain, Eagle and Summit Counties.

Challis Volcanics[1]

Eocene (?), Oligocene, and Miocene, lower (?) : Southern central Idaho.

Original reference: C. P. Ross, 1930, Idaho Bur. Mines and Geology Pamph. 33.

C. P. Ross, 1934, U.S. Geol. Survey Bull. 854, p. 46–53, pl. 1. Volcanics comprise all Tertiary volcanic rocks in Casto quadrangle except Snake River basalt. Includes Yankee Fork rhyolite member. No complete section exposed. Thicknesses: about 3,400 feet on Camas Creek; 1,482 feet on Merino Creek. Overlie Casto volcanics. Oligocene (?).

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1095, 1120–1121, pl. 1. Described in Borah Peak quadrangle. Divided into (ascending) latite-andesite member, about 1,000 feet; basalt and related flows, about 2,500 feet; and Germer tuffaceous member, from knife-edge to over 500 feet. Locally succeeded by Donkey fanglomerate (new).

A. L. Anderson, 1956, Idaho Bur. Mines and Geology Pamph. 106, p. 18–28, pl. 1. Age given as Oligocene for exposures in Salmon quadrangle. As in other localities, the formation can be subdivided into units of somewhat variable composition, recognizable as equivalent to similar units in other parts of the region. Yankee Fork rhyolite member missing. Ignimbrites not common. Underlies Carmen formation (new).

A. L. Anderson, 1957, Idaho Bur. Mines and Geology Pamph. 112, p. 16. In Baker quadrangle, unconformably underlies Kenney formation (new).

A. L. Anderson, 1959, Idaho Bur. Mines and Geology Pamph. 118, p. 15, 22–25. In North Fork quadrangle, unconformably overlies Kriley formation (new) and underlies Geertson beds. Thickness 0 to 800 feet. Age of Challis still under study.

U.S. Geological Survey currently designates the age of the Challis Volcanics as Eocene (?), Oligocene, and early Miocene (?) on the basis of a study now in progress.

Named for Challis National Forest and town of Challis, Custer County.

Chalmers Quartz Monzonite

Tertiary: Central Colorado.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 84–85, pl. 1. Fine-grained equigranular rock with clearly visible quartz, feldspar, biotite, and hornblende. Varies from pinkish gray through bluish gray to olive green. There are no exposures of Chalmers in place, but abundant float on hills indentifies the underlying rock masses. Surrounding sedimentary rocks are Pierre shale, Fox Hills sandstone, and Denver formation. Shown on plate 1 as Chalmers granite.

Named for occurrences in Chalmers Ridge, in sec. 13, T. 11 S., R. 76 W., and Bald Knob, 1 mile to the north, South Park, Park County.

Chalybeate Limestone Member (of Porters Creek Formation)

Chalybeate Limestone Member (of Clayton Formation)

Paleocene: Eastern Mississippi and western Alabama.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–196, p. 9–10. Proposed to designate beds of the Clayton formation that are in Mississippi and west of the Tombigbee River in Alabama. Consists of hard crystalline extremely fossiliferous limestone, interbedded soft to tough marls, dark leaf-bearing shales, glauconitic sand, and fossiliferous siltstone at top. Thickness at type locality about 80 feet; thins southward to less than 10 feet in Clay County, Miss.; from there southeastward along strike to Tombigbee River, thickens to about 25 feet. Mississippi Geological Survey reports for Tippah, Union, and Pontotoc Counties divided the Clayton into two unnamed members, a basal limestone and marl member and an upper marl, clay, and sand member. The highest fossiliferous siltstone here included in Chalybeate member was regarded as base of the Porters Creek clay in Mississippi reports. This siltstone is here included in the Clayton in order to make base of the clay the base of the Porters Creek throughout Mississippi. Chalybeate may include equivalents of only the lower beds of Pine Barren member.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 37, 38, 39. Reallocated to member status in Porters Creek formation because Clayton formation is not recognized west of central Alabama. Exposed in Sumter County, Ala., where it rests on eroded surface of Cretaceous Prairie Bluff chalk.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 88, pl. 5. Chalybeate limestone member of Clayton formation used in this report.

Type locality: Ravine just north of main street of Chalybeate, probably in south-center of sec. 3, T. 2 S., R. 4 E., Tippah County, Miss.

Chama Clay[1]

Miocene(?): Northwestern New Mexico.

Original reference: C. R. Keyes, 1906, Geol. Soc. America Bull., v. 17, p. 725.

Derivation of name not given.

Chaman series[1]

Eocene: Arizona, Colorado, and New Mexico.

Original reference: C. R. Keyes, 1907, Iowa Acad. Sci. Proc., v. 14, p. 223–228.

Derivation of name not stated.

Chamberlain Shale[1]

Precambrian (Belt Series): Central southern Montana.

Original reference: C. D. Walcott, 1899, Geol. Soc. America Bull., v. 10, p. 199–215.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Mapped only in Little Belt Mountain region where it is sole unit that can be correlated with Ravalli group.

Type localities: On ridges between Chamberlain and Sawmill Creeks, southeast of Neihart. In Little Belt Mountains.

Chambers Tuff (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 15 (fig. 3), 20–21, 23–25. Name proposed for formation that comprises strata between top of Buckshot ignimbrite (new) and base of Bracks rhyolite (new). Tuff is moderate to well bedded, pale yellowish brown, grayish green, and pale red to dark reddish brown. In southern part of area, contains a persistent layer of coarse sandstone with lenses of cobble conglomerate about 130 feet above base. Thickness 558 feet. Where Buckshot is absent, the Chambers (new) and Colmena (new) may be differentiated by identifying the horizon of the Buckshot; where identity of Buckshot horizon is problematic, lithostratigraphic name of Vieja will still be applicable to combined sequence; similiarly, where Bracks rhyolite is absent, the undifferentiated Vieja may serve as a map unit; the Chambers-Capote Mountain contact can be established in some places but not everywhere. Although superposition demonstrates that the Chambers is younger than the Colmena, fossils seem to indicate the same geologic age.

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Quad. Map 23. Described in Van Horn Mountains area where it consists of a lower member 510 feet thick and an upper member 140 feet thick. Includes local basalt flow about 100 feet thick in northernmost exposure. About 40 feet of Pantera trachyte is interbedded in Chambers tuff in northern Sierra Vieja. Overlies Buckshot ignimbrite.

Type locality: About 12 miles north of Candelaria, Rim Rock country, Presidio County. Name derived from Chambers Ranch.

Chambersburg Limestone[1]

Middle Ordovician: Central southern Pennsylvania, western Maryland, and northwestern Virginia.

Original reference: G. W. Stose, 1906, Jour. Geology, v. 14, p. 211.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 195–201. In Chambersburg area, the Chambersburg limestone, as name was originally applied, included all limestone between Stones River limestone and Martinsburg shale, thus including Lowville limestone in lower part. The Lowville part was definitely distinguished in the description as the 150 feet at base carrying distinctive Lowville fossils *Cryptophragmus antiquatus* Raymond (*Beatricea gracilis* Ulrich) and *Tetradium cellulosum* (Hall). At present, only part of original Chambersburg above the Lowville is included by Ulrich in the Chambersburg; hence, the Chambersburg is herewith redefined to apply only to part of original Chambersburg limestone overlying the part of Lowville age. Underlies Martinsburg shale. Thickness 563 feet on Tumbling Run, 1½ miles southwest off Strasburg. Overlies Lenoir limestone; underlies Martinsburg shale (Trenton member).

L. C. Craig, 1941, Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1963–1964. Chambersburg limestone divided into three formations with their type sections 2 miles southwest of Marion, Pa. Formations (ascending): Shippensburg (new), Mercersburg (new), and Greencastle.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 35–114. Discussion of stratigraphy of Shenandoah Valley. Study shows that so-called Athens and Whitesburg, as developed near Harrisonburg, are laterally continuous with greater part of Chambersburg limestone, which is supposed to be younger than the Athens. New classification is proposed for lower Middle Ordovician. Lincolnshire limestone includes lower beds of Chambersburg as identified by Butts (1940); Edinburg formation (new) corresponds to substantial part of Chambersburg formation of Pennsylvania; Oranda formation (new) corresponds to the "*Christiania*" [*Bimuria*] bed of Chambersburg limestone of southern Pennsylvania.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 707–779. Type section of Chambersburg limestone was divided into three formations, Shippensburg, Mercersburg, and Greencastle (Craig, 1941) as result of fundamental disagreement with previous faunule zone correlations. Shippensburg and Mercersburg are redefined, and term Greencastle discarded in favor of Oranda. Report describes these units in detail and gives geologic section.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept. 14], Washington County, p. 63–66. Thickness 100 to 225 feet. Underlies Martinsburg shale; overlies New Market limestone.

F. M. Swartz and R. B. Thompson, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 1–14. In Franklin County, overlies St. Paul group, geographically extended into area, where it replaces Stones River limestone as mapped by Stose (1909, U.S. Geol. Survey Geol. Atlas, Folio 170).

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation as mapped consists of dark-gray thin-bedded limestones (Oranda) at top; gray argillaceous limestone (Mercersburg) in middle; dark-gray cobbly thin, irregularly bedded limestone (Shippensburg) below. Occurs only southwest of Susquehanna River.

Named for exposures west of Chambersburg, Franklin County, Pa.

Chambless Limestone

Lower Cambrian: Southern California.

J. C. Hazzard, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 241. Listed as an algal limestone 170 to 220 feet thick underlying Cadiz formation and overlying Kelso shale (new).

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, p. 30 (table 1), pl. 3. Described as massive light- to dark-gray limestone in beds 1 to 10 feet thick. Underlies Cadiz formation (redefined); overlies Latham shale (new) which replaces preoccupied name Kelso. Type locality designated.

Type locality: About 2 miles northeast of Chambless at an old quarry which is on north side of a large wash and near its mouth. Named after Chambless Station on U.S. Highway 66, approximately 12 miles east of Amboy, San Bernardino County.

†Chamiso Formation[1]

Chamiso Member (of Mesaverde Formation)

Upper Cretaceous: Southwestern New Mexico.

Original reference: D. E. Winchester, 1920, U.S. Geol. Survey Bull. 716–A.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 71. Winchester's Chamiso formation, comprising 1,850 feet of continental rocks of Montana age overlying Bell Mountain sandstone, is here reduced to rank of member in Mesaverde formation.

C. H. Dane, A. A. Wanek, and J. B. Reeside, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 191. Abandoned in favor of Crevasse Canyon formation for Alamosa Creek area.

Named for Chamiso Creek, T. 2 N., R. 9 W., Socorro County.

Champ Clark Group

Mississippian (Kinderhook Series) : Eastern Missouri and western Illinois.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1). 14–20. Proposed for succession of conformable formations that overlies unconformity at top of Devonian-Silurian strata and underlies unconformity at top of Louisiana limestone. Comprises (ascending) Sylamore, Grassy Creek, Saverton, and Louisiana formations. Underlies Hannibal group. As thus defined, group includes strata believed by some to be Mississippian and by others to be Devonian. Coincides with Fabius group of Weller and others (1948) named for outcrops on Fabius River in Marion County, Mo. Formations included in this group [Fabius] are not exposed along Fabius River. Because name Fabius has been introduced so recently and because exposures at Louisiana are excellent and much better known, it seems desirable to drop name Fabius.

A. J. Scott, 1958, Dissert. Abs., v. 19, no. 5, p. 1056. Study of conodont zones indicate Devonian-Mississippian boundary should be placed at base of Glen Park formation and that Champ Clark group, which includes Sylamore, Grassy Creek, Saverton, and Louisiana formations be considered youngest Devonian series in Illinois.

Name is derived from Champ Clark Bridge at Louisiana, Mo. All formations of group are exposed in Mississippi River bluff at Louisiana, 1,000 feet northwest of bridge in NE¼ sec. 18, T. 54 N., R. 1 W., Pike County, Mo.

Champion Shell Bed (in Kiowa Shale)[1]

Cretaceous (Comanche Series) : Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 358–371.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 28. Occurs at base of Kiowa shale in type area.

Named for Champion Draw, an arroyo on Medicine Lodge River crossed by Atchison, Topeka, and Santa Fe Railway at Belvidere, Kiowa County.

†Champlain Group[1]

Cambrian, Ordovician, and probably some Silurian: New York.

Original reference: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, Geology of the second district, p. 99–126, 429.

Named for Lake Champlain.

Champlainian Series

Champlainic System[1]

Middle Ordovician: North America.

Original references: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, Geology of the second district, p. 100–101, 102–126, 429; J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 875, 876; Charles Schuchert and Joseph Barrell, 1914, Am. Jour. Sci., 4th ser., v. 38, no. 223, p. 16, 25 (table 1).

Charles Schuchert, 1943, Stratigraphy of the Eastern and Central United States: New York, John Wiley and Sons, Inc., p. 38–42. Emmons included in Champlain group all formations from base of Potsdam (Upper Cambrian) to base of Ontario group (Silurian). In present book, term Champlainian is used to embrace Chazy and Mohawk stages. Middle Ordovician.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2. Ordovician comprises three series (ascending) : Canadian, Champlainian, and Cincinnatian. Champlainian has two stages, Chazy and Mohawkian. Chart shows Mohawkian divided into Black River and Trentonian.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–33. Chazyan, Blackriveran, and Trentonian succeed the Canadian in New York, and are classified as separate series, or as two series (Chazyan and Mohawkian) or as one (Champlainian).

Name derived from Lake Champlain.

Chana Member (of Pecatonica Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 12. Dolomite, nonargillaceous, sandy, thick-bedded. Thickness about 6 feet. Shown on columnar section as underlying Dane member (new) and overlying Hennepin member (new).

Occurs in Dixon-Oregon area.

Chanac Formation[1]

Pliocene: Southern California.

Original reference: J. C. Merriam, J. P. Buwalda, and B. L. Clark, 1916, California Univ. Pub., Dept. Geol. Bull., v. 10, p. 111–115.

H. E. Wood 2d and others, 1941, Geol Soc. America Bull., v. 52, no. 1, p. 17, pl. Clarendonian (lower Pliocene).

Exposed along Chanac Creek, Tejon Hills, Fresno County.

Chances Branch Dolomite Member (of Maynardville Limestone)

Upper Cambrian: Southwestern Virginia and northeastern Tennessee.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Prelim. Map 76 (2 sheets). Gray fine-crystalline laminated dolomite with interbedded mottled limestone near base and interbedded dark coarse-crystalline dolomite near top. Thickness 142–172 feet. Overlies Low Hollow limestone member (new) ; underlies Copper Ridge dolomite.

R. L. Miller and J. O. Fuller, 1954, Virginia Geol. Survey Bull. 71, p. 37–39; R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 16, 89, 90, pl. 1. Thickness given as much as 209 feet. Type locality and derivation of name given.

Type section: In Rose Hill district, Lee County, Va. Name derived from Chances Branch in western part of district, where a complete section is exposed in roadcut a few hundred feet east of creek and just south of Smith Chapel. Also exposed along Low Hollow, and along Fourmile Creek both north and south of Fourmile fenster and south of Virginia-Tennessee State line.

Chanchelulla Formation[1]

Devonian(?) : Northwestern California.

Original reference: N. E. A. Hinds, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 292.

D. P. Cox, 1956, Dissert. Abs., v. 16, no. 10, p. 1884. Pennsylvanian.

Name suggested because of wide exposure on and near Chanchelulla Peak in northeast corner Red Bluff quadrangle, Klamath Mountains.

Chanchelulla Greenstone[1] or Meta-Andesite[1]

Devonian(?) : Northwestern California.

Original references: N. E. A. Hinds, 1932, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 20, no. 11, p. 375–410; 1933, California Jour. Mines and Geology, v. 29, nos. 1, 2.

Named because of wide exposure on and near Chanchelulla Peak in northeast corner of Red Bluff quadrangle.

†Chandler Formation[1]

Pennsylvanian: Central Oklahoma.

Original reference: C. T. Kirk, 1904, Oklahoma Dept. Geol. and Nat. Hist. 3d Bien. Rept., p. 9.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey. System boundary not established and concept not useful.

Named for Chandler, Lincoln County.

Chandler Formation (in Nanushuk Group)

Lower and Upper Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160 (table 1), 154, figs. 2, 3. Most of formation in southern exposures is nonmarine sandstone and conglomerate. To the north, it grades into shale with interbedded sandstone and coal. Contains a few fresh- to brackish-water mollusks in northerly exposures. Thickness along Chandler River about 4,700 feet but includes units of marine strata of Umiat formation (new). Intertongues northward with Umiat formation in two major (marine) tongues—Hatbox (new) below and Niakogon (new) above—and several minor tongues (unnamed). Overlies Tuktu member (new) of Umiat formation in southern part of outcrop area. Underlies Prince Creek and Schrader Bluff formations (new). Lower and Lower(?) Cretaceous.

R. L. Detterman *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 237, fig. 2. Redefined. Northward and eastward, it intertongues with, and grades into marine equivalents, the Grandstand and Ninuluk formations (new). Lithologic unit remains much the same as originally defined, but lower tongue renamed Killik tongue (new) and type localities for both major tongues have been changed. Lower and Upper Cretaceous.

Type locality: On Chandler River where river crosses Northern Foothills section of Arctic Foothills province.

Chandler Falls Member (of Trenton Formation)

Middle Ordovician: Northern Michigan.

R. C. Hussey, 1952, Michigan Dept. Conserv., Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14, 23–25. At Chandler Falls, consists of 45 feet of limestone, dolomite, shale and shaly limestone; calcareous layers vary in thickness from 1 to 18 inches and occur chiefly in lower part of section;

shale and argillaceous limestone make up central and upper portions of exposure. Conglomerate about 5 feet thick occurs about 11 feet above base. This conglomerate probably marks base of Trenton. Underlies Groos Quarry member (new); overlies Bony Falls member (new) of Black River formation. Deposition was practically continuous at some localities from Black River to Trenton time and dividing line between the two formations becomes an arbitrary one.

Type locality: At Chandler Falls, T. 39, N., 22 W., Delta County, on Escanaba River, 3 miles north of Escanaba. Chandler Falls is site of hydroelectric powerplant.

Chaney Gypsum Member (of Blaine Gypsum)[1]

Chaney Gypsum Member (of Flowerpot Shale)

Permian: Southwestern Oklahoma and western Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 41, 55.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 30. Shown on chart as member of Flowerpot shale in western Texas.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 15–16, 17 (fig. 3), 18, pl. 1. Described in Carter area, Oklahoma, as gray white massive gypsum 1 to 3 feet thick, 42 to 50 feet below top of Flowerpot; stratigraphically below Kiser gypsum member. Blaine formation redefined in this report.

Name derived from Chaney Salt Plain on Elm Fork of Red River, 4 miles east of Texas line, Harmon County, Okla.

Chaney Ranch Sandstone

Eocene: Central California.

M. B. Payne, 1951, California Div. Mines Spec. Rept. 9, p. 3, 15–18, 21, 22, pl. 4. White, fine- to medium-grained, anauxitic sandstone. Measured thickness at type section 232 feet. Disconformably underlies Kreyenhagen formation; conformably overlies Capita member (new) of Domengine formation. North of Chaney Ranch Canyon toward Gres Canyon, the Temblor overlaps both the Kreyenhagen and the Chaney Ranch; in this area only 20 feet of the Chaney Ranch are exposed.

Type section: Chaney Ranch Canyon in NW cor. sec. 19, T. 14 S., R. 12 E., Panoche quadrangle, Fresno County. Named from nearby Chaney Ranch.

Chaneysville Sandstone Member[1] (of Mahantango Formation)

Middle Devonian: South-central Pennsylvania.

Original references: Bradford Willard, 1935, Geol. Soc. America Proc. 1934, p. 361; 1935, Geol. Soc. America Bull., v. 46, no. 8, p. 1279, 1282, 1283.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart above Gander Run shale and below Frame shale. Middle Devonian.

Named for village (which is also spelled Cheneysville) in Bedford County.

Channahon Limestone[1]

Lower Silurian: Northeastern Illinois.

Original reference: T. E. Savage, 1910, Illinois Geol. Survey Bull. 16, p. 334.

Outcrops in south bank of Des Plaines River, 1 mile southeast of Channahon, Will County.

Chanute Formation (in Ochelata Group)

Chanute Shale (in Kansas City Group)[1]

Chanute Shale Member (of Kansas City Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southern Iowa, northwestern Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 109.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40 (table), 43. Lowermost formation in Ochelata group. Thickness about 200 feet near Kansas-Oklahoma State line; 40 feet or less in vicinity of Bartlesville. Normally overlies Drum limestone and underlies Iola limestone. Over Chautauqua Arch County, in parts of which Drum limestone is absent, a prominent sandstone that forms lower part of Chanute is here named Noxie sandstone lentil; near State line, includes Cottage Grove sandstone in upper part.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 294 (table), 295. Chanute shale as used here [Adams County] follows practice of Missouri Survey in including all beds between Wyandotte above and Westerville below. Includes Raytown and Cement City limestones which may be present in section but are difficult to recognize in well logs. Kansas City group.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Columnar section, Jackson and Cass Counties, shows Chanute shale comprises (ascending) Quivera shale, Cement City limestone, Union Station shale (new), Paola limestone, Muncie Creek shale, Raytown limestone, and Liberty Memorial shale (new) members. Overlies Cherryvale shale, which includes Westerville limestone at top; underlies Iola limestone. Kansas City group.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2032–2033; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vi (fig. 2), 12–13. Miscorrelation of Iola formation by Haworth and Bennett (1908, Kansas Univ. Geol. Survey, v. 9) in tracing limestone in this part of section northeastward to Kansas City has been responsible for long standing error in nomenclature of Missourian units in northeastern Kansas and northwestern Missouri. Settlement of Iola problem has led to changes in Missouri Survey's classification of middle and upper units of Kansas City group so as to bring interstate agreement in nomenclature. Union Station shale (Clair, 1943) is suppressed because it is synonymn for Chanute shale as a whole. Paola limestone, Muncie Creek shale, and Raytown limestone, which were classed as members of Chanute shale, are recognized as belonging to Iola formation. Liberty Memorial shale (Clair, 1943) is suppressed as junior synonym of Lane shale. Thus, Chanute shale overlies Drum limestone and underlies Iola formation.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 36. Thickness of formation 6 to 7 feet east of Louisville, Nebr.; about 10 feet near Kansas City; 25 feet in northeastern Kansas; about 100 feet in southern Kansas.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. Thickness about 2 feet in Madison and Adair

Counties, Iowa. Underlies Iola formation; overlies Drum formation. Kansas City group.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 28–31, pls. 1, 2, measured sections. Rocks assigned to Chanute formation, in Oklahoma, were included by Ohern (1910) in lower part of Ochelata member of his Ramona formation (southern area) and in lower part of unnamed interval between Dewey and Avant limestone lentils of Copan member of his Wann formation (northern area). According to classification used on Geologic Map of Oklahoma (Miser, 1926), these beds lie at base of Ochelata formation (Ochelata group), occupying lower part of interval between Dewey and Avant limestones. On Geologic Map of Oklahoma, (Miser, 1954), they are shown as Chanute formation, lying between Dewey formation below and Iola limestone (formation) above. Thickness in Creek County 45 to 110 feet. Formation crops out across Oklahoma in direction slightly west of south from Kansas-Oklahoma line to North Canadian River. Name is not applied farther south.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Consists of greenish-gray, fossiliferous upper shale bed of varying thickness separated from lower greenish-gray shale by thin coal smut. Thickness about 5 feet. Underlies Iola limestone; overlies Drum limestone. Kansas City Group.

Named for development in vicinity of Chanute, Neosho County, Kans.

Chaos Crags Dacites

Cenozoic: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 298, 343, 380; R. D. Evans and Howel Williams, 1935, Am. Jour. Sci., 5th, v. 29, no. 173, p. 449, 450, 451. Dacite described at and in vicinity of Chaos Crags.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, nos. 1–2, p. 77 (table 2), 79, 80. Listed on tables and mentioned in text in report on uranium geochemistry of Lassen volcanic rocks.

Chaos Crags are in northwestern part of Lassen Volcanic National Park.

Chaos Jumbles Flows, Dacite

Recent: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 356. Name applied to flows forming Chaos Jumbles. Age of Jumbles approximately 200 years.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta, v. 8, p. 77 (table 2). Listed on table accompanying report on uranium geochemistry of Lassen volcanic rocks.

Chaos Jumbles is in northwestern part of Lassen Volcanic National Park.

Chaparral Volcanics (in Alder Group)

Precambrian (Yavapai Series) : Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 30–31, pl. 1. Comprises interbedded rhyolitic and andesitic tuffaceous sedimentary rocks. Andesitic tuffaceous rock somewhat variable in texture, structure, and mineral composition. Most abundant type is fine-grained well-foliated fissile rock that ranges in color from green or greenish gray to green mottled with irregular patches and streaks of grayish yellow green or pale yellowish green. Intercalated in these finer grained andesitic tuffaceous rocks in subordinate amounts are beds from 1 to 50 feet thick of medium- to coarse-grained andestic tuff. Rhyolitic tuffaceous rock is fine-grained finely laminated fissile phyllite that ranges in lithologic composition from relatively pure rhyolitic rock to mixed rhyolitic and andesitic rock; yellowish gray to very light gray, and locally has greenish cast. Thickness not known nor can it be approximated. Lies between two major faults, Chaparral on northwest and Spud on southeast.

Named from exposures in Chaparral Gulch, Jerome area, Yavapai County. Crops out in northeastward-trending belt in southwest corner of area. Crops out over strike length of 4½ miles and over width ranging from 1,500 to 3,500 feet.

Chapel Coal Member (of Modesto Formation)

Pennsylvanian: Western and northern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 38, 49 (table 1), pl. 1. Replaces name Trivoli (No. 8) coal so that name Trivoli can be retained for the sandstone. In southeastern area, occurs above Trivoli sandstone member and below New Haven coal member; in southwestern area, above the Trivoli and below Carlinville limestone member; in western and northern area, above the Trivoli and below Cramer limestone member (new). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: SW¼ sec. 3, T. 8 N., R. 5 E., Peoria County. Name derived from Graham Chapel, about 2 miles north of type locality.

Chapel Rock Member (of Munising Formation)

Upper Cambrian: Northern Michigan.

W. K. Hamblin, 1958, Michigan Dept. Conserv., Geol. Survey Div. Pub. 51, p. 6 (fig. 1), 77–95, 114, fig. 70. Well-sorted medium-grained sandstone characterized by large-scale crossbedding. Varying amounts of scattered pebbles near base of section. Thickness from 40 to 60 feet along Pictured Rocks and throughout most of Alger County. Thins gradually to the east. Underlies Miners Castle member (new); overlies Jacobsville formation.

Type locality: Chapel Rock near eastern end of Pictured Rocks cliffs in Alger County. Name derived from Chapel Rock, of type locality, which is along southern coast of Lake Superior.

Chapin Member (of Hampton Formation)

Chapin Beds (in Kinderhook Group)[1]

Mississippian (Kinderhook): Central northern Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 52, 91, 104, 108.

L. R. Laudon, 1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf., p. 246; L. R. Laudon and B. H. Beane, 1937, Iowa Univ. Studies in Nat. History, v. 17, no. 6, p. 236–237. Hampton is redefined by excluding from it the North Hill member, as exposed at Burlington, and the lower gray limestone ledges of Chapin member of north-central Iowa which are correlatives of the Chouteau of Missouri. As thus restricted, the Hampton includes the dolomitic upper part of the Chapin, the Maynes Creek, Eagle City, and Iowa Falls members. [This restriction of the Hampton seemingly restricts the Chapin.]

Named for exposures in abandoned quarry 1 mile west of Chapin, Franklin County.

Chapin Wash Formation

Pliocene, lower(?) : West-central Arizona.

S. G. Lasky and B. N. Webber, 1949, U.S. Geol. Survey Bull. 961, p. 14 (table 2), 23–34, pls. 1, 2. Alluvial-fan and playa deposits—fanglomerate, conglomerate, sandstone, siltstone, mudstone, clay, and limestone; in part gypsiferous. Consists mainly of pink to red and brown clay, mudstone, siltstone, and sandstone, with gradations into one another. Thickness ranges from fraction of a foot to possibly 1,500 feet or more. Rests with angular unconformity upon older rocks. Overlain in part conformably by Cobwebb basalt (new) and in part unconformably by Sandtrap conglomerate (new) and younger rocks. These formations assigned to Pliocene because they rest with angular unconformity upon Miocene(?) rocks and are overlain with angular unconformity by early Pleistocene(?) basalt. Because Chapin Wash formation is oldest of the formations, it is tentatively assigned to lower Pliocene. Shown on plate 1 as Pliocene(?) and on plate 2 as early Pliocene(?).

Named for exposures along Chapin Wash in Artillery Mountains, about 30 miles east of Colorado River. Formation crops out roughly in form of elongated "U," 6 to 7 miles long and 3 to 5 miles wide, in valley between Rawhide and Artillery Mountains.

Chapman Dolomite[1]

Permian: Central Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 353, 358.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Oklahoma Geological Survey abandoned name in its earlier sense. Not a recognizable unit. If validated, name would preoccupy Chapman sandstone of Maine.

Named for Chapman's amphitheater, at head of Salt Creek, Blaine County.

Chapman Sandstone[1]

Lower Devonian: Northeastern Maine.

Original reference: H. S. Williams, 1899, Am. Jour. Sci., 4th ser., v. 8, p. 360, footnote.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart above Square Lake limestone and below Moose River sandstone.

Type locality: Along east bank of south branch of Presque Isle Brook, about 1 mile from south line of Chapman Township and about 1 mile west of Tweedy on road running southwest from Presque Isle, Aroostook County.

Chapman Trachyte[1]

Devonian(?) : Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 109, 110, 162–163.

Occurs in northwest corner of Chapman Township, Aroostook County.

Chapman Gulch Glaciation

Pleistocene (Cochrane?) : West-central Colorado.

R. L. Nelson, 1954, Jour. Geology, v. 62, no. 4, p. 333–334, 340, fig. 2, table 4. Time of post-Wisconsin glaciation in Frying Pan Valley. Older than the climatic optimum and Neoglaciation; younger than Hell Gate glacial substage (new). Marked by moraine and outwash deposits.

Name derived from a till deposit at 11,400 feet in Chapman Gulch. In Frying Pan River drainage just west of Continental Divide in Sawatch Range.

Chapman Ranch Formation[1] (in Arbuckle Group)

Chapman Ranch Member (of McKenzie Hill Formation)

Lower Ordovician: Central southern Oklahoma.

Original reference: Josiah Bridge, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 7, p. 982–983.

C. E. Decker, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1313, table 1; 1939, Oklahoma Geol. Survey Circ. 22, p. 15, 16 (table 1). Reallocated to McKenzie Hill as basal member of formation, because it seems apparent that Ulrich intended to apply this name to the heavy limestone beds above the dolomite rather than for the dolomite; name Butterly is proposed for the underlying dolomite. Underlies McMichel member (new).

Named from Chapman Ranch on U.S. Highway 77, Murray County.

Chapman Ridge Sandstone

Middle Ordovician: Eastern Tennessee.

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Qual. Map GQ–76; 1960, Map GQ–126. New formational name for strata in the Knoxville area that were previously called Tellico sandstone; this renaming is outgrowth of belief that the sandstone now included in the Chapman Ridge does not correlate with Tellico sandstone at its type locality. Consists of from 700 to 900 feet of calcareous sandstone interbedded with shale and silty shale. Includes all strata below lower tongue of Ottosee shale, or where this unit is missing, between the Holston "marble" through to the contact of sandstone with the shale and limestone beds of the Ottosee.

Type locality: Exposures along Alcoa Pike, State Highway 73, where highway cuts through Chapman Ridge south of Looney Island, Knoxville quadrangle [Knox County].

Chapparal Sandstone (in Saavedra Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11. White sacchariodal sandstone weathering into round-edge slabs. Large fossil tree trunks. Thickness 24 feet.

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Chappel Limestone

Chappel Formation[1]

Lower Mississippian: Central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 91–92, 96.

F. B. Plummer, 1939, *in* West Texas Geol. Soc. [Guidebook] Nov. 11–12, p. 15. Subdivided to include Ives conglomerate at base.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 27, 42, 44 (fig. 2), 49–52. Proposed here that unit formerly designated Chappel formation be termed Chappel limestone because unit is persistently calcitic and that Ives conglomerate member be termed Ives breccia, a unit of formational rank. At type locality, Chappel is approximately 24 inches thick and consists of crinoidal limestone wherein abundant to scattered larger pelmatozoan fragments are tightly bonded by a matrix of fine-grained limestone; upper 10 to 11 inches is tough, medium- to dark-gray rock with brownish, olive, or bluish cast, fairly typical of much of the Chappel on east side of Llano uplift; lower 13 to 14 inches have been leached to a marly appearance and a lighter yellowish gray color. At type locality, Chappel is directly overlain by about 50 feet of shales of Barnett formation; a few hundred feet to the south, a lens of Ives breccia intervenes between the Chappel and the Honeycut. In eastern half of Llano uplift, the Chappel is similar to type section, but thickness may be as much as 14 feet, although it seldom exceeds 3 to 5. In eastern areas overlaps Honeycut, but, in western areas, overlaps limestone of Gorman formation. Because limestones of Gorman formation are readily soluble, the Chappel is commonly preserved in solution structures that developed previous to Barnett time. Approximately 45 feet of Chappel was measured in one of these structural sinks about 1,500 feet east of Joe Davis Hollow on north bank of San Saba River in McCulloch County.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 20–32. Chappel formation differentiated into two facies: normal and sink-hole; the facies are determined in part, at least, by topography of Ellenburger surface on which Chappel was deposited. Subdivided into four members (ascending): King Creek marl (new), Ives conglomerate, Espey Creek limestone (new), and Whites Crossing coquina (new). Lower Mississippian, ranges perhaps from lower Kinderhook through Burlington.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, pl. 1. Overlies Houy formation (new). King Creek marl member of Plummer's (1950) Chappel formation is surely identified only at its type locality where it constitutes a few inches of the Houy formation.

W. H. Hass, 1959, U.S. Geol. Survey Prof. Paper 294–J, p. 365–396. Discussion of conodont fauna of the Chappel. Also discusses formation as described by Cloud and Barnes (1948) with relationship to formation as described by Plummer (1950).

Type locality: Three miles southeast of San Saba, San Saba County. Name derived from village of Chappel. Exposed at many places along east, north, and west margins of Llano uplift.

Chaquaqua Member[1] (of Lykins Formation)

Triassic(?): Southeastern Colorado.

Original reference: J. T. Duce, 1924, Colorado Geol. Survey Bull. 27, pt. 3, p. 81–82.

Named for exposures in Chaquaqua Canyon, Las Animas County.

Chaquaqua shale[1]

Upper Jurassic: Northeastern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geological formation of New Mexico, p. 3, 6.

Exposed in Chaquaqua Canyon in northeast New Mexico.

Charcoal Canyon Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3). Discussion of Paleozoic continental margin in central Nevada. Clipper Canyon sequence comprises (ascending) Charcoal Canyon, Petes Summit, Sams Spring, and Joes Canyon formations (all new). Clipper Canyon sequence is isolated by surrounding Tertiary volcanic rocks.

Clipper Canyon, Toquima Range, Nye and Lander Counties.

Charco Azul Formation

Pliocene: Panamá and Costa Rica.

R. A. Terry, 1941, Geog. Rev., v. 31, no. 3, p. 381 (fig. 5), 382; A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 249–250. Base is heavy conglomerate; grades upward into sandstones and foraminiferal shales. Maximum thickness more than 4,000 feet. Overlies Armuelles formation. Pliocene.

Along shore of Charco Azul Bay and elsewhere in Burica Peninsula. Extends into Costa Rica.

Chardon Siltstone Member (of Orangeville Shale)

Chardon Sandstone[1] Member (of Orangeville Shale)

Mississippian: Northeastern Ohio.

Original reference: C. S. Prosser, 1912, Ohio Geol. Survey, 4th ser., Bull. 15, p. 219–229.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1363–1364; J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 42. Renamed Chardon siltstone member. Consists of thin- to thick-bedded gray siltstones and intercalated silty shale. Thickness about 8 feet. Occurs in Orangeville about 30 feet above Berea sandstone. Lithologically similar to Aurora member; names Chardon and Aurora may have been applied to different parts of a single unit.

Typically exposed in Stebbins Gulch near Chardon, in northwestern Geauga County.

Chariton Conglomerate Member (of Pleasanton Formation)[1]

Chariton Conglomerate (in Pleasanton Group)

Pennsylvanian (Missouri Series): Southeastern Iowa and northern Missouri.

Original reference: H. F. Bain, 1896, Iowa Geol. Survey, v. 5, p. 394–398.

L. M. Cline, 1951, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 30. Referred to as Chariton conglomerate in Pleasanton group.

Named for exposures along Chariton River near mouth of Snort Creek, Appanoose County, Iowa.

Charles Formation (in Madison Group)

Charles Formation (in Big Snowy Group)

Mississippian: Subsurface in central and eastern Montana and adjacent areas.

O. A. Seager, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 861–864. Term introduced to describe series of interbedded limestones, dolomite, anhydrite, and shales that lie between basal member (Kibbey) of Scott's Big Snowy group and the Madison. Lies at depths of 6,350 to 6,815 feet in Carter Oil Co.'s Northern Pacific test No. 1, sec. 19, T. 4 N., R. 62 E., Fallon County, Mont. Possible that Charles sediment fills gap between Madison and Big Snowy time and should be included in Madison; however, widespread development of porosity in upper part of Madison indicates that the time break is here; hence, Charles is considered basal member of Big Snowy group.

L. L. Sloss, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 65 (chart), 66–67, 68 (cross sections). Assigned to Madison group. Overlies Mission Canyon limestone. Reconsideration of relationships strongly suggests that the Charles is recognizable in many outcrop areas of central and western Montana.

J. M. Andrichuk, 1958, Habitat of Oil: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 230. Perry and Sloss (1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10) defined Charles in type well between depths of 3,050 and 3,810 feet. Nordquist (1953, Billings Geol. Soc. Guidebook 4th Ann. Field Conf.) showed that depth of 3,050 feet in type well marks top of so-called Kibbey limestone. In this report, boundaries of Charles in type well are selected at 3,200 and 3,800 feet in agreement with Nordquist.

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 330–332, 333 (fig. 2). This report follows Sloss and places Charles in Madison group. Formation is believed to be transitional laterally in subsurface into upper beds of Mission Canyon limestone, middle unit of Madison group as here recognized.

Named for occurrence in Arro Oil and Refining Co. and California's Co. Charles No. 4 [referred to by later authors as type well], sec. 21, T. 15 N., R. 30 E., Garfield County, Mont.

Charleston Sandstone[1]

Pennsylvanian: Western West Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487, 508.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 79. Massive sandstone near Charleston, Kanawha County, W. Va., formed where Buffalo and Mahoning (Conemaugh), Freeport, and East Lynn (Allegheny), and Roaring Creek (Kanawha) sandstones join to form one sandstone bluff, the intervening coals and shales being absent.

Named for exposures at Charleston, Kanawha County.

Charlevoix Limestone

Charlevoix Stage[1]

Middle Devonian: Northwestern Michigan.

Original reference: E. R. Pohl, 1930, U.S. Nat. Mus. Proc., v. 76, art. 14, p. 2–25.

L. S. Sloss, 1939, Jour. Paleontology, v. 13, no. 1, p. 52. For purposes of this report, Pohl's divisions of Traverse beds, Petoskey, Charlevoix, and Gravel Point are referred to as faunal zones.

G. A. Cooper and A. S. Warthin *in* G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1752, chart 4. Charlevoix limestone occurs on shore of Lake Michigan in Emmet and Charlevoix Counties between the "upper blue shale" (zone 6) of Gravel Point limestone and base of Petoskey limestone; the "upper blue shale" is correlated with upper Alpena (approximately Dock Street clay) of Alpena County; lower part of Petoskey at Bayshore is correlated with Norway Point formation of Alpena County. Thus Charlevoix occupies position of Four Mile Dam limestone. It is suggested that Charlevoix may represent a western shore phase of Four Mile Dam although there is no fossil evidence to support this contention.

Probably named for Charlevoix County.

Charlottesville Formation

[Precambrian]: Western Virginia.

W. A. Nelson, 1949, (abs.) Virginia Acad. Sci. Proc. 1948–1949, p. 140. Overlies Johnson Mill graphite schist (new); underlies Catoctin schist.

Discussion of structure and stratigraphy of the Blue Ridge in Albemarle and adjacent counties. Main Blue Ridge mountain is an overturned anticline, with axial plane dipping 28° to southeast, and a thrust fault bordering it on its western edge.

Charlton Formation[1]

Pliocene: Southeastern Georgia and northeastern Florida.

Original reference: J. O. Veatch and L. W. Stephenson, 1911, Georgia Geol. Survey Bull. 26, p. 60, 392–400.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 72. Mapped in Georgia as Pliocene.

R. O. Vernon, 1952, *in* A summary of the geology of Florida and a guidebook to the Cenozoic exposures of a portion of the state: Florida Geol. Survey, p. 58, 59. Prior to 1942, Pliocene series in Florida was considered composed of Citronelle formation, Tamiami limestone, Buckingham marl, Bone Valley gravel, Alachua formation, Charlton formation, and Caloosahatchee marl. Additional well data and fieldwork has presented evidence that places beds formerly called Tamiami limestone, Buckingham marl, and upper beds of Hawthorn into Tamiami formation. The Charlton is similar in fauna and lithology to the Buckingham and is also placed in the upper Miocene.

Named for exposures in Charlton County, Ga.

Charrette Limestone[1]

Middle Ordovician: Eastern Missouri.

Original reference: G. C. Broadhead, 1873, Missouri Geol. Survey Rept. 1855–1871, p. 49–50.

Named for Charrette, Warren County.

Charter Member (of Mount Simon Formation)

Upper Cambrian: Northern Illinois (subsurface).

J. S. Templeton, Jr., 1950, Illinois Acad. Sci. Trans., v. 43, p. 153 (fig. 2), 154 (fig. 3), 156. Name applied to the coarse-grained to conglomeratic uppermost member of formation. Type section extends from depths of 1,381 to 1,648 feet. Thickness of member 145 to 315 feet. Overlies Gunn member (new); underlies Eau Claire formation.

Type well: McQueen No. 1 (well 6) in SW¼NE¼NE¼ sec. 27, T. 42 N., R. 3 E., DeKalb County. Name derived from Charter Oak School, 3½ miles north of type well.

Chartresan series[1]

Mississippian: Illinois.

Original reference: C. R. Keyes, 1933, Pan-Am. Geologist, v. 60, no. 1, p. 45, 49.

Name derived from old French Fort Chartres, which once occupied a spot near mouth of Kaskaskia River just above the present hamlet of Chester.

Chase Group[1]

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: C. S. Prosser, 1895, Jour. Geology, v. 3, p. 771–786.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 68–71; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41–45. Stratigraphically expanded upward to include the Odell and Nolans formation; that is, the upper boundary is at top of Herington limestone member of Nolans limestone. As redefined, includes (ascending) Wreford limestone, Matfield shale, Barneston limestone, Doyle shale, Winfield limestone, Odell shale, and Nolans limestone. Underlies Wellington formation of Sumner group (Leonard series); overlies Speiser shale of Council Grove group (Wolfcamp series). Thickness in Kansas about 335 feet.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. In Oklahoma, Herington limestone and Fort Riley limestone are only units of group mapped.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 73 (table 3), 105–119. As presently defined, group includes beds from base of Wreford limestone upward to top of Nolans (Herington) limestone. In southern Kansas and northern Oklahoma, group consists of over 340 feet of red and green shales and persistent chert-bearing limestones. Southward, limestones thin and chert content diminishes abruptly. In Pawnee County, includes (ascending) Wreford limestone, Matfield shale, Fort Riley limestone, Doyle shale, and Winfield limestone. Wolfcamp series. South of Pawnee County, rocks of group grade laterally into Asher formation of central Oklahoma.

C. C. Branson, 1960, Oklahoma Geology Notes, v. 20, no. 9, p. 229–235. Suggested that term Lyon series be used for Permian rocks in Kansas, Oklahoma, and Nebraska. Series would comprise Admire, Council Grove, and Chase groups.

Named for Chase County, Kans.

Chase Channel Formation

Pleistocene (Nebraskan and Aftonian): Central Kansas (subsurface).

R. C. Moore, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 7, p. 1278. Deposits established as age equivalents of the Blanco formation (type locality in Texas) are termed Rexroad formation in Oklahoma and southwestern Kansas, Chase Channel formation (Holdrege and Fullerton members) in central Kansas, and Broadwater formation or Holdrege and Fullerton formations in Nebraska.

O. S. Fent, 1950, Kansas Geol. Survey Bull. 85, p. 64, 127, 128, 129. In type well, is lowermost Pleistocene. Occurs below Grand Island member of Meade formation and above Permian Harper sandstone. Thickness 59 feet.

Type well: Test hole 20–9–10dc (N) in SW¼SE¼ sec. 10, T. 20 S., R. 9 W., drilled by Kansas Geological Survey, October 1946. Type locality is buried filled valley named Chase Channel from its development at town of Chase, Rice County.

Chatcha Limestone

See Chacha Limestone

Chatham Granite[1] or Group

Upper Devonian(?): East-central New Hampshire.

Original reference: M. P. Billings, 1928, Am. Acad. Arts Sci. Proc., v. 63, p. 82, map.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1892–1893. Referred to as a group which includes quartz diorite, granodiorite, and quartz monzonite. A petrographically distinct unit, but not mapped separately from Meredith porphyritic granite and pegmatites of the area. Assigned to New Hampshire magma series in Belknap Mountains.

Alonzo Quinn, 1937, Geol. Soc. America Bull., v. 48, no. 3, p. 378. Granite includes Winnipesaukee quartz diorite of Winnipesaukee region.

M. P. Billings, 1945, Am. Jour. Sci., 5th ser., v. 243–A, p. 43. Upper Devonian(?).

Crops out in Chatham Township, North Conway quadrangle.

†Chatham series[1]

Upper Triassic: North Carolina.

Original reference: E. Emmons, 1857, Am. Geology, p. iv, v, vi, 19.

Chatham County.

Chatham Hill Formation

Middle Ordovician (Mohawkian): Southwestern Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 53, chart 1 (facing p. 130). Base of formation generally not well exposed; transitional with underlying black graptolitic shales of Rich Valley formation (new). Upper part is cherty dark-bluish-gray limestone. Top prominently defined by succeeding ledges of calcarenite forming lower part of Wassum formation (new). Total thickness about 450 feet. Occurs in area for which Porterfield stage is named. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: Two miles south of Chatham Hill, Chatham Hill (TVA 218–NE) quadrangle. Named from exposures adjacent to Viriginia Highway 16 along lower northwestern slopes of Walker Mountain.

Chatsworth Drift

Pleistocene (Wisconsin): Northern Illinois.

H. B. Willman and others, 1942, Illinois Geol. Survey Bull. 66, p. 145 (fig. 85), 146 (fig. 86), 162. Consists largely of till. Thickness probably as much as 40 feet. Overlies Bloomington and Farm Ridge drifts; underlies Marseilles drift. [Report lists six drifts in the Tazewell; for sequence see under Shelbyville.]

Occurs in moraine along east side of Streater quadrangle, La Salle County. Named for village of Chatsworth, which is located on moraine, in southeastern Livingston County.

†Chattahoochee Bed (proper)[1]

Miocene, lower: Northwestern Florida and southwestern Georgia.

Original reference: A. F. Foerste, 1894, Am. Jour. Sci., 3d, v. 48, p. 41–54.

Named for exposures at Old Chattahoochee Landing, Gadsden County, Fla.

†Chattahoochee Formation[1]

Eocene, lower: Alabama.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–1888, map.

Type locality not stated.

Chattahoochee facies (of Tampa Stage)

†Chattahoochee Formation[1]

Miocene, lower: Florida and Georgia.

Original reference: D. W. Langdon, Jr., 1889, Am. Jour. Sci., 3d, v. 38, p. 322-324.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 16 (table 1), 17–20, figs. Term Chattahoochee revived to include updip silty and clayey facies of Tampa stage. Thickness 119 feet near Jim Woodruff Dam, Fla. Name St. Marks is here revived to include calcareous downdip facies of Tampa stage.

C. W. Hendry, Jr., and J. W. Yon., Jr., 1958, Florida Geol. Survey Rept. Inv. 16, p. 28–33. Detailed discussion in vicinity of Jim Woodruff Reservoir. Facies underlies clastics of Hawthorn formation and unconformably overlies Suwannee limestone. Exposed thickness about 160 feet. Type locality stated.

Type locality: Jim Woodruff Dam section located on dam access road in SW¼ sec. 29, T. 4 N., R. 6 W., directly below U.S. Engineers office on east side of Apalachicola River. Named for exposures along Chattahoochee River, especially at Chattahoochee Landing, Gadsden County, Fla.

Chattanooga Shale[1]

Upper Devonian and Mississippian: Tennessee, Alabama, Arkansas, Kentucky, Mississippi, and Oklahoma.

Original reference: C. W. Hayes, 1891, Geol. Soc. America Bull., v. 2, p. 143.

J. H. Swartz, 1924, Am. Jour. Sci., 5th ser., v. 7, no. 37, p. 24–30. In type area, Chattanooga shale is overlain by thin hard gray shale containing *Lingula melie*. This shale is herein named Glendale. This shale has been regarded as part of overlying Fort Payne chert. Glendale is lower Cuyahogan in age. In type area and along Cumberland escarpment, the Chattanooga is divisible into at least three members: upper black shale of Sunbury (in places perhaps post-Sunbury) age: lower black shale of Cleveland (and in places perhaps pre-Cleveland) age; and middle gray clay shale of Bedford-Berea age. Upper part of Chattanooga in Clinch Mountain area is of late Cuyahogan age. Maury shale is separated from

Chattanooga by marked unconformity which increases to west and decreases to east, probably disappearing before eastern Tennessee is reached. It [Maury] is basal Ridgetop, not upper member of Chattanooga.

J. H. Swartz, 1927, Am. Jour. Sci., 5th ser., v. 14, no. 84, p. 485–499. Big Stone Gap shale of Ulrich and Stose (1923) has been shown by direct and continuous tracing to be northward continuation of Chattanooga shale of type area. Big Stone Gap shale abandoned for prior term Chattanooga shale. Thoughout whole area, Chattanooga shale is divisible into three members: upper black shale member to which term Big Stone Gap is here restricted; midde gray shale member here called Olinger member; and lower black shale member here designated Cumberland Gap member. Olinger member is same age as Cumberland Gap member, with which it intertongues to south. Big Stone Gap member separated from underlying Olinger member by unconformity which is most marked in southeastern Tennessee and which may be absent in northeastern Tennessee and southwestern Virginia.

K. E. Born and H. B. Burwell, 1939, Tennessee Div. Geology Bull. 47, p. 48–49. Chattanooga shale, throughout most of central Tennessee, consists of three members: thin conglomeratic phosphatic dark-colored sandstone at base (Hardin sandstone); ubiquitous black shale member; and thin green phosphatic nodular soft shale unit at top (Maury green shale). In Clay County, underlies Fort Payne formation and overlies the Richmond group: Mississippian (Kinderhook group).

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1752–1753, chart 4. At its type section (Swartz, 1924) determined Chattanooga shale to be in part Upper Devonian and in part Lower Mississippian. Here section consists of about 11 feet of shale; the lowest 8 feet corresponds to Cleveland shale; next overlying 9 inches of mottled shale are assigned to the Bedford-Berea; next three-eighths inch of black shale is said to be of Sunbury age; over the Sunbury 2⅓ feet of hard shale (Glendale) is correlated with lower Cuyahoga of Ohio. These are long-ranging correlations and are not based on best of evidence, but, if Swartz is correct, main body of the Chattanooga at its type locality is correlated with Cleveland shale, which is herein regarded as Devonian. Correlation of these black shales is so difficult that age of each occurrence must be considered on its own merits. In northeastern Arkansas, black shales called Chattanooga contain Middle Devonian or lowest Upper Devonian fossils; these occurrences should be renamed or referred to Trousdale shale, Geneseo equivalent in west Tennessee.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 880–895. Belt of outcrop of Chattanooga shale extends from Cumberland, Monroe, and Allen Counties, Ky., through Clay, Macon, and Sumner Counties, Tenn.; encircles Central basin along the Highland Rim, and joins again from Lincoln to Hardin County before entering Alabama, where it extends to Birmingham. Crops out in eastern Tennessee from Chattanooga to Cumberland Gap and along Clinch Mountain, extending into Virginia. Type Chattanooga is detached from both the shale of eastern Tennessee and that around Central basin and has not been correlated definitely with either. Thickness 20 to 35 feet in Chattanooga district, but only 10 feet exposed in type section on Cameron Hill; it is not a representative section for any region. Chattanooga shale has same time limits as New Albany shale in Indiana and Kentucky. All divisions of the New Albany, their stratigraphic relations, and lithic characters are duplicated in the Chattanooga. Terms New Albany and Chattanooga may be used interchangeably. Chattanooga in central Tennessee comprises (ascending) Trousdale, Dowelltown (new), Gassaway (new), Eulie (new), and Westmoreland (new) formations. Underlies Maury or New Providence shale.

W. H. Hass, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1189. Chattanooga shale in vicinity of Chattanooga, consists of three members: upper and lower black shale, and a middle gray shale. Conodonts present in all three members. Conodonts were collected at type locality in Chattanooga and near Apison, 16 miles east of Chattanooga. At Apison locality, upper black shale member contains lower Mississippian conodonts and is correlated with Sunbury shale of Ohio. Lower black shale at both localities contains conodonts that correlate it with Huron shale of Ohio, a formation classified as Upper Devonian by U.S. Geological Survey. Middle gray shale contains Huron conodonts, but its age is equivocal as J. H. Swartz has reported macrofossils from it which he considers to be of early Mississippian age. Presence of Huron conodonts in lower black shale member of Chattanooga shale is younger than the black shale sequence of the North Central States.

G. G. Huffman, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 2, p. 448. In Muskogee County, Okla., unconformably overlies Sylvan shale.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000) : U.S. Geol. Survey. Chattanooga shale (Mississippian and Devonian) mapped in northeastern and central eastern Oklahoma.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 2–23. First reference to Chattanooga shale is brief. It appears as part of descriptive matter on geologic column that the "Chattanooga black shale" is of Devonian age, that it is overlain by Fort Payne chert of Carboniferous age and underlain by Rockwood formation of Silurian age, and that it is 35 feet thick. The "Chattanooga black shale" consists of two lithologic units: upper gray shale, 3 to 4 feet thick, and a lower black shale. Swartz (1924) named upper gray-shale unit of Hayes' Chattanooga the Glendale shale. Swartz was of the opinion that beds he identified as Glendale were, prior to his work, a part of Fort Payne chert. Name Glendale shale not used in present report; beds so named by Swartz are called Maury formation. At reference section herein designated, Chattanooga consists of lower Dowelltown member and upper Gassaway member. Thickness throughout much of area 25 to 35 feet. In some areas, includes Hardin sandstone member (about 16 feet thick) below the Dowelltown. As delimited in present report, the Chattanooga shale of type locality (locality 226) is the Cumberland Gap member of Swartz's (1927) section. The immediately overlying beds which Swartz assigned to his Olinger and Big Stone Gap members are herein placed in Maury formation. Underlies Maury formation; the two problably are separated by a unconformity throughout much of south-central Tennessee and north-central Alabama. Considered to be of Late Devonian age though oldest beds could be of late Middle Devonian. Conodonts discussed.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey County Rept. 3, p. 30–33. Name, as applied in Alabama, includes sandstone and black shale deposits that occur stratigraphically between Red Mountain formation of Silurian age and Fort Payne chert of Mississippian age.

Overlies Chickamauga limestone in northwestern part of Madison County. Thickness about 8 feet in Madison County. Devonian.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 38–40, pls. 1, 2, 4, 5. Formation described on south and west flanks of Ozark uplift where it is as much as 70 feet thick and consists of basal Sylamore sandstone member and overlying black shale member. Unconformably underlies St. Joe or Reeds Spring limestone; unconformably overlies beds ranging in age from Lower Ordovician Cotter, as near Spavinaw, to Sallisaw formation of Devonian age near Marble City. Kinderhookian.

G. G. Huffman and J. M. Starke, Jr., 1960, Oklahoma Geology Notes, v. 20, no. 7, p. 159-163. Proposed that term Chattanooga be retained for Late Devonian-Early Mississippian lying immediately below the St. Joe group and that the formation be divided into two members; the lower, or Sylamore, sandstone member and the upper, or Noel, black shale member.

J. C. Cobb and J. L. Kulp, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 223–224. Discussion of U-Pb age of Chattanooga shale. Possible that true age of the Chattanooga is about 350 million years.

Type locality: Hillside exposure at north end of Cameron Hill, Chattanooga, Hamilton County, Tenn. Standard section: Cut on Tennessee Highway 26, at east approach to Sligo Bridge over Caney Fork, 7.1 miles east of courthouse at Smithville, DeKalb County, Tenn.

Chattanoogan Series[1]

Devonian-Mississippian: North America.

Original references: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 29; C. Schuchert, 1924, Textbook geology, p. 335.

Chauga zone[1]

Cambrian(?): Northwestern South Carolina.

Original reference: C. E. Sloan, 1905, South Carolina Geol. Survey, geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2.

Named for exposures along upper half of Chauga River, Oconee County.

Chaumont Formation[1] or Limestone (in Black River Group)

Middle Ordovician: New York, and Ontario, Canada.

Original references: G. M. Kay, 1929, Jour. Geology, v. 37, no. 7, p. 644–671; 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 9, p. 1214.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, pl. 2. Plate 2 shows Chaumont underlies Amsterdam limestone in Lake Champlain region.

G. M. Kay, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 588 (fig. 2), 593 (table 2), 594 (table 3), 595–597, 599. Uppermost formation of Black River group in New York. Separable into two members, Leray and Watertown limestones, only in limited area near Watertown. Underlies Rockland formation (type section in Ontario); overlies Lowville. Geographically extended into Ontario.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 24. Name was proposed to include (ascending) Leray, Glenburnie, and Watertown members. Leray consists of 13 feet of heavy-bedded dark-brownish-gray to black limestone containing chert. In type region of Chaumont, Leray is separated from Watertown by 2 feet of fossiliferous shale, the Glenburnie. Watertown comprises 13 feet of massive limestone. Outside type area, it is difficult to separate Leray and Watertown. Underlies Rockland formation; overlies Lowville.

D. W. Fisher, 1957, New York State Mus. Bull. 359, p. 13–15. Discussion of Mohawkian (Middle Ordovician) biostratigraphy of Wells outlier, Hamilton County. Chaumont limestone consists of about 9 feet of massive blocky argillicalcilutite with much black chert. Not certain whether the Chaumont at this locality consists of the Leray or Watertown members, or includes both. Overlies Lowville limestone; underlies Rockland (Napanee) limestone.

Named for Chaumont Bay, Lake Ontario, Jefferson County, N.Y.

Chaumontian Stage

Ordovician (Black Riveran): New York.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 94 (table 3). Name used in list of stage names for uppermost division of Black Riveran series. Younger than Lowvillian [stage]; older than Rocklandian stage of Trentonian series.

Name probably derived from Chaumont Bay, Lake Ontario, Jefferson County, for which Chaumont formation is named.

†Chautauqua Conglomerate[1]

Pennsylvanian: New York.

Original reference: J. P. Lesley, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 89, 96.

Probably Chautauqua County.

†Chautauqua Sandstone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: G. I. Adams and E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 57–60.

Named for Chautauqua Sandstone Hills, which extend through parts of Chautauqua, Woodson, Wilson, Montgomery, Greenwood, and Elk Counties.

Chautauquan Group[1]

Chautauquan Series

Chautauquan Stage

Upper Devonian: North America.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 54, 60–61, table (facing p. 62). Chautauquan series embraces strata from base of Chemung to base of Bradfordian series of former classifications. Chautauquan was viewed by New York State geologists as marking close of Devonian and overlying Bradfordian was considered of Mississippian age. Name Bradfordian series is here abandoned, and term Conewango series is applied to Devonian part of the Bradfordian "series." Conewango series is a closing phase of Upper Devonian sedimentation in New York and Pennsylvania. Chautauquan series comprises Girard stage below and Chadakoin stage above.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey 4th ser., Bull. G–19, p. 240–253. Major units of Chautauquan stage (division) of marine Upper Devonian in northwestern, north-central, and central Pennsylvania are (ascending) Chemung, Canadaway, Conneaut, and Conewango groups.

G. A. Cooper, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. As shown on correlation chart, Devonian comprises (ascending) Ulsterian, Erian Senecan, Chautauquan, and Bradfordian (in part) series. Chautauquan comprises Cassadaga (new) and Conewango stages. Upper Devonian.

I. H. Tesmer, 1954, Dissert. Abs., v. 14, no. 12, p. 2317–2318. Chautauquan series reduced to Chautauqua group and incorporated in upper part of Senecan series.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 12, p. 8, 9. Chautauquan series redefined to include all Upper Devonian rocks. As redefined, includes in western New York (ascending) Seneca, Arkwright, and Conewango groups. Occurs above Middle Devonian Erian series.

L. V. Rickard, 1957, New York State Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17. General stratigraphic column of Wellsville area shows Chautauquan series comprises (ascending) Canadaway, Chadakoin, and Conewango groups. Above Senecan series; below Knapp "formation," Kinderhookian series.

Named for exposures in Chautauqua County, N.Y.

Chaves shale[1]

Permian: Southeastern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 258; 1915, Conspectus of the geologic formations of New Mexico: Des Moines, Robert Henderson, State printer, p. 3, 6.

In Guadalupe Mountains. Derivation of name not given.

Chavez Member (of Morrison Formation)

Upper Jurassic: Northwestern New Mexico.

C. T. Smith, 1951, *in* New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 13 (chart), 38. Series of variegated sandstone and siltstone beds underlying Prewitt sandstone member (new) and overlying Thoreau formation (new).

C. T. Smith, 1954, New Mexico Bur. Mines Mineral Resources Bull. 31, p. 15–16, pl. 1. Alternating variegated greenish siltstone, purplish-to-reddish sandy mudstone, and white-to-buff coarse-grained conglomeratic sandstone; locally, units contain silty layers and mud-ball zones; much sandy material is strongly laminated; variegated red, purple, and green mudstone bed about 15 feet thick present near top of formation; beds of sandstone are 3 to 6 feet thick; siltstone 1 to 3 feet, mudstone layers 3 inches to 2 feet. Thickness 160 feet at type section (herein designated); thins to west; about 200 feet along eastern boundary of quadrangle; less than 100 feet near Chaco Canyon Road.

J. A. Momper and W. W. Tyrrell, Jr., 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 18. Upper Jurassic.

Type section: In sec. 19, T. 14 N., R. 13 W., south of Mount Powell near western edge of Thoreau quandrangle. Named for exposures on crest of Chako Canyon Road about 5 miles north of Chavez Siding on Atchison, Topeka, and Santa Fe Railway.

Chazy Group[1] or Limestone[1]

Middle Ordovician: Eastern New York and western Vermont.

Original reference: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, geology 2d dist., p. 107, 315, 429.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, 119–178. Series includes Stones River group with Murfreesboro, Mosheim, and Lenior limestones, and Blount group with Holston limestone, Whitesburg limestone, Athens formation, and Ottosee limestone. Overlies Beekmantown group; underlies Lowville-Moccasin formation of Black River group.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 819–866. In Tazewell County, Va., strata embraced by the Chazyan and Black River groups of Butts (1940) are divisible into 29 distinctive zones. Detailed work indicated that supposedly diagnostic criteria for recognition of the Chazyan and Black River formations of Ulrich and Butts are unreliable and that succession of formations given by Ulrich and Butts is incorrect. The newly recognized zones are grouped into eight formations (ascending): Cliffield, with Blackford, Five Oaks, Lincolnshire, Ward Cove and Peery members; Benbolt limestone with Shannondale and Burkes Garden members; Gratton limestone; Witten limestone; Moccasin formation; and Eggleston formation. Terms Stones River, Murphreesboro, Mosheim, Lenoir, Blount, Holston, Ottosee, Lowville and Lowville-Moccasin should not be used in Tazewell County and other parts of southwestern Virginia. The succession beds described is clearly post-Beekmantown, but beds above *Camarocladia* zone (upper part of Witten) may by younger than hitherto believed. Moccasin and Eggleston may be early Trenton but present evidence not conclusive. Boundary between Chazy and Black River not clearly defined in Tazewell County. Series and group classification of formations can be made only after regional studies between New York localities and Tazewell County have been completed.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 522 (fig. 3), 524 (table), 548–554. Chazy group, in eastern New York, comprises (ascending) Day Point, Crown Point, and Valcour limestones. Inasmuch as Day Point beds thin and pinch out, north of west-central Vermont, and inasmuch as Valcour undergoes considerable change in lithology and obliteration of fossils eastward from Lake Champlain, Crown Point limestone is only term used along Lake Champlain appropriate in west-central Vermont [this report]. Here Chazyan sequence (Chazy group) is Crown Point limestone, Beldens formation with Weybridge member (both new), and Middlebury limestone (new). Overlies Beekmantown group (Beekmantownian).

Marshall Kay, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1171–1172. Highgate Springs sequence of Middle Ordovician rocks lies structurally below and west of thrusts bounding the Rosenberg, Philipsburg, and Granby slices for 100 miles from Chittendon County, Vt., to Bagot County, Quebec. Three formations are Chazyan: Beldens, Carman (new), and Youngman (new). Disconformably overlying Chazyan at Highgate Springs is 80 feet of Isle la Motte limestone having Trenton fossils.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 35–114. In proposed reclassification, lower Middle Ordovician of Shenandoah Valley is divided into six time-stratigraphic units (ascending) New Market limestone (new), Whistle Creek limestone (new), Lincolnshire limestone, Edinburg formation (new), Oranda formation (new), and Collierstown limestone (new). At least part of New Market limestone is linked with part of New York Chazy and type Lenoir; Lincolnshire seems to be post-Chazy. Whistle Creek, if at all Chazy, could be represented only in upper part of the Valcour; probably Whistle Creek, as well as some of succeeding beds, is younger than Chazy and older than typical Black River.

Marshall Kay, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1198. Bolarian series (new, Bolar Valley, Va.) comprises rocks younger than Lincolnshire, about late Chazyan, and older than Nealmont, early Trentonian.

Marshall Kay and W. M. Cady, 1947, Science, v. 105, no. 2736, p. 601. Cady (1945) included Crown Point, Beldens, and Middlebury formations in Chazy "group" in west-central Vermont. Name Crown Point is herein replaced by Burchards limestone, and the Burchards and Beldens are included in Chipman group (new). Kay (1945) studied "Chazy" rocks of northern Lake Champlain and described the Carman quartzite and Youngman formation as succeeding the Beldens in Highgate Springs slice. Carman and Youngman compose Maquam group (new). Chazy sequence in New York is Day Point, Crown Point, and Valcour. Inasmuch as these three sequences have been called Chazy for nearly a century, it is recommended that Chazyan series consists of Chipman and Maquam groups, as well as the Chazyan series of New York. This use of Chazy is considered to have priority over the Chazyan of Grabau (1909) which added the Black River group and of Ulrich (1911) which was a composite of widely scattered stratigraphic units.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1400–1406. Rocks younger than Canadian or Beekmantownian and older than Cincinnatian series are commonly referred to Middle Ordovician and placed in two series, Chazyan and Mohawkian. The Mohawkian is herein divided into Bolarian and Trentonian series. Chazyan, as originally defined, included Black River group as well as Chazy, but name should be restricted to the latter. Chazyan has two groups, Chipman and Maquam. The Chipman, present in Vermont and southeastern Quebec, is thought to be older than base of Chazy limestone in New York, correlated Maquam group of Vermont. Black River and Trenton formations in New York and Ontario lie with regional unconformity on the Chazyan, Canadian, and Upper Cambrian, and Precambrian. The Chazy, Black River, and Trenton commonly have been classified as groups of Middle Ordovician. They are comparable in stratigraphic magnitude and are separated by persistent regional unconformities. The Chazyan along Allegheny synclinorium includes Five Oaks-Blackford and Lincolnshire formations. Chazyan is followed by Bolarian series which term is used in preference to Black Riveran.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 66, no. 3, p. 253–254, chart 2. In type area, in Champlain Valley, Chazyan stage includes about 1,000 feet of relatively pure thick-bedded limestone. These deposits are separated from shale belt on the east by major thrust zone (Logan's Line) and from contemporaneous deposits both north and south by gap of more than 100 miles. Hence, recognition of Chazyan rocks outside Champlain Valley rests entirely on faunal criteria. Chazyan fauna has turned out to be somewhat restricted, and provincial facies not clearly recognizable elsewhere. This is illustrated by Lincolnshire formation of Virginia and Tennessee which has been referred to Chazyan by most students and is so placed in present chart but which Cooper believes should be lifted to base of Black River stage because of numerous faunal affinites with that stage that are unknown in type Chazyan. In Champlain Valley, the middle Chazyan, Crown Point, limestone is characterized by gastropod *Maclurites magnus*. In this region, there is no similar species above or below and, thus, from early days of Ordovician stratigraphy, *Maclurites magnus* came to be regarded as guide to Middle Chazyan. It is now known that similar large species of *Maclurites* occur higher in Ordovician in central and southern Appalachians, *Tetradium cellulosum* and *Cryptophragmus* led Ulrich and others to identify Lowville formation in Appalachians and central basin of Tennessee. In southern Appalachians *Cryptophragmus* is common in Witten formation, which was hitherto called Lowville. On basis of its supposed Lowville age, all rocks below were placed in Chazyan. This accounted for Chazyan age of Ottosee and Athens of Virginia. The latter formations with *Nemagraptus* and other graptolites of Normanskill assemblage were thus dated as Chazyan. Similarly, the Carters formation of Tennessee was dated as Lowville because of abundant *Tetradium cellulosum* in its lower beds. By this correlation, entire Stones River group was assigned to Chazyan in spite of fact that Stones River contained no Chazyan species other than *Maclurites*. Now known that *Cryptophragmus* and *T. cellulosum* have considerable range. Fauna of Witten limestone accompanying *Cryptophragmus* is that of the Chaumont or Rockland beds, and Carters limestone is now recognized as equivalent to Tyrone limestone and correlated with Rockland. Result has been to leave scope of Chazyan stage outside Champlain Valley in confusion and uncertainty. Suggested that it might be desirable to abandon Chazyan as stage name in standard section and choose term with new type section somewhere in central or southern Appalachian trough. However, name Chazyan stage is retained for present chart.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 1, 7–8, chart 1. Five stage terms proposed (ascending): Whiterock, Marmor, Ashby, Porterfield, and Wilderness. Older terms, Chazyan and Black River, are no longer useful because they have been so defined that they do not describe the stratigraphy. Recent studies have shown that Chazyan of Ulrich included rocks from Chazyan to Trenton and that Black River of Ulrich was in large part of Trenton age. Grabau's (1909) usage of Chazyan included Black River, which is herein regarded more closely related to overlying Rockland than to Chazy group below. Ulrich's (1911) conception of Chazy was for interval between Lowville and top of Canadian (Beekmantown or Knox dolomite) which is far too inclusive. Marmor stage includes Chazy group of rocks and its correlatives. Ashby stage includes Elway and Lincolnshire formations which Kay (1948) placed in his Chazyan.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 55–106. Middle Ordovician limestones of the Chazyan, Bolarian, and Trentonian series are exposed in western anticlines in Appalachian Mountains of West Virginia and in Virginia northeast of the New River. The Chazyan comprises Lurich formation or group (new) with Blackford, Elway, and Five Oaks formations, and overlying Lincolnshire formation. In Appalachian Valley, the Chazyan includes St. Paul group and Lincolnshire formation. The Chazyan epoch is represented in two stages, the Lurichian and Lincolnshirian.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, p. 65–96. Discussion of Ordovician classification. Chazyan series corresponds to the Chazy limestone as originally used for rocks above the Calciferous and below the Black River near Lake Champlain. Classification of rocks younger than Canadian and older than Trentonian concerns sequences (a) along Lake Champlain, containing type Chazy, (b) northwestern New York, containing typical Black River and Trenton, and (c) Appalachians, particularly the Virginias, where there are type sections of the Bolarian series and a number of recently named stages (Cooper, 1956). Classification and correlation discussed within past few years (Cooper, 1956; Kay, 1956; Twenhofel and others, 1954) must be reconsidered. Chazy limestones lie on the Canadian along Lake Champlain; now that Canadian age of Beldens limestone has been recognized, there is no problem in placement of boundaries. Chazy lies on a regional unconformity with an overlapping basal quartz sandstone. Chazy has long been divided into three lithologic and faunal stages (Brainerd and Seely, 1888, Am. Geologist, v. 2) which were given "substage" names Day Point, Crown Point, and Valcour (Cushing, 1905). As stages, these have been called Dayan, Crownian and Valcourian (Oxley, 1952, unpub. thesis). Appalachian region has been thought to have fuller sequences of post-Canadian rocks than New York, but recent studies cast doubt on this assumption. If an Appalachian standard were established, it would be possible to correlate to New York sequences but there are problems of correlation within Appalachian sections. To the southwest, there is disagreement whether base of Trentonian is within Witten formation or at top. Cooper (1956) placed lowest Trentonian as well as Black River equivalents in Wilderness stage. Kay (1947) defined Bolarian series as extending from top of Lincolnshire limestone to base of Nealmont which seems lowest Trentonian. Lincolnshire was classified as Chazyan. Rocks younger than Canadian have been assigned by Cooper (1956) to Marmor, Ashby, Porterfield, and Wilderness stages. Because type Marmor is isolated from that of others, the rocks between the Elway and Lincolnshire formations of type Ashby are herein referred to as Blackford "stage." Thus, Virginia sequence consists of Blackford, Ashby, Porterfield, and Wilderness stages. If Youngman formation and St. Dominique limestone of Highgate Springs sequence are Chazyan, as they seem, they contain fossils that have been considered distinctive of Marmor, Ashby, and Porterfield stages in Appalachians, rather than of Marmor alone. Fossils in Youngman generally resemble those in the Porterfield; those in St. Dominique resemble those in type Chazy and the "Ashby". The Highgate sequence suggests that base of Bolarian series may be within upper Chazyan series rather than above it. In the north, it is possible to subdivide Chazyan and Blackriveran series each into three stages. In the Appalachians, it is best to establish provincial stages from single sequence as in the Virginias; Blackford, Ashby, and Porterfield are in such a sequence. Place of Marmor stage is in dispute. Porterfield and pre-Trentonian part of Wilderness constitute type Bolarian series. Blackford and Ashby stages are believed to be Chazyan but not to constitute the whole of that series; they are in a provincial series that is approximately St. Paul group (Neuman, 1951).

W. M. Cady and E-an Zen, 1960, Am. Jour. Sci., v. 258, no. 10, p. 728–739. In west-central Vermont, Chipman formation, with Burchards, Weybridge, Beldens, and Bridport members, is Beekmantown rather than

Chazy as stated in previous reports. In this area, the Middlebury limestone is Chazy.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–33. Chazyan series or "Chazy stage" was divided into three "substages" by Cushing that have become Dayan, Crownian, and Valcourian stages (Oxley and Kay, 1959), recognizable in type area by their distinctive fossil assemblages. Cooper (1956) places whole type Chazy in his Marmor "stage" considering the succeeding Ashby and Porterfield "stages" of southern Appalachians to be post-Chazy and at least partly pre-Black River. But fossils thought diagnostic of Porterfield "stage" are in argillaceous strata of type Chazyan (Kay, 1958). Cooper introduced an earlier post-Canadian "stage," the Whiterock, below the Marmor, basing it on faunas found in Nevada; whether these are older than type Chazyan, or represent different faunal facies or province is difficult to determine because of their isolation. Flower (1957, New Mexico Bur. Mines Mineral Resources Mem. 2) concurs in believing them younger than Canadian and older than Dayan; the Whiterockian is so placed in table in present report. Chazyan series comprises (ascending) Whiterockian, Dayan, Crownian, and Valcourian stages; occurs above Canadian series and below Blackriveran.

Named for exposures at Chazy, Clinton County, N.Y.

Chazyan Series[1], Stage, Epoch

Middle Ordovician: North America.

Original reference: A. W. Grabau, 1909, Jour. Geology, v. 17, no. 3; E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22.

See **Chazy Group** or **Limestone.**

Cheaha Sandstone Member (of Talladega Slate)[1]

Cheaha Quartzite Member (of Talladega Series)

Paleozoic(?): Eastern Alabama.

Original reference: Charles Butts, 1926, Alabama Geol. Survey Special Rept. 14, p. 54, 58, map.

R. H. Griffin, 1951, Alabama Geol. Survey Bull. 63, p. 28–30. Described in the Hillabee area where Talladega series is divided into Cheaha quartzite, Erin slate, and a group of quartzites, phyllites, and slates lying below, between, and above the two members. Maximum thickness of quartzites about 2,600 feet; variations in thickness caused in part by folding and thrust faulting. Upper limit of Cheaha placed at point in section where phyllite becomes dominant rock type owing to the marked diminution in number and thickness of the quartzite beds; boundary is expressed topographically by the generally well-defined eastern base of Talladega-Rebecca Mountain.

Named from fact that Cheaha Mountain, Clay County, is formed by the sandstone.

Checkerboard Limestone (in Pleasanton Group)

Checkerboard Limestone (in Skiatook Group)

Checkerboard Limestone Member (of Coffeyville Formation)[1]

Pennsylvanian ((Missouri Series): Northeastern and central Oklahoma, and southern Kansas.

Original reference: L. L. Hutchinson, 1911, Oklahoma Geol. Survey Bull. 2, p. 151–164.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40 (table), 42. Rank raised to formation in Skiatook group. Overlies Seminole sandstone; underlies Coffeyville shale (restricted).

M. C. Oakes and J. M. Jewett, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 634 (fig. 1), 638–639. Geographically extended into southern Kansas where it overlies Hepler sandstone.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 91. In Kansas, included in Pleasanton group; underlies shales below Knobtown sandstone. Thickness ranges from featheredge to about 6 feet.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 16–17. Name Checkerboard seems to have crept into general usage without formal definition. Hutchinson (1911) made reference to it by name. Smith (1914, U.S. Geol. Survey Bull. 541) used name without describing it, Fath and Emery (1917, Oklahoma Geol. Survey Bull. 35) described the Checkerboard and designated type exposure. Checkerboard limestone in Creek County [this report] is single bed about 2½ feet thick. Conformably overlies Seminole formation; conformably underlies Coffeyville formation. Skiatook group.

Type locality: Exposures along Checkerboard Creek in T. 15 N., R. 11 E., Washington County, Okla.

Chediski White Sandstone Member (of Troy Quartzite)[1]

Middle Cambrian: Central eastern Arizona.

Original reference: F. F. Burchard, 1931, U.S. Geol. Survey Bull. 821–C.

Age currently considered by U.S. Geological Survey to be Middle Cambrian.

Forms cliff on northeast face of Chediski Mountain, Fort Apache Indian Reservation.

Chehalis Formation[1]

Miocene, lower: Southwestern Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 15, p. 10–22.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 100. As a result of later studies, Chehalis formation has been abandoned as a stratigraphic name.

Named for Chehalis River in Chehalis, Grays Harbor County.

Chehalis Sandstone[1]

Eocene: Southwestern Washington.

Original reference: A. C. Lawson, 1894, Am. Geologist, v. 13, p. 436–437.

In vicinity of Chehalis, Lewis County.

Chelan (batholithic) Complex

Chelan Granodiorite[1]

Upper Jurassic(?): Central Washington.

Original reference: A. C. Waters, 1932, Jour. Geology, v. 40, no. 7, p. 605.

J. D. Barksdale, 1948, Northwest Sci., v. 22, no. 4, p. 165. Northeastern contact of Chelan batholithic complex makes straight line N. 40°–45° W. across Methow quadrangle from near its southeast corner. Granitic rocks of complex can be traced southwest into area mapped by Waters (1932) as Chelan granodiorite. Detailed study of granitic rocks was not made in quadrangle, but some samples revealed that rock is true biotite granodiorite of medium grain and quite different from typical basic granodiorite described by Waters. Waters assigned Chelan granodiorite of type area to Jurassic(?). Some granite rocks of Chelan complex in Methow quadrangle apparently cut formations as young as Upper Cretaceous.

Named from Chelan Mountains, Chelan County, where it is typically exposed.

Chelsea Sandstone Member (of Senora Formation or Cabaniss Formation)

Chelsea Sandstone Lentil (of Cherokee Formation)[1]

Chelsea Sandstone Member (of Scammon Formation)

Pennsylvanian (Des Moines Series): Northeastern Oklahoma, southeastern Kansas, and southwestern Missouri.

Original reference: G. C. Clark and C. L. Cooper, 1927, Oklahoma Geol. Survey Bull. 40–H, fig. 3.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Included in Scammon formation (new) above Tiawah limestone.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 53, 57–58, 59. In Scammon formation. Present in exposures in strip mines in Crawford County, Kans., and Barton County, Mo., where in many areas it rests upon an erosion surface extending down through lower beds and locally through the Tiawah limestone and underlying Tebo coal. Typically a gray to brown very fine grained micaceous finely to coarsely crossbedded sandstone. Thickness 5 to 30 feet.

J. V. A. Trumbull, 1957, U.S. Geol. Survey Bull. 1042–J, pl. 16. Shown on correlation chart as sandstone member near base of Senora formation. The Cherokee formation of former usage in northeastern Oklahoma included rocks from the McAlester through the Senora formation.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Member of Cabaniss formation in Kansas.

Forms prominent escarpment from upper branches of Whiteoak Creek, thence south and west to Chelsea, Rogers County, Okla.

Cheltenham Clay Member (of Spoon Formation)

Cheltenham Fire Clay[1]

Cheltenham Formation (in Cherokee Group)

Pennsylvanian: Missouri and Illinois.

Original reference: H. A. Wheeler, 1896, Missouri Geol. Survey, v. 11, 1st ser., p. 247.

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, v. 28, 2d ser., p. 39–71, pl. 6. Rank raised to formation Cherokee group. Made up of three distinct clays: lower, very dark or fairly dark, black, brown, or gray semiflint and flint fire clay; middle, light-gray fairly hard semiplastic clay, 6 to 20 feet thick; and upper, light- to dark-gray plastic clay, 0 to 15 feet. Overlies Graydon formation; underlies Loutre formation (new).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1). Name Cheltenham clay member of Spoon formation (new) is applied locally to dominantly clay unit that is composite of several underclay members. Stratigraphic range varies from place to place. In southwestern Illinois, occurs above DeKoven coal member (new); in western Illinois, occurs above Browning sandstone member.

Named for fire-clay seam in Cheltenham district in southern part of St. Louis, Mo.

Chemard Lake Lignite Lentil (of Naborton Formation)

Paleocene (Midway): Northwestern Louisiana.

D. P. Meagher and L. C. Aycock, 1942, Louisiana Dept. Conserv. Geol. Pamph. 3, p. 13, 14. Lentil at top of Naborton formation.

G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 98–100, pl. 4. Consists of lignite and lignitic clays that interfinger and mutually replace each other or are both replaced by other sediments in upper part of Naborton. Maximum thickness 10 feet. Limited at top by basal sands of Dolet Hills member of Logansport formation.

Type locality: One mile northwest of Chemard Lake at Coal Bed Springs in bluffs facing Dolet Brake and Dolet Bayou, in NW¼ sec. 3, T. 11 N., R. 11 W., 2½ miles southwest of Evelyn and 2 miles northwest of Rambin's store, De Soto Parish. Has been traced around outcrop area of Naborton formation from Chemard Lake to Rockdale.

Chemehuevi Formation

Chemehuevi Gravel[1]

Pleistocene: Western Arizona and southeastern Nevada.

Original reference: W. T. Lee, 1908, U.S. Geol. Survey Bull. 352, p. 18.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1443–1450. Chemehuevi formation consists chiefly of sand, silt, and clay. Strongly unconformable on the old river gravels.

C. R. Longwell, 1946, Am. Jour. Sci., v. 244, no. 12, p. 820 (fig. 2), 827. Although sediments are unconsolidated and easily eroded, hundreds of remnants lie at various levels along the valley below the Grand Canyon.

Named for Chemehuevi Valley, south of The Needles, along the Colorado River, Mohave County, Ariz.

Chemehuevis Formation

See Chemehuevi Formation.

Chemung Formation[1]

Chemung Formation (in Conneaut Group or Seneca Group)

Chemung Stage

Upper Devonian: New York, western Maryland, Pennsylvania, and Virginia.

Original reference: J. Hall, 1839, New York Geol. Survey 3d Rept., p. 322–326.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 246, 247. Group, in south-central New York and adjacent Pennsylvania, consists of Cayuta formation and Wellsburg formation with Fall Creek conglomerate locally at top.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 322–333. Chemung, except where removed by erosion on the anticlines, persists throughout full width of Appalachian Valley northwest of Little North Mountain in Virginia and West Virginia, and in the continuation of that belt southwest to vicinity of New River. Approximate thickness 2,000 feet in its full development in Appalachian Valley. In West Virginia, thins out entirely near Narrows of New River. In Virginia, overlies Brallier shale; underlies Hampshire (Catskill) formation.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1734, chart 4. Devonian subdivided into 10 stages that represent grouping of formations on faunal and paleogeographic basis. Group term Chemung is elevated to stage rank because of widespread and distinctive character of its fossils. Stage has same limits that Chadwick (1935, Am. Mid. Nat., v. 16, no. 6) gave to group. Chemung stage follows Finger Lakes stage (new) and is followed by Cassadaga (new) stage.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Formation described in Hollidaysburg and Huntingdon quadrangles, Pennsylvania, where it is 2,400 to 3,500 feet thick. Includes Piney Ridge sandstone, Allegrippis sandstone, and Saxton conglomerate members. Overlies Brallier shale; underlies Hampshire formation.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept.] Washington County, p. 91–92; T. W. Amsden, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept.] Washington County, p. 99 (table 4), 122. Uppermost member of Jennings formation. Overlies Parkhead member; underlies Catskill formation.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 31. Oldest rocks in Chautauqua County, N.Y., are assigned to Seneca group. The group is divided into four formations, youngest of which is Chemung. The Chemung in turn is divided into three formations; the two youngest, Angola shale and Hanover shale are exposed in Chautauqua County. Pipe Creek shale included in Hanover shale. Thickness about 340 feet. Underlies Dunkirk shale member of Canadaway group.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1). Chemung formation includes Wiscoy member in some areas and Hanover member in others.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Conneaut group includes "pink rock" of drillers and "Chemung" and "Girard" formations of northwestern Pennsylvania.

Named for occurrence in valley of Chemung River and in town of Chemung, Chemung County, N.Y.

Chenango Sandstone Member (of Skaneateles Formation)

Middle Devonian: Central New York.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180. Proposed to replace Colgate sandstone of Cooper, 1930 (not Calvert, 1912).

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart shows Chenango sandstone above Butternut shale and below Stone Mill limestone. Middle Devonian.

[G. A. Cooper], 1955, *in* New York State Geol. Assoc. [Guidebook] 27th Ann. Mtg., p. 10, 11. Uppermost member of formation. Grades downward into Butternut member. Thickness 60 feet.

Type section: Quarry at top of hill just south of buildings on Colgate University campus and overlooking Chenango Valley to northwest, Hamilton County.

Cheneyan Stage

Paleocene: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 967–982, 1005. A stage, based on a foraminiferal assemblage. Comprises beds below base of Martinez and top of typical Moreno shale. Occurs above Upper Cretaceous Ciervian stage (new).

Occurs in Great Valley in both surface and subsurface. Named from Jergins Oil Co.'s Cheney Ranch Well 1, sec. 29, T. 14 S., R. 13 E. [Fresno County].

Cheney Gulch Granite

Precambrian: West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 19–20, pl. 3. Fine- to medium-grained biotite granite with a hypidiomorphic granular texture. Occurs as small masses intrusive into Lawler Peak granite (new). Intrudes Hillside mica schist (new).

Largest outcrops lie in a belt 1 mile long and nearly one-half mile wide in upper part of Mineral Creek basin. Named from exposures along west bank of Cheney Gulch, a tributary to Mineral Creek, Bagdad area, Yavapai County.

Chengwatana Series[1]

Precambrian (Keweenawan): Eastern Minnesota.

Original reference: C. W. Hall, 1900, Am. Assoc. Adv. Sci. Proc., v. 49, p. 191.

Crops out on Snake River at Chengwatana, Pine County.

Chepultepec Dolomite[1] (in Knox Group)

Chepultepec Formation

Lower Ordovician: Northern Alabama, Georgia, eastern Tennessee, western Virginia, and southern West Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 549, 638–640, pl. 27.

W. P. Woodward, 1939, West Virginia Geol. Survey [Rept.], v. 12, p. 9, 10–11. Discussed with Cambro-Ordovician limestones. In northeastern belt, overlies Conococheague formation; underlies middle Beekmantown, or Canadian (Nittany dolomite). Included in or represents, what has been mapped as Stonehenge member of Beekmantown group.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 56 (table 5), 57–58, pt. 1, pls. Included in Knox group. Underlies Longview dolomite; overlies Copper Ridge dolomite. Consists largely of well-bedded fairly light mostly fine- to medium-grained dolomite, much of it slightly silty; thin layers of dark dolomite; dark bluish aphanitic limestone prominent in upper part in southeastern belts. Thickness commonly 700 to 750 feet.

A. T. Allen, 1953, Georgia Geol. Survey Bull. 60, p. 185–186. Geographically extended into Georgia where it is referred to as formation. Near Graysville, Catoosa County, approximately 1,400 feet thick, only upper 153 feet measured. Overlies Copper Ridge formation; underlies Longview formation.

R. L. Miller and J. O. Fuller, 1954, Virginia Geol. Survey Bull. 71, p. 47–54, pls. Dolomite described in Rose Hill district where it forms roughly parallel belts on opposite sides of axis of Powell Valley anticline. Two-fold division apparent in all sections: lower or sandy member and upper or argillaceous dolomite member. Thickness 697 to 776 feet. Overlies Copper Ridge dolomite; underlies Longview dolomite.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 11 (table 1), 26–29. Thickness 266 to about 500 feet in Rockingham County. Overlies Conococheague limestone; underlies Beekmantown formation.

Named for exposures near Chepultepec, Blount County, Ala., 30 miles northeast of Birmingham.

Chequamegon Sandstone[1] (in Bayfield Group)

Precambrian: Northwestern Wisconsin.

Original reference: F. T. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 33.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1479, 1481. Uppermost formation in Bayfield group. Thickness 1,000 feet. Overlies Devils Island sandstone.

G. O. Raasch, 1950, Illinois Acad. Sci. Trans., v. 43, p. 147. Examination of evidence on which Thwaites established his Chequamegon formation reveals that his Chequamegon brownstone formation is none other than Port Wing brownstone member (new) of Orienta formation repeated by faulting. Contact of Chequamegon formation with the supposedly underlying Devils Island formation is reported by Thwaites only from type locality, Devils Island. The beds here that he [Thwaites] considers to be Chequamegon, he assigns to basal Chequamegon. Suggested in present report that these basal beds are Devils Island formation rather than the Chequamegon brownstone and that a fault contact lies offshore to the south and there separates the Devils Island from the brownstone that forms southern islands of Apostle group. Chequamegon formation is dropped from Bayfield group.

Named from exposures on Chequamegon Bay.

†Cheraw Cobbles[1]

Pliocene(?) and Pleistocene: Northeastern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies, published in 1908 in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 20.

Named for development around Cheraw, Chesterfield County.

†Cherokee Limestone[1]

Cambrian (probably lower): Northwestern South Carolina.

Original reference: E. Sloan, 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 432.

†Cherokee Limestone[1]

Mississippian: Southeastern Kansas and southwestern Missouri.

Original reference: W. P. Jenney, 1893, Am. Inst. Mining Engrs. Trans., v. 22 (author's ed. August 1893), p. 178, 186, 191–202.

Named for Cherokee County, Kans.

Cherokee Shale[1] **or Group**

Pennsylvanian (Des Moines Series): Eastern Kansas, southwestern Iowa, western Missouri, and southeastern Nebraska.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 105–106.

W. G. Pierce and W. H. Courtier, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 17; 1938, Kansas Geol. Survey Bull. 24, p. 33–35, fig. 2. Cherokee shale, southeastern Kansas, includes Little Cabin sandstone member near base. Bluejacket sandstone member near middle, and Breezy Hill limestone member (new) at top. Thickness about 425 feet. Overlies Mississippian limestone; underlies Fort Scott limestone.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18–23; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193–195. Group in southeastern Kansas subdivided into 15 formations or cyclothems (cyclic formational units) as follows (ascending): Riverton, Neutral, Columbus, Bluejacket, Knifeton, Weir-Pittsburg, Pilot, Scammon, Mineral, Fleming, Coalvale, Croweburg, Ardmore, Bevier, and Mulky.

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 28, p. 29–92. pls. 5, 6, measured sections. Group, as defined in this report, is composed of several new formations. Names of well-known coal beds have been used in order to reduce to minimum the introduction of new names. Sequence (ascending) unnamed shale and sandstone of local occurence, Graydon formation, Cheltenham, Loutre (new), Tebo (new), Ardmore, Bevier, and Lagonda. Group is restricted by removal of Squirrel sandstone which is placed in overlying Henrietta group.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 31). Correlation chart shows that group in Iowa includes Munterville and Seahorne limestones.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 37–47. Group is defined to include all strata from base of Pennsylvanian north of Kansas-Oklahoma line to base of Fort Scott limestone. In Kansas, comprises 16 cyclothems. Classification is modified from that of Abernathy (1937) in that Croweburg and Ardmore are combined into Ardmore cyclothem; Stice cyclothem (new) occurs above the Bevier; term Mulky is discarded and terms Breezy Hill and Blackjack Creek are used.

T. R. Beveridge, 1951, Missouri Geol. Survey and Water Resources, v. 32, 2d ser., p. 51–55, pl. 11. Cherokee group, in Weaubleau Creek area, comprises Dederick subgroup (undifferentiated) and Graydon formation. Overlies Burlington formation; underlies Tertiary(?) unconsolidated upland gravels.

W. B. Howe, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2087. Formation in northern Oklahoma includes (ascending) older Pennsylvanian units, Little Cabin sandstone, Bluejacket sandstone, Broken Arrow coal, Verdigris limestone, sandstone (Squirrel sand), Iron Post coal, Kinnison shale (new), and Breezy Hill limestone members.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 68–90. McQueen defined top of the Cherokee as the base of Squirrel sandstone, but this boundary is not now recognized by Missouri Geological Survey. Cherokee is defined as extending from base of Pennsylvanian to base of Fort Scott.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1523–1526. Rocks of Krebs and Cabaniss groups (both new) are nearly but not quite the same, stratigraphically, as Cherokee rocks of southeastern Kansas. Hartshorne sandstone and possibly some lower McAlester rocks are older than any Cherokee rocks of Kansas; Thurman sandstone, Stuart shale, and lower part of Senora formation are probably not represented in Cherokee rocks of Kansas because of progressive northward overlap in post-Boggy rocks. Otherwise the Krebs and Cabaniss rocks are equivalent to Cherokee rocks of Kansas.

W. V. Searight, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2747–2749. In reclassification of Desmoinesian (Pennsylvanian) of northern midcontinent, term Cherokee is replaced by Krebs and Cabaniss groups.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, 132 p. Term Cherokee readopted for Kansas and Missouri. Krebs and Cabaniss relegated to subgroup status. Cherokee subdivided into (ascending) Riverton, Warner, Rowe, Dry Wood, Bluejacket, Seville, Weir, Tebo, Scammon, Mineral, Robinson Branch, Fleming, Croweburg, Verdigris, Bevier, Lagonda, Mulky, and Excello formations. Underlies Marmaton group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Chart shows that group in Kansas includes Krebs and Cabaniss formations.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 34, fig. 5. Section between base of Marmaton group to top of Mississippian system is designated Cherokee group. Although this may include a part of either the Atoka or Morrow series, Iowa Geological Survey has not differentiated them. Other States have further subdivided the Cherokee in Krebs-Cabaniss subgroups. Mulky coal, Bedford coal, Bevier coal, Ardmore limestone, and Whitebreast coal have been recognized.

Named for exposures in Cherokee County, Kans.

†Cherokee Slates[1]

Lower Cambrian: Western North Carolina.

Original reference: W. C. Kerr, 1869, North Carolina Geol. Survey Rept. 2, p. 13–35.

Named for development in Cherokee County, along Valley River.

Cherric period[1]

Precambrian: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46, p. 207.

Cherry shale[1]

Lower Ordovician: Eastern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53, 78.

Fully exposed on Cherry Creek, north of Ely, White Pine County.

Cherry Canyon Formation (in Delaware Mountain Group)

Lower Permian (Guadalupe Series): Western Texas and southern New Mexico.

P. B. King *in* R. K. DeFord and E. R. Lloyd, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 4 (fig. 2), 8. Delaware Mountain group divided into (ascending) Brushy Canyon, Cherry Canyon, and Bell Canyon formations (all new).

P. B. King *in* F. E. Lewis, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 92. Subdivided into (ascending) Getaway, South Wells, and Manzanita (new) members.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 579–581 (fig. 7), pl. 2. Consists largely of sandstone with several prominent limestone members; sandstones are fine grained, thin bedded, and finely laminated and have straight smooth bedding planes; in lower half, ripple marking and channeling is common feature; limestones are commonly interbedded with the sandstones, either in nodules and thin lenticular layers or in members that locally have considerable prominence. Thickness about 1,000 feet. Overlies Brushy Canyon formation; underlies Bell Canyon formation. Along west side of Guadalupe Mountains, members of formation thicken northward, the intervening sandstones disappear, and the units coalesce into a solid mass, here termed the Goat Seep limestone.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 38, pl. 3 [1949]. On west side of Guadalupe Mountains, upper three-fourths of Cherry Canyon interfingers with the Goat Seep; lower fourth persists as a layer of sandstone 200 or 300 feet thick; its outcrop extends northward past Cutoff Mountain into New Mexico and forms a weak sandy break in the limestone succession.

Named for Cherry Canyon, a shallow gorge that drains eastward from Pine Spring, south of new route of U.S. Highway 62, to a point 3 miles east of D Ranch headquarters, where gorge joins Lamar Canyon, Culberson County, Tex. Crops out in wide belt along crest of Delaware Mountains and forms upper half of slope below the Capitan limestone cliffs near Guadalupe Peak.

Cherry Canyon Schists

Precambrian: Western Utah and eastern Nevada.

R. B. Nelson, 1959, Dissert. Abs., v. 20, no. 3, p. 997. Name appears only in stratigraphic section. Thickness over 3,000 feet. Underlies unnamed metaquartzite; overlies Trout Creek schists (new).

Stratigraphic section covers northern Snake Range and the Kern Mountains in eastern Nevada and southern Deep Creek Range in western Utah.

Cherry Creek Group[1]

Cherry Creek Metamorphics or Gneiss

Cherry Creek Series

Precambrian: Central southern and southwestern Montana.

Original reference: A. C. Peale, 1896, U.S. Geol. Survey Geol. Atlas, Folio 24.

E. S. Perry, 1948, Montana Bur. Mines and Geology Mem. 27, p. 2–3. Series includes Axes Creek phase (new) in area of Axes Creek, Beaverhead County.

E. W. Heinrich, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1329. Cut by Blacktail granite gneiss (new).

E. W. Heinrich, 1949, Montana Bur. Mines and Geology Mem. 30, p. 6–8. Thickness of series about 30,000 feet in southern end of Ruby Range; contains seven main marble horizons. Younger than Pony series.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 20, 27, 29, 34. South of line connecting Melrose, Whitehall, Three Forks, and Livingston, series underlies Flathead sandstone.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 350–351, pl. 1. Group described and mapped in Lima region, Montana. Intruded by Dillon granite gneiss (term replaces Blacktail granite gneiss, preoccupied). Stratigraphic relations between Pony group and Cherry Creek not clear in this area.

R. R. Reid, 1957, Montana Bur. Mines and Geology Mem. 36, p. 4–7, 14, geol. map. Metamorphics and gneiss mapped and described in Tobacco Root Mountains. Within map area, Cherry Creek and Pony metamorphics are separated by a seemingly continuous greenish quartzite layer with only small isoclinal folds present within it. Foliation in Cherry Creek metamorphics appears to be everywhere parallel to that in Pony metamorphics in vicinity of contact. Discordance suggested by Tansley and Schafer (1933, Montana Bur. Mines and Geology Mem. 9) not observed. Most significant structural fact is that Cherry Creek metamorphics dip beneath Pony metamorphics. Unless some kind of large scale structural overturning has occurred, Cherry Creek metamorphics in Tobacco Root Mountains, are older than Pony metamorphics (in range in which their type locality has been defined). This is contrary to generally accepted opinion.

First described in vicinity of Cherry Creek, southwestern corner Three Forks quadrangle.

Cherry Creek Member (of Venango Formation)

Upper Devonian (Conewangan): Southwestern New York.

I. H. Tesmer, 1954, Dissert, Abs., v. 14, no. 12, p. 2317, 2318. Name proposed for succession of gray siltstones and shales which overlie Panama conglomerate member.

Occurs in Cherry Creek quadrangle.

Cherry Mound shale

Cretaceous: Northeastern Texas.

F. E. Lozo, 1951, Fondren Sci. Ser. 4, p. 74. Exposures of post-Grayson clay or shale of Bergquist (1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 98) in Grayson County at Pawpaw Branch and along Rock Creek in northwestern part of county, near Pottsboro cutoff railroad underpass of M. K. & T., at type locality of foraminifera *Flabellammina denisonensis* in city of Denison, and in branch of Choctaw Creek north of Cherry Mound, northeastern Grayson County, are believed to be contemporaneous and as such are informally called Cherry Mound shale. Evidence indicates this shale is Buda equivalent.

Cherry Ridge Conglomerate[1] (in Cherry Ridge Group)

Upper Devonian or Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 64.

Caps Collins high knob just west of Cherry Ridge post office, Wayne County.

Cherry Ridge Group[1]

Cherry Ridge Redbeds (in Catskill facies group)

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 64.

Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 577–581. Cherry Ridge red beds applied to dominantly red succession of somewhat varied lithology which separates Elk Mountain and Honesdale sandstones. Unit discussed under heading of Catskill facies group.

Bradford Willard and R. E. Stevenson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2272. Sequence lists Cherry Ridge red shale, 275 feet thick, in interval between Honesdale and Elk Mountain sandstones.

Well exposed near Cherry Ridge post office, Wayne County.

Cherry Ridge Limestone[1] (in Cherry Ridge Group)

Upper Devonian or Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 65–66.

Extends over large part of Wayne County. Probably named from Cherry Ridge post office.

Cherry Ridge Red Shale[1] (in Cherry Ridge Group)

Upper Devonian or Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania Geol. Survey Rept. G_5, p. 66.

Probably named from Cherry Ridge post office, Wayne County.

Cherry Ridge Sandstone[1] (in Cherry Ridge Group)

Upper Devonian or Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 64.

Forms a conspicuous rock ledge at hundreds of places in all parts of Wayne County. Probably named from Cherry Ridge post office, Wayne County.

Cherry Ridge Shales[1] (in Cherry Ridge Group)

Upper Devonian or Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 64.

Probably named for Cherry Ridge post office, Wayne County.

Cherryvale Shale[1] (in Kansas City Group)

Cherryvale Shale (in Skiatook Group)

Cherryvale Shale Member (of Kansas City Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 47–48, 102.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40 (table), 42. Included in Skiatook group. Occurs between Dennis limestone below and Drum (equivalent to Dewey) limestone above. Precisely equivalent to Nellie Bly formation (Gould, 1925, from unpub. ms. of D. W. Ohern) of northeastern Oklahoma, which by misunderstanding of section near Coffeyville was formerly thought to be an expansion of shale equivalent to part of Drum of Kansas. Thickness about 90 feet at Cherryvale; 10 feet or less west of Coffeyville; southward increases to about 125 feet east of Bartlesville and to more than 300 feet in latitude of Tulsa.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Columnar section, Jackson and Cass Counties, Mo., shows Cherryvale shale, in Kansas City group, comprises (ascending) Fontana shale, Block limestone, Wea shale, and Westerville limestone members. Overlies Dennis limestone; underlies Chanute shale.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 191. South of Linn County, where Westerville and Block limestones have not been identified, the interval between the Drum and Winterset limestones is known as Fontana-Quivira or Cherryvale shale. Near Cherryvale, unit comprises about 60 feet of bluish-gray silty shale containing layers of blue dense limestone near top.

R. C. Moore, 1948. Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030, 2031 (fig. 4). Cherryvale formation (shale), at type locality, consists entirely of shale, but farther north there are persistent limestones (Block, Westerville) that extend into Iowa and Nebraska. Formation, as recognized by interstate agreement of Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947, comprises (ascending) Fontana shale, Block limestone, Wea shale, Westerville limestone, and Quivira shale members. Overlies Dennis formation; underlies Drum limestone. Kansas City group. Classification of Missourian strata in northern Oklahoma diverges from interstate usage.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420–421. Thickness of formation about 24½ feet in Madison and Adair Counties, Iowa. Comprises (ascending) Wea-Fontana members, Westerville limestone, and Quivira shale members. Overlies Dennis formation; underlies Drum formation. Kansas City group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Comprises (ascending) Fontana shale, Block limestone, and Wea shale members. Members not differentiated in Madison County but tentatively identified in Crescent quarry, Pottawatamie County. Formation in Madison County consists of thinly bedded dark-gray shale with several thin beds of dense dark-blue-gray fossiliferous limestone. *Derbyia* and *Chonetes* abundant, latter occurring in such large numbers as to form thin coquinalike zones. Thickness about 9 feet. Underlies Westerville limestone; overlies Dennis limestone.

Named for exposures in vicinity of Cherryvale, Montgomery County, Kans.

Cherry Valley Limestone Member (or Marcellus Shale)[1]

Middle Devonian: Central and east-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, chart.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 179–180. West of Onesquethaw Creek limestones of the Stony Hollow member (new) of Marcellus become the Cherry Valley limestone as exposed in Stony Creek, Schoharie Valley.

L. V. Rickard, 1952, Am. Jour. Sci., v. 250, no. 7, p. 511–522. Overlies Union Springs member; underlies Chittenango shale. Thickness at type section 4⅔ feet; 14 to 25 feet in Berne quadrangle. This study shows Cherry Valley limestone extends farther east than was previously known. It was found at 19 new localities in Schoharie and Albany Counties.

Type section: Cox's Ravine, three-fourths mile northwest of Cherry Valley, Otsego County.

Cherryville Quartz Monzonite

Mississippian(?) to Permian(?): Western North Carolina and western South Carolina.

W. R. Griffitts and W. C. Overstreet, 1952, Am. Jour. Sci., v. 250, no. 11, p. 783–786, 787. A monazite-free rock in which three varieties have been recognized: the commonest, a gray even-grained massive to faintly gneissic muscovite-biotite rock; a muscovite-quartz monzonite; and a quartz-biotite. Unit was included in Whiteside granite as mapped by Keith and Sterrett (1931, U.S. Geol. Survey Bull. 660–D); hence, Whiteside granite is herein restricted to area of its type locality. Considered to be very late Paleozoic and younger than Toluca quartz monzonite (new).

W. C. Overstreet and W. R. Griffitts, 1955, Geol. Soc. America Guidebook 1955 Ann. Mtg., p. 566. A probable Devonian age (about 285 million years) was obtained on a sample of monazite from the Cherryville quartz monzonite.

J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Mapped as Paleozoic.

U.S. Geological Survey currently designates the age of the Cherryville as Mississippian(?) to Permian(?) on the basis of a study now in progress.

Named for exposures near Cherryville, Gaston County, N.C.

Chesapeake Group[1]

Miocene, middle and upper: Delaware, eastern Maryland, North Carolina, and Virginia.

Original reference: N. H. Darton, 1891, Geol. Soc. America Bull., v. 2, p. 431–450, map.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 33–37. Described in Prince Georges County and District of Columbia. Comprises (ascending) Calvert, Choptank, and St. Marys formations. Overlaps unconformably across Eocene Nanjemoy formation and Aquia greensand and Upper Cretaceous Monmouth formation on to the Patapsco formation of Potomac group; overlain unconformably by Brandywine formation or by Pleistocene sand and gravel.

L. W. Stephenson and F. S. MacNeil, 1954, Geol. Soc. America Bull., v. 65, no. 8, p. 733–738. Yorktown formation geographically extended into eastern Maryland. [Hence, group in Maryland includes four formations as it does in Virginia.]

Named for fact that strata border the Chesapeake Bay in Maryland and Virginia.

Cheshewalla Sandstone Member (of Vamoosa Formation)

Cheshewalla Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: D. E. Winchester, K. C. Heald and others, 1918, U.S. Geol. Survey Bull. 686–G, p. 60–61.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 12 (fig. 1), 41–43, pl. 1. Reallocated to member status in Vamoosa formation. Commonly a buff thin-bedded to massive, crossbedded fine to very fine grained sandstone or siltstone. Thickness 7 to 20 feet; average 15 feet. In northeastern part of county, closely overlain by Bowring limestone member (new); since the Bowring is commonly absent, best criteria for identifying Cheshewalla is position: 60 to 100 feet below top of Labadie limestone member; beyond northern limit of the Labadie, the Bowring is at many places present 5 to 15 feet above top of Cheshewalla; overlies Tallant formation.

Named for exposures along Cheshewalla and Nelagoney Creeks, SE¼ sec. 10, T. 25N., R. 10 E., in east central Osage County.

Cheshire Quartzite[1]

Lower Cambrian: Western Massachusetts, western Connecticut, southeastern New York, and southwestern Vermont.

Original references: B. K. Emerson, 1892, U.S. Geol. Survey Hawley sheet, that is, proof sheets of geologic maps and text intended for a geological folio, but never completed and published in that form, although cited in U.S. Geol. Survey Bull. 191, 1902; 1898, U.S. Geol. Survey Mon. 29, p. 18; 1899, U.S. Geol. Survey Bull. 159.

E. C. Jacobs, 1935, (abs.) Geol. Soc. America Proc. 1934, p. 85. In Green Mountains, westernmost nappe is made up of Cheshire quartzite, infolded with a fine-grained graywacke, which has been traced from Essex Junction into southern Quebec, where it is known as Gilman "quartzite." In Vermont, this rock has been named Brigham Hill graywacke.

E. C. Jacobs, [1937], Vermont State Geologist 20th Rept., p. 100–101. Includes Brigham Hill graywacke phase.

H. E. Hawkes, Jr., 1941, Geol. Soc. America Bull., v. 52, no. 5, p. 649–666. Concluded that roots of Taconic thrust fault most probably lie between dolomite of Pico Peak series (new) and Cheshire quartzite.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 525, 526–528. In stratigraphic succesion in west-central Vermont, Cheshire quartzite, about 1,000 feet thick, occurs above "Mendon series" and below Dunham dolomite.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 12 (fig. 2), 13 (table 1), 17–18, geol. map. Thickness in Castleton area about 400 feet. Underlies Dunham dolomite; overlies Mendon series with unconformity. As defined here, the Cheshire contains only massive pure quartzite, and subjacent dark-gray quartzites and phyllites hitherto included in Cheshire by other workers are assigned to underlying Mendon series.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 21 (table 1), 36–38. Thickness about 1,000 feet in Green Mountain anticlinorium. Underlies Dunham dolomite; contact transitional; grades downward into Moosalamoo member of Mendon formation; where Moosalamoo member is absent, Cheshire rests on Forestdale member.

Typical exposures at and near Cheshire, Berkshire County, Mass.

†Cheshire Schist[1]

[Middle Ordovician]: Massachusetts.

Original reference: R. Pumpelly, 1894, U.S. Geol. Survey Mon. 23.

Cheshire, Berkshire County.

Chester Amphibolite[1]

Original references: B. K. Emerson, 1892, U.S. Geol. Survey Hawley sheet, that is, proof sheets of geologic maps and text intended for a geologic folio, but never completed and published in that form, although cited in U.S. Geol. Survey Bull. 191, 1902; 1894, U.S. Geol. Survey Mon. 23, p. 29–30; 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 78–156, pl. 34.

Named for occurrence at Chester, Mass.

Chester Hornblendite

Age not stated: South-central Connecticut.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 50. Black medium- to coarse-grained igneous rock. Crops out within an area of Sterling gneiss for about 100 feet in a dikelike exposure.

Only outcrop is east of Saybrook State Highway and south of road leading from village of Chester to the Chester Railroad Station, town of Chester, Middlesex County.

†Chester Sandstone[1]

Mississippian: Illinois and Missouri.

Original reference: G. C. Swallow, 1858, Am. Assoc. Adv. Sci. Proc., v. 11, pt. 2, p. 5.

Named for exposures at Chester, Randolph County, Ill.

Chester Series

Chester Group[1]

Upper Mississippian: Illinois, Indiana, Iowa, Kentucky, Missouri, and Tennessee.

Original reference: A. H. Worthen, 1860, Am. Assoc. Adv. Sci. Proc., v. 13, p. 312–313.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 134–137. Chester series comprises (ascending) New Design, Homberg, and Elvira groups (all new). Chester series everywhere overlies Meramec strata (herein classified as group in Valmeyer series) unconformably, and in Monroe County, Ill., it overlaps from the Ste. Genevieve onto the St. Louis. Pennsylvanian strata are everywhere separated from older beds in upper Mississippi valley by an unconformity. In southwestern Illinois, the Chester series is completely overlapped, and Pennsylvanian beds rest upon all formations from the Kinkaid to Ste. Genevieve or possibly St. Louis limestone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 91–196, chart 5. In standard Mississippian section, Chesterian series comprises (ascending) New Design, Homberg, and Elvira groups and some post-Elvira strata. The group names introduced by Weller (1939) have had little usage to date. Following formations included in standard section (ascending): Aux Vases sandstone, Renault limestone, Bethel sandstone, Paint Creek formation. Cypress sandstone, Golconda formation, Hardinsburg sandstone, Glen Dean limestone, Tar Springs sandstone, Vienna limestone, Waltersburg sandstone, Menard limestone, Palestine sandstone, Clore formation, Degonia sandstone, and Kinkaid limstone. Chesterian series follows Meramecian series.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 35–52. In southern Indiana, rocks of Chester series have been subdivided into many formations, most of which are too thin to map on scales ordinarily used. Since names are well established in Indiana geologic literature, it is considered best to form mapping units by combining formations into groups rather than to alter the established names. In area of this report [Huron area, south-central Indiana], exposed rocks of late Mississippian age divided into (descending) Stephensport, West Baden, and Blue River (new) groups. Boundary between Chester series and underlying Meramec series falls within Blue River group.

Named for Chester, Randolph County, Ill.

Chester County Gneiss[1]

Precambrian(?): Southeastern Pennsylvania.

Original reference: T. D. Rand, 1900, Philadelphia Acad. Nat. Sci. Proc. 1900, pt. 1.

Well exposed in William's quarry, on Phoenixville Branch of Pennsylvania Railroad near Aldham Station.

Chesterfield Group[1]

Upper Triassic: Eastern Virginia.

Original reference: N. S. Shaler and J. B. Woodworth, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 435–436.

In Richmond Basin.

Chesterfield Limestone[1]

Precambrian: Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199, p. 114–115, fig. 25.

Adirondack Mountains.

Chesterian Series

See **Chester Series.**

Chestnut Sandstone Member (of Pottsville Formation)[1]

Lower Pennsylvanian: Central Alabama.

Original reference: C. Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175, p. 10.

Named for Chestnut Ridge, Jefferson County.

†Chestnut Hill Schists and Gneisses[1]

Precambrian (Glenarm Series): Southeastern Pennsylvania.

Original reference: C. E. Hall, 1881, Pennsylvania 2nd Geol. Survey Rept. C_6, p. 24–27, map.

Judith Weiss, 1949, Geol. Soc. America Bull., v. 60, no. 10, p. 1691. Discussion of structure, petrology, and metamorphism of the Wissahickon schist. Chestnut Hill schists correspond to the rocks of the garnet and staurolite zones of this paper.

Extends from vicinity of Chestnut Hill to Delaware County line at Bryn Mawr.

Chestnut Ridge Sandstone

Lower Mississippian (Kinderhook): Southwestern Pennsylvania.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Prog. Rept. 126, p. 16–17. Name will probably be used, following more definitive study of area, for unit here termed Sandstone J. Consists of massive nonfossiliferous crossbedded sandstones with few interbedded gray micaceous thin-bedded shales; formerly included in upper part of Pocono formation. Thickness 142 to 700 feet. Underlies Loyalhanna limestone; disconformably overlies Conglomerate I (Lick Run conglomerate).

Well exposed in flanks of Chestnut Ridge in gorges of Youghiogheny River, Fayette County, and Conemaugh River, forming border of Indiana and Westmoreland Counties, and along Route 40 over crest of ridge east of Uniontown, Fayette County.

Chesuncook Limestone

Silurian: North-central Maine.

Bradford Willard, 1945, Jour. Paleontology, v. 19, no. 1, p. 67–68. Described as limestone, fossiliferous in part. Total thickness about 350 feet. Part of Ripogenus [Ripogenous] series. Associated igneous intrusives. Age designated Silurian. Name attributed to L. W. Fisher (written commun., 1941).

A. J. Boucot, 1954, Am. Jour. Sci., v. 252, no. 3, p. 144–148. Discussion of stratigraphic relationships with Toppan's Ripogenous [Ripogenus] series, and Fisher's Chesuncook limestone and Ripogenus volcanics.

Occurs along shore of Chesuncook Lake, Piscataquis County.

Chetoh Formation

Miocene, lower, to Pliocene, lower: Northeastern Arizona and northwestern New Mexico.

P. W. Howell, 1959, Dissert. Abs., v. 20, no. 2, p. 641. Composed largely of sands and silts with lenses of white, rhyolitic ash. Much of the ash converted to montmorillonite. Younger than Zuni pebble zone (new); older than Bidahochi formation.

In Chetoh country, a section of Colorado Plateau north of Little Colorado River, extending from Zuni Uplift west to Painted Desert.

Chetopa shales[1]

Middle Pennsylvanian: Kansas.

Original references: C. R. Keyes, 1931, Pan-Am. Geologist, v. 56, p. 349; 1932, v. 57, p. 217, 219, 223.

Named for railroad station near Kansas-Oklahoma line, across Grand River from Cherokee County.

Chewacla Marble[1]

Precambrian: Eastern Alabama.

Original reference: W. F. Prouty, 1916, Alabama Geol. Survey Bull. 18, p. 94–95.

J. W. Clarke, 1952, Georgia Geol. Survey Bull. 59, p. 14. Incidental mention in discussion of Hollis quartzite with which it is associated in Alabama.

First described in vicinity of Olepika, Lee County.

Chewaucan Formation[1]

Pleistocene: Central southern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Typically exposed along Chewaucan River in vicinity of Chewaucan Marsh, Lake County.

Chewelah Argillite[1] (in Stevens Series)

Upper Mississippian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 63, map.

K. P. McLaughlin and M. E. Simons, 1951, Jour. Paleontology, v. 25, no. 4, p. 515. Age designated as Upper Mississippian on basis of faunal collections.

Exposed between North and South forks of Chewelah Creek and to north and south of Chewelah, Stevens County.

Cheyenne Sandstone[1]

Cheyenne Sandstone Member (of Purgatoire Formation)

Lower Cretaceous: Southwestern Kansas, southeastern Colorado, and western Oklahoma.

Original reference: F. W. Cragin, 1889, Washburn Coll. Lab. Nat. History Bull. 2, no. 10, p. 65.

Bruce Latta, 1947, Kansas Geol. Survey Bull. 65, p. 75-86. In Kiowa County, Cheyenne sandstone unconformably overlies Permian Whitehorse sandstone and conformably underlies Kiowa shale. Thickness 32½ to 94 feet.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in Cimarron County as member of Purgatoire formation.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 17 (table 3), 97-99. Extended into Baca County, Colo., where it is lower member of Purgatoire formation. Underlies Kiowa shale member; overlies Morrison formation. Thickness 50 to 134 feet.

Named for Cheyenne Rock at Belvidere, Kiowa County, Kans.

Chicago Formation[1]

Silurian (Niagaran): Northeastern Illinois.

Original reference: D. O. Taylor, 1930, Illinois Acad. Sci. Trans., v. 22, p. 473-477.

Chicago area, Cook County.

†Chicago Group[1]

Silurian: New York.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 28.

Chicago Limestone[1]

Lower Mississippian: Central northern Utah.

Original reference: S. G. Olmstead, 1921, Econ. Geology, v. 16, p. 443, 452, 453.

Ophir district.

Chicago Mound Formation

Permian (Big Blue Series): Northeastern Kansas and southeastern Nebraska.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 36 (fig. 14), 37. Name used for formation between West Branch shale above, and Towle shale below. Includes (ascending) Falls City limestone, Hawxby shale, and Aspinwall limestone. Thickness about 22 feet. Names Falls City, Hawxby, and Aspinwall were given for what were supposed to be members, but Moore ranked them on a cyclothemic basis as formations in Kansas. It is believed that they are members of a formation in

Nebraska and Kansas, and formational name Chicago Mound is applied to them.

Crops out in slopes and cuts along Highway 10, southeast of Chicago Mound, a well-known topographic feature southwest of Maple Hill, Wabaunsee County, Kans.

Chickachoc Chert

Chickachoc Chert Lentil (in Atoka Formation)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 903. In extreme northwestern Ouachitas, this formation [Wapanucka], together with the Barnett Hill formation (new), as well as the Primrose, was erroneously designated by Taff (1902, U.S. Geol. Survey Geol. Atlas, Folio 79) as Chickachoc chert lentils. Since proper position of beds, now designated as Primrose, Wapanucka, and Barnett Hill, has been established, it seems advisable to discard Chickachoc as a formational name.

T. A. Hendricks, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 66, sheet 3. Rank raised to formation. Described in block southeast of Katy Club fault in western part of Ouachita Mountains where it overlies Springer formation and underlies Atoka formation. Consists of greenish gray to tan clay shale that weathers to a tan clay and contains beds and lenses of spiculite; where fresh, spiculite is dark bluish gray and very hard; where weathered, resembles a coarse-grained sandstone or porous chert. As many as 10 beds of spiculite, each more than 5 feet thick, are present locally. In general, base of a bed of spiculite, about 10 feet thick, is assumed to be base of formation; a bed of spiculite 20 to 50 feet thick is present in middle part; a massive spiculite bed 30 to 120 feet thick constitutes top member. Estimated thickness 600 feet.

Named for post office called Chickachoc in 1901 and located at or near present station of Chockie on Missouri, Kansas, and Texas Railroad, just east of border of Coalgate quadrangle, Atoka County.

Chickahominy Formation

Eocene, upper: Southeastern Virginia (subsurface).

J. A. Cushman and D. J. Cederstrom, 1945, Virginia Geol. Survey Bull. 67, p. 2–3. Proposed for beds approximately 80 feet thick that consist of blue, gray, and dull-brown clays containing a fauna of Jackson age. Overlain by Miocene Chesapeake group; underlain by lower and middle Eocene Pamunkey group.

Type locality: Wells 2 and 4 at Navy Mine Depot, Yorktown, York County.

Chickaloon Formation[1]

Eocene or Paleocene(?): Central southern Alaska.

Original reference: G. C. Martin and F. J. Katz, 1912, U.S. Geol. Survey Bull. 500, p. 15, 42–52, map.

T. G. Payne, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–84. Age given as Paleocene(?) on map legend.

F. F. Barnes and T. G. Payne, 1956, U.S. Geol. Survey Bull. 1016, p. 14–18, pls. 1, 2. Comprises between 3,000 and 5,000 feet of claystone, siltstone, sandstone, a few thin beds of fine-grained conglomerate, and many beds of coal in Wishbone Hill district. Underlies Wishbone formation (new); in fault contact with Arkose Ridge formation (new). Of continental origin and contains abundant flora that may be either Paleocene or Eocene in age.

Covers greater part of valley of Chickaloon River south of Castle Mountain, Cook Inlet region.

Chickamauga Limestone[1]

Middle and Upper Ordovician: Eastern Tennessee, northern Alabama, northwestern Georgia, and southwestern Virginia.

Original reference: C. W. Hayes, 1891, Geol. Soc. America Bull., v. 2, p. 143, 148.

Charles Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175. In north-central Alabama, includes Attalla chert conglomerate member at base.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 18–19, geol, map. In its type area, the Chickamauga includes a number of stratigraphic units elsewhere recognized. They are named (in descending order) and grouped into map units on accompanying geologic map as follows: Maysville formation, Trenton limestone, Lowville limestone, Lebanon limestone, Lenoir (Ridley) limestone, Mosheim limestone, Murfreesboro limestone, and Newala limestone.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 64–97, pls. Mapped in eastern Tennessee. Occurs above Knox group and below Reedsville shale. Equivalents to the east are (ascending) Lenoir limestone, Holston formation, Ottosee shale, Moccasin formation, and Martinsburg shale. Explanatory text gives detailed explanation of previous usage of term and present status of stratigraphy of the Chickamauga. Middle Ordovician.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 144–145. Discussion of Middle Ordovician rocks of Tellico-Sevier belt, eastern Tennessee, and analysis of stratigraphic nomenclature. Recent work indicates that Keith's Athens shale, Tellico sandstone, Sevier shale, and Bays sandstone of southeastern belt (under discussion) are equivalents of Keith's Chickamauga and Moccasin limestone of northwestern belts.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 53–56. Except for Butts' use of name Chickamauga in Alabama, term Chickamauga has passed into disuse. Name was used so broadly throughout Southern Appalachians that it lost its value when Middle and Upper Ordovician limestones and shales were studied in detail. As originally defined by Hayes, term embraced all strata between Knox and Rockwood formations. This included what is now known as the Murfreesboro, Lenoir, Mosheim, Lebanon, Lowville, Trenton, and Upper Ordovician.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 56–57. As originally defined, Chickamauga included all limestone above Knox dolomite and beneath Sevier shale (which at that time was extended to include Martinsburg and Reedsville shales) and in this sense was used in all folios of southern Appalachian region beginning with Hayes (1894, Folio 2) and ending with Butts (1910, Folio 175). The Chickamauga as mapped in the folios, included equivalents of Kingsport and Mascot formations of this report [Mascot-Jefferson City zinc district, Tennessee] in those areas in southeastern Tennessee, northwestern Georgia, and northeastern Alabama where they were represented by Newala limestone (Butts and Gildersleeve, 1948). With close of folio mapping in Appalachian region, name Chickamauga fell into disuse, but it was revived by

Rodgers (1953) as a convenient general term for mapping. Unit, as now defined, includes limestone strata of Middle and Late Ordovician age. Unit is thinnest along southeastern edge of Appalachian Valley where it represents a very short span of time; it is thickest in sections near Cumberland Plateau Front where it represents practically all of Middle and Late Ordovician time. Ulrich, about 1900, began dividing Chickamauga limestone into a number of formations. Some of these were described by him in 1911 (Geol. Soc. America Bull., v. 22); others appeared only as names in correlation charts; and others were names used in note books and unpublished manuscripts. Only a few were ever adequately described, and fewer still have been mapped in detail. Ulrich's general concept of stratigraphy of the Chickamauga limestone was given by him in 1911; by Butts (1928, Washington Acad. Sci. Jour., v. 18, no. 37); and by Ulrich (1930, U.S. Natl. Mus. Proc., v. 76, art. 21). In general, Ulrich believed that strata included in Chickamauga group consisted of a few widely distributed formations at base, correlating with formations of Black River or later age elsewhere, and a great thickness of strata in between not equivalent to any formations elsewhere, the so-called Blount group, wedged in middle between Chazy and Black River beds. No complete section of the Blount has even been found, and at present the idea that such a unit exists has been discarded. Present theory is that a thick limestone sequence, Chickamauga limestone, developed in central and western parts of Appalachian Valley of east Tennessee and adjacent states and that this grades laterally southeastward into a complementary shale and sandstone sequence, the Sevier shale and higher formations, developed along the southeastern side of valley. The two sequences intertongue in a central belt, and by close of Middle Ordovician time shale deposition had lapped westward almost completely across the valley. In Mascot-Jefferson City district, the Chickamauga limestone—the Middle Ordovician limestone sequence—is made up of three units originally classed as formations: Mosheim limestone, Lenoir limestone, and Holston marble. In present report, the Mosheim is regarded as a member of the Lenoir.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey Rept. 3, p. 21–25. Chickamauga limestone, as used in this report [Madison County], includes deposits that have stratigraphic paleontologic relation to same rocks in interior basin of Tennessee and Kentucky. Formation includes thick sequence of rocks, primarily limestone, which lie below Red Mountain formation of Silurian age and, in Hamilton County, Tenn., is known to lie above Newala limestone of Early Ordovician age. In area of outcrop in Madison County, Red Mountain limestone is missing, and the Chickamauga lies unconformably below Chattanooga shale. Complete thickness does not crop out in county.

G. B. Martin, 1960, Gulf Coast Assoc. Geol. Soc. Trans., v. 10, p. 201–205. In northwestern Alabama, upper part of "Chickamauga" limestone, a catchall term, can be divided into Leipers and Fernvale formations on basis of diagnostic bryozoan species. Recommended that use of name "Chickamauga" be avoided in favor of Leipers and Fernvale formations.

Named for exposures along Chickamauga Creek east of Chattanooga, Tenn., and branches of that creek in Ringgold quadrangle, Georgia.

†Chickasaw Formation[1] or Group[1]
†Chickasawan Formation[1] or Stage[1]

Eocene: Mississippi, southern Alabama, Arkansas, and Louisiana.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 344–345.

Named "for the four Chickasaw bluffs, of which Memphis bluff is the last," along Mississippi River in northwestern Mississippi, within the the "Chickasaw Purchase."

Chickasaw Creek Shale or Formation (in Stanley Group)

Mississippian (Meramecian) : Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 856, 874–878. Name Chickasaw Creek siliceous shale proposed for uppermost formation in group. Measurable thickness at type locality about 270 feet; thins along southern rim of Tuskahoma syncline to only a few feet. Overlies Moyers formation (new) ; contact not exposed at type locality but is well exposed at site designated as second type locality. Underlies Wildhorse Mountain formation (new) of Jackfork group. Included in Pushmataha series (new). Bendian period.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 38–40. Formation consists of from 80 to more than 300 feet of dark-blue-gray shales interbedded with thinner laminated black siliceous shales, containing some cherty beds, and with sandstones. Thickness 270 feet at type locality; thins eastward to where it is only a few feet thick at south end of Tuskahoma syncline, and then thickens eastward in Kiamichi Mountain and in Botukola syncline. Overlies Moyers formation; underlies Wildhorse Mountain formation of Jackfork group. Mississippian (Meramecian).

Type locality: Immediately south of Chickasaw Creek in center of south line of the SW¼, 600 feet north of section line of sec. 7, T. 1 S., R. 13 E., Atoka County. Second type locality: Center of W½NE¼NE¼ sec. 26, T. 1 S., R. 12 E.

Chickasawhay Limestone

Chickasawhay Formation (in Limestone Creek Group)

Chickasawhay Marl (in Vicksburg Group)

Chickasawhay Marl Member (of Byram Marl)[1]

Oligocene, upper: Southeastern Mississippi and southwestern Alabama.

Original reference: B. W. Blanpied and others, 1934, Shreveport Geol. Soc. 11th Ann. Field Trip, p. 3, 4, 12, 16–19, charts.

B. W. Blanpied and R. T. Hazzard, 1938, (abs.) Am. Assoc. Petroleum Geologists 23d Ann. Mtg., Program, p. 11. Chickasawhay formation included in Limestone Creek group. Overlies Bucatunna formation. Miocene.

C. W. Cooke, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 10, p. 1560, 1561. Lower Chickasawhay beds are equivalent of Flint River formation of Alabama, Georgia, and Florida and of Suwannee limestone of Florida. Considered to be of Vicksburg age. Oligocene-Miocene boundary discussed. Oligocene.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1314, 1315 (fig. 1), 1346–1349. Chickasawhay limestone as herein defined is Lower Chickasawhay of Shreveport Geological Society Guidebook (1934) ; the Upper Chickasawhay is renamed Paynes Hammock sand. Overlies

Bucatunna clay member of Byram formation. Thickness about 15 to 20 feet. Believed that too many names are in use for equivalents of Chickasawhay limestone in southeast. Name Chickasawhay limestone could replace Flint River formation and unless Suwannee is emended to include the Byram, it could replace that name as well. Upper Oligocene.

C. W. Cooke, 1959, U.S. Geol. Survey Prof. Paper 321, p. 2 (table 1). Age shown as Late Oligocene.

Type section (Lower Chickasawhay): On Highway 45, 3 miles north of Waynesboro, Wayne County, Miss. Named for exposures on Chickasawhay River.

Chickasha Formation[1] (in El Reno Group)

Permian: Central southern and southwestern Oklahoma.

Original reference: C. N. Gould, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, p. 324–341, map.

L. V. Davis, 1955, Oklahoma Geol. Survey Bull. 73, p. 51–54, fig. 4 (correlation chart), pl. 1. Described in Grady and Stephens Counties where it crops out in a broad band circling southeastern end of Anadarko basin and has a maximum width of about 30 miles. An extremely heterogeneous mixture of sandstones, shales, siltstone, and siltstone conglomerates. Thickness in area of type locality 135 to 230 feet. Overlies Duncan sandstone; contact gradational. Conformable with overlying Dog Creek shale and Blaine formation undifferentiated.

Type locality: Southwestern part of T. 4 N., R. 5 W., Grady County. Named because city of Chickasha is built on formation.

Chickies Quartzite[1] **or Slate**

Lower Cambrian: Southeastern Pennsylvania.

Original reference: J. P. Lesley, 1876, Pennsylvania 2d Geol. Survey Rept. A., p. 60.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 34 (chart), 36–43; A. J. Stose and G. W. Stose, 1944, U.S. Geol. Survey Prof. Paper 204, p. 6–13, pl. 1. Described as quartzite north of Hanover-York Valley and as slate south of Hanover-York Valley. In both areas, includes Hellam conglomerate member at base. Thickness about 350 feet to about 1,000 feet. Overlies Precambrian; in some areas, base not exposed. Underlies Harpers phyllite.

B. F. Howell, Henry Roberts, and Bradford Willard, 1950, Geol. Soc. America Bull., v. 61, no. 12, pt. 1, p. 1361. Chickies quartzite used rather than Hardyston in Buckingham area, Bucks County, Carries basal conglomerate believed to be the Hellam.

Bradford Willard and others, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. C–9, p. 10, 38–41. Term Chickies quartzite used in Buckingham and Langhorne areas, Bucks County. Approximately correlative of Hardyston quartzite but distinguished by its basal member, Hellam conglomerate. Only recorded fossils: *Scolithus* and *Olenellus*. Thickness about 900 feet. Upper contact not exposed; lower contact, now hidden, is said to be with Precambrian crystalline rocks.

Name from outcrops at Chickies Rock above Columbia on Susquehanna River, Lancaster County.

Chico Formation[1]

Chico Group[1]

Chico Series[1]

Lower(?) and Upper Cretaceous: Northern California.

Original reference: W. M. Gabb, 1869, California Geol. Survey Pal., v. 2, p. XIV, as reported by J. D. Whitney from unpublished paper by Gabb, and footnote by Gabb, on p. 129.

F. M. Anderson, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1612. Chico series is nowhere found in single section but on the whole aggregates 25,000 feet or more. Begins with unconformity and overlaps in late Albian time; embraces all succeeding stages known in Europe, probably up to highest. Subdivided into Gaines group (new), western Shasta County, 5,300 feet; Panoche group, Diablo Range, 14,700 feet; Moreno group, Diablo Range, 5,000 feet.

F. M. Anderson, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1863; 1940, 6th Pacific Sci. Cong. Proc., v. 1, p. 394–398. Marine Upper Cretaceous detrital deposits in California and Oregon constitute Chico series. It is well represented in Great Valley of California where it has aggregate thickness of 26,700 feet. Representative exposures lie along west border of valley, generally in monclinal attitude, for about 400 miles. Divided into three major groups: Pioneer (new), Panoche, and Orestimba (new).

J. A. Taff, G. D. Hanna, and C. M. Cross, 1940, Geol. Soc. America Bull., v. 51, no. 9, p. 1311–1328. Results of study show that Chico Creek must be considered type locality of Chico formation (group). Cretaceous rocks exposed in Chico Creek comprise series of clastics 2,000 feet in thickness, resting unconformably on older Sierra Nevada metamorphics and covered by Tertiary volcanics. Fauna is abundant, but only meager evidence exists to correlate it with other Cretaceous localities in central valley of California.

J. M. Kirby, 1942, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 899. Chico series includes following formations (ascending): Golden Gate, Mills, Sites, Funks, Guinda, and Forbes (all new). Discussion of area on west side of Sacramento Valley south of Willows, Glenn County.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 1, p. 130–134 [preprint 1941]. For many years, Upper Cretaceous was known practically everywhere in Coast Ranges as the Chico although it was frequently recognized that the various occurrences were not always equivalent to Chico Creek section in Butte County. In 1915, term Panoche was introduced for Cretaceous along west side of San Joaquin Valley north of Coalinga. Later work has shown that Panoche, as mapped at that time, includes Knoxville, Paskenta, and Horsetown and extends across several disconformities. Recently term Chico series has been used for all Upper Cretaceous and the Panoche as upper group of this series. This usage makes the Chico include beds separated by disconformity which locally becomes pronounced unconformity. Terms Pacheco and Asuncion groups are proposed for the Upper Cretaceous of central Coast Ranges. The groups are separated by event termed Santa Lucian orogeny.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 1, p. 183–186 [preprint 1941]. Chico series divided into Pioneer (lowest), Panoche, and Moreno groups. Groups are subdivided into stages based on distribution of faunas. Depositional hiatus separates Chico from underlying Shasta series.

J. M. Kirby, 1943, California Div. Mines Bull. 118, pt. 3, p. 601–605; 606–608. Term Chico group used in these reports [Rumsey Hills and Sites anticline areas] to include formations named in reference by Kirby (1942) cited above. Overlies Horsetown formation of Shasta group. Upper Cretaceous.

J. M. Kirby 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 279–305. Discussion of stratigraphy of Chico series on west side of Sacramento Valley. Scope of term Chico series as herein applied conforms to that established by F. M. Anderson in that it includes all Upper Cretaceous sediments exposed along west side of Sacramento Valley and elsewhere in California. Seems certain that both Pioneer and Panoche groups of Anderson (Pacheco and lower Asuncion groups of Taliaferro) are represented along west side of Sacramento Valley. Moreno group (and its equivalent, the upper Asuncion group) has not been found in area under discussion, nor at any locality elsewhere in Sacramento Valley. Formational units of series are (descending) Forbes, Guinda, Funks, Sites, Yolo (replaces preoccupied name Mills), and Venado (replaces preoccupied name Golden Gate). Evidence of mid-Cretaceous disturbance of Santa Lucian orogeny, postulated by Taliaferro as separating Chico and Shasta series and as basis for his Pacheco and Asuncion groups, respectively, in Santa Lucia Range and elsewhere in Central Coast Ranges, is meager in area of this report. Maximum age range of series appears to be from Albian to lower Campanian.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 18 (table 3), 39–46, pls. Most typically developed exposures of Chico formation in area of this report [Coast Ranges immediately north of San Francisco Bay region] are on eastern slopes of Vaca Mountains. Thickness 9,000 to 12,000 feet. Chico strata exposed in Martinez syncline east and west of Martinez belong to upper part of sequence and are overlain with slight unconformity by Martinez formation.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 31. Term Chico has been so broadly applied that it no longer has resonable stratigraphic significance. Hence, in this report [San Jose-Mount Hamilton area], term Oakland conglomerate is used instead of conglomerate member of Chico as was used by Lawson (1914, U.S. Geol. Survey Geol. Atlas, Folio 193), and overlying Cretaceous rocks are named Berryessa formation.

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–88. Most extensive formation mapped in Haywood quadrangle; it is monotonous succession of biotitic arkosic sandstone and clay shale with minor siltstone and a few lenses of conglomerate overlying Oakland conglomerate. These rocks are designated Chico formation of Lawson (1914, U.S. Geol. Survey Geol. Atlas, Folio 193) although name is not entirely satisfactory. Thickness at least 2,000 feet; may be as much as 6,000; appears to thicken southeastward. In most places, overlain by Sobrante sandstone. If Chico is time-rock term, it should be properly applied only to Upper Cretaceous part of post-Oakland, pre-Tertiary section near Hayward and another name should be given to any Lower Cretaceous beds present. Lower(?) and Upper Cretaceous.

D. L. Peck, R. M. Imlay, and W. P. Popenoe, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1968–1984. Upper Cretaceous rocks in Siskiyou County, Calif., and in adjoining Jackson County, Oreg., are herein defined as Hornbrook formation. A new name to differentiate them from Chico formation in California is justified by their remote position and by their complete lack of faunas in common with Chico at its type section. Chico should be abandoned as group or series name because it has been used with many different meanings. It may be retained as formational name for rocks at and near type locality on Chico Creek. Thus restricted, the name is applied to rocks of late Coniacian to early Campanian age exposed in small area including Chico Creek, Butte Creek, Mill Creek, Deer Creek, Pence (or Pentz) ranch, and Tuscan Springs.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 8. Discussion of geology of Pleasanton area, Alameda and Contra Costa Counties. Rocks previously referred to as "Chico formation" are recognized as constituting two distinct formations, Niles Canyon and Del Valle (both new).

C. A. Hall, Jr., D. L. Jones, and S. A. Brooks, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2855, 2859. Sedimentary rocks of Cretaceous age exposed along Pacific Coast south of Pescadero Point, Calif., were originally assigned to Chico formation by Branner, Arnold, and Newsom (1909, U.S. Geol. Survey Geol. Atlas, Folio 163). Application of this term to beds lithologically different, located nearly 200 miles from type locality of Chico formation, is unwarrented in absence of established continuity between the two sections. Name Pigeon Point formation is herein proposed for the beds exposed south of Pescadero Point, San Mateo County.

Type locality (Taff, Hanna, and Cross): In canyon of Chico Creek, 8 to 16 miles northeast of Chico, Butte County. Chico Creek has cut gorge 1,000 to 1,500 feet deep through late Tertiary lava flows and tuff beds of Tuscan formation, exposing the Chico.

Chico Phonolites

Quaternary: Northeastern New Mexico.

Helen Stobbe, 1948, (abs) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1355. Occur as flows chiefly. Incidental mention only.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1021 (table 2), 1023, 1034–1036, pl. 1; H. R. Stobbe, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1073–1077. Green, fine-grained, porphyritic, soda-rich extrusives and intrusives with large feldspar phenocrysts. Some pyroxene needles. Heavily jointed. Quaternary age. Derivation of name and geographic distribution given.

Named after excellent exposures in township of Chico. Occur abundantly in triangular area between Laughlin Peak, Temples Peak, and Turkey Mountain in eastern Colfax County.

Chico Creek Beds (in Panoche Group)

Upper Cretaceous (Chico Series): Northern California.

F. M. Anderson, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1612. Incidental mention.

Occurs in Diablo Range.

Chicoma Volcanic Formation

Tertiary, middle: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103; 1938, Jour. Geology, v. 46, no. 7, p. 939–940. Consists mainly of andesite and latite flows; maximum thickness several thousand feet. Probably oldest of the four Tertiary formations named in area; succeeded by Ortega formation (new). Tertiary formations overlie pre-Tertiary rocks with angular unconformity. Rocks represent much eroded and partly buried remnants of volcanic field which dominated ancestral Valles Mountains.

Occurs in Abiquiu quadrangle, Rio Arriba County. Forms Abiquiu and Chicoma Peaks.

Chico Martinez Chert Member (of Monterey Formation)

Miocene (Mohnian-Delmontian): Southern California.

L. B. McMichael, chm., 1959, San Joaquin Geol. Soc. Guidebook Field Trip, May 9, Road log, topog. profile, columnar section, map. Overlies Antelope shale member; underlies Chico Martinez (Belridge) diatomite. Thickness about 700 feet. McDonald shale, Antelope shale, and Chico Martinez chert members are equivalent to McLure shale member of Monterey.

Occurs along Chico Martinez Creek, Kern County.

Chicopee Formation

Pre-Carboniferous(?): Southern California.

R. B. Guillou, 1953, California Div. Mines Spec. Rept. 31, p. 5, 7–10, pl. 1. Lime silicate-bearing quartzites and cross-laminated quartzites which crop out beneath the Saragossa thrust in Chicopee Canyon. These quartzites were included in Saragossa quartzite by Vaughan (1922). Thickness about 1,000 feet. In fault contact with older Baldwin gneiss (new) except in two localities where the quartzite overlies gneiss by what may be depositional contact. Stratigraphically underlies Furnace limestone. Locally intruded by Cactus quartz monzonite.

J. F. Richmond, 1955, Dissert. Abs., v. 15, no. 3, p. 394; 1960, California Div. Mines Spec. Rept. 65, p. 11. Replaced by term Chicopee Canyon; name Chicopee preempted.

Type locality: Chicopee Canyon, near Baldwin Lake, San Bernardino Mountains, San Bernardino County.

Chicopee Shale[1]

Upper Triassic: Central Massachusetts and central Connecticut.

Original reference: B. K. Emerson, 1891, Geol. Soc. America Bull., v. 2, p. 451–456.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Name replaced by Turners Falls sandstone (new) in Greenfield and northern part of Mount Toby quadrangles. Unit can not be traced into this area from its type area.

Best exposed along railroad cut near Holyoke Dam, Mass. Extends southward through Chicopee, Mass.

Chicopee Canyon Formation

Pre-Carboniferous: Southern California.

J. F. Richmond, 1955, Dissert. Abs., v. 15, no. 3, p. 394; 1960, California Div. Mines Spec. Rept. 65, p. 11–15, pl. 1. Name Chicopee formation proposed by Guillou (1953) for series of metamorphosed quartzites beneath gray marble of Furnace formation in Johnston Grade area about 7 miles northeast of Delamar Mountain. Name Chicopee is preempted and it is here proposed that name be amended to Chicopee Canyon. Rocks similar to those described by Guillou are poorly exposed in same stratigraphic position over area of a square mile on eastern and southeastern flanks of Delamar Mountain; upper part of Chicopee Canyon crops out north of Bertha Peak. Two members recognized. Lower, minimum thickness 1,000 feet, consists of crossbedded quartzite, thin-bedded quartzite, and micaceous quartzites; intruded at base by tonalite porphyry. Upper, consists of two distinctive units, 370 feet of massive quartzite overlain by 75 feet of andalusite-bearing rock. Conformably underlies Furnace formation. No fossils found in formation. Tops of beds established by truncated crossbedding indicate that strata are right side up across measured sections. As lower part of Furnace formation is Mississippian, Chicopee Canyon is early Mississippian or pre-Mississippian.

Exposed in San Bernardino Mountains, north of Big Bear Lake, San Bernardino County. Name derived from Chicopee Canyon. Quartzites exposed principally in faulted eroded anticline overturned to northwest.

Chico Ridge Limestone (in Graford Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: G. Scott and J. M. Armstrong, 1932, Texas Univ. Bull. 3224, p. 31.

Forms extensive upland known as Chico Ridge, south of Chico and north of Lake Bridgeport Dam, Wise County.

Chico Shunie Quartz Monzonite

Mesozoic(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 15 (table 1), 23–27, pl. 1; 1946, U.S. Geol. Survey Prof. Paper 209, p. 17–20, pl. 3 [1947]. The typical quartz monzonite is slightly foliated to massive and coarsely porphyritic. Light pinkish gray on fresh fracture and weathers to light brown. Conspicuous crystals of pink feldspar an inch or less in length occur in coarse groundmass. Other intrusive rocks of comparable structure mapped with this formation but may include rocks of several ages. Intrusive into Cardigan gneiss (new); intruded by border facies of Cornelia quartz monzonite (new). Underlies Daniels conglomerate (new).

Named from representative exposures in the Chico Shunie Hills, and is exposed over wide area in the southwestern part of the Ajo quadrangle, Pima County.

†Chico-Tejon series[1]

Upper Cretaceous and Eocene: California.

Original reference: C. A. White, 1889, U.S. Geol. Survey Bull. 51, p. 11–14.

Chief Consolidated Limestone[1]

Ordovician: Central northern Utah.

Original reference: G. W. Crane. 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

Probably named for Chief Consolidated mine.

Chignik Formation[1]

Upper Cretaceous: Southwestern Alaska.

Original reference: W. W. Atwood, 1911, U.S. Geol. Survey Bull. 467, p. 24, 41–48, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,-000): U.S. Geol. Survey. Appears on map legend.

Type section: In Whalers Creek, one-half mile from shore of Chignik Lagoon; Alaska Peninsula.

Chikaskia Sandstone Member (of Harper Sandstone)

Permian (Leonard Series): Southern Kansas and northern Oklahoma.

G. H. Norton, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1557. Member, 100 to 125 feet thick, is marked by benches of red sandstone separated by red and gray shales; contains numerous geoidal sugary-dolomite concretionary lentils. Overlies Stone Corral member; underlies Kingman sandstone member (new).

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1782–1785. Basal member of Harper sandstone (restricted). Has three-fold character: (1) highly variable sand and shale section at base; (2) a series of bench-forming well-cemented even-bedded red sandstones; and (3) white sandstones, dolomite lentils and concretions in red shale. Type locality designated.

Type locality: In sec. 10, T. 31 S., R. 6 W., Harper County, Kans. Named for exposures along Chickaskia River.

Childress Dolomite Member (of Marlow Formation)

Childress Dolomite Member (of Dog Creek Shale)[1]

Permian (Guadalupe Series): Northern and central northern Texas.

Original reference: A. M. Lloyd and W. C. Thompson, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 952, pl. 10.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Assigned to Marlow formation at base of Whitehorse group. Guadalupe series.

Named for outcrops in and around Childress, Childress County.

Childs Latite

Pliocene(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 15 (table 1), 47–48, pl. 1. Augite, latite, coarsely porphyritic, in thick flows, from 30 to 80 feet thick, of aa and block lava. Rocks are light gray to reddish and weather dark brown, with conspicuous mottling. Maximum exposed thickness about 700 feet. Appears to rest on Black Mountain andesite (new) at north end of Childs Mountain. Elsewhere the Black Mountain rests on the latite. It is possible that apparent occurrence of the Black Mountain beneath it is due to faulting. Also underlies Daniels conglomerate (new) in Childs Mountain.

James Gilluly, 1946, U.S. Geol. Survey Prof. Paper 209, p. 44–45, pl. 3 [1947]. In two northern localities, the latite is overlain by Batamote andesite flows. In the canyon 6½ miles west of Batamote well, on north side of Childs Mountain, the latite appears to rest on the Batamote andesite, suggesting that the latite is merely an intercalation in the Batamote series. This apparent anomaly may be due to faulting.

Flows are widespread in Ajo region from Crater Mountains north of Ajo quadrangle to Puerto Blanco Hills south of it. In Ajo quadrangle, Pima County, the largest exposures are along west slope of Childs Mountain, from which formation is named.

†Chilhowee Conglomerate[1]

Lower Cambrian: Southeastern Tennessee.

Original reference: A. Keith, 1895, Philos. Soc. Washington Bull., v. 12, p. 75, pl. 1.

Chilhowee Group[1]

Lower Cambrian and Lower Cambrian(?): Eastern Tennessee, Maryland, western North Carolina, and Virginia.

Original reference: J. M. Safford, 1856, Geol. Reconn. Tennessee 1st Rept., p. 149, 152–153.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 26–40. Name extended into Virginia although the group there may not be exactly equivalent to group in Chilhowee Mountain, Tenn. Two sets of formation names have been given individual members of group in Virginia. Names used north of Roanoke are: Loudoun formation, Weverton sandstone, Harpers shale, and Antietam sandstone; names south of Roanoke: Unicoi formation, Hampton shale, and Erwin quartzite. The Unicoi is equivalent to the Loudoun and Weverton. Basal Cambrian. Underlies Shady-Tomstown dolomite.

G. W. Stose and A. J. Stose, 1947. Am. Jour. Sci., v. 245, no. 10, p. 626. In Hot Springs area, North Carolina, group comprises (ascending) Vann quartzite (new), Sandsuck shale, Cochran quartzite, Nebo quartzite, Murray shale, Hesse quartzite, Shady dolomite, and Rome formation. Unconformable above early Precambrian granite gneiss. Lower Cambrian.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 14–23, pl. 1. Described in Elkton area, Virginia, where it comprises (ascending) Loudoun, Weverton, and Harper formations and Antietam quartzite. Overlies Catoctin greenstone; underlies Tomstown dolomite. Base of group considered base of Cambrian.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, pls. Group mapped in eastern Tennessee. Overlies Ocoee series and Mount Rogers volcanic complex or, where they are absent, the crystalline complex. Southwestern sequence comprises (ascending) Cochran conglomerate, Nichols shale, Nebo sandstone, Murray shale, and Hesse sandstone with Helenmode member at top. Northeastern sequence comprises (ascending) Unicoi, Hampton, and Erwin formations; Erwin formation has Helenmode member at top. Underlies Shady dolomite. Lower Cambrian.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 964. Group has for many years been classed by U.S. Geological Survey as Cambrian on basis of occurrence of trilobites, brachiopods, and other fossils in its upper part, the occurrence of *Scolithus* in upper and middle parts, the sedimentary homogeneity of the group, and presence in many places of well-marked unconformity at base. Relations are confused, however, because in places the Chilhowee lies on earlier sedimentary and volcanic rocks with only minor unconformity, or even conformably, and many geologists have termed these earlier rocks Cambrian also; the underlying Ocoee was thus placed in the Cambrian by Keith. Paleontological data to fix as Cambrian the age of the Chilhowee group itself are decisive only for its upper part. U.S. Geological Survey now restricts beds classed as Cambrian to those for which paleontological data are available. Helenmode formation at top of Chilhowee group is classed as Cambrian, and remaining unfossiliferous formations are termed Precambrian(?); group as a whole is classed as Cambrian and Precambrian(?).

P. B. King and H. W. Ferguson, 1960, U. S. Geol. Survey Prof. Paper 311, p. 28, 32–45, pl. 1. In area of this report [Carter and Johnson Counties, Tenn.], group comprises (ascending) Unicoi, Hampton, and Erwin formations. Overlies Mount Rogers volcanic group; underlies Shady dolomite. Lower Cambrian.

R. B. Neuman and R. L. Wilson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–131. In Blockhouse quadrangle, Tennessee, includes (ascending) Cochran formation, Nichols shale, Nebo quartzite, Murray shale, Hesse quartzite, and Helenmode formation. Overlies Wilhite formation of Walden Creek group; sequence broken by faulting. Underlies Maryvale limestone of Conasauga group; sequence broken by faulting. Most of Chilhowee group is now questionably assigned to Early Cambrian because recoverable fossils of Early Cambrian age are confined to Helenmode formation. Lower Cambrian and Lower Cambrian(?). An age determination of 584±30 million years was made from rubidium-strontium ratio in glauconite from sample of Murray shale.

Named for Chilhowee Mountain, Sevier and Blount Counties, Tenn.

Chilibrillo Limestone Member (of Caimito Formation)

Chilibrillo [Limestone or Formation]

Miocene, lower: Panamá.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (correlation chart). Name Chilibrillo used on correlation chart.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 235, 246 (fig. 12); W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 32, pl. 1. Chilibrillo limestone member is the Emperador limestone of Reeves and Ross (1930, U.S. Geol. Survey Bull. 821) and Chilibrillo formation of Kellogg (1931, Final report on field investigations of the Madden Dam and Reservoir site at Alhajuela, Panama Canal Zone: Panama Canal Rept.). Maximum thickness 100 feet; pinches out on either side of Madden basin. Overlies unnamed pyroclastics clay member; underlies unnamed calcareous siltstone member. Fossil evidence favors Miocene age, presumably early Miocene. Type region noted.

Type region: East side of Madden basin, between Madden Lake and Río Chilibrillo, C.Z.

Chillicothe till[1]

Pleistocene: Ohio to Minnesota and northern Wisconsin.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203.

Chilliwack Granodiorite[1] and Quartz Diorite

Lower Cretaceous and younger: Southern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1913, Canada Dept. Int. Rept. Chief Astronomer 1910, v. 2.

H. A. Coombs, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1948. Daly concluded Chilliwack granodiorite might have been intruded as late as Miocene; equally probable is a Jurassic age which corresponds with numerous other batholiths in Cascade Range.

Peter Misch, 1952, The Mountaineer, v. 45, no. 13, p. 4 (geol. map), 14–16. Discussion of geology of northern Cascades of Washington. Chilliwack granodiorite and quartz diorite are at least in part later than Lower Cretaceous. Younger than Skagit gneisses.

First described from occurrence at Chilliwack Lake, British Columbia.

Chilliwack Group

Carboniferous: Southern British Columbia, Canada, and northern Washington.

C. E. Cairnes, 1944, Hope [quadrangle], Yale and Westminster districts, British Columbia (1:253,440): Canada Geol. Survey Map 737-A. Described in Yale and New Westminster districts, British Columbia. Series is predominantly sedimentary and has provided collections of marine forms regarded as most probably Upper Carboniferous though they may be Permian. Extent of group beyond its type area has not been determined. It is part of a belt of strata which, particularly north and west of Fraser River, is so greatly deformed and altered that it could not be subdivided in spite of the fact that poorly preserved fossil remains indicate presence of younger beds. A large body of volcanic rocks is apparently interbedded with Chilliwack strata at international boundary.

W. R. Danner, 1958, Dissert. Abs., v. 18, no. 1, p. 195. Chilliwack group in northwestern Whatcom County, Wash., is in part divisible into a lower formation of clastics, volcanics, and limestones containing fusulinids, endothyroids, algae, corals, brachiopods, and large crinoid stems of probable early Pennsylvanian or late Mississippian age and an upper formation composed mostly of clastics and limestones containing fusulinids and bryozoa of early Permian (Wolfcampian) age.

It is not clear what relationship the Chilliwack group bears to units described as Chilliwack series and Chilliwack volcanic formation.

Chilliwack Series[1]

Carboniferous and older(?): Southern British Columbia, Canada, and central northern Washington.

R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, p. 507-516, maps 15, 16, 17. From Skagit River to gravel plain traversed by lower Fraser River, the Boundary belt crosses a number of formations which range in age from Miocene to Carboniferous, if not to Precambrian. Oldest fossiliferous sediments so far discovered date from Upper Carboniferous; these belong to thick group of rocks here named Chilliwack series, most of which are believed to be Carboniferous. A thick andesitic group forms upper part of Chilliwack series as exposed near Tamihy Creek and is named Chilliwack volcanic formation. Certain phases of Chilliwack series are probably contemporaneous with Hozomeen series. The Slesse diorite and the Chilliwack granodiorite are both in batholithic intrusive relation to Chilliwack series. Map 16 shows Chilliwack series extending south of international boundary.

H. A. Coombs, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1497. Carbonaceous phyllites crop out at widely scattered localities in vicinity of Mount Baker. Daly's (1912) Chilliwack series (not to be confused with Chilliwack volcanic formation), only 5 miles north of phyllites under Mount Baker, is composed of slates, phyllites, and limestones. It is probable that phyllites surrounding Mount Baker belong in this same general sequence.

Named for exposures along Chilliwack River, Skagit Mountain Range, British Columbia.

Chilliwack Volcanic Formation[1]

Upper Carboniferous: Southern British Columbia, Canada, and central northern Washington.

R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, p. 507, 521–522, map 16. A thick andesitic group forms upper part of Chilliwack series as exposed near Tamihy Creek and is here named Chilliwack volcanic formation. Consists mainly of thick, massive flows, which are so welded and altered as to make individual flows difficult to distinguish. Lavas are commonly amygdaloidal, with calcite filling pores; many andesites have been altered to typical greenstones and green schists; augite has relations and abundance observed in olivine-free basalts. Estimated thickness at least 2,000 feet. Map 16 shows formations extending south of international boundary.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 16–17. List shows Carboniferous sequence in northern Washington (ascending) Hozomeen series, Chilliwack volcanic formation, and Vedder greenstone. Text states that "associated with Chilliwack series are altered gabbro masses termed Vedder formation." [Use of term Chilliwack is not clear here.]

H. A. Coombs, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1496–1497. Older rocks project above surface of Mount Baker lavas in vicinity of Herman Mountain. This older rock is part of a series containing greenstone, sandstone, and graywacke. Greenstone may correspond to Daly's (1912) Chilliwack volcanic formation, type area of which is only 6 miles north of Herman Mountain; it is also possible that the greenstone may correspond to Daly's (1912) Vedder greenstone located 18 miles to northwest.

Named for exposures along Chilliwack River, British Columbia.

Chilton Sandstones (in Kanawha Formation[1] or Group)

Pennsylvanian: Western West Virginia.

Original reference: I. C. White, 1908, West Virginia Geol. Survey, v. 2–A, p. 271.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 81, 104. Massive sandstones in Kanawha group.

Probably named for occurrence at Chilton, Kanawha County.

Chimneyhill Limestone[1] (in Hunton Group)

Silurian: Central southern Oklahoma.

Original reference: C. A. Reeds, 1911, Am. Jour. Sci., 4th, v. 32, p. 256–268.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132–134. Subdivided into (ascending) Hawkins, Keel, Cochrane, and Dillard members (all new). Underlies Henryhouse formation; unconformably overlies Sylvan shale. Alexandrian-Niagaran.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 7–25; 1960, Oklahoma Geol. Survey Bull. 84, pt. 6, p. 27–66. Formation is complicated stratigraphic sequence which includes several members separated from one another by unconformities. Considering these complications, it might be advisable to drop name and elevate each member to rank of formation. However, Chimneyhill is retained here because it makes convenient stratigraphic unit. All members are similar in lithology, being fairly pure limestones with low silt and clay content.

Comprises (ascending) Ideal Quarry (replaces Maxwell's preoccupied Hawkins limestone), Keel, Cochrane, and Clarita (replaces Maxwell's preoccupied Dillard) members. Thickness 60 feet at type locality with all members present; 70 feet at old Hunton townsite, all members present; 70 feet southwest of Wapanucka, Clarita member absent. Overlies Sylvan formation; underlies Henryhouse, Haragan, or Bois d'Arc formation. Chimneyhill includes strata which represent a rather long time span, probably including representatives of both the Lower and Middle Silurian. Reeds stated type locality was at confluence of three small creeks, sec. 4, T. 2 N., R. 6 E., but this section number is in error; only Chimneyhill present in section 4 is in southwest corner and this outcrop is not on the creek. There are exposures of formation along Chimneyhill Creek in SE¼ sec. 5, T. 2 N., R. 6 E., and this is probably locality referred to by Reeds and is here designated type section.

Type locality: SE¼ sec. 5, T. 2 N., R. 6 E., Pontotoc County. Named for Chimneyhill Creek which crosses formation in northeastern corner of Arbuckle Mountains.

Chimney Rock Tongue (of Rock Springs Formation)

Upper Cretaceous: Southwestern Wyoming.

L. A. Hale, 1950, Wyoming Geol. Soc. Guidebook 5th Ann. Field Conf., p. 52, fig. 1. Sandstone tongue of the Rock Springs; extends into Mancos shale; underlies Black Butte tongue (new).

L. A. Hale, 1955, Wyoming Geol. Soc. Guidebook 10th Ann. Field Conf., p. 90 (fig. 1), 91 (fig. 2), 92, 93 (fig. 3). Name applied to prominent littoral and epineritic sandstones which project eastward from main body of Rock Springs into marine shales. Composed of three prominent cliff-forming reddish-brown sandstones; each successive sandstone projects farther into enclosing shale before losing its identity. Contact with overlying Black Butte tongue sharp.

Named for Chimney Rock, sec. 6, T. 16 N., R. 102 W., Sweetwater County. Forms prominent hogback in Linwood-Spring Gap area.

China Mountain Formation

Lower and Middle(?) Triassic: North-central Nevada.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]; H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–15]. Conglomerate, sandstone, shale, and yellowish, impure dolomite. At base, fanglomerate and conglomerate up to 100 feet thick, containing chert and quartzite fragments up to 2 feet in diameter. May include at top the thinned equivalent of Favret formation. Thickness about 500 feet. Overlies Koipato and Havallah formations with angular unconformity.

Type locality: West slope of China Mountain, Golconda quadrangle.

China Ranch Beds

Quaternary: Southeastern California.

J. F. Mason, 1948, Geol. Soc. America Bull., v. 59, no. 4, p. 336 (table 1), pl. 2. Light-colored saline clays with bedded gypsum; lacustrine origin. Thickness about 1,200 feet. Unconformably overlain by Quaternary gravel beds; uncomformable below unnamed lake beds.

Occurs in Tecopa area, in southeasternmost corner of Inyo County.

Chinati Series[1]

Permian: Southwestern Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Mineral Survey Bull. 8, p. 10–25.

J. W. Skinner, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 180–188. Udden recognized three formational divisions in Chinati series (ascending): Cieneguita, Alta, and Cibolo. He assigned entire series to Permian. Present report is a study of section selected by Udden as type of all three of his formations. Concluded that Udden's original age assignment was very nearly correct, much more so than later correlations based on fossils collected from exposures other than type locality.

Described in Shafter district, Chinati Mountains, Presidio County.

Chinati Mountain Volcanic Series or Group

Tertiary: Western Texas.

C. C. Rix, 1952, Geologic map of Chinati Peak quadrangle, Presidio County, Texas (1:48,000): Texas Univ. Bur. Econ. Geology, Prelim, ed. As shown on map legend, Chinati Mountain volcanic series occurs above Buck Hill volcanic series. Oligocene and younger.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 558. Chinati Mountain series in Chinati Mountains may be same age as Rawls basalt.

D. L. Amsbury, 1957, Dissert, Abs., v. 17, no. 9, p. 1981. Chinati Mountain group (emended) overlies Petan trachyte (new).

D. L. Amsbury, 1958, Texas Bur. Econ. Geology Quad. Map 22. Chinati Mountain group, composed of more than 3,500 feet of plagioclase trachyte, rhyolite, and tuff, crops out south of Shely fault to form Chinati Mountains. Group is here expanded to include 1,500 feet of plagioclase trachyte, tuff, and local basal conglomerate which are probably older than lowest unit at type locality as designated by Rix (1953, unpub. thesis). Where base is exposed, group overlies Comanche strata; in fault contact with older Shely group (new). Older than Allen intrusive complex.

First mapped in Chinati Peak quadrangle, Presidio County.

Chinitna Shale,[1] **Siltstone,** or **Formation**

Chinitna Shale Member (of Shelikof Formation)

Upper Jurassic: Central southern Alaska.

Original reference: G. C. Martin and F. K. Katz, 1912, U.S. Geol. Survey Bull. 485, p. 65, table opposite p. 30, map.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 202 (table 1), 207. Member of Shelikof formation. Gray shale with stringers of fine and coarse sandstone and buff-weathering limestone. Thin porphyry sill intrudes section at Wide Bay. Thickness 400 to 1,300 feet. Overlies Tuxedni sandstone on Iniskin-Chinitna Peninsula. Underlies unnamed gray sandy shale unit of Shelikof.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Chinitna siltstone consists of approximately 2,000 feet of arenaceous siltstone which lies conformably between Tuxedni and Naknek formations in area between Chinitna and Iniskin Bays.

R. W. Imlay, 1953, U.S. Geol. Survey Prof. Paper 249–B, p. 49–51, table 5 facing p. 60. Tonnie member, which previously was assigned to Tuxedni formation, forms roughly lower third of Chinitna formation. Formation underlies Naknek formation in Cook Inlet region and as mapped at Matanuska Valley may include beds older than typical Chinitna.

Well exposed on west side of Chisik Island, on both shores of Chinitna and Oil Bays, and on east shore of Iniskin Bay. Occurs in area extending from Iniskin Bay to Tuxedni Bay, Cook Inlet region.

Chinle Formation[1] (in Dockum Group)

Upper Triassic: Northern Arizona, southwestern Colorado, southeastern Nevada, northern New Mexico, and Utah.

Original reference: H. E. Gregory, 1915, Am. Jour. Sci., 4th, v. 40, p. 102.

H. R. Stagner, 1941, *in* L. H. Daugherty, Carnegie Inst. Washington Pub. 526, p. 10, 11–12. In Blue Forest locality, Arizona, three units are recognized in Chinle formation: lower bentonitic shale zone; Newspaper Rock sandstone (new) leaf shale unit; and upper bentonitic shale zone.

H. E. Thomas and G. H. Taylor, 1946, U.S. Geol. Survey Water-Supply Paper 993, p. 20, 22–23. Described in Cedar City and Parowan Valleys, Utah, where it is 1,950 feet thick, overlies Shinarump conglomerate and underlies Navajo sandstone. Section in Coal Creek Canyon described in detail (beds numbered 15 through 30). No perceptible stratigraphic break noted between Chinle and Navajo. Between shaly sandstones and sandy shales that are typical of Chinle and massive beds that are clearly identifiable as Navajo, there is transition zone several hundred feet thick which might doubtfully be included in either formation. This transition zone, represented in Coal Creek section by beds 26 to 30 is here assigned to Chinle, although beds 26 and most of 27 are quite similar to typical Navajo.

J. M. Gorman and R. C. Robeck, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 44. Assigned to Dockum group.

V. C. Kelley and G. H. Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. In Lucero uplift comprises two members: red shale below and sandstone member here named Correo. Overlies Shinarump conglomerate; underlies Wingate sandstone.

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. Described in Sandoval and Rio Arriba Counties, N. Mex., where it unconformably overlies Cutler, Yeso, and San Andres formations and underlies Wingate(?) sandstone. Lower part of formation divided into (ascending) Agua Zarca sandstone member, Salitral shale tongue, and Poleo sandstone lentil (all new).

Ernest Dobrovolny and C. H. Summerson, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 62. In Quay County, N. Mex., subdivided into two members: lower, unnamed; upper, herein named Redonda. Overlies Santa Rosa sandstone; underlies Wingate(?) sandstone.

H. E. Gregory and N. C. Williams, 1947, Geol. Soc. America Bull., v. 58, no. 3, p. 227–228. Described in Zion National Monument where it is subdivided into four members: lower unnamed sandstone, 20 to 60 feet; Petrified Forest member (new), 300 to 400 feet; Springdale sandstone member (new) 40 to 180 feet; and upper sandstones, 500 to 800 feet. Overlies Shinarump conglomerate; underlies Navajo sandstone.

C. R. Longwell, 1952, Utah Geol. Soc. Guidebook 7, p. 34, 35. In Muddy Mountains, Nev., the Chinle formation with Shinarump member at base is 1,500 to 2,500 feet or more thick. Underlies Aztec sandstone; overlies Moenkopi formation. In Frenchman Mountain area, underlies Thumb formation (new) with angular unconformity.

P. D. Procter, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 18–38, pl. 2. In Silver Reef area, Utah, Chinle formation consists of about 1,100 feet of alternating sandstones and shales with exception of two small beds of cherty limestone. On basis of color and lithology, formation is subdivided into a lower member consisting predominantly of dark-red shales and minor interbedded red sandstones 265 feet thick overlying Shinarump formation, a prominent 5- to 15-foot bed of white arkosic sandstone, 10 to 15 feet of purplish- to bluish-gray bentonitic shales with included banded chert, 310 feet of deep-red to brick-red sandstone and shales with an included 1-foot bed of white silicified limestone, 65 feet of buff weathering to white sandstone overlain by 35 feet of lavender to purple sandstone together known as Silver Reef sandstone (Reeside and Bassler, 1922, U.S. Geol. Survey Prof. Paper 129) and an upper Chinle which consists of more than 400 feet of red shales and sandstones with some white, friable sandstone beds locally more than 10 feet thick. Lower Chinle subdivided into (ascending) Hartley shales and sandstones, Fire Clay Hill bentonitic shales, and Trail Hill sandstone members (all new). These members do not have wide areal extent. Upper Chinle subdivided into (ascending) Silver Reef sandstone, and Duffin sandstone and shale (new) members.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. In northwestern Mora County, N. Mex., conformably overlies Santa Rosa sandstone; underlies Naranjo formation (new). Thickness 640 feet.

J. H. Stewart and J. F. Smith, Jr., 1954, Intermountain Assoc. Petroleum Geologists [Guidebook] 5th Ann. Field Conf., p. 29–33. Chinle in southeastern Utah has been divided into six units (ascending) : claystone and sandstone unit, a sandstone commonly called "Moss Back," variegated claystone unit, reddish-orange unit, limy unit, and reddish siltstone unit. Four of these units appear to be correlative with the four divisions of Chinle recognized by Gregory (1917, U.S. Geol. Survey Prof. Paper 93) in Navajo Indian Reservation of Arizona. Claystone and sandstone unit is equivalent to "D" division, the variegated claystone unit equivalent to "C" division, the limy unit equivalent to "B" division, and reddish siltstone unit equivalent to "A" division. Overlies Moenkopi; underlies Wingate.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2518–2519, 2520, 2522. As restricted herein, includes beds between top of Shinarump conglomerate and disconformity at base of Moenave formation (Dinosaur Canyon member). At Kanab, and elsewhere in southwestern Utah, restricted Chinle includes only lower part of Chinle as mapped by Gregory (1950, U.S. Geol. Survey Prof. Paper 220). Units 26 and 27 of Coal Creek Canyon section of Chinle (Thomas and Taylor, 1946) are here designated Shurtz sandstone tongue of Navajo sandstone; units 28, 29, and 30 of Thomas and Taylor's section are here designated Cedar City tongue of Kayenta formation.

R. C. Robeck, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 10, p. 2499, 2502 (fig. 2). In Temple Mountain area, Utah, comprises (ascending) Temple Mountain (new), Moss Back, and Church Rock members. Overlies Moenkopi formation; underlies Wingate sandstone.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (table), 5–7. Contact between Chinle formation and Glen Canyon group in Navajo country lies between Gregory's "A" and "B" (1917, U.S. Geol. Survey Prof. Paper 93) divisions of the

Chinle. Rocks long assigned to Chinle formation are therefore included in Glen Canyon group. The "A" division has been reassigned to Wingate sandstone and is herein named Rock Point member of Wingate. This reassignment of the Chinle "A" was based upon intertonguing between the Wingate sandstone and the Chinle "A" in several areas.

J. H. Stewart, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 441–462. Discussion of proposed nomenclautre of part of Upper Triassic strata in southeastern Utah. Chinle is subdivided into (ascending) Temple Mountain, Shinarump, Monitor Butte, Moss Back, Petrified Forest, Owl Rock, and Church Rock members. Overlies Moenkopi formation; underlies Wingate sandstone.

J. A. Momper, 1957, Four Corners Geol. Soc. [Guidebook] 2d Field Conf., p. 86 (chart), 91, 92. Agua Zarca and Salitral members removed from Chinle and assigned to Moenkopi formation.

J. P. Akers, M. E. Cooley, and C. A. Repenning, 1958, New Mexico Geol. Soc. Guidebook 9th Field Conf., p. 91. Chart shows that Chinle in St. Johns area, Black Mesa basin, comprises (ascending) Shinarump, Mesa Redondo, and Petrified Forest members.

E. M. Shoemaker and W. L. Newman, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1838, 1841, 1845. In salt anticline region, overlies Pariott member (new) of Moenkopi.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2004–2005. Stratigraphic nomenclature revised in Tucumcari-Sabinoso area, New Mexico. Chinle stratigraphically restricted above to exclude Redonda member which is herein given formation rank.

Named for Chinle Valley, northeastern Arizona.

Chinook Pass Diorite Porphyry

See Keechelus Andesitic Series.

Chino Quarry Limestone[1]

Upper Paleozoic(?): Southern California.

Original reference: J. W. Daly, 1935, Am. Mineralogist, v. 20, no. 9, p. 638–647, map.

A. O. Woodford, R. A. Crippen, and K. B. Garner, 1941, Am. Mineralogist, v. 26, no. 6, p. 351, 354–355. Probably Upper Paleozoic.

Well exposed in Chino Quarry at Crestmore, Riverside County.

Chino Quarry Quartzite[1]

Paleozoic(?): Southern California.

Original reference: J. W. Daly, 1935, Am. Min., v. 20, no. 9, p. 638–647, map.

Named for quarry at Crestmore.

Chipman Formation

Chipman Group

Lower Ordovician: West-central Vermont.

Marshall Kay and W. M. Cady, 1947, Science, v. 105, no. 2736, p. 601. Group named to include the Burchards (new) and succeeding Beldens limestone and dolomites. Underlies Middlebury limestone. Chazyan series.

W. M. Cady and E-an Zen, 1960, Am. Jour. Sci. v. 258, no. 10, p. 728–739. Chipman formation of west-central Vermont is rock unit in uppermost part of Lower Ordovician, of Beekmantown age, between underlying Bascom formation and overlying rocks of Middle Ordovician (Chazy) age. Structural setting is Middlebury synclinorium and adjacent areas to west. Characterized by four principal rock types: buff to brown, sharply defined, and laterally persistent beds of massive dolomite; white to blue-gray limestone; gray limestone with thin interbeds of sandy limestone; and blue-gray limestone with irregular spots of dolomite. These lithofacies are interbedded in type section. Formation was first referred to as group (Kay and Cady, 1947) but is herein reduced to formation rank. Beldens formation and Weybridge member of Beldens (Cady, 1945), the Burchards limestone (Kay and Cady, 1947), and Bridport dolomite (Cady, 1945) are redefined as members of Chipman. Weybridge and Burchards have not been mapped north of Middlebury synclinorium, whereas Beldens and Bridport are considered formations in northwestern Vermont (Kay, 1958) that correlate in time with all or part of Chipman formation. All units of Chipman overlie Bascom formation and underlie Middlebury limestone. In Cornwall area, the Chipman is exposed in belt of discontinuous outcrops of rock of Beekmantown age that extends from about 1 mile south of village of Cornwall through The Ledges into town of Weybridge. Chipman is in section that, at latitude of The Ledges, includes three Cambrian formations—Winooski dolomite, Danby formation, and Clarendon Springs dolomite—as well as Ordovician formations of Beekmantown, Chazy, Black River, and Trenton age. Distribution and relationships of units are about as described and mapped by Cady (1945), though their terminology is partly changed. Shelburne is referred to as a formation; the "Crown Point limestone" becomes Burchards member of Chipman formation; and Orwell limestone is now assumed to be Black River age rather than Trenton. Cutting and Bascom formations and Bridport dolomite member are as mapped by Cady (1945) at Bascoms Ledge, but Middlebury limestone is expanded westward and downward stratigraphically to top of Bridport and includes rocks that had been interpreted as "Crown Point limestone" and "Beldens formation." Orwell limestone on summit of De Long Hill was misidentified as Beldens during previous mapping. The first and apparently the correct, interpretation of stratigraphic relationships of Beldens and Burchards members to Bridport member was given by Augustus Wing (*in* Dana, 1877, Am. Jour. Sci., 3d, v. 13, no. 77; no. 78). One of the purposes of present paper is to call attention to Wing's conclusions in further support of the inclusion of the Bridport as a member of Chipman and the time-stratigraphic unity of the various lithofacies of the Chipman. Wing referred to both the Bridport and the Beldens as unit 6, the "*Rhynchonella* beds" and left no doubt that the two are to be correlated. Beneath the Beldens in section near and north of Cornwall village is Burchards, a limestone that Wing referred to as unit 5c. He mentioned the local occurrence of this unit in The Ledges north of Cornwall. Recent mapping shows that the Burchards is a lithofacies extensive enough to be mapped as member of the Chipman north and south of village of Cornwall. Also in section near and north of Cornwall is Weybridge member (Cady, 1945), which was referred to by Wing as the "striped stratum" in the "*Rhynchonella* beds." Wing also mentioned the "striped stratum" in the "*Rhynchonella* beds" at Bascoms Ledge. There the "*Rhynchonella* beds" are now known as Bridport member of Chipman. Brainerd (1891, Geol. Soc. America Bull., v. 2, p. 293–300) assigned a Chazy age to Zone 4 of Bascom formation ("Calciferous D4") and to whole sequence now known as Burchards and Beldens members of Chipman in The Ledges north of Cornwall village. This incorrectly made these units younger than Bascom Zone 4 and Bridport (Beekmantown) of section at Bascoms Ledge. Cady (1945) recognized Zone 4 of the Bascom in The Ledges in Cornwall but followed Brainerd in correlating Wing's unit 5c (the Burchards) with Crown Point limestone of middle Chazy age. The Beldens was mistakenly extrapolated into section east of and stratigraphically above the Bridport southwest of De Long Hill (Cady, 1945). The rock above the Bridport here is actually Middlebury limestone, which is of Chazy age. Kay and Cady (1947) proposed that the "Crown Point" formation east of Champlain thrust in west-central Vermont be designated Burchards limestone with type locality in belt of outcrop between Cornwall village and The Ledges. This seemed advisable because of structural separation from typical Crown Point limestone. Kay (1950; 1958) recognized fauna in the Weybridge supporting a late Beekmantown age as well as stratigraphic correlation of the Weybridge and the Beldens with Bridport. Rock of Chazy age in vicinity of Shoreham village is structurally isolated from Middlebury limestone and lithically and faunally like the typical Crown Point limestone; it is here continued as the Crown Point.

Named from Chipman Hill in outcrop belt north of Middlebury village, Addison County.

Chipola Formation (in Alum Bluff Group)[1]

Chipola facies (of Alum Bluff Stage)

Miocene, lower: Northwestern Florida and southeastern Alabama.

Original reference: Julia Gardner, 1926, U.S. Geol. Survey Prof. Paper 142, p. 1–2.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 161–167. Typical part of formation is fine blue-gray to yellow sand crowded with shells. This facies appears to be confined to vicinity of Chipola and Apalachicola Rivers, where it lies at base of formation and is about 10 feet thick. Beds above it are less fossiliferous, and the sand is more or less cemented by calcium carbonate. Farther west are two principal facies—sandy limestone, which for most part is buried beneath younger deposits, and a coarse light-colored sandy facies including lenses of light-colored or variegated clay; this latter facies may be littoral equivalent of the limestone. Thickness at least 20 feet; as much as 56 feet has been reported. Seems to merge laterally into Hawthorn formation. Underlies Shoal River formation; directly and unconformably overlain by Duplin marl from Washington County eastward.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 22–24. A facies in Alum Bluff stage. At type locality, facies is blue-gray to yellowish-brown highly fossiliferous marl studded with molluscan shells; thickness about 28 feet. This marly facies is restricted to vicinity of Chipola and Apalachicola Rivers. Farther west Cooke (1945) recognized two facies: sandy limestone which for the most part is buried and light-colored coarse sandy facies with lenses of clay. Lower Miocene.

C. W. Cooke, 1959, U.S. Geol. Survey Prof. Paper 321, p. 2 (table 2). Table shows Chipola as middle Miocene.

Type locality: McClelland's Farm, near Bailey's ferry, northern Calhoun County, Fla. Named for exposures on Chipola River, Jackson County. Type locality of facies: Tenmile Creek, from bridge to one-half mile below bridge on Marianna-Clarksville Road, 2,376 feet south of NW cor. sec. 12, T. 1, N., R. 10 W., 22 miles south of Marianna, Calhoun County.

†Chipola Marl Member (of Chipola Formation)[1]

Miocene, lower: Northern Florida and southeastern Alabama.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 112–113, 120, 122, 157, 324.

Named for exposures on Chipola River, especially at McClelland Farm, south of Tenmile Creek, Jackson County, Fla.

†Chippewa Felsite (in Ashbed Group)[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: W. C. Gordon, 1905, Michigan Acad. Sci. 7th Rept., p. 188–195.

Crops out only in Black River and on Chippewa Bluff near Bessemer, Gogebic County.

Chippewa Granite[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1934, New York State Mus. Bull. 296, p. 86.

Exposed in valley of Chippewa Creek, Hammond quadrangle. Derivation of name not stated.

†Chippewa Porphyry (in Ashbed Group)[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: F. E. Wright and A. C. Lane, 1909, Michigan Geol. Survey Rept. State Board 1908, pl. 1.

Porcupine Mountains.

Chippewa Quartzite[1]

Precambrian (upper? Huronian): Central northern Wisconsin.

Original reference: E. T. Sweet, 1876, Wisconsin Acad. Sci. Trans., v. 3, p. 40–55.

Named for exposures on Chippewa River, Chippewa County.

†Chiquito sandstone

Precambrian (Chuaran series): Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 112. Lowermost beds are shallow-water deposits with abundant ripple marked bedding planes. Massive sandstones follow; then shaly sandstones. Thickness 300 to 400 feet. Underlies Gunther dolomite (new); overlies Cardenas lava series (new).

[C. R.] Keyes, 1939, Pan-Am. Geologist, v. 71, no. 1, p. 69. Name previously used for another unit and is abandoned in favor of the new name Aguja sandstone.

Name derived from the Rio Colorado Chiquito or Little Colorado River, opposite the mouth of which the strata are well exposed.

Chiquito sandstones[1]

Permian (Aubreyan series): Northern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 251, 336.

Named for exposures in lower valley of Rio Chiquito Colorado in Grand Canyon region.

Chiricahua Limestone[1] (in Naco Group)

Permian: Southeastern Arizona and southwestern New Mexico.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 532, 536.

F. F. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, pt. 1, p. 498. Concha limestone is undoubtedly same unit which Stoyanow (1926, Am. Jour. Sci., 5th, v. 12; 1936) mentioned from the Chiricahua Mountains and correlated with the Kaibab. He proposed Chiricahua limestone for these beds, but no type section was ever designated or described, and term has seldom been used by later writers. Suggested that terms Chiricahua limestone and Snyder Hill formation be suppressed and that term Concha limestone be used for the light-colored cherty limestones of southeast Arizona that contain Kaibab fauna and overlie Scherrer formation.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 11 (table 2), 41–43, pl. 1. Included in Naco group. In Peloncillo Mountains, term Chiricahua limestone is used for cherty limestone overlying Scherrer quartzite. Belived that Chiricahua limestone and Concha limestone are same stratigraphic unit and that the terms are synonymous; because of priority, term Chiricahua limestone should be retained. In Peloncillo Mountains, consists principally of thick-bedded light-gray medium-grained limestone containing irregularly shaped grayish-pink chert nodules. Estimated thickness 800 feet. Underlies McGhee Peak formation (new) of Bisbee group; intruded by Cienega Peak granite (new).

Exposed in Chiricahua Mountains near New Mexico border.

Chiricahuan series[1]

Upper Cambrian: Arizona and New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State printer, p. 4, 6.

Chisholm Shale[1]

Chisholm Formation

Chisholm Shale (in Bright Angel Group)

Middle Cambrian: Eastern Nevada, northwestern Arizona, southeastern California, and western Utah.

Original reference: C. D. Walcott, 1916, Smithsonian Misc. Colln., v. 64, no. 5, Pub. 2420, p. 409–410.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1158 (fig. 6), 1160. Thickness emended [type section] 137 feet. Overlies Lyndon limestone; underlies Highland Peak limestone.

H. E. Wheeler, 1940, Nevada Univ. Bull., Geology and Mining Ser., no. 34, p. 12 (fig. 2), 14–15. Underlies Peasley limestone (new); Highland Peak limestone restricted to exclude Peasley.

H. E. Wheeler, 1943, Geol. Soc. America Bull., v. 54, no. 12, pt. 1, p. 1794, 1816–1817, pl. 1. Geographically extended into western Grand Canyon area, Arizona, where it is about 99 feet thick. Underlies Peasley limestone and overlies Lyndon shale.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 32, 35. Geographically extended into Wah Wah Range, Utah, where it is 56 feet thick. Not distinguished from Peasley and Lyndon limestones in House Range, and here the undifferentiated unit is named Millard limestone. Through discovery of Lyndon limestone in southeastern California, the Chisholm could be differentiated there. In Nopah-Johnnie region, Chisholm shale includes members 5F and 5G of Hazzard's (1937, California Jour. Mines and Geology, v. 33, no. 4) Cadiz formation.

H. E. Wheeler and V. S. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 10, p. 2413 (fig. 2), 2414. Generalized discussion of designation of stratigraphic units. Chisholm shale is included in Bright Angel group in one area, and classed as member of Bright Angel shale in another area.

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 339, pls. 32, 33. In Nye and Clark Counties, Nev., underlies Jangle limestone (new); conformably overlies Lyndon limestone.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 48 (fig. 3), 49–50. Proposed here that name Chisholm formation be applied to unit in House Range that Wheeler (1948) designated as Burnt Canyon limestone. Wheeler assigned only a 35–foot shale unit to the Chisholm in the Wah Wah Range. A second 10-foot shale bed with a *Glossopleura* fauna occurs about 150 feet above Chisholm shale of Wheeler. Proposed here that the entire 195-foot shale and limestone sequence be assignd to Chisholm formation. Elsewhere in eastern Great Basin, Chisholm shale occurs in middle of Millard limestone of Cohenour (1959) in Sheeprock Range and of Rigby (1958) in Stansbury Mountains. Further east, the Chisholm merges into lower part of Ophir shale and in Tintic and Ophir districts; to the west, the shales finger out. As defined in this paper, the Chisholm underlies the Dome and overlies the Howell in the House and Wah Wah Ranges and underlies the Peasley and overlies the Lyndon in Pioche district.

Type locality: Vicinity Chisholm mine and Half Moon Gulch, 2 to 3 miles northwest of Pioche, Nev.

Chisholm Creek Shale Member (of Wellington Formation)

Permian: Central Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 5, 11–12. Soft blocky drab claylike shales which weather greenish. Locally, thin zones of red clay. Thickness approximately 40 feet. Underlies Carlton limestone member; overlies Annelly gypsum member (new).

Type locality: Along east branch of Chisholm Creek, beginning in SW sec. 35, T. 26 S., R. 1 E., Kechi Township.

Chisik Conglomerate Member (of Naknek Formation)[1]

Chisik Member (of Naknek Formation)

Upper Jurassic: Central southern Alaska.

Original reference: G. C. Martin and F. J. Katz, 1912, U.S. Geol. Survey Bull. 485, p. 68–69.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Chisik member, 300 to 600 feet thick, consists of a sandstone and a conglomerate facies. On south shore of Chinitna Bay and on Oil Bay, member almost entirely of sandstone. On east shore of Iniskin Bay, member consists of conglomerate which extends as a tongue into the sandstone. Conglomerate facies traced eastward to within 2 miles of Iniskin Bay, where it gradually interfingers with sandstone. Underlies unnamed siltstone member.

A. S. Keller amd H. N. Reiser, 1959, U.S. Geol. Survey Bull. 1058–G, p. 269–270, 287, pls. 29, 30. Martin and Katz (1912) originally applied name Chisik to a conglomerate at base of Naknek formation and treated it as a unit of formational rank overlying Chinitna shale and underlying Naknek formation. Martin (1926, U.S. Geol. Survey Bull. 776) treated the Chisik conglomerate as basal member of Naknek formation, and this is its present usage. The Chisik consists of irregularly banded marine conglomerate which, north of area of this report [Katmai region], may be as much as 1,000 feet thick. Underlies unnamed member of Naknek.

Type locality on Chisik Island, Cook Inlet region.

Chisna Formation[1]

Carboniferous: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 33, map.

Crops out at head of Chisna River and in hills east and west of the Chisna, central Copper River region.

Chisos Volcanics

Chisos Beds[1]

Upper Cretaceous and Tertiary: Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 60–67.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol. Survey Prof. Paper 312, p. 16–17, pl. 1. Volcanics described in Terlingua district where they consist of lava flows, tuffs, and interbedded sedimentary rocks. Principal occurrence is at Fresno mine, where they unconformably overlap Boquillas flags. South of mapped area volcanics overlie Tornillo rocks in apparent conformity. Thickness not determined. Age cannot be closely estimated; probably ranges through uppermost Cretaceous well into Tertiary.

Named for Chisos Mountains, Brewster County.

Chispa Andesite[1]

Tertiary: Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 64.

Chispa Hills, Goldfield district.

Chispa Summit Formation[1]

Upper Cretaceous (Gulf Series): Southwestern Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 271, 426, 431.

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology, Geol. Quad. Map 23. Described in Van Horn Mountains. Formation is a marine sequence of flaggy limestone and calcareous shale that crops out in narrow band along western margin of mountains and in northwest-trending belt in central Van Horns south of Willoughby Windgap. Thickness at Chispa Summit 840 feet; section incomplete. Lower 150 feet composed predominantly of pale yellowish-brown flaggy fossiliferous microcrystalline limestone with interbeds of calcareous, illitic shale; above lower 150 feet limestone content decreases and rocks are mostly grayish-orange, gypsiferous, calcareous illitic shale. Lies disconformably on Buda limestone; contact sharp. Underlies Tertiary Colmena formation.

First described in Chispa Summit region, western Jeff Davis County.

Chita Sand Member (of Catahoula Formation)[1]

Miocene: Eastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 715, 717.

F. E. Smith, 1958, Soc. Econ. Paleontologists Mineralogists and Houston Geol. Soc. Guidebook Ann. Field Trip, p. 9 (columnar section), 13–14. Basal member of Catahoula. Underlies Onalaska clay member. Thickness 10 to 80 feet. Age of Catahoula, as used in Texas and Louisiana, is still in question. Columnar section of field trip area [Brazos River valley] shows Oakville-Catahoula as Miocene.

Type locality: Exposures along north facing escarpment near Chita, Trinity County.

Chitistone Limestone[1]

Upper Triassic: Eastern Alaska.

Original reference: O Rohn, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 426.

F.H. Moffit, 1938, U.S. Geol. Survey Bull. 894, p. 44–52, pl. 2. Bluish-gray limestone, prevailingly in thicker beds and with fewer and thinner shale partings than the overlying Nizina limestone. Black chert bodies of irregular form numerous in places. Thickness 1,900 feet in Nizina district.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Exposed at junction of Nizina and Chitistone Rivers, hence the name. Nizina-Tanana region.

Chitka Point Formation

Tertiary or Quaternary: Alaska.

H. A. Powers, R. R. Coats, and W. H. Nelson, 1960, U.S. Geol. Survey Bull. 1028–P, p. 539–541. pl. 69. Lava flows and flow breccia of porphyritic andesite, interbedded with marine conglomerate; conglomerate confined to lower part of formation; lava flows and breccia emplaced above water form upper part; at type section, contains carbonized broken fragments of woody material. No complete section compiled but thickness probably exceeds 1,000 feet. Overlies Amchitka formation (new) with angular unconformity, and dikes of porphyritic rock similar to lava of Chitka Point cut Banjo Point formation (new) and Amchitka formation; south of Chitka Point, underlies gravel deposit of hornblende andesite. Age estimated as middle to late Tertiary; no evidence to rule out possibility that formation might be early Quaternary.

Type locality: At Chitka Point, Amchitka Island (Aleutian Islands). Underlies most of mountainous west half of island.

Chittenango Member (of Marcellus Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 131, 219.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180. Identification of Stony Hollow member (new) as sandstone equivalent of Cherry Valley limestone helps clarify section along Catskill Front. Beds hitherto classified as "Marcellus" shale (Bakoven of Chadwick) immediately underlie the Stony Hollow member and are now proved to be equivalent of Union Springs member. The Stony Hollow underlies Mount Marion formation of Grabau at its type section; consequently the Mount Marion is interpreted as sandy facies of Chittenango black shale member overlying the Cherry Valley to the west.

G. A. Cooper, 1943, *in* Winifred Goldring, New York State Mus. Bull. 332, p. 249 [1946]. Name Berne member was designated to cover the gray sandy equivalents of the Union Springs, Cherry Valley, and Chittenango members. Now that the Cherry Valley equivalent has been definitely recognized, the name Berne must be restricted wholly to the Chittenango sandy shale equivalent about 100 to 150 feet thick.

R. E. Stevenson, 1948, New York State Sci. Service Rept. Inv. 1, p. 2 (chart). Chart shows Chittenango member overlies Cherry Valley and underlies Bridgewater member.

Type section: In small gully 0.7 mile north of village of Chittenango Falls, Madison County.

Chiulos Shale Member (of Great Blue Formation)

Upper Mississippian: Western Utah.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 90–93, 170, 172, 174–175, pls. 1, 21. Primarily black fissile shale with many interbedded ribs of quartzite near center. Thickness about 1,818 feet. Overlies a lower limestone member about 911 feet thick; in fault contact with upper limestone member that is about 1,410 feet thick.

Described in Sheeprock Mountains, Tooele and Juab Counties.

Chiva Chiva Andesite

Oligocene or Miocene: Panamá.

[T. F. Thompson] 1943, Panama Canal, Spec. Eng Div., 3d Lock Proj., pt. 2, chap. 3, p. 26. Light-gray andesite porphyry. In intrusive contact with an agglomerate of basement complex. Occurs as thick dike or elongated plug. Pre-Pliocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 331–332. Type locality stated. Oligocene or Miocene.

Type locality: Quarry 6.5 kilometers northeast of Pedro Miguel, C.Z. Chiva Chiva is name of group of houses about 3 kilometers northeast of Pedro Miguel. Road that runs by quarry is called Chiva Chiva Road.

Chiwapa Sandstone Member (of Ripley Formation)

Upper Cretaceous: Northeastern Mississippi.

F. F. Mellen, 1958, Mississippi Geol. Survey Bull. 85, p. 49–54. Proposed for a sand or sandstone member at top of Ripley formation throughout outcrop belt of the unit in Clay, Chickasaw, Union, and Tippah Counties. Characteristically a "bored" or "horseshoe" limestone or calcareous sandstone; irregularly indurated. Thickness approximately 80 feet. Overlies Ripley marlstone; coarseness of Chiwapa sands suggests possibility of unconformity; separated from overlying Prairie Bluff-Owl Creek by sharp contact that may represent an unconformity or diastem.

Type locality: On branch of Chiwapa Creek at old CWA rock quarry 1½ miles south of Pontotoc in NW¼NW¼ sec. 16, T. 10 S., R. 3 E., Pontotoc County.

Chiwaukum Schist

Pre-Ordovician: Central Washington.

B. M. Page, 1940, Stanford Univ. Abs. Dissert., v. 15, p. 118. Mainly quartz feldspar, biotite, and graphite. Younger than Swakane gneiss.

R. M. Pratt, 1959, Dissert. Abs., v. 19, no. 12, p. 3278. Oldest rock units in Mount Stuart area are Chiwaukum schist and Peshastin slate. The Chiwaukum is a banded staurolite-kyanite-garnet-bearing quartz-biotite schist characterized by much carbonaceous matter and numerous quartz lenses.

First described in area northwest of Wenatchee, Chelan County. Mount Stuart area includes parts of Chelan, Kittitas, and King Counties.

Chloride Formation[1]

Devonian or Mississippian(?): Southwestern New Mexico.

Original reference: C. R. Keyes, 1904, Am. Jour Sci., 4th, v. 18, p. 360–362.

Probably named for town in northwestern part of Sierra County.

Chloride Granite

Precambrian(?): Northwestern Arizona.

M. G. Dings, 1951, U.S. Geol. Survey Bull, 978–E, p. 129–130, pl. 18. Light-gray medium-grained gneissoid granite. Gneissic structure, which is general conforms to schistosity of older folded rocks, in many places grades into a schist as borders of older rocks are approached. Locally granite shows considerable variation in texture, ranging from fine to moderately coarse. Weathers yellowish brown. Has intruded amphibolite and older granite gneisses. Formerly a part of Ithaca Peak porphyry.

Exposed north and northwest of Chloride, in Wallapai mining district, Mohave County.

Chloridian series[1]

Upper Cambrian: Arizona and New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State printer, p. 4, 6.

Chloropagus Formation

Miocene, upper, to Pliocene, lower: Western Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 95–97, 138–139, figs. 5, 6, 8. Section exposed in Green Hill area is (ascending) basalt more than 500 feet; breccia and agglomerate, 500 feet; basalt, 200 feet; tuff and breccia grading to siliceous shale, 50 feet; basalt, 450 feet; siliceous shale, 5 feet; tuffaceous sandstone and shale, 15 feet; basalt, 200 feet. Aggregate thickness over 1,920 feet. Base not exposed in Hot Springs Range but supposedly rests on basement rock. Conformably underlies Desert Peak formation (new). Southwest of Fallon, conformably overlies Old Gregory formation (new). Rocks show several important facies changes as they are traced away from Chloropagus.

Type area in middle foothills of Hot Springs (Kawsoh) Mountains 1 to 2 miles north of Desert Peak, in vicinity of Green Hill *(chloropagus)*, Desert Peak quadrangle. Identified over wide area in western Trinity

Range to north, and also crops out 30 miles north of Desert Peak, and adjacent hills to northeast and southwest.

†Choccolocco Shale[1]

Lower Cambrian: Alabama.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. on Cahaba coal field, p. 148, map.

Named for Choccolocco, Calhoun County.

Chocolay Group

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Oldest of the four groups in the series. As defined here, equivalent to the Lower Huronian of earlier reports. Comprises (ascending) Fern Creek formation, Sturgeon quartzite, and Randville dolomite and their stratigraphic equivalents. In parts of Iron and Dickinson Counties, only unit of group is Randville dolomite (in southern Iron County, its partial correlative, the Saunders formation); Mesnard quartzite and Kona dolomite, exposed at Mount Chocolay and adjacent area to the west, are accepted as direct correlatives of Sturgeon quartizite and Randville dolomite. Group unconformably overlies post-Dickinson granitic rocks; underlies Menominee group.

Named for Mount Chocolay and for Chocolay Junction on the Duluth, South Shore, and Atlantic Railroad, about 3 miles southeast of Marquette, Marquette County.

Chocorua Granite[1]

Upper Devonian or Upper Carboniferous: Northern New Hampshire.

Original reference: C. H. Hitchcock, 1874, Geology of New Hampshire, pt. 1, p. 508–545.

Well exposed on Mount Chocorua, Carroll County.

†Choctaw Buhrstone (in Claiborne Group)[1]

Eocene, middle: Southern Alabama and Mississippi.

Original reference: W. J. McGee, 1890, Am. Jour. Sci., 3d, v. 40, p. 27, 30, 32.

Name probably derived from the broad belt of the formation across Choctaw County, Ala.

†Choctaw Limestone[1]

Lower Cretaceous (Comanche Series): Northeastern Texas.

Original reference: F. W. Cragin, 1894, Colorado Coll. Studies, v. 5, p. 41.

Named for Choctaw Creek, Grayson County.

†Choctawhatchee Formation[1]

Choctawhatchee Stage

Miocene, middle and upper. Western and northeastern Florida.

Original reference: G. C. Matson and F. G. Clapp, 1909, Florida Geol. Survey 2d Ann. Rept., p. 114–122, table.

R. H. Smith, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 264, 269–272. Term Permenters Farm beds proposed for beds that lie above *Arca* zone in Choctawhatchee formation. Beds have been assigned to overlying *Ecphora* zone by earlier workers. Formation includes (ascending) *Yoldia* zone, *Arca* zone, Permenters Farm beds, *Ecphora* zone, and *Cancellaria* zone.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 168. Name Choctawhatchee formation abandoned. *Yoldia* and *Arca* zones transferred to Shoal River formation; *Ecphora* and *Cancellaria* zones classified as Duplin marl.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 16 (table), 18 (fig. 2), 27–36, fig. 3. Choctawhatchee stage includes all Miocene sediments of post-Alum Bluff age in Florida panhandle and their equivalents in Central and Western Gulf States. In Florida panhandle, four biofacies, *Yoldia, Arca, Ecphora,* and *Cancellaria,* are recognized. These biofacies considered faunizones within Choctawhatchee formation. Type exposure of formation designated as type exposure of stage. Term Permenters Farm beds dropped.

Named for exposure on Choctawhatchee River, Walton County.

Chokecherry Dolomite[1]

Chokecherry Dolostone

Upper Cambrian and Ordovician(?): Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

C. B. Bentley, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 6, p. 24. Chokecherry dolomite is equivalent to both Notch Peak limestone (Upper Cambrian) and Pogonip group of Lower Ordovician age. Proposed that Cambrian part of Chokecherry dolomite be renamed Notch Peak and Ordovician part be renamed Pogonip formation.

K. F. Bick, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1067–1068. Cambro-Ordovician boundary lies within the Chokecherry dolostone; approximately lower third of formation is Late Cambrian and remainder Early Ordovician, the boundary being at change from thick-bedded to thin-bedded rocks. Overlies Hicks formation. Discussion of Deep Creek Mountains area.

L. F. Hintze, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 50. Recommended that terms Chokecherry dolomite and Opohonga limestone be abandoned in Gold Hill and Tintic mining districts.

A. R. Palmer, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B290. In Deep Creek Range, Utah, Chokecherry dolomite overlies Corset Spring shale, geographically extended into this area.

U.S. Geological Survey currently designates the age of the Chokecherry Dolomite as Upper Cambrian and Ordovician(?) on the basis of faunal studies.

Named for exposures in Chokecherry Canyon just south of Gold Hill quadrangle.

Cholla Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 10, 16, pl. 27. Consists of following divisions (ascending): white shaly sandstone with numerous fragments of silicified wood, buff-streaked sandstone, platy thin-bedded shale, crossbedded and streaked sandstone, light-buff limestone, crumbly yellow shale, gray limestone, friable light-yellow sandstone, crossbedded pinkish sandstone, platy light-colored sandstone, and massive crossbedded sandstone. Thickness 68 feet. Underlies unnamed shale and sandstone division; overlies unnamed limestone and sandstone division.

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Cholla Canyon Tongue (of Cliff House Sandstone)

Upper Cretaceous: Northwestern New Mexico.

P. T. Hays and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144, sheet 1. Described as small tongue of Cliff House sandstone in Menefee formation. As a result of this tonguing, approximately 60 feet of beds at top of Menefee formation are replaced northeastward by Cliff House sandstone. Contacts are sharp.

Exposed within southeasterly trending band about one-half mile wide and about 3 miles southwest of edge of Barker Dome tongue. These exposures are along southwestern flanks of Barker and Southern Ute Domes and are especially well developed at the head of Cholla Canyon, in secs. 9, 10, and 15, T. 31 N., R. 14 W., San Juan County.

Chopaka Basic Intrusives[1]

Carboniferous(?): Central northern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

Caps Chopaka Mountain, Wash.

Chopaka Schist[1]

Carboniferous(?): Central northern Washington.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

Caps Chopaka Mountain.

Choptank Formation[1] (in Chesapeake Group)

Miocene, middle: Eastern Maryland and Virginia.

Original reference: G. B. Shattuck, 1902, Science, new ser., v. 15, p. 906.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 77–78. Consists of fine yellow quartz sand, bluish-green sandy clay, slate-colored clay, and, locally, ledges of indurated material. Two well-defined fossil zones. Thickness variable; 50 feet at Nomini Cliffs, Va., where entire formation is exposed between St. Mary's formation above and Calvert formation below.

L. W. Stephenson and F. S. MacNeil, 1954, Geol. Soc. America Bull., v. 65, no. 8, p. 733–738. Yorktown formation geographically extended into Maryland where it transgresses both the St. Marys and Choptank formations.

Named for exposures on Choptank River, Md., a short distance below Dover Bridge, Talbot County.

Choptankian Substage

Miocene, middle: Maryland, New Jersey, and Virginia.

D. S. Malkin, 1953, Jour. Paleontology, v. 27, no. 6, p. 767, 768. Substage based on microfaunal assemblages; includes all sediments deposited in central Atlantic Coastal Plain province during time of accumulation of Choptank formation, type exposure of which is considered exemplary of the substage. In sequence, the Choptankian succeeds Calvertian substage and is followed by St. Marysan substage.

Chorrera Basalt

Oligocene or Miocene: Panamá.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 898 (table 2). Listed on correlation chart together with Cerro Gigante basalt and Bruja dolerite. Units are unconformable below Gatún formation and above upper Caimito members. Lower Miocene. "Basalt" is used in this paper as field term applied to basic fine-grained igneous rocks including "andesite" and "basalt."

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat. v. 5, Amérique Latine, fasc. 2a, p. 332. Oligocene or Miocene.

Occurs in Gatún Lake area.

Chota Formation

Middle Ordovician: Eastern Tennessee.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 141, 145 (chart), 157–160, pls, 27, 28. Name applied to a unit which is formed dominantly of gray quartzose calcarenite, 550 to 900 feet thick, and which is underlain by Tellico formation and overlain by Sevier formation. Formation is thinnest in northeast part of homocline; thickens to northeast to 650 feet 3 miles southwest of its truncation by Guess Creek fault; at type locality 900 feet. This is same unit as "sandstone lentil of the Sevier formation" of Keith (1895, 1896) and Holston formation of Rodgers (1953) as mapped in this area.

Type locality: Near Chota School, on Tennessee Highway 72, Vonore quadrangle, Monroe County.

†Chouteau Group[1]

Mississippian: Missouri.

Original reference: G. C. Broadhead, 1874, Missouri Geol. Survey, v. 1, p. 26–65.

Chouteau Limestone[1]

Chouteau Group

Chouteau Limestone (in Easley Group or Sulphur Springs Group)

Lower Mississippian: Central and eastern Missouri and southwestern Illinois.

Original reference: G. C. Swallow, 1855, Missouri Geol. Survey 2d Ann. Rept., pt. 1, p. 101, sections opposite p. 98, 103.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3. p. 189–202. Formation in southwestern part of State includes (ascending) Compton, Northview, Pierson, and Reeds Spring members; in southeastern part of State, includes Fern Glen member; in central part of State, includes

Sedalia member; in northeastern part of State, undifferentiated. Underlies Burlington limestone; overlies Hannibal shale or Bushberg sandstone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5. Chouteau limestone included in Easley group (new). In standard Mississippian section, occurs above Maple Mill shale and below Gilmore City limestone.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 46–56. Formation described in Boone County, where it is as much as 68 feet thick. In this report, name Chouteau is used in unrestricted sense of Swallow. Term is applied to the limestone between the Bushberg sandstone and Burlington limestone. In Sulphur Springs group. Weller placed the Chouteau in Easley group, but this term has not been generally accepted in Missouri. Kinderhookian.

E. L. Clark and T. R. Beveridge, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 71–75. [Reprinted from Kansas Geol. Soc. Guidebook 16th Regional Field Conf.] Redefined as group to include (ascending) Compton, Sedalia, and Northview formations. This usage follows Broadhead (1874) by using Chouteau in unrestricted sense and ranking it as a group. At the time that Moore (1928) restricted the Chouteau, he believed the Kinderhookian-Osagean line to be between the Chouteau (restricted) or Compton and Sedalia. The Kinderhookian-Osagean line is now believed to be at the top of the Northview. Overlies Sylamore formation; underlies Pierson formation.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 31–35. Chouteau is used in this report for the limestone that in western and central Illinois rests conformably on Maple Mill formation and in eastern and southern Illinois on New Albany formation. Uppermost limestone of Kinderhook series in these areas and is unconformably overlain by Osage group of Valmeyer series.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 9 (fig. 2), 39–42. Formation described in Bowling Green quadrangle where it is as much as 25 feet thick. Overlies Hannibal formation; underlies Burlington formation. The Reeds Spring and Pierson formations are not of Chouteau age, as Branson (1944) believed, but are younger than the Chouteau.

Charles Collinson and A. J. Scott, 1958, Illinois Geol. Survey Circ. 254, p. 3, 5–6. In southern Illinois, Chouteau limestone underlies State Pond member (new) of Springville formation and is uppermost unit in Kinderhook series. Thin and discontinuous; thickness not more than 2 or 3 feet.

Charles Collinson and D. H. Swann, 1958, Geol. Soc. America Guidebook Field Trip St. Louis Mtg., p. 24 (fig. 3), 46 (fig. 8), 49–51. Described in western Illinois where it is as much as 70 feet thick. Overlies Hannibal shale; underlies Sedalia formation. Beds to which name Chouteau is applied in Illinois probably correlate with Compton limestone of Chouteau group in type area.

Named for Chouteau Springs, Cooper County, Mo.

†Chowan Formation (in Columbia Group)[1]

Pleistocene: Eastern North Carolina, eastern Maryland, and eastern Virginia.

Original reference: W. B. Clark, 1910, Geol. Soc. America Bull., v. 20, p. 651.

Named for Chowan River, N.C.

Choza Formation[1] (in Clear Fork Group)

Lower Permian (Leonard Series): Central and central northern Texas.

Original reference: J. W. Beede and V. V. Waite, 1918, Texas Univ. Bull. 1816, p. 49, map.

M. G. Cheney, 1940, Am Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Assigned to Clear Fork group. Underlies San Angelo sandstone of El Reno group; overlies Vale formation. Includes Merkel dolomite member. Leonard series.

E. C. Olson, 1951, Jour. Geology, v. 59, no. 2, p. 178–181. Vertebrate fauna discussed.

C. O. Dunbar and others, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, chart 7. Chart shows Choza formation below San Angelo [sandstone] of Pease River group; El Reno group not used in Texas.

Named for Choza Mountain, near Tennyson, Coke County.

Christine Member (of Yegua Formation)

Eocene (Claiborne): Southern Texas.

H. D. McCallum, 1947, South Texas [Geol. Soc. Guidebook] 14th Ann. Mtg. Field Trip, p. 5. Third member of the Yegua. Contact with underlying Cistern member (new) is within a graben.

Named for town of Christine, Atascosa County.

Christy Creek Siltstone Member (of Brodhead Formation)

Lower Mississippian: Northeastern Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 179, 180–182, pl. 17. Massive siltstone at base of Brodhead formation, Morehead facies (new). Commonly 80 to 90 feet thick; 130 feet thick at type locality. Underlies Frenchburg siltstone member (new).

Typical exposure: Steep valley bluff and hillside slope above north side of Christy Creek valley, immediately north of State Highway 32, just east of Deep Fork Branch, 3¾ miles east of Morehead, Rowan County. Name taken from Christy Creek, a tributary to Triplett Creek. Can be traced northward to Ohio River where it is at horizon of Byer member of Logan formation in Scioto County, Ohio.

Chrysler Limestone

†Chysler Waterlime[1]

Upper Silurian and Lower Devonian: Central New York.

Original reference: G. H. Chadwick, 1930, Geol. Soc. America Bull., v. 41, p. 81.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 534, chart 3. Term Chrysler was proposed by Chadwick for beds here called Rondout. Beds called Rondout in this column include more than those to which name has latterly been confined in type region in east, but agree with those to which name was originally applied there; hence, Chadwick now considers his term Chrysler to be superfluous.

U.S. Geolgical Survey currently designates the age of the Chrysler Limestone as Upper Silurian and Lower Devonian on the basis of a study now in progress.

Named for Chryslers Glen, Syracuse quadrangle.

Chuar Group[1]

Chuar Series

Precambrian (Grand Canyon Series) : Northern Arizona.

Original reference: C. D. Walcott, 1883, Am. Jour. Sci., v. 26, p. 439–442, 484.

J. F. Mason, 1948, Geol. Soc. America Bull., v. 59, no. 4, p. 350. Incidental mention of Chuar series.

C. E. Van Gundy, 1941, Geol. Soc. America Bull., v. 62, no. 8, p. 953, 954, pl. 1. Upper group of Grand Canyon series. Stratigraphically restricted; lower member reassigned to Nankoweap group. Thickness in Basalt Canyon, 5,098 to 5,323 feet. Disconformably overlies Nankoweap group.

Named for Chuar Valley, Grand Canyon region.

Chuarian series[1]

Precambrian: Northern Arizona and New Mexico.

[Original reference]: C. R. Keyes, 1906. Am. Jour. Sci., 4th ser., v. 21, p. 298.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107, 109, 111. In Grand Canyon of Arizona, Chuaran series includes the following formations: Chiquito, Gunther, Jupiter, Oso, Venus, Marble, and Final. Older than Kwaguntan series (new) ; younger than Cardenas lava series (new).

Grand Canyon region.

Chubb Siltstone Member (of Maroon Formation)[1]

Chubb Siltstone Member (of Minturn Formation)

Pennsylvanian or Permian: Central Colorado.

Original reference: D. B. Gould, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 7, p. 971–1009.

C. A. Arnold, 1941, Michigan Univ. Mus. Paleontology Contr., v. 6, no. 4, p. 59–70. Mentioned in discussion of some Paleozoic plants from central Colorado and their stratigraphic significance. Plants are not proof of Permian or even late Pennsylvanian age.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 43, pls. 1, 8. Described in South Park area where it is 1,827 feet thick at type locality. Underlies Pony Spring siltstone member; overlies Coffman conglomerate here included at top of Weber(?) formation.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 820, 836, pls. 1, 8. Chubb siltstone considered member of Minturn formation in this report [Permo-Pennsylvanian zeugogeosyncline, Colorado and New Mexico]. Underlies Pony siltstone member and overlies Coffman conglomerate here considered member of Minturn. Assumed to be Desmoinesian because of position in section.

Type locality (Stark and others) : East side of Chubb Gulch in sec. 16, T. 13 S., R. 77 W., Park and Chaffee Counties.

Chubbuck Marble Member (of Essex Series)

Precambrian: Southern California.

J. C. Hazzard and E. F. Dosch, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 309. A marble, quartzite, and schist unit, 500 to 600 feet thick. Middle member of series; overlies a basal quartz-feldspar-biotite gneiss and underlies an upper 5,000-foot unit of quartz-feldspar-biotite gneiss.

Occurs in the Piute and Old Woman Mountains, San Bernardino County. [Probably named from Chubbuck on the Santa Fe Railroad.]

Chuckanut Formation[1]

Eocene: Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington Univ. Pub. in Geology, v. 2, p. 93, 136–138.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 75–90. pl. 11. Essentially massive crossbedded to stratified medium- to coarse-grained grayish-brown to brownish-gray sandstone; subordinate amounts of sandy shales, varying in color from gray to light and dark brown; lenses of conglomerate locally as much as 100 feet thick. Two type sections measured: along Chuckanut Drive on east shore of Samish Bay, thickness 11,272 feet, and along west shore of Lake Whatcom, thickness 8,930 feet. Field and drill hole evidence indicates total thickness may be more than 16,000 feet in western Whatcom County. Formation may represent time interval beginning in late Cretaceous and continuing into middle or possible late Eocene. Overlies schists and igneous rocks.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull., v. 71, no. 10, chart 10e (column 59). Listed on Cretaceous correlation chart with note that unit may be all Tertiary.

Well exposed along Chuckanut Drive on Pacific Highway, western Whatcom County.

Chuckwalla Complex

Precambrian: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 12, 16–20. Diorite-granite complex, locally including migmatities and banded gneiss and some involved metasediments. In Maria Mountains, unconformably underlies Paleozoic Maria formation (new); in Orocopia Mountains, in fault contact with Orocopia schist (new), considered younger. In Little San Bernardino Mountains, Chuckwalla complex is cut by Fargo Canyon diorite (new).

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 491. Granite of Chuckwalla complex named Berdoo granite.

Named for exposure in Chuckwalla Mountains, Palm Springs-Blythe area, Riverside County.

Chuctanunda Creek Dolomite or Formation

Lower Ordovician (Lower Canadian): East-central New York.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76 (fig. 2), 77, 90–92. Name proposed for sequence of medium- to thick-bedded buff-weathering blue-gray medium-grained dolomites. Lower half is dark-blue tó gray variegated noncherty coarse dolomarenite, locally laminated; small amounts of silt and angular sand present. Upper half is a siliceous dolomilutite, fine- to medium-grained, brownish-gray to blue-gray, and markedly cherty with much interstitial silica; chert mainly stringy or hackly. Thickness 40 feet at type locality. Unconformably underlies Cranesville dolomite (new); unconformably overlies Tribes Hill formation (Fonda member, new). Offlaps Tribes Hill formation in a northward direction.

Named for exposure along North Chuctanunda Creek within city of Amsterdam, Montgomery County.

Chuctenunda[1]

Chuctenunda Shale Member (of Canajoharie Shale)

Middle Ordovician: Eastern New York.

Original reference: Rudolf Ruedemann and C. H. Chadwick, 1935, Science, new ser., v. 81, no. 2104, p. 400.

Rudolf Ruedemann, 1947, Geol. Soc. America Mem. 19, p. 119. Referred to as Chuctenunda shale member of Canajoharie. Overlies Fort Plain shale member; underlies Gansevoort shale member.

Type locality and derivation of name not given but may have been named from Chuctenunda Creek near Amsterdam, Montgomery County.

Chucunaque Formation

Miocene or Pliocene: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie. Heidelberg, v. 8, Abt. 4a, no. 29, p. 133, 134 (correlation chart). Underlies Piliguilla conglomerate; overlies Pucro sandstone. Upper Miocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 332. Undefined name; also used by Terry (1956, California Acad. Sci. Occasional Paper 23) without definition. Miocene or Pliocene.

In Darién area.

Chugwater Formation[1]

Chugwater Group

Permian and Triassic: Wyoming, Colorado, and central southern Montana.

Original reference: N. H. Darton, 1904, Geol. Soc. America Bull., v. 15, p. 394–401.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 12, 41–48, pl. 17. In present discussion [southern margin Absaroka Range], term Chugwater formation is applied to all strata between Dinwoody and Sundance formations. Thickness 1,250 feet. Comprises (ascending) Red Peak (new), Crow Mountain (new), Popo Agie, and Gypsum Spring (new) members. Triassic.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2; 1950, Nebraska Geol. Survey Bull. 13–A, p. 2 (fig. 2), 3. Chugwater as now used in Wyoming is synonymous with Spearfish (redefined). Freezeout tongue of Chugwater is here designated as a member or formation in Phosphoria group.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 133–136. Rank raised to group. Compromises (ascending) Dinwoody formation, Red Peak formation, Alcova dolomite, Crow Mountain formation, Popo Agie formation, Wyopo formation (new), and Gypsum Spring formation. Overlies Phosphoria; underlies Sundance. Triassic.

J. D. Love and others, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 17. Name, Chugwater, has been used as both a group and a formation name by various investigators. Some authors have included the Dinwoody formation in the Chugwater along with four younger

Triassic units—the Red Peak, Alcova. Crow Mountain and Popo Agie—and two Jurassic formations—the Nugget ("Wyopo") and Gypsum Spring. Chugwater as used in present report [central Wyoming] is considered to be a formation 1,000 to 1,250 feet thick, overlying Dinwoody formation and underlying the Nugget, Gypsum Spring, and younger Jurassic formations. Comprises (ascending) Red Peak, Alcova, and Popo Agie members. Triassic.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027-B, p. 51–52, pl. 6. Formation described in Crazy Woman Creek area, Johnson County, Wyo., where it overlies Permian red shale and gypsum sequence and is unconformably overlain by Gypsum Spring formation. Thickness 750 to more than 800 feet. In most places, divisible into three units (ascending): Red Peak, Alcova, and Crow Mountain members. Threefold division feasible only where Alcova member is present. Triassic.

C. A. Burk and H. D. Thomas, 1956, Wyoming Geol. Survey Rept. Inv. 6, p. 5, 6 (fig. 1). Overlies Goose Egg formation (new) at type section of Goose Egg formation.

N. C. Privrasky and others, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 52–54. Chugwater, as redefined by Darton (1908) for Laramie basin, included sediments between Jurassic Sundance formation and Permian Forelle limestone. Chugwater of present report is restricted to sediments beneath the Sundance and above Goose Egg formation which includes, in part, Forelle limestone member, lower unnamed shale member, Ervay limestone member, and upper unnamed shale member. Formation comprises (ascending) Red Peak shale, Alcova limestone, Crow Mountain sandstone, and Popo Agie shale.

W. P. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 26–28, pls. Formation, in Buffalo-Lake De Smet area, Wyoming, consists chiefly of dark-red siltstone, sandstone, and shale. Forms conspicuous band of red outcrops adjacent to east flank of Bighorn Mountains in southwestern, west-central, and northwestern parts of area. Thickness 810 feet. Three members recognized: lower, similar to Red Peak member in central Wyoming; middle, tentatively correlated with Alcova member; and upper, similar to Crow Mountain member in central Wyoming. Unconformably underlies Gypsum Spring formation; overlies unnamed sequence of red shale, siltstone, and gypsum, about 180 feet thick, which unconformably overlies Tensleep sandstone. Triassic.

T. A. Steven, 1960, U.S. Geol. Survey Bull. 1082-F, p. 338–339, pl. 12. Described in Northgate district, Jackson County, Colo., where it is about 690 feet thick on northern flank of Sentinal Mountain. Nonmarine strata chiefly impure red shales and sandstones. Underlies Sundance formation; overlies Forelle(?) limestone. Permian and Triassic.

Named for Chugwater Creek near Iron Mountain, Wyo.

Chumway Rhyolite

Oligocene: Central Colorado.

J. E. Bever, 1954, Dissert. Abs., v. 14, no. 7, p. 1088. Oligocene extrusive rocks are here named Guffey volcanics with the upper section correlated with Thirty-nine Mile andesite series, and the lower section here designated the Chumway rhyolite. They covered most of area with flows and tuffs thousands of feet thick.

Guffey area [Park County].

†Chupadera Formation[1]

Permian: New Mexico.

Original reference: E. H. Wells, 1919 [1920], New Mexico State School Mines Bull. 3, p. 10–11, 17–18.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 668 (footnote). Term abandoned.

Christina Lochman-Balk, 1959, New Mexico Geol. Soc. Guidebook 10th Field Conf., p. 100. Recent mapping has recognized the Yeso, Glorieta, and San Andres formations; term Chupadera has lapsed from usage and should be abandoned.

Named for Chupadera Mesa, eastern Socorro County.

Church Limestone Member (of Howard Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, Iowa, southern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull., 2d ser., v. 1, p. 42, 54.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 170 (fig. 34), 173–174. Most persistent and important limestone member of Howard formation. Commonly a single massive bed of dark-blue to blue-gray limestone. Thickness ranges from about 1½ to 6 feet, the average a little more than 2 feet. Underlies Winzeler shale member; overlies Aarde shale member. Where Bachelor Creek limestone is absent and Aarde shale cannot be differentiated, Church limestone is considered as forming basal unit of the Howard, resting on Severy-Aarde shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 19. Mentioned as occurring in Iowa and Missouri.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 19–20. Church, Winzeler, and Utopia members of Howard limestone are readily distinguishable in Missouri as the two thin limestones with intervening shale described as units of the Howard by McQueen and Greene (1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, pl. 5).

Named for Church Farm, on Turner Creek, southeast of Du Bois, Nebr.

Church Creek Beds

Eocene to Oligocene: Southern California.

Parry Reiche, 1937, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 24, no. 7, p. 144–146, geol. map. Sandstones and siltstones; lower part buff heavy-bedded well-cemented feldspathic sandstone; upper part interbedded buff and gray finer less well indurated sandstones and siltstones, with minor dark gray mudstones. Thickness about 600 feet. Bounded above by Church Creek fault and below by depositional contact with crystalline basement.

Area of study is Santa Lucia quadrangle, southwestern Monterey County.

Church Rock Member (of Chinle Formation)

Upper Triassic: Northeastern Arizona, southwestern Colorado, and southeastern Utah.

J. H. Stewart, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 448 (fig. 4), 459–460, 461 (fig. 8). Described in southeastern Utah where it is composed of pale-reddish-brown and light-brown very fine grained sandy siltstone; siltstone may be structureless, horizontally laminated to very thick bedded, or, in places, ripple laminated. Sandstone more common in northern part of southeastern Utah where it includes unit termed Bowknot bed. Thickness ranges from wedge-edge to 400 feet in Utah. Conformably overlies Owl Rock member in most of southeastern Utah. Conformably overlies Moss Back member in San Rafael Swell, and unconformably overlies Moenkopi formation in Moab area. Disconformably underlies Wingate sandstone. Member thickens abruptly north of Elk Ridge area, probably by incorporating strata which are equivalent to Owl Rock farther south. Extends into Monument Valley, Ariz. Rock Point member of Wingate sandstone, which is largely, or entirely, the same unit as Church Rock member, is present in large part of Arizona and locally extends into west-central New Mexico. Name Church Rock is used in southeastern Utah and in areas in Arizona north of Laguna Creek, and name Rock Point member of Wingate is used in New Mexico and in areas of Arizona south of Laguna Creek. Church Rock member corresponds to A division of Chinle formation described by Gregory (1917 U.S. Geol. Survey Prof. Paper 93). Name credited to Witkind and Thaden.

J. H. Stewart and others, 1959, U.S. Geol. Survey Bull. 1046–Q, p. 517–520. In San Juan County, Utah, includes Hite bed (new).

Named for exposures in Monument Valley area, Arizona. In west-central Colorado, constitutes entire Chinle formation.

Church Run Conglomerate[1]

Pennsylvanian: Pennsylvania.

Original reference: J. F. Carll, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 38–40.

In hilltops at Church Run, Warren County.

Churn Creek Member[1] (of Cuyahoga Formation)

Churn Creek Shale Member (of New Providence Formation)

Churn Creek Siltstone and Shale Member (of Logan Formation)

Lower Mississippian: Southern Ohio and northeastern Kentucky.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 763.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 134, pl. 6. In upper part of New Providence column in Lewis County, Ky., siltstone beds become fewer as well as thinner, with argillaceous to silty shale becoming prevalent; no sharp break occurs between these two divisions. This upper zone, 75 to 100 feet thick, is interpreted as the "Churn Creek" of Hyde (1915) and termed Churn Creek shale member. Occurs above Vanceburg siltstone member in Vanceburg facies of formation. Considered Lower Mississippian.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 63–64. Churn Creek siltstone and shale member included in Vanceburg facies of Logan formation in Ohio. Underlies Vinton sandstone member; overlies Vanceburg siltstone member, but no dependable horizon separates the two, distinction being made on basis of larger sandstone content of Vanceburg.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 3 (table 1), 25. Here considered member of Cuyahoga formation in Vanceburg facies. Editor's note states Hyde (1921, Ohio Geol. Survey Bull. 23) correlated Buena Vista sandstone with Berne and lower portion of Byer in discussing geology of Camp Sherman quadrangle; such a correlation would necessitate placing Rarden, Vanceburg, Churn Creek, and most of Portsmouth shale in Logan formation.

Named for Churn Creek, southeastern Adams County, Ohio.

Chusa Tuff Member (of Catahoula Tuff)[1]

Oligocene or Miocene, lower: Southwestern Texas.

Original reference: T. L. Bailey, 1926, Texas Univ. Bull. 2645, p. 65, 89–105, 178–179.

Named for exposures on slopes of La Chusa Mesa, in southeastern McMullen County.

Chuska Sandstone[1]

Pliocene(?): Northwestern New Mexico and northeastern Arizona.

Original reference: H. E. Gregory, 1916, U.S. Geol. Survey Water-Supply Paper 380.

J. T. Hack, 1942, Geol. Soc. America Bull., v. 53, no. 2, p. 350. Tentatively correlated with Bidahochi formation.

J. E. Allen, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 11, p. 2569–2571. Overlies Tohatchi formation with angular unconformity. Thickness about 1,100 feet. Pliocene(?).

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 97–99. Massive crossbedded silica-cemented sandstone about 1,000 feet thick. Overlies, commonly with marked angular unconformity, formations ranging from Summerville upwards to Tohatchi formation of Mesaverde group. The Chuska is penetrated and overlain by volcanic rocks in vicinity of Washington Pass, 6 miles north of area [Tohatchi quadrangle]. Similar Tertiary beds occur between Gallup and Zuni 40 miles to south. Widespread similar sediments interbedded with volcanic debris near White Cone, Ariz., contain fossils indicative of an upper or middle Pliocene age. Chuska believed to be of upper Tertiary and probably Pliocene age.

C. A. Repenning and J. H. Irwin, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1821–1826. Because Bidahochi and Chuska formations are associated with apparently contemporaneous volcanic rocks and are lithologically similar, and because of the apparent comparison of the surfaces upon which the Bidahochi formation, the Chuska sandstone, and the Tertiary rocks of the Zuni Plateau were deposited, it is believed that the Chuska should tentatively be considered equivalent to lower member of Bidahochi.

H. E. Wright, Jr., 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1829 (fig. 2), 1830, 1831. Gradationally overlies Deza formation (new).

H. E. Wright, Jr., 1956, Geol. Soc. America Bull., v. 67, no. 4, p. 413–434. As restricted herein, forms cap rock of Chuska Mountains, which extend 60 miles along Arizona-New Mexico State line north of Gallup, N. Mex. Maximum thickness about 1,750 feet. Unfossiliferous; crossbedded throughout; contains no shale or conglomerate interbeds; several thin ash beds. Restricted Chuska and underlying Deza formation, together forming Gregory's Chuska sandstone, truncate Mesaverde group (Upper Cretaceous) and are unconformably overlain by middle or upper Pliocene volcanics. Suggested Miocene(?) age based on physiographic data. Discussion of origin of Chuska sandstone. Theory of correlation of Chuska and Bidahochi considered unacceptable.

C. A. Repenning, J. F. Lance, and J. H. Irwin, 1958, New Mexico Geol. Soc. Guidebook 9th Field Conf., p. 123–129. Hack (1942) tentatively correlated the Chuska with the Bidahochi. Repenning and Irwin (1954) accepted and elaborated these correlations to the extent of tentatively correlating the Chuska with lower member of Bidahochi. Although this correlation seems within reason in light of present information, the reasoning used to defend it is, in some respect, in error. Formation currently assigned a Pliocene(?) age until more convincing evidence becomes available.

Named for Chuska Peak, McKinley County, N. Mex.

Cialitos Limestone

Upper Cretaceous: Puerto Rico.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 47, 48 (table 4). A distinctive creamy-white, coarsely crystalline limestone.

Occurs in Barrio Cialtos, Arecibo district.

Cibao Formation in Río Guatemala Group)

Cibao Limestone[1] or Marl

Oligocene and Miocene: Puerto Rico.

Original reference: B. Hubbard, 1920, Science, new ser., v. 51, p. 396.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas. 1948, U.S. Geol. Survey Oil and Gas. Inv. Prelim. Map 85. Cibao marl included in Río Guatemala group (new). Consists of soft argillaceous marls, chalky limestones, and local thin beds of sand and clay. Best developed in inter-bioherm area and in western and eastern clastic basins. Maximum thickness approximately 230 meters midway between the Río Manatí and Río Indio in inter-bioherm area. Westward, entirely replaced by Lares limestone of western bioherm area. Upper 50 meters of Cibao continues in outcrop across eastern bioherm into eastern clastic basin. The Cibao becomes increasingly impure toward eastern extremity of outcrop area. Near eastern extremity, overlaps San Sebastián formation and rests on uneven surface of Cretaceous rocks. Transitional into upper Lares limestone. In western clastic area, contains sequence of predominantly clastic sediments herein named Guajataco member. Cibao marl is absent in vicinity of town of Florida, where western bioherm persisted until deposition of Aguada limestone (new) began. Some beds of the Cibao intervene between eastern bioherm and Aguada limestone. Middle Oligocene-lower Miocene, top uncertain.

Type locality: In barrio Cibao, north of Lares.

Cibola limestone[1]

Silurian(?): Southwestern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State printer, p. 3, 6.

Crops out at Cibola mill, at Silver City, Grant County.

Cibolo Formation[1]

Permian: Southwestern Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Min. Survey Bull. 8, p. 10–25.

J. W. Skinner, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 180–188. Contact with underlying Alta transitional. All except uppermost part of Cibolo of Udden is regarded as upper Wolfcamp in age. At type section, upper member of Cibolo is overthrust on limestones of upper Permian (Capitan) age.

C. C. Rix, 1952, Geologic map of Chinati Peak quadrangle, Presidio County, Texas: Texas Univ. Bur. Econ. Geology, Prelim. ed. Stratigraphically below Ross Mine formation (new). Leonard series.

Named for Cibolo Creek and Cibolo Ranch, Presidio County.

Cienda Limestone (in Pacheta Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12. Minutely clastic argillaceous limestone with glauconite in matrix and numerous larger inclusions of broken shell and chert. Weathers into round-edged slabs. Very rich in silicified ammonites. Thickness 4 feet. Underlies Black Knob dolomite (new); overlies Tusonimo limestone (new).

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Cienega Peak Granite

Cretaceous or Tertiary: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 12–13, table 1, pl. 1. Holocrystalline equigranular fine-grained light-pink rock with hypidiomorphic texture. Intrudes Chiricahua limestone and basal conglomerate and sandstone of McGhee Peak formation (new). Probably intrusive into Granite Gap granite (new) in area south of Preacher Mountain fault. Lenses out north of Cienega Peak.

Forms an almost vertical sill or laccolith which makes up Cienega Peak, a prominent landmark on western side of Peloncillo Mountains just north of Granite Gap, Hidalgo County.

Cieneguilla Formation

Pennsylvanian (Des Moines): Northern New Mexico.

J. A. Young, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1247. Arkose, arkosic sandstone, arenaceous, carbonaceous, and calcareous shale, and thin beds of limestone. Thickness more than 2,200 feet. Upper beds interfinger with lower beds of a thick sequence of red arenaceous shale.

Exposed in valley of Coyote Creek, north of Black Lake, northern Sangre de Cristo Mountains.

Cieneguilla Limburgite.

Tertiary: North-central New Mexico.

C. E. Stearns, 1953, Am. Jour. Sci., v. 251, no. 6, p. 424 (fig. 3), 445–451. Proposed for series of flows and ejectamenta, with associated waterlaid beds, exposed in vicinity of La Cienega. Thickness at type locality 590 feet. At Cieneguilla, overlain with angular unconformity by Pleistocene alluvium of Santa Fe Plateau, Pleistocene basalt of the Mesa Negra, and by younger alluvium in Santa Fe Creek. Base of section not exposed; maximum stratigraphic interval concealed estimated to be 50 feet. Underlain by Espinaso volcanics (new) and separated from them by time interval during which a small body of augite quartz latite was intruded, solidified, and exposed by subsequent erosion. Appears to be Oligocene or earliest Miocene.

Type locality: Canyon of Santa Fe Creek between settlements of Canyon and Cieneguilla, Cerrillos Hills, Galisteo-Tonque area.

Cieneguita Formation

Cieneguita Beds[1]

Middle and Upper Pennsylvanian: Southwestern Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Min. Survey Bull. 8, p. 10–25.

C. C. Rix, 1952, Geologic map of Chinati Peak quadrangle, Presidio County, Texas (1:48,000): Texas Univ. Bur. Econ. Geology, Prelim. ed. Formation consists of quartz-pebble conglomerate, coarse sandstone, sandy shale, and reef limestone. Underlies Alta formation. Strawn-Canyon (?), Cisco series.

Named for Cieneguita Ranch, Presidio County.

Cierbo Sandstone (in San Pablo Group)[1]

Cierbo Stage or Substage

Miocene, upper: Western California.

Original reference: B. L. Clark, 1921, Jour. Geology, v. 29, p. 586–614.

J. E. Eaton, U. S. Grant, and H. B. Allen, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 199–200. The Monterey comprises three substages (ascending): Briones, Cierbo, and Neroly. Substages can be recognized strandward by distinctive echinoderm faunas and by a number of more or less distinctive mollusks.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 16 (fig. 2), 40–42, pls. Formation described in Tesla quadrangle. Unit herein called Cierbo was described as undifferentiated Miocene by Anderson and Pack (1915, U.S. Geol. Survey Bull. 603). A transgressive formation structurally involved in the regional folding and faulting. Rests with angular unconformity on Panoche; overlain conformably to unconformably by Neroly formation. Estimated maximum thickness about 500 feet. San Pablo group.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 78–80, pls. 11–13. Exposed in southern parts of Carquinez and Mare Island quadrangles and rests with erosional unconformity on Briones sandstone. In San Pablo area, approximately 900 feet thick; consists of basal unit composed of alternating layers of fine- and coarse-grained brownish-gray sandstone; upper 160 feet is yellowish- and brownish-gray concretionary medium-grained sandstone; crossbedded pebbly and conglomeratic sandstone rests on the concretionary sandstones, and the contact is regarded as top of Cierbo. Underlies Neroly sandstone. In Los Medanos Hills, unconformably overlies Markley sandstone.

J. W. Durham, 1954, California Div. Mines Bull. 170, chap. 3, p. 24 (fig. 2), 26 (fig. 4). Listed as megafaunal stage. Follows Briones and precedes Neroly.

C. A. Hall, Jr., 1958, California Univ. Pub. Geol. Sci., v. 34, no. 1, p. 26–27, fig. 2, geol. map. In Pleasanton area, the Cierbo is 750 to 2,000 feet thick. Overlies Briones formation; underlies Neroly sandstone. In some areas, underlies Livermore gravels with angular discordance. Upper Miocene. Term San Pablo group not used in this report. Considered advisable to redefine term San Pablo formation and designate Cierbo and Neroly as members.

Type section: South side of Canada del Cierbo near Carquinez Straits, Carquinez quadrangle, San Francisco Bay region.

Ciervian Stage

Late Cretaceous: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 982–985, 1005. Uppermost of six stages, based on foraminiferal assemblages, in Upper Cretaceous column between top of Moreno and base of Panoche, as defined by Anderson and Pack (1915). Stage corresponds to Moreno shale at its type locality. Lower part of stage is represented by three facies, one composed of shales and the others of silty shales and silts. Includes interval between Paleocene Cheneyan stage (new) and Upper Cretaceous Ingramian stage (new).

Occurs in Great Valley in both surface and subsurface. Named after Ciervo Hills [Fresno County], in vicinity of which wells furnished typical material. Stage is well represented in upper 2,100 feet of Cretaceous strata exposed in Moreno Gulch, Fresno County.

Ciervo Shale (in Panoche Group)

Upper Cretaceous: Central California.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec., Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Green shale and brownish-green sandstone. Thickness 3,470 feet. Includes Ortigalita sandstone member (new). Overlies Benito sandstone (new); underlies Marlife shale (new). Name credited to D. W. Sutton (unpub. thesis).

Type locality: Papanatas Canyon. Name derived from Ciervo Mountain in south-central sec. 5, T. 17 S., R. 13 E., Fresno County.

Cima Sandstone Lentil (in Dos Palos Shale Member of Moreno Formation)

Upper Cretaceous or Paleocene(?): Southern California.

M. B. Payne, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1953; 1951, California Div. Mines Spec. Rept. 9, p. 6 (fig. 2), 8 (fig. 4), 9, 22–23, pls. 2, 3, 4, 5. A 60-foot lens lying 185 feet below top of Dos Palos shale member (new). On the basis of this mapping, it is concluded that Anderson and Pack (1915) show base of Moreno formation in Ortigalita Creek some 1,800 feet stratigraphically lower than their type Moreno in Moreno Gulch.

Type locality: Escarpado Canyon, secs. 7 and 8, T. 15 S., R. 12 E., Panoche Hills, Fresno County. Escarpado Canyon is 6 miles south of Moreno Gulch and 2 miles north of Panoche Creek. Cima is Spanish word for peak given to hill 1,800 feet south and 50 feet west of NE cor. sec. 7.

Cimarron Anhydrite (in Hennessey Formation)

Permian: Western Oklahoma.

Henry Schweer *in* O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1553 (fig. 9). Shown on cross section as occurring near the base of the formation.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 106. Rejected by Oklahoma Geological Survey. Name preoccupied; used by Cragin (1896) for a Permian group in Kansas and by Keyes (1904) for the Permian of New Mexico.

Occurs in Woods County.

†Cimarron Formation[1]

Permian: New Mexico.

Original reference. C. R. Keyes, 1904, Am. Jour. Sci., 4th, v. 18, p. 360–362.

†Cimarron Group[1]

Cimarron Series

Permian: Central southern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 18–48.

J. E. Adams and others, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1677, 1678. Cimarron series of northern Midcontinent region should be abandoned and its constituent strata reclassified as belonging to Leonard series and Guadalupe series.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1764 (fig. 3), 1766–1814. Succeeding Milan limestone, top member of Wellington formation, without a break, are red shales and sandstones and higher evaporite beds of Kansas which constitute Cimarron series, which includes all succeeding Permian redbeds of the state, divided by Cragin (1896) into Salt Fork and Kiger divisions. Series comprises (ascending) Ninnescah shale, Stone Corral dolomite, Nippewalla group (new, which includes Harper sandstone redefined, Salt Plain formation, Cedar Hills sandstone, and Flowerpot shale), Blaine formation, Whitehorse formation, Day Creek dolomite, and Big Basin formation. Overlies Big Blue series.

G. E. Condra and E. C. Reed, 1959, Nebraska Geol. Survey Bull. 14A, p. 24–30. Formations of Cimarron series are well developed in northern Oklahoma and southern Kansas from which some of them extend subsurface to southern and western Nebraska and grade into Permian redbed section of Rocky Mountain, Laramie Range, Hartville, and Black Hills regions. Correlations discussed.

Named for Cimarron River.

Cimarron Creek Latite[1]

Miocene or Pliocene: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1907, U.S. Geol. Survey Geol. Atlas, Folio 153.

Exposed in drainage of Cimarron Creek in Ouray and Lake City quadrangles.

Cimarronian series[1]

Carboniferous: Texas.

Original reference: C. R. Keyes, 1909, Iowa Acad. Sci. Proc., v. 16, p. 159, 163.

Rio Grande Valley.

†Cincinnati Beds (proper)[1]

Middle and Upper Ordovician: Southwestern Ohio and north-central Kentucky.

Original reference: E. Orton, 1873, Ohio Geological Survey, v. 1, p. 370–387.

Named for exposures at Cincinnati, Ohio.

Cincinnati Group[1]

Upper Ordovician: Cincinnati arch region (surface and subsurface).

Original reference: F. B. Meek and A. H. Worthen, 1865, Philadelphia Acad. Nat. Sci. Proc., v. 17, p. 155.

A. M. Gutstadt, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 3, p. 513–547. Term Cincinnati group revived for body of rocks continuous with Cincinnatian series in Cincinnati arch region. In subsurface, group is composed of (descending) Maysville-Richmond formation and Eden shale. Exact relationships of Cincinnati group to underlying Trenton group not precisely known. Correlated with Maquoketa group.

Type locality: Region about Cincinnati, Ohio.

†Cincinnati Limestone[1]

Upper Ordovician: Southwestern Ohio.

Original reference: W. W. Mather, 1859, Rept. State House Artesian Well at Columbus, Ohio, p. 6.

Cincinnatian Series[1]

Cincinnatian Epoch[1]

Upper Ordovician: North America.

Original references: F. B. Meek and A. H. Worthen, 1865, Philadelphia Acad. Nat. Sci. Proc., v. 17, p. 155; J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 876, 877.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 90–93. Cincinnatian series as developed in Minnesota is essentially Maquoketa formation, which is often considered a group or series.

R. H. Flower, 1946, Bulls. Am. Paleontology, v. 29, no. 116, p. 107–120. Cincinnatian series comprises Covington subseries with Eden and Maysville groups, and Richmond subseries with Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations. Systematic description of cephalopods.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 2, chart 2. As shown on correlation chart, Cincinnatian series comprises Edenian, Maysvillian, Richmondian, and Gamachian (in Canada) stages.

A. M. Gutstadt, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 3, p. 513–547. Name Cincinnatian series, a time-stratigraphic term, is restricted to rocks of Late Ordovician age, wherever they occur. Most of "formations" assigned to Cincinnatian series are actually biostratigraphic zones. Name Cincinnati group revived for body of rocks continuous with type Cincinnatian series in Cincinnati arch region.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1029–1068. There is general agreement as to how local section in Cincinnati region should be subdivided into formational units, but there are differences of opinion as to how these formations should be named and grouped into larger units. If reference section of Cincinnatian in Cincinnati region is considered to include all strata between Point Pleasant (Cynthiana) beds and the Brassfield and their lateral equivalents, eight reasonably distinct formational units can be recognized in sequence. In ascending order, these are Eden, Fairview, McMillan, Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations. Eden formation may be considered reference standard for an early Cincinnatian Eden stage; Fairview and McMillan formations constitute standard for medial Cincinnatian Maysville stage; the Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations define Richmond stage of Cincinnatian. Eden, Fairview, and McMillan rocks constitute Covington group, which contains standard section of both Eden and Maysville stages.

M. P. Weiss and C. E. Norman, 1960, Ohio Geol. Survey Inf. Circ. 26, p. 1–14, chart 1. Report traces development of stratigraphic classification of Ordovician rocks in Cincinnati region.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–33. Cincinnatian series comprises Edenian, Maysvillian, and Richmondian stages. Boundary between Trentonian and Cincinnatian series has been defined variably because of selection of differing horizons in known successions and varying correlations between type sections in separated areas. Boundary in North America is taken invariably as separating "Middle" and "Upper" Ordovician, although in European terms assuming the Caradocian to be "Middle," the American boundary lies within the Cincinnatian under any definition of series. With respect to base of Cincinnatian or "Upper Ordovician," using New York stages as applied herein, the boundary has ranged from the base to the top of the Pictonian. In present report, the lower series boundary is placed above all the Utica; the Pictonian is placed at top of Trentonian.

Type locality: Region about Cincinnati, Ohio.

Cincinnatus Sandstone[1]

Upper Devonian: Central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 24, chart.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown as shale and sandstone. Underlies Kattel shale.

Typical exposures along Otselic River. Named from Cincinnatus Township, Cortland County.

Cinder Cone Basalts, Lavas, Tuffs

Recent: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci. v. 21, no. 8, p. 225, 374, 375. Names applied to basalts at Cinder Cone. Latest activity at Chaos Crags and Cinder Cone belongs to last few centuries.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta, v. 8, p. 82. Mentioned in report on uranium geochemistry of Lassen volcanic rocks.

Cinder Cone is in Lassen Volcanic National Park.

Cinnamon Ridge Member (of Flat Ridge Formation)

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 48, 49, 51–52, pls. 1, 60. Blue dense basalt, with veins of epidote and red jasper, a green amygdaloidal basalt with epidote-filled vesicles, and a tuff. These are underlain by an agglomerate and flow breccia containing angular blocks of purplish-blue flow-banded vesicular basalt, of red rhyolite, of red jasper, and of granite, in epidotic groundmass. Thickness about 190 feet. Beds thin out east of Wolfpen Branch. Lies near base of formation.

Named from Cinnamon Ridge, 1 mile west of Gossan Lead district. Occurs west of Comers Rock-Blue Spring Gap Road and northwest of Comers Rock village, Gossan Lead district. Section measured on Cinnamon Ridge, Mouth of Wilson quadrangle, Grayson County.

Cintura Formation[1] (in Bisbee Group)

Lower Cretaceous (Comanche Series): Southeastern Arizona.

Original reference: F. L. Ransome, 1904, U.S. Geol. Survey Prof. Paper 21, p. 56, 68.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8 (table), 76, pl. 1. Top of Bisbee group. Occupies less than 2 square miles of area of this report [central Cochise County]; forms eastern slopes of Mule Mountains. Consists of sandstone, mudstone, and a few thin limestone beds. As much as 1,800 feet thick in Bisbee quadrangle but only a few hundred feet of basal part represented in area of this survey. Overlies Mural limestone, contact transitional, first thick sandstone in transitional series selected as base of Cintura; underlies Quaternary.

Named for Cintura Hill near northern edge of Bisbee quadrangle.

Cinturan series[1]

Lower Cretaceous: Arizona.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 64, no. 2, p. 125–140.

Circle Volcanics[1]

Lower Mississippian: Northeastern Alaska.

Original reference: J. B. Mertie, Jr., 1930, U.S. Geol. Survey Bull. 816, p. 85.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Named for exposures along east bank of Yukon River for about 15 miles upstream from Circle, Eagle-Circle district.

Cisco Group[1]

Cisco Formation[1]

Cisco Series

Upper Pennsylvanian: Central northern and central Texas.

Original reference: E. T. Dumble, 1890 Texas Geol. Survey 1st Ann. Rept., p. lvii, pl. 3.

Wallace Lee and C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geol. Pub. 3801, p. 12–90, 118–134. Group, in Brazos River valley and Colorado River valley, includes (ascending) Graham, Thrifty, Harpersville, and Pueblo formations. Moran and Putnam formations formerly included in the Pennsylvanian are now placed in the Permian, thus restricting definition of Cisco group.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 90–92. Cisco series includes Pennsylvanian sediments above widespread disconformity which followed deposition of Home Creek limestone of Caddo Creek group, Canyon series. The Cisco is intended to be approximate Texas equivalent of Virgil series of northern midcontinent region. Upper boundary for series and Pennsylvanian system is placed at disconformity in Harpersville formation about Waldrip-Newcastle coal zone and below *Schwagerina*-bearing "Waldrip limestone No. 3" and Saddle Creek limestone. As thus defined, Permian-Pennsylvanian boundary is 40 to 150 feet below Saddle Creek limestone. "Harpersville" beds below boundary are assigned to Obregon (new) and Chaffin formations of Thrifty group; those above systemic boundary are assigned to Saddle Creek formation of expanded Pueblo group. Series comprises Graham and Thrifty groups.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 288 (fig. 1), 299. Rocks of Kawvian series (new) are widespread in North America. In north-central Texas, series includes the Canyon and Cisco groups.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80. In Colorado River area, Texas, base of rocks classed as Permian lies about 50 feet below Saddle Creek limestone member of Pueblo formation. Beds between Saddle Creek units and boundary at base of Permian are assigned to Waldrip shale member of Pueblo. First limestone above disconformity is a 1-foot fusuline-bearing limestone called Waldrip No. 3 limestone by Drake (1893). Disconformity marks top of Cisco group. In accordance with Cheney's (1940) classification, term Harpersville is suppressed.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58 (table 1), 68–74, pl. 27. Drake (1893, Texas Geol. Survey 4th Ann. Rept., pt. 1) referred lower part of what is now considered Cisco group, including his Bluff Creek and Campophyllum beds, to Cummins' (1891) Canyon division. To Cummins' Cisco division he referred the rocks from base of his Trickham bed up to base of his Coleman Junction bed (Coleman Junction limestone of Putnam formation, Wichita group, Moore, 1949). Plummer and Moore (1921, Texas Univ. Bull 2132) reclassified Drake's beds as members and considered his Bluff Creek bed to be a member of their Graham formation. Gunsight limestone (Plummer, 1919) and the newly named Wayland shale were also included in Graham formation which they placed in Cisco group. Plummer and Moore (1921) placed upper boundary of Cisco at top of their Coleman Junction limestone. Thus they considered Cisco group to consist of all beds from their Home Creek limestone to top of their Coleman Junction limestone. They placed in Thrifty formation all beds between their Wayland shale and top of Breckenridge limestone (Drake's Chaffin bed). Their Harpersville formation consisted of Drake's Waldrip and Saddle Creek beds. They also included the Pueblo, Moran, and Putnam formations in this Cisco group. Sellards (1933, Texas Univ. Bull. 3232) considered top of Home Creek as base of Cisco group, but lowered top of Cisco to top of Plummer and Moore's (1921) Camp Colorado limestone of Pueblo formation. Bullard and Cuyler (1935, Texas Univ. Bull. 3501) retained these boundaries but raised Graham-Thrifty boundary to top of Speck Mountain limestone member. Present report [Brown and Coleman Counties] places top of Thrifty formation of Cisco group at top of Chaffin limestone member, the most persistent mappable unit in that part of stratigraphic sequence, and uppermost unit in which distinctive Pennsylvanian fusulinids have been found. Because boundary between Permian and Pennsylvanian is obscure and probably gradational, no definite upper boundary between the two systems has been drawn. Formations and members of Cisco group as recommended in this report are (ascending) Graham formation with Bluff Creek shale, Gunsight limestone, Wayland shale, and Ivan limestone members; and Thrifty formation with Speck Mountain limestone, Breckenridge limestone, Parks Mountain sandstone, and Chaffin limestone members. Overlies Caddo Creek formation of Canyon group; underlies Pueblo formation of Wichita group. Thickness about 400 feet.

Named for Cisco, Eastland County.

Cisco Branch facies[1] (of Floyds Knob Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 210–219.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. Correlation chart lists Cisco Branch facies of Floyds Knob formation.

Name derived from Cisco Branch, a tributary to Salt Creek which flows mainly across secs. 9, 17, and 18, T. 7 N., R. 1 E., Monroe County.

Cisco Lake Sandstone

Pennsylvanian: North-central Texas.

F. B. Plummer, 1947, Jour. Geology, v. 55, no. 3, pt. 2. p. 194 (table 1). Name appears on table of Pennsylvanian formations.

F. B. Plummer, H. B. Bradley, and F. K. Pence, 1949, Texas Univ. Bur. Econ. Geology Pub. 4915, p. 8, pls. 2, 6. In Eastland County, the Cisco Lake sandstone directly overlies the lower Crystal Falls limestone; in Brown County overlies Curry clay.

First mentioned as cropping out at Cisco Lake spillway, Eastland County.

Cisneros Basalt (in Hinsdale Series)

Pliocene: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 3, 38, 51–53, pl. 1. Dark-gray slightly vesicular porphyritic olivine basalt. Thickness 10 to 30 feet. Overlies Cordito member (new) of Los Pinos formation with slight angular unconformity. Not overlain by younger rocks and original upper surfaces have been destroyed. Name credited to Butler (unpub. dissert.).

Named for Cisneros Park, in NW¼ T. 29 N., R. 8 E. Found in Las Tablas quadrangle, west and north of Canon del Agua, and in extreme NE cor. secs. 16 and 17, T. 29 N., R. 9 E.

Cistern Member (of Yegua Formation)

Eocene (Claiborne): Southern Texas.

H. D. McCallum, 1947, South Texas [Geol. Soc. Guidebook] 14th Ann. Mtg. Field Trip, p. 4, 5. Black to gray sandy clay. Member is downthrown on the Imogene fault and overlies the so-called Dime Box member.

Derivation of name not stated. Dime Box member occurs in Lee County.

†Citico Conglomerate[1]

Citico Conglomerate Member (of Sandsuck Shale)

Lower Cambrian: Eastern Tennessee and western North Carolina.

Original reference. A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 2.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 29. In eastern Tennessee, Citico conglomerate may be used as a member name for conglomerate beds and lenses within Sandsuck shale, especially south of Miller Cove fault.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 954. Citico, as used by Keith, is abandoned.

Named for Citico Creek, Monroe County, Tenn.

Citronelle Formation[1]

Pliocene: Gulf Coastal Plain from eastern Texas to Virginia, inclusive.

Original reference: G. C. Matson and E. W. Berry, 1916, U.S. Geol. Survey Prof. Paper 98–L, p. 167–208.

C. J. Roy, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 10, p. 1553–1559. Type locality of Citronelle, as designated by Matson and Berry (1916), is significant mainly because of exposure of plant-bearing clays near Lamberts Station about 5 miles south of Citronelle, Ala. Flora from these clays was correlated with Pliocene by Berry. Recent studies have shown that these clays are faulted and overlain unconformably by sand of the so-called Citronelle formation. Structural evidence indicates that the clays are older than the sands, hence, flora of the clays can not be used to correlate the sands. Suggested that term Citronelle, as formation name, be dropped.

G. F. Brown and others, 1944, Mississippi Geol. Survey Bull. 60, p. 45, 46, 54–59. Graham Ferry formation (new) of Pliocene and Pleistocene age disconformably underlies Citronelle formation.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Citronelle formation of Mississippi and Alabama and the unnamed fluvial (?) sands of Georgia may be of early Pleistocene age. Citronelle and unnamed sands shown on chart as Pliocene.

C. W. Carlston, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1119–1121, pl. 1. Late Pliocene or early Pleistocene.

R. O. Vernon, 1952, *in* A summary of the geology of Florida and a guidebook to the Cenozoic exposures of a portion of the State: Florida Geol. Survey, p. 59. Prior to 1942, Pliocene series in Florida was composed of Citronelle formation, Tamiami limestone, Buckingham marl, Bone Valley gravel, Alachua formation. Charlton formation, and Caloosahatchie marl. Vernon (1942) dated a part of Citronelle formation as possibly early Nebraskan and the remainder as Pleistocene alluvium. This fieldwork cast some doubt on dating of "Pliocene" beds in south peninsula. Cooke (1945, Florida Geol. Survey Bull. 29) continued to recognize these units as Pliocene.

J. A. Doering, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1882. Citronelle, of south Mississippi and Alabama, which was considered to be, in part, a residual formation (Doering, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 5), is now recognized to be equivalent of Willis formation of Texas and Louisiana. Name Citronelle has priority, and it is herein used for combined Citronelle-Willis. Formation was originally correlated as Pliocene in age by Matson and Berry (1916) on evidence of single fossiliferous outcrop located a few miles south of Citronelle. Doering (1935) pointed out that the fossil bed appeared to be a part of the underlying formation. This opinion was concurred with by later investigators. Citronelle is now believed to be Pleistocene.

V. T. Stringfield and P. E. LaMoreaux, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 4, p. 742–757. Age discussion. Red Bluff locality on Perdido Bay, Baldwin County, Ala., described by Matson and Berry (1916), restudied. Here, as much as 45 feet of Citronelle exposed. Exposures show that bed containing fossil plants is underlain by orange-colored sand and clay typical of Citronelle. Flora considered to be Pliocene in age. In addition to fossil evidence, oldest marine terrace of Pleistocene age in Florida is underlain by Citronelle formation, indicating that formation is older than oldest Pleistocene.

J. A. Doering, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 764–786. Age problem discussed. Fossil evidence supports no more than a pre-Nebraskan determination, thus making an early Pleistocene correlation as plausible as one of late Pliocene.

K. B. Ketner and L. J. McGreevy, 1959, U.S. Geol. Survey Bull. 1074–C. p. 71–72. Cooke and Mossom (1929, Florida Geol. Survey 20th Ann. Rept.), assigned certain clayey, micaceous sands of peninsular Florida to the Citronelle. However, Citronelle formation of Pliocene or later age, apparently does not extend into peninsular Florida. Clayey, micaceous sand, which has been considered an equivalent of Citronelle, is late middle Miocene or early late Miocene in age.

J. A. Doering, 1960, Jour. Geology, v. 60, no. 2, p. 182–201. Citronelle formation of eastern Gulf Coast region extends northward across coastal plains of Georgia, South Carolina, North Carolina, and Virginia, as gravelly sand formation 100 feet thick, covering 30,000 square miles of upland area. These deposits were shown on early geological maps as the Lafayette or Altamaha formation, of late Pliocene or early Pleistocene age. In more recent geological reports, the deposits have been ignored or included in underlying Tertiary or Cretaceous formations; miscorrelations at State boundaries are involved in these later interpretations. Determinations made on basis of plant fossils indicate early Pleistocene (preglacial) age.

Type locality: Exposures around Citronelle, Mobile County, Ala., especially along Mobile and Ohio Railroad for a distance of 3 or 4 miles.

City Bluffs Shale (in Shawnee Formation)[1]

Pennsylvanian: Northwestern Missouri and southwestern Iowa.

Original reference: G. L. Smith, 1909, Iowa Geol. Survey, v. 19, p. 613, 615, 617, 622, 631.

Named for City Bluffs, now known as Burlington Junction, Nodaway County, Mo.

City Creek Limestone

Upper Devonian: Central northern Utah.

A. E. Granger and others, 1952, Utah Geol. Soc. Guidebook 8, p. 8, pls. 1, 2. Fossiliferous gray shaly limestone. Medium to thick bedded, and commonly shows an incipient large-scale-pencil fracture at right angles to the bedding. Weathers to mottled olive tan. Thickness 160 feet. Overlies Swan Peak(?) quartzite with apparent conformity. Underlies Madison limestone.

J. E. Brooks, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 55. In areas of Becks Spur and City Creek

Canyon, Edvalson (1947, unpub. thesis) described section of Upper Devonian rocks to which he applied name Becks formation. The Becks underlies the Madison and rests on quartzose sandstones and quartzites which were provisionally referred to Swan Peak quartzite. Granger and Sharp (1952) applied name City Creek to these same rocks. Granger (1953) abandoned name City Creek and applied name Pinyon Peak.

Granger (1953), U.S. Geol. Survey Circ. 296 did not use term City Creek. It may be inferred from this report that he abandoned term City Creek in favor of Pinyon Peak.

On the Salt Lake Salient and in City Creek Canyon in Wasatch Mountains east of Salt Lake City.

City Creek Series

Precambrian: Central Arizona.

E. D. Wilson, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1118 (table), 1126–1127. Series of shale beds with some interbedded quartzite. At northern base of Mazatzal Mountains, series comprises (ascending) well-stratified grayish-black to purplish siliceous shale member at least 800 feet thick; 15-foot member of alternating shale and novaculitic quartzite; thin-bedded friable maroon shale member about 50 feet thick; 10-foot member of alternating novaculitic quartzite and shale; and thin-bedded maroon to purple shale member with some interbedded quartzite, apparent thickness at least 1,000 feet. Farther northwest, in bluffs fronting East Verde River, series consist of very thin bedded friable grayish-green shale; thickness of this member not determined. Total thickness about 2,000 feet. Relation of series to other Precambrian rocks unknown. Unconformably underlies Tapeats sandstone; appears only in fault contact with Yaeger greenstone.

At northern base of Mazatzal Mountains on western side of City Creek (long 111°30′W.).

Clackamas Gravels

Pleistocene: Northwestern Oregon.

R. C. Treasher, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2034. Name applied to gravels deposited from eroded Troutdale formation in Clackamas Valley.

R. C. Treasher, 1942, Geologic map of the Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. Described as poorly indurated, rudely bedded conglomerate; this lack of structure is principal feature distinguishing Clackamas from the Troutdale. Thickness as much as 100 feet.

Forms cover on terraces east of Carver; west of Carver, forms cover on terraces to Clackamas; northwest of Clackamas forms valley fill.

Claflin Ranch Formation

Tertiary: Southeastern Arizona.

Kenyon Richard and J. H. Courtright, 1960, Arizona Geol. Soc. Digest, v. 3, p. 1, 6. A thick series of clastic beds unconformably underlying Silver Bell formation. Enclosed within these thin- to thick-bedded clastics are angular blocks of andesite-schist conglomerate over 50 feet in length and 25 feet in thickness. Resembles Tucson Mountain chaos as it is exposed one-half mile south of Gates Pass.

Present in Silver Bell area and in South Tucson Mountains.

Claggett Formation[1] **or Shale** (in Montana Group)

Claggett Shale Member (of Cody Shale)

Upper Cretaceous: Central Montana and northern Wyoming.

Original reference: J. B. Hatcher and T. W. Stanton, 1903, Science, new ser., v. 18, p. 211–215.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–111. In Hardin area, Big Horn and Yellowstone Counties, Wyo., considered upper member of Cody shale. Thickness 367 feet. Overlies shale member equivalent to Eagle sandstone; underlies Parkman sandstone.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Claggett shale mapped in northwestern Wyoming.

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, pl. 7. Plate 7 shows Livingston formation intertongues with Claggett, Judith River, Bearpaw, Lennep, Hell Creek, Tullock, and Lebo formations.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 108 (fig. 1), 115. Claggett shale described on northwest flank of Sweetgrass arch, northwestern Montana. Commonly medium gray, soft, and silty. Thickness 420 feet on Goosebill Butte; 90 feet in western part of Sweetgrass Hills. Overlies Eagle sandstone; underlies Judith River formation.

Named for old Fort Claggett (now called Judith), at mouth of Judith River, Mont.

Claiborne Group[1]

Eocene, middle: Gulf Coastal Plain from Georgia to southern Texas.

Original reference: T. A. Conrad, 1847, Philadelphia Acad. Nat. Sci. Proc., v. 3, p. 280–282.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 58–160. Group comprises (ascending) Carrizo sand; Reklaw formation with Newby glauconitic sand and Marquez shale members (both new); Queen City sand with Omen glauconitic sand member; Weches glauconite marl with Tyus marl, Viesca glauconitic marl and Therrill clay members (all new); Sparta sand; Stone City beds (formation); Crockett formation with Wheelock marl, Landrum shale, Spiller sand, and Mount Tabor shale members (all new); and Yegua formation. Overlies Sabinetown shale of Wilcox group; underlies Uvalde(?) formation. Middle Eocene.

C. W. Cooke, 1939, Jour. Paleontology, v. 13, no. 3, p. 337-340. Gosport sand of Alabama, heretofore classified as topmost formation of Claiborne group (Eocene), and only known formation of "upper Claiborne" age, proves to be nearly equivalent to Moodys marl of Mississippi, the basal formation of Jackson group. Recommended that name Gosport be replaced by Moodys and that Claiborne group be restricted to formations heretofore classified as lower Claiborne.

H. A. Tourtelot, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 6. In Quitman fault zone, group includes Tallahatta formation, Zilpha clay, Winona sand, Kosciusko sand, Wautubbee formation, and Cockfield formation.

P. L. Applin and E. R. Applin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1732–1733. Avon Park limestone, Tallahassee limestone (with nonfossiliferous facies) and Lake City limestone (early middle Eocene) represent Claiborne group in Florida Peninsula, and where all three units are present they appear to make, in most places, a conformable sequence. In J. S. Cosden's Lawson well No. 1, Marion County, beds of lignite occurring at contact of Lake City with nonfossiliferous limestone are believed to indicate local unconformity. Along northeast coast of Florida and in south half of peninsula, nonfossiliferous limestone is not present and the Avon Park rests on Lake City limestone.

L. D. Toulmin, Jr., 1944, Southeastern Geol. Soc. [Guidebook] 1st Field Trip, p. 10–11. Group, in Alabama, comprises (ascending) Tallahatta, Lisbon, and Gosport formations. Overlies Hatchetigbee formation of Wilcox group; underlies Moodys Branch marl of Jackson group.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. As mapped, group includes Tallahatta formation, Zilpha clay, Winona sand, Neshoba sand, Sparta sand, Cook Mountain formation, and Cockfield formation.

E. H. Rainwater, chm., 1945, Southeastern Geol. Soc. [Guidebook] 3d Field Trip, p. 47–51. Claiborne group in subsurface in western Florida is subdivided into Lisbon and Tallahatta formations in accordance with usage in Alabama. Overlying Gosport formation also was formerly included in Claiborne, but is now generally considered lower Jackson in age. Overlies Wilcox group not subdivided in subsurface of western Florida.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Group, in Alabama and Georgia, comprises (ascending) Tallahatta formation, Lisbon formation, and Gosport sand.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 88–111. Rocks assigned to Claiborne group of peninsular Florida differ in faunal content and lithology from those recognized throughout Gulf Coast elsewhere. In general, Claiborne group of northern and peninsular Florida is composed of carbonates and evaporites and that of western Gulf Coast is composed of clastics, largely sands and clays. An occasional fossil common to both sections support stage-age assignments, but these are insufficient to allow extension of Gulf Coast formational nomenclature to carbonate rocks of Florida. Applin and Applin (1944) erected three formations in Claiborne group: Lake City limestone (early middle Eocene), Tallahassee limestone (late middle Eocene), and Avon Park limestone (late middle Eocene). In western Florida, Claiborne group is not present at surface, but two-fold division can be recognized in subsurface, Gosport at top and Lisbon formation at base. Disconformably underlies Moodys Branch formation of Jackson group. Claiborne-Jackson contact discussed [see Jackson group].

G. E. Murray *in* W. C. Holland, L. W. Hough, and G. E. Murray, 1952, Louisiana Dept. Conserv. Geol. Bull. 27, p. 77–78, pls. 11, 12. Current usage of Claiborne group is in time-stratigraphic sense, including within its limits many lithologic types deposited during several advances and retreats of sea. Recommended that Claiborne be utilized strictly as group name for clastic facies in central and western Gulf Coast Plain below Jackson stage and above Wilcox group. So used, it would be partially the arenaceous counterpart of calcareous Lisbon group of eastern Gulf Coast.

James Turner, 1952, Mississippi Geol. Survey Bull. 76, p. 10. In Yalobusha County, Claiborne [group] includes (ascending) Meridian formation, Tallahatta, Winona, Zilpha, and Kosciusko formations.

H. V. Andersen, 1960, Louisiana Dept. Conserv. Geol. Bull. 34, p. 85–94, maps. Group, in Sabine Parish, comprises (ascending) Cane River, Sparta, Cook Mountain (with Dodson member equivalent, Milams and Saline Bayou members), and Cockfield formations. Overlies Wilcox group (rock term); underlies Jackson group.

Named for exposures at Claiborne Bluff and Claiborne Landing, on Alabama River, Monroe County, Ala.

†Claiborne Sand (in Claiborne Group)[1]

Eocene, middle: Southern Alabama and Mississippi.

Original reference: T. A. Conrad, 1847, Philadelphia Acad. Nat. Sci. Proc., v. 3, p. 280–281.

G. D. Harris, 1940, Science, v. 92, no. 2386, p. 257–258. Name Claiborne in geologic literature discussed. Possibly name Claiborne sands should not be abandoned.

Named for exposures at Claiborne Bluff, on Alabama River, in Monroe County, Ala.

Claiborne Stage, Age

Eocene, middle: Gulf Coastal Plain from Georgia to southern Texas.

G. E. Murray, 1953, Mississippi Geol. Soc. [Guidebook] 10th Field Trip, p. 54. In discussing subsurface stratigraphy of Beauregard and Allen Parishes, La., Murray (1952) used Claiborne as a rock-unit term and utilized three unnamed stages between Jackson and Sabine stages. This usage is improper and should not be followed. Instead, Claiborne stage should consist of all deposits in Gulf and Atlantic Coastal Plain province formed during fluctuations of middle Eocene sea, beginning with close of withdrawal of Sabinian sea and ending with first transgression of Jacksonian sea. The Reklaw-Queen City, Cane River-Sparta, and Cook Mountain-Cockfield cycles of deposition, and their demonstrable equivalents should be considered substages. Type exposures of Gosport, Lisbon, and Tallahatta formations in Alabama, exposures at Claiborne Bluff and Claiborne Landing on Alabama River, Monroe County, Ala., and type exposures of Reklaw, Queen City, Winona-Zilpha-Weches-Cane River, Sparta, Cook Mountain, and Yegua-Cockfield formations in Mississippi, Louisiana, and Texas are exemplary of the stage. Claiborne age includes all time covered by deposition of these deposits.

Clallam Formation[1]

Miocene: Northwestern Washington.

Original reference: R. Arnold, 1906, Geol. Soc. America Bull. v. 17, p. 451–468, map.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 118, 173, 175. Recent studies indicate that sandstones and shales occurring along sea-cliffs between Clallam Bay and Pysht are probably correlative, at least in part, with middle Miocene Astoria formation of southwestern Washington and western Oregon. Former broad usage of name Clallam should be restricted to Miocene part of stratigraphic section along northern side of Olympic Peninsula. May become desirable to abandon name

Clallam and use only term Astoria formation. Massive sandstones, conglomerates, shaly and pebbly sandstones, and interstratified clay shales constitute greater part of formation. Appears to be unconformable upon Oligocene shales. Uppermost beds have been largely removed by erosion.

R. D. Brown, Jr., and H. D. Gower, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2492, 2494, 2511. Conformably overlies Twin River (redefined).

H. D. Gower, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–129. Described in Pysht quadrangle. Term used in restricted sense of Weaver (1937). Thick-bedded and crossbedded light-olive-gray fine- to coarse-grained sandstones. Estimated thickness more than 2,500 feet. Overlies Twin River formation. Much of coastal section highly deformed and inland poorly exposed. Miocene.

Well exposed in region between Clallam Bay and Pillar Point, Clallam County.

Clan Alpine Volcanics

Miocene, middle to upper(?): Western Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 182–183, pls. 10, 11. Include rhyolite, quartz latite and dacite tuffs, breccias, and flows. Rhyolites range in color from pale yellowish brown to dark yellowish brown and pale red. Thickness of individual flows ranges from few feet up to 40 feet, the tuffs from few inches to massive beds of 40 feet or more. Quartz latites range in color from medium light gray to light brownish gray, brownish gray, and pale red purple and may well represent the dominant volcanic. Total thickness in excess of 3,000 feet in southern part of range and increases northward. Oldest rock in area; unconformably underlies Middlegate formation (new).

Named for exposures in southern parts of Clan Alpine Range. Extends well to northward to form important part of that mountain mass. Churchill County.

Clancy Granodiorite

Upper Cretaceous: Southwestern Montana.

Adolph Knopf, 1957, Am. Jour. Sci., v. 255, no. 2, p. 81, 91–92, map facing p. 88. A light-gray coarse-grained rock in which quartz is conspicuous. Represents the second intrusion of the Boulder bathylith. Cuts the older Unionville granodiorite (new).

Named from the Kain quarry on Clancy Creek, Jefferson County.

Claremont Shale (in Monterey Group)[1]

Miocene, middle: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 69 (table 14), 70, pl. 11. Described in Contra Costa County where it occurs as band about 1,000 feet wide southwest of Pinole and trends northwestward toward shore of San Pablo Bay. Fine-grained light-colored moderately hard slightly bituminous shale locally containing thin layers of grit and fine conglomerate; east of Berkeley, formation is a series of alternating thin layers of siliceous shale or chert and partings of shale. Probable average thickness south of San Pablo Bay 800 feet. Conformably underlies Oursan sandstone; overlies Sobrante sandstone.

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–88. In Hayward quadrangle, Claremont shale ranges in thickness from 150 to 300 feet. Mapped for convenience as Claremont, though quite possibly from a younger formation of Monterey group, is a siliceous mudstone containing ovoid masses that may be diatoms; it crops out between Leona rhyolite and serpentine in hill above Hayward High School, several miles west of main Tertiary outcrops. Conformably overlies Sobrante sandstone; underlies unnamed middle sandstone and shale of Monterey group.

C. A. Hall, Jr., 1958, California Univ. Pubs., Geol. Sci., v. 34, no. 1, p. 16–18, fig. 2, geol. map. Claremont shale, in Pleasanton area, Alameda and Contra Costa Counties, is about 700 feet thick. Overlies Sobrante sandstone; underlies Oursan sandstone. Term Monterey group not considered appropriate in this area.

Named for exposure on Claremont Creek, Concord quadrangle.

†Claremore Formation[1]

Pennsylvanian: Northeastern and central eastern Oklahoma.

Original reference: C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910, Oklahoma State Univ. Research Bull. 3, p. 6, 7, 10.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. A vaguely defined unit including Fort Scott limestone and subjacent strata. Abandoned by Oklahoma Geological Survey.

Named for Claremore, Rogers County.

Clarendon Beds[1]

Pliocene: Texas.

Original reference: J. W. Gidley, 1903, Am. Mus. Nat. History Bull., v. 19, p. 632–635.

Named for Clarendon, Donley County.

Clarendon Dolomite

Cambrian: West-central Vermont.

G. W. Bain, 1938, New England Intercollegiate Geol. Assoc. [Guidebook] 34th Ann. Field Mtg., p. 8. Name applied to massive gray-weathering dolomite which represents most of lower half of Rutland formation in this area. Dolomite contains small percentage of coarse sand grains. Thickness 2,000 to 3,000 feet.

Best exposed in Clarendon and along Tinmouth Channel, Rutland County.

Clarendon Gravel[1]

Pleistocene: Northwestern Pennsylvania.

Original reference: E. H. Williams, Jr., 1920, Am. Philos. Soc. Proc., v. 59, p. 62, 73.

Named for Clarendon, Warren County.

Clarendonian Age

Pliocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 12, pl. 1. Provincial time term, based on the Clarendon local fauna (and member?), near Clarendon, Donley County, Texas. Covers the interval between the Barstovian (Miocene) and Hemphillian (Pliocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for the North American continental Tertiary. [For sequence see under Puercan.]

D. I. Axelrod, 1957, Am. Jour. Sci., v. 255, no. 10, p. 695 (fig. 1). Table shows Clarendonian as late Miocene and early Pliocene. Determination based on paleoclimatic analyses of sequences of Late Tertiary floras.

Clarendon Springs Dolomite[1] (in Stockbridge Group)

Upper Cambrian: West-cental Vermont and Massachusetts

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 397.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 525, 536–539. Keith included in Clarendon Springs all dolomite beds between uppermost sandy strata of limestones of overlying Shelburne marble. In some localities along western side of area, the dolomite includes horizons both above and below a sandstone. Rogers (1937, Geol. Soc. America Bull., v. 48, no. 11) indicates stratigraphic break above the dark-gray dolomites and suggests that the sandstone is basal to certain of the higher strata. Break was not noted in eastern area. Upper strata of dolomite facies grade laterally into limestones and marbles. Thicknesses: 120 feet at Brandon, 80 feet at Middlebury, 45 feet at New Haven.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 23–24. In Castleton area, unit is 130 to 175 feet thick. Overlies Danby formation; underlies Boardman formation (new).

A. B. Shaw, 1951, Jour. Paleontology, v. 25, no. 1, p. 97. Includes Milton dolomite facies.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 21 (table 1), 42. In this report [vicinity of Rochester and East Middlebury], name Clarendon Springs is used according to definition of Cady (1945). Thickness about 200 feet. Top of section in western sequence. Overlies Danby formation.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. In Cheshire quadrangle, Massachusetts, included in Stockbridge group. Thickness 0 to 800 feet. Contact with underlying Kitchen Brook dolomite (new) not observed; underlies Shelburne marble.

Type locality: Clarendon Springs, Rutland County, Vt.

Clarion Clay (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania, Ohio, and West Virginia.

Original reference: W. G. Platt, 1880, Pennsylvania 2d Geol. Survey Rept. H_5.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 44, table 1. Clarion clay listed as member of Clarion cyclothem in Perry County. Underlies Clarion (No. 4a) coal; overlies Canary ironstone. Allegheny series.

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. Survey Rept. Inv. 17, p. 16. Clarion underclay mentioned in report on high-alumina clays of West Virginia. Samples collected in Randolph County. Basal member of Allegheny series.

Name derived from Clarion, Clarion County, Pa.

†Clarion coal group[1] (in Allegheny Formation)

Pennsylvanian (Allegheny Series): Southeastern Ohio and southwestern and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 474–477.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 56–59. Rogers (1858) used Clarion as a group name for beds between the Freeport (Lower?) sandstone above and Tionesta sandstone below. As originally defined, it included beds now assigned to Brookville, Lower, Middle, and Upper Kittanning, Lawrence, and Scrubgrass cyclothems. Clarion cyclothem is restricted to the members lying between Scrubgrass and Winters cyclothems.

Type area: Clarion River valley, western Pennsylvania.

Clarion cyclothem or cyclic group

Pennsylvanian (Allegheny Series): Southeastern Ohio and southwestern Pennsylvania.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 6. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 44, table 1, geol. map. Includes Clarion shale and sandstone, 42 feet, Canary ironstone; Clarion clay, 3 feet, and Clarion (no. 4a) coal. Occurs below Scrubgrass cyclothem and above Brookville cyclothem. In area of this report, the Allegheny series is described on a cyclothemic basis; nine cyclothems are named. [For sequence see Brookville cyclothem.]

E. G. Williams, 1957, Dissert. Abs., v. 17, no. 12, p. 2982. Clarion cyclic group recognized in Clearfield Basin, Pennsylvania.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 56–59. Rogers (1858, Geology of Pennsylvania, v. 2, pt. 1) used Clarion as a group name for beds between the Freeport (Lower?) sandstone above and Tionesta sandstone below. As originally defined, it included beds now assigned to Brookville, Lower, Middle, and Upper Kittanning, Lawrence, and Scrubgrass cyclothems. Clarion cyclothem is now restricted to four members lying between Scrubgrass and Winters cyclothems. Members (ascending) Clarion shale and (or) sandstone, Canary ironstone, Clarion underclay, and Clarion (No. 4a) coal members. In this report, the Allegheny series is described on a cyclothemic basis; 13 cyclothems are name. [For sequence see Brookville cyclothem.]

First described in Perry County, Ohio.

Clarion Formation[1] (in Allegheny Group)

Pennsylvanian: Pennsylvania.

G. H. Ashley, 1923, Eng. Mining Jour.-Press, v. 115, no. 25, p. 1108; 1926, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 65, p. 29, pl. 4. Clarion formation, Allegheny group, comprises (ascending) Brookville or A coal, Clarion sandstone, Clarion or "A" coal, and Vanport limestone. Overlies Homewood formation which includes Homewood sandstone; underlies Kittanning formation.

C. K. Graeber and R. M. Foose, 1942, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 54, p. 40–45. Lowermost formation in Allegheny group. Includes strata from base of Lower Kittanning clay to base of clay beneath Brookville coal. Comprises (ascending) Brookville coal, Clarion sandstone, Clarion clay, Lower Clarion coal, Upper Clarion coal, Vanport limestone, Lower Kittanning sandstone. Thickness 120 to 145 feet. Underlies Kittanning formation; overlies Homewood sandstone of Pottsville series. Area of report Brookville quadrangle.

E. G. Williams and R. P. Nickelsen, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 36–50. Discussion of correlation of Pottsville and lower Allegheny series in Clearfield and Centre Counties. Clarion formation (Allegheny series) which overlies the Pottsville is 65 to 190 feet thick and consists of cyclic sequences of clay, coal, shale, siltstone, silty shale, and sandstone. Includes (ascending) Brookville coal, Clarion sandstone, Clarion coal, Vanport limestone, and Kittanning sandstone. Underlies Kittanning formation. Reference sections designated. Stratigraphic nomenclature of Clarion formation is more confused and uncertain than that of other formations of the Allegheny. This is due partly to inherent complexity of formation, partly to rather loose definition and description of type sections and partly to questionable correlations between type sections.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook for Field Trips, Pittsburgh Mtg., p. 70 (fig. 5), 71. Allegheny group comprises (ascending) Clarion, Kittanning, and Freeport formations. The Clarion overlies Mercer formation of Pottsville group.

E. G. Williams, 1960, Jour. Paleontology, v. 34, no. 5, p. 910 (fig. 2). Formation includes (ascending) Clarion coals, Clarion sandstone, Vanport limestone, and Lower Kittanning sandstone. Overlies Mercer formation, which has Homewood sandstone and shale at top; underlies Kittanning formation, which has Lower Kittanning coal in lower part.

Reference section (31): Northeast rectangle of Glen Richey quadrangle, Clearfield County, in coal strip mines on western end of large hill, one-half mile east of Krebs. Reference section (32): In south-central rectangle of Clearfield quadrangle, Clearfield County, in coal strip mines on a small hill 0.4 mile northeast of mouth of Clearfield Creek. Name derived from Clarion, Clarion County.

Clarion Sandstone Member (of Allegheny Formation)[1]

Clarion Sandstone (in Clarion Formation)

Pennsylvanian: Western Pennsylvania, Maryland, eastern Ohio, and West Virginia.

Original reference: J. J. Stevenson, 1878, Pennsylvania 2d Geol. Survey Rept. K_3, p. 25, 38.

C. K. Graeber and R. M. Foose, 1942, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 54, p. 50. Sandstone between Clarion coals and Brookville coal in Clarion formation. Thickness 5 to 25 feet thick. Not always present, in which case the horizon is shale or sandy shale. In some areas, cuts out part or all of Brookville coal. Area of report is Brookville quadrangle.

Wilber Stout, Karl Ver Steeg and G. F. Lamb, 1944, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Generalized section of Ohio lists Clarion sandstone below Canary ore and above Winters coal.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 22. Clarion sandstone listed with recognizable members of Allegheny formation in Harrison County. Occurs above Clarion coal and below Vanport limestone.

E. G. Williams, 1960, Jour. Paleontology, v. 34, no. 5, p. 910 (fig. 2). As shown on generalized section of Allegheny group, Clarion formation includes (ascending) Clarion coals, Clarion sandstone, Vanport limestone, and Lower Kittanning sandstone.

Name derived from Clarion, Clarion County, Pa.

Clarion shale and (or) sandstone

See Clarion cyclothem.

Clarita Limestone

Oligocene: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no. 29, p. 133, 134 (correlation chart). Underlies Arusa formation. Middle Oligocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 332. Undefined name. Oligocene. Note on derivation of name.

Río Clarita is small stream about 30 kilometers east southeast of El Real de Santa Maria, in Darién area.

Clarita Member (of Chimneyhill Limestone)

Middle(?) Silurian: South-central Oklahoma.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 19–25, fig 4; 1960, Oklahoma Geol. Survey Bull. 84, pt. 6, p. 52–67. Name proposed to replace Maxwell's (1936) preoccupied name Dillard. Fossiliferous limestone ranging from fine calcilutite to coarse calcarenite. Most common facies is calcilutite. Thickness varies; commonly less than 20 feet; maximum thickness 45 feet (on Lawrence uplift). Unconformably overlies Cochrane; base of Clarita marked by a few inches of shale or shaly limestone. Unconformably underlies Hunton marlstone; at some places it is the Henryhouse and at other places the Haragan that overlies the Clarita.

Type locality: About 3 miles west of Clarita, Coal County, in vicinity of old Hunton townsite NW¼ sec. 8, T. 1 S., R. 8 E. This is not same as type locality designated for the Dillard.

Clark Formation[1]

Pennsylvanian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell, 1896, U.S. Geol. Survey Geol. Atlas, Folio 26, p. 3.

Named for Clark Gap, in Flat Top Mountain, Mercer County, W. Va.

Clark Canyon Lavas

Tertiary, upper, or Pleistocene: Southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 377, pl. 1. Name applied to sheet of dense, aphanitic basaltic lava.

Crops out along Clark Canyon, near Armstead, Beaverhead County.

†Clark County littorals[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 79–83.

Named for exposures in Clark County.

†Clark Fork Beds[1]

Clark Fork Beds or Member (of Polecat Bench Formation)

Paleocene: North-central Wyoming.

Original reference: W. Granger, 1914, Am. Mus. Nat. History Bull., v. 33, p. 204.

G. L. Jepson, 1940, Am. Philos. Soc. Proc., v. 83, no. 2, p. 237–238. Uppermost unit of Polecat Bench formation (new). Occurs 3,000 to 3,500 feet above base of formation. Overlies Silver Coulee beds (or member); underlies Eocene Gray Bull beds. Clark Fork fauna appears in uppermost 500 feet of formation and seems to be increasingly abundant toward top of Clark Fork beds.

F. B. Van Houten, 1944, Geol. Soc. America Bull., v. 55, no. 2, p. 178, pl. 2. Beds underlie Willwood formation (new).

Named for Clark Fork basin.

Clarkforkian Age

Paleocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 9, pl. 1. Provincial time term, based on the Clark Fork member (and faunal zone) of the Polecat Bench formation, type locality, scarp forming divide between Bighorn and Clark Fork basins and exposures near its base, Park County, Wyoming. Includes the interval between the Tiffanian (Paleocene) and Wasatchian (Eocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for the North American continental Tertiary. [For sequence see under Puercan.]

Clark Island Granite

Age not stated: Southern Maine.

F. Chayes, 1952, Jour. Geology, v. 60, no. 3, p. 215–217, 218, 220, 225, 253. Discussion of finer grained calcalkaline granites of New England. Detailed petrographic description given of Clark Island granite.

Specimens collected at Clark Island, Knox County.

Clark Peak Schist[1]

Paleozoic and Triassic(?): Southeastern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 93, 94, 247.

Exposed in Juneau district. Named for Clark Peak, Juneau district.

Clark Reservation Member (of Manlius Limestone)

Clark Reservation Limestone[1] (in Manlius Group)

Lower Devonian: Central New York.

Original reference: Burnett Smith, 1929, New York State Mus. Bull. 281, p. 26, 27, 30–35.

G. H. Davis 3d, 1953, New York State Mus. Circ. 35, p. 10. Termed a member of Manlius limestone.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 2 (columnar section), 4–5. Jamesville limestone and Clark Reservation limestone grouped under heading of transitional beds between Manlius group below and Helderberg group above.

Type section: In cliff south of lake which is in Clark Reservation State Park, west of Jamesville, Onondaga County.

Clarksburg Fire Clay Shale (in Conemaugh Formation)[1]

Clarksburg underclay member

Pennsylvanian: Northern West Virginia and eastern Ohio

Original reference: R. V. Hennen, 1912, West Virginia Geol. Survey Rept. Doddridge and Harrison Counties, p. 236.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 152. Member of Little Clarksburg cyclothem in report on Athens County. Light- to dark-gray clay or clay shale. Commonly massive and may be calcareous, micaceous, silty, and sandy. Maximum thickness less than 3 feet; average 10 inches. Associated with some development of Little Clarksburg coal, above, and (or) redbed, below. Conemaugh series.

Named for association with Little Clarksburg coal.

Clarksburg Limestone Member (of Conemaugh Formation)[1]

Clarksburg limestone member

Upper Pennsylvanian: Western West Virginia, western Maryland, eastern Ohio, and southwestern Pennsylvania.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 88.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 33; D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 59–60, geol. map. Reports refer to unit as Clarksburg limestone or limestone member of Conemaugh series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 152. Member of Little Clarksburg cyclothem in report on Athens County. Thickness 6 inches to 10 feet; average 4½ feet. Above Clarksburg redbed member and below Clarksburg underclay member. In type area, 20 to 30 feet thick, directly underlies Little Clarksburg coal, and separated from Morgantown sandstone below by 25 to 40 feet of soft shales. Conemaugh series.

Well exposed along bed of Elk and West Fork River, in vicinity of Clarksburg, Harrison County, W. Va.

Clarksburg Red Shale (in Conemaugh Formation)[1]

Clarksburg redbed member

Pennsylvanian: West Virginia and southwestern Pennsylvania.

Original reference: R. V. Hennen, 1912, West Virginia Geol. Survey Rept. Doddridge and Harrison Counties, p. 240.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 152. Redbed member of Little Clarksburg cyclothem in report on Athens County. The member is one of the rather thick and conspicuous redbeds that locally more or less unite to fill interval between Ames limestone and Connellsville sandstone and even up to Pittsburgh coal. Thicknesses range from less than 5 feet to more than 32 feet. Below Clarksburg limestone and above Morgantown sandstone and shale member. Conemaugh series.

Named for Clarksburg, Harrison County, W. Va.

Clarksburg Volcanics[1] Member (of Michigamme Slate)

Precambrian (Animikie Series): Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 604.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 36. Lower part of Michigamme slate in Marquette district, includes Bijiki iron-formation, Clarksburg volcanics, and Greenwood iron-formation members. Included in Animikie series.

Named for exposures east and west from Clarksburg, Marquette County.

Clarks Mill Beds[1]

Lower Devonian: Central Pennsylvania.

Original reference: E. W. Claypole, 1885, Pennsylvania 2d Geol. Survey Rept. F_2, p. 59–62, 181–184.

Exposed at Clark's Mill, Centre Township, Perry County.

Clarks Spring Member (of Secret Canyon Shale)

Middle Cambrian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 14–16, pl. 2. Thin-bedded limestone with prominent yellow or red argillaceous partings. The thin limestone bands are commonly one-fourth to one-half inch thick and rarely exceed 2 inches in thickness. Limestone is fined grained, silty, and blue, contrasting markedly with the yellow, or more rarely, red clay partings, which range from one-eighth to one-fourth inch thick. Locally mottled with yellow or red patches. Thickness probably 425 to 450 feet. Contacts between Clarks Spring member and lower shale member below and Hamburg dolomite above are gradational.

Type locality: Especially good exposures of the member provided by roadcuts in upper New York Canyon, just north of Clarks Spring, from which the member takes its name, Eureka mining district, Eureka County.

Clarkston Gravels, deposits

Clarkston Stage

Pleistocene (pre-Wisconsin): Eastern Washington and western Idaho.

R. L. Lupher, 1944, Geol. Soc. America Bull., v. 55, no. 12, p. 1433–1455. Stream and lake deposits older than scabland-Touchet stage [of Snake River Canyon] are well developed in Lewiston-Clarkston region about 100 miles above mouth or Snake River. Immediately southwest of Clarkston, an abandoned course of Snake River is filled with gravel to depth of at least 425 feet. The Clarkston gravels, except near canyon sides and in local tributary canyons, are composed of nearly equal amounts of basalt and pre-Tertiary igneous and metamorphic rocks. Occasional large angular erratics imbedded in stream gravels indicate that Clarkston fill accumulated during a glacial stage. The Clarkston stage is probably pre-Wisconsin.

R. L. Lupher, 1945, Jour. Geology, v. 53, no. 5, p. 337–348. Clarkston stage defined as an episode of proglacial aggradation, especially time during which Clarkston deposits accumulated. Followed earlier Pleistocene deposition, deformation, and dissection but antedated Wisconsin stage. Stream gravels (Clarkston) accumulated to depth of more than 400 feet in Snake River Canyon and in lower parts of most tributary canyons.

Type area: Center of area is at Clarkston, Wash.

Clarksville Member (of Waynesville Formation)

Clarksville division (in Richmond Group)[1]

Upper Ordovician: North-central Kentucky and southwestern Ohio.

Original reference: A. F. Foerste, 1909, Denison Univ. Sci. Lab. Bull. 14, p. 292.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on generalized section of Ohio as middle member of Waynesville formation. Underlies Blanchester member; overlies Fort Ancient member.

Named for Clarksville, Clinton County, Ohio.

Clarno Formation[1]

Eocene: Central northern Oregon.

Original references: J. C. Merriam, 1901, Geol. Soc. America Bull., v. 12, p. 496–497; 1901, California Univ. Pub., Bull. Dept. Geol., v. 2, no. 9, p. 285.

W. D. Wilkinson, 1939, Geologic map of the Round Mountain quadrangle, Oregon (1:96,000): Oregon Dept. Geology and Mineral Industries. Underlies John Day formation. Stratigraphic position and presence of fossil leaves indicate Eocene age.

A. C. Waters and others, 1951, U.S. Geol. Survey Bull. 969–E, p. 111–115, pl. 21. Oldest rocks in Horse Heaven district are andesites, tuffs, and tuffaceous sediments that constitute a part of Eocene Clarno formation. Within area the Clarno appears at surface chiefly along a strip about 4 miles long and 1½ to 2 miles wide lying between Cherry Creek and Horse Heaven Mountain. In central and western part of area, it is buried beneath andesite flows and rhyolite volcanoes that make up the higher ridges. In southern part of area, erosion has cut deeply enough to reveal large patches of Clarno rocks. Uptilted beds between southeastern corner and northern edge of area are 5,800 feet thick; base and top not exposed; nearly all measured units vary greatly in thickness along strike. Subdivided into four units. Unit 1, the oldest, consists of andesite flows interbedded with layers of clay; thickness about 600 feet. Unit 2 consists of about 1,350 feet of tuffs and a few andesite flows. Unit 3 about 1,700 feet thick. Unit 4 consists of white coarse-grained tuffs and sandy tuffs that are largely rhyolitic in composition; thickness at least 2,100 feet, top not exposed.

Typically exposed at Clarno's Ferry, on the John Day, east of Antelope near town of Fossil, on Cherry Creek and Burnt Ranch.

Claron Limestone[1] or **Formation**

Eocene(?): Southwestern Utah.

Original reference: C. K. Leith and E. C. Harder, 1908, U.S. Geol. Survey Bull. 338, p. 41.

E. F. Cook, 1952, Utah Geol. Soc. Guidebook 7, p. 96. In Pine Valley Mountains, Washington County, overlies Kaiparowits formation. Forms pink band 460 feet thick, consisting largely of lacustrine limestones with iron-stained basal conglomerate 30 to 80 feet thick. Eastward overlies successively older formations until it rests directly on Navajo sandstone.

J. H. Mackin, 1954, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–14. Claron formation consists of conglomerate, red and gray sandstone and siltstone, and pink and white limestone; aggregate thickness about 1,400 feet in Granite Mountain area. Essentially identical in lithology with, and probably equivalent to, Eocene Wasatch formation at Cedar Breaks (Pink Cliffs) in Colorado Plateau. Overlies Iron Springs formation which replaces Pinto sandstone abandoned in area. Conformably underlies sequence of lava flows and pyroclastic rocks. Eocene(?).

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 37–38. Formation consists of as much as 1,500 feet of fluvial and lacustrine sediments. In Pine Valley Mountains, underlies Quichapa group (new) with disconformity; overlies Kaiparowits formation; in some areas, appears to grade into the Kaiparowits, but in other places an erosion surface is present at base of Claron; where the unconformity is angular, basal Claron cuts sharply across a surface of low relief developed on truncated formations down to Navajo sandstone. Three-fold division: an upper white limestone and calcareous marl; pink calcareous sandstone; and basal pink conglomerate. Thickness 0 to 1,000 feet; average 500 feet. Upper Cretaceous(?).

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 100–103. Underlies Needles Range formation (new) and in some areas Isom formation (new).

C. M. Tschanz, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B295. Studies indicate that lacustrine limestone near top of Claron is Oligocene or earliest Miocene, instead of Eocene as formerly believed.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 32–36. Although Claron (Wasatch) formation is listed as Cenozoic, the lower part of it may be Late Cretaceous. No evidence by which precise age of Claron in southwest Utah can be determined. The Claron unconformably overlies formations from Kaiparowits down to Navajo sandstone; it is overlain conformably or accordantly by Quichapa formation. lower member of which has zircon age of 28 million years. Age range could be very Late Cretaceous to Oligocene.

Occurs at and around Mount Claron, Iron Springs region, Iron County.

Clarysville Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland and northeastern West Virginia.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 573.

Exposed in Hoffman Drainage Tunnel at Clarysville, Allegany County, Md.

Claverack Conglomerate (in Schodack Formation)

Cambrian: Eastern New York.

G. H. Chadwick, 1946, Am. Jour. Sci., v. 244, no. 8, p. 585. Name given to limestone conglomerate in upper part of Schodack formation. Has been mistakenly termed Burden conglomerate.

Type locality: Ham's Mills [Catskill quadrangle].

Clay City Siltstone Member (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 122, 123–124. Thin persistent calcareous siltstone 1½ to 5 feet above base of New Providence formation, Stanton facies (new). Thickness 6 inches to 3 feet. In some areas, overlies Henley shale member.

Well exposed along secondary road, one-half mile northeast of Clay City, Powell County.

Clay Creek Limestone[1] Member (of Kanwaka Shale)

Pennsylvanian (Virgil Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas, Geol. Soc. 6th Ann. Field Conf., Guidebook, p. 94, 96 (table).

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24. Thickness about 1 foot in Weeping Water valley, Cass County.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii, 17. Overlies Jackson Park shale member; underlies Stull shale member.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 62 (fig. 23), 67. Dark-blue to bluish-gray limestone, commonly massive and dense; fusulines locally abundant. Thickness as much as 5 feet. Underlies Stull shale member; overlies Jackson Park shale member.

Type locality: Clay Creek, about 1 mile west of Atchison, Atchison County, Kans. Persistent as far southward as Osage County, Kans.

Claymont Clay Bed (in Silverado Formation)

Paleocene: Southern California.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Pisolitic sandy clay. At type locality, 4 to 6½ feet thick and is about 165 feet above base of formation. Clay is underlain gradationally by coarse-grained pebbly quartz-anauxite mudstone and grades upward into coarse-grained quartzose sandstone also containing some anauxite.

Type locality: On Claymont property of Gladding McBean Co. located near divide between Gypsum Creek and Sierra Canyon, northwestern Santa Ana Mountains, Orange County.

Claypole Hills Sandstone (in McLeansboro Formation)

Pennsylvanian: Southeastern Illinois and southwestern Indiana.

J. A. Culbertson, 1932, The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 7. Coarse massive sandstone. Overlies St. Wendells limestone; underlies Friendsville coal.

Type locality and derivation of name not stated.

Claypool Formation[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: J. R. Bunn, 1930, Oklahoma Geol. Survey Bull. 40PP, p. 9.

Covers large area to south and east of Claypool, Jefferson County.

Clay Spur Bentonite Bed (in Mowry Shale)[1]

Clay Spur Bed (in Belle Fourche Shale)

Lower Cretaceous: Northeastern Wyoming, southeastern Montana, and western South Dakota.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165, p. 4.

M. M. Knechtel and S. H. Patterson, 1955, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-36. Clay Spur bentonite bed is one of uppermost strata of Mowry shale. Bed is present at or near surface almost everywhere in vicinity of contact between Mowry and Belle Fourche shales as mapped in this report [northern Black Hills district, Montana, Wyoming, and South Dakota]. Thickness as much as 7 feet, but commonly 2 to 4 feet. Although thickness in a few places is less than 2 inches, no outcrop of uppermost Mowry strata has yet been noted at which this bed is missing. Lower Cretaceous.

86–87. Clay Spur bentonite bed occurs in Belle Fourche-type shale; seems more logical to include it in the Belle Fourche than in the Mowry.

Named for exposures near Clay Spur, sec. 30, T. 47 N., R. 63 W., Weston County, Wyo.

Claysville Limestone Member (of Greene Formation)[1]

Permian: Western Pennsylvania.

Original reference: W. T. Griswold and M. J. Munn, 1907, U.S. Geol. Survey Bull. 318, p. 78.

Named from town in Donegal Township, Washington County.

Clayton Basalts

Quaternary: Northeastern New Mexico.

Helen Stobbe, 1948, (abs.), Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1354. Predominantly olivine basalts but include olivine basalts with quartz inclusions, analcime basanite, nepheline basalts, haüyne basalt, and olivine-free basalts.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1021 (table 2), 1023, 1028–1030, pl. 1; H. R. Stobbe, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1059. At least 75 percent, by estimate, are medium-gray to black, fine- to medium-grained, slightly vesicular olivine basalts occurring as surface flows and scoria cones. Most vesicular flows weather to a red brown; less vesicular flow rock tends to remain black. Age, derivation of name, and geographic distribution given.

G. H. Wood, Jr., S. A. Northrop, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–141 (sheet 2). Flows range from 10 to 50 feet in thickness and average about 20 feet.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 71–72, 75, 77–79, 115–116, 118, 126–127, 133–135, 137. Undifferentiated Clayton basalt caps broad mesas throughout central Union County. Individual sheets were named for ease of discussion although they are petrographically nearly identical: Carrizo, Herringa, Clayton Mesa (original type Clayton basalt of Collins), Apache, Seneca, and Gap flows.

Named after outcrops on large Folsom-Clayton Mesa near town of Clayton, Union County. Also occur in Colfax County.

Clayton Clay[1]

Pleistocene, upper: Connecticut.

Original reference: R. F. Flint, 1933, Geol. Soc. America Bull., v. 44, no. 5, p. 965–987.

Exposed at Clayton, Hartford County.

Clayton Formation (in Midway Group)[1]

Paleocene: Southern Alabama, southwestern Georgia, northeastern Mississippi, southeastern Missouri, and southern Tennessee.

Original reference: D. W. Langdon, 1891, Geol. Soc. America Bull., v. 2, p. 589–605.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 43, 44. Exposed at a few places in southern Illinois but probably generally present at base of Tertiary sediments. Characteristically a more or less marly glauconitic sand generally about 5 to 8 feet thick. Formerly considered

J. D. Haun, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p.

member of Porters Creek formation. Overlies McNairy formation; underlies Porters Creek clay.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Age shown as Paleocene.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 6–10. East of Butler County, Ala., name Clayton is used for all of Midway beds. In Butler County and westward in Alabama and Mississippi, it is used only for beds below Porters Creek clay. In Butler and Wilcox Counties, includes McBryde limestone member and Pine Barren member (both new). In western Alabama and Mississippi, the Clayton is represented by single unit, Chalybeate limestone member (new). In western Alabama and east-central Mississippi, the Clayton thins to a few feet and may be overlapped by Porters Creek clay in places. From Chickasaw County northward in Mississippi, formation thickens and in northern Mississippi is probably 60 feet thick. At Clayton, Ala., section consists of lower zone of about 35 feet of sand and limestone, grading from noncalcareous, *Halymenites*-bearing sand at base, through coarse sandy limestone to sand-free hard white limestone at top, and an upper zone of about 15 feet of hackly gray clay. Formation thickens eastward to nearly 130 feet in Chattahoochee River, where upper clay is represented by smooth-textured argillaceous limestone. In northern Mississippi, includes a bed of calcareous siltstone formerly regarded by Mississippi Geological Survey as base of Porters Creek. This revision is made to make base of the clay consistently the base of the Porters Creek in Mississippi and also because this siltstone carries the large nautiloid *Hercoglossa ulrichi*, a marker for upper part of Clayton in central Alabama. Underlies Porters Creek clay.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart shows Clayton in Mississippi, Alabama, and Georgia. In Georgia, undifferentiated; in Alabama, includes Pine Barren member below and McBryde limestone member above; in Mississippi includes Chalybeate limestone member. Underlies and interfingers with Porters Creek clay.

L. W. Stephenson, 1955, U.S. Geol. Survey Prof. Paper 274–E, p. 98, 100, 101. In Stoddard County, Mo., underlies Porters Creek clay and unconformably overlies Owl Creek formation. Thickness 5 to 10 feet. In Pulaski County, Ill., unconformably overlies McNairy sand.

Type locality: Cut on Central Georgia Railroad about 1 mile east of Clayton, Barbour County, Ala.

Clayton Sandstone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 298, 383.

Type locality: On waters of Griffith Creek, on road that descends into this valley, 1.2 miles northeast of Clayton, Summers County. Also occurs in Mercer and Monroe Counties ,W. Va., and in Giles County, Va.

Clayton Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 298, 384.

Type locality: On waters of Griffith Creek, on road that descends into this valley 1.2 miles northeast of Clayton, Summers County. Also occurs in Mercer and Monroe Counties.

Clayton Mesa Flow or Tongue (of Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 1, 12, 133, 134, 143 (fig. 20). East of type locality, Clayton basalt consists of many long tongues. For purposes of this report, these tongues have been named, from south to north, Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that gave rise to these basalts are unknown.

Present in eastern Union County.

†Clayton Peak Quartz Diorite[1]

Upper Cretaceous or Tertiary, lower: Northern central Utah.

Original references: S. F. Emmons, 1903, Am. Jour. Sci., 4th, v. 16, p. 141–147; F. F. Hintze, Jr., 1913, New York Acad. Sci. Annals, v. 23, p. 85–143.

In Park City and adjacent districts, Summit County.

Claytonville Dolomite[1] (in Whitehorse Group)

Permian (Guadalupe Series): Central northern Texas.

Original reference: M. G. Cheney, 1929, Texas Univ. Bull. 2913, p. 26, pl. 1.

T. S. Jones, 1953. Stratigraphy of the Permian Basin of west Texas: West Texas Geol. Soc. p. 30 (fig. 9). Shown on chart as occurring near top of Whitehorse group.

Caps escarpment 2 miles west of Sweetwater, Nolan County; also at town of Claytonville, Fisher County.

Claytonville Gypsum (in Double Mountain Group)[1]

Permian: Central northern Texas.

Original reference: H. T. Morley, 1929, Texas Bur. Econ. Geology, geol. map of Fisher County.

Fisher County.

Clear Branch Sandstone[1]

Lower Devonian: Northern central Alabama.

Original references: C. Butts, 1927, Am. Jour. Sci., 5th, v. 14, p. 366, 367; 1927, U.S. Geol. Survey Geol. Atlas, Folio 221.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart below Frog Mountain sandstone.

Named for exposures at Clear Branch Gap through Red Mountain in Jefferson County, 5 miles south-southwest of Bessemer, Jefferson County.

Clear Creek Gneiss[1]

Precambrian: Central northern Colorado.

Original references: J. Underhill, 1906, Colorado Univ. Studies, v. 3, no. 4, p. 270; 1906, Colorado Sci. Soc. Proc., v. 8, p. 103–122.

Occurs along Clear Creek, Jefferson and Clear Creek Counties.

Clear Creek Gravels

See **Moncrief Member** (of Wasatch Formation)

Clear Creek Greenstone[1]

Mississippian(?): Northwestern California.

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 226, 233, 238.

Probably named for exposures on or near Clear Creek, Shasta County.

Clear Creek Limestone[1] or Chert

Clear Creek Chert (in Ulsterian Group)

Lower or Middle Devonian: Southwestern Illinois and southeastern Missouri.

Original reference: A. H. Worthen, 1866, Illinois Geol. Survey, v. 1, p. 126–129.

J. M. Weller, 1940, *in* J. M. Weller and G. E. Ekblaw, Illinois Geol. Survey Rept. Inv. 70, p. 7, 14–15; J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 24. Described in Illinois as Clear Creek chert in Ulsterian group; most extensively exposed and probably thickest of Devonian formations. Consists principally of novaculitic chert with variable amounts of fine-grained siliceous limestone. Thickness not accurately measured; not less than 300 feet and may attain maximum considerably in excess of that figure. Unconformably overlies Backbone limestone; underlies Dutch Creek sandstone. Grassy Knob and Clear Creek cherts are so similar they are difficult to differentiate except where intervening Backbone limestone or its cherty equivalent can be identified.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown as Lower or Middle Devonian.

Carey Croneis, 1944, Illinois Geol. Survey Bull. 68, p. 103 (chart), 114–115. Described in southeastern Missouri as Clear Creek chert; outcrops restricted to Perry County; largest exposure is between Wittenberg and mouth of Apple Creek where syncline carries the Bailey below the surface. Consists of white to buff to chrome yellow thin-bedded chert with brown to reddish ferruginous bands and some concretionary limonitic masses; strata range from about 1 inch to 1 foot in thickness and include thin interbedded layers of deeply weathered siliceous limestone and ferruginous clay. Thickness about 300 feet. At most places, superjacent strata have been largely removed either by erosion or through faulting. Thus, contact with Dutch Creek and Grand Tower beds cannot be studied satisfactorily; top of formation can be determined approximately in some areas by position of residual sandstone blocks probably marking the Dutch Creek beds that separate the Clear Creek from overlying Grand Tower formation; some older strata may have been included in Clear Creek and in places it may have been mistaken for Bailey and Grassy Knob strata. Disconformably overlies Bailey formation.

Named from exposures on Clear Creek, Union County, Ill.

†Clear Creek Limestone Member (of Graford Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 392.

C. O. Nickell *in* Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 97, 105. The group of limestones in upper part of Winchell member of Graford includes the Clear Creek limestone of Drake (1893) and Plummer and Moore (1921, Texas Univ. Bull. 2132) plus some higher beds heretofore included in Placid shale member of Plummer and Moore.

Named for Clear Creek, Brown County.

†Clear Creek Sandstone (in Cherokee Shale)[1]

Pennsylvanian: Western Missouri.

Original reference: G. C. Broadhead, 1874, Missouri Geol. Survey, v. 1, p. 57–61, 69, 100.

Named for exposures on Clear Creek, Vernon County.

Clear Creek Series[1]

Mississippian(?): Northwestern California.

Original reference: O. H. Hershey, 1903, Am. Geologist, v. 31, p. 231–245.

Southern part of Klamath Mountains.

Clear Creek Volcanic Series[1]

Triassic(?): Northwestern California.

Original reference: O. H. Hershey, 1904, Am. Geologist, v. 33, p. 248–256, 347–360.

Trinity and Shasta Counties.

†Clear Fork Group[1]

Pennsylvanian: Western Missouri.

Original reference: G. C. Broadhead, 1873, Missouri Geol. Survey Prelim. Rept. on Iron Ores, pt. 2, p. 169, 170.

Named for exposures on Clear Fork, 6 miles southwest of Kansas City.

Clear Fork Group[1]

Clear Fork Formation[1]

Lower Permian (Leonard Series): Central and central northern Texas.

Original reference: E. T. Dumble and W. F. Cummins, 1890, Texas Geol. Survey 1st Ann. Rept., p. 188, pl. 3.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 42. Term Wichita group (restricted) used for beds of Leonard age between base of Clear Fork group and top of Wolfcamp series. Cheney proposes to abandon term Wichita. Clear Fork group comprises (ascending) Arroyo formation about 250 feet; Vale formation, with Bullwagon dolomite at top and about 360 feet of red shale below; and Choza formation.

L. R. Page and J. R. Adams, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 57. Underlies San Andres group.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 97. Clear Fork group includes (ascending) Arroyo, Vale, and Choza formations. Overlies Lueders group; underlies El Reno (San Andres) group. Leonard.

Robert Roth, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1412; 1945, Geol. Soc. America Bull., v. 56, no. 9, p. 898, 905. Overlies Wichita group; underlies Pease River group.

C. O. Dunbar and others, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, chart 7 (column 74). Correlation chart shows Clear Fork group in Texas comprises (ascending) Arroyo, Vale, and Choza formations;

underlies Pease River group; overlies Wichita group. Name not used in Oklahoma. Leonardian.

Probably named for Clear Fork of Brazos River, Jones and Shakelford Counties, Tex.

Clear Lake Sediments[1]

Pleistocene: Northern California.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 201–202.

Lake County.

Clear Lake Volcanic series

Quaternary: Northern California.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), 34–35. Shown on columnar section as comprising (ascending) rhyolite tuff, olivine basalt, Perini Hill flows (new), Boggs Mountain flows (new), Cobb Mountain volcanics (new), pyroxene dacite, obsidian, and Konocti volcanics (new). Age relations of individual units are imperfectly known because some units are isolated and contacts of contiguous flows are commonly obscured by sliding. Rhyolite tuffs and olivine basalt flows are intercalated with uppermost Cache beds; apparently younger than Sonoma volcanics (of middle or upper Pliocene age).

Report covers area of Lower Lake quadrangle, in Coast Ranges, about 70 miles north of San Francisco.

Cleary Coal Member (of Menefee Formation)

Upper Cretaceous: Northwestern New Mexico.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2149, 2157, fig. 3. Proposed for the beds formerly included in upper part of the Gibson coal member of Mesaverde formation which overlie the Point Lookout sandstone in southern part of San Juan Basin. Coal-bearing sandstone and shale unit, 250 to 300 feet thick.

Named from abandoned Cleary mine in SW¼ sec. 31, T. 19 N., R. 1 W., San Juan Basin; 2 miles west of La Ventana.

Cle Elum Formation

Cretaceous: Central Washington.

R. L. Lupher, 1944, Washington Div. Geology Rept. Inv. 11, p. 7, 12–15, pl. 2. Conglomerate, breccia, mudstone, and shale; arenaceous deposits rare; conglomerates predominate in east and argillaceous materials in west. Commonly less than 15 feet thick. Underlies Swauk formation; overlies a basement composed of peridotite and serpentine.

Occurs as series of restricted exposures that extend from upper Peshastin Creek near Blewett Pass westward to Cle Elum River Canyon, Chelan and Kittitas Counties.

Cleetwood Dacite Flow, Lava

Cleetwood Cove Dacite Flow, Lava

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 38–39. Cleetwood Cove dacite is one of final flows of Mount Mazama. Lava is a black, yellow, or brown glass and is broken and rough on top. Fills an old valley at head of Cleetwood Cove; has thickness of over

300 feet in middle and tapers to thin edge on both sides. Extends from rim of Crater Lake northeastward for nearly 3 miles where it disappears beneath the plain of pumice and glacial material. Forms crest of rim for nearly a mile, extending upon both sides of Cleetwood Cove, where it makes prominent cliffs. Upper part of sides of Cleetwood Cove is a cliff of dacite, beneath which is a layer of pumice succeeded downward by 350 feet or more of exposed andesitic flows. These subdacite lavas are continuous around head of cove, but are not exposed. At head of cove, they are covered by dacite which flowed down inner slope of rim from caved-in tunnel of Rugged Crest to lake. Some distance above lake, upon both sides, the flow and platy structure of the dacite overlying andesite dip toward central stream, which in places dips toward lake at angle of 35° and lies parallel to present surface. [See Sun Creek Dacite Flow.]

J. E. Allen, 1936, Jour. Geology, v. 44, no. 8, p. 741–744. Diller believed that Cleetwood flow was in process of extrusion at time of collapse of Mount Mazama. The still motile lava poured back down into newly formed caldera, producing structure he labeled "backflow." This feature was used as evidence for theory of collapse of Mount Mazama as opposed to explosion. Suggested herein that the "backflow" is simply filling of the inclined vent of Cleetwood flow, which apparently came up along an east-west fissure dipping steeply southward into prehistoric mountain and which was subsequently exposed in crater wall.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 50–52, 62, 63, 120, 138, pl. 1. In sections northwest of the Wineglass, the Wineglass welded tuff overlies Cleetwood lava (flow).

Cleetwood Cove is on northern rim of Crater Lake.

Clem Creek Sandstone Tongue (of Wann Formation)

Clem Creek Sandstone Member (of Ochelata Formation)[1]

Clem Creek Sandstone Member (of Wann Formation)

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: W. B. Emery, 1918, U.S. Geol. Survey Bull. 686–B, p. 2, 3.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 14 (table 1), 15 (fig. 3), 17–18. Member of Wann formation in report on Pawnee County. Overlies "Washington Irving" member or in some places separated from it by as much as 38 feet of silty maroon shale. Underlies an unnamed section of gray shale, the topmost unit of the Wann.

Named for exposures along Clem Creek in northwestern part of T. 23 N., R. 11 E., Osage County.

Clement Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., fig. 3. Shown on columnar section as underlying Hely member (new) and overlying Stillman member (new).

Occurs in Dixon-Oregon area.

Clementsville Limestone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 160–162, pls. 6, 15. Limestone 10 to 15 feet thick. Included in Liberty facies (new) of formation. At type section, Clementsville underlies a 60-foot unnamed silty shale unit and overlies a 25-foot unnamed shale unit. Stratigraphically above Caney Creek member (new).

Type section: At Clementsville, along State Highway 70 (and adjacent slopes) from Woods Creek valley to upland; base of section one-half mile southeast of Clementsville: top of section one-half mile farther along highway. Named from village in western Casey County, 1 mile from Adair County line.

Cleopatra Quartz Porphyry[1]

Precambrian: Central Arizona.

Original references: L. E. Reber, Jr., 1920, Am. Inst. Mining Engrs. Trans.; J. L. Fearing, Jr., 1926, Econ. Geology, v. 21, p. 757–773.

L. E. Reber, Jr., 1938, Arizona Bur. Mines Bull. 145, Geol. Ser. 12, p. 59, 62. May have been early differentiation product of Bradshaw granite.

Jerome district.

Clermont Group (in Allegheny Formation)[1]

Pennsylvanian: Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1882, Am. Philos. Soc. Proc., v. 19, p. 337–348.

Elk County.

Clermont Limestone (in Allegheny Formation)[1]

Pennsylvanian: Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1880, Pennsylvania 2d Geol. Survey Rept. R, p. 46, 128.

In vicinity of Clermont, McKean County.

Clermont Shale (in Maquoketa Group)[1]

Clermont Shale Member (of Maquoketa Formation)

Upper Ordovician: Northeastern Iowa.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 98.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 50). Shown on correlation chart as shale member of Maquoketa formation. Overlies Elgin shaly limestone member; underlies Fort Atkinson limestone member.

Named for exposures at Clermont, Fayette County.

Cleveland magnafacies[1]

Upper Devonian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 28–29.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 46. The complete succession of magnafacies as outlined by Caster for southern New York and northwestern Pennsylvania is not represented in the Genesee group. At Cayuga Lake, except for the Geneseo shale, the group is presumably within the Big Bend magnafacies. Westward, the rock changes to black and dark-gray thin-bedded shales which fit the description of the Cleveland magnafacies of Caster. The Geneseo and Middlesex black shale bands correspond to the Cleveland magnafacies; black shales of the Hamilton, notably the Marcellus, are likewise Cleveland type. If the facies are to be given names and more or less specific boundaries, the Geneseo and Middlesex black shales may be considered tongues extending eastward from the main mass of the Cleveland magnafacies. The Rhinestreet black shale, higher in the Devonian of western New York, may also be considered a tongue of the Cleveland magnafacies.

Name derived from Cleveland shale.

Cleveland Member (of Ohio Shale)

Cleveland Shale[1]

Upper Devonian: Northern Ohio.

Original reference: J. S. Newberry, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 19, 21.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 37; Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 141. Ohio shale has been divided into three parts: Cleveland shale, Chagrin shale, and Huron shale.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1352–1353. At type locality, Cleveland member consists of about 60 feet of tough bituminous black shale. Thins eastward to featheredge west of Ohio-Pennsylvania line. Overlies Chagrin shale, and in some areas contact is sharply defined and in others there is transition zone; underlies Bedford shale.

J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 15, 16. In outcrops along Rocky River north of Berea, Ohio, Cleveland member is 100 feet thick. Upper part is typically hard dull-grayish-black shale which weathers to thin chips that are commonly stained rusty reddish brown. Lower part of member, which was called Olmsted member by Cushing (Cushing, Leverett, and Van Horn, 1931, U.S. Geol. Survey Bull. 818), contains, in addition to black shale, many beds of bluish-gray or gray clay shale that range in thickness from an inch to several feet; some gray to brown siltstones; many small nodules of pyrite; and several thin siliceous limestones that are characterized by cone-in-cone structure. Conodont fauna found in upper 25 feet of Cushing's Olmsted member is identical with conodont fauna of the Cleveland (Hass, 1947, Jour. Paleontology, v. 21, no. 2). The Cleveland and Huron members are practically identical in lithologic character, and in Erie and Lorain Counties the contact between these two black shales is drawn arbitrarily below lowest cone-in-cone layer and above uppermost zone containing large septarian concretions.

Named for exposures at Cleveland, Cuyahoga County.

Cleveland Sandstone (in Kanawha Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: D. B. Reger, 1916, West Virginia Geol. Survey Rept. Lewis and Gilmer Counties, p. 75, 172.

Crops out along north bank of Little Kanawha River at Cleveland, Webster County.

Cleveland County red lands[1]

Eocene: Southeastern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 58–59.

Named for exposures at O. H. Mark's place, Red Land Township, Cleveland County.

Cleveland Gulch Quartzite Member (of Hopewell Series)

Precambrian (Proterozoic): Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 42, pl. 3. A particularly prominent quartzite in the series. Of sedimentary origin. Interspersed with Picuris basalts and Vallecitos rhyolites.

Exposed between Tusas and Kiawa Mountains, Petaca area, Rio Arriba County.

Clews Fanglomerate

Miocene: Southern California.

F. M. Byers, Jr., 1960, U.S. Geol. Survey Bull. 1089–A, p. 15–18, pls. 1, 2. Consists of lower unit of fine-grained tuffaceous sediments, middle unit of ridge-forming reddish-brown fanglomerate, which volumetrically constitutes about 90 percent of formation, and upper unit of sandstone with included tuff beds. Thickness 560 to 660 feet. Unconformably overlies pre-Tertiary plutonic rocks; wedges out westward between plutonic rocks and Alvord Peak basalt (new); where Alvord Peak is missing, Clews is overlain by Spanish Canyon formation (new). Middle Tertiary, possibly early or middle Miocene.

Type locality: Clews Ridge, southeastern part of Alvord Mountains, San Bernardino County.

†Click series[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lvii, 274, pl. 3.

Probably named for Click, Llano County.

Cliff House Sandstone (in Mesaverde Group)[1]

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

Original reference: A. J. Collier, 1919, U.S. Geol. Bull. 691–K.

P. T. Hayes and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144. In Barker Dome-Fruitland area, New Mexico, includes (ascending) Barker Dome, Cholla Canyon, Beechatuda and Ute Canyon tongues (all new). Overlies and intertongues with Menefee formation; underlies and intertongues with Lewis shale.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2158–2159. Nomenclature of Mesaverde group in San Juan Basin, N. Mex., revised. Name Cliff House sandstone replaces Chacra sandstone throughout former extent of that unit.

Named for exposures in canyons above the cliff houses of Mesa Verde National Park, Montezuma County, Colo.

Cliffield Formation

Cliffield Group

Middle Ordovician: Southwestern Virginia and northeastern Tennessee.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 823–833, 862–868, 884 (fig. 3), pl. 5. In Tazewell County, the strata embraced by the Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Cliffield is proposed for zones 1 through 9, including the succession from the base of basal clastics to top of second zone of calcilutite. Facies variations whereby lithologically distinctive zones grade locally into a thickness of indistinguishable calcilutites prevent succession herein assigned to the Cliffield from being subdidived into mappable formations. Where various zones are distinct, as in most parts of Tazewell County, five members are recognized (ascending) : Blackford, Five Oaks limestone, Lincolnshire limestone, Ward Cove limestone, and Peery limestone (all new). Maximum thickness 1,142 feet south of St. Clair Station; minimum thickness 345 feet, on northwest side of Thompson Valley. Underlies Benbolt limestone (new) ; contact a disconformity; disconformable upon Beekmantown dolomite; top of Beekmantown is an erosion surface with maximum relief of about 200 feet. As here defined, includes beds which Butts has called Murfreesboro, Mosheim, Lenoir, Holston, and Ottosee.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 54–71. Cliffield group is used to apply to middle Ordovician formations southeast of Clinch Mountain, in Burkes Garden quadrangle. As thus used, includes Blackford, Five Oaks, Lincolnshire, Effna, Whitesburg, Athens, and Peery formations. Approximately equivalent to Butts' (1940) Mosheim-Lenoir-Holston-Whitesburg-Athens succession of the southeastern belts of Appalachian Valley.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1145–1160. Cliffield group in southeastern Virginia and northeastern Tennessee includes Blackford, Five Oaks, Lincolnshire, Thompson Valley (new), Ward Cove (restricted), and Peery formations.

Type section: Exposures along Pounding Mill Branch and U.S. Route 19, south of Norfolk and Western underpass; top is exposed at intersection of U.S. Route 19 and County Road 637, and base is exposed along east side of U.S. Route 19 about 50 yards south of highway underpass. Name taken from Cliffield, a store and station along Norfolk and Western Railroad, about 8 miles southwest of North Tazewell, Tazewell County, Va.

†Cliffwood Clays[1]

Upper Cretaceous: Northeastern New Jersey.

Original reference: H. B. Kummel and G. N. Knapp, 1904, New Jersey Geol. Survey, v. 6, p. 166.

Exposed in clay pits about Cliffwood and at Cliffwood Point on south shore of Raritan Bay.

Clifton Formation[1]

Middle Silurian: West-central Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1876, Elements of geology of Tennessee, p. 108, 142–146.

Named for exposures at Clifton, Wayne County.

Clifton Forge Sandstone Member (of Keyser Limestone)[1]

Lower Devonian: Central western Virginia and West Virginia.

Original reference: F. M. Swartz, 1929, U.S. Geol. Survey Prof. Paper 158–C, p. 29.

P. H. Price and E. T.Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 206. Present in Greenbrier County, W. Va.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 38, 42–44. Big Mountain shale member, which maintains its identity into Bath County, Va., is believed to pass literally into lower portion of Clifton Forge sandstone of Alleghany County, Va., and adjacent areas.

F. G. Lesure, 1957, Virginia Polytechnic Inst. Engineering Expt. Sta. Ser. 118, p. 45. Commonly white to medium-light-gray fine-grained porous crossbedded and cross-laminated sandstone; some medium-dark-gray fine-grained argillaceous limestone. Thickness 79 feet in Clifton Forge iron district. Underlies unnamed upper part of Keyser; overlies Tonoloway limestone.

Named for exposures at Clifton Forge, Va.

†Clifty Conglomerate Lentil[1] (in Lee Formation)

Pennsylvanian: Eastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33B, p. 370–371.

White County.

Clifty Limestone[1]

Middle Devonian: Northwestern Arkansas.

Original reference: H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

H. D. Miser, 1944, Illinois Geol. Survey Bull. 68, p. 132, 134 (fig. 27). Sandy compact light-bluish-gray fossiliferous limestone. Maximum thickness 2½ feet. Overlies Penters chert; underlies Sylamore sandstone member of Chattanooga shale.

Named for East Fork of Little Clifty Creek, Eureka Springs quadrangle, Carroll County.

†Clifty Shale[1]

Pennsylvanian: Eastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33B, p 370–371.

Clifty and Bon Air, White County.

Climax Porphyry

Tertiary(?): Colorado.

E. J. Eisenach and Edward Matsen, 1954, Mining Eng., v. 6, no. 3, p. 27; J. W. Vanderwilt and R. U. King, 1955, Mining Eng., v. 7, no. 1, p. 43–44; S. W. Wallace and others, 1960, *in* Guide to the geology of Colorado: Rocky Mountain Assoc. Geologists, p. 238–252. Name applied to porphyry in Climax stock.

Well displayed in Climax mine at Climax, Lake County.

†Clinch Red Shale[1]

Upper Ordovician: Eastern Tennessee.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 297, 298.

Named for exposures on Clinch Mountain, Hancock and Hawkins Counties.

Clinch Sandstone[1] **or Quartzite**

Lower and Middle Silurian: Eastern Tennessee, southwestern Virginia, and southern West Virginia.

Original reference: J. M. Safford, 1856, Geological Reconnaissance of Tennessee 1st Rept., p. 157.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey and Gas Inv. Prelim. Map 76. Sandstone, in Rose Hill district, Lee County, Va., is 257 feet thick and includes Hagan and Poor Valley Ridge members (both new). Overlies Sequatchie formation; underlies Clinton shale.

John Rodgers, 1953, Tennessee Div. Geol. Bull. 58, pt. 1, p. 100–104, pls. Safford's description makes it clear that in Clinch Mountain area he included in the Clinch the whole thickness of rocks now classed in the Silurian system. Keith (1896, Morrison folio; 1901, Maynard folio) followed this same usage in mapping this belt. Probably both lower and middle Silurian rocks are included. A few feet of upper Silurian or even lower Devonian is present at top, but representatives of the different series do not appear to be separately mappable. On present map the whole unit in this belt is mapped as Clinch sandstone. Clinch sandstone and Rockwood formation are mainly contemporaneous phases of lower and middle Silurian. In areas intermediate between the two type localities, they grade into each other, though in any one section the sandstone lies chiefly below. Thickness of Clinch sandstone about 500 feet on Clinch Mountain. Overlies Juniata formation.

Named for exposures on Clinch Mountain, Hancock and Hawkins Counties, Tenn., and Scott County, Va.

†Clinch Mountain Sandstone[1]

Upper Ordovician and Silurian: Eastern Tennessee and western Virginia.

Original reference: J. M. Safford, 1856, Geol. Reconn. Tennessee 1st Rept., p. 157.

Named for exposures on Clinch Mountain, Hancock and Hawkins Counties, Tenn., and Scott County, Va.

†Cline[1]

Upper Cretaceous (Gulf Series): Southern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 114.

Probably named for Cline, Uvalde County.

Clinetop Algal Limestone Member (of Dotsero Formation)

Upper Cambrian: Central northwestern Colorado.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 892 (fig. 2), 893, 898, 899–904. Proposed for ledge-forming algal limestone and conglomerate unit, 3 to 5 feet thick, at top of Dotsero formation. At most places, lower half of member consists of course flat-pebble conglomerate, and upper half consists of crystalline to dense algal limestone with a crinkly wavy structure. Overlies Glenwood Canyon member (new). Underlies Dead Horse conglomerate member (new) of Manitou formation.

Type locality: In Clinetop area, Garfield County, where unit trends northeastward across NE¼ sec. 35, T. 3 S., R. 90 W., about 1 mile east of Clinetop Road and SW¼ sec. 23, T. 3 S., R. 90 W., near Sixmile Lake.

†Clingman Conglomerate (in Chilhowee Group)[1]

Precambrian: Western North Carolina and eastern Tennessee.

Original reference: Arthur Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 3.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 280–281. In Knoxville and Mount Guyot quadrangles, Keith (1895, Mount

Guyot folio, unpub.) mapped three conglomerates, the Cades, Thunderhead, and Clingman, which, in region to the south he later classified as Great Smoky quartzite. Cades conglomerate is lower member of Great Smoky quartzite. Thunderhead conglomerate forms the middle and upper members. Nantahala slate, which overlies upper members of Great Smoky, was called Hazel slate. The quartzite, which lies east of Nantahala slate at Newfound Gap, Keith called Clingman conglomerate, and he interpreted the quartzite as overlying the Nantahala (Hazel) slate. Structural evidence shows that these beds are overturned and that the quartzite here is the upper member of the Great Smoky on the east overturned limb of a syncline enclosing Nantahala slate. South of Newfound Gap, upper quartzite member is exposed at Mount Collins on Park Road that leads to Clingman Dome. Southwest of Mount Collins, Nantahala slate is in narrow syncline, on south limb of which are exposed the underlying upper quartzite of Great Smoky formation, and, farther south, the middle (conglomerate) beds. These conglomeratic beds in outcrops at Parking Overlook at Clingmans Dome are massive micaceous quartzite in 20-foot beds. It is these beds that Keith (Mount Guyot folio) called Clingman conglomerate, which he regarded as upper member of the Great Smoky and so mapped it at Clingmans Dome on crest of Great Smoky Mountains to west. The conglomeratic quartzite that crops out at Clingmans Dome is identical in lithologic character and stratigraphic position with middle member of Great Smoky quartzite exposed on U.S. Highway 276 and lies well down in the quartzite.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 958. Keith originally placed upper part of sequence here termed Great Smoky group in Hazel slate and Clingman conglomerate; these names are now abandoned. Clingman conglomerate was supposed to be highest stratigraphic unit in Great Smoky Mountains. Keith (1907, U.S. Geol. Survey Geol. Atlas, Folio 143) merged it with his Great Smoky conglomerate, apparently on assumption that it had been duplicated structurally. At Clingmans Dome and other parts of the mountains, coarse sandstone overlies, in stratigraphic sequence, argillaceous rocks that are here classed as parts of Anakeesta formation (new). It is believed that these units of coarse sandstone are layers of Thunderhead lithology that intertongue at varying stratigraphic levels with Anakeesta. The type Clingman is probably equivalent to upper beds of Thunderhead sandstone and lower part of Anakeesta formation on Mount Le Conte, but other units mapped as Clingman lie at different and higher levels. It seems best to class these, depending on locality, as beds in the Anakeesta, as tongues of the Thunderhead, or as unnamed parts of the Great Smoky group.

Named for Clingmans Dome, Swain County, N.C.

Clinton Formation, Shale, or Group

Clinton Formation (in Niagara Group)[1]

Clinton Formation (in Red Mountain Group)

Middle Silurian: New York to northeastern Tennessee; also Michigan.

Original reference: T. A. Conrad, 1839, Philadelphia Acad. Nat. Sci. Jour., v. 8, pt. 1, p. 228–235.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 22 (fig. 6). Group includes Willowvale shale (new) in Clyde and Sodus Bay quadrangles.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 8, 50–145. Clinton group, in Niagaran series, comprises (ascending) Rose Hill formation, Keefer sandstone, and Rochester shale. Occurs above Tuscarora sandstone of Medinan series.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 2, p. 535, chart 3. In this report [Silurian correlation chart], term Clinton is used as group in central and western New York and from central Pennsylvania to northeastern Tennessee and shown to include many formations. From southeastern Tennessee to northwestern Georgia, the Clinton is shown as a formation in Red Mountain group.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76 (2 sheets). In Rose Hill oil field, Virginia, Clinton shale, overlies Poor Valley Ridge member (new) of Clinch sandstone. Underlies Cayuga dolomite.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 5–190. A comprehensive report on Clinton group of western and central New York. Included in Niagaran series. Overlies Albion group; underlies Lockport group. units discussed are the Thorold, Oneida, Neahga, Maplewood, Furnaceville iron ore, Reynales, Bear Creek, Sodus (lower and upper), Wolcott limestone, Westmoreland (new), Willowvale, Dawes (new), Kirkland, Herkimer, and Rochester.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Clinton group, in Niagaran series. Comprises (ascending) Osgood, Laurel, and Waldron formations. Overlies Medina group; underlies Louisville formation.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 79–83. Clinton shale, in Lee County, Va., includes about 400 feet of shale and sandstone lying between Clinch sandstone below and Hancock dolomite above.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1982 (fig. 3), 1993. Discussion of stratigraphy of Medinan group, New York and Ontario. Silurian system is divided into Medinan, Clinton, and Niagara groups, the three comprising Ontarian series. Clintonian [Clinton] group comprises (ascending) Reynales, Irondequoit, Rochester, and Decew formations in vicinity of Hamilton; Neahga, Reynales, Irondequoit, and Decew, at Decew Falls; Thorold (part), Neahga, Reynales, Irondequoit, Rochester, and Decew at Niagara Gorge; and Thorold, Maplewood, Furnaceville, Reynales, Sodus, Williamson, Irondequoit, Rochester, and Decew in Genesee Gorge. For mapping purposes, Grimsby-Thorold contact is retained as Medinan-Clinton boundary.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. No. 1. Rock units of New York Silurian are divided into (ascending) Medina, Clinton, Lockport, Salina, and Bertie groups. Lower and middle parts of Clinton group are in Ontarian stage; upper Clinton strata are in Tonawanda(n) stage (new). Because Thorold of Gillette (1947) is not continuous with type Thorold at Thorold, Ontario, name Kodak (Chadwick, 1917) is revived for basal sandstone of Clinton group in New York. Term Wallington is proposed for limestone formerly regarded as Reynales at Rochester and eastward. Niagaran series.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. As mapped, Clinton group includes Rose Hill formation, Keefer sandstone, and Rochester shale.

Characteristically exposed around Clinton, Oneida County, N.Y.

Clinton Granitic Gneiss

Pre-Triassic: South-central Connecticut.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as red or pink medium- to coarse-grained platy gneiss; composed of pink microcline, quartz, white oligoclase or albite, and biotite.

H. M. Mikami and R. E. Digman, 1957, Connecticut Geol. Nat. History Survey Bull. 86, p. 25, 51, pls. 1, 2. Described in Guilford quadrangle where is has concordant relationship with Haddam tonalite.

Named for town of Clinton, Middlesex County.

†Clinton Quartzites[1]

Silurian: Eastern New York.

Original reference: C. A. Hartnagel, 1905, New York State Mus. Bull. 80, p. 346.

Clipper Gap Formation[1]

Mississippian(?): Northern California.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey Geol. Atlas, Folio 66.

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 283. Cosumnes formation (new) rests unconformably on the Calaveras (Clipper Gap) formation.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 15). Shown on correlation chart in Chesterian series.

Named for exposures at village of Clipper Gap, Placer County.

Cloice Member (of Lake Waco Formation)

Cretaceous (Gulf Series): Central Texas.

W. S. Adkins and F. E. Lozo *in* F. E. Lozo, 1951, Fondren Sci. Series, no. 4, p. 122, 139 (fig. 17), 144 (fig. 18). Consists of dark, silty, calcareous shales with subordinate limestone beds. Thickness 35 feet. Middle member of formation; underlies Bouldin member (new); overlies Bluebonnet member (new).

Type section: Cloice Branch, McLennan County; type area is along the Bosque Escarpment southwest to Moody Hills.

†Cloquet Slate[1]

Precambrian (upper Huronian): Northeastern Minnesota.

Original reference: J.E. Spurr, 1894, Am. Jour. Sci., 3d, v. 48, p. 159–166.

Exposed along St. Louis River not far from Duluth, near Thomason, Carlton, and Cloquet, Carlton County.

Clore Limestone[1]

Clore Sandstone (in Elvira Group)

Upper Mississippian (Chester Series): Southern Illinois, southern Indiana, and western Kentucky.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 129.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 838–839. Assigned to Elvira group (new). In standard Mississippian section, underlies Degonia sandstone and overlies

Palestine sandstone. Recognized as distinct formation as far east as central Christian County, Ky. Farther east, overlying Degonia is not distinguishable, and beds from base of Clore to top of Chester constitute one of thickest limestone sections of Chester series in Eastern Interior basin. This consists of 250 to 300 feet of light- to dark-gray or locally bluish limestone with lenticular shale and sandstone strata and some chert. East of Logan County, Ky., this part of geologic column becomes predominantly shale, and Clore formation has not been differentiated from remainder of Elvira group. In Indiana, the Clore is known as the Gennet Creek formation and consists of 10 to 35 feet of predominantly shaly beds.

C. A. Malott, 1952, Stratigraphy of Ste. Genevieve and Chester formations of southern Indiana: Ann. Arbor, Mich., The Edwards Letter Shop, p. 6. Name Clore limestone extended to Indiana and applied to shale and limestone interval underlying Degonia sandstone and overlying Palestine sandstone. [This appears to be interval to which name Gennet Creek was applied.]

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, pl. 1. Clore limestone shown on stratigraphic column of upper Chester rocks in Indiana as 10 to 35 feet of soft greenish-gray shale and thin beds of yellow impure limestone. Term Elvira group not applied in Indiana.

Named for Clore School, Randolph County, Ill. Typically exposed in heads of ravines along southwest side of high ridge extending from Clore School to Randolph County Farm.

Closed Volcanics

Tertiary: Northwestern Wyoming.

R. D. Krushensky, 1960, Dissert. Abs., v. 21, no. 4, p. 849. Volcanic breccias and some sandstones and conglomerates. Overlie Squaw flows (new); underlie unit referred to as post-Closed volcanics.

Hurrican Mesa area, Park County.

Cloudburst Formation

Upper Cretaceous(?) and Tertiary: Southeastern Arizona.

J. D. Pelletier, 1957, Mining Engineer, v. 9, no. 7, p. 760. Contains two members. Upper member is conglomerate made up mainly of quartz monzonite fragments but containing some fragments of older rocks in area. Matrix tends to be arkosic, but granitic sand and gravel not uncommon. Con glomerate poorly cemented but relatively well sorted, having beds of sand and gravel alternating with beds of larger boulders. Tuff beds in conglomerate and in the underlying member, which is composed of interbedded flows, flow breccias, and conglomerate. Unconformably underlies Gila(?) conglomerate.

At San Manuel mine [just south of town of Tiger].

Cloudcap Dacite Flow

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 34, 35. Cloud Cap, on eastern crest of rim, marks point of departure of stream of dacite which spreads to northeast. It forms large part of Redcloud Cliff, which takes its name from the reddish-yellow tuff or tuffaceous dacite that underlies principal flow. This flow, which appears to be made up of at least three streams, forms prominent cliff for over one-half mile along rim of Crater Lake and has thickness of over 300 feet. It appears to form one-third of inner slope of crest. This flow presents series of cliffs about its borders, especially on northwest. [See Sun Creek Dacite Flow.]

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 40, 54. Cloudcap and Redcloud dacites were erupted after andesitic phase of Mazama's activity had come to end. Cloudcap flow is older than the much thicker Redcloud flow (lava).

Cloudcap is on eastern side of Crater Lake.

Cloud Chief Formation

Cloud Chief Gypsum[1] (in Double Mountain Group or Whitehorse Group)

Cloud Chief Gypsum Member (of Whitehorse Formation)

Permian: Southwestern Oklahoma and northern Texas.

Original reference: C. N. Gould, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, p. 324–341, map.

N. H. Darton, L. W. Stephenson, and Julia Gardner, 1937, Geologic map of Texas (1:500,000): U.S. Geol. Survey. Mapped in Double Mountain group.

Robert Roth, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21 no. 4, p. 421–433. Cloud Chief formation mentioned in general discussion of loose application of Kansas formation names in Texas.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1527–1529. Upper member of Whitehorse group. Cloud Chief dolomite facies of Weatherford area should not be considered as Quartermaster as was proposed by Green (1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11). Overlies Rush Springs sandstone; underlies Doxey shale of Quartermaster group.

Robert Roth, N. D. Newell, and B. H. Burma, 1941, Jour. Paleontology, v. 15, no. 3, p. 313. Table shows Cloud Chief gypsum as member of Whitehorse formation. Whitehorse and Quartermaster formations are placed in Custer group.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 668, pl. 2. Uppermost formation in Whitehorse group. Term Double Mountain group abandoned.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Formation as mapped includes Day Creek dolomite member in northwestern Oklahoma and Weatherford member in central western part. Shown above Whitehorse group.

L. V. Davis, 1955, Oklahoma Geol. Survey Bull. 73, p. 75–77. In Grady County, formation is about 15 feet thick. Unconformably overlies Rush Springs sandstone. Crops out in widely scattered outliers so only lower part is present.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 40–43. In Harper County, name Cloud Chief formation applied to dolomite, red shale, and gypsum overlying Whitehorse group. Thickness 25 feet; only lower part present. Includes Day Creek dolomite member at base. Doubtfully referred to Ochoan series. Correlated with Taloga formation and Day Creek dolomite of Kansas.

C. O. Dunbar, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, chart 7. Permian. Correlation chart shows Cloud Chief present in Oklahoma but not in Texas.

Typically exposed near town of Cloud Chief, Washita County, Okla.

Cloudy Pass Diorite

Tertiary: North-central Washington.

E. A. Youngberg and T. L. Wilson, 1952, Econ. Geology, v. 47, no. 1, p. 4 (fig. 2), 5. Named on map legend. Believed to be related to Tertiary Cloudy Pass intrusives which are exposed to west of area.

Occurs at Holden mine, at Holden, Chelan County.

Clough Formation or **Quartzite**

Clough Conglomerate[1]

Lower Silurian: Western New Hampshire, north-central Massachusetts, and southeastern Vermont.

Original reference: M. P. Billings, 1934, Science, v. 79, no. 2038, p. 55–56.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 468, 481–483. Further description of conglomerate.

J. B. Hadley, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 119, 129–130. Termed a formation in Mount Cube quadrangle, New Hampshire, because considerable mica-schist is present and conglomerate beds are subordinate. Thickness 600 to 1,200 feet in this area.

J. B. Hadley, 1949, Bedrock geology of the Mount Grace quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–3]. Formation geographically extended to Massachusetts. Age shown as Silurian.

G. E. Moore, Jr., 1949, Geol. Soc. America Bull., v. 60, no. 10, p. 1617, 1626–1628, pl. 1. Termed a quartzite in Keene-Brattleboro area, New Hampshire-Vermont, since quartzite more abundant than quartz conglomerate, quartz-mica schist and mica schist.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000) U.S. Geol. Survey. Mapped as quartzite. Represented in chlorite metamorphic zone by gray to white quartzite and quartz conglomerate. More coarsely crystalline white quartzite and quartz conglomerate in garnet and staurolite zones where mica schist with biotite, garnet and (or) staurolite also occurs. Similar schist with sillimanite rather than staurolite occurs in the sillimanite zone.

A. J. Boucot and others, 1958, Geol. Soc. America Bull., v. 69, no. 7, p. 855–870. Upper part of Clough formation at Skitchewaug Mountain, near Springfield, Vt., and on Croydon Mountain, near Claremont, N.H., contains fossils of Silurian or Devonian age. On lithologic basis, it is probable that lower part of Bernardston formation, including the conglomerates, quartzites, and calcareous quartzite, is lateral equivalent of Clough formation and that limestone associated with Bernardston formation is lateral equivalent of Fitch formation. If Clough formation at Skitchewaug Mountain were of Devonian age, the stratigraphy of Connecticut Valley region would be complicated by fact that the Clough and overlying Fitch formations elsewhere are of Silurian age.

Named for Clough Hill district, Moosilauke quadrangle, New Hampshire.

Clovelly Stage

Miocene: Southeastern Louisiana (subsurface).

C. M. McLean, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 241, 242 (fig. 1), 243. A stage name, based on faunal assemblages occurring in the sediments commonly termed "Lower" Miocene in the subsurface of southeastern Louisiana. Duck Lake and Napoleonville stages proposed as replacements for the "Middle" and "Upper" Miocene respectively. Names were selected arbitrarily only because the denoted fields demonstrate representative sections for each; nothing in way of principal producing members is implied.

Clover Formation

Oligocene(?): Northeastern California.

Cordell Durrell, 1957, Pacific Petroleum Geologist, v. 11, no. 3, p. 3. Andesite mudflow breccia about 550 feet thick. Unconformable below Delleker formation (new), unconformity marked by faulting. Lies on Lovejoy basalt (new) and other older rocks.

Occurs in Grizzly Mountains and to the northwest in Blairsden quadrangle, Plumas County.

Clover Member (of Loysburg Formation)

Middle Ordovician (Chazyan): Central and south-central Pennsylvania.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Laminated, rather pure limestone. Thickness 46 feet at type locality. Upper member of formation; overlies unnamed lower member.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 3, 4, 5, 7. Upper member of formation. Principally sublithographic, somewhat magnesian limestone in Centre, Huntingdon, and northern Blair Counties. White-weathering dense laminated sublithographic limestone occurs north of Union Furnace. Thickness 40 to 80 feet in type section. Overlies "tiger-striped" beds of the formation; underlies Eyer member of Hatter formation. Formerly included in Carlim limestone of the Tyrone district. Derivation of name.

Type section: At Union Furnace, Huntingdon County. Named for Clover Creek east of Williamsburg, Blair County.

Clover Quartzites[1]

Clover Canyon Quartzites[1]

Precambrian: Northwestern Nevada.

Original reference: C. King, 1878, U.S. Geol. Expl. 40th Par., v. 1, p. 69.

Humboldt Range, Pershing County.

Clover Creek Granodiorite

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 11, pl. 1. Chiefly granodiorite; distinguished by salt and pepper appearance resulting from imperfectly formed hornblende and sphere crystals sprinkled through the rock. Finer fabric was significant factor in separating these rocks from mineralogically similar Giant Forest pluton.

Three small masses totaling about a square mile crop out near West Fork of Clover Creek and south of Colony Meadow, Sequoia National Park.

Clover Creek Greenstone[1]

Permian: Northeastern Oregon.

Original reference: James Gilluly, 1937, U.S. Geol. Survey Bull. 879.

W. D. Smith and J. E. Allen, 1941, Oregon Dept. Geology and Mineral Industries Bull. 12, p. 6 (fig. 2), 7–8. Described in Wallowa Lake quadrangle where it is 3,000 to 5,000 feet thick. Base not observed. Conformably underlies a unit termed Lower Sedimentary Series, or where series is lacking unconformably underlies Martin Bridge formation.

Named for exposures along Clover Creek in secs. 24, 25, 26, and 35, T. 7 S., R. 42 E., Baker County.

Clover Creek Limestone (in Chester Group)[1]

Mississippian: Western central Kentucky.

Original reference: A. F. Foerste, 1910, Kentucky Geol. Survey Rept. Prog. 1908 and 1909, p. 83, 85.

Named for exposures at mouth of Clover Creek, Breckinridge County.

Cloverly Formation[1]

Cloverly Group

Lower Cretaceous: Central eastern, and northern Wyoming and central southern Montana.

Original reference: N. H. Darton, 1904, Geol. Soc. America Bull., v. 15, p. 394–401.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 42–45. In Bighorn Canyon-Hardin area, Montana-Wyoming, formation is 300 to 400 feet thick, includes Pryor conglomerate member at base and Birdhead sandstone member at top. Overlies Morrison formation; underlies Thermopolis shale. Lupton (1916, U.S. Geol. Survey Bull. 621) called the 20 feet of sandstone at top of Darton's type Cloverly Greybull sandstone. This unit has been called member of Cloverly but not always top member. Overlying Greybull sandstone member in Bighorn Basin is unit of shales and rusty-weathering sandstones which Darton called "rusty series" or "rusty beds." The "rusty beds" have been included in Thermopolis shale by some workers and in Greybull sandstone by other workers. If Cloverly formation from Birdhead sandstone down to the variegated beds is correlative with Darton's "rusty beds," then Cloverly in Bighorn Canyon-Hardin area includes strata younger than type Cloverly. Inclusion of "rusty beds" in the Cloverly constitutes a redefinition of Cloverly as described by Darton. This redefinition is justifiable because Darton's upper unit of Cloverly, the Greybull sandstone member, is not readily separated in many localities from underlying "rusty beds." Top of Cloverly—if it is to occur at a lithologic break of considerable area extent—should be placed either below Greybull sandstone member and above variegated beds in middle of Cloverly or below black Skull Creek shale (or its stratigraphic equivalent) and above the so-called rusty beds.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 56–57. In Johnson County, Wyo., overlies Morrison formation and underlies Skull Creek shale. Thickness 135 to 165 feet.

A. B. Shaw, 1957, Rocky Mountain Assoc. Geologists Guidebook to geology of North and Middle Parks Basin, Colorado, p. 48, 49 (fig. 1). Base of Cretaceous comprises tripartite unit traditionally divided into Lakota sandstone, Fuson shale, and Dakota sandstone. In Laramie Basin, same division is recognizable, but the three names are not used; instead, entire unit is called Cloverly formation. In this report, both sets of names are used for North Park, Colo., but Cloverly is elevated to rank of group.

R. M. Moberly, Jr., 1958, Dissert. Abs., v. 18, no. 1, p. 198. Includes Little Sheep mudstone (new), Pryor conglomerate tongue, and Lovell member (new).

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 35–37. Described in Buffalo-Lake DeSmet area, Johnson and Sheridan Counties, Wyo., where it is 156½ feet thick, overlies Morrison formation, and underlies Skull Creek shale.

Ralph Moberly, Jr., 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1143 (fig. 2), 1145–1149, pl. 1. As redefined here, includes nonmarine sedimentary rocks which lie above Morrison formation and below Sykes Mountain formation (new). Comprises (ascending) Little Sheep Mountain (new), Pryor conglomerate, and Himes (new) members. Thickness 382 feet at type locality.

D. L. Eicher, 1960, Yale Univ. Peabody Mus. Nat. History Bull. 15, p. 5–11, 13, 15–16. Underlies rusty beds of Thermopolis shale.

Arthur Mirsky, 1960, Dissert. Abs. v. 21, no. 4, p. 850–851. Formation, in southern Big Horn Mountains, Wyo., includes Otter Creek sandstone member (new) in lower part. Upper part of Cloverly is referred to as the Mudstone member. Overlies Morrison formation; underlies Rusty Beds member of Thermopolis.

Type locality: Near Cloverly, about 15 miles northeast of Basin, Bighorn County, Wyo.

Clovis Beds

Clovis Formation

Pleistocene: Central eastern New Mexico.

Ernst Antevs, 1936, Acad. Nat. Sci. Philadelphia Proc., v. 87, p. 305–306 [1935]. A generalized profile comprises (descending) several feet of red-brown wind-blown sand; a few feet of blue-gray clay—a lake deposit—forming one to three distinct beds (containing bones of mammoth and extinct bison, mollusks, diatoms, Folsom points, other points and charcoal and burned animal bones); and yellow sand with bones of horse and camel but without artifacts.

Ernst Antevs *in* H. M. Wormington, 1949, Denver Mus. Nat. History Pop. Ser. 4, p. 189. The beds which contain the old artifacts, extinct horse, camel, bison, and mammoth, diatoms and mollusks are separated by disconformities from beds below and above and constitute the Clovis formation.

Exposed some 15 miles southwest of Clovis and an equal distance to the southeast.

Cloyd Conglomerate Member (of Price Formation)

Mississippian (Kinderhookian): Southwestern Virginia.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 343–346, 347. Coarse-grained white quartz sandstone having lenses and layers of conglomerate with quartz pebbles as much as 1½ inches in diameter; lies at base of formation. Name Ingles conglomerate has been applied to this sandstone because similar sandstone occurs in Ingles Mountain a few miles southeast of Radford; sandstone in Ingles Mountain, however, is Clinch sandstone; hence, name Cloyd is here substituted for Ingles.

Lynn Glover, 1953, (abs.) Virginia Jour. Sci., new ser., v. 4, p. 260–261. Rusty-weathering flaggy marine sandstones and shales overlie the Devonian Broadford sandstone and are terminated by the Cloyd member of Mississippian Price formation.

Named for exposures in Cloyd Mountain, the part of Little Walker Mountain southwest of New River in Pulaski County.

Clugston Limestone[1]

Paleozoic(?): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 71, map.

Mapped around headwaters of Clugston Creek, Stevens County.

Clyde Formation (in Wichita Group)[1]

Clyde Group

Permian (Wolfcamp Series): Central and central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Texas Univ. Bull. 2132, p. 192, 197–198, charts.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 94. Rank raised to group. Includes Grape Creek formation below and Talpa formation above. Underlies Lueders group; overlies Belle Plains group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as a formation where it is 500 feet thick and consists of regular beds of moderately hard medium- to fine-grained gray limestones, in layers 1 to about 10 feet, alternating with shale and marl beds of about same thickness. Includes strata above Bead Mountain limestone member of Belle Plains formation to base of Lueders limestone. Comprises Grape Creek limestone member below and Talpa limestone member above. Division of the Clyde into members in this area is not as natural as in country north of Abilene; in area herein mapped, units might appropriately be treated as formations.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 274–276, pls. 11, 12. Described in Brazos River area. Includes all rocks between top of Bead Mountain limestone member of underlying Belle Plains formation and base of overlying Lueders limestone. Thickness 220 feet in northwestern Callahan County; 225 feet in west-central Throckmorton County. Includes five members (ascending): unnamed shale, Grape Creek limestone, unnamed shale, Talpa limestone, and unnamed shale. Wichita group.

Named for town of Clyde, 8 miles west of Baird, Callahan County.

Coachella Fanglomerate[1]

Miocene, upper(?): Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 386–387, 391, map.

W. P. Woodring, 1932, Carnegie Inst. Washington Pub. 418, p. 12, 25. Discussion of age of marine Tertiary deposits of Colorado Desert, Calif. Vaughan considered Coachella fanglomerate to be Quaternary age. It is much older and occupies same stratigraphic position as "Indio formation" (Buwalda and Stanton, 1930). Paleontological evidence points to the conclusion that the marine beds of Colorado Desert are of Miocene age. There is little on which to base a conclusion as to what part of coastal Miocene section is represented, but evidence indicates late Vaqueros age, that is, late lower Miocene. The "Indio formation" and "Coachella fanglomerate" occupy the same stratigraphic position with reference to marine beds [Imperial formation; late lower Miocene] as the Palm Spring formation (new) which overlies the Imperial, but because both are closer to head of trough, their base may lie at lower horizon.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 323–326, pls. 1, 4. Described in San Gorgonio Pass area where it is composed of two members; an upper, 3,750 feet thick, consisting of massive conglomerate with interlayered flows of olivine basalt and associated dikes, and a lower, 850 feet thick, consisting of well-indurated massive conglomerate and basal breccia of gray schist fragments. Fanglomerate shows marked lateral variation in composition. In typical section noted, eastward-dipping Coachella beds lie with depositional contact on crystalline complex and to the east are unconformably overlain by Painted Hill formation. Some rocks mapped by Vaughan as Coachella fanglomerate belong to younger units in section, but formational name is retained for the prominent cliff-forming beds exposed along east wall of Whitewater Canyon near trout farm. No fossils have been found in the Coachella, but its unconformable position beneath early Pliocene(?) Imperial formation and its high degree of induration and well-developed jointing suggest an age at least as old as late Miocene. Map bracket shows upper Miocene(?); figure 2 shows upper Miocene; table 1 shows upper Miocene(?).

Typical section exposed in Whitewater Canyon near trout farm, Riverside County. Rocks crop out over area of about 6 square miles north of Painted Hill and east of Whitewater River. Named for Coachella Valley.

Coahuila Group

Coahuila Series

Lower Cretaceous: Southwestern Texas, and Coahuila, Durango, and Nuevo Leon, Mexico.

R. W. Imlay, 1940, Geol. Soc. America Bull., v. 51, no. 1, p. 124–125. Proposed as a group term to designate Lower Cretaceous strata older than Trinity as that term is generally understood in Texas. Includes strata older than *Dufrenoya texana* zone which were deposited in ancestral Gulf of Mexico, in Mexican sea, and in closely connected waters.

R. W. Imlay, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 1005–1007, chart 10a. Redefined as Coahuila series and subdivided into Nuevo Leon and Durango groups. This usage retains Comanche series in sense originally defined by Hill, emphasizes magnitude of Coahuila time, and permits convenient grouping of Mexican formations.

Named after Mexican state of Coahuila, where it is fully developed in both near-shore and off-shore facies. Crops out in small areas in southwestern Texas.

Coahuila Silt[1]

Pleistocene: Southern California.

Original reference: G. D. Hanna, 1926, California Acad. Sci. Proc., 4th ser., v. 14, no. 18, p. 435.

Exposed where San Diego-El Centro Highway crosses New River about 1 mile west of El Centro, Imperial County.

Coalbank Hill Member (of Molas Formation)

Mississippian-Pennsylvanian: Southwestern Colorado.

W. M. Merrill and Richard W. Winar, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2115 (fig. 4), 2116–2119. Basal member of formation. Includes red mudstones and siltstones containing solution-rounded limestone boulders and chert fragments and overlying structureless mudstones and siltstones. This is "transition zone" mentioned by earlier writers; the "rubble breccia" of upper Redwall and the "residual soil" in lower part of basal member of Naco (Huddle and Dobrovolny, 1952, U.S. Geol. Survey Prof. Paper 233–D); and lowest member of Molas as subdivided by Wengerd and Strickland (1954). Thickness about 56 feet at type locality; 13 feet at Stag Mesa; 5 feet at Ouray. Underlies middle unnamed member; unconformably overlies Leadville limestone. Where Leadville is absent, overlies Ouray limestone; contact appears gradational. No fossils. Age defined only by stratigraphic position, post-Leadville, pre-middle Molas. Mississippian-Pennsylvanian boundary probably contained within it or overlying member.

Type area: Coalbank Hill on U.S. Highway 550, 33 miles north of Durango County.

Coal Bluff Marl Member (of Naheola Formation)

Coal Bluff Beds (in Nanafalia Formation)

†Coal Bluff Beds or Series[1] } (in Wilcox Group)
Coal Bluff Formation

Paleocene: Southern Alabama.

Original reference: D. W. Langdon, Jr., 1894, Alabama Geol. Survey Rept. on Coastal Plain, p. 421.

J. E. Brantly, 1920, Alabama Geol. Survey Bull. 22, p. 148–150. Nanafalia divisible into three phases based both on lithology and fossil content. Lowest of the three phases is referred to as Coal Bluff beds, and two upper phases as Gullette Bluff beds. Smith used term Coal Bluff to apply to lignite beds at base of Nanafalia. In present report, name is extended to include all strata (42 to 70 feet) below Gullette Bluff beds.

J. A. Cushman, 1944, Cushman Lab. Foram. Research Contr., v. 20, pt. 2, p. 29–52. Allocated to member status in Naheola formation. Deposits, from which fauna herein described as collected, have been considered lower part of Coal Bluff beds of Langdon and Ackerman formation of Cooke (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 2). Paleocene.

Lyman Toulmin, Jr., 1944, Alabama Acad. Sci. Jour., v. 16, p. 42. "Coal Bluff beds" listed as uppermost unit in Naheola formation. Overlies "Oak Hill beds".

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 13–14. Name Coal Bluff marl member is restricted to lower glauconitic sandy marls and shales of Brantly (1920). The upper coarse sands are considered to be of Wilcox age. Thickness varies from place to place, probably averages 35 feet. Present at top of formation. Traced from western Butler County west to eastern Choctaw County, beyond which it becomes nonfossiliferous and is not differentiated from rest of Naheola.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 42, 44, 48–49, 51 (fig. 7). Member described in Choctaw County where it consists of fine- to medium-grained marine sand and thin platy limonite zones; disconformably overlies lignite at top of Oak Hill member (new); unconformable with overlying glauconitic sand and marl of Nanafalia formation of Wilcox group or with gravelly basal sand member of Nanafalia where it is present. Thickness 60 feet.

W. F. Roux, Jr., 1958, Dissert. Abs., v. 19, no. 5, p. 1056. Coal Bluff formation, Wilcox group, consists of lower glauconitic and upper nonglauconitic members. Overlies Naheola formation; underlies Nanafalia formation.

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 79–95. Term "Coal Bluff Section" was used by Smith (1886, Alabama Geol. Survey Bull. 1) and "Coal Bluff beds" was used by Brantly (1920) to designate 40 to 70 feet of glauconitic sand, crossbedded sand, and laminated clay and sandy clay that overlie Oak Hill member. Lignite at bottom of the "Coal Bluff beds" is now included in Oak Hill member, and a bed 20 feet or more thick, of yellow to white crossbedded sand with clay pebbles 10 to 40 feet above the lignite bed is now included in Nanafalia formation as Gravel Creek sand member (new). The intervening beds make Coal Bluff marl member.

Named from Coal Bluff, on west side of Alabama River in sec. 7, T. 11 N., R. 7 E., Wilcox County.

Coalburg Sandstones (in Kanawha Formation[1] or Group)

Pennsylvanian: Western West Virginia.

Original reference: I. C. White, 1908, West Virginia Geol. Survey, v. 2–a, p. 271, 468.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 91, 104. Upper and lower Coalburg sandstones in Kanawha group. Lower unit typically exposed in Logan and Mingo Counties.

Probably named from occurrence at Coalburg, Kanawha County.

Coalburg Shale (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: D. B. Reger, 1921, West Virginia Geol. Survey Rept. Nicholas County, p. 243.

At Mollie Frame Farm mine, 0.3 mile west of Birch River village, and at south end of Powell Mountain, on Brushy Fork of Muddlety Creek, Nicholas County.

Coal City Limestone (in Henrietta Group)

Coal City Limestone Bed (in Pawnee Limestone Member of Oologah Formation)

Coal City Limestone Member (of Pawnee Limestone)

Pennsylvanian (Des Moines Series): Southeastern Iowa and northeastern Missouri.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 59–60, 63, 64. Light-blue-gray hard finely crystalline limestone in two massive beds; weathers buff; fossiliferous. About 2 feet thick. At type locality, base of limestone is about 12 feet above top of Mystic coal. In Putnam County, Mo., lies several feet below underclay of Worland cyclothem and is separated from underlying Pawnee limestone by several feet of shales. Henrietta group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. v. (fig. 1), 7. In Missouri, Coal City limestone member of Pawnee limestone is lateral equivalent of the Laberdie member; term Coal City has priority, and Laberdie is suppressed in favor of Coal City. Overlies Mine Creek shale member; underlies Bandera formation.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 15, 16 (fig. 2). In Nowata County, Okla., considered a bed in Pawnee limestone member of Oologah formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull., 15, p. 31, fig. 5. Uppermost member of Pawnee limestone. Thickness 2 to 2½ feet in Appanoose County; about 1 foot in Madison County. Overlies Mine Creek shale member. Underlies Bandera shale.

Type section: In east bluff of Chariton River in SE¼ sec. 16, T. 67 N., R. 16 W., near Coal City in southeastern Appanoose County, Iowa.

Coal Creek Limestone[1] Member (of Topeka Limestone)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 42, 52, 53.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 164–165. Coal Creek limestone member of Topeka formation; overlies Holt shale member; underlies Severy shale of Wabaunsee group. This classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947. In Kansas, consists of light-bluish-gray limestone and nodular shale or dark-blue massive limestone which weathers light bluish gray or brown. Thickness 2 to 5 feet. Not positively identified south of Kansas River.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull., 15, p. 15, fig. 5. Medium- to dark-gray dense limestones interbedded with fossiliferous shales; locally contains dark chert. Thickness 5 to 6 feet. Upper unit of Topeka; overlies Holt shale member.

Type locality: About three-fourths mile north of Union, Cass County, Nebr.

Coal Creek Quartzite[1]

Precambrian: Central northern Colorado.

Original reference: M. F. Boos and C. M. Boos, 1934, Geol. Soc. America Bull., v. 45, no. 2, p. 306.

G. D. Fraser, 1949, (abs.), Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1960. Fine-grained quartz-muscovite-biotite schist interbedded with the quartzite contains a few garnet crystals and, locally, abundant cordierite. Believed to be younger than Idaho Springs formation and older than some of the granite in the area. Outcrop area described.

Crops out in triangular area 7 miles long and up to 3 miles wide near mouth of Coal Creek Canyon, Jefferson and Boulder Counties.

Coal Creek Serpentine

Precambrian: Central Texas.

V. E. Barnes, 1940, *in* Geol. Soc. America [Guidebook] 53d Ann. Mtg., p. 53 (geol. map.) Named and mapped in Cut Off Gap area.

Frederick Romberg and V. E. Barnes, 1949, Geophysics, v. 14, no. 2, p. 152–154, fig. 1. Discussed as Coal Creek serpentine mass. Bordered along south and for the western half of its distance along north by Big Branch gneiss; for remainder of distance on northern side, bordered by Packsaddle schist.

V. E. Barnes, [1952?]. Geologic map of the Willow City quadrangle, Gillespie and Llano Counties, Texas (1:31,168): Texas Univ. Bur. Econ. Geology. Only about 15 percent of mass is in Willow City quadrangle. The rest is in Blowout quadrangle.

V. E. Barnes, [1952?], Geologic map of the Blowout quadrangle, Blanco, Gillespie, and Llano Counties, Texas (1:31,680): Texas Univ. Bur. Econ. Geology. Age of serpentine is in question. It is cut by aplites, pegmatites, and quartz bodies derived from Town Mountain granite, making it the older. Its outcrop shape is that of an intrusive into Big Branch gneiss but it is not proven that Big Branch gneiss did not actually assimilate the Packsaddle schist from around the serpentine.

Name derived from Coal Creek, an intermittent stream which crosses the mass in Willow City quadrangle.

Coaldale Chert

Ordovician(?): Central western Nevada.

B. M. Page, 1949, (abs.) Geol. Soc. America Bull., v. 60. no. 12, pt. 2, p. 1943. Mentioned in discussion of structure of Candelaria district. Numerous pre-Permian contortions and faults occur in unit.

Candelaria district, Mineral County.

Coaledo Formation (in Arago Group)[1]

Eocene, upper: Southwestern Oregon.

Original reference: J. S. Diller, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 319–320.

F. E. Turner, 1938, Geol. Soc. America Spec. Paper 10, p. 27–31. As exposed in sea cliffs about Cape Arago and Sunset Bay, comprises three divisions. Lower, approximately 1,600 feet thick, consists principally of sandstone with subordinate amounts of shale; middle, about 3,200 feet thick, predominantly soft fine sandstone and shales; upper, about 1,200 feet, principally medium and coarse sandstone with occasional thin beds of shale and one 10-foot bed of low-grade lignite. Contact with overlying Bassendorf shales obscured. Fauna discussed.

J. E. Allen and E. M. Baldwin, 1944, Oregon Dept. Geology and Mineral Industries Bull. 27, p. 21–27, pls. 1, 5. Lower, middle, and upper members mapped and described in Coos Bay quadrangle. Thickness about 6,015 feet. Underlies Bastendorf [Bastendorff] shale; unconformable above Umpqua formation. Upper Eocene.

D. C. Duncan, 1953, U.S. Geol. Survey Bull. 982–B, p. 58–60, pl. 5. Thickness about 5,600 feet where exposed along sea cliffs at mouth of Coos Bay. Overlies Umpqua formation; underlies Bastendorf [Bastendorff] shale. Late Eocene.

Well exposed in vicinity of Coaledo, Coos County.

Coalfield Sandstone (in Crooked Fork Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Includes both massive and thin phases. Thickness 30 to 60 feet; in Crooked Fork section 42 feet; west of Oneida and in southeast part of Barthell Southwest quadrangle thins to 10 or 15 feet. In Morgan County, sandstone locally splits into two or three benches. Underlies Glenmary shale (new); overlies Burnt Mill shale (new).

Underlies town of Coalfield, Petros quadrangle, Morgan County.

†Coalinga Beds[1]

Miocene and Pliocene: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 174–185.

Named for exposures north, northwest, and west of Coalinga, Fresno County.

Coalmont Formation[1]

Paleocene-Eocene: Northern Colorado.

Original reference: A. L. Beekly, 1915, U.S. Geol. Survey Bull. 596, p. 20, 49–71.

R. F. Walters, 1957, Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Park Basins, Colorado, p. 86–87. Continental deposits of heterogeneous lithology with sandstone predominant. On basis of floral fossil evidence, has been considered Paleocene in age; no diagnostic vertebrates found. It is possible, on basis of regional geologic history, that uppermost part of formation is lower Eocene (Wasatch) in age.

W. J. Hail, Jr., and E. B. Leopold, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B260–B261. Presence of Paleocene leaves indicates Paleocene age for lower part of formation; presence of pollen of *Platycarya*. Gramineae, and *Tilia crassipites* indicate upper part of formation is Eocene. Formation has aggregate thickness of as much as 9,000 feet in parts of North Park. Unconformably overlies rocks mostly of Cretaceous age and is unconformably overlain locally by White River formation of Oligocene age and by North Park formation of late Miocene age.

Well exposed along North Platte River, North Park. Name derived from Coalmont, Jackson County.

Coalvale Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 196. Cherokee group is divided into 15 cyclic formational units. The Coalvale, 11th in the sequence (ascending), occurs below the Croweburg and above the Fleming. Average thickness 9 feet. Includes coal here named Arcadia. [For complete sequence see Cherokee group.]

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 45. Overlies Fleming cyclothem and underlies Ardmore cyclothem redefined to include Croweburg cyclothem of Abernathy (1937).

Type locality and derivation of name not given. Cherokee outcrop in Kansas covers an area of about 1,000 square miles and includes parts of Labette, Bourbon, Crawford, and Cherokee Counties.

Coal Valley Formation (in Wassuk Group)

Pliocene, lower and middle: Western Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 29–33, 64–66, figs. 2, 3, and 4. Consists of five mappable lithologic units (ascending): alternating conglomerate, sandstone, lake beds, with hornblende andesite pyroclastics and flows, rhyolite tuffs—thickness 850 feet; grit and andesite tuff—thickness 150 feet; sandstone, diatomaceous shale, pebble conglomerate, and andesite tuff—thickness 1,350 feet; sandstone—thickness 575 feet; and alternating sandstone, conglomerate, diatomaceous shale, andesite tuff, granitic breccia—thickness 400 feet. Aggregate thickness 3,325 feet. Conformably underlies Morgan Ranch formation (new) and unconformably overlies Aldrich Station formation (new). Chart shows Coal Valley overlying and interfingering with Kate Peak andesite. Represents a deposit which records a change from subaerial and fluviatile to lacustrine conditions within a short distance, a change comparable to that found in small lake-delta deposit.

D. I. Axelrod, 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 2, p. 97–104. In Verdi area, overlies Kate Peak andesite.

D. I. Axelrod and W. S. Ting, 1960, California Univ. Pubs. Geol. Sci., v. 39, no. 1, p. 3. In fault contact with upper Pliocene Wichman formation (new).

Type area in Coal Valley adjacent to Lewis Terrace, which lies 4 miles south of Morgan's Ranch, Hawthorne quadrangle.

Coalville Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 138, 139 (fig. 2), 145 (fig. 3). Marine sandstone and coal of late Greenhorn age. Thickness 175 feet (east) to 223 feet (west). Contains the prominent "Wasatch" coal. Overlies Chalk Creek member (new); contact transitional. Underlies Allan Hollow shale member (new). Comprises units 11–13 as described by Wegemann (1915, U.S. Geol. Survey Bull. 581, pt. 2), and Cobban and Reeside (1952).

Well exposed in ridge that strikes N. 35 E., from Coalville townsite, Summit County.

Coamo Formation

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 149-152. Chiefly massive tuff breccias and bedded tuffs including ashflow deposits. Between Ciales and Orocovis, formation is characterized by abundance of tuffs, tuff breccias, and volcanic conglomerates and by an extensive and thick basal sequence of redbeds including numerous ashflows. In north-central Puerto Rico consists of two distinct parts: lower, mostly red, sequence that consists principally of andesitic tuffs (mostly ashflows) and an upper massive nonred sequence of poorly stratified andesitic tuff breccia; locally in lower red part of formation is rudistid-bearing Botijas limestone member (new). Along southern flank of Puerto Rico anticlinorium, conformably overlies Cariblanco formation (new); along north side of anticlinorium, strata tentatively assigned to the Coamo lie in several fault blocks; eastward along its northern belt of outcrops, strata equivalent to the Coamo both thin and interfinger into upper part of strata correlated with the Cariblanco. Southeast of Rio Piedras, identity of Coamo is lost. Because of this interfingering and thinning, thickness of the Coamo ranges from a few inches to approximately 7,000 feet. Appears to be gradational into overlying rocks of probable early Tertiary age. Name credited to Lynn Glover (in press).

Named for outcrops in and near Coamo in south-central Puerto Rico.

Coamo Tuff Limestone[1]

Upper Cretaceous: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Ann., v. 26, p. 19, 61.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47. In Ponce district, underlies Guayabal limestone and overlies Peñuelas shale. Thickness 300 feet.

Well developed in vicinity of Coamo Reservoir near Coamo Springs.

Coamo Springs Limestone Member (of Naranjo Formation)

Coamo Springs Limestone Series[1]

Eocene, middle: Puerto Rico.

Original reference: E. T. Hodge, 1920, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 2, p. 153.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 52, 54. Underlies Canas Arriba formation (new); overlies Rio Jueyes series. Thickness 1,000 feet. On basis of fossil evidence, age is considered to be Eocene, probably upper. Term "series" is taken from original surveys but is misnomer.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 73–77. Member of Naranjo formation (new). Overlies Miramar member (new). Interfingers with Río Descalabrado member and is also overlain by it. Mitchell (1922, New York Acad. Sci. Scientific survey of Porto Rico and the Virgin Islands, v. 1) called slightly different facies of the limestone both Coama (equivalent to Coamo) tuff limestone and Guayabal limestone. Older name of Hodge takes priority. Hodge did not select type area; type area for amended Coamo Springs is herein designated.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 84. Member of Naranjo formation. Consists of 0 to 3,800 feet of pure massive algal limestone, characteristically white, but may vary to gray, red, or pale orange. Overlies Los Puertos member (new). Traced for about 60 kilometers from Salinas to southeast part of Jayuya quadrangle.

Type area: Northwest end of Cerro de las Cuevas. Excellent exposures occur at quarries along Camino Naranjo in this area. Named from a thermal spring in Coamo River Water Gap, Coamo-Guayama district.

Coane Formation (in Veredas Group)

Pennsylvanian (Missouri Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 58 (fig. 6), 59–61. Name applied to basal formation of group. At type locality, consists of light-bluish-gray to gray cherty limestone; in other areas, lower part of formation contains clastic beds of gray shales and sandstones. Thickness varies from about 58 feet at type section to more than 100 feet in the Ladron Mountains. Underlies Adobe formation (new); overlies Bolander group (new).

Type locality: West face of northwest side of Oscura Mountains, eastern part of SE¼ sec. 36, T. 5 S., R. 5 E., Socorro County.

Coasters Harbor Island Arkose[1]

Carboniferous: Southern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 380.

Occurs at south end of Coasters Harbor Island.

Coast Range Diorite[1]

Age(?): Alaska.

Original reference: A. C. Spencer, 1906, U.S. Geol. Survey Bull., 287, map opposite p. 12.

Coast Range Intrusives[1]

Jurassic or Cretaceous: Southeastern Alaska, and British Columbia and Yukon Territory, Canada.

Original reference: A. F. Buddington, 1929, U.S. Geol. Survey Bull. 807, p. 116–119.

Hyder district, Alaska.

†Coata Sandstone Member (of Atoka Formation)[1]

See Coody Sandstone Member.

Cobb Mountain Volcanics (in Clear Lake Volcanic Series)

Quaternary: Northern California.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), 47, pl. 7. Rhyolite flows and tuffs about 200 to 1,500 feet thick. Shown on columnar section above Boggs Mountain flows (new) and below a 100 to 300 foot unit of pyroxene dacite; age relations of individual units of series are imperfectly known because some units are isolated and contacts of contiguous flows are commonly obscured by sliding.

Vicinity of Cobb Mountain, Lower Lake quadrangle, in Coast Ranges, about 70 miles north of San Francisco.

Cobham conglomerate member[1] (of Knapp formational suite)

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 61, 112, 116, 117, table opposite p. 61.

Exposed along southeast and southwest faces of Cobham Hill, at Glade, Warren County.

Cobleskill Limestone or Dolomite[1]

Upper Silurian (Cayuga Series): New York, and Ontario, Canada.

Original reference: C. Schuchert, 1903, Am. Geologist, v. 31, p. 160–175.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 9–10, 11, 13, fig. 1. In the west, overlies Bertie limestone; eastward overlies Brayman shale (redefined). Underlies Rondout dolomite.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Lower Devonian Helderbergian series (revised) consists of nine formations, five of which are present in central New York: Cobleskill, Rondout, Manlius, Coeymans, and Kalkberg. Cobleskill consists of nearly barren central and western dolomite facies, 10 to 17 feet thick.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Shown on correlation chart as Upper Silurian, Murderian stage (new).

Named for exposures on Cobleskill Creek, Schoharie County, N.Y.

Cobourg Limestone[1] (in Trenton Group)

Middle Ordovician: Ontario, Canada, and northwestern New York.

Original reference: P. E. Raymond, 1921, Canada Geol. Survey Mus. Bull. 31, Geol. Ser. 38, p. 1.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 277–281. Term Cobourg limestone replaced "Picton limestone" which had been applied to the heavy-bedded limestones with gastropod fauna and underlying thinner bedded limestone with *Rafinesquina deltoidea* exposed at Picton, Ontario. Term Picton preoccupied. Formation separable into two members here designated as Hallowell and Hillier. In standard section of Trenton group, occurs above Sherman Fall formation and below Collingwood shale.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 601–602. Along West Canada Creek, N.Y., the Cobourg is subdivided into Rust and Steuben members (both new). Overlies Russia member (new) of Denmark formation. Underlies Holland Patent (upper Utica). Thickness 175 feet.

Named for Cobourg, Northumberland County, Ontario.

Cobourgian (Cobourg) Stage or Substage

Middle Ordovician (Trentonian): Eastern North America.

G. M. Kay, 1937, Geol. Soc. America Proc. 1936, p. 82. Stage in later Trenton. Followed by Collingwood and Gloucester stages.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 277–283, 293, 298. Discussion of stratigraphy of Trenton group. List of formations of Cobourg age. Cobourg time [followed Sherman Fall] marked by retreat of sea from Adirondack arch into Ontarian basin. In Cobourg stage, the arch continued to rise, and trough on east was restricted by incursion of sediments on its eastern side; boreal faunas again invaded northern part of region. Cobourg followed by Collingwood and Gloucester stages.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1415. Stage in upper Trentonian. Most of true Utica is Cobourgian.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30–31. Probably term stage is too high an order for the named divisions of the Trentonian; they can be considered substages of a smaller number of stages. The Cobourg-Collingwood-Gloucester seems to be time-equivalent of Utica group but name Utica is strongly associated with black shale facies. Hence, uppermost Trentonian stage is designated Pictorian. The Cobourgian forms most of section in gorge at Trenton Falls.

Name derived from Cobourg, Ontario, Canada, from which Cobourg limestone was named.

†Cobscook Series[1]

Silurian and Devonian: Southeastern Maine.

Original reference: N. S. Shaler, 1886, Am. Jour. Sci., 3d, v. 32, p. 44–60.

Named for development in Cobscook Bay district, east coast of Washington County.

Cobscook Bay Series[1]

Silurian and Devonian: Southeastern Maine.

Original reference: H. S. Williams, 1900, U.S. Geol. Survey Bull. 165, p. 34–35.

On extreme southeast coast.

Coburn Formation[1] or Limestone (in Trenton Group)

Middle Ordovician: Central and south-central Pennsylvania.

Original reference: R. M. Field, 1919, Am. Jour. Sci., 4th, v. 48, p. 404, 420.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 3 (fig. 3); no. 2, p. 114. Coburn limestone comprises the somewhat coquinal limestone succeeding the Salona and underlying black shale of Antes formation (new). Section at type locality has not been described, and only section at Salona seems to have been studied adequately. Here thickness is 300 feet. Correlated with Cobourg limestone of Ontario. Trenton group. Mohawkian.

Named from town in Center [Centre] County.

Cobwebb Basalt

Pliocene, lower(?): West-central Arizona.

S. G. Lasky and B. N. Webber, 1949, U.S. Geol. Survey Bull. 961, p. 14 (table 2), 34–35, pls. 1, 2. Hypersthene(?)-augite-olivine basalt. Most of rock is gray to brown and fine-grained to aphanitic and contains only a few vesicles, but where relatively thick the upper part is black, mostly is aphanitic, and highly vesicular. Maximum thickness about 250 feet. Lies conformably upon Chapin Wash formation (new), but overlaps onto Artillery formation (new) along Burro Wash, where Chapin Wash formation thins out. Unconformably underlies Sandtrap conglomerate (new). Because of its conformity with Chapin Wash formation, it is thought to belong to same geologic epoch as that formation and, therefore, to be tentatively of lower Pliocene age. Shown on plate 1 as Pliocene(?) and on plate 2 as early Pliocene(?).

Named from exposure on Cobwebb Hill, in upper Chapin Wash in Artillery Mountains, about 30 miles east of Colorado River.

Cocalico Shale[1]

Ordovician: Southeastern Pennsylvania.

Original reference: G. W. Stose and A. I. Jonas, 1922, Washington Acad. Sci. Jour., v. 12, p. 359, 365.

F. M. Swartz, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1568. Cocalico shale is known by this name only along a 24-mile belt centering about 30 miles east-southeast of Harrisburg. Rests on Beekmantown, and is perhaps 1,000 feet thick, with its summit everywhere truncated by present level of erosion, so that relations to overlying sediments are not directly established.

Named for exposures on Cocalico Creek, Lancaster County.

Cochahee Sandstone Member (of Vamoosa Formation)

Cochahee Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: D. E. Winchester, K. C. Heald, and others, 1918, U.S. Geol. Survey Bull. 686–G, p. 60.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 12 (fig. 1), 47–48, pl. 1. Reallocated to Vamoosa formation. Near type locality, the Cochahee is a buff thin- to medium-bedded fine-grained sandstone exhibiting "bar structure," ripple marks, and crossbedding. In T. 24 N., member consists of at least 10 feet of buff sandstone and may include a 12-foot contorted sandstone separated from the lower bed by 20 feet of shale. Occurs above Jonesburg sandstone member and below Wynona sandstone member.

Named for exposures on headwaters of Cochahee Creek, in southwest part of T. 25 N., R. 10 E., Osage County. [Probably considered type locality by Tanner.]

Cochise Formation[1]

Middle Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 466, 479, 480, 482.

D. J. Cederstrom, 1946, Am. Jour. Sci., v. 244, no. 9, p. 607. Represented by 50 feet of poorly exposed shales beneath Abrigo formation in Dragoon Mountains.

Type locality: Whetstone Mountains, Cochise and Pima Counties.

Cochise limestones[1]

Lower Cretaceous (Comanche Series): Southeastern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 250, 336.

Probably named for exposures at or near Cochise, Cochise County.

Cochise Peak Quartz Monzonite

Triassic or Jurassic: Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 9, 63–65, pl. 5. Generally light greenish gray, weathering to rather dark-grayish-brown colors. Generally spangled with conspicuous flesh-colored crystals of microcline as much as 4 centimeters long. Abundance of crystals ranges greatly. In places, rock grades into mylonites. Most contacts are faults and thus give little direct clue to original intrusive relations. Older than Stronghold granite with which it is in contact in three areas of Pearce quadrangle.

Crops out in belt extending from northern side of Cochise Peak, south-southeastward for nearly 3 miles, to the divide at Middle Pass, central Cochise County. Belt ranges in width from about 1,000 feet to nearly one-half mile. Numerous other small bodies and blocks recognized in area but are too small to be mapped.

Cochran Formation

Cochran Conglomerate[1]
Cochran Quartzite } (in Chilhowee Group)

Lower Cambrian(?): Eastern Tennessee and western North Carolina.

Original reference: A Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16.

G. W. Stose and A. J. Stose, 1947, Am. Jour. Sci., v. 245, p. 626 (table), 628–629 (fig. 1). Cochran quartzite listed with rocks exposed in Hot Springs window, North Carolina. Thickness 1,200 to 1,400 feet. Includes Nichols shale and quartzite lentil of Keith. Overlies Sandsuck shale; underlies Nebo quartzite. Lower Cambrian.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 12, 13 (table 3). Two sets of formation names for Lower Cambrian clastic rocks are in current usage in eastern Tennessee and western North Carolina. The northeast Tennessee names, Unicoi, Hampton, and Erwin, are used in this report for same rocks which Keith (1904, U.S. Geol. Survey Geol. Atlas, Folio 116) and Stose and Stose (1947) named Cochran, Nichols, Nebo, Murray, and Hesse, all defined by Keith (1895) in Chilhowee Mountains area, Blount and Sevier Counties, Tenn. Hot Springs area lies midway between type localities for each group of names. Cochran conglomerate included in Unicoi formation of this report.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 962. Base of Cochran formation redefined at higher level, at base of persistent beds of arkose and quartzite, in part maroon; shale, sandstone, and conglomerate beneath is redefind as Sandsuck formation. Cambrian and Precambrian(?).

U.S. Geological Survey currently designates the age of the Cochran Formation as Early Cambrian(?) on the basis of a study now in progress.

Type locality (Rodgers, 1953): Cochran Creek on south side of Chilhowee Mountain, Blount County, Tenn. Makes crest of mountain northwest of lower course of creek.

Cochrane Glacial Substage

Pleistocene (Wisconsin): North America.

Kirk Bryan and L. R. Ray, 1940, Smithsonian Misc. Colln., v. 99, no. 2, p. 70; Kirk Bryan, 1941, Smithsonian Misc. Colln., v. 99, no. 23, p. 57 (table 1). Cochrane glacial substage mentioned in discussion of Folsom culture of late glacial age. Long Draw glacial substage of Colorado is considered equivalent of the Cochrane and Fennoscandian substages, to which an age of 10,000 years may be assigned.

T. N. V. Karlstrom, 1955, (abs.) Geol. Soc. America Bull., v. 66, no. 12, pt. 2, p. 1582. Radiocarbon determinations give Wisconsin glaciations beginning 7,000 B.C. (Cochrane). "Little ice age" began 3,500 B.C.

T. N. V. Karlstrom and Meyer Rubin, 1955, (abs.) Geol. Soc. America Bull. v. 66, no. 12, pt. 2, p. 1582; T. N. V. Karlstrom, 1956, U.S. Geol. Survey Bull. 1021–J, p. 303–330. Precise position of Cochrane readvances in Pleistocene continental chronology has long been uncertain. Recent radiocarbon results indicate that the Cochrane preceded rather than followed the Altithermal climatic period and suggest that the Cochrane be considered a Wisconsin event of substage rank. Radiocarbon dates also substantiate correlation of the Mankato with Fennoscandian substage of European chronology, and correlation of the Cochrane with a post-Fennoscandian climatic event.

M. M. Leighton, 1957, Jour. Geology, v. 65, no. 1, p. 109. Cochran[e] excluded from classification of Wisconsin stage because it is believed to represent only a minor incident in final climatic adjustment to present intraglacial stage, the Recent.

Name derived from Cochrane, Ontario.

Cochrane Limestone Member (of Chimneyhill Limestone)

Lower Silurian: South-central Oklahoma.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132, 133. White to grayish-white, but locally bluish- or greenish-gray, massive crystalline limestone containing glauconite. Average thickness 12 to 15 feet. Unconformably underlies Dillard limestone member (new); conformably overlies Keel limestone member (new).

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 4 (fig. 2), 6 (fig. 3), 13 (fig. 5), 16–19. Unconformally underlies Clarita member (name replaces Maxwell's preoccupied Dillard); unconformably overlies Keel member. Type locality stated.

Type section: SE¼ sec. 5, T. 2 N., R. 6 E. [Pontotoc County]. Well exposed along banks of small tributary entering Chimneyhill Creek.

Cockeysville Marble[1]

Cockeysville Formation

Lower Paleozoic(?): (Glenarm Series): Maryland, northern Delaware, southeastern Pennsylvania, and northeastern Virginia.

Original reference: G. H. Williams and N. H. Darton, 1892, U.S. Geol. Survey map of Baltimore and vicinity, to accompany "Guide to Baltimore" prepared for Baltimore meeting Am. Inst. Mining Engineers, Feb. 1892.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12] Carroll and Frederick Counties, p. 55. On geologic map of Carroll County (1928), all marble and limestone exposed in crystalline rocks of Piedmont upland are mapped as Cockeysville, but name Cockeysville is now restricted to narrow band of marble overlying Setters formation in southeast corner of Carroll County. Marble in northeastern Carroll County is now mapped as Wakefield marble, and in western part of Carroll County and eastern part of Frederick County, where marble is associated with volcanic rocks, the albite-chlorite schist facies of the Wissahickon formation, and the Marburg schist, it is mapped as Wakefield marble and Silver Run limestone on the Frederick County geologic map (1938). Thickness estimated 400 feet.

W. C. Rasmussen and others, 1957, Delaware Geol. Survey Bull. 6, v. 1, p. 95 (table 13), 96 (fig. 21), 100–102, pls. Cockeysville marble crops out in two places in Delaware, one near Hockessin in headwaters of Mill Creek and the other in valley of Pike Creek at foot of Pleasant Hill. Underlies Wissahickon formation. Glenarm series. Precambrian(?).

P. W. Choquette, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1027–1052. Formation is sequence of intricately folded carbonate-rich metasedimentary rocks about 750 feet thick and of pre-Silurian age. Formation lies near base of Glenarm series which mantles five elongated domes of Precambrian(?) basement gneiss at eastern edge of Piedmont province. Overlies Setters formation; underlies Wissahickon formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Probably lower Paleozoic.

Named for exposures at Cockeysville, Baltimore County, Md.

Cockeysville Volcanics[1]

Precambrian: Maryland.

Original reference: E. B. Mathews, 1963, Geologic map of Maryland: Maryland Geol. Survey.

Cockfield Formation (in Claiborne Group)[1]

Cockfield Formation (in Yegua Group)

Eocene, middle: Northwestern Louisiana, Mississippi, and eastern Texas.

Original reference: T. W. Vaughan, 1895, Am. Geologist, v. 15, p. 220.

J. Huner, Jr., 1939, Louisiana Geol. Survey Bull. 15, p. 119–142. Described in Caldwell and Winn Parishes, La., where it overlies Little Natches member (new) of Cook Mountain formation. Underlies Jackson group. Name Cockfield has been in common use in Louisiana since 1905, although there have been many suggestions to alter it.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 68–73. In this report, formation is expanded to include all beds below Moodys Branch of basal Jackson and above the Wautubbee. This usage is in agreement with usage of term Cockfield in Louisiana where type section is located. Term Cockfield does not have priority over either Yegua or Lufkin but is well established in Louisiana literature and is preferred over Yegua in this report. Cockfield of Mississippi has been considered both a member of Lisbon formation and a separate formation. Formation maintains thickness of about 50 feet across Clarke County and gradually thickens northwestward from this area to maximum of about 450 feet in Holmes and Yazoo Counties.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Formation shown on correlation chart in Mississippi; overlies Gordon Creek shale member of Cook Mountain formation; underlies Moodys Branch marl.

A. A. L. Mathews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 1, 4. Included in Yegua group. In Brazos County, overlies Easterwood shales (new); underlies Rock Prairie sandstone (new) of Jackson group. Estimated thickness 723 feet.

U.S. Geological Survey has restored the term Cockfield for use in Mississippi, Louisiana, and Arkansas to replace the term Yegua which is restricted to Texas.

Named for Cockfield Ferry on Red River, near Petite Ecore, Winn Parish, La.

†Cockfield Lignite[1]

Eocene, middle: Louisiana and Mississippi.

Original reference: E. N. Lowe, 1915, Mississippi Geol. Survey Bull. 12, p. 77.

Named for Cockfield Ferry, Winn County, La.

Cockfield Ferry Beds[1]

Eocene, middle: Northwestern Louisiana, Mississippi, and eastern Texas.

Original reference: T. W. Vaughan, 1895, Am. Geologist, v. 15, p. 220.

Named for Cockfield Ferry, on Red River, near Petite Ecore, Winn County, La.

Cockrum Sandstone (in Dakota Group)

Upper Cretaceous: Southwestern Kansas and southeastern Colorado.

B. F. Latta, 1941, Kansas Geol. Survey Bull. 37, p. 21 (table 1), 73–79, pl. 1. Name introduced to designate sandstone that overlies Kiowa shale; classed as uppermost division of the Dakota, here considered a group, and includes beds that have formerly been designated under name of Dakota sandstone. Composed of fine- to medium-grained light-tan, buff, brown, or reddish-brown sandstone, commonly ferruginous, and light-colored shale or clay. Thickness as much as 125 feet. In Stanton County, disconformably underlies Ogallala formation; in Hamilton County, conformably underlies Graneros shale; basal contact not exposed in Stanton County but is exposed in Prowers County, Colo.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Rocks which comprise Dakota formation, Kiowa shale, and Cheyenne sandstone formerly were classed as Dakota group. Use of this grouping has been discontinued. Cockrum sandstone of southwestern Kansas is equivalent in age to part of Dakota formation.

Named from outcrops along Cockrum Branch of Bear Creek in S½ sec. 9, T. 29 S., R. 43 W., and from outcrops along Bear Creek in southwestern Stanton County, Kans.

Cocoa Sand Member (of Yazoo Clay)

Cocoa Sand Member (of Jackson Formation)[1]

Eocene, upper: Southwestern Alabama and eastern Mississippi.

Original reference: J. A. Cushman, 1925, Cushman Lab. Foram. Research Contr., v. 1, pt. 3, p. 65–69.

[U. B. Hughes] 1940, Mississippi Geol. Soc. [Guidebook] Field Trip Feb. 10 and 11, second day's field trip, p. 2. Referred to as sand member of Yazoo clay.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12; F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1315 (fig. 1). Correlation chart shows Cocoa sand member of Yazoo clay.

H. A. Tourtelot, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 6. In Choctaw County, Ala., member consists of lower marly fine-grained sand phase and upper coarser calcareous sand phase. Lower phase, 10 to 20 feet thick, is clayey and marly fine-grained micaceous sand that is bluish gray or greenish blue on fresh outcrop; upper phase, 20 to 50 feet thick, is medium-grained calcareous sand containing irregular ledges of glauconitic limestone and marl at top.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1838 (fig. 6), 1839. In Mississippi and Alabama, Cocoa sand member is overlain by Pachuta marl member and underlain by North Creek clay member (both new).

Named for abandoned country post office called Cocoa, which stood in SW¼ sec. 13, T. 11 N., R. 5 W., Choctaw County, Ala., about 2½ miles east of Melvin, on road to Gilberton.

Coconino Sandstone (in Aubrey Group)[1]

Permian: Arizona, southeastern Nevada, and southern Utah.

Original reference: N. H. Darton, 1910, U.S. Geol. Survey Bull. 435, p. 21, 27.

E. D. McKee, 1938, Carnegie Inst. Washington Pub. 492, p. 14–17. Conformably underlies Toroweap formation (new).

E. D. Koons, 1945, Geol. Soc. American Bull., v. 56, no. 2, p. 154. In Grand Canyon area, overlies Hermit shale and underlies Toroweap formation. Thickness 100 feet in eastern part of area, thinning westward to 50 feet along Queantoweap Valley.

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 532–534. Type section not designated by Darton or by later workers. Section at Aubrey Cliffs can be considered as type section, because it is near place where Marvine (1875, U.S. Geog. and Geol. Surveys West of 100th Meridian, v. 3, pt. 2) studied rocks he designated Aubrey group of which the Coconino is a member. Thickness 405 at Aubrey Cliffs section. Lowest beds in abrupt contact with Supai redbeds.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 38 (table), 46. In Henry Mountains region, Utah, is as much as 600 feet thick. Consists of tangentially cross-laminated gray to white fine-grained quartz sandstone. Believed to be equivalent to and grade laterally into Cutler formation to east. Underlies Kaibab limestone. Base of section in this report.

R. E. Lehner, 1958, U.S. Geol. Survey Bull. 1021–N, p. 540–543. Described in Clarkdale quadrangle, Arizona, where it is 500 to 650 feet thick. Conformably overlies Supai formation and passes laterally into its upper part through intertonguing. Underlies Toroweap formation, contact sharp. McKee (1934, Carnegie Inst. Washington Pub. 440) reported thickness of 1,000 feet at Pine, Ariz.; this is thickest section known.

Type section (McNair): Aubrey Cliffs, Coconino County, Ariz. Underlies entire Coconino Plateau as well as extensive plateau country north of Grand Canyon.

Codell Sandstone Member (of Benton Shale)

Codell Sandstone Member (of Carlile Shale)[1]

Upper Cretaceous: Western Kansas, eastern Colorado, and southeastern South Dakota.

Original reference: N. W. Bass, 1926, Kansas Geol. Survey Bull. 11, p. 28, 64.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull, 89, p. 24. Referred to as Codell sandstone zone in Blue Hill shale member of Carlile shale.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10b (column 53). Shown on correlation chart as member at top of Benton shale, Morgan County, Colo.

R. C. Barkley, 1953, South Dakota Geol. Survey Rept. Inv. 72, p. 17, 18. Thickness about 6 feet where exposed in Davison County. Occurs at top of Carlile.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 16 (table 3), 121. Uppermost member of Carlile shale. In Baca County, Colo., consists of 2½ to 3 feet of light-tan to rusty-brown hard finely crystalline limestone containing a few sand grains. Overlies Blue Hill shale member; underlies Fort Hays limestone member of Niobrara formation.

M. A. Jenkins, Jr., 1957, Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Parks Basin, Colorado, p. 53, pl. 1. Upper member of Benton formation in Red Dirt Creek area, Grand County, Colo. Thickness about 46 feet. Underlies Fort Hays member of Niobrara.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on correlation chart as uppermost member of Carlile shale. Overlies Blue Hill shale member; underlies Fort Hays limestone member of Niobrara chalk.

Named for exposures in bluffs along Saline Valley in Ellis County, Kans., 5 miles south and west of Codell.

Codorus Limestone[1]

Cambrian and Ordovician: Southeastern Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 1, p. 454.

Codorus Creek, York County.

Cody Shale[1] **(in Colorado Group or Montana Group)**

Upper Cretaceous: Wyoming and Montana.

Original reference: C. T. Lupton, 1916, U.S. Geol. Survey Bull. 621, p. 166, 171, table.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 126 (fig. 2), 138. In Wind River Mountains, consists of about 4,500 feet of dark-gray shales interbedded with thin sandstone members. Overlies Frontier formation; underlies Mesaverde formation. Name Cody preferred to Steele because Cody was described as resting on the Frontier in Bighorn basin whereas the Steele was described as resting on the Niobrara. Near Wind River Mountains, there is no lower division that should be differentiated as Niobrara formation although fossils of Niobrara age are present.

S. K. Fox, Jr., 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1967. Analysis of 94 species of late Cretaceous Foraminifera from three well-exposed sections of Cody shale in northern Wyoming and southern Montana indicates correlation of the Cody with Niobrara chalk of Great Plains and with upper part of Alberta shale of Canada. Correlation of entire Cody shale with the Niobrara supports Reeside's conclusions from mollusk evidence but is contrary to frequent practice of designating the lower Cody as Carlile in age.

C. J. Hares and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 51. Stratigraphic section [southeastern part of Wind River basin and adjacent area in central Wyoming] shows that Cody shale overlies Wall Creek sandstone member of Frontier formation and underlies Parkman sandstone member of Mesaverde formation. Includes Shannon sandstone member in upper part. Term Cody as used here replaces terms Carlile shale, Niobrara shale, and Steele shale as used in this area by Hares (1916, U.S. Geol. Survey Bull. 1641–I.)

G. R. Downs, 1947, Wyoming Geol. Assoc. Guidebook 2d Ann. Field Conf., p. 138, 139. Consists of series of gray to black marine shales, shaly buff sandstones (upper part only), gray calcareous shale, and a few thin bentonites. Maximum thickness about 3,500 feet at type locality; thins to about 2,600 feet in southeastern part of Bighorn basin. Unconformably overlies Frontier formation and conformably underlies Mesaverde formation. Near Elk basin oil field and Montana-Wyoming line, Claggett shale, Eagle sandstone, and Telegraph Creek formation occupy same stratigraphic interval as upper part of Cody elsewhere in Bighorn basin. Near city of Cody, the Eagle sandstone and Telegraph Creek sandy shale "shale out," and the shale facies are included in the Cody as there defined. The buff to gray Claggett sandy shale equivalent forms top of the Cody shale. Montana group.

J. D. Love and others, 1948, Wyoming Geol. Survey Bull. 40, p. 5–8, 41. Measured sections show that Cody shale underlies Bacon Ridge sandstone (new) in southeast part of Jackson Hole area. Overlies Frontier formation. This contact is established in conformity with U.S. Geological Survey classification and common usage for central Wyoming. At type area of Frontier, this contact may come well down within the Frontier. Contact is arbitrarily placed at approximate point below which sandstones predominate and above which sandy shales predominate. This contact is gradational within an interval of approximately 20 feet. Maximum thickness 2,211 feet.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map OM–111; P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 50–62, pls. 1, 2. Cody shale, in Bighorn River Canyon, Hardin area, Big Horn County, Mont., comprises (ascending) lower shale, 205 feet; Greenhorn calcareous member, 97 feet; Carlile shale member, 280 feet; Niobrara shale member, 409 feet; Telegraph Creek member, 867 feet; shale member equivalent to Eagle sandstone, 375 feet; Claggett shale member, 367 feet. Overlies Frontier formation; underlies Parkman sandstone. Colorado and Montana groups.

J. B. Wilson, 1951, Wyoming Geol. Survey Rept. Inv. 3, p. 3–11. In Powder River basin, includes Shannon sandstone and Sussex sandstone members. Sussex is known primarily in subsurface.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 61–63, pls. 6, 8. Described in Crazy Woman area, Johnson County, Wyo., where it is about 3,670 feet thick, overlies Frontier formation and underlies Parkman sandstone. Includes Shannon sandstone member.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Cody, as mapped in northeastern Wyoming, includes Shannon sandstone member 2,000 feet above base and Sussex sandstone member 2,500 feet above base.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 12 (fig. 3), 15, 16, 17–34, pls. 1, 2. Described in Hardin district, Montana and Wyoming where it includes all units between Mowry shale and Judith River formation. As thus defined, the Cody comprises (ascending) Belle Fourche shale, Greenhorn calcareous shale, Carlile and Niobrara shale (undifferentiated), Telegraph Creek shale, unnamed sandy shale, and Claggett shale members. Colorado and Montana groups. Strata formerly designated Frontier formation are assigned to Belle Fourche member. Following changes in local nomenclature favored by the authors have not been adopted by the Geological Survey: elimination of name "Cody shale"; introduction of name Steele shale to designate a formation containing the three members of the Cody (Telegraph Creek, unnamed member, and Claggett member) that fall within Montana group; promotion to formation rank of each of the three members of the Cody (Belle Fourche, Greenhorn, and Carlile-Niobrara) that are included in the Colorado group.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 46–57, pls. 1, 3. Formation includes sequence of marine sandstone and shale of Late Cretaceous age which in Buffalo-Lake De Smet area overlies conglomeratic sandstone of Frontier formation and underlies Parkman sandstone. Intense folding and faulting at some places and poor exposures at other prevent reliable measurement of thickness of formation in Buffalo-Lake De Smet area; thickness about 3,550 feet near Elgin Creek about 3 miles south of area. Seven members recognized (ascending): unnamed lower shale, Greenhorn calcareous, Carlile shale, Niobrara shale, unnamed sandstone and shale, Shannon sandstone, unnamed upper shale. Colorado and Montana groups.

Named for exposures at Cody, Park County, Wyo.

Coe Group

Middle Silurian (Niagaran): Northwestern Illinois.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 9 (fig. 2), 18. Includes all Niagaran formations in the clastic-free sedimentation belt. As here defined, comprises the Waukesha, Racine, and Port Byron formations as Savage (1926, Geol. Soc. America Bull., v. 37) differentiated them. Interreef rocks of group are distinguished by brownish-gray color, low terrigenous clastic content, absence of chert, and limited facies variations; differ from Bainbridge group in being predominantly dolomite. [Report deals with Niagaran reefs in Illinois and their relation to oil accumulation; much data relative to thickness and distribution of units are based on subsurface studies.]

Typical strata are well exposed in Coe Township, Whiteside County, especially in bluff extending eastward from Cordova and crossing the township in secs. 1–4, T. 19 N., R. 2 E.

Coetas Formation[1]

Pliocene: Western Texas

Original reference: L. T. Patton, 1923, Texas Univ. Bull. 2330, p. 80–86.

Well exposed on Coetas Creek, in eastern part of Potter County.

Coeur d'Alene facies (of Belt Series)

Precambrian: Northern Idaho and western Montana.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1877. Within its northern basin, Belt series is divisible into facies that differ in lithology, stratigraphic sequence, thickness, recorded conditions of deposition, fauna, and flora. Coeur d'Alene facies characterized by sandstones and argillaceous beds throughout the Striped Peak (lower Spokane), by reduction of carbonate rocks in the Siyeh equivalent (lower Wallace), and by tripartite division of Ravalli, which is clastic throughout. Closely related to Purcell.

In Coeur D'Alene region.

†Coeur d'Alene Series[1]

Precambrian (Belt Series): Northeastern Idaho and central western Montana.

Original reference: D. F. MacDonald, 1906, U.S. Geol. Survey Bull. 285, p. 42–43.

Coeur d'Alene Mountains region, Idaho.

Coeymans Limestone (in Helderberg Group)[1]

Coeymans Limestone Member (of Helderberg Limestone)

Lower Devonian: Eastern New York, western Maryland, New Jersey, eastern Pennsylvania, Virginia, and northern West Virginia.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 51–55, 89. Includes Stormville sandstone member at top in Monroe County and Elbow Ridge sandstone member (new) in Franklin County. Thicknesses: 40 feet at Nearpass quarries. New Jersey; 80 feet, Monroe County; 40 to 50 feet, Carbon County; 3 to 10 feet, central and south-central Pennsylvania; 50 to 55 feet near Monterey, Va. Overlies Keyser limestone; underlies New Scotland formation.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 274–276. Member is limited at top by New Scotland limestone or Healing Springs sandstone where present at base of New Scotland. Overlies Keyser limestone member. Thickness 17 to 50 feet.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 32, 67–82. Coeymans formation of this report is a well-defined lithologic unit that apparently can be traced continuously in several belts from Pennsylvania across Maryland into West Virginia and western Virginia. Consists of limestone with sandstone facies in northwestern belts.

Thickness as much as 35 feet. Overlies Keyser limestone; underlies New Scotland limestone. Helderberg group.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 83. Member consists of blue massive crystalline and very fossiliferous limestone, some chert, and sandstone bed near base. Thickness 8 to 13 feet. Underlies New Scotland limestone member; overlies Keyser limestone.

L. V. Rickard, 1955, (abs.) Geol. Soc. America Bull., v. 66, no. 12, pt. 2, p. 1608. Westward from Helderbergs of eastern New York, Coeymans limestone thickens to nearly 100 feet at Cherry Valley. The thickened Coeymans splits into three parts: lower and middle parts grade laterally into Olney, Elmwood, Clark Reservation, and Jamesville members of type Manlius; upper part continues westward to Chittenango Falls. Thus, most of Manlius in central New York is facies of Coeymans of eastern New York. Lower Devonian. Silurian-Devonian boundary appears to be stratigraphically lower than is currently placed.

L. V. Rickard, 1955, New York State Geol. Assoc. 27th Ann Mtg., p. 7. Helderbergian series (revised) consists of nine formations, only five of which are present in central New York: Cobleskill, Rondout, Manlius, Coeymans, and Kalkberg. New Scotland (restricted), Becraft, Alsen, and Port Ewen are not present in central New York. Coeymans limestone of central New York, overlying Jamesville member of Manlius, is entirely younger than Coeymans of eastern New York. Name Deansboro is proposed for this part of the Coeymans. Underlies Kalkberg cherty limestone. Helderbergian series.

L. V. Rickard, 1956, Dissert. Abs., v. 16, no. 1, p. 102. Coeymans formation thickens to nearly 100 feet at Cherry Valley. Slightly further, the Coeymans splits into three parts. Lower part, for which name Dayville limestone is proposed, grades laterally into Olney limestone of Syracuse area. Middle part rapidly changes into the Elmwood, Clark Reservation, and Jamesville members of the Manlius. For upper beds, which continue westward as far as Chittenango Falls, name Deansboro limestone is proposed. Base of Devonian system of New York is apparently not at base of Coeymans limestone of eastern part of state where it had been placed for many years. Present information indicates that underlying Rondout and Cobleskill formations are probably also Devonian in age.

F. G. Lesure, 1957, Virginia Polytechnic Inst. Bull., Engineering Expt. Sta. Ser. 118, p. 20 (table 2), 46–47. In Clifton Forge district, underlies Healing Springs sandstone and overlies Keyser formation. Thickness 12 to 20 feet. Helderberg group. Lower Devonian.

W. A. Oliver, Jr., 1960, Jour. Paleontology, v. 34, no. 1, p. 59–100. Oldest formation in Helderberg group in eastern New York. West of Albany area, higher formations of group (New Scotland and Becraft limestones) and Oriskany group are cut out one by one by pre-Onondaga erosion until, in area between Oriskany Falls and Manlius, the Coeymans limestone is overlain directly by Onondaga limestone, except where local patches of Oriskany intervene. A bioherm or reef facies is present in Coeymans at several places within Oriskany Falls-Manlius area. This facies has not previously been noted in print. Rugose coral fauna described. Fauna strongly suggests Early Devonian age.

Named for exposures at Coeymans, Albany County, N.Y.

Coffee Sand[1] } (in Selma Group)
Coffee Formation }

Upper Cretaceous: Western Tennessee and northeastern Mississippi.

Original reference: J. M. Safford, 1864, Am. Jour. Sci., 2d, v. 37, p. 361, 362–363.

L. W. Stephenson and W. H. Monroe, 1940, Mississippi Geol. Survey Bull. 40, p. 140–147. Crops out in Mississippi in belt about 10 miles wide west of Eutaw formation and east of Selma chalk except in central Lee County where it intertongues and merges with lower part of Selma chalk. Includes Tupelo tongue. Average thickness about 200 feet in Prentiss and Alcorn Counties.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Included in Selma group.

W. S. Parks, 1960, Mississippi Geol. Survey Bull. 87, p. 22, 26, 40–52, pl. 4. Formation described in Prentiss County where it is about 27 feet thick. Disconformably overlies Tombigbee sand member of Eutaw formation; conformably underlies Demopolis formation.

Named for exposures at Coffee Landing, Hardin County, Tenn.

Coffee Creek Formation

Mississippian: Central Oregon.

C. W. Merriam, 1942, Jour. Paleontology, v. 16, no. 3, p. 372. Marine limestones and sandstones 900 to 1,000 feet thick. Disconformably underlies Spotted Ridge formation (new). Lower Carboniferous.

C. W. Merriam and S. A. Berthiaume, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 149–151. Type section shows about 75 feet of strata dipping about 53° NW.; these outcrops probably represent higher part of formation. Thickness difficult to determine due to deformation; estimate is based on width of outcrop in anticlines on Coffee Creek and north of Coyote Butte, where in latter locality strata are nearly vertical. Base of formation nowhere exposed.

Type section: In sec. 30, T. 18 S., R. 25 E., one-fourth mile east of spring at Mills sheep camp, southeast of Paulina, Crook County. Named for exposures on Coffee Creek which enters Grindstone Creek south of Wade Butte.

Coffee Mill Hammock Marl Member (of Fort Thompson Formation)

Coffee Mill Hammock Marl[1]

Pleistocene: Southern Florida.

Original reference: E. H. Sellards, 1919, Florida Geol. Survey 12th Ann. Rept. p. 73, 74.

G. C. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 73. Name Coffee Mill Hammock marl revived and given member status in Fort Thompson formation. Member is contemporaneous with upper part of Anastasia formation.

J. R. DuBar, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 136 (fig. 4), 145, 146–147. At type locality and at most river localities, Coffee Mill Hammock marl conformably overlies a fresh-water marl or limestone and is, in turn, overlain unconformably by sands of Pamlico formation or by Lake Flirt marls. Thickness at type locality 3 to 6 feet; in some areas, marl does not form actual bed but is preserved as fillings in solution holes and pockets in limestone below.

In this report, all Fort Thompson deposits that underlie Coffee Mill Hammock marl have been grouped together and named Okaldakoochee marl.

Named for exposures at Goodno's Landing, Fort Thompson, and at Coffee Mill Hammock, De Soto County, 12 miles above Labelle. [Referred to as type locality by some authors.]

Coffeen Limestone Member (of Bond Formation)

Pennsylvanian: Central and southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), 71, pl. 1. Name applied to limestone overlying Witt coal member (new). Thickness as much as 20 inches. Stratigraphically below Millersville limestone member. Name credited to H. J. Gluskoter (unpub. ms.). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NW¼SE¼ sec. 7, T. 8 N., R. 2 W., Montgomery County. Named from village of Coffeen, 5 miles southwest of type exposure.

Coffee Ranch[1]

Pliocene: Western Texas.

Original reference: R. D. Reed, 1933, Geology of California, p. 303.

In Hemphill County.

Coffeyville Formation[1] (in Skiatook Group)

Pennsylvanian (Missouri Series): Southeastern Kansas and northeastern and central Oklahoma.

Original reference: F. C. Schrader and Erasmus Haworth, 1905, U.S. Geol. Survey Bull. 260, p. 448.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guide Book 11th Ann. Field Conf., p. 39, 40. Name Coffeyville restricted to strata between top of Checkerboard limestone below and base of (Hogshooter) Dennis formation above. Included in Skiatook group.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 33–39. Consists of seven zones, four of shale and three of sandstone. Thickness 175 to 235 feet. In all but a few localities, the Winterset (upper) member of Hogshooter is the capping bed, but locally the Coffeyville is succeeded by the Canville, Stark, or Lost City members.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 57–60. In Tulsa County, consists of five zones, two of sandstone, and three of shale. Thickness as much as 440 feet.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 63–70. Coffeyville, in Seminole County, is made up of six lithologic units. De Nay limestone member, a shale, a middle (No. 1) sandstone, a shale, an upper (No. 2) sandstone, and a shale. Maximum thickness 260 feet. Overlies Seminole formation; underlies Nellie Bly formation. Interval designated by Morgan (1924, Oklahoma Bur. Geology Bull. 2) as Francis formation is herein described under headings of Coffeyville and Nellie Bly.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 14, 17–20, pls. 1, 2. Described in Creek County where it conformably overlies Checkerboard limestone and conformably underlies Hogshooter formation. Shiatook group. Thickness 375 to 500 feet. Name Coffeyville not in current use in Kansas.

Named for exposures at Coffeyville, Montgomery County, Kans. Mapped as far south as Okfuskee County, Okla.

†Coffeyville Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: E. Haworth and J. Bennett, 1908, Kansas Acad. Sci. Trans., v. 21, pt. 1, p. 74.

Named for Coffeyville, Montgomery County.

Coffin Butte Volcanics

Eocene, middle: Northwestern Oregon.

I. S. Allison, 1953, Oregon Dept. Geology and Mineral Industries Bull. 37, p. 3–5. Proposed for a complex of basaltic flows, breccias, tuffs, and tuffaceous shales that make up eastern edge of Coast Range in northwest part of quadrangle. Thickness on Coffin Butte about 600 feet; formation crops out across a belt at least 2 and perhaps 3½ miles wide in direction perpendicular to regional strike; if moderate dip persists, uniformly thickness may be 5,000 to 10,000 feet, or at steeper angles, 10,000 to 15,000 feet. Stratigraphic relationship not clear; regional contact inferred to be a high-angle fault contact, probably a thrust. Correlation with Siletz River volcanic series (Snavely and Baldwin, 1948) to northwest appears reasonabe; because the two are disconnected and are not yet known to be exactly contemporaneous, separate names are retained.

Type locality: Coffin Butte, Albany quadrangle, where volcanics are exposed in several large cuts and quarries. Volcanics extend southwesterly from Coffin Butte on northeast through Vineyard Hill and other ridges north and northwest of Corvallis to vicinity of Philomath and Wren, and westward across northern Benton County.

Coffman Conglomerate Member (of Maroon Formation)[1]

Coffman Conglomerate Member (of Minturn Formation)

Coffman Conglomerate Member (of Weber ? Formation)

Pennsylvanian: Central Colorado.

Original reference: D. B. Gould, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 7, p. 971–1009.

C. A. Arnold, 1941, Michigan Univ. Mus. Paleont. Contr., v. 6, no. 4, p. 60. Contains *Calamites* and *Lepidodendron* which tentatively date bed as Pennsylvanian.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 35 (table 7), 39 (table 10), 40–41, 150, pl. 8. Reallocated to member status in unit termed Weber(?) formation. Overlies middle unnamed shale and limestone member; underlies Chubb siltstone member of Maroon formation. Arkosic conglomerate with interbedded sandstone and shale. Thickness 20 to 1,000 feet. Pennsylvanian.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 811, 814, 820, 836. Reallocated to member status in Minturn formation. Basal unit of formation; underlies Chubb siltstone member.

Type section: In unnamed valley in sec. 24, T. 13 S., R. 77 W., about 2 miles north of Coffman Park, Chaffee and Park Counties.

Coggon Limestone[1] Member (of Wapsipincon Formation)

Middle Devonian: Central eastern Iowa.

Original reference: W. H. Norton, 1894, Iowa Acad. Sci. Proc., v. 1, pt. 4, p. 23, 24.

E. H. Scobey, 1940, Jour. Sed. Petrology, v. 10, no. 1, p. 38–40. Lowermost member of Wapsipinicon. Underlies Otis limestone member; overlies Gower formation. Bertam member of Norton (1895) is here considered a local phase of the Coggan. Age shown on chart as Middle Devonian(?).

Type exposures at Coggon, Linn County, at crossing of Buffalo River by Illinois Central Railway.

Cohansey Sand[1]

Miocene(?) and Pliocene(?): New Jersey.

Original reference: H. B. Kummel and G. N. Knapp, 1904, New Jersey Geol. Survey, v. 6, p. 137.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 4 (fig. 2), 61. Thickness 100 to 250 feet. Chiefly quartz sand with local beds of clay and gravel. Overlies Kirkwood formation; underlies Beacon Hill gravel. Chart shows age as middle Miocene.

D. S. Malkin, 1953, Jour. Paleontology, v. 27, no. 6, p. 766, 771. Classified as upper Miocene but is probably a diachronic facies including beds of middle and late Miocene.

J. P. Owens and J. P. Minard, 1960, Johns Hopkins Univ. Studies in Geology No. 18, p. 27. Age of Cohansey sand is problematical. May be late Miocene or younger, perhaps Pliocene.

Named for exposures along Cohansey Creek, Cumberland County.

Coharie Formation (in Columbia Group)[1]

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

Original reference: L. W. Stephenson, 1912, North Carolina Geol. Survey, v. 3, p. 273–277.

G. E. Siple, 1957, Carolina Geol. Soc. Guidebook for South Carolina Coastal Plain Field Trip, Nov. 16–17, table 1, following p. 1. In sequence listed for South Carolina and Middle Atlantic Coast, Coharie occurs below Sunderland and above Hazelhurst.

Named for Great Coharie Creek, a tributary of Black River in North Carolina.

Cohn Coal Member (of Mattoon Formation)

Pennsylvanian: Eastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 41, 51 (table 1), 83, pl. 1. Name applied to coal member in lower part of formation. Stratigraphically below Merom sandstone member. Thickness 2 inches. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼ sec. 1, T. 11 N., R. 12 W., Clark County. Exposure is 2 miles southeast of Cohn, now called Livingston.

Cohn cyclothem (in McLeansboro Group)

Cohn cyclothem (in Mattoon Formation)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 18–19; J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). Occurs above the LaSalle cyclothem and below the Bogota cyclothem (new). Total thickness 7½ inches.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In lower part of Mattoon formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification retained but is independent of rock-stratigraphic classification.

Type locality: About 2 miles northwest of Cohn in NE¼ sec. 1, T. 11 N., R. 12 W., Clark County.

Cohutta Conglomerate[1]

Lower Cambrian(?): Northwestern Georgia.

Original reference: C. W. Hayes, 1891, Geol. Soc. America Bull., v. 3, pl. 3, p. 4.

A. S. Furcron and K. H. Teague, 1947, Georgia Geol. Survey Bull. 53, p. 19. Several zones of pebbles and cobbles occur in Ocoee series of Murray County; they are unusual and represent an inconspicuous part of the series. Perusal of Hayes unpublished report of Dalton quadrangle indicates that these local conglomerates represent his "Cohutta conglomerate," but it is questionable if they have sufficient stratigraphic continuity to deserve formational recognition.

Probably named for Cohutta Mountain, Gilmer and Fannin Counties.

Cohutta Schist

Precambrian; Northwestern Georgia.

A. S. Furcron, K. H. Teague, and J. L. Calver, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1195. Thrust faults supplementary to the mapped overthrust, which separates the eastern crystalline block from known Paleozoic sediments of the Great Valley, bring up a Precambrian biotite augen gneiss, Fort Mountain gneiss, intruded by granite upon which Ocoee rocks are unconformable. Talc deposits and associated schists, Cohutta schist, occur in upthrust block of Fort Mountain gneiss but not in Ocoee series.

A. S. Furcron and K. H. Teague, 1947, Georgia Geol. Survey Bull. 53, p. 6–9, pl. 1. Cohutta schist, believed to be oldest formation in area (Murray County), represents remnants of a metasedimentary formation which is included in Fort Mountain gneiss. Intruded by Corbin granite. Derivation of name given.

Named from Cohutta Mountain one of southernmost conspicuous elevations of Great Smoky Mountains. Formation contains talc deposits in Fort and Cohutta Mountain districts.

Coker Formation (in Tuscaloosa Group)

Upper Cretaceous: West-central Alabama.

L. C. Conant and W. H. Monroe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 37. Consists of apparently nonmarine beds above the Eoline formation (new) and below the Gordo formation (new). Thickness 150 to 250 feet. Examples of varied lithology are (1) basal strongly cross-bedded channel sand, upper part locally finely laminated and containing macerated plant remains; (2) massive carbonaceous and varicolored clay containing nodules of granular siderite; locally clay occupies a channel which in places may extend to base of formation; (3) interbedded purple and gray mottled clay and highly crossbedded fine-grained micaceous yellow sand containing brecciated clay; (4) bentonite bed near base in one area; and (5) local occurrences of chert gravel which resemble gravel of the Gordo. The gravel is tentatively retained in the Coker because of the strikingly abrupt and widespread appearance of gravel in the Gordo; further investigations may indicate advisability of redefining contact so as to include all of the gravel and coarse sand in the Gordo.

W. H. Monroe, L. C. Conant, and D. H. Eargle, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 197–200. At designated type locality, both top and bottom contacts are well exposed.

C. W. Drennen, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 3, p. 536. Stratigraphically extended below to include all outcropping pre-Gordo sediments of the Tuscaloosa group except sediments designated Vick formation (Conant, 1946), which may be Tuscaloosa in age. Coker thus consists regionally of a lower Eoline member and an upper unnamed member.

Type locality: Section on road from Spring Hill School in secs. 21 and 22, T. 21 S., R. 11 W., 3 miles south of Coker, Tuscaloosa County.

Coki Point megabreccia lithofacies (of Tutu Formation)

Upper Cretaceous: Virgin Islands.

T. W. Donnelley, 1960, Dissert. Abs., v. 20, no. 7, p. 2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. An intercalated slumped mass of andesite and limestone blocks, which have neritic fauna of corals, gastropods, pelecypods (including rudistid *Caprinuloidea*), and echinoids, and is of apparent Cenomanian age.

Report discusses geology of St. Thomas and St. John Islands.

Colbert cyclothem

Lower Pennsylvanian: Southern Illinois.

H. R. Wanless, 1956, Illinois Geol. Survey Circ. 217, p. 5, pl. 1. Substituted for former cyclothem name, Davis, because latter name is preempted. Underlies Dekoven cyclothem; overlies Stonefort cyclothem. Includes Davis coal bed which name is retained.

Type section: One-half mile west of Colbert School in the SE¼SW¼ sec. 23, T. 10 S., R. 7 E., Saline County.

Colbert Porphyry[1]

Precambrian: Central southern Oklahoma.

Original reference: C. A. Reeds, 1926, Am. Mus. Nat. History Jour., v. 26, p. 470–474, map.

R. E. Denison, 1959, (abs.) Oklahoma Acad. Sci. Proc. 1958, p. 124. Incidental mention in discussion of rhyolites of Oklahoma.

Occurs in Arbuckle Mountains. Derivation of name not stated.

Colchester Coal Member (of Carbondale Formation)

Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 36, 46 (table 1), 62, 67, pl. 1. Basal member of Carbondale formation (redefined). Occurs below Shawneetown coal member (new) or below Francis Creek shale member. In western and northern area, replaces LaSalle (No. 2) coal so that name LaSalle can be retained for LaSalle limestone. Thickness about 2 feet. Coal named by Worthen (1868, *in* Geology and Paleontology, v. 3, Illinois Geol. Survey). Presentation of new rock-stratigraphic classisfication of Pennsylvanian strata in Illinois.

Type locality: Secs. 12 and 13, T. 5 N., R. 4 W., Colchester quadrangle, McDonough County.

†Colchester Formation[1]

Lower Cambrian: Northwestern Vermont.

Original reference: A. Keith, 1923, Am. Jour. Sci., 5th, v. 5, p. 110, 129.

Named for good exposures 1 to 2 miles north of Colchester village in town of Colchester, Chittenden County.

Cold Spring horizon[1]

Miocene or Pliocene: Eastern Texas.

Original reference: E. T. Dumble, 1915, Geol. Soc. America Bull., v. 26, p. 468, 470, 472, 473, 476.

West of Trinity River, San Jacinto County.

Cold Springs Granite[1]

Precambrian: Southwestern Oklahoma.

Original reference: C. H. Taylor, 1915, Oklahoma Geol. Survey Bull. 20.

Cold Springs area, Kiowa County.

Coldwater Formation

Coldwater Sandstone Member (of Tejon Formation)[1]

Eocene: Southern California.

Original reference: W. S. W. Kew, 1924, U.S. Geol. Survey Bull. 753.

W. C. Putnam, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 697 (fig. 3). Shown on columnar section of Ventura region as underlying Sespe formation and overlying Cozy Dell member. Thickness 1,500 to 2,000 feet. Member of Tejon formation.

F. R. Kelley, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 1, p. 6. Sediments locally known as Coldwater in Santa Barbara County redefined as Sacate formation.

T. L. Bailey, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1924. Referred to as Coldwater formation. Type locality stated.

Type locality: On Coldwater Creek, a westerly branch of lower Sespe Creek, 5½ miles northwest of Fillmore, Ventura County.

Coldwater Shale[1]

Coldwater Formation

Mississippian: Southern Michigan.

Original reference: A. C. Lane as reported by M. E. Wadsworth, 1893, Michigan Geol. Survey Rept. 1891 and 1892, p. 66.

V. B. Monnett, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 4, p. 630 (fig. 1), 636–651. Formation consists of the gray and gray-blue shales underlying Marshall formation in all parts of Southern Peninsula of Michigan. At most places, overlies black shale of Sunbury formation, but locally, especially in western and southwestern Michigan, it directly overlies Ellsworth green shale or Antrim black shale. Character of Coldwater sediments changes from east to west. Western facies consists of 565 to 1,080 feet of shale, in many places calcareous, with some interbedded dolomites; eastern facies characterized by siltstones and fine-grained sandstones interbedded with the shales; red shales and siltstones common in upper sediments of facies. A redbed at base of formation is only zone that can be recognized in both western and eastern facies. Kinderhook. Subsurface data.

Named for exposures on Coldwater River, in Branch and Hinsdale Counties.

Colebrooke Schist[1]

Pre-Cretaceous: Southwestern Oregon.

Original reference: J. S. Diller, 1903, U.S. Geol. Survey Geol. Atlas, Folio 89.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2784. In Port Orford area, basal beds of Days Creek formation (new) containing *Buchia crassicollis* Keyserling rest generally on Riddle formation, but locally overlap onto Colebrooke schist. Contact with Colebrooke schist is masked by slumping of the schist and is inferred from mapping. Contact of Days Creek with Galice formation and Colebrooke schist is interpreted as angular unconformity.

W. P. Irwin, 1960, California Div. Mines Bull. 179, p. 30. Colebrooke schist is considered correlative with South Fork Mountain schist (new). Colebrooke schist occurs in Port Orford quadrangle, Oregon, principally in two areas surrounded by sandstone and shales of Myrtle formation of Diller that ranges from late Late Jurassic to Cretaceous in age. Diller (1903, U.S. Geol. Survey Geol. Atlas, Folio 89) described the Colebrooke as sericite schists, phyllites, and slates that were derived from sedimentary rocks, and he considered it equivalent to schists along South Fork of Trinity River. On geologic map of Oregon, Wells (1955, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-38) discarded name Colebrooke schist and showed those areas of rocks as having been derived from Rogue formation, which consists of lava flows, tuff, agglomerate, flow breccia, mostly of dacitic and andesitic composition, and of Jurassic age. He described rocks formerly named Colebrooke schist as banded crystalline rocks made up of dark hornblende-rich layers and light siliceous layers. Colebrooke schist is overlain unconformably by Myrtle formation of Diller.

Colebrooke Butte and surrounding country in Port Orford quadrangle are mapped as in this formation.

†Cole Camp Sandstone (in Van Buren Formation)[1]

Lower Ordovician (Beekmantown): Central Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 364–369.

Named for outcrops on Cole Camp Creek, Cole County.

Cole Canyon Dolomite[1]

Middle Cambrian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 5 (fig. 2), 8. Described in East Tintic Mountains, where it conformably overlies Bluebird dolomite and concordantly underlies Opex formation. As mapped by U.S. Geological Survey, it is 830 to about 900 feet thick and includes lower dolomite member of Opex dolomite as defined by Loughlin (1930). Lower 600 feet consists of alternating beds of light-gray laminated dolomite resembling Dagmar limestone and massive dusky-blue-gray commonly "twiggy" dolomite resembling the Bluebird; light-gray beds weathering creamy white are 1 foot or so to about 25 feet thick, but one bed is 60 to 90 feet thick; dark-colored beds are 10 to 30 feet thick. Zone that was formerly considered part of Opex is 125 to about 300 feet thick, consists chiefly of dusky blue-gray dolomite with some "twiggy" beds, some beds of mottled crossbedded dusky-blue-gray dolomite, and few, if any, interlayered white beds. Base of Cole Canyon is placed at base of lowest creamy-white laminated dolomite, and top is placed at base of sequence of thin-bedded limestones and dolomites of Opex. Middle Cambrian.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 14 (fig. 3), 21–22, geol. map. In Stansbury Mountains, 320 to 370 feet thick; underlies Opex formation and overlies Bluebird dolomite. Mapped as originally used by Loughlin.

J. K. Rigby, 1959, Utah Geol. Soc. Guidebook 14, p. 14 (table 1), 25–26, 29 (fig. 9), pl. 1. In southern Oquirrh Mountains, about 200 feet thick; underlies Opex dolomite and overlies Bluebird dolomite. Cole Canyon dolomite of type area as originally defined by Loughlin (1919) probably correlates well with the rocks here included in the formation.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 52–53, pls. 1, 17. Described in Sheeprock Mountains where it is about 899 feet thick and consists of nearly equal parts of dolomite and limestone. Overlies Marjum formation; in fault contact with Opex formation.

Named for exposures along west slope of Cole Canyon, which extends north from Eureka Gulch three-fourths mile west of Eureka, Tintic district, Juab County.

Coleman Bed, Clay, or Limestone (in Admiral Formation)[1]

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept. pt. 1, p. 421, 424.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 96. Name Jim Ned shale proposed to replace Drake's Coleman bed; name Coleman preoccupied.

Named for Coleman, Coleman County.

†Coleman division[1]

Permian: Central Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxvii, pl. 3.

Named for Coleman County and for occurrence near town of Coleman.

Coleman Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: F. and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. H_3, p. 286, 292.

Probably named for exposures at or near Coleman, Somerset County.

Coleman Junction Limestone Member (of Putnam Formation)[1]

Coleman Junction Formation (in Putnam Group)

Permian (Wolfcamp Series): Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Putnam group. Underlies Hords Creek formation in Admiral group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as member of Putnam formation. Consists of two to four subdivisions of limestone that are separated by thin shales. Thickness 8 to 25 feet. Overlies Santa Anna Branch shale member; underlies Lost Creek shale member of Admiral formation.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 271–272, pl. 11. Extended into Brazos River valley where it is 4 to 15 feet thick. Overlies Santa Anna Branch shale member. In area of present report, the Admiral formation cannot easily be distinguished from underlying Putnam formation or overlying Belle Plains formation; therefore; the Coleman Junction limestone member of the Putnam, the four members of the Admiral formation, and Jim Ned shale member of Belle Plains formation have been mapped as one unit.

Named for Coleman Junction, Coleman County.

Coleraine Shale or Formation

Upper Cretaceous (Colorado Series): Minnesota.

C. R. Stauffer *in* C. R. Stauffer and G. A. Thiel, 1933, Minnesota Geol. Survey Bull. 23, p. 18. Name appears in geologic column of Minnesota as Coleraine (Pierre) shale. Stratigraphically above Dakota sandstone.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 8 (geol. column), 104–105. Discussed as Coleraine formation in Colorado series. Mostly iron-bearing shales but includes conglomerates and sandstones; some shales fossiliferous. Thickness in Itasca County about 32 feet and here consists mostly of conglomerates and iron ore and occurs above Precambrian Biwabik formation; in Stearns County, about 73 feet and here consists mostly of argillaceous shales (data taken from well). Geologic column shows Coleraine (Benton) formation stratigraphically above Dakota formation. Underlies drift, sands, gravels, and boulder beds.

H. R. Bergquist, 1944, Jour. Paleontology, v. 18, no. 1, p. 7, 8–9. Coleraine formation as used in this report includes all Cretaceous conglomerates of Mesabi Range as well as the shales. Probably more than 100 feet thick. Shales occur only in upper part of Cretaceous sediments in western part of area; conglomerate exposures seem to be more extensive and are only representative of formation in eastern part. Section in Canisteo-Walker pits near Coleraine was considered as type, but subsequent mining has removed much of the Cretaceous.

Well exposed in opencut mines at Coleraine and Calumet, Itasca County.

Coles Brook Limestone[1]

Precambrian: Western Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 27–28.

Well exposed 1 mile northwest of Bancroft Station, in Middlefield, where Boston and Albany Railroad cuts off a loop of Westfield River and Coles Brook enters this loop from north.

Colesburg dolomite[1]

Silurian (Niagaran): Central eastern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 149, 150.

Charles Schuchert, 1943, Stratigraphy of the Eastern and Central United States: New York, John Wiley and Sons, p. 697. Listed with abandoned names. Lower Silurian (Alexandrian).

Named for Colesburg, Delaware County.

Colestin Formation

Eocene, upper: Southwestern Oregon.

F. G. Wells, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–89. Stratified water-deposited tuffs and conglomerates derived from volcanic rocks; contains a few interbedded flows. Varies in thickness and in some places is absent; maximum thickness is 2,000 feet in valley of Cottonwood Creek. Transitional with overlying Roxy formation (new); gradationally overlies Umpqua formation.

Well exposed both in natural cliffs and road cuts along former and present U.S. Highway 99, in valley of Cottonwood Creek, Jackson County. Name derived from Colestin Springs.

Colfax Formation[1]

Upper Jurassic: Northern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, charts facing p. 217, 221.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 975. Upper part of Mariposa slate was separated by Smith (1910), as Colfax formation, apparently because it contained ammonite *Perisphinctes colfaxi* Hyatt, which he and Crickmay (1931, Am. Philos. Soc. Proc., v. 70, no. 1) considered Portlandian. Such an age assignment needs checking by additional fossil collecting because type of *P. colfaxi* is reported to be lost and original description and illustrations are not adequate for generic determination.

Occurs in Gold Belt region, northern Sierra Nevada.

Colgate Member (of Fox Hills Sandstone)[1]

Upper Cretaceous: Eastern Montana, southwestern North Dakota, northwestern South Dakota, and western Wyoming.

Original reference: W. R. Calvert, 1912, U.S. Geol. Survey Bull. 471, p. 189–198.

A. J. Collier and M. M. Knechtel, 1939, U.S. Geol. Survey Bull. 905, p. 10, pls. 1, 3. In McCone County, Mont., member is about 80 feet thick. Upper member of Fox Hills; overlies an unnamed basal member; underlies Hell Creek member of Lance formation. Footnote (page 10) states that since present report was written the Hell Creek has been raised to rank of formation in the official classification of the Geological Survey.

C. P. Bromley, 1955, U.S. Atomic Energy Comm. [Pub.] RME–1066 (rev.), p. 7 (fig. 2). Mapped in Niobrara County, Wyo.

R. E. Stevenson, 1957, Areal geology of McIntosh quadrangle (1:62,500): South Dakota Geol. Survey. Geographically extended into McIntosh quadrangle, South Dakota, where it caps several small buttes and rims the lower Hump Creek and White Shirt Creek valleys. Varies from gray calcareous or siliceous graywacke sandstone to a buff or white subgraywacke sand. Characterized by clay seams, carbonaceous streaks, clay pebble layers, cross-lamination, oscillation ripple marks, wood fragments, and *Inoceramus*. Thickness not more than 15 feet. Overlies Bullhead member.

Typically developed between Colgate Station and Glendive, Dawson County, Mont.

†Colgate Member (of Skaneateles Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 219, 221.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180. Name abandoned. Replaced by Chenango sandstone member.

Named from exposures on campus of Colgate University.

Colina Limestone (in Naco Group)

Permian: Southeastern Arizona and southwestern New Mexico.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 1, 23–25, 38–41; James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 42–44, pl. 5. Most characteristic lithologic feature is dominance of dense limestone that appears very dark gray to almost black on fresh fracture. It seems safe to conclude that in central Cochise County any continuous such limestone that is as much as 25 feet thick is part of the Colina limestone. Generally weathers dark gray but locally weathers light gray or almost white. Contains abundance of gastropods, especially of a very large *Omphalotrochus*. Thickness at type section 633 feet. Lower boundary of Colina taken arbitrarily at highest of the dolomite beds that weather to an orange-red surface. Overlies Earp formation (new); underlies Epitaph dolomite (new) with gradational contact and underlies Scherrer formation with sharp contact. Age considered as Wolfcamp (Permian?) and Leonard(?).

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 38–39, tables 1, 2, pl. 1. Crops out on western slope of main ridge of Peloncillo Mountains and north and east of Cienega Peak, N. Mex. Incomplete section north of Cienega Peak 504 feet thick. Mapped as Permian.

Type section: On west slope of Colina Ridge (from which named), in Tombstone Hills, 4,000 feet south of Horquilla Peak, Ariz.

Collao Member (of Robles Formation)

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., and Lynn Glover 3d, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I–319. A succession of rocks consisting of siltstone and fine-grained sandstone, lenses of conglomerate, a unit of limestone, and unit of lapilli tuff characterized by reddish-brown color. A thin andesite lava is interstratified with the siltstone northeast of Vertedero. Estimated thickness about 200 meters. Overlies Las Tetas lava member; underlies Cariblanco formation (new).

Type section: Begins on Highway 1 at point 1.1 kilometers S. 75° E. of intersection of Highway 1 and Highway 162 and extends northwestward along banks of Highway 1 and Highway 162 and up north side of ridge south of Highway 162 to top of ridge above prominent outcrops of limestone, Cayey quadrangle.

Collazo Shale[1]

Tertiary: Puerto Rico.

Original reference: C. A. Reeds, 1916, New York Acad. Sci. Annals, v. 26, p. 437 [1915].

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 321. Name apparently synonymous with San Sebastián shales. Name not now used.

College Hill Limestone[1]

Upper Ordovician: Central Tennessee.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 276.

Well exposed on College Hill, Nashville, Davidson County.

College Point Stage[1]

Pleistocene: Southeastern New York.

Original reference: J. B. Woodworth, 1901, New York State Mus. Bull. 48, p. 621–663.

Nassau County and Borough of Queens, Long Island.

Collier Flows

Recent: Southwestern Oregon.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, p. 62. Discussion of volcanoes of Three Sisters region. Name is applied to flows from Collier Cone.

Collier Cone is between North Sister Mountain and Yapoah Cone.

Collier Limestone Member (of Collier Formation)

Cambrian(?): Southeastern Oklahoma.

W. D. Pitt, 1955, Oklahoma Geol. Survey Circ. 34, p. 16–18, pl. 1. Consists largely of interbedded fissile shale and dark-bluish-gray finely crystalline limestone at top of Collier formation. Thickness 50 to 150 feet. Contact with Crystal Mountain sandstone above is generally traceable in mapped area (Ouachita Mountains) and it is recommended that unit be considered a separate formation if it also proves traceable in type area of Collier shale in Arkansas.

Prominent outcrops occur along west side of ridge in NW¼ sec. 27, T. 5 S., R. 23 E., McCurtain County.

Collier Shale[1]

Collier Formation

Cambrian: Southwestern Arkansas and southeastern Oklahoma.

Original references: A. H. Purdue, 1909, Geol. Soc. America Bull., v. 19, no. 557; 1909, Slates of Arkansas: Arkansas Geol. Survey, p. 30, 31.

W. D. Pitt, 1955, Oklahoma Geol. Survey Circ. 34, p. 15–18, pl. 1. Described in Ouachita Mountains of Oklahoma as Collier shale formation. Overlies Lukfata sandstone (new). Lower part consists of variegated normally brown fissile shale which locally contains numerous laminations of siltstone, sandstone, and silty limestone about 180 feet thick. Upper part is a limestone varying in thickness from 50 to 150 feet and termed the Collier limestone, upper member of Collier shale. Limestone underlies Crystal Mountain sandstone and forms prominent outcrops in mapped area. It is recommended that the limestone be considered a separate formation if it also proves traceable in the type area of the Collier shale. Cambrian(?).

Named for Collier Creek, Montgomery County, Ark.

Collierstown Limestone

Middle Ordovician: Western Virginia.

B. N. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 85 (fig. 7), 90, 104. Predominantly shell limestone and medium-grained calcarenite with intercalated buff argillaceous limestones and buff shales, some of which are probably metabentonites. Thickness commonly less than 75 feet; at type locality 58 feet. Overlies Edinburg formation (new); underlies Martinsburg formation.

Type locality: North of State Highway 251, about 2 miles east of Collierstown (8 miles west of Lexington), Rockbridge County, Va. In Shenandoah Valley, occurs in westernmost belt of Middle Ordovician limestone, along foot of Little North Mountain; thicker and more widespread in middle and western belts of James River district.

Collings Ranch Conglomerate

Pennsylvanian (Virgil Series): Southern Oklahoma.

W. E. Ham, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2035–2045. Thick-bedded limestone boulder conglomerate; nonfossiliferous. Thickness about 2,000 feet. Complete section nowhere exposed because of erosion at top and faulting locally at base. Rests with pronounced angular unconformity upon steeply dipping rocks of Arbuckle anticline. Exposed beneath conglomerate are West Spring Creek formation of Arbuckle group; Joins, Oil Creek, McLish, Tulip Creek, and Bromide formations of Simpson group; and Viola limestone. Underlies Vanoss limestone.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped with rocks of Virgil age.

Type area: Sec. 25, T. 1 S., R. 1 E. Named from Ellsworth Collings Ranch [Murray County], near U.S. Highway 77.

Collingston Conglomerate

See Collinston Conglomerate.

Collingsworth Gypsum Member (of Blaine Formation)[1]

Permian: Southwestern Oklahoma and central northern Texas.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 356, footnote.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 17 (fig. 3), 23–24, pl. 1. Described in Carter area, Oklahoma, as massive white gypsum 22 feet thick, underlain by an unnamed gray dolomite 1 foot thick and overlain by an unnamed red shale unit generally 15 feet thick. Occurs below the Mangum dolomite member and above the Cedartop gypsum member.

Named from Collingsworth County, Tex., just west of Greer County, Okla., where the gypsum is well exposed.

Collingwood Formation[1]

Upper Ordovician: Ontario, Canada, and surface and subsurface in Michigan and subsurface in Wisconsin.

Original reference: P. E. Raymond, 1912, Canada Geol. Survey Summ. Rept. 1911, p. 354.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 250 (fig. 8), 283–284. Consists of alternating beds of limestone and shale. In type section, overlain by Blue Mountain shale. Thickness 26 feet at type section. Underlies Gloucester shale. Believed to persist from Collingwood to shore of Lake Ontario. In Jefferson County, N.Y., there are many exposures of contact of Deer River black shale on upper Cobourg limestone along Sandy Creek; former is considered to be of Collingwood age. In Oneida County, Holland Patent shale, upper member of Utica formation, is, in its lower part, of Collingwood age. In present report, included in Trenton group, above Cobourg limestone and below Gloucester shale. Mohawkian series. Middle Ordovician.

A. E. Wilson, 1946, Canada Geol. Survey Mem. 241, p. 28. Eastview and Billings formations of Ottawa-St. Lawrence Lowland represent continuous sequence of beds. Together they make up former Collingwood and Gloucester of the basin. They are defined by lithology, the Eastview being limestone interbedded with shale and the Billings all shale. Terms Collingwood and Gloucester are retained as time terms.

G. V. Cohee, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 33. In subsurface of southeastern Michigan, the Upper Ordovician rocks are about 750 feet thick and are divided into three units: Utica, Lorraine, and Queenston shales. The dark-gray to black Utica is 150 to 200 feet thick. It thins northward, and, in Northern Peninsula, Bruce Peninsula, and on Manitoulin and adjacent islands, it is represented by Collingwood formation. Collingwood was identified in one well in Door County, Wis., but could not be identified farther south. In southwestern Ontario, beds of Upper Ordovician age crop out locally on Manitoulin and adjacent islands, along shore of Georgian Bay, and southeastward in Ontario where they are divided into (ascending) Collingwood, Gloucester, Dundas, Meaford, and Queenston formations. The Collingwood, 30 to 40 feet thick, was formerly assigned to Utica because of its lithologic similarity to the Utica of New York. According to Sproule (1936, Canada Geol. Survey Mem. 202), the Collingwood rests on Trenton limestone. At north edge of Sheguindah, Manitoulin Island, Ontario, the Collingwood rests on the Precambrian. Overlying Collingwood are dark-brown to black shales which in earlier reports were referred to as Gloucester formation. In recent reports, the Canada Geological Survey includes both Collingwood and Gloucester in Billings formation which is 100 to 270 feet thick in southwestern Ontario. Kay (1937) correlates the Collingwood and Gloucester with the Trenton of New York.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 46). Shown on correlation chart in Northern Peninsula of Michigan. Occurs above Stewartville limestone. Trentonian.

B. A. Liberty, 1954, Michigan Geol. Soc. [Guidebook] Ann. Field Trip June 19–20, p. 7–17. Discussion of Ordovician of Manitoulin Island. Collingwood has been used in Ontario nomenclature as time term. In present report, strata of this unit comprise rock unit to which name Collingwood is applied. Unit is about 22 feet thick, but thickness varies over short distances. Where it lies, under transgressive overlap conditions, on apices of Precambrian quartzite ridges, thickness may be only a few inches. Contact with overlying Sheguindah formation.

Well exposed at Collingwood, Ontario.

Collingwoodian (Collingwood) Stage or Substage

Middle Ordovician (Trentonian) : Eastern North America.

G. M. Kay, 1937, Geol. Soc. America Proc. 1936, p. 82. Collingwood and Gloucester are stages in latest Trenton.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30–31. Trenton group was divided by Raymond (1916, Harvard Coll. Mus. Comp. Zoology Bull., v. 56) into succession of faunal zones that he thought time-stratigraphic but which he called formations. In time, these became stages: Rocklandian, Kirkfieldian, Shorehamian, Denmarkian, Cobourgian, Collingwoodian, and Gloucesterian of Kay (1937; 1943; 1948). The Cobourg-Collingwood-Gloucester seems to be time-equivalent to Utica group, but name Utica is strongly associated with black shale facies. Hence, term Pictonian stage is applied to uppermost Trentonian.

Name derived from Collingwood, Ontario, Canada, for which Collingwood formation was named.

Collins Hill Formation

Middle or Upper Ordovician(?) : Central Connecticut.

John Rodgers, R. M. Gates, and J. L. Rosenfeld, 1959, Connecticut Geol. and Nat. History Survey Bull. 84, p. 19, 20, 21, 22, 24, fig. 3. Rusty-weathering graphitic garnetiferous two-mica schist, commonly containing sillimanite and (or) kyanite. Commonly has basal conglomerate gneiss associated with overlying well-banded unit consisting of fine-grained quartzite with manganiferous garnet and cummingtonite and of laminated amphibolite with relatively large garnets locally. Persistent amphibolite and calc-silicate layers in lower part. Interbedded calc-silicate and fine-grained biotite-muscovite-gneiss abundant to west in upper part. Unconformably overlain by Bolton group from Great Hill north. Rests unconformably on Middletown formation and on granitic rocks (Glastonbury and Maromas gneisses), which have discordant, possibly intrusive, contacts with Middletown but fail to transgress into the Collins Hill along many miles of mutual contact. Unit has been included in Bolton schist by many recent workers. Middle Ordovician(?).

G. P. Eaton and J. L. Rosenfeld, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 2, p. 170 (fig. 1), 171 (table 1). Unconformably underlies Great Hill formation (new). Unconformably overlies Glastonbury and Maromas formations. Previous workers with the exception of Percival (1842, Report on the Geology of the State of Connecticut: New Haven) grouped the sequence of rocks from Collins Hill schist through Camp Jenkins schist as a single formation, and believed it to be intruded by Glastonbury, Maromas, and Haddom gneisses. Present work shows that these rocks represent four distinct formations, with unconformity separating Collins Hill from the others.

Named from Collins Hill in central Portland, Middlesex County.

Collinston Conglomerate (in Salt Lake Group)

Miocene, upper, and Pliocene, lower: Northeastern Utah.

Neal Smith, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 73, 75 (fig. 2). Collingston conglomerate consists of about 2,500 feet of boulder and cobble conglomerate with a white calcareous and tuffaceous(?) matrix. Unconformably underlies West Spring formation (new); in fault contact with upper Paleozoic rocks in Cache

Valley; at north end of Wellsville Mountain overlies Wasatch group. Name credited to J. S. Williams (unpub. ms.).

R. D. Adamson, C. T. Hardy, and J. S. Williams, 1955, Utah Geol. Soc. Guidebook 10, p. 1 (table 2), 2 (table 1), 4–6, 9 (fig. 3). Collinston conglomerate intertongues with Cache Valley formation herein considered to include unit formerly termed West Spring formation. Thickness about 1,500 feet. Poorly exposed.

Type area: Northern end of Wellsville Mountains, Cache County.

Collinsville cyclothem (in McLeansboro Group)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 11; J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, (table 1). In sequence, occurs below Shoal Creek cyclothem and above Trivoli cyclothem. Thickness about 42 feet.

Named from exposures along Canteen Creek, near Collinsville, Madison County.

Collinsville Granite Gneiss[1]

Pre-Triassic: North-central Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 105–107 and map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as a gneiss. Pre-Triassic.

Well-exposed at Collinsville, Hartford County.

Collinsville Limestone[1] (in McLeansboro Formation)

Collinsville Limestone (in McLeansboro Group)

Pennsylvanian: Southwestern Illinois.

Original reference: A. H. Worthen, 1873, Illinois Geol. Survey, v. 5, p. 315.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2). Shown on correlation chart as formation in McLeansboro group; stratigraphically below Shoal Creek limestone and above Trivoli limestone.

First described near Collinsville, Madison County.

Collores Limestone[1]

Upper Cretaceous: Puerto Rico.

Original reference: C. R. Fettke, 1924, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 2, p. 149.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47, 48 (table 4). Thickness 300 feet. Lower part equivalent to La Muda limestone and upper part equivalent to Trujillo Alto limestone of Fajardo district.

Named for typical development in barrio of Collores de Piedras, Humacoa district.

Collores Member (of Augustinillo Formation)

Eocene, middle: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 94–96; 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 84–85. Consists largely of thin-bedded hard buff- to creamy-colored argillaceous limestones with some layers of reddish-brown calcareous mudstones and siltstones. Layers and lenses of Coamo Springs limestone not uncommon. Thickness about 6,800 feet. To the west, interfingers with Monserrate member (new) of Augustinillo. Overlies and interfingers with Guayo member of Naranjo formation (both new). Middle Eocene.

Type locality: At Camino Collores bed of the Río Guayo near bend. Crops out in northwest part of Ponce quadrangle. Named for Poblado Collores, 1.4 kilometers southwest of Cerro Augustinillo.

Colma Formation

Pleistocene, upper: Central western California.

J. Schlocker, M. G. Bonilla, and D. H. Radbruch, 1958, U.S. Geol. Survey Misc. Geol. Inv. Map I–272. Sequence of unconsolidated sand deposits that are similar in appearance and physical properties and occupy approximately the same stratigraphic position; they may not all be contemporaneous. Fine- to medium-grained sand with minor amounts of clay; evenly spaced horizontal or nearly horizontal bedding or continuous inclined bedding; rarely massive; in places includes clay beds 6 inches to 5 feet thick. On Angel Island, thickness 5 to 50 feet; at north end of Ocean Beach, at least 40 feet thick and appears to thicken and dip gently southward under dune sand of Golden Gate Park.

Occurs on Angel Island and at several points on San Francisco Peninsula. Name derived from town of Colma, 4½ miles south of San Francisco North quadrangle near center of area in which formation is best developed.

Colmar shales[1]

Upper Ordovician: Iowa.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 55, p. 217–222.

Colmena Tuff or Formation (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13 (fig. 3), 17, 19–20. Named proposed for beds of rhyolitic tuff-conglomerate. Described as light brown, interbedded with variegated tuff principal colors of which are brown, pink, and red; near mouth of Capote Creek, contains beds of tuffaceous nonmarine limestone 4 to 10 feet thick; near Loma Plata, contains beds of silty claystone and a layer of glassy flow-rock. Deposited on rough topography of Gill breccia (new), consequently is missing in some places, though its thickness exceeds 450 feet in others. In most places, overlain by Buckshot ignimbrite (new); where Buckshot is absent, the Colmena is overlain by Chambers tuff (new).

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Quad. Map 23. Described in Van Horn Mountains area, where it is 190 to 310 feet thick. Rests on Chispa Summit formation in the northern Sierra Vieja; on Cox limestone, Finlay limestone, Benevides formation, Eagle Mountains sandstone, Buda limestone, and Chispa Summit formation in isolated outcrops along eastern margin of Van Horns northward to Hammer Handle Canyon; on Eagle Mountains sandstone, Buda limestone, and Chispa Summit formation directly west of Willoughby Wind gap along the western margin; and on Cox sandstone at southeastern and southwestern flanks of Colquitt syncline.

Type locality: Four miles due east of Candelaria, Rim Rock country, Presidio County. Name derived from Colmena Canyon.

†Colob Sandstone[1]

Jurassic(?): Southwestern Utah.

Original reference: E. Huntington and J. W. Goldthwait, 1903, Jour. Geology, v. 11, p. 46–63.

Name probably derived from Colob Creek on Colob Plateau (spelled Kolob on some maps), Washington County.

Colony Creek Shale Member (of Caddo Creek Formation)

Colony Creek Shale

Upper Pennsylvanian: West-central Texas.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 20. Proposed that name Colony Creek shale be given to beds between Ranger and Home Creek limestones and that name Hog Creek shale, misapplied by Drake and others, be dropped.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 51. Shown on columnar section, Brown and Coleman Counties, as Colony Creek shale member of Caddo Creek formation. Underlies Home Creek limestone member; overlies Ranger limestone member of Brad formation. Thickness about 20 feet. Mainly gray shale; locally contains thin beds of sandstone; not present in areas of reefs of Ranger limestone.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 67. Because of confusion that has resulted from miscorrelations of Home Creek limestone and misapplication of term "Hog Creek," adoption of Cheney's term Colony Creek shale is herein recommended for shale member below Home Creek limestone member. Unit is gray shale that contains conspicuous fine-grained thinly to thickly and irregularly bedded sandstone near top. In southern part of area, Colony Creek is about 25 feet thick; locally, member is absent and Home Creek limestone member is contiguous with limestone members of Brad formation. Average thickness of member about 60 feet in north-central Brown County.

Type area: Branching headwaters of Colony Creek in vicinity of Colony School, 4 miles west of Ranger in northeastern Eastland County.

Colony School Conglomerate (in Strawn Group)

Pennsylvanian: Central Texas.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 85. Basal conglomerate that occurs at contact of the Strawn and Marble Falls limestone. Made up of well-rounded pebbles ranging from size of large sand grains to 1 inch in diameter and set in matrix of reddish brown sand. Thickness about 1 foot.

Located 0.15 mile east of Colony School, San Saba County.

†Colorado Conglomerate[1]

Pennsylvanian: Pennsylvania.

Original reference: J. F. Carll, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 38–40, 46.

In hilltops at Colorado, Warren County.

Colorado Group,[1] Shale,[1] or Formation[1]

Lower and Upper Cretaceous: Colorado, Idaho, Iowa, Kansas, Montana, Nebraska, New Mexico, North Dakota, South Dakota, and Wyoming.

Original reference: F. V. Hayden, 1876, U.S. Geol. and Geog. Survey Terr. 8th Ann. Rept., p. 45.

Eugene Stebinger, 1919, U.S. Geol. Survey Bull. 691–E, p. 154 (table), 157–164. Colorado shale, in Birch Creek-Sun River area, Montana, overlies Kootenai formation and underlies Virgelle sandstone of Montana group. Thickness about 1,800 feet. Includes Blackleaf sandy member (new) at base.

C. F. Bowen, 1919, U.S. Geol. Survey Bull. 691–F, p. 189 (table), 195–197. Colorado shale, in Musselshell Valley, Mont., is about 2,200 feet thick, overlies Kootenai formation and underlies Eagle sandstone of Montana group. Includes Big Elk sandstone member (new). Upper Cretaceous.

A. J. Collier and S. H. Cathcart, 1922, U.S. Geol. Survey Bull. 736–F, p. 172 (table). Group, in Little Rocky Mountain region, Montana, comprises (ascending) Thermopolis, Mowry, and Warm Creek (new) shales. Overlies Kootenai formation; underlies Eagle sandstone of Montana group. Upper Cretaceous.

S. G. Lasky, 1936, U.S. Geol. Survey Bull. 870, p. 23–26, pl. 1. Colorado formation, in Bayard area, New Mexico, rests upon Beartooth quartzite with apparent disconformity. Upper limit is either present land surface or an older erosion surface buried under volcanic rocks of region, so that full thickness is not present. Separable into two mappable units: an upper sandstone member and a lower shale member. Thickness 320 to 450 feet.

C. H. Rankin, 1944, New Mexico Bur. Mines Mineral Resources Bull. 20, p. 5–26. Colorado group, in this report [northern New Mexico], comprises (ascending) Graneros shale, Greenhorn limestone, Carlile shale, and Niobrara formation. Overlies Dakota(?) sandstone. Top of Niobrara not recognized with certainty. In previous reports on Cretaceous rocks of New Mexico, writers have followed nomenclature established by Cross (1901 [1899], U.S. Geol. Survey Geol. Atlas, Folio 60) and have described all rocks between Dakota sandstone and Mesaverde coal measures as Mancos shale. Present study reveals that all divisions of Colorado group (Mancos shale) as described in southern Colorado, except Fort Hayes limestone and Apishapa shale, can be recognized in northern New Mexico.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. As shown on correlation chart, Colorado group comprises Mowry shale and Warm Creek shale. Overlies Thermopolis shale; underlies Telegraph Creek formation. Upper Cretaceous.

W. A. Cobban and J. B. Reeside, Jr., 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1892–1893. Uncrushed ammonites have been collected from Mowry shale and equivalent rocks at several localities in Colorado, Wyoming, and Montana. These collections show that impressions and crushed internal molds of ammonites previously assigned to Upper Cretaceous genera *Metoicoceras*, *Acompsoceras*, and *Neocardioceras* (as *Kanabiceros*) belong to Lower Cretaceous genera *Gastroplites* and *Neogastroplites*. Largest collection of *Gastroplites* from United States consists of more than 1,400 uncrushed specimens from a single concretion in the Colorado shale near Harlowton, Mont. In northwestern Colorado, it [*Gastroplites*] occurs in middle of Mowry member of Mancos shale; in Wyoming, known from Aspen shale along western edge of Green River basin, and from Mowry on western margin of Bighorn basin, eastern flank of Black Hills. In Montana, genus occurs in Mowry shale in Pryor Mountain and in Colorado shale on Middle Dome, southeast of Harlowton. Largest collection of *Neogastroplites*, containing 800 specimens, is from concretions in Mowry shale near Cody, Wyo. Genus occurs in Aspen shale in Green River basin, and in Mowry shale in Wind River basin and along eastern flank of Bighorn Mountains, in Thermopolis shale in Bighorn Mountains, in Mowry shale near Pryor Mountains, and in Colorado shale in Livingston area, in Judith Basin, and near Great Falls.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2170–2198. Colorado shale of central and northwestern Montana and equivalent rocks on north flank of Black Hills are dominantly dark-gray marine shales. It has been customary to treat Colorado shale as a single formation, with one or two members. Detailed studies show that Colorado shale is divisible into many lithologic units that can be correlated with standard section in Black Hills. Formation in Black Hills that are equivalent to Colorado shale are (ascending) Fall River sandstone, Skull Creek shale, Newcastle sandstone, Mowry shale, Belle Fourche shale, Greenhorn formation, Carlile shale, and Niobrara formation.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10b. Reference sequence for Upper Cretaceous, Western Interior, North America, shows Colorado group comprises (ascending) Belle Fourche shale, Greenhorn limestone, Carlile shale, and Niobrara formation. Occurs above Lower Cretaceous Mowry shale and below Telegraph Creek formation.

W. A. Cobban, 1953, U.S. Geol. Survey Prof. Paper 243–D, p. 45–54. Colorado shale, near Mosby, Mont., is 1,930 feet thick, and includes Mosby sandstone member 743 feet below top. Cenomanian ammonite fauna.

R. B. Johnson and G. J. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map 146. Colorado group, in Huerfano County, Colo., comprises (ascending) Graneros shale, Greenhorn limestone, Carlile shale, Niobrara formation. Overlies Dakota sandstone; underlies Pierre shale of Montana group.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Colorado group mapped in northwestern Oklahoma. Exposed part equivalent to Greenhorn limestone and Graneros shale.

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 24, 34 (fig. 3). Colorado shale, in Lake Valley quadrangle, overlies Sarten formation. Upper Cretaceous (Benton age).

J. P. Greis, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 449–450. In Williston basin, Colorado group, which formerly included all of Graneros formation around Black Hills, has now been restricted to Upper Cretaceous and includes Belle Fourche shale, together with overlying Greenhorn, Carlile, and Niobrara formations. Term Belle Fourche shale now used in the basin wherever underlying Mowry can be differentiated, except in Little Rocky Mountains where name lower Warm Creek shale is applied.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. As mapped, Colorado group comprises (ascending) Belle Fourche shale, Greenhorn formation, Carlile shale, and Niobrara formation. Colorado shale includes equivalents of Fall River, Skull Creek, Newcastle, Mowry, Belle Fourche, Greenhorn, Carlile, and Niobrara formations and locally Telegraph Creek formation.

P. W. Richards, 1957, U.S. Geol. Survey Bull. 1021–L, p. 414–417. Colorado shale described in area east and southeast of Livingston, Mont. Name

Colorado shale has been used in parts of Montana for thick predominantly shale sequence that lies above Kootenai formation, and, in most places, below Virgelle sandstone or Eagle sandstone; locally underlies Telegraph Creek sandstone. Colorado shale, which includes sandstone, particularly in west-central Montana, contains both Lower and Upper Cretaceous strata; its vertical range, therefore, does not coincide with Upper Cretaceous Colorado group. Cobban (1951) compared Colorado shale of central Montana with equivalent rocks of Black Hills. From his report, it is evident that some formational names of Black Hills can be used as members of Colorado shale in central Montana. Some formation names in use in Bighorn basin, Wyoming, are not common to Black Hills and central Montana areas but have been used around Pryor Mountains and Bighorn Mountains. In present report, Colorado shale has been divided into 10 units, and these are compared, where possible, with Black Hills and central Montana or Bighorn basin formations. Unit 7, about 100 feet thick, is herein named Boulder River sandstone member.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 26–28, pls. 1, 2. Formation described in southern Elkhorn Mountains, Mont. Subdivided into three map units: lower black shale, 215 to 325 feet thick; sand and siliceous mudstone, 610 to 920 feet thick; and upper black shale unit, 265 to 390 feet. Overlies Kootenai formation, probably with slight erosional unconformity. Grades upward into sequence of feldspathic sandstone and tuff beds herein named Slim Sam formation. Where Slim Sam formation is absent, the Colorado underlies Elkhorn Mountains volcanics (new). Colorado formation as herein used includes beds of both Early and Late Cretaceous age.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2786–2796. Colorado group revised on Sweetgrass arch, Montana. Rocks formerly assigned to Colorado shale are divided into lower unit, Blackleaf formation with four named members, and an upper unit, Marias River formation (new) with four named members. Overlies Kootenai formation; underlies Telegraph Creek formation. Early Late Cretaceous.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Group comprises (ascending) Graneros shale, Greenhorn limestone, Carlile shale, and Niobrara chalk. Overlies Dakota formation; underlies Pierre shale of Montana group.

J. B. Reeside, Jr., and W. A. Cobban, 1960, U.S. Geol. Survey Prof. Paper 355, p. 8–11. Colorado shale, in Teigen area, central Montana, includes Arrow Creek member (new) which underlies Mowry member.

Mineral Research and Devel. Dept. Rept. 12, pt. 2, p. 33–38, 41–42. In southwestern Montana includes Geyser bentonite bed (new) and Greenhorn bentonite bed (new). Great Northern Railway Co. Mineral Resources Research and Development Department. 1960, Great Northern Railway Co.

Colorado shale, in Winnett-Mosby area, Montana, includes following members: Skull Creek Shale, Mowry Shale, Belle Fourche Shale, Mosby Sandstone, Carlile Shale, and Niobrara Shale. In area of Bearpaw Mountains, includes following members: Fall River Sandstone, Skull Creek Shale, Newcastle Sandstone, Mowry Shale, Belle Fourche Shale, Greenhorn Limestone, Carlile Shale, Niobrara Shale, and Telegraph Creek.

Named for exposures along eastern base of Colorado or Front Range, Colo.

†Colorado Series[1]

Upper Cretaceous: Colorado.

Original reference: G. H. Ashley, 1923, Eng. and Min. Jour.-Press, v. 115, no. 25, p. 1106–1108.

Colpitts Group

Middle Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 247–255. Name applied to sequence of limestone, sandstone, and shale which crops out only between Snow Mountain and Suplee in western end of pre-Tertiary area. Less than 500 feet thick in most places; may exceed 800 feet of Freeman Creek. Comprises two formations: Weberg below and Warm Springs above (both new). In type area, Colpitts lies across narrow southwestern part of eastward-trending Mowich anticline. Along western part of anticline, Colpitts lies upon Mowich group and below Hyde formation (new) without appreciable angular discordance. Where Mowich group is absent, as along Warm Springs Creek and in Camp Creek valley, Colpitts lies upon Triassic and Paleozoic beds with high-angle discordance.

Type area: On east side of Warm Springs Creek valley in secs. 19, 20, 29, and 30, T. 18 S., R. 26 E., Crook County. Named for Willard Colpitts Ranch on upper Warm Springs Creek.

Colquitt Formation[1]

Upper Cretaceous (Gulf Series): Southwestern Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 271, 441, 452.

Type locality: On Colquitt Ranch below Chispa Summit, western Jeff Davis County.

Colter Formation

Miocene, middle: Northwestern Wyoming.

J. D. Love, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1899, 1904–1907, fig. 1. Sequence of gray, green, and brown water-laid pyroclastic rock, sandstone, and claystone. Characterized throughout by abundance of mafic volcanic material, both in lithic fragments and in tuff. Thickness in vicinity of type section 7,000 feet, exclusive of basal part of formation which is so distorted by basalt intrusions that character and thickness of the rocks have not been adequately determined. Unconformably overlain by rocks of middle Pliocene age and unconformably overlies all older rocks. On East Fork of Pilgrim Creek, unconformably overlies Pinyon conglomerate of Paleocene age.

Type section: On Pilgrim Creek about 5 miles northeast of Colter Bay, on Jackson Lake, from which the formation takes its name. Section extends eastward from east face of Pilgrim Peak across Pilgrim Creek for distance of about 1 mile, and lies in secs. 20, 21, 22, 27, 28, and 29, T. 46 N., R. 114 W., unsurveyed, Teton County.

Colton Formation

Eocene: Central Utah.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 120–121, pls. 2, 3. Consists of reddish-pink sandstones and shales. Varies greatly in thickness; about 3,400 feet near town of Green River, Utah; near Soldier Summit, disappears into Green River formation. Believed to be equivalent in age to part of Green River formation with which it interfingers on its upper boundary. May correlate with unit herein referred to as Uinta(?). Exposed in extreme southwestern part of Uinta basin. Forms base of Roan Cliffs from Price River to Roan Plateau in Colorado.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205-D, p. 122, 139. Formal proposal of name. Gray, pepper-and-salt sandstone, greenish-buff sandstone, and siltstone that commonly weathers golden brown, and shale ranging from deep red to variegated and gray. Thickness 1,500 feet at Kyune, 2 miles east of Colton, where it underlies Green River formation; overlies Flagstaff formation; both contacts clearly defined; westward, grades laterally into beds of Green River type. In some areas, overlies North Horn formation. Unit has been referred to as an upper member of Wasatch formation.

C. L. Gazin, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 135. Spieker's Colton formation may be westward continuation, in Utah, of (upper portion?) De Beque formation.

Named for exposures in hills north of Colton at head of Price Canyon, Utah County.

†Columbia Granite[1]

Precambrian: Central Virginia.

Original reference: A. I. Jonas, 1928, Virginia Geol. Survey prelim. ed. geol. map of Virginia.

G. W. Stose and A. J .Stose, 1948, Am. Jour. Sci., v. 246, no. 7, p. 405–406. In Arvonia slate district, granite near Carys Brook had been termed Columbia granite by Jonas (1932). However, it differs from Columbia granite in texture and composition. The contact of the two granites is an overthrust fault on which the Columbia granite and associated rocks rode northwestward over the granite at Carys Brook and the Peters Creek formation.

Named for occurrence at Columbia, on Fluvanna-Goochland County line, north of James River.

Columbia Group[1]

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

Original references: W. J. McGee, 1886, Rept. Health Office District of Columbia for 1885, p. 20; 1886, Am. Jour. Sci., 3d v. 31, p. 473.

C. J. Cederstrom, 1957, U.S. Geol. Survey Water-Supply Paper 1361, p. 31–32. Quaternary system in Virginia Coastal Plain is represented chiefly by deposits of sand and clay that mantle the older formations to a height of about 270 feet above sea level. They are collectively called Columbia group. Units included are Brandywine, Coharie, Sunderland, Wicomico, Penholoway, Talbot, and Pamlico formations.

Other units included in group are: Bridgeton, Cape May, and Pensauken Formations.

Named for District of Columbia.

Columbia Ford Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Derivation of name not stated.

Columbian Marble[1]

Columbian Marble Member (of Boardman Formation)

Columbian Marble Member (of Shelburne Formation)

Lower Ordovician: West-central Vermont.

G. W. Bain, 1931, Am. Jour. Sci., 5th ser., v. 22, no. 132, p. 508, 509, 510, 511. In list of formations, Columbian deposit (marble) overlies Intermediate limestone and underlies West Blue deposit. Ordovician (Chazy).

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 25–26, 27. Rank reduced to member at top of Boardman formation (new). Generally white-weathering white and blue-gray marble; occasional threads of green silicates wind irregularly through the white marble. Maximum thickness 600 feet. Underlies Bascom formation; overlies Intermediate dolomite member of Boardman. Lower Ordovician.

J. B. Thompson, Jr., 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 75 (table 1). In Clarendon-Dorset area, is uppermost member of Shelburne formation. Thickness 200 to 250 feet. Overlies Intermediate dolomite member.

Occurs in Addison and Rutland Counties.

Columbiana Formation

Middle Ordovician (Mohawkian): Central Alabama.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 57, chart 1 (facing p. 130). Black graptolitic shale. Thickness a few inches to 325 feet. Disconformably underlies Frog Mountain sandstone; overlies Pratt Ferry formation (new). Name attributed to B. N. Cooper and G. A. Cooper.

Type section: Just west of Simpson Springs 2½ miles northwest of Calera, Shelby County. Named from Columbiana 15-minute quadrangle in which east side of Calera is located.

Columbia River Basalt[1]

Miocene and Pliocene(?): Oregon, Washington, and northern Idaho.

Original reference: I. C. Russell, 1893, U.S. Geol. Survey Bull. 108, p. 20–22, map.

R. C. Treasher, 1942, Geologic map of Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. In Portland area, underlies Troutdale formation.

W. C. Warren and Hans Norbisrath, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 220 (table 1), 233–234. Overlies Scappoose formation (new) in upper Nehalem River valley. Thickness as much as 1,000 feet.

E. M. Baldwin, 1950, Oregon Country Geol. Soc. News Letter, v. 16, no. 11, p. 93. Underlies Molalla formation (new).

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 3–5, pls. 1, 2. Discussion of lower Columbia River valley, Oregon and Washington. Term Columbia River basalt used in present report to apply only to the Miocene flows as restricted by Merriam (1901, California Univ. Pub., Bull. Geology Dept., v. 2, no. 9) and Lindgren (1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2). Basalt is interbedded with Astoria formation of middle Miocene age. Total thickness of basalt flows as much as 1,000 feet in Portland area; 2,000 feet in Columbia River Gorge. Columbia River basalts in vicinity of Salem and Stayton, Oreg., were named Stayton lavas by Thayer (1939) because Columbia River basalt had not then been traced into that area. Now seems advisable to drop name Stayton lavas in preference to Columbia River basalt. In Columbia River Gorge, the basalt lies on erosional surface cut in sediments of Eagle Creek formation (lower Miocene). In central Oregon, the Columbia River basalt lies on erosion surface developed on John Day formation of late Oligocene or early Miocene. Middle and upper Miocene.

H. H. Waldron and L. M. Gard, Jr., 1954, U.S. Geol. Survey Geol. Quad. Map GQ-48. Mapped in Hay quadrangle, Washington, where it may be as much as 5,000 feet thick.

T. P. Thayer, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Maps MF-49 and MF-50. Mapped in Aldrich Mountain and Mount Vernon quadrangles, Oregon, where it underlies Mascall formation and unconformably overlies unnamed volcanic conglomerate. Middle Miocene.

Howel Williams, 1957, A geologic map of the Bend quadrangle, Oregon, and a reconnaissance geologic map of the central portion of the High Cascade Mountains (1:125,000): Oregon Dept. Geology and Mineral Industries. Southern edge of Columbia River basalt plateau passes through northeast corner of Bend quadrangle, where thin, scattered outliers rest conformably or with only slight disconformity on John Day formation. Maximum thickness 300 feet. Middle Miocene.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 15-16. In early geologic studies, such names as Columbia lava and Columbia River basalt were applied to mass of dominantly basaltic rocks in region drained by Columbia River. As originally defined (Russell, 1893), this unit included Snake River basalt. Current usage in Idaho restricts term to unit that consists mainly of flows of basaltic and kindred composition that extend interruptedly from vicinity of South Mountain, Owhyee County, through western Idaho at least as far north as Kootenai County. Maximum thickness of lava in the unit as thus limited probably more than 3,000 feet. Flows are associated with sedimentary beds which in some places reach thicknesses in excess of 1,000 feet. These sedimentary beds include strata that in southern Idaho have been referred to Payette formation (Miocene and Pliocene?) and others farther north that contain flora typical of Latah formation (middle or upper Miocene). Younger than Challis volcanics.

J. W. Hosterman and others, 1960, U.S. Geol. Survey Bull. 1091, p. 7, pls. 3, 4, 5. Although Columbia River basalt may range in age from Miocene to Pliocene, it is considered to be product of many closely related eruptions and is classed as one formation. Thickness ranges from several feet at flanks of steptoes and embayments along eastern margin of Columbia Plateau to more than 1 mile near center where subsidence is greatest. In general vicinity of clay deposits in Washington and Idaho, the Latah formation is interbedded with Columbia River basalt.

Columbia River valley.

Columbus Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 21; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 196. Cherokee group is divided into 15 cyclic formational units. The Columbus, third in the sequence (ascending), occurs above the Neutral and below the Bluejacket. Average thickness 30 feet. Includes Columbus coal. [For complete sequence see Cherokee group.]

Type locality and derivation of name not given. Cherokee outcrop in Kansas covers an area of about 1,000 square miles and includes parts of Labette, Bourbon, Crawford, and Cherokee Counties.

Columbus Limestone[1]

Middle Devonian: Central and north-central Ohio, and Ontario, Canada.

Original reference: W. W. Mather, 1859, Rept. State House Artesian Well at Columbus, Ohio, p. 25.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 128–129, chart facing p. 108. Comprises Bellepoint, Marblehead, and Venice members. Thickness 80 to 125 feet. Overlies Lucas formation; underlies Delaware formation; in some area, Marcellus formation is present between the Columbus and Delaware.

J. W. Wells, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 280–282. In Logan County, includes East Liberty bone bed near top.

Wilber Stout and R. A. Schoenlaub, 1945, Ohio Geol. Survey, 4th ser., Bull. 46, p. 21. In southwestern Delaware County, comprises Bellepoint, Eversole, and Klondike members.

J. W. Wells, 1947, Ohio Jour. Sci., v. 47, no. 3, p. 119–126. Discussion of paleoecological analysis of Devonian rocks of Columbus region. Chart shows that Columbus formation, 105 feet thick, comprises (ascending) Bellepoint, Eversole, and Delhi (Klondike) members. Underlies Delaware formation; overlies Silurian (Monroe formation).

R. C. Moore, 1948, Geol. Soc. America Bull., v. 59, no. 4, p. 309 (fig. 2). Columnar section shows that Columbus formation, 105 feet thick, comprises (ascending) Bellepoint, Eversole, and Delhi members.

G. M. Ehlers, E. C. Stumm, and R. V. Kesling, 1951, Devonian rocks of southeastern Michigan and northwestern Ohio: Ann Arbor, Mich., Edwards Brothers, Inc., p. 9. Prosser (1903, Jour. Geology, v. 11) believed that beds in northwestern Ohio which he called Columbus were same beds that Mather (1859) and Newberry (1873) described by that name from quarries in vicinity of Columbus. As now recognized, Columbus limestone is absent in northwestern Ohio, and the younger Dundee limestone was the one to which Prosser referred.

G. A. Stewart, 1955, Ohio Jour. Sci., v. 55, no. 3, p. 147–179. Discussion of age relations of middle Devonian limestones in Ohio. In central Ohio, the Columbus comprises (ascending) Bellepoint, Eversole(?), and Delhi members; in north-central Ohio comprises (ascending) Bellepoint, Marblehead, and Venice members. Maximum thickness 105 feet. Underlies Delaware limestone. Overlies Bass Island (Silurian) series. Gives review of terminology.

C. R. Stauffer, 1957, Jour. Geology, v. 65, no. 4, p. 376–383. Overlies Detroit River group in northern Ohio and in Ontario. Was correlated with Onondaga limestone of New York by James Hall and others. True Onondaga is now known to occur beneath horizon of Detroit River group in Mackinac Straits region of Michigan and throughout most of its occurrence in Ontario. Eastward along line of major axis of Lake Erie, the Detroit River group pinches out, and Columbus limestone lies directly on Onondaga limestone in Norfolk and Haldimand Counties, Ont.

Named for exposures at Columbus, Ohio.

†Columbus Marl[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72, 84–86.

Named for Columbus, Hempstead County.

Columbus Quartzite[1]

Pennsylvanian: Central northern Utah.

Original reference: L. A. Palmer, 1906, Mines and Min., v. 26, p. 438–439.

Probably named for Columbus Consolidated Mine.

†Columbus Sand[1]

Upper Cretaceous: New Jersey.

Original reference: G. N. Knapp, as reported by R. D. Salisbury, 1899, New Jersey Geol. Survey Ann. Rept. State Geologist, 1898, p. 35, 36.

Named for occurrence at Columbus, Burlington County.

†Columbus Sandstone (in Cherokee Shale)[1]

Pennsylvanian: Southeastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 106.

Named for outcrops along Brush Creek, east of Columbus, Cherokee County.

†Colville Granite or Granodiorite[1]

Cretaceous: Northeastern Washington.

Original reference: J. T. Pardee, 1918, U.S. Geol. Survey Bull. 677.

W. H. Irwin, 1938, Geol. Soc. America Bull., v. 49, no. 11, p. 1628, 1637–1638. Coarse-grained granite, exposed at Grand Coulee Dam and southward in Grand Coulee, represents a marginal facies of Colville batholith and should be known as Colville granite. Cut by vertical dikes composed of a fine-grained slightly porphyritic granite.

Name derived from Colville batholith in Colville Indian Reservation.

Colville Group

Colville Series[1]

Upper Cretaceous: Northern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 248.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160 (table 1), 164–167, figs. 2, 3. Redefined as Colville group, basal member of which is distinctive unit consisting of black shale with limestone interbeds. Lithologically, group includes clastic rocks ranging from shale to conglomerate, limestone, low-grade oil shale, and coal. Total thickness about 5,200 feet. Divided into nonmarine Prince Creek formation (new) and marine Schrader Bluff formation (new), which are approximately of equivalent age. Formations intertongue and are not always readily distinguishable. Unconformably overlies Nanushuk group; underlies Sagavanirktok (new) and Gubik formations. Type exposures cited. Now evident from faunal analyses that rocks are all of Upper Cretaceous age.

C. L. Whittington, 1956, *in* George Gryc and others, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 244–246, figs. 2, 3, 4. Nonmarine Tuluvak tongue of Prince Creek formation, recognizable in nearly all pertinent surface and subsurface sections, is wedge dividing marine rocks of group into two major formations: Seabee formation below and Schrader Bluff formation above.

R. M. Chapman and E. G. Sable, 1960, U.S. Geol. Survey Prof. Paper 303–C, p. 69–70, 126, pls. 8, 9, 18. Prince Creek formation is only representative of group in Utukok-Corwin region.

Type exposures: Along Colville River from approximately the junction with Prince Creek east and north to 70th parallel. Well exposed in river cuts; on Colville River, cuts form bluffs that are nearly continuous from Umiat north to Ocean Point. Extend west to about longitude of Ikpikpuk River and east to Canning River.

Colville Quartzite[1]

Mississippian(?): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 68, map.

K. P. McLaughlin and Merton E. Simons, 1951, Jour. Paleontology, v. 24, no. 4, p. 515 (table 1). Mississippian(?) age determination made on basis of fossils collected in limestone occurring in Colville quartzite.

Mapped near Colville, Stevens County.

Colvin Limestone Member (of Washington Formation)[1]

Colvin Run Limestone[1] (in Washington Group)

Permian: Southwestern Pennsylvania and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 23, 39.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 135, 147, 177, 485. Colvin Run limestone in Washington group described in Klondike district, Fayette County, where it is composed of light- and dark-gray massive limestone beds separated by light calcareous shales. Ranges in thickness from 0 to 12 feet; averages 5 feet. Lies 75 feet above Waynesburg coal and 20 to 25 feet below Woodglen limestone (new).

Named for exposures along Colvin Run, Greene County, Pa.

Colwood Formation[1]

Recent: Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington Univ. Pub. Geology, v. 2.

San Juan Islands.

Comanche Series[1]

Lower and Upper Cretaceous: Gulf Coastal Plain.

Original reference: R. T. Hill, 1887, Am. Jour. Sci., 3d ser., v. 33, p. 298.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. In terms of European equivalents, Comanche series includes Gargasian, Albian, and Lower Cenomanian stages. Succeeds Coahuila series of Mexico. Includes (ascending) Trinity, Fredericksburg, and Washita groups.

Named for Comanche County, Tex.

Comanche Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 385.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec. [Guidebook] Spring Mtg., p. 72. About 300 feet thick, divided into three parts by 8 to 10 feet of hard massive sandstone associated with 10 to 15 feet of shaly friable sandstone and clay. Underlies Antelope Creek bed; overlies Wilbarker Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Comanche Creek, Mills County.

†Comanche Peak Group[1]

Lower Cretaceous (Comanche Series): Central Texas.

Original reference: B. F. Shumard, 1860, St. Louis Acad. Sci. Trans., v. 1, p. 583, 584.

Named for Comanche Peak, Hood County.

Comanche Peak Limestone (in Fredericksburg Group)[1]

Lower Cretaceous (Comanche Series): Eastern Texas.

Original reference: R. T. Hill, 1889, Texas Geol. Survey Bull. 4, p. xiv, xvii-xix.

W. O. George, 1952, U.S. Geol. Survey Water-Supply Paper 1138, p. 14 (table 7), 22. Described in Comal County where it is composed chiefly of hard gray-white massive limestone; beds of marl containing *Exogyra texana* Roemer present locally. Thickness 20 to 55 feet; average 40 feet. Conformably overlies Walnut clay, similarity of beds to Walnut clay make it difficult to define lower limits of Comanche Peak. Conformably overlies Edwards limestone.

F. E. Lozo and others, 1959, Texas Univ. Bur. Econ. Geology Pub. 5905, 226 p. Discussed in symposium on Edwards limestone. Hill (1891, Geol. Soc. America Bull., v. 2) emended Comanche Peak formation to exclude most of older strata (Walnut and Glen Rose) originally included in Comanche Peak group by Shumard (1860). White chalky limestone of type section is 100 feet thick and is essentially same facies represented by Goodland limestones from Tarrant County north. Comanche Peak thins to south as Edwards limestone thickens and, in Colorado Valley area, encroaches on underlying marly limestones of Walnut strata. Fredericksburg group.

Named for Comanche Peak, Hood County.

†Combahee Shale[1]

Miocene, lower and upper: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South

Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 18, name only, not defined; 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 435, 464, 465.

Probably named for exposures on Combahee River, Colleton County.

Combe Sandstone[1]

Upper Jurassic: Northern California.

Original reference: C. H. Crickmay, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 81.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–175, table 2. Shown on paleotectonic map as overlying Foreman formation.

Type locality: Combe Canyon, north of Mount Jura.

Combined Metals Member (of Pioche Shale)

Combined Metals Bed[1]

Lower Cambrian: Southeastern Nevada.

Original reference: L. G. Westgate and Adolph Knopf, 1932, U.S. Geol. Survey Prof. Paper 171, p. 54–55.

A. R. Palmer, 1958, Jour. Paleontology, v. 32, no. 1, p. 154, 155. Considered a member of Pioche shale.

Pioche district, Highland Peak and Pioche quadrangles.

Combs Limestone[1]

Upper Devonian: Northeastern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 78.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1742. Listed with names not included on Devonian correlation chart.

Named for Combs Peak in vicinity of Eureka, Eureka County.

Combs Mountain Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 169, 170–171, pl. 15. Predominantly siltstone with lesser amounts of shale and limestone. Thickness 75 to 90 feet. Underlies Indian Fort shale member (new); overlies Conway Cut siltstone member (new). Included in Irvine facies (new) of Brodhead formation.

Type locality: Along secondary road leading to ridge between Floyds Branch and Carpenters Hollow; top of section 1 mile south of Webb School, 8 miles east of Berea, 2¼ miles south of Combs Mountain, Madison County. Name taken from Combs Mountain, a topographic outlier developed on a fault block in southeastern part of Madison County.

Comerio Beds[1]

Lower Cretaceous(?): Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 61.

Comers Granite Gneiss

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Geol. Survey Bull. 72, p. 37–38, pl. 1. Equigranular to porphyritic rock which consists of pink microcline and quartz in greenish-gray matrix composed of chlorite and epidote.

Quartz usually has blue color. Injected with pink pegmatite related to Carsonville granite. May be composite rock formed by partial replacement of older rocks by Carsonville granite. Contains less mafic minerals than Carsonville granite, otherwise the two rocks are similar in mineral content.

Named from Comers Rock village in northwestern part of Independence quadrangle. Occurs in wide area in northwestern part of Elk Creek anticline, northwest of Point Lookout Mountain. Well exposed on Elk Creek and its tributaries, south and southeast of Elk Creek village, and on Turkey Fork east of Tims Knob.

Comet Shale

Middle Cambrian: Southeastern Nevada.

J. F. Mason *in* A. W. Grabau, 1936, Paleozoic formations in the light of the pulsation theory, v. 1, Lower and Middle pulsations: 2d ed., Peiping, China, University Press, Natl. Univ. Peking, p. 274–276. Predominantly shaly beds 545 feet thick. Underlies Lyndon limestone; overlies Forlorn Hope shale (new). Pioche shale of Walcott (1908), and Westgate and Knopf (1927) includes Comet shale, Forlorn Hope shale, and Pioche shale as used here.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1149, 1152–1154, 1158 (fig. 6), 1159, 1160. Thickness at type locality herein designated 370 feet. Overlies Pioche shale (restricted); underlies Lyndon limestone. Base of Comet is 4-foot zone of fossiliferous, gray oolitic limestone banded rusty brown; above this, formation consists of interbedded drab- and green-tan, micaceous, arenaceous, chunky and some fissile shale, and much arenaceous limestone, which is purer and increases in amount upward so that upper 65 feet consists largely of limestone. Derivation of name given.

Type locality: On west face of divide between Burrows Canyon and Lyndon Gulch, Highland Range. Section well exposed and undisturbed by faults. Name derived from Comet mine on west side of Highland Range.

Comet Creek Bed[1]

Lower Cretaceous: Western Oklahoma.

Original reference: R. T. Hill, 1895, Am. Jour. Sci., 3d., v: 50, p. 228.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Oklahoma Geological Survey abandoned name in its earlier sense.

Named for Comet Creek in Custer County.

Commerce Sandstone[1]

Tertiary: Southeastern Missouri.

Original reference: C. L. Drake, 1918, Missouri Bur. Geol. and Mines, v. 15, 2d ser., p. 191.

Well exposed in cuts on St. Louis and San Francisco Railroad in and just north of Commerce, Scott County.

Commercial Limestone Member (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 40, maps, sections.

Probably named for Commercial mine, Bingham district.

Commonwealth Ore Formation[1]

Age(?): Northern Michigan.

Original reference: C. L. Rominger, 1881, Michigan Geol. Survey, v. 4, pt. 2, p. 223.

Commonwealth mine, Menominee iron region.

†Como Beds[1]

Lower Cretaceous: Wyoming.

Original reference: W. B. Scott, 1897, Introduction to geology, p. 477, 491.

Compton Limestone[1]

Compton Formation (in Chouteau or St. Joe Group)

Compton Limestone Member (of Chouteau Formation)

Mississippian: Southwestern Missouri.

Original reference: R. C. Moore, 1928, Missouri Bur. Geology and Mines, v. 21, 2d ser., p. 60, 108–109, 111, 118–122, 131, 158.

J. G. Grohskopf, E. L. Clark, and S. Ellison, 1943, Missouri Geol. Survey and Water Resources 62d Bienn. Rept., App. 4, p. 9. Average thickness about 15 feet in Barry County. May rest upon Chattanooga, Sylamore, Fortune (new), or Cotter. Oldest limestone of Mississippian age known in southwestern Missouri and represents lower 10 to 15 feet of beds called St. Joe in northern Arkansas.

E. B. Branson, 1938, Missouri Univ. Studies, v. 13, no. 3, p. 10; 1944, v. 19, no. 3, p. 179 (fig. 3), 193. Compton represents lower part of Chouteau and should not be considered a separate formation. Underlies Northview member.

T. R. Beveridge and E. L. Clark, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 71, 72 (fig. 1), 73, 75 [reprinted from Kansas Geol. Soc. Guidebook 16th Field Conf.]. Chouteau is redefined as group to include (ascending) Compton, Sedalia, and Northview formations. Usage of name Compton is extended laterally to replace the "Chouteau (restricted)" of previous literature. Original type area is along James River in vicinity of now nonexistent Compton post office which stood in NW¼NW¼SE¼ sec. 9, T. 29 N., R. 19 W., Webster County. The Compton is not exposed in immediate vicinity of namesake post office site, and type section is herein redesignated. In Christian and Barry Counties, the St. Joe is raised to rank of group comprising (ascending) Compton, Northview, and Pierson formations.

Type section (Beveridge and Clark): Center SE¼SE¼S½ sec., 3, T. 29 N., R. 19 E., on northwest side of gravel road, Webster County. This section is 2 miles northeast of Compton post office site, and shows the Compton in its entirety. Named for exposures along James River in vicinity of Compton, near west line of Webster County.

Comstock Formation

Eocene: Western Oregon.

P. E. Turner, 1938, Geol. Soc. America Spec. Paper 10, p. 21–22, 23. Name proposed for approximately 1,000 feet of nonmarine sediments that occur between overpass south of Comstock and first outcrops of base of Fisher formation, and for a comparable thickness of similar continental beds stratigraphically below base of Fisher along line of its outcrop from Coyote Creek, 20 miles northwest of Comstock, to vicinity of London about 8 miles southeast. Beds consists of sandstones, tuffs, and locally shaly silts. The Fisher is identified on basis of lithologic similarity to type occurrence west of Eugene. Relations of Comstock to formations above and below not entirely clear. At Hill 506 in Cottage Grove quadrangle, the Fisher lies with angular discordance upon the Comstock. Contact with underlying Spencer formation not directly observable. Evidence suggests that Comstock rests with angular discordance upon underlying marine Eocene and that it overlaps successively older beds along the line of its exposure from Coyote Creek to London.

H. E. Vokes, P. D. Snavely, Jr., and D. A. Meyers, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–110. Included in redefined Spencer formation.

Area discussed is in Cottage Grove, Elmira, and Eugene quadrangles.

Comus Formation

Lower and Middle Ordovician: North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler Peak quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–10]; H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–15]. Interbedded chert, slate, and argillite. Chert is dark gray, green, brown, and black. Slate and argillite are dark gray, green, or black. Estimated thickness more than 2,000 feet. In thrust contact with Valmy formation (new) and unconformably overlain by Battle formation (new).

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2831–2832. Comus formation was mapped in Golconda quadrangle (Ferguson, Roberts, and Muller, 1952) as in normal contact with Preble formation of Middle or Late Cambrian age. Restudy of type locality has shown that the contact is a high-angle fault. Upper Cambrian rocks that may have been present between Preble and Comus have been cut out along the fault. The chert and shale unit of northwest side of Battle Mountain, originally assigned to Comus, is now referred to upper part of Valmy formation.

Type locality: Near Comus, in Golconda quadrangle, Humboldt County.

Comyn Formation (in Marble Falls Group)

Pennsylvanian (Morrow): North-central Texas (subsurface).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 84 (fig. 5), 85. Name applied to subsurface section of Marble Falls group in Ranger area. Occurs between depths of 4,132 and 4,320 feet in type well. Underlies DeLeon Springs formation (new) of Big Saline group.

M. G. Cheney, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 211. Plummer (1944, Texas Univ. Bur. Econ Geology Pub. 4401) assigned name Sloan to outcropping Morrowan rocks and this name should replace Comyn.

G. L. Turner, 1957, Abilene and Fort Worth Geol. Soc. Guidebook Joint Field Trip, p. 63–64. Problem of whether the Comyn is Morrowan or late Mississippian has not been definitely resolved.

Type well: Roxana Petroleum Co. Seaman No. 1, Palo Pinto County. Name derived from town in Comanche County.

Conanicut Arkose[1]

Carboniferous: Southern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 380.

Occurs on eastern side of Mackerel Cove, Conanicut Island.

Conant Limestone Member (of Carbondale Formation)

Pennsylvanian: Southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 48 (table 1), pl. 1. Proposed for limestone formerly called Jamestown. Name Jamestown to be used for coal member underlying the Conant. Stratigraphically below Anvil Rock sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NW¼NE¼ sec. 34, T. 5 S., R. 4 W., Perry County. Name derived from village of Conant about 2 miles east of type outcrop.

Conasauga Shale,[1] Limestone,[1] Formation, or Group

Middle and Upper Cambrian: Northeastern Georgia, northern Alabama, eastern Tennessee, and southwestern Virginia.

Original reference: C. W. Hayes, 1891, Geol. Soc. America Bull., v. 2, p. 143, 144–148.

T. L. Kesler, 1950, U.S. Geol. Survey Prof. Paper 224, p. 17–19, pl. 1. Described in Cartersville district, Georgia, as Conasauga formation. Consists largely of metashale containing unevenly distributed thin and thick beds of weakly calcareous metasiltstone. Maximum thickness 2,000 feet; top not exposed. Overlies Rome formation.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1 (plates); pt. 2, p. 46 (fig. 3), 47–53. In eastern Tennessee, the Conasauga varies in lithology and three phases are recognized: northwestern phase largely of shale, central phase of alternating shale and limestone formations, and southeastern phase principally of dolomite but including some limestone and shale. In northwestern phase, Conasauga shale includes Pumpkin Valley shale member below and Maynardville limestone member above. In central phase (between Knoxville and Morristown, and north of Clinch Mountain), Conasauga group consists of six formations (ascending): Pumpkin Valley shale, Rutledge limestone, Rogersville shale, Maryville limestone, Nolichucky shale, and Maynardville limestone. Southeast boundary of central phase is marked by disappearance of Rogersville shale and merging of Maryville and Rutledge formations, here largely dolomite, into Honaker dolomite. In southeastern phase, sequence is (ascending) Honaker dolomite, Nolichucky shale, and Maynardville limestone. To the northeast, in Virginia, the shale units thin to disappearance until the whole is carbonate rock with some shaly dolomite beds (the Elbrook dolomite). Overlies Rome formation; underlies Copper Ridge dolomite and to southeast Conococheague limestone.

R. L. Miller and J. O. Fuller, 1954, Virginia Geol. Survey Bull. 71, p. 28–33. Term Conasauga shale extended into western Lee County, Va., where it is applied to beds previously called Nolichucky shale. Only upper half of Conasauga exposed; underlies Low Hollow limestone member of Maynardville limestone.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 54. Conasauga group is an interfingering complex of shale, limestone and dolomite, mainly of Middle Cambrian but partly of Late Cambrian age, of which Elbrook dolomite, Honaker dolomite, and Nolichucky shale are representatives in northeasternmost Tennessee [this report]. In this region, group is exposed in two separate areas: one to north along southeast edge of Appalachian Valley, and the other to southwest near Elizabethton, in trough of Stony Creek syncline. In northern occurrence, the interval is all dolomite, the Elbrook; to the southwest, the Nolichucky shale is at top and underlying dolomite is Honaker.

Named for exposures in Conasauga Valley, Dalton quadrangle, northwestern Georgia.

Conasaugan Series

Middle Cambrian: Southeastern United States.

A. W. Grabau, 1937, Paleozoic formations in the light of the pulsation theory, v. 3, Cambrovician pulsation, pt. 2, Appalachian, Palaeocordilleran, Pre-Andean, Himalayan, and Cathaysian geosynclines: Peiping, China, Univ. Press, Natl. Univ. Peking, p. 10, 282. Both the Nolichucky and Conasauga are here referred to the Middle Cambrian and for this series, as developed in southern Appalachian geosyncline, name Conasaugan is proposed; succeds the Stonehengian.

Concentrator Volcanics

Cretaceous(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 15 (table 1), 27–32, pl. 1; 1946, U.S. Geol. Survey Prof. Paper 209, p. 22–25, pl. 3 [1947]. Andesite, keratophyre and quartz keratophyre flows, breccias, and tuffs, highly altered and of complex structure. Rocks range in color from white through buff and gray to red and brown. Flow breccias most abundant, tuffs next, and flows subordinate. Several hundred to perhaps over 3,000 feet thick. Younger than Cardigan gneiss (new); intruded by Cornelia quartz monzonite (new).

Named from conspicuous outcrops on Concentrator Mountain, southeast of Ajo, Ajo quadrangle, Pima County. Exposed in two relatively small areas, aggregating less than 2 square miles.

Concha Limestone (in Naco Group)

Concha Limestone (in Snyder Group)

Permian: Southeastern Arizona.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 1, 29–30, 42–43. In Naco group. Lower beds, for most part, are fine-grained calcareous sandstone which weathers gray; probably nowhere more than 50 feet thick. Above basal sandy beds, formation consists of gray medium-grained highly fossiliferous limestone which contains abundant irregular nodules of light-colored chert weathering pale brown. Thickness at type section 129½ feet. Overlies Scherrer formation (new); unconformably underlies Glance conglomerate of Bisbee group.

D. L. Bryant, 1955, Dissert Abs., v. 15, no. 7, p. 1224. Excluded from Naco group because it is not present in type area of original Naco. Type Concha equivalent to only basal part of an additional 1,000 feet of limestone in other localities. Concha limestone (expanded) assigned to Snyder Hill group.

F. F. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 498. Suggested that terms Chiricahua limestone and Snyder Hill formation be suppressed and term Concha limestone be used for the light-colored cherty limestones of southeast Arizona that contain Kaibab fauna and overlies Scherrer formation.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 41–43. Believed that Concha limestone and Chiricahua limestone are same stratigraphic unit and that terms are synonymous; term Chiricahua has priority. In this report [central Peloncillo Mountains], term Chiricahua is used for cherty limestone overlying Scherrer quartzite and considered uppermost unit of Naco group.

Type section: On east end of Concha Ridge, a conspicuous transverse spur of Scherrer Ridge in Gunnison Hills, NW¼ sec. 28, T. 15 S., R. 23 E., central Cochise County.

Conch Point Shale

Miocene, lower: Panamá.

R. A. Terry, 1956, California Acad. Sci. Occasional Paper 23, p. 52, 77. Massive poorly bedded soft gray clay shale underlying Bastimentos shale which it resembles closely. On Columbus Island, surface structure is gently rounded dome on which early Miocene Conch Point shale crops out at crest, over an area of about 1 mile, surrounded by middle Miocene Bastimentos shale. Seismograph survey indicates structure is cut by fault striking N. 24° E.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 332. Miocene. If these strata are same age as early part of Uscari shale of Costa Rica, name Conch Point should be suppressed. Note on derivation of name.

Conch Point is on west side of Isla de Colón, 8 kilometers northwest of town of Bocas del Toro.

Concord Formation[1]

Oligocene: Western California.

Original reference: B. L. Clark, 1918. California Univ. Pub., Dept. Geol. Bull., v. 11, p. 54–111.

G. C. Lutz, 1951, California Univ., Dept. Geol. Sci. Bull., v. 28, no. 13, p. 373, 374, 381. Mentioned as underlying Sobrante sandstone in southwest limb and in part of northeast limb of Bear Creek anticline. Overlies Kirker tuff. Described as fine- to medium-grained buff-colored mottled sandstone. May be several hundred feet thick.

Occurs in San Francisco Bay region.

Concord Granite[1] (in New Hampshire Plutonic Series)

Upper Devonian(?): Central and southern New Hampshire.

Original reference: C. H. Hitchcock, 1873, Rept. Geol. Survey New Hampshire 1872, p. 9, 12.

Katharine Fowler-Lunn and Louise Kingsley, 1937, Geol. Soc. America Bull., v. 48, no. 10, p. 1369, 1371–1373. Assigned to New Hampshire magma series.

Katharine Fowler-Billings, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1250, 1268–1270, pl. 1. Summary discussion.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Mapped together with Bickford granite; unit designated "binary granite" on map. Included in New Hampshire plutonic series.

City of Concord is in outcrop area.

Concreto Shale[1]

Pennsylvanian: Southeastern Kansas.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Bull. 238, p. 20.

Named for Concreto, Allen County.

Condor Member (of Highland Peak Formation)

Condor Formation (in Ophir Group)

Condor Member (of Swasey Limestone)

Middle Cambrian: Eastern Nevada and western Utah.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 39, fig. 5. Name applied to lowermost 117 feet of type Swasey as described by Deiss (1938). Consists largely of thinly interbedded calcareous, argillaceous, and arenaceous strata. Underlies unnamed upper part of Swasey; overlies Dome limestone. This unit, although more dolomitic, was referred to as Highland Peak unit "F" in Pioche district by Wheeler and Lemmon (Nevada Univ. Bull., Geology and Mining Ser., no. 31).

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 35, 46–47, pl. 1, measured sections. In Sheeprock Mountains, rank raised to formation in Ophir group. Thickness 107 to 135 feet. Overlies Dome limestone.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 47, 51. Name Condor as used by Wheeler (1948) and Cohenour (1959) replaced by Whirlwind formation (new).

U.S. Geological Survey currently classifies the Condor as a member of Highland Peak Formation on the basis of a study now in progress.

Type section: In Panaca Hills, Pioche district, Nevada. Name derived from Condor Canyon, about 2 miles north of type section; member is exposed on north wall near mouth of canyon. Recognized in Wah Wah and House Ranges, Utah.

Cone Calcareous Member (of Marias River Shale)

Upper Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2792 (fig. 3), 2794; 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 91. Chiefly highly calcareous dark-gray shale at type section. Other less abundant but easily recognized lithologies include persistent bed of large septarian concretions of dark-gray limestone at base; a widespread 4-foot-thick bed of white bentonite 12 feet above base; and several layers of thin-bedded ledge-forming clastic fossiliferous limestone at top. It is the so-called Greenhorn of Sweetgrass arch. About 54 feet thick at type section. Underlies Ferdig shale member (new); overlies Floweree member (new).

Type section: On south side of small conical hill below U.S. Geological Survey vertical angle bench mark (VABM) Cone in NW¼ sec. 13, T. 22 N., R. 1 W., Vaughn quadrangle, Teton County.

Conecuh Sands[1]

Pleistocene: Southeastern Alabama.

Original reference: E. A. Smith, L. C. Johnson, and D. W. Langdon, Jr., 1894, Alabama Geol. Survey Rept. Coastal Plain, p. 27, 56–57.

Probably named for Conecuh River.

Conejo Volcanics[1]

Miocene: Southern California.

Original reference: N. L. Taliaferro, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, p. 800–801.

O. P. Jenkins and others, 1949, California Div. Mines Bull. 142, p. 140. Composed of basalt flows and pyroclastics with minor basalt and andesite dikes. Overlies olivine basalt which in turn overlies Topanga formation.

W. E. Kennett *in* L. E. Redwine and others, 1952, Cenozoic correlation section paralleling north and south margins, western Ventura basin, from Point Conception to Ventura and Channel Islands, California: Am. Assoc. Petroleum Geologists, Pacific Sec., sheet 2. Cited on chart as underlying Monterey formation and overlying Rincon formation on San Miguel and Santa Rosa Islands. Thickness 2,500 to 2,900 feet.

Occurs in Conejo Mountains, western end of Santa Monica Mountains.

Conejos Formation (in Potosi Volcanic Group)

Conejos Andesite (in Potosi Volcanic Series)[1]

Conejos Quartz Latite (in Potosi Volcanic Series)

Tertiary, middle or upper: Southwestern Colorado and northern New Mexico.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13, p. 20, 38–39.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 96–102, pl. 1. Redescribed as quartz latite. Geographically extended into New Mexico where it becomes thinner and is predominantly a sand and gravel formation. Greatest thickness about 4,000 feet in basin at head of Rio Blanco in central part of Summitville quadrangle, Colorado. Thickness of 3,000 feet or more in central area and thins in all directions from central part, but, except on extreme edges of formation, is rarely less than 1,000 feet thick. Underlies Beidell quartz latite.

T. A. Steven and J. C. Ratte, 1960, U.S. Geol. Survey Prof. Paper 343, p. 10, 11–13, pl. 2. Term Conejos formation considered more appropriate than petrographic term quartz latite. In Summitville district, formation consists largely of flat-lying dark rhyolitic rocks. Underlies Fisher quartz latite. Middle or later Tertiary.

W. R. Muehlberger and others, 1960, New Mexico Geol. Soc. Guidebook 11th Ann. Field Conf., p. 100. In Brazos Peak quadrangle, New Mexico, the Conejos quartz latite underlies Toltec andesite member (new) of Treasure Mountain rhyolite.

Named for exposures along Conejos River. Most widely distributed and best exposed in Summitville, Conejos, and Del Norte quadrangles, Colorado. In general way, outcrops confined to an area about 130 miles long in north and south dimension; about 60 miles wide in northern third, and about 50 miles wide just north of Colorado-New Mexico State line.

Conemaugh Formation[1]

Conemaugh Group or Series

Pennsylvanian: Pennsylvania, western Maryland, eastern Ohio, northern Virginia, and western West Virginia.

Original reference: F. Platt, 1875, Pennsylvania 2d Geol. Survey Rept. H, p. 8.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 181–211. Conemaugh series in Ohio varies from 350 feet in southern part of Lawrence County to 518 feet at eastern edge of Jefferson County. Comprises 39 members including 12 coal beds.

W. O. Hickok, 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 77–99. Group described in Fayette County, Pa. Consists of sandstone, red and gray shale, limestone, thin coal beds, and small amounts of low-grade fire clay. Base is at top of Upper Freeport coal and top at base of Pittsburgh coal. Divided into nine parts (ascending): Mahoning, Buffalo, Saltsburg, Grafton, Barton, Morgantown, Lonaconing, Connellsville, and one which has not been named but which contains Little Pittsburgh coal.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 665, 666, chart 6. Referred to as series. Above Allegheny and below Monongahela.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 57–72, table 1. Conemaugh series, in Perry County, described on cyclothemic basis. Comprises seven cyclothems. [For sequence see Mahoning cyclothem.] About one-half the strata in the series are present in county.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 28–34. Conemaugh series described in eastern Ohio. Following limestone members are discussed (ascending): Mahoning, Cambridge, Bloomfield, Ewing, Ames, Gaysport, Elk Lick, Clarksburg, Summerfield, and Pittsburgh. Cyclothemic classification not used in this report.

T. W. Amsden, 1954, Maryland Dept. Geology, Mines and Water Resources Bull. 13, p. 53–65. Only complete section of formation in Maryland is in Georges Creek-Upper Potomac basin where it ranges from 825 to 925 feet in thickness. Includes claystone, shale, sandstone, fresh-water limestone, red shale, marine shale, and coal beds. Lower and upper members recognized. Lower member extends from top of Upper Freeport coal to top of Barton coal, and upper member comprises strata between Barton coal and base of Pittsburgh coal.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 24–65. Entire series present in Morgan County. Strata included in series extend from Upper Freeport (No. 7) coal to base of Pittsburgh (No. 8) coal. Total thickness 365 feet. Forty-two members described (including coal members). Cyclothemic classification not used in this report.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 93-157. Series described in Athens County. Thickness about 545 feet. Fifteen cyclothems described. [For sequence see Mahoning cyclothem.]

J. J. Burke, 1958, Science, v. 128, no. 3319, p. 302. Formation in vicinity of Pittsburgh includes (ascending) Nadine limestone (new), Woods Run limestone, and Carnahan Run shale (new).

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 11–13. Series consists of gray and tan sandstones, red and tan shales, some limestones, clays, and several thin coal seams. Average thickness about 600 feet. Main outcrop area is irregular belt extending through central part of state from Preston to Wayne County. Underlies Monongahela series; overlies Allegheny series.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 69 (fig. 4), 71, fig. 9. Group, between 600 and 900 feet thick, differs from the Pottsville and Allegheny, in that it contains red beds and more persistent marine beds, the latter being good stratigraphic guides. Such marine beds include Brush Creek, Cambridge, and Ames limestone which grade eastward into marine shale facies. Ames limestone represents highest known occurence of marine strata in coal measures of Pennsylvania. This persistent bed is present throughout Conemaugh belts of western Pennsylvania, West Virginia, Ohio, and Kentucky. There is faunal evidence for Conemaugh equivalents in northern anthracite field of eastern Pennsylvania and Eastern Interior Coal basin of Illinois. Overlies Allegheny group; underlies Monongahela group.

Carlyle Gray, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Conemaugh formation consists of cyclic sequences of red and gray shales and siltstones with thin limestones and coals; massive Mahoning sandstone commonly present at base; Ames limestone present in middle of sections; Brush Creek limestone in lower part of section.

Named for exposures along Conemaugh River, Pa.

Conestoga Limestone[1]

Cambrian(?) and Lower Ordovician: Southeastern Pennsylvania.

Original reference: G. W. Stose and A. I. Jonas, 1922, Washington Acad. Sci. Jour., v. 12, p. 359, 365–366.

A. I. Jonas and G. W. Stose, 1936, Geol. Soc. America Bull., v. 47, no. 10, p. 1671–1673. On basis of fossils collected at Henderson, Conestoga limestone in Chester Valley is of Beekmantown age (upper Canadian of Ulrich). In Norristown area, the Conestoga overlies Elbrook limestone and Ledger dolomite, and southwestward, near Coatesville, overlaps older limestones down to Antietam quartzite and Harpers phyllite. Chester Valley lies south of Mine Ridge anticline, which extends from New Providence eastward to Valley Forge. The Conestoga of type locality, in the Lancaster, York, and Hanover Valleys, lies north of Mine Ridge axis, and its southwestern end is in strike with Frederick Valley, although separated from it by an area of Triassic rocks. Without fossil evidence, it cannot be decided whether the Conestoga or area north of Mine Ridge is of Beekmantown age, as that of Chester Valley, or whether it is in part older, and of Upper Cambrian and basal Ordovician age, like the limestones of Frederick Valley. The Conestoga is not known to be faunal equivalent of Frederick limestone and cannot at present be correlated with it.

B. L. Miller, 1937, Geol. Soc. America Bull., v. 47, supplement, p. 2017–2019. Discussion of the above paper by Jonas and Stose. This author [Miller] believes Conestoga limestones are of Ordovician age, younger than Beekmantown and older than the Martinsburg and to be correlated with Jacksonburg of Lehigh Valley.

A. J. Stose and G. W. Stose, 1944, U.S. Geol. Survey Prof. Paper 204, p. 34–38, pl. 1. Described in Hanover-York district where it is poorly exposed and no continuous section can be measured. Unconformable on underlying formations—Kinzers formation, Ledger dolomite, Vintage dolomite, and Antietam quartzite. Lower Ordovician(?); may be in part Upper Cambrian.

Carlyle Gray, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation mapped as Ordovician.

Named for outcrops along Conestoga Creek south of Lancaster.

Conewago Conglomerate Member (of Gettysburg Shale)

Conewago Group[1]

Upper Triassic: South-central Pennsylvania.

Original reference: G. H. Ashley, 1931, Pennsylvania Topog. and Geol. Survey, ser. 4, Bull. G–1, p. 77.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. C–67, p. 107, 115, 118. Member of Gettysburg shale. Consists of thick lenticular zone in which are numerous beds of hard red pebbly arkosic sandstone and conglomerate. Conglomerate beds of the Conewago begin to appear southwest of Airy Hill School at western border of York County. They thicken northeastward and just beyond Harmony Grove make a ridge 400 feet higher than lowland that is crossed by York-Dillsburg Road. Hard conglomerate beds increase in number and thickness northeastward and form Conewago Mountain, a ridge attaining 1,050 feet altitude at its highest point, south and southeast of Andersontown. Conglomerates thin rapidly northeastward and finger into red shale and sandstone, and high ridge ends in two low spurs northwest of Strinetown. Maximum thickness 7,300 feet. Stratigraphically below Heidlersburg member.

A. J. Stose and G. W. Stose, 1944, U.S. Geol. Survey Prof. Paper 204, p. 56. Derivation of name.

Named for Conewago Hills in New Cumberland quadrangle.

Conewango Clay[1]

Pleistocene: Northwestern Pennsylvania.

Original reference: E. H. Williams, Jr., 1920, Am. Philos. Soc. Proc., v. 59, p. 62, 63.

Named for Conewango Creek, Warren County.

Conewango Formation[1]

Conewango Group, Series, or Stage

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

Original references: C. Butts, 1908, Pennsylvania Topog. and Geol. Survey Rept. 1906–1908, p. 191, 198; 1910, U.S. Geol. Survey Geol. Atlas, Folio 172.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Generalized succession for marine Upper Devonian of northwestern Pennsylvania (and southwestern New York) shows Conewango group comprises (ascending) Panama conglomerate, Venango and Riceville formations. Occurs above Conneaut group.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1734, chart 4. Term Conewango is herein elevated to rank of stage. Occurs above Cassadaga stage (new). Bradfordian series, Upper Devonian.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 50–67. Conewangan series includes Cattaraugus and Oswayo formations. Upper Devonian.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30–33. Group comprises (ascending) Cattaraugus, Oswayo, and Knapp formations. Underlies Arkwright group (new). Chautauquan series. Upper Devonian.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17 (table 2), 19–20. Group comprises (ascending) Wolf Creek conglomerate, Cattaraugus shale, and Oswayo shale. Overlies Chadakoin group; underlies Lower Mississippian Knapp "formation." Approximately same as Venango group (Carll, 1880).

Named for exposures in valley walls and uplands bordering Conewango Creek, south of New York boundary.

Coney Limestone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Mercer, Monroe, and Summers Counties, p. 298, 379.

Type locality: In vicinity of Avis, just opposite Coney Island, Summers County.

Coney Shale (in Bluefield Formation)[1]

Mississippian: Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 298, 380.

Type locality: On east side of New River, just east of Avis and just opposite Coney Island, Summers County. Also exposed in Mercer and Monroe Counties, W. Va., and in Giles and Tazewell Counties, Va.

Confederate Limestone (in Hoxbar Group or Deese Group)

Confederate Limestone Member (of Hoxbar Formation)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 15.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 697, chart 6 (column 37). Reallocated to Deese group and given formational status. Base of Hoxbar is drawn above the Confederate limestone, rather than just below it, as the boundary between Desmoinesian and Missourian deposits preferably should coincide with the Deese-Hoxbar contact.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Petroleum geology of southern Oklahoma, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2). Formation at base of Hoxbar group, Missouri series. At type locality, the Confederate comprises 30 feet of finely crystalline limestone varying from thin bedded to massive and from cream to dark tan in color; overlying 10 feet of calcareous shale with 2 feet or more of dense gray limestone at base. Crinerville beds (or member) occur 400 to 500 feet above base of Hoxbar.

B. H. Harlton, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 221. In Cement Pool area, Caddo and Grady Counties, the Confederate overlies West Arm formation (new) of Deese group.

Named because it is well exposed a short distance west of Oklahoma Confederate Veterans Home, in SE¼ sec. 36, T. 4 S., R. 1 E., on southwest outskirts of Ardmore, Carter County.

†Congaree Clay Member[1] (of McBean Formation)

Eocene, upper: Eastern Georgia.

Original references: J. O. Veatch and L. W. Stephenson, 1911, Georgia Geol. Survey Bull. 26, p. 267; 1915, U.S. Geol. Survey Water-Supply Paper 341, p. 77, 268.

Named for Congaree, Richland County, S.C.

Congaree Formation

†Congaree Shales[1] or phase[1]

Eocene, middle: Central southern South Dakota.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published 1908 in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 16.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 20 (fig. 2), 21–23. Though Sloan's Congaree phase was vaguely defined, he evidently intended to include in it clay, sand, and buhrstone of early Claiborne age. Veatch and Stephenson (1911, Georgia Geol. Survey Bull. 26) accepted Congaree in this sense for use in Georgia and described Congaree clay as basal member of McBean formation, oldest formation of Claiborne age known to them there. How much of their Congaree is Claiborne is still uncertain. Cooke and Shearer (1918, U.S. Geol. Survey Prof. Paper 120–C) supposed that all their Congaree was Jackson and transferred it to Barnwell formation under name of Twiggs clay member. Later Cooke (1943, U.S. Geol. Survey Bull. 941) restored that facies consisting of thin-bedded or laminated sand and clay to McBean formation. It now appears that deposits of Claiborne and Jackson age have never been properly delimited in either Georgia or South Carolina. A large part of the deposits in Georgia mapped as Barnwell is of Claiborne age. This includes much of Twiggs clay member of Barnwell of eastern Georgia. Name Congaree is here revived and deemed of formational rank because it is equivalent to the Tallahatta formation of Mississippi and Alabama. Term formation is preferred to clay or shale because much sand as well as clay and shale are included. At designated typical exposure, formation is 21 feet thick and unconformably underlies Warley Hill marl. Overlies Black Mingo formation. Included in lower Claiborne.

Typical exposure: Section in roadcut west of Halfway Swamp one-half mile east of Creston, Calhoun County, S.C. Name derived from Congaree River.

Conglomerate Point Breccia

Pliocene: Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. In a deeply eroded volcanic neck which intruded the Grotto batholith.

In Skykomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

Congo Cay Limestone Member (of Tutu Formation)

Upper Cretaceous: Virgin Islands.

T. W. Donnelley, 1960, Dissert. Abs., v. 20, no. 7, p. 2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. Thickness 100 to

300 feet. Occurs near top of formation. Virgin Island group considered of Cenomanian age.

Report discusses geology of St. Thomas and St. John Islands.

Conneaut Group[1] or Formation

Conneaut Stage

Upper Devonian: Northeastern Ohio, southwestern New York, and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 136.

G. H. Chadwick, 1936, New York State Mus. Bull. 307, p. 78, 96. Group includes Cotton formation (new).

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 44. Referred to as Conneaut stage of Chautauquan series.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 27–50. Group, in Wellsville quadrangle, comprises (ascending) Wellsville formation (new), Hinsdale sandstone, Whitesville formation (new), "Catskill" sedimentation, and Germania formation (new). Embraces strata between Cuba formation of Canadaway group below and Cattaraugus formation above.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 11-12. In Cherry Creek quadrangle, Chadakoin formation contains about 420 feet of siltstone and shales which lie between top of Northeast shale member of Canadaway formation and base of Panama conglomerate member of Cattaraugus formation. These strata are equivalent to Conneaut group of Caster (1934). As Chadakoin formation is here assigned to Arkwright group, term "Conneaut group" has no status.

Hugo Greiner, 1957, Yale Univ. Peabody Mus. Nat. History Bull. 11, p. 9 (table), 10, 54–55. Discussion of evolution and paleoecology of *Spirifer disjunctus* in Catskill delta. Collections were made from Conneaut stage which according to table includes Cuba standstone, Volusia (Girard) shale, Lillibridge sandstone, Dexterville shale, Hinsdale sandstone, Ellicott shale, and "Chadakoin" formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Conneaut group, as mapped, consists of alternating gray, brown, greenish, and purplish shales and siltstones; includes "pink rock" of drillers and "Chemung" and "Girard" formations of northwestern Pennsylvania.

Named for exposures on Conneaut Creek in Ohio and Pennsylvania.

†Conneaut limestone member[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, table opposite p. 61.

Connell Sandstone Member (of Oil Creek Formation)

Middle Ordovician: Western Texas (subsurface).

R. H. Schweers, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 12, p. 2029–2036. Medium- to coarse-grained sandstone at base of Oil Creek formation. Thickness 40 feet at type locality.

Type locality: Texas Co. W. E. Connell No. 33 in NE¼NE¼ sec. 1, Block B–22, Public School Land Survey, Jordan area, Ector County, between 8,822 and 8,862 feet.

Connellsville Member (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Topog. and Geol. Atlas 27, p. 31.

Pittsburgh area.

Connellsville Red Bed (in Conemaugh Formation)[1]

Connellsville redbed member

Pennsylvanian: Western Pennsylvania, southeastern Ohio, and northern West Virginia.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, pl. 6.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 154. Referred to as Connellsville redbed member of Little Waynesburg cyclothem in report on Athens County. At places, the interval between the Little Clarksburg and Pittsburgh coals is occupied almost entirely by redbeds. The lowermost of these is Connellsville redbed. whose position is equivalent to upper part of Connellsville sandstone. Average thickness 8 feet.

Name probably derived from Connellsville, Fayette County, Pa.

Connellsville Sandstone Member (of Conemaugh Formation)[1]

Connellsville sandstone and shale member

Upper Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: F. Platt, 1876, Pennsylvania 2d Geol. Survey Rept. L.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 60–61, geol. map. In Morgan County, Connellsville sandstone and shale member of Conemaugh series occupies interval between Clarksburg coal and Lower Pittsburgh limestone. Predominantly gray to tan, micaceous, sandy shales with beds of shaly, thin to platy bedded sandstones; rapid facies changes occur in interval so that local areas consist of erratic developments of thick sequences of sandstones separated by sandy shales. Thickness 20 to 40 feet. In most of county, base of member can be placed only approximately; top of member is indefinite because of rapid changes in character of Lower Pittsburgh interval.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 153–154. Referred to as shale and sandstone member of Lower Little Pittsburgh cyclothem in report on Athens County.

Well exposed in town of Connellsville, Fayette County, Pa. Also caps hills in Ligonier Valley, southwestern Pennsylvania.

Connelly Conglomerate

Connelly Conglomerate (in Oriskany Group)[1]

Lower Devonian: Southeastern New York.

Original reference: G. H. Chadwick, 1908, Science, new ser., v. 28, p. 346–348.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 730–732. Thickness 45½ feet at Highland Mills, N.Y. Overlies Central Valley sandstone (new); underlies Highland Mills member (new) of Esopus formation. Oriskany age. [Oriskany group not used in this report.]

Typically exposed on hill above South Rondout (Connelly post office), Rhinebeck quadrangle, Ulster County, and in creek bank opposite.

Conner facies (of Dunham Dolomite)

Lower Cambrian: Northwestern Vermont.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Named used only on correlation chart. Underlies Mallett facies of Dunham dolomite; overlies Gilman quartzite. Refers to Shaw (unpub. thesis, 1949).

Connoquenessing Formation (in Pottsville Group)

Connoquenessing Sandstone Member (of Pottsville Formation)[1]

Connoquenessing Sandstone

Lower Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q.

M. N. Shaffner, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 151. Columnar section, Donegal quadrangle, shows Connoquenessing sandstone, Pottsville series, underlying the Mercer and overlying Mauch Chunk.

R. E. Lamborn, 1954, Ohio Geol. Survey Bull. 53, p. 43–46, geol. map. Eastward from Stark County, the Massillon (Conoquenessing) sandstone is well developed on outcrop in Ohio and western Pennsylvania. In Beaver County, Pa., it was described as Connoquenessing sandstone by White (1878) and divided into Upper and Lower Connoquenessing sandstone with Quakertown coal between. Southwest from Stark County, the Massillon is irregularly present but found close above the Quakertown coal and thus corresponds in position to the Connoquenessing sandstone of Pennsylvania.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook for Field Trips Pittsburgh Mtg., p. 68–71. Formation in Pottsville group. Underlies Mercer formation. The Connoquenessing, where most complete, is about 175 feet thick and consists of two sandstones, the Upper and Lower Connoquenessing separated, by Quakertown coal and shales.

Exposed along bed of Connoquenessing Creek, Lawrence County, Pa.

Conococheague Group

Conococheague Limestone[1] (in Knox Group)

Upper Cambrian: Central southern Pennsylvania, western Maryland, Tennessee, and northwestern Virginia.

Original reference: G. W. Stose, 1908, Jour. Geology, v. 16, p. 701.

C. R. L. Oder, 1934, Jour. Geology, v. 42, no. 5, p. 478–479, 492, 493, 496. Conococheague-Copper Ridge formation in eastern Tennessee contains Morristown below and Bloomingdale members. Overlies Maynardville limestone; underlies Chepultepec formation.

B. N. Cooper, 1936, Virginia Geol. Survey Bull. 46–L, p. 136–137, pl. 14. Referred to as formation in Marion area where it consists chiefly of thick-bedded coarsely crystalline gray cherty dolomite but contains characteristic beds of limestone, sandstone, and edgewise conglomerate. Thickness about 1,200 feet. Unconformably overlies Nolichucky formation; conformably underlies Chepultepec formation. Ozarkian.

B. N. Cooper, 1939, Virginia Geol. Survey Bull. 55, p. 13–17, pls. 1, 3. Formation described in Draper Mountain area where it is about 1,500 feet thick. Overlies Elbrook formation; underlies Nittany dolomite. Cambrian. Virginia Geological Survey has discontinued use of Ozarkian as systematic term.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 86–90. In Virginia, the Conococheague limestone includes all strata between Elbrook dolomite or Nolichucky below and Chepultepec limestone above. Predominant characteristic is thick-bedded blue limestone which forms about 75 percent of formation. Thickness 2,013 feet in Washington County. Conococheague of Virginia is correlated with that of Pennsylvania and Tennessee and with Gatesburg dolomite of central Pennsylvania. Conococheague is correlated with Copper Ridge dolomite of northwestern belts of Appalachian Valley in Virginia.

H. P. Woodward, 1949, West Virginia Geol. Survey, v. 20, p. 169–190. Conococheague limestone described in West Virginia where it crops out in Berkeley and Jefferson Counties. Overlies Elbrook limestone; underlies Chepultepec-Stonehenge limestone. Thickness 1,800 to 2,000 feet.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 33–34, pl. 1. In Elkton area, Virginia, overlies Elbrook dolomite and underlies Beekmantown dolomite (including Chepultepec limestone). Thickness about 2,000 feet.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County Rept. 14, p. 45–57. Conococheague limestone described in Washington County, where it is as much as 1,913 feet thick. Includes Big Spring member (new) in lower part. Overlies Elbrook formation; underlies Beekmantown limestone.

J. L. Wilson, 1952, Geol. Soc. America Bull., v. 63, no. 3, p. 305–316. Discussion of Conococheague formation in Shenandoah-Cumberland Valley of Virginia, West Virginia, Maryland, and Pennsylvania. Includes Big Spring Station member (replaces term Big Spring member) in lower part in Maryland and Pennsylvania. A section of the formation, 1,650 feet thick, measured by Stose just west of village of Scotland on Conococheague Creek, 3 miles northeast of Chambersburg, Pa., became unofficially the type section, although the section is incomplete and its lower part is structurally distorted. Minor anticlinal axis passes through the village exposing lower part of Conococheague on both its flanks. Beds across axis are covered, and section cannot be traced across it at Scotland. Stose overestimated height of fold, believing that underlying Elbrook formation was exposed along it south of Scotland (1909, map). Fossils of Trempealeauian age (high in Conococheague) discovered within this supposed Elbrook inlier 1½ miles north of Stonehenge village indicate that structure is relatively small. Therefore, on west limb of this minor fold at Scotland, less of lower Conococheague is repeated than Stose believed and his estimated total thickness is too small. About 500 feet of lower Conococheague (a part of Big Spring Station member at base) is present on east flank of fold at Musser Farm, on east edge of Scotland village. These beds are not present in Stose's section. Big Spring Station section of this report is almost complete and is about 1,900 feet thick. General facies change from west to east from arenaceous dolomite (Gatesburg formation) to silt-laminated limestone (Conococheague formation) is indicated in geosyncline. Trilobites identified from Warrior, upper Elbrook, and lowest Conococheague formations, indicate Dresbachian age for these beds. Trilobites of Franconian age from middle Gatesburg and lower Conococheague show more complex relationships. Trempealeauian trilobites are identified from upper Conococheague.

G. W. Stose, 1953, Geology of the Carlisle quadrangle, Pennsylvania: U.S. Geol. Survey Geol. Quad. Map [GQ–28]. Conococheague limestone crops out in irregular belt that extends entirely across north-central part of quadrangle, bordering the belt of Elbrook limestone on north. Distinctive feature of Conococheague is occurrence of Cryptozoon beds, made up of rather pure blue limestone, up to 4 or 6 inches thick, showing concentric layers, convex upward. Partial section exposed at Bonnybrook about 784 feet. Map legend gives thickness about 2,000 feet. Underlies Beekmantown limestone; overlies Elbrook limestone. Upper Cambrian.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 61–63, pls. As mapped in southeastern Tennessee, about 1,100 feet or more thick. Included in Knox group. Underlies Jonesboro limestone; overlies Maynardville limestone. Corresponds roughly to Copper Ridge dolomite to northwest.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 33. Oder's (1934) Morristown seems to correspond to entire Copper Ridge as herein delimited, and his Bloomingdale is now thought to belong to lower part of Chepultepec dolomite as now recognized. Limestone facies of the Copper Ridge is commonly known as the Conococheague limestone, which name has been extended from Pennsylvania into Virginia and Tennessee.

W. J. Sando, 1958, Geol. Soc. America Bull., v. 69, no. 7, p. 838 (fig. 2), 839. Formation, in vicinity of Chambersburg, Pa., stratigraphically restricted at top to exclude beds previously referred to as "upper member of Conococheague;" these beds are herein named Stoufferstown member of Stonehenge.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Pennsylvania Geol. Survey, 4th ser., Atlas 167–D. In Richland and adjacent quadrangles, formation is subdivided into (ascending) Buffalo Springs, Snitz Creek, Schaefferstown, Millbach, and Richland members (all new). Underlies Stonehenge formation of Beekmantown group. Base of Cambrian not exposed in Richland quadrangle.

Carlyle Gray and D. M. Lapham, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 148–151. Formation divided into five members (ascending): Buffalo Springs, Snitz Creek, Schaefferstown, Millbach, and Richland. Not certain that all of these members belong with Conococheague as defined by Stose (1908). At Cornwall iron mines, south of Lebanon, the Conococheague contains two units known locally as Mill Hill slate and Blue conglomerate.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as Conococheague group. Includes Buffalo Springs, Snitz Creek, Schaefferstown, Millbach, and Richland formations.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28 (table), 55–56, 126, pl. 1. Included in Knox group. Thickness in Denton Valley, Va., 2,200 feet. Underlies Jonesboro limestone; overlies Conasauga group. Mapped in northeastern Tennessee.

Named for Conococheague Creek in Scotland, Franklin County, Pa.

Conover Slate[1]

Precambrian (upper Huronian): Northeastern Wisconsin.

Original reference: R. C. Allen and L. P. Barrett, 1915, Michigan Geol. and Biol. Suvey Pub. 18, geol. ser. 15, p. 123–129.

Conover district, Vilas County.

Conowingo Breccia

Age not stated: Northeastern Maryland.

O. P. Bricker and others, 1960, Pennsylvania Geologists Guidebook 25th Ann. Field Conf., p. 8, 11. Mentioned in road log (stop 2). Occurs at contact zone with Port Deposit granodiorite.

Occurs near Conowingo Dam on Susquehanna River, Cecil County, Md.

Conquista Clay Member (of McElroy Formation)

Eocene: South-central Texas.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2626 (table 1), 2631. Substituted for preempted Falls City shales (Ellisor, 1933). At type locality, consists of about 70 feet of pale-yellowish-brown to chocolate bentonitic clay. Overlies Dilworth sandstone member; underlies Stones Switch sandstone member of Whitsett formation.

Type locality: Bluff adjoining historic Conquista Crossing on San Antonio River 3¾ miles southwest of Falls City, Karnes County. This is same type locality as Falls City shales.

Conshohocken Clay[1]

Ordovician(?), or Cretaceous(?): Southeastern Pennsylvania.

Original references: T. C. Hopkins, 1899, Am. Geologist, v. 23, p. 102; 1899, Science, new ser., v. 9, p. 139; 1900, Geol. Soc. America Bull., v. 10, p. 480–482; 1900, Pennsylvania State Coll. Ann. Rept. 1899–1900.

Occurs on hill north of Conshohocken, Montgomery County.

Contadero Formation

Upper Devonian: Central southern New Mexico.

F. V. Stevenson, 1944, Dallas Digest (Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Joint Ann. Mtg.), p. 94–95. Series of carbonaceous shales and limestones. Basal gray limestone beds conformably overlie Sly Gap formation, and gray calcareous shales comprising top beds of formation unconformably underlie Caballero formation. Possibly a different facies of Ready Pay member (new) of Percha shale.

F. V. Stevenson, 1945, Jour. Geology, v. 53, no. 4, p. 239–241, fig. 2. Thickness at type section 66½ feet. Type section location further described. In a north-south cross section, formation roughly resembles shape of shallow bowl. Upper Devonian.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 35 (fig. 16), 53, 55 (fig. 25). Underlies Alamogordo formation and Andrecito member (new) of Lake Valley formation in parts of San Andres Mountains.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 30–31. Type Contadero formation revised to exclude upper beds containing Percha fauna and to include at base barren silty shales that locally exhibit sharp contact with underlying Sly Gap formation.

At Rhodes Canyon, 45 feet of section measured. Formation thins to the north and south, pinching out north of Sly Gap and south of Dead Man Canyon.

Type section: In S½ sec. 8, T. 13 S., R. 4 E., on north slope of Rhodes Canyon, near an abandoned mining claim. Noted only in central part of San Andres Mountains.

Contention Series[1]

Lower Cretaceous(?): Southeastern Arizona.

Original reference: W. P. Blake, 1902, Tombstone and its mines.

Tombstone district. Derivation of name not stated.

Continental Peak Formation

Eocene, upper(?): West-central Wyoming.

R. L. Nace, 1939, Wyoming Geol. Survey Bull. 27, p. 11 (chart), 21–25, pl. 1. Reddish-brown, gray, and green fine- to medium-grained thin- to thick-bedded and massive, blocky, and crossbedded tuff and tuffaceous sandstone. Thickness 145 to 250 feet. Disconformably overlies Bridger formation; disconformably underlies Beaver Divide conglomerate member (new) of Chadron formation.

Type section: West side of Continental Peak near center sec. 35, T. 27 N., R. 101 W., Fremont County.

Contra Costa Group

Miocene, upper, to Pliocene, middle: Northern California.

C. R. Ham, 1952, California Div. Mines Spec. Rept. 22, p. 6 (fig. 3), 14–15. Lawson (1914) mapped and described continental deposits within Las Trampas Ridge area as Orinda formation. Lawson and Palache (1902) designated lower Pliocene silt, sandstone, and conglomerate in Berkeley Hills as type Orinda. Subsequent work to the east by D. E. Savage and others (unpub. rept.) [1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2] has shown need for revision of terminology. They suggest term Contra Costa group to include five formations, the Orinda being at base. Within Las Trampas Ridge area only two of the five formations, Orinda and Mulholland, are recognized, the Grizzly Peak, Siesta, and Bald Peak formations being absent. Overlies San Pablo group.

Type locality not stated.

Contra Costa Lake Bed[1]

Pliocene: Western California.

Original reference: J. G. Cooper, 1894, California Acad. Sci. Proc., 2d ser., v. 4, p. 169.

Exposed on northeast slope of hills west of San Pablo Creek, forming body between Contra Costa and Alameda Counties in that part of its course about 4½ miles northeast of State University, San Francisco Bay region.

Converse Formation (in Wilcox Group)

Paleocene, middle: West-central Louisiana.

H. V. Andersen, 1960, Louisiana Dept. Conserv., Geol. Bull. 34, p. 55–58. Consists of fine- to medium-grained sand which can be either massive, thin, or crossbedded. Contains lenses of clay or silt sufficiently calcareous locally to produce caliche. Thickness at least 155 feet in vicinity of Converse (100 feet plus in water wells and at least 55 feet along State Highway 174); traced in subsurface as far as Negreet, where it attains thickness of 232 feet. Overlies Cow Bayou formation; underlies Lime Hill formation.

H. V. Andersen, ed., 1960, Type localities project unit 1: Baton Rouge, La., Soc. Econ Paleontologists and Mineralogists, Gulf Coast Sec., p. [14–15]. Middle Paleocene.

Type locality: Series of outcrops along State Highway 174 starting at city limits of Converse, 0.55 mile west of K.C.S. Railroad crossing and extending westward for a distance of 1.7 miles. This includes three major outcrops in secs. 8 and 9, T. 9 N., R. 13 W., Sabine Parish.

Conway Formation

Conway Schist[1]

Ordovician and Silurian(?): Western Massachusetts, southwestern New Hampshire, and southeastern Vermont.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, Mon. 29, p. 183–225.

M. E. Willard, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–85. Redefined as a formation containing four lithologic members, in order of decreasing age: schist-quartzite, schist-marble, amphibolite, and phyllite members. Detailed lithologic descriptions. Ordovician and Silurian(?).

Named for development along the rivers in Conway and Deerfield, Franklin County, Mass.

Conway Granite[1] (in White Mountain Plutonic-Volcanic Series)

Mississippian(?): Northern and central New Hampshire.

Original references: C. H. Hitchcock, 1874, The geology of New Hampshire, pt. 1, p. 508–545; 1877, pt. 2, p. 142–143.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Belongs to White Mountain plutonic-volcanic series of Mississippian(?) age.

Named for town of Conway, Carroll County.

Conway Cut Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 169–170, pl. 15. Massive siltstone 75 feet thick. Basal member of Brodhead formation, Irvine facies (new). Underlies Combs Mountain siltstone member (new); overlies New Providence formation, Boone Gap facies (new).

Name derived from Conway Cut of Louisville and Nashville Railroad, just south of Conway, northern Rockcastle County. Unit is well exposed at Boone Gap on Rockcastle-Madison County line, where it forms the cliff rock and hillside above cut for U.S. Highway 25.

Cooda Sandstone

See Coody Sandstone.

Coody Sandstone Member (of Atoka Formation)[1]

Middle Pennsylvanian: Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 27–28. Basal member of Atoka formation. Thickness 15 to 115 feet. Separated from overlying Pope Chapel sandstone member by unnamed shale 35 to 72 feet thick. Unconformable with underlying Morrow group.

Named for exposures along Coody (Coata) Creek in secs. 34 and 35, T. 15 N., R. 19 E., Muskogee County.

Cooke Grainite[1]

Precambrian: Central southern Montana.

Original reference: T. S. Lovering, 1930, U.S. Geol. Survey Bull. 811–A, p. 17.

W. H. Parsons and E. L. Bryden, 1952, Michigan Acad. Sci., Arts and Letters, Papers, v. 37, p. 253. Cited as Cooke City granite, a pinkish rock with no gneissic structure.

Well exposed near Cooke in southeastern corner of Park County.

Cooke City Granite

See **Cooke Granite.**

Cook Inlet Gravels[1]

Pleistocene: Central southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 174–175.

Extends from Cook Inlet along drainage basin of Skwentna River as far as Tordrillo Mountain, Cook Inlet region.

Cook Mountain Formation (in Claiborne Group)[1]

Eocene, middle: Southern and eastern Texas, northwestern Louisiana, and eastern Mississippi.

Original reference: W. Kennedy, 1892, Texas Geol. Survey 3d Ann. Rept., p. 54–57.

J. Huner, Jr., 1939, Louisiana Geol. Survey Bull. 15, p. 84–110. In Caldwell and Winn Parishes, La., divided into (ascending) Dodson (new), Milams, Saline Bayou, and Little Natches (new) members. Thickness 99 to 185 feet. Overlies Sparta sand; underlies Cockfield formation.

H. B. Stenzel, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 9, p. 1663–1675. Cook Mountain formation replaces term Crockett formation. Name Cook Mountain believed to be preferable because of more extensive usage in Texas and Louisiana. Wheelock marl, Landrum shale, Spiller sand, and Mount Tabor shale, previously defined as members of Crockett, are here reallocated to Cook Mountain formation.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 261–263. In south Texas, divided into (ascending) Garceno sandstone, Veleno, and Falcon sandstone members (all new). Thickness 1,700 feet. Overlies Mount Selman formation; underlies La Perla shale member (new) of Yegua formation.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. As mapped, overlies Sparta sand and underlies Cockfield formation.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart shows that Cook Mountain in Mississippi includes (ascending) Archusa marl, Potterchitto sand, and Gordon Creek shale members. Overlies Sparta sand; underlies Cockfield formation. Mississippi

Geological Survey uses Wautubbee formation instead of Cook Mountain and Kosciusko sand instead of Sparta sand.

Named for Cook Mountain, Houston County, Tex.

Cook Ranch Formation[1]

Oligocene, middle: Southwestern Montana.

Original reference: A. E. Wood, 1933, Jour. Mammalogy, v. 14, no. 2, p. 134–135.

Jean Hough, 1955, Jour. Paleontology, v. 29, no. 1, p. 26–28. Cook Ranch formation of Wood is included in Sage Creek formation as redefined in this paper.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 373, 374, pl. 1. Rhyolitic lava flows and volcanic tuff and breccia associated with Cook Ranch formation are here named Cook Ranch rhyolites and Cook Ranch volcanics, respectively.

First described from locality near Cook Sheep Co., Home Ranch, 8.1 miles north and east of Dell Railroad station, T. 12 S., R. 33 E., secs. 27 and 34, Beaverhead County.

Cook Ranch Rhyolites

Oligocene, middle: Southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 373, pl. 1. Pink and buff rhyolitic lava flows that are intercalated between pyroclastic deposits that have been correlated with the Cook Ranch formation.

Exposed on the southwest side of the Blacktail Range, Beaverhead County.

Cook Ranch Volcanics

Oligocene, middle: Southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 374, pl. 1. Named for beds of volcanic tuff and white acidic volcanic breccia associated with sediments of Cook Ranch formation. Some volcanic ash present at type locality. Northward, the ash content increases, and the formation grades into interbedded tuffs, volcanic breccias, and agglomerates at the foot, on the slopes, and near the crest of the Blacktail Range.

Type locality: At south end of Red Rock Mountains. [The compiler notes that the unit is not mapped at the south end of Red Rock Mountains but that it is mapped around the southern end of the Blacktail Range]. These rocks probably once covered entire southeastern end of the Blacktail Range, Beaverhead County.

Cooks Canyon Agglomerate[1]

Upper Jurassic: Northern California.

Original reference: C. H. Crickmay, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 81.

Type locality: Ridge between Cooks Canyon and Lights Creek, Mount Jura.

Cooks Peak Granodiorite Porphyry

Tertiary: Southwestern New Mexico.

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, pl. 1. Name appears on explanation of map.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38

p. 39. Described as porphyritic andesine and green hornblende partly altered to biotite and chlorite. Groundmass consists of andesine, quartz, orthoclase, and magnetite. Younger than Colorado shale and older than Rubio Peak volcanic rocks.

Mapped on flanks of Cooks Peak, Cooks Range, Lake Valley quadrangle.

Cool Creek Formation[1] (in Arbuckle Group)

Lower Ordovician: Southern Oklahoma.

Original reference: E. O. Ulrich, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 105.

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55, 56. Included in Arbuckle group. Occurs above Wolf Creek dolomite and below Alden limestone.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 25, measured sections; 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1319–1320, table 1. Consists primarily of thin beds of limestone, some of which are shaly and sandy. Thickness 1,513 to 1,687 feet in Arbuckles; 1,015 feet in Wichitas. Underlies Kindblade formation (new). Overlies Strange formation (new) or where Strange is absent, the McKenzie Hill. Type locality and derivation of name given.

Type section: Sec. 18, T. 2 S., R. 2 E., along U.S. Highway 77 about 4 miles north of Springer. Named for Cool Creek, headwaters of which flow across the formation about 6 miles north of Springer, Carter County.

Cooledge Chalk[1]

Upper Cretaceous: Eastern Texas.

Original reference: J. A. Waters and W. A. Reiter, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, p. 322–323.

Well exposed 3 miles northwest of Cooledge, on main road to Hubbard, Limestone County.

Coombs Limestone Member (of Islesboro Formation)[1]

Cambrian(?): Central southern Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 2–3.

H. W. Allen, 1951, Maine State Geologist Rept. 1949–1950, p. 79. Sequence of metamorphosed sedimentary rocks in area of Rockland quadrangle, Knox County, is (ascending) Islesboro formation containing Coombs limestone member at top; Battie quartzite; Penobscot formation; and Rockland formation consisting of Weskeag quartzite member at base, a siliceous limestone member above the quartzite, and Rockport limestone member at top.

Named for exposures near Coombs Point, on northeastern shore of Islesboro, Waldo County.

Coon Creek Tongue (of Ripley Formation)[1]

Upper Cretaceous: Western Tennessee and northern Mississippi.

Original reference: B. Wade, 1917, Johns Hopkins Univ. Circ., new ser., Whole No. 293, p. 74, 101.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Correlation chart shows Coon Creek tongue as occurring in Tennessee and Mississippi.

N. F. Sohl, 1960, U.S. Geol. Survey Prof. Paper 331–A, p. 13–15. Wade (1917) recognized two divisions of Ripley formation below McNairy sand member in southern Tennessee: "Ferruginous clay horizon" immediately below the NcNairy and a "Coon Creek horizon" immediately above the Selma chalk. Wade (1926 U.S. Geol. Survey Prof. Paper 137) lumped these two horizons into Coon Creek tongue. Wade stated that Coon Creek tongue thinned northward but was recognizable at Kentucky line and that the ferruginous clay merged north into the McNairy. Whitlach (1940, Tennessee Div. Geology Bull. 49) misinterpreted this statement and assumed Wade to mean the whole of the Coon Creek was lost northward. The ferruginous clay appears to be merely a transition zone between typical Coon Creek tongue and McNairy sand member and, as treated in this report, is included in McNairy sand from which it becomes indistinguishable both to the north and to the south. At type locality Coon Creek tongue is typified by massive dark- to bluish-gray micaceous glauconitic calcareous fossiliferous silty sand beds which some authors have called "marls." Lower part of unit is gradational into transitional clay in lower part of Ripley and thin interbeds of sand and sandy clay are common. At top of tongue, generally unfossiliferous noncalcareous thin-bedded sand is common. Coon Creek varies in age along outcrop belt; at type locality, sand contains *Exogyra cancellata* Stephenson; in Mississippi, a few miles south of State line, member lies entirely above that zone. Sand of Coon Creek grades upward through thinner bedded lighter colored sand and clay beds into McNairy sand member. Thickness as much as 60 feet.

Named for exposures along Coon Creek, McNairy County, Tenn.

Coonewah Bed (in Annona Chalk)

Upper Cretaceous: Northern Mississippi.

F. F. Mellen, 1958, Mississippi Geol. Survey Bull. 85, p. 29-40. Name applied to a 2-foot bed of relatively pure chalk near top of the Annona.

Type locality: West valley wall of Coonewah Creek approximately at the SE cor. SW¼ sec. 22, T. 10 S., R. 5 E., Lee County, 2½ miles west of Verona.

Cooney Quartz Latite[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures in canyon of Mineral Creek near old mining camp of Cooney, Mogollon district.

Coon Mountain Sandstone Member (of Pueblo Formation)[1]

Coon Mountain Sandstone Member (of Stockwether Formation)

Permian (Wolfcamp Series): Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 417.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to Stockwether, which is here given formational status in Pueblo group (redefined) and assigned to the Permian.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 75, 76. Member of Pueblo formation in report on Brown and Coleman Counties where it is placed above Camp Creek shale member and below Stockwether limestone member. In northern Brown County, extensive channel erosion has removed Saddle Creek limestone member in many places, especially over wide area on Coon Mountain. In places, channel erosion has cut down to within about 50 feet of Chaffin limestone member of Thrifty formation. The sandstone and conglomerate deposited in these channels was called Coon Mountain bed by Drake (1893). Plummer and Moore (1921, Texas Univ. Bull. 2132) considered it of Cretaceous age. As the unit was not extensively exposed in area mapped by Moore (1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80), he did not use the name. Exact relations of Coon Mountain sandstone member to beds surrounding it are only partially known. The thick body may be a complex of two or more channels, the later one or ones superposed on the earlier in the outcrop area. The member is tentatively placed in the section where Drake placed it until future detailed work explains its relations more exactly.

Named for Coon Mountain, Brown County.

Cooper Limestone[1]

Middle Devonian: Central and northeastern Missouri.

Original reference: G. C. Swallow, 1855, Missouri Geol. Survey 2d Ann. Rept., pt. 1, p. 108, 196.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 136–138. Thickness as much as 30 feet, rarely more than 20; average less than 15. Formation not continuous but represents erosional remnants. Unconformable on Jefferson City over most of its extent in central Missouri, though locally rests on St. Peter sandstone; in northeastern Missouri, unconformable on Kimmswick and Maquoketa and locally unconformable below Ashland formation; unconformably underlies Callaway limestone in Boone and Cooper Counties but westward it is unconformable below Bushberg sandstone.

Named for exposures in Cooper County.

Cooper Marl[1]

Oligocene: Eastern South Carolina and eastern Georgia.

Original reference: M. Tuomey, 1848, South Carolina Agr. Survey 1st Rept., p. 162–169, 190, 211.

C. W. Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 40 (chart), 74–76. Geographically extended into Georgia where thickness is about 33 feet. Thickness in South Carolina 76 feet. Unconformably underlies Flint River formation; overlies Ocala formation with apparent conformity; contact with Barnwell formation not observed, but presumably is younger than Sandersville member (new) and perhaps conformable with it.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Shown on correlation chart in upper part of Jackson group in Georgia. Eocene.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 27–28. Cooper marl, currently referred to late Eocene (Jackson), is reassigned to early Oligocene(?) on basis of its mollusks, foraminifers, and cetaceans. In some areas, unconformably overlies Castle Hayne limestone.

L. N. Smith and H. S. Johnson, 1958, Carolina Geol. Soc. Guidebook, p. [5]. Shown on correlation chart as Eocene (Jackson).

H. E. Malde, 1959, U.S. Geol. Survey Bull. 1079, p. 7–26, pl. 1. Cooper marl, oldest exposed formation in Charleston phosphate area, South

Carolina, is a soft, very fine grained, impure carbonate deposit. Dips southward from 8 to 14 feet per mile and overlies beds of Eocene age upturned on the north. Thickness 200 feet near Charleston; thins and pinches out 20 miles north; thickens southwestward to at least 280 feet. Unconformably underlies Ladson formation (new); in other areas, underlies Duplin marl, unnamed lower Miocene(?) sandy limestone, or Hawthorn(?) formation. Paleontologic evidence indicates that Cooper marl is of Oligocene age, basal beds exposed inland at Harleyville being early Oligocene and higher beds nearer the coast late Oligocene.

Named for exposures along Cooper River, S.C.

Cooper Creek Limestone (in Henrietta Group)

Cooper Creek Limestone (in Marmaton Group)

Pennsylvanian (Des Moines Series): Iowa and northern Missouri.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 27 (fig. 2), 62, 65, 69. Proposed for Bain's (1896, Iowa Geol. Survey, v. 5) "Floating rock." Consists of light-gray fragmental nodular limestone admixed with green clay; algal. Separated from underlying Worland limestone and overlying Exline limestone (new) by intervals containing clay and shale. Thickness 2 to 4 feet in Appanoose County, Iowa. Not well developed in Putnam County, Mo., and, if present, represented only by nodular limestone. Included in Henrietta group.

W. B. Howe, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 9, p. 14. Sni Mills limestone is correlated with Cooper Creek limestone of southern Iowa on basis of lithologic similarity and position in stratigraphic succession. Cooper Creek (in Marmaton group) has been correlated with Lonsdale limestone of western Illinois. These correlations extend recognition of upper member of Lenapah (Sni Mills limestone) into Iowa and probably Illinois. Name Sni Mills has priority over Cooper Creek, and name Cooper Creek should be suppressed.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 30, fig. 5. Lenapah limestone is represented in Iowa by Cooper Creek limestone (Sni Mills in Missouri). Thickness 3 to 5 feet, Madison County; 7 feet, Appanoose County.

Named for occurrence along tributary ravines of Cooper Creek, in pastures in vicinity of Centerville, Appanoose County, Iowa.

Cooper Peak Dolomite

Lower Devonian: Northeastern Nevada.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 35–36, pl. 1. Name applied to dolomite in Cooper Peak structural unit in Roberts Mountains. Similar to dolomites of Lone Mountain formation. At Cooper Peak, light-gray dolomites are thrust over lower Nevada formation along Cooper Peak thrust. No fossils found at Cooper Peak, but 2½ miles west in same ridge a well-preserved fauna indicates Lower Devonian age, not far from Oriskany stage, but possibly as old as Helderberg.

Roberts Mountains, Eureka County.

Coopers Lake Limestone Member[1] (of Jefferson Limestone)

Upper Devonian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 43.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4 (facing p. 1788). Correlation chart shows age as Upper Devonian.

Type locality: On southeast slope of southwestern peak of White Ridge, in SW¼ sec. 16, T. 22 N., R. 11 W. Named for the fact that it forms a large part of Jefferson limestone over northeastern part of Coopers Lake quadrangle, especially in Powell County.

Coos Conglomerate[1]

Coos Conglomerate Lentil (in Empire Formation)

Pliocene, lower: Southwestern Oregon.

Original reference: W. H. Dall, 1897, U.S. Geol. Survey 18th Rept., pt. 2, p. 336–343.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, chart 11. Coos conglomerate considered a lens in Empire formation.

Exposed at Fossil Point, Coos Bay region, Coos County.

Coos Group[1] or Quartzite[1]

Paleozoic(?): Northern New Hampshire.

Original reference: C. H. Hitchcock, 1870, 2d Ann. Rept. Geol. and Min. New Hampshire, p. 34, map.

Extends over large part of Coos County and southwestward across western part of New Hampshire to Massachusetts line.

†Coosa Shale[1]

Middle and Upper Cambrian: Western Georgia and eastern Alabama.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. on Cahaba coal field, p. 148, map, structure sec. facing p. 162.

Named for Coosa Valley, between Rome, Ga., and Gadsden, Ala.

†Coosa Valley[1] (Shales and Sandstones)

Lower, Middle, and Upper Cambrian: Eastern Alabama.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–1888, geog. map of Alabama.

Named for Coosa Valley.

Copake Limestone[1]

Lower Ordovician: Southeastern New York.

Original reference: J. D. Dana, 1879, Am. Jour. Sci., 3d, v. 1, p. 376–383.

J. D. Weaver, 1957, Geol. Soc. America Bull., v. 68, no. 6, p. 734–736, pl. 1. Described in area of type section. Owing to structural complexity and to absence of diagnostic fossils, accurate stratigraphic definition of term is difficult, but Copake limestone may be defined as series of dolomitic limestones with about 90 feet of irregularly crossbedded sandy dolomites at its base and containing worm borings and a planispiral gastropod resembling *Ophileta*. Thickness at type section 212 feet; top not exposed. Younger than Pine Plains formation.

Type section: On southern end of Tom Hill, northeast of Copake, Columbia County. Upper part of section is well exposed in small quarry near junction of Route 22 and road leading to town; base of section is in a series of small cliffs about 500 feet west of main quarry.

†Copan Formation[1]

Pennsylvanian: Northeastern and central Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 29.

Named for Copan, Washington County.

Copco Basalts

Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 48. Name applied to basalts erupted in vicinity of present Copco Lake. Basalts are characterized by abundant clusters of large olivine and plagioclase crystals. Otherwise essentially similar to Plutos Cave, Butte Creek, and Butte Valley basalts (all new).

Copco Lake is in northwestern part of Macdoel quadrangle, Siskiyou County.

Copeland Formation

Age not stated: Eastern Maine.

L. A. Wing, 1957, Maine Geol. Survey GP. and G. Survey 1, sheet 1. Whitish gray muscovite quartz schist with interbedded quartzite; locally may contain minor biotite and chlorite. Name credited to J. M. Trefethen (1950, Preliminary map of Bucksport area, Maine: Maine Univ.). [Compiler was unable to locate this reference.]

Report covers parts of Hancock and Penobscot Counties.

Copenhagen Formation

Middle Ordovician: Northeastern Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 28. Overlies Antelope Valley limestone (new) in Antelope Valley, Nev. Name credited to C. W. Merriam (unpub. ms.).

G. W. Webb, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2339–2340. Underlies Eureka quartzite. Thickness about 600 feet; no completely exposed section found. Localities and fossils noted.

Probably named for occurrence in Copenhagen Canyon, in Monitor Range, Eureka County. Well exposed on west face of Antelope Range, across valley and on the east, and about seven-eighths of a mile south of Eureka County line.

Coplay Limestone[1]

Lower and Middle Ordovician: Southeastern Pennsylvania.

Original reference: E. T. Wherry, 1909, Science, new ser., v. 30, p. 416.

Bradford Willard, 1958, Pennsylvania Acad. Sci., v. 32, p. 177, 179–182. Proposed to reinstate Coplay formation for Lower and lower Middle Ordovician beds between Upper Cambrian Allentown and Middle Ordovician Jacksonburg formations. Name Beekmantown, as applied to these beds, is inappropriate because of lack of correlation with type Beekmantown and because of presence of post-Beekmantown fossils. Coplay is a high-magnesium carbonate rock; colors vary through blue, medium to light gray, rarely dark gray, black or pinkish; beds range from dense through arenaceous; many strata are crystalline or marbloid; commonly massive bedded. No known section is complete; at type locality, calculated thickness about 1,500 feet.

Type locality: Along west bank of Lehigh River in vicinity of towns of Coplay and West Catasauqua, Lehigh County. Formation crosses central Northampton and Lehigh Counties in broad east-west belt which separates underlying Allentown (south) from overlying Jacksonburg (north).

Copley Greenstone

Copley Meta-Andesite[1]

Copley Metavolcanics

Devonian(?): Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Survey Geol. Atlas, Folio 138.

A. R. Kinkel, Jr., and J. P. Albers, 1951, California Div. Mines Spec. Rept. 14, p. 4. Named Copley meta-andesite by Diller (1906) unit is renamed Copley greenstone because it is a greenish metamorphosed rock in which primary ferromagnesian minerals have been altered to chlorite and epidote.

A. R. Kinkel, Jr., W. E. Hall, and J. P. Albers, 1956, U.S. Geol. Survey Prof. Paper 285, p. 1, 9–17, pl. 1. Composed of volcanic flows, volcanic breccia, and tuff of intermediate and basic composition, and a few beds of shale and rhyolitic tuff; lower part of formation contains massive flows, and upper part contains much pillow lava and pyroclastic material. Thickness at least 3,700 feet; base not exposed in mapped area (Shasta County). Conformably underlies Balaklala and in some areas interfingers with it.

I. E. Klein, 1960, Sacramento Geol. Soc. [Guidebook] Field Trip June 3, 4, and 5, p. 11. Intruded by Mule Mountain granite (new).

Named for occurrence in vicinity of Copley, Redding quadrangle.

Copperas Creek Sandstone Member (of Carbondale Formation)

Copperas Creek Sandstone (in McLeansboro Group)

Copperas Creek Shale and Sandstone (in McLeansboro Formation)[1]

Pennsylvanian: Western and central Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 112, 114, 194. Savage applied name Copperas Creek to shale and overlying sandstone; Copperas Creek is herein restricted to the sandstone unit, and name Sheffield applied to the shale. The sandstone is light olive green to brownish gray; commonly has brown limonitic specks, is massive and locally, crossbedded; and has channel and nonchannel phases. Thickness 3 to 27 feet; it is thickest where it cuts out Sheffield shale, Brereton limestone, and dark shale and rests directly on Herrin (No. 6) coal. Included in Sparland cyclothem, near base. McLeansboro group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 48 (table 1), 65, pl. 1. Reallocated to member status in Carbondale formation (redefined). Stratigraphically below Danville (No. 7) coal member and above Pokeberry limestone member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Along Copperas Creek, Glasford quadrangle, Fulton County.

Copper Belle Monzonite Porphyry

Triassic or Jurassic: Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 60–63, pl. 5. Hand specimens of the monozonite porphyry differ greatly owing to diversity of metamorphism. Ranges from light gray through buff to dark greenish gray, or even uniform pink; texture, however, remains remarkably constant in all varieties, being characterized by conspicuous phenocrysts of feldspar (1 to 10 millimeters in length). Groundmass everywhere clearly crystalline but aphanitic. Most exposed bedrock contacts are with Escabrosa limestone. All exposed contacts in Gleeson district are faults.

Named for exposures on and near the Copper Belle claim, on west slope of Gleeson Ridge in Gleeson district, central Cochise County. Outcrops form nearly complete elliptical ring on lower slopes of Gleeson Ridge. Smaller outcrops in alluvial areas to east and northeast, and considerable body exposed in Courtland district near and east of abandoned post office. Other smaller bodies exposed in the county.

Copper City Flow (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Persistent lava flow of exceptional thickness, about 500 feet. Overlies St. Louis conglomerate.

J. C. Wright and H. R. Cornwall, 1954, Bedrock geology of the Bruneau Creek quadrangle, Michigan: U.S. Geol. Survey Geol. Quad. Map [GQ–35]. Ophitic basalt flow with numerous pegmatitic layers in the upper half in Bruneau Creek quadrangle.

Mapped in vicinity of Copper City, Ahmeek quadrangle, Houghton County.

Cooper Creek Beds[1]

Precambrian (upper Keweenawan): Northwestern Wisconsin.

Original reference: F. T. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 42, 43, 44, 67.

Named for exposures on Copper Creek, Douglas County.

Copper Creek Member (of Muldoon Formation)

Lower Mississippian: Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Basal member of formation consisting of clastics. Thickness 860 feet. Underlies Garfield member (new); overlies Milligen formation.

Deposited in Muldoon trough, aligned N. 30° W.

Copper Harbor Conglomerate

Copper Harbor Group[1]

Precambrian (upper Keweenawan): Northwestern Michigan.

Original reference: A. C. Lane and A. E. Seaman, 1907, Jour. Geology, v. 15, p. 680, 690.

W. S. White, 1952, Jour. Sed. Petrology, v. 22, no. 4, p. 190. Conglomerate about 4,000 feet thick; contains a few lava flows. Overlies newly defined Portage Lake lava series; underlies younger shales and sandstones of the Keweenawan series.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ-27 [1954]. Red to brown boulder conglomerate with subordinate amounts of pebble conglomerate and beds of coarse arkosic sandstone; most of the detrital material is rhyolitic in composition; three units of mafic flows distinguished. Underlies Nonesuch shale. Designated as upper Keweenawan.

Named for exposures around Copper Harbor, Keweenaw County.

Copperhill Formation (in Great Smoky Group)

Precambrian: Southeastern Tennessee, central northern Georgia, and southwestern North Carolina.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 9–21, pl. 1, map. Consists of massive beds of metagraywacke or biotite gneiss, mica schist, metaconglomerate, micaceous quartzite, metaarkose, and occasional dark slates: includes epidote-amphibolite sill. Estimated thickness 2,000 to 5,000 feet; base not exposed. Underlies Hughes Gap formation (new), transition zone a few hundred feet thick.

Named after town of Copperhill, Polk County, Tenn., in vicinity of which formation is well exposed.

Copper Mountain Greenstone or Amphibolite Schist[1]

Age(?): Southeastern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 414–415.

Copper Mountain, Prince William Sound region.

†Copper Mountain Porphyry[1]

Eocene: Colorado.

Original reference: S. F. Emmons, 1898, U.S. Geol. Survey Geol. Atlas, Spec. Folio 48.

On Copper Mountain, Tenmile district.

Copper Queen Limestone[1]

Upper Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 469–471, 480–482.

F. W. Galbraith and W. B. Loring, 1951, Arizona Bur. Mines Bull. 158, Geol. Ser. 19, p. 30. Thickness in Swisshelm district 175 feet.

Named for Copper Queen mining area of Bisbee, where it is a good horizon.

Copper Ridge Dolomite[1] (in Knox Group)

Upper Cambrian: Eastern Tennessee, Alabama, northwestern Georgia, and southwestern Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 548, 635–636, pl. 27.

C. R. L. Oder, 1934, Jour. Geology, v. 42, no. 5, p. 476–479. Discussion of subdivision of Knox dolomite in east Tennessee. Conococheague-Copper Ridge formation, which overlies Maynardville limestone (new), is subdivided into Morristown dolomite and Bloomingdale limestone members (both new).

Charles Butts, 1940, U.S. Geol. Survey Geol. Atlas, Folio 226. Described in Montevallo-Columbiana quadrangles, Alabama, where it is 1,750 feet thick, overlies Ketona dolomite (Bibb dolomite absent in this area), and underlies Chepultepec dolomite.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 90–95. Copper Ridge overlies Nolichucky shale and extends upward to Chepultepec limestone. Northwest of Greendale syncline, Washington County, the Copper Ridge and Beekmantown form continuous vertical mass 2,400 feet thick with no recognizable break between them. Occurrence of Chepultepec fossils at or very near middle of similar section in Tennessee, 3½ miles southeast of Cumberland Gap, proves mass is about equally Copper Ridge and Beekmantown. Equivalent to Conococheague.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76; R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 17–20, pl. 1, geol. sections. Basal formation of Knox group. In Lee County, Va., underlies Chepultepec dolomite; overlies Chances Branch dolomite member (new) of Maynardville limestone. Thickness 840 feet. Upper Cambrian.

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 3, 14–19. Stratigraphic section at Lee Valley, Hawkins County. This section is compared with Thorn Hill section (which includes type locality of Copper Ridge) as measured by Hall and Amick (1934, Tennessee Acad. Sci. Jour., v. 9). Thickness of Copper Ridge 925 feet. Underlies Chepultepec dolomite; overlies Maynardville member of Nolichucky shale.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 227, p. 25–29, chart 1, pl. 1. Described in Mascot-Jefferson City zinc district, Tennessee, where it is 943 feet thick; overlies Maynardville limestone member of Nolichucky shale and underlies Chepultepec dolomite. As thus defined, the formation in the type section is specifically units 203 to 304 of Hall and Amick's (1934) section. Unit could be logically divided into two members: a thick lower member composed mainly of dark thick-bedded cherty dolomite and an upper member consisting of light-colored thinner bedded dolomite, also chert-bearing and containing many arenaceous beds. If such a division were made, break would come within unit 282 in Thorn Hill section and at base of unit 148 in Lee Valley section (Rodgers and Kent, 1948). Oder (1934) divided Copper Ridge into two members, Morristown and Bloomingdale. Oder's Morristown seems to correspond approximately to entire Copper Ridge as here delimited. Bloomingdale member is now thought to belong to lower part of Chepultepec dolomite as now recognized. Copper Ridge is dolomite in type area, and this dolomitic phase extends along western side of Appalachian Valley in East Tennessee and southeastward into and across Mascot-Jefferson City district. To southeast of this area, beds of limestone wedge into section and on eastern side of Appalachian Valley, particularly in belts southeast of Bays Mountain syncline, entire formation is slightly magnesian limestone. This limestone extends northeastward along eastern side of Appalachian Valley into Virginia, and in the central and northern parts of that State it extends progressively into western belts as well until, in northern Virginia, Maryland, and southern Pennsylvania, the limestone phase extends almost entirely across the Appalachian Valley. This limestone facies is commonly known as Conococheague limestone. and that name has been extended from Pennsylvania into Virginia and Tennessee. Ulrich recognized presence of Conococheague limestone in these areas but contended it was older than Copper Ridge dolomite and that it thinned westward and was overlapped unconformably by the Copper Ridge. Historical summary of usage of name and notes on type locality. Ulrich proposed term Copper Ridge chert for his second division of Knox dolomite of eastern Tennessee and southwestern Virginia. Name was taken from Copper Ridge, the long, narrow, monoclinal ridge at northwest base of Clinch Mountain, recognizable as distinct topographic feature from Russell County, Va., to a few miles west of Knoxville. East of gap at Speers Ferry, Va., where Troublesome Creek cuts through ridge to join Clinch River, the ridge is known as Moccasin Ridge, and name Copper Ridge is transferred to next structural belt to northwest (see Estillville 30 minute quadrangle and Clinchport and Duffield 7½-minute quadrangles). Type locality is along "the road from Bean Station to Evans Ferry, on Clinch River" (Ulrich, 1911, p. 636), now U.S. Highway 25-E. It is shown on Morristown folio (Keith, 1896) and on Avondale 7½-minute quadrangle sheet of TVA series. Wilmarth, 1938 (U.S. Geol. Survey Bull. 896) states formation was "named for Copper Ridge, northeast of Knoxville, Tenn.," and Resser (1938, Geol. Soc. America Bull. Spec. Paper 15) says that "type locality for Copper Ridge formation is on Copper Ridge, Knox County, Tenn., (Ulrich, 1911)." Cooper (1944, Virginia Geol. Survey Bull. 60) makes similar statement. The only section of formation on Copper Ridge mentioned by Ulrich in his original description is the one in Grainger County, discussed in this report. Ulrich stated to writer [Bridge] on several occasions that this is section to which he was referring in the "Revision" and that he regarded it as type section.

Type locality (Butts. 1940): Gorge of Forked Deer Creek through Copper Ridge, 1 mile northwest of Thorn Hill, Grainger County, Tenn., and 13 miles northwest of Morristown.

Type locality (Bridge, 1956): Along road from Bean Station to Evans Ferry, on Clinch River (Ulrich, 1911), now U.S. Highway 25-E. This locality is now submerged by Cherokee Lake, and Bean Station is a new location, more than 1 mile to the west.

Ulrich (1911, p. 635, 636) states "The resistant character and finally great abundance of this chert [Copper Ridge] almost invariably gives rise to broad and long ridges, among which that known as Copper Ridge, in northeast Tennessee, is the excellent example chosen to supply the name and type of the member or formation. The road from Beans Station to Evans Ferry, on Clinch River (see Morristown quadrangle), follows Indian Creek, where it cuts through Copper Ridge, Tenn."

Copper River Silts and Gravels[1]

Pleistocene: Southeastern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 410-412.

Along Copper River above Taral and on tributaries of that part of river, Copper River region.

Copps Formation

Copps Group[1]

Precambrian: Northwestern Wisconsin and northwestern Michigan.

Original reference: R. C. Allen and L. P. Barrett, 1915, Jour. Geology, v. 23, p. 697.

G. I. Atwater, 1938, Geol. Soc. America Bull., v. 49, no. 2, p. 171-179. Referred to as a formation made up of graywacke and gray slate with Copps conglomerate at base.

Named for Copps mine, sec. 15, T. 47 N., R. 43 W., Wisconsin.

Coqui Limestone[1]

Age(?): Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 29.

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 322. Berkey suggested name for limestone occurring near Coqui, but term has not been used since.

Coquille Formation

Pleistocene: Southwestern Oregon.

E. M. Baldwin, 1945, Jour. Geology, v. 53, no. 1, p. 39–42. Name proposed for estuarine deposits which unconformably underlie Elk River beds (restricted) just north of mount of Coquille River. Formation consists of conglomerate, sand, and thin-bedded sandy clay; stumps, logs, peat, and other woody material common. Total exposed thickness probably more than 200 feet; measured section 93 feet; dip as high as 25°. At mouth of Whiskey Run, the Coquille unconformably overlies Umpqua formation and unconformably underlies Elk River beds.

P. D. Snavely, Jr., and H. E. Vokes, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 97. Crops out along sea cliff near Cape Kiwanda where it consists of poorly sorted coarse sand and gravel, together with peat, carbonaceous shale, and clay. Minimum thickness about 30 feet. Rests with angular unconformity upon mudstone of Oligocene age. Also occsurs near Nestucca Bay in a sea cave cut in basaltic sandstone of Nestucca formation (new). Formation is a Pleistocene estuarine fill.

Named for exposures between Whiskey Run and Cut Creek just north of mouth of Coquille River, Coos County.

Coralline Falls Limestone[1]

Devonian: Kentucky.

Original reference: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, p. 95–97.

Coral Ridge Member (of New Providence Formation)

Lower Mississsippian: Northern Kentucky and southern Indiana.

J. E. Conkin, 1957, Bulls. Am. Paleontology, v. 38, no. 168, p. 114–116, 119–120, 152. Basal member of New Providence formation, Silver Hills facies. Divisible into two parts, lower and upper, on basis of fauna. Consists largely of green- to blue-gray shales; ironstone lenses, ironstone cone-in-cones, and ironstone nodules common in upper part but virtually lacking in lower part. Thickness as much as 52 feet. Underlies Button Mold Knob member (new); overlies Underwood-Falling Run formations.

Type locality: East quarry of Coral Ridge Brick and Tile Co., Coral Ridge, Jefferson County, Ky. Base not exposed at type section.

Coralville Limestone[1]

Coralville Limestone Member (of Cedar Valley Formation)

Upper Devonian: Central eastern Iowa.

Original references: C. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 149; 1913, Iowa Acad. Sci. Proc., v. 20, p. 205, 206.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1751, chart 4. Shown on correlation chart as uppermost member of Cedar Valley formation. Overlies Rapid limestone member. Correlated with Callaway limestone of Missouri. Middle Devonian. Age of entire Cedar Valley is difficult to establish, and dating of some of its parts presents problems.

M. A. Stainbrook, 1944, Illinois Geol. Survey Bull. 68, p. 182 (chart), 185. Three members of the Cedar Valley are recognized: Linwood, Littleton, and Coralville.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 157. Independence shale is stratigraphically below the Cedar Valley and above the Wapsipinicon. The Independence by its fossils is lower Upper Devonian; hence, the Cedar Valley is Upper Devonian in age and post-Independence.

Typically exposed in quarries about 1 mile northeast of Coralville, Johnson County.

Corbett Sandstone (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 533–534, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 23–24, pl. 1. Chiefly sandstone, in part quartzitic and massive, and variably black, brown, and white in color. Ripple marks and crossbedding common. In part, the formation contains beds of shale that alternate with the sand and range from 1 to 15 feet in thickness. Includes several limestone members in eastern part of Eureka section. Thickness is 4,000 feet in Sylvanite section, where full original thickness is present, and ranges from 1,500 to 3,000 feet in Eureka section. Disconformably underlies Playas Peak formation (new) and conformably overlies Howells Ridge formation (new). Trinity age.

Named from Corbett Ranch at Granite Pass, Sylvanite district, in Little Hatchet Mountains.

Corbin Conglomerate (in Briceville Formation)

Corbin Conglomerate Lentil[1] or Member (of Lee Formation)

Pennsylvanian: Central Kentucky and northern Tennessee.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 3.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 686, chart 6 (column 18). Corbin conglomerate, prominent in Kentucky, extends into northern Tennessee, where it is included in basal part of Briceville formation.

Named for Corbin, Whitley County, Ky.

Corbin Granite[1]

Precambrian: Northwestern Georgia.

Original reference: C. W. Hayes, 1901, Am. Inst. Mining Engineers Trans., v. 30, p. 406–410.

A. S. Furcron and K. H. Teague, 1947, Georgia Geol. Survey Bull. 53, p. 12–14, pl. 1. Intrudes Cohutta schist and Fort Mountain gneiss.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 277. Corbin granite is exposed southwest of Salem Church granite and just east of the Cartersville overthrust, along which the Corbin granite is sheared to an augen gneiss and some layers to a seritic or graphitic schist; basal beds of Pine Log conglomerate rest on that granite which is brought up in an anticline. Salem Church granite resembles phases of Corbin granite and, because of this similarity, has been called Corbin granite (Furcon and Teague, 1945, Georgia Geol. Survey Bull. 51). The Corbin is here considered a hybrid rock and regarded as part of injection complex that occurs below Hurricane graywacke (new).

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 41. Strongly gneissic aggregate of feldspar, smoky-blue quartz, biotite, augite, and garnet. Intrusive into Talladega series.

Named for development around Corbin, Bartow County.

Corbin City Limestone[1] Member (of Drum Limestone)

Pennsylvanian (Missouri Series): Eastern Kansas and northwestern Missouri.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guide Book, p. 92, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030; 1949, Kansas Geol. Survey Bull. 83, p. 99–100. Predominantly a crossbedded oolite locally 40 feet or more thick. Disconformably overlies Dewey limestone member; underlies Chanute formation.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37. Type locality stated. Unit absent in Nebraska.

Type locality: Corbin City, 2 miles south of Cherryvale, Montgomery County, Kans.

Corbin Ranch Formation (in Simpson Group)

Middle Ordovician: Southern Oklahoma.

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, p. 7, 55, 94–101, fig. 1. Cooper (1956) subdivided the Bromide into Mountain Lake and overlying Pooleville members. Mountain Lake is essentially Ulrich's Cool Creek; Pooleville appears to be essentially Ulrich's Criner formation plus his Webster (name preempted). Corbin Ranch formation is erected to include topmost Simpson dense limestone (with shale breaks) in stratigraphic position between underlying Bromide Pooleville member and overlying Viola limestone. Appears to be exact equivalent of Edson's (1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf.) unnamed formation of lower Prosser age; it is topmost limestone of Ulrich's Webster; comprises topmost 15 to 20 feet of Cooper's Pooleville member. Thickness at type locality 19 feet; 24 feet on Colbert Creek, southwest of Davis. Disconformable relationship with underlying Bromide Pooleville and overlying Viola limestone.

Type section: On Carleton W. Corbin Ranch, on west side of Oklahoma Highway 99, 3 miles south of Fittstown, Pontotoc County.

Corcoran Clay Member (of Tulare Formation)

Pliocene, upper, and Pleistocene(?): Southern California (subsurface).

J. W. Frink and Harry A. Kues, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 11, p. 2357–2371. Massive greenish-gray silty clay, highly diatomaceous. Thickness 50 to 120 feet. Lies 200 to 800 feet beneath the surface and extends over an area greater than 4,000 square miles.

U.S. Geological Survey currently classifies the Corcoran Clay as a member of Tulare Formation on the basis of a study now in progress.

Type section: W½ cor. sec. 15, T. 15 S., R. 14 E., U.S. Bureau of Reclamation test hole. Named for town of Corcoran, Kings County, near which it was first recognized.

Corcoran Member (of Price River Formation)

Upper Cretaceous (Montana): Central western Colorado.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 188, 190–191, fig. 2. Unit of littoral marine sandstone and associated coal-bearing rocks which lies above Sego member and is separated from it by thin tongue of Mancos shale with disconformity at its base; underlies Cozzette member (new) and is separated from it by tongue of Mancos shale. Average thickness about 100 feet. At the base, a massive littoral marine sandstone tongue grades downward and eastward into Mancos; first appears near Big Salt Wash and is traceable eastward into Grand Mesa where it disappears; where overlain by coal measures, commonly pure white, and miners call it the "White Pioneer." Series of offshore bar sandstones appears above it near Watson Creek in Grand Mesa and forms eastern limit of the 50 feet or so of coal-bearing rocks. Erdmann (1934, U.S. Geol. Survey Bull. 851) described main coal zone of member as series of overlapping and isolated lenses of coal in thick deposit of carbonaceous shale and called it the Palisade coal. In Neslen facies.

Named from exposures near old Corcoran mine north of Palisade, Mesa County. In Book Cliffs.

Cordell Dolomite or Formation (in Manistique Group)

Cordell Member[1] (of Manistique Formation)

Middle Silurian (Niagaran): Northern Michigan and eastern Wisconsin, and Ontario, Canada.

Original reference: R. B. Newcombe, 1933, Michigan Geol. Survey Pub. 38, p. 23, 37.

R. R. Shrock, 1940, Wisconsin Acad. Sci., Arts, and Letters, Trans., v. 32, p. 207–208, pl. 3. Geographically extended into eastern Wisconsin. Dark-gray thin- and uneven-bedded somewhat saccharoidal dolomite; silicified fossils; chert nodules and lenses common in lower half. Thickness about 45 feet. Overlies Schoolcraft member; underlies Racine dolomite.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 536, chart 3. Cordell dolomite and Schoolcraft dolomite replace term Waukesha in eastern Wisconsin.

G. M. Ehlers, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (chart), p. 19–20, 21–22, 28. Rank raised to formation in Manistique group. Thickness at type section (herein designated) about 77 feet. Overlies Schoolcraft dolomite; underlies Engadine dolomite. Traced from northeastern Wisconsin to region of Owen Sound, Ontario.

Type section: Abandoned quarry of Scott Quarry Co., excavated in north side of outlier of formation in SW¼ sec. 29, T. 44 N., R. 4 W., about 1 mile southeast of Cordell, Chippewa County, Mich.

Cordito Member (of Los Pinos Formation)

Pliocene: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 38, 48–50, pl. 1. Rhyolite-fragment conglomerate, tuff, and sandstone with minor rhyolite flows. Maximum thickness about 600 feet. Unconformably underlies Cisneros (new) and Dorado (new) basalts; disconformably overlies Jarita basalt (new) and Biscara (new) and Biscara-Esquibel (new) members of Los Pinos formation. Name credited to Butler (unpub. dissert.).

Named from exposures in Canyon de Cordito, 4 miles south of Tres Piedras, Las Tablas quadrangle.

Cordova Dolomite

Silurian (Niagaran): Northwestern Illinois and northeastern Iowa.

T. E. Savage, *in* C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 537, chart 3. Proposed for beds formerly called Waukesha dolomite in northwestern Illinois and Iowa. Underlies Port Byron dolomite; overlies Joliet dolomite (restricted).

Well exposed in quarry of U.S. Gypsum Co., 1½ miles south of Cordova, Rock Island Ill.

Corduroy Member (of Supai Formation)

[Permian]: Central Arizona.

R. L. Jackson, 1951, Plateau, v. 24, no. 2, p. 86–88. Uppermost member of Supai in Fossil Creek and Fort Apache areas. Overlies Apache [Fort Apache] member. Name credited to S. S. Winters (unpub. thesis).

Type locality and derivation of name not stated. Winters (1951, Plateau, v. 24, no. 1) described, but did not name, an uppermost member of Supai exposed west of Corduroy Creek, Fort Apache Indian Reservation.

Coriba formation[1]

Miocene: Central northern Oregon and southern Washington.

Original reference: E. T. Hodge, 1931, Geol. Soc. America Bull., v. 42, p. 991, footnote.

Corinth Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Northern West Virginia and western Maryland.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 574.

Named for exposures at east end of cut on Baltimore & Ohio Railroad at Corinth, W. Va.

Cork Hill Gneiss

Precambrian: Northern New Jersey.

J. M. Hague and others, 1956, Geol. Soc. America Bull., v. 67, no. 4, p. 468, 469, fig. 18. Graphitic gneiss, garnet gneiss, and pyroxene gneiss at Mount Eve. Light pyroxene gneiss north of McAfee. Thickness, 500 feet at Glenwood, 1,000 feet at Franklin, 800 feet at Sterling, and 1,900 feet at Limecrest. Underlies Wildcat marble (new); overlies Franklin marble.

In Franklin-Sterling area.

Corliss Conglomerate[1]

Corliss Conglomerate Member (of Morses Line Slate)

Corliss Limestone Breccia

Lower Ordovician: Northwestern Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 377.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1015, 1021, 1045, 1074–1075. Described as a limestone breccia. Name should not be applied to depositional basal breccias in other areas; applicable only at type locality. Thickness about 30 feet. Presumably underlain by Highgate slate and overlain by a dark slate, which may be Grandge formation (new).

A. B. Shaw, 1951, Jour. Paleontology, v. 25, no. 1, p. 98. Corliss breccia abandoned as a formation. Included in Morses Line slate as a local lens.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 553, pl. 1. Member of Morses Line slate. Middle(?) Ordovician.

Type locality: Corliss Ledge, 5 miles northeast of St. Albans, Franklin County.

Corn Creek Limestone (of Placid Formation)

Pennsylvanian (Canyon): North-central Texas.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 51 (columnar section). Incidental mention. Name credited to W. A. Jenkins, Jr. (unpub. thesis).

Section is of Permian rocks along Colorado River.

Cornelia Quartz Monzonite

Tertiary, lower (?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9 p. 15 (table 1), 32–38, pl. 1; 1946, U.S. Geol. Survey Prof. Paper 209, p. 25–33, pl. 3 [1947]. Made up of several varieties of rocks that range from fine-grained equigranular quartz diorite through equigranular quartz monzonite and porphyritic quartz monzonite to aplite and pegmatite. Has dioritic border facies. Contacts between monzonite and diorite nearly everywhere sharp and clean cut and are easier to draw than those between keratophyre and diorite. The equigranular facies of quartz monzonite, which is preponderant, commonly is light pinkish gray but ranges from white, chalky varieties to green-gray rocks. Intrudes Concentrator volcanics (new) in neighborhood of the New Cornelia mine; farther west invades Cardigan gneiss (new), and 1½ miles above Tule well the border facies cuts the Chico Shunie quartz monzonite (new). Unconformably underlies Locomotive fanglomerate (new), Daniels conglomerate (new), and probably the Sneed andesite (new).

Exposed over area of about 6 square miles, embracing much of the Little Ajo Mountains, Ajo quadrangle, Pima County. Most easterly exposure is at southeast end of the New Cornelia mine, south of Ajo.

Cornell Member[1] (of Portage Formation)

Cornell Shale and Sandstone

Upper Devonian: Central New York.

Original reference: Burnett Smith, 1935, New York State Mus. Bull. 300, p. 10, 57–62.

G. A. Cooper and others, 1942, Geols. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown as shale and sandstone; above Sherburne sandstone and below Ithaca shale.

Type locality: On south side of Fall Creek Gorge, not far from Cornell University campus, Ithaca. Named from outcrops at foot of Ithaca Falls near mouth of gorge.

Cornell Ranch Member (of Sycamore Formation)

Mississippian: Central southern Oklahoma.

J. D. Prestridge, 1959, *in* Petroleum Geology of southern Oklahoma, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 158 (fig. 2), 159–161, 163. Comprises up to 80 feet of silty to sandy, clayey, cherty limestones, dolomitic claystones, and dark-gray calcareous clayey shales; at base is a soft green shale, locally pyritic and glauconitic, that lies with apparent conformity on Woodford formation. Above green shale is a series of gray silty, clayey dolomitic limestones that are locally glauconitic. Remainder of member consists of alternating beds of dark-gray calcareous shales and silty, clayey limestones; it is in this sequence that bulk of chert in Sycamore occurs. Underlies Worthey member (new).

Type section: On Cornell Ranch, SE¼SE¼SE¼ sec. 25, T. 2 S., R. 1 E., 2 miles north of Springer, Carter County.

Cornett Basalt Member (of Flat Ridge Formation)

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 48, 49, 50, 51, pls. 1, 60. Green amygdaloidal basalt flow, or series of flows, whose vesicles are filled by quartz and epidote. In some places, a few feet of green quartzite occur at base. West of Cornett Store, member contains beds of purple and green tuffaceous slate. Generally occurs at base of formation.

Name from Cornett Store (erroneously named Cornell Store on Mouth of Wilson quadrangle) 3 miles southwest of Cinnamon Ridge. Mapped in extreme western part of Gossan Lead district.

Cornfield Series[1]

Tertiary or Pleistocene: Northeastern Arizona.

Original reference: A. B. Reagan, 1932, Kansas Acad. Sci. Trans., v. 35, 253–258.

Cornfield Harbor Clays[1]

Pleistocene: Eastern Maryland.

Original references: W. H. Dall, 1897, 55th Cong., 2d sess., H. Doc. 5; 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 336, table opposite p. 334.

Cornfield Harbor, near Federalsburg, Caroline County.

Cornfield Springs Formation[1]

Upper Cambrian: Southeastern California and southeastern Nevada.

Original reference: J. C. Hazzard and J. F. Mason, 1936, Geol. Soc. America Bull., v. 47, no. 2, p. 229–240.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 318–320, p. 277 (fig. 3C). Extended into Nopah and Resting Springs area, Inyo County, Calif. Thickness 2,957 feet. Overlies Bonanza King formation; underlies Nopah formation (new).

J. C. Hazzard and J. F. Mason, 1953, Am. Jour. Sci., v. 251, no. 9, p. 643–655. Geographically extended into Goodsprings area, Nevada, where it lies within Goodsprings dolomite of Hewett (1931).

A. R. Palmer and J. C. Hazzard, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2494–2499. On basis of paleontological data, age of Cornfield Springs formation at its type locality is designated as Upper Cambrian. On basis of this evidence, name Cornfield Springs was misapplied in Nopah area. Unit designated Cornfield Springs in Nopah area should now be considered an unnamed division in upper part of Bonanza King formation.

Named for good exposures east of Cornfield Springs, Providence Mountains, San Bernardino County, Calif.

Corning Creek zone (in Negaunee Formation)[1]

Precambrian (middle Huronian) : Northern Michigan.

Original reference: J. L. Adler, 1935, Jour. Geology, v. 43, no. 2, p. 113–132.

Type locality not stated. Map shows Corning Creek and West Corning Creek, Marquette County.

Cornish sandstone member[1]

Permian: Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 18.

Named for occurrence in vicinity of Cornish, Jefferson County.

Cornishville Formation

Cornishville Limestone Member (of Perryville Formation)[1]

Middle Ordovician: Central Kentucky.

Original reference: A. F. Foerste, 1912, Denison Univ. Sci. Lab. Bull. 17, p. 23, 31, 33, 36, 132, 133.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1635–1636. The Cornishville with its supposedly recurrent upper Benson fauna is actually uppermost Benson and the entire Perryville is a Benson facies.

J. A. Stokley and F. H. Walker, 1953, Kentucky Geol. Survey, ser. 9, Rept. Inv. 8, p. 44–45. At Harrodsburg, Mercer County, the Cornishville formation is 6 feet thick; overlies Salvisa formation.

Named for Cornishville, Mercer County.

†Cornwall Limestones[1]

Silurian and Devonian: Southeastern New York.

Original reference: E. C. Eckel, 1902, New York State Geologist 20th Ann. Rept., p. 148.

Name probably taken from some one of the places in Orange County that bears the name Cornwall.

Cornwall Shale[1]

Cornwall Shale (in Onondaga Formation or Group)

Middle Devonian: Southeastern New York, and northern New Jersey.

Original reference: C. A. Hartnagel, 1907, New York State Mus. Bull. 107, p. 39–54.

Bradford Willard, 1937, Am. Jour. Sci., v. 33, no. 196, p. 271, 272. In proposed succession in Green Pond Mountain area, New Jersey, Cornwall shale is assigned to Onondaga formation. Overlies Kanouse sandstone and conglomerate.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 138. Referred to as Cornwall member of Onondaga group.

G. A. Cooper, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart shows age as Lower or Middle Devonian.

Named for occurrence at Cornwall, Orange County, N.Y.

†Cornwall Slates[1]

Upper Cambrian: Southeastern Pennsylvania.

Original reference: J. P. Lesley and E. V. d'Invilliers, 1886, Pennsylvania 2d Geol. Survey Rept. 1885, p. 526.

Exposed in railroad cut at Cornwall Station, Lebanon County.

Coronado Quartzite[1]

Upper Cambrian: Central eastern Arizona.

Original reference: W. Lindgren, 1905, U.S. Geol. Survey Prof. Paper 43, p. 59.

A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 478. Fossil evidence may suggest a Middle Cambrian age for the unit.

Several areas of this formation crown summit and westerly slope of Coronado Mountain, northwest of Morenci, Greenlee County.

Corough Sandstone Member (of Catahoula Formation)

Miocene (?): East-central Texas.

W. L. Russell, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 68, fig. 3. Name applied to sandstone occurring roughly 175 feet above base of Catahoula. Thickness 0 to 40 feet.

Type locality: Where a road crosses member about 2½ miles west-southwest of Erwin, Grimes County. Name derived from land survey at type locality.

Corozal Limestone[1]

Paleocene or Eocene: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 23.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47, 48 (table 4). Upper Cretaceous.

R. C. Mitchell, 1956, Am. Assoc. Petroleum Geologists Bul., v. 50, 12, p. 2971. Upper Paleocene or lower Eocene. This age determination credited to Kaye (1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 1) who described limestone section at Corozal.

Present in San Juan district.

†Corral Sandstone (in Cheyenne Sandstone)[1]

Lower Cretaceous (Comanche): Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 361, 366.

Named for the natural corral, a short box canyon on Lanphier claim, in southeastern corner of Kiowa County.

Corral Creek Glacial Substage

Pleistocene (Wisconsin): Southern Rocky Mountains.

L. L. Ray, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 314. Two stages of glaciation believed to be of Wisconsin age recognized along northern Front Range. Younger is termed Corral Creek, and older Home.

L. L. Ray, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 2007; Kirk Bryan and L. L. Ray, 1940, Smithsonian Misc. Colln., v. 99, no. 2, p. 33–34; L. L. Ray, 1940, Geol. Soc. America Bull., v. 51, no. 12, pt. 1, 1860–

1862. Represents third of five substages in southern Rocky Mountains. Preceded by Home substage and followed by Long Draw substage.

Named for moraine in valley of Corral Creek, Cache la Poudre Valley.

Corral Hollow Shales[1] (in Franciscan Formation)

Jurassic(?): Western California.

Original reference: C. F. Tolman, Jr., 1915, Nature and science on Pacific coast: San Francisco, Elder and Co., p. 45.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 15. Incidental mention in discussion of Franciscan formation in San Jose-Mount Hamilton area.

First described in Alameda County [near Livermore].

Correo Sandstone Member (of Chinle Formation)

Upper Triassic: West-central New Mexico.

V. C. Kelley and G. H. Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. Dark-brown and buff medium to massive crossbedded standstone, 90 to 120 feet thick. Overlies unnamed red shale member; disconformably underlies Wingate sandstone.

Caswell Silver, 1948, Am. Assoc. Petroleum Geologist Bull., v. 32, no. 1, p. 72, 73, fig. 2. Interbedded sandstone and conglomerate. Unevenly and irregularly crossbedded. Pinches out westward. Derivation of name given.

Named from exposures 1 mile north of settlement of Correo, Valencia County. Crops out along lower bench at south edge of Mesa Gigante, north of Correo.

†Corrigan Formation[1]

Lower Devonian: Western Maryland.

Original reference: A. W. Grabau, 1910, Michigan Geol. and Biol. Survey Pub. 2, geol. ser. 1, p. 231, 234.

Named for occurrence at Corriganville, Allegany County.

Corrigan Formation[1]

Oligocene and Miocene(?): Eastern Texas.

Original reference: E. T. Dumble, 1911, Texas Acad. Sci., v. 11, p. 51.

J. W. Stovall, 1948, Am. Jour. Sci., v. 246, no. 1, p. 84. At least a part of the Corrigan beds were deposited in Oligocene seas.

Named for Corrigan, Polk County.

Corry Sandstone[1]

Corry Formation (in Pocono Group)

Mississippian: Northwestern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. Q_4, p. 92–94.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1347–1369; J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 40. At type locality, consists of about 20 feet of gray and white siltstone and some interbedded fine-grained sandstone. At many places, the Corry can be separated into three units: lower of massively bedded siltstones and fine-grained sandstones; medial of thinner bedded siltstones intercalated in silty mudrock and silty shale; and upper of massive siltstones separated by some thin shaly partings.

Westward from type locality, the Corry thins and, in area between Riceville and Strand School, grades laterally into Shellhammer Hollow formation (new). Throughout most of outcrop, overlies Riceville shale; contact conformable. Underlies Orangeville shale (Hungry Run sandstone member, new, or Bartholomew siltstone member, new). The Corry can be considered an eastward facies of Berea sandstone.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey. Mapped in Pocono group.

Type locality: Colgrove quarry (now abandoned), 1 mile south of Corry, Erie County.

Corryville Shale Member (of McMillan Formation)[1]

Corryville Formation (in Maysville Group)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and northern Kentucky.

Original reference: J. M. Nickles, 1902, Cincinnati Soc. Nat. History Jour., v. 20, p. 75, 83.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington Ky., Kentucky Univ., p. 11. Corryville listed with formations exposed in northern Kentucky.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf., Guidebook 6, pl. 1. Shown on chart of Ordovician rocks exposed in Jefferson and Switzerland Counties as Corryville formation in Maysville group. Blue dense to crystalline limestone beds and blue-gray soft gray clay shale; fossiliferous. Thickness 20 to 45 feet. Underlies Mount Auburn formation; overlies Bellevue formation.

Named for Corryville, near Cincinnati, Ohio.

Corset Spring Shale

Upper Cambrian: East-central Nevada and western Utah.

Harald Drewes and A. R. Palmer, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 1, p. 106 (fig. 2), 108 (fig. 3), 115–116, 117. A 65-foot unit of olive-gray predominantly clay shale with characteristic pencil fracture that overlies Johns Wash limestone (new); near middle of formation, 5 to 15 feet of medium-gray thick-bedded medium-coarse, crystalline, and clastic limestones separate a lower shale unit from an upper one. Distribution irregular because thrust fault commonly follows unit. Undisturbed sections show sharp lower contact and a gradational upper contact with overlying (unnamed) cherty limestone. Upper contact is placed at highest shale in a sequence of alternating shale and limestone lenses.

Harald Drewes, 1958, Geol. Soc. America Bull., v. 69, no. 2, p. 224 (fig. 2), 226–227, pl. 1. Trilobite assemblage indicates early Trempealeau age. Formation probably correlative of part of Dunderberg shale of Eureka district and part of Mendha formation of Pioche district.

C. B. Bentley, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 6, p. 21–22. Dunderberg shale is basal Franconian and is equivalent to a sandstone, shale, and limestone unit about 600 feet above base of Mendha limestone at Pioche, Nev. Dunderberg is present in Snake Range, Nev., where Drewes and Palmer (1957) called it Corset Spring shale. Although they correlated it with Dunderberg shale of Eureka, Nev., and found basal Franconian fossils, they designated it as

Trempealeauan (Drews, 1958). Underlying Corset Spring shale is 228 feet of limestone designated by Drewes and Palmer the Johns Wash limestone, supposedly of upper Franconian and basal Trempealeauan age. Present writer [Bentley] does not agree with this dating or with nomenclature involved. Formation names used by Drewes and Palmer, at least those for Upper Cambrian, should be suppressed, and section renamed with either Eureka district or House Range terminology.

A. R. Palmer, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B289–B290. Unit that has been called "Dunderberg shale" by Bentley and by those who have studied it in western Utah is not equivalent to whole of Dunderberg shale exposed near Eureka and Cherry Creek, Nev. Evidence indicates that name "Dunderberg shale" should no longer be used for a thin unit of interbedded limestones and shales occurring in western Utah and containing *Elvinia* zone trilobites. This unit is better named Corset Spring shale. Bentley has pointed out correctly that the Corset Spring shale, which occurs in Snake Range just west of Nevada-Utah line, is equivalent to his "Dunderberg shale." Name Corset Spring extended into Deep Creek Range, where it occurs above Hicks formation and below Chokecherry dolomite.

Type section: Segment B of measured section (fig. 2), southern Snake Range, Nev. No suitable geographic name near this section but there is alternate section at elevation 10,500 above Corset Spring on northeast flank of peak 11,064, two miles east of Lincoln Peak, and shale is named for that spring.

Corsicana Marl (in Navarro Group)[1]

Upper Cretaceous (Gulf Series): Northeastern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 342–343.

D. L. Frizzell, 1954, Texas Bur. Econ. Geology Rept. Inv. 22, p. 51–52, pls. Overlies Nacatoch sand; underlies Kemp clay. Foraminifera described.

Type locality: Pit Corsicana Brick Co., 2 miles south of courthouse at Corsicana, Navarro County.

Corson diabase[1]

Precambrian: Southeastern South Dakota(?) and northwestern Iowa.

Original references: C. R. Keyes, 1914, Iowa Acad. Sci. Proc., v. 21, p. 187; 1914, Science, new ser., v. 40, p. 144.

Probably named for Corson, Minnehaha County, S. Dak.

Corta Sandstone (in Joserita Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11. Hard-cross-bedded partly quartzitic and partly calcareous reddish-brown and in places whitish sandstone. Thickness 35 feet. Underlies Quimbo dolomite (new); overlies Espinal grit (new).

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Cortado Formation

Pennsylvanian (Des Moines): Northern New Mexico.

J. A. Young, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1247. Arkose, arkosic sandstone, arenaceous, carbonaceous, and calcareous shale, and a few thin beds of limestone. Thickness over 3,300 feet. Overlies Whiskey Canyon limestone.

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 51. Presentation of better locality data (from unpub. thesis of Young).

First described from occurrence near mouth of Rio Grande del Rancho Canyon, northern Sangre de Cristo Mountains, Taos County.

Cortlandt Complex

Cortland Series[1]

Age undetermined: Eastern New York.

Original references: J. D. Dana, 1880, Am. Jour. Sci., 3d, v. 20, p. 194–220; 1881, Am. Jour. Sci., v. 22, p. 103–119.

G. P. Woollard, 1948, Am. Geophys. Union Trans., v.. 29, no. 3, p. 316. Referred to as Cortlandt complex, a norite intrusive.

N. C. Steenland and G. P. Woollard, 1952, Geol. Soc. America Bull., v. 63, no. 11, p. 1075–1104. Cortlandt complex is a body of igneous rocks, composed of norite, diorite, and pyroxenite. Outstanding features are: (1) unusual suite of basic rocks; (2) systematic zoning of rock types; (3) conspicuous banding in parts of complex; and (4) funnel shape for complex as a whole and similar shape for some of its constituent parts. Report is based on 185 gravity and magnetic stations established over complex and contiguous areas. Complex is in region of granitic rocks and lower Paleozoic sediments.

First described in township of Cortlandt, northwestern part of Westchester County, between Croton River on south and parallel of Peekskill on north. Covers area of about 24 square miles.

Corwin Formation[1] (in Nanushuk Group)

Lower and Upper Cretaceous: Northwestern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 244.

E. G. Sable, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2641–2643, fig. 3. Restricted in Utukok-Corwin area to the predominantly nonmarine facies of Nanushuk group which overlies and intertongues with Kukpowruk formation (new) and underlies Prince Creek formation of Colville group. Upper contact with Prince Creek formation not exposed but may represent an unconformity. Thickness at type section about 15,500 feet; thins northeastward to about 4,500 feet on lower Utukok River. Age redesignated at late Early and Late Cretaceous, not older than middle Albian. Type locality given.

R. M. Chapman and E. G. Sable, 1960, U.S. Geol. Survey Prof. Paper 303–C, p. 101–125, pls. Formation described in Utukok-Corwin region. Consists predominantly of nonmarine rocks (coastal facies with possibly some inland facies); intertongues with and overlies Kukpowruk formation. Shale, siltstone, claystone, sandstone, coal, conglomerate, ironstone, clay, and bentonitic clay are commonest rock types. Thins eastward in northern part of region and also thins northward from more than 15,400 feet near Corwin Bluff to about 4,500 feet along lower Utukok River.

Type locality: Corwin Bluff vicinity in sea cliffs from 0.6 mile west of Thetis Creek and west for 11 miles, thence 0.3 mile upstream along small creek which enters the ocean at this point; Cape Lisburne region.

Coso Formation

Pliocene, upper, or Pleistocene, lower: Eastern California.

J. R. Schultz, 1937, Carnegie Inst. Washington Pub. 487, p. 79. Alluvial gravels, tuffs, and lake beds that form a unit sharply differentiated from other rock types in region. Conformably overlain by basaltic lava; overlies granite. Thickness about 300 feet.

R. H. Hopper, 1947, Geol. Soc. America Bull., v. 58, no. 5, p. 415, 416, pl. 1. Thickness about 500 feet. Basal material consists of reddish arkose and buff gravel, sandstone, and shale; above is about 200 feet of well-stratified thin-bedded white and light-buff lake beds, with interbedded white rhyolite tuffs. Alluvial fan material below tuffs has yielded vertebrate fauna. Rests on erosion surface cut in granitic rocks; overlain without angular discordance by flows of basaltic lava.

Exposed on west, north, and east flanks of Coso Range, Inyo County.

Coso Granodiorite

Upper Mesozoic: Southern California.

V. C. Kelley, 1937, Econ. Geology, v. 32, no. 8, p. 993, 994 (fig. 2), 996 (fig. 4). Mentioned as lobe of Coso batholith. Intrusive into Pennsylvanian limestone.

V. C. Kelley, 1938, California Jour. Mines and Geology, v. 34, no. 4, p. 514, pl. 7. Megascopically a coarse-grained light-colored granitoid rock in which the principal minerals are quartz, feldspar, and green hornblende,

Occurs in Darwin silver-lead district in the Coso Range, Inyo County. Batholithic in extent and underlies most of plateau south and west of Darwin Hills.

Cosumnes Formation (in Amador Group)

Middle (?) and Upper Jurassic: East-central California.

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 283. Basal formation of Amador group at its northern section. Basal beds consist of alternate sandstones and conglomerates 1,200 feet in thickness; these pass upward into sheared arkosic sandstones and dark clay-slate which, in turn, grade upward into thin-bedded tuffs and fine sediments; basic flows and red and green cherts locally present in upper part. Thickness 4,400 feet to east of Calaveras anticline; thicker on west owing to presence of rhyolite flows and agglomerates. Underlies Logtown Ridge agglomerates (new); unconformably overlies the Calaveras (Clipper Gap formation).

J. H. Eric, A. A. Stromquist, and C. M. Swinney, 1955, California Div. Mines Spec. Rept. 41, p. 10–11, pls. 1, 2. Described in Angels Camp and Sonora quadrangles, Calaveras and Tuolumne Counties, where maximum thickness is about 1,500 feet, base not exposed. Consists of metavolcanics, chiefly thin-bedded tuff, with minor slate; dark-gray to black slate, quartzite, chert, and minor conglomerates. Unconformably underlies Logtown Ridge formation; unconformably overlies Calaveras formation. Age considered to be Middle or Late Jurassic. Perisphinctid ammonite collected from unit.

Type locality: At northern type section of Amador group on Cosumnes River, Eldorado and Amador Counties.

Cottage Grove Sandstone[1] Member (of Chanute Shale)

Pennsylvanian (Missouri Series): Southeastern Kansas and northeastern Oklahoma.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 92, 97.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 61 (fig. 6), 63–64. Described in Washington County where it is 6 to 50 feet thick. Occurs above unit referred to as Thayer coal member and below unnamed carbonaceous shale member.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 84. Yellowish-brown or tan thin-bedded to massive sandstone; comprises upper one-third to one-half of Chanute shale in southeastern Kansas; occurs only locally in northeastern Kansas. Thickness featheredge to 60 feet.

Named for Cottage Grove Township in Allen County, Kans.

Cotter Dolomite[1]

Lower Ordovician: Northern Arkansas, southern Missouri, and Oklahoma.

Original reference: A. H. Purdue and H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

J. G. Grohskopf, E. L. Clark, and S. P. Ellison, 1943, Missouri Geol. Survey and Water Resources 62d Bienn. Rept., app. 4, p. 7–9. Underlies Fortune formation (new).

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 15, 32–39, pls. Predominantly cherty dolomite varying from gray to buff; fine-grained to coarse-grained; thin to massive bedded. Thickness 340 feet in vicinity of Cotter. Includes Crooked Creek chert bed (new) in lower part and Jenkins Branch chert bed (new) near middle. Underlies Powell dolomite; unconformably overlies Theodosia formation (new) of Jefferson City group. As used in this report, term Cotter is restricted to those beds which crop out in vicinity of type area. Type section designated. Lower half of what Weller and St. Clair (1928, Missouri Bur. Geology and Mines, v. 22, 2d ser.) called Cotter is here included in Theodosia formation.

G. G. Huffman, 1953, Oklahoma Geol. Survey Guide Book 1, p. 5, 7. Unconformably overlies Precambrian Spavinaw granite. Where exposed near Qualls, Cherokee County, is succeeded by Burgen sandstone.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 23. In Mascot-Jefferson City zinc district, Tennessee, names Kingsport and Mascot (both new) replace terms Jefferson City formation and Cotter-Powell beds. There is no possibility that these formations can ever be traced into Appalachian Valley. Kingsport limestone corresponds to some part of Jefferson City formation of Ozark region, and Mascot dolomite corresponds to some part of the Cotter, but there is n evidence to indicate that Jefferson City-Cotter boundary is same as Kingsport-Mascot boundary.

Type section: Starting at valley bottom just upstream from west end of White River bridge at Cotter and extending to top of hill westward along U.S. Highway 62, Baxter County, Ark.

Cotton Formation (in Conneaut Group)

Upper Devonian: North-central Pennsylvania and central New York.

G. H. Chadwick, 1936, New York State Mus. Bull. 307, p. 78, 96. Name proposed for mass of continental strata. Briefly mentioned in discussion in which a number of beds loosely termed "Catskill" are reassigned.

G. A. Cooper and others, 1942. Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Geographically extended into New York.

Named from Cotton Creek in Bingham and Genesee Townships, Potter County, Pa.

†Cottondale Formation (in Tuscaloosa Group)

Upper Cretaceous: West-central Alabama.

L. C. Conant and W. H. Monroe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 37. Comprises the apparently nonmarine gravelly sand and carbonaceous clay which lie between the Paleozoic basement and the overlying marine Eoline formation (new). Sand and clay members vary in thickness though most outcrops show 25 to 50 feet of gravelly sand overlain by a few feet of carbonaceous clay. Sand is cross bedded, coarse to fine grained; gravel present in lower half, chiefly as thin stringers, but toward base is abundant enough to form beds; clay typically forms one or two layers at top, but locally occupies entire thickness of formation; upper part of clay locally lignitic. Thickness 30 to 100 feet; topographic irregularities on Paleozoic floor cause corresponding differences in thickness of formation. Upper contact of formation locally sharp but in some places appears to be gradational. Flora indicates Upper Cretaceous age.

W. H. Monroe, L. C. Conant, and D. H. Eargle, 1946, Am. Assoc. Petroleum Geologists Bull, v. 30, no. 2, p. 192–194. Commonly 25 to 75 feet of cross-bedded slightly micaceous sand, which is coarser or even gravelly at base and is overlain by 2 to 8 feet of carbonaceous or lignitic clay; at many places dark-gray and purple clays are interbedded with the sand; at some places, entire interval is represented by dark-gray to purple clay as much as 50 to 60 feet thick. Type locality designated.

C. W. Drennen, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 3, p. 528. Name abandoned. Sediments heretofore designated Cottondale are included in the Eoline, which is here reduced to member status in the Coker formation (revised).

Type locality: East of Cottondale in sec. 25, T. 21 S., R. 9 W., Tuscaloosa County. Named for Cottondale, about 6 miles east of Tuscaloosa, where several exposures are present along Southern Railway and nearby county roads.

Cotton Valley Formation or **Group**

Upper Jurassic: Subsurface in northern Louisiana, southern Arkansas, western Mississippi, and eastern Texas.

H. K. Shearer, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 6, p. 722, 723, 724–725. Dominantly marine beds, made up of various types of shale, sand, and limestone, underlying Travis Peak red beds; includes Schuler facies (or limestone). Thickness about 3,240 feet at Rodessa, La. Name approved by Shreveport Geological Society.

W. B. Weeks, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 8, p. 966. Geographically extended into Arkansas where it overlies the Smackover limestone and Bucker anhydrite.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 25–27. Further desribed in Arkansas where it underlies Hosston formation (new). Jurassic age favored on basis of fossils.

F. M. Swain, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 578 (table 1), 579–582. Rank raised to group. Includes rocks between base of Hosston formation (Travis Peak of East Texas petroleum geologists) and top of Buckner formation, or top of Smackover formation in areas where Buckner is not recognizable. Consists of Schuler formation above and Boosier formation below.

T. H. Philpott and R. T. Hazzard, 1949, *in* Shreveport Geol. Soc. Guidebook 17th Ann. Field Trip, fig. 5 (correlation chart); L. A. Goebel, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1978–1979. Proposed that Cotton Valley as a formation be restricted to the gray sands and shales above a major unconformity that exists within the formation and that Haynesville formation be used for the red sands, shales, and anhydrite below unconformity.

Type locality: Cotton Valley field, Webster Parish, La.

Cottonwood Beds[1]

Miocene: North-central Oregon.

Original reference: W. D. Matthew, 1900, Am. Mus. Nat. History Bull., v. 12, p. 23.

Rattlesnake Creek, near Cottonwood, John Day region.

Cottonwood Beds (in Horsetown Group)

Lower Cretaceous (Shasta Series): Northern California.

F. M. Anderson, 1938, Geol. Soc. America Spec. Paper 16, p. 32 (fig. 1), 38 (table 1), 63–67, table 2. Name applied to lower part of Horsetown group. Beds, which vary in thickness from 3,480 feet on North fork of Cottonwood River to 8,400 feet on Dry Creek, contain a succession of distinctive faunal zones. Consist of sandstone and conglomerate in lower part with shales in upper part. Underlie Hulen beds (new) though the boundary is more one of paleontological distinction; overlie Shasta group.

Type area: Along Cottonwood River [Shasta County]. Beds form a belt 2½ miles broad, crossing North and Middle forks of Cottonwood River; from the latter stream, belt extends in southwest course by Dry Creek, northern Tehama County, and thus across the delta area.

†Cottonwood Formation (in Council Grove Group)[1]

Permian: Eastern Kansas.

Original reference: C. S. Prosser, 1894, Geol. Soc. America Bull., v. 6, p. 37–41.

Named for Cottonwood Valley, Chase and Lyon Counties.

Cottonwood Limestone (in Council Grove Group)[1]

Cottonwood Limestone Member (of Beattie Limestone)

Permian: Eastern Kansas, southeastern Nebraska, and north-central Oklahoma.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 112–114.

G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1, p. 13. Beattie formation (new) comprises (descending) Morrill limestone, Florena shale, and Cottonwood limestone members.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 47. Member of Beattie limestone. Underlies Florena shale member; overlies Eskridge shale. Thickness about 6 feet. Wolfcamp.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Cottonwood limestone in Council Grove group mapped in Oklahoma.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 101–103. In Pawnee County, classed as limestone in Council Grove group. Overlies Eskridge shale and underlies Garrison shale. As currently classified in Nebraska, Kansas, and north-central Oklahoma, the Cottonwood is basal member of Beattie formation overlain in turn by Florena shale and Morrill limestone members. Members of Beattie can be identified in Pawnee County just south of Arkansas River in two northernmost outliers of Cottonwood limestone. Only Cottonwood member is traceable for any distance across county. Accordingly, Beattie formation has been ignored in subdividing Council Grove group for this report. Maximum development is along Arkansas River where Cottonwood occurs as single resistant bed of light-greenish-gray limestone 2.2 feet thick. Wolfcamp series.

Named for Cottonwood Falls, Chase County, Kans.

Cottonwood Quartzite

Precambrian: Northern Utah.

N. E. A. Hinds, 1938, Am. Jour. Sci., 5th, v. 35, no. 210, 445. Cottonwood quartzite over 10,000 feet thick, mentioned in discussion of Precambrian Arizonan revolution in western North America.

This may or may not be same unit referred to as Cottonwood schists and gneisses.

Present in Wasatch, Uinta, and other ranges of northern Utah.

Cottonwood Rhyolite[1]

Tertiary, middle or upper: Northwestern Arizona.

Original references: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743; Carl Lausen, 1931, Arizona Bur. Mines Bull. 131, Geol. Ser. 6, p. 37.

Occurs about headwaters of Cottonwood Canyon, Oatman district.

Cottonwood Schists and Gneisses[1]

A name that has been rather loosely applied to the Precambrian schists and gneisses of Cottonwood Creek region, central Wasatch Mountains, Utah.

†Cottonwood Shales (in Council Grove Group)[1]

Permian: Eastern Kansas.

Original reference: C. S. Prosser, 1894, Geol. Soc. America Bull., v. 6, p. 38–39.

In Cottonwood Valley and at Manhattan and vicinity, Riley County.

Cottonwood white layer[1]

Eocene, middle: Wyoming.

Original reference: W. D. Matthew and W. Granger, 1909, Am. Mus. Nat. History Mem., v. 9, p. 295.

Bridger Basin.

Cottonwood Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept. pt. 1, p. 374, 382.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec., [Guidebook] Spring Mtg., May 11–12, p. 72. Chiefly white friable sandstone, 300 feet thick. Underlies Hanna Valley bed; overlies Spring Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Cottonwood Creek, San Saba County.

Cottonwood Creek Formation

Miocene, middle to upper: Southern California.

Otto Hackel and K. F. Krammes, 1958, San Joaquin Geol. Soc. [Guidebook] Spring Field Trip May 17, p. 4, road log (p. 6), geol. map. Series of light-colored coarse sands and conglomerates. Unconformably overlies Round Mountain silt; unconformably underlies Kern River formation. Can be traced north and west into Mon Bluff formation (new).

Type locality: Near Round Mountain, Kern County.

Cottonwood Draw banded layers[1] (in Wind River Formation)

Eocene, lower: Wyoming.

Original reference: W. Granger, 1910, Am. Mus. Nat. History Bull., v 28, p. 244.

Along Cottonwood Creek, near Lost Cabin, northeast corner of Fremont County.

†Cottonwood Falls Limestone[1]

Permian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 112–114.

Named for Cottonwood Falls, Chase County.

Cottonwood Spring Basalt (in Buck Hill Volcanic Series)

Cottonwood Spring Basalt (in Green Valley Volcanic Series)

Oligocene and younger(?): Western Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Green Valley volcanic series is divided into (ascending) Pruett formation, Cottonwood Spring basalts, and Duff tuff. Consists of basaltic lava flows up to 325 feet thick.

S. S. Goldich and G. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Oct. 29–31, p. 14 (table 1), 17 (fig. 3), 20. Included in Buck Hill volcanic series. [Authors made no reference to previous use of Green Valley volcanic series.] Derivation of name given.

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1144 (fig. 3), 1156–1159, 1171 (fig. 6), 1179, (measured section 5, type section), pl. 1. Dense to vesicular and amygdaloidal flows; trachyandesite to olivine basalt. Flows vary in number and in thickness. Maximum thickness 325 feet in area west of Whirlwind Spring; in type section, flows aggregate 300 feet, and lowermost flow, 40 to 50 feet thick, rests on Pruett formation; on Potato Hill, total thickness of 166 feet includes six flows. On Crossen Mesa, Cottonwood Spring basalt rests on tuff deposited on weathered surface of Potato Hill andesite. Age Eocene(?).

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 550–551, pl. 1. Traced across Cathedral Mountain quadrangle, Cottonwood Spring basalt flows occupy position between Potato Hill andesite and Duff formation, a relationship which is maintained across the south-north length of Alpine quadrangle. Thickness 220 to 332 feet. Top of Eocene is placed at disconformity between Crossen trachyte and Sheep Canyon basalt; suggested that overlying lava and tuff layers are Oligocene and younger(?), and map bracket shows this age for Cottonwood Spring basalt.

Type section: In vicinity of elevation 4,054 feet, south of Cottonwood Spring, Buck Hill quadrangle, Brewster County.

Cotui Limestone

Cotui Limestone Member (of San Germán Formation)

Upper Cretaceous: Southwestern Puerto Rico.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 198. Massive rarely thick-bedded limestone near top of San Germán formation. Includes microcoquino and pellet limestone with some argillaceous limestone. Maximum thickness 75 meters. Stratigraphically above Cabo Rojo member. Maestrichtian.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 340, 341, 342, pl. 1. Cotui limestone is highest unit in San Germán except southeast of Cabo Rojo, where about 150 meters of andesitic volcanic rock, shale, and conglomerate overlie it. Mitchell (1922) used term San Germán to describe the massive limestone herein called Cotui limestone. Definition of San Germán has been expanded in present report.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico.: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 53, 67. Referred to as Cotui limestone. Outcrops occur along western margin of Peñuelas quadrangle, where unit crops out in low hills surrounded by alluvium. In Mayagüez area, Mattson includes this limestone as a member of his San Germán formation. Relationship of the Cotui to underlying Mayagüez group could not be discerned in area of present report.

Well exposed in quarries along south edge of Guanajibo Valley, Mayagüez area.

Couch Formation

Pliocene, lower: Western Texas.

G. L. Evans, 1949, West Texas Geol. Soc. Guidebook Field Trip 2, Nov. 6–9, p. 4 (table 1), 5–6. Compact well-sorted calcareous sand and gravel; typically pinkish gray. Thickness at type locality 125 feet; thickness varies markedly with relief of underlying bedrock; maximum development in deeper pre-Cenozoic valleys; thins and wedges out against higher ridges and divides on bed rock surface. Underlies Bridwell formation (new); unconformably overlies Triassic and Cretaceous rocks.

D. C. Van Siclen, 1957, Jour. Geology, v. 65, no. 1, p. 49 (fig. 2), 51, 52. Thickness 200 feet. Stratigraphic section lists formation under Pliocene (Miocene?).

Type locality: About 7 miles east of Crosbyton, Crosby County. Named for Couch Ranch, in Blanco Canyon. Extends northward into Texas panhandle.

Coudersport Member (of Cattaraugus Formation)[1]

Upper Devonian: North-central Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 581.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 287–288. Green standstone 10 to 20 feet thick, about 100 feet below [above] base of Cattaraugus. Persists into Potter, Tioga, and probably McKean Counties and perhaps as far as Cameron, Clinton, Lycoming, and Sullivan Counties. Not to be confused with Oswayo which it closely resembles.

Named for Coudersport, Potter County, where it occurs in quarries along west side of town.

†Coulters Ferry Sands[1]

Upper Cretaceous: Northeastern Mississippi.

Original reference: E. W. Hilgard, 1860, Mississippi Geol. and Agric. Rept., p. 66, 67, 73.

Named for exposures at Coulter's Ferry, on Old Town Creek, near its confluence with the Tombigbee, sec. 34, T. 10, R. 7 E., Monroe County.

Council Grove Group[1]

Permian: Eastern Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: C. S. Prosser, 1902, Jour. Geology, v. 10, p. 709.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 45–49. As defined in Kansas, includes (ascending) Foraker limestone, Johnson shale, Red Eagle limestone, Roca shale, Grenola limestone, Eskridge shale, Beattie limestone, Stearns shale, Bader limestone, Easly Creek shale, Crouse limestone, Blue Rapids shale, Funston limestone, and Speiser shale. Thickness 310 to 330 feet. Overlies Admire group; underlies Chase group.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, includes only Cottonwood limestone, Neva limestone, and Red Eagle limestone.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 73 (table 3), 77–105. As presently applied, group includes beds from base of Americus limestone upward to base of Wreford limestone. Lies with apparent conformity between underlying Admire group and overlying Chase group. Thickness increases from 321 feet in Kansas to about 480 feet in Pawnee County. In southwest part of T. 22 N., R. 4 E., Wreford limestone, base of which defines upper limit of group, loses its identity; farther south, therefore, Council Grove and overlying Chase groups cannot be differentiated. They grade laterally into Konawa-Asher sequence of central Oklahoma. Group subdivided into limestone and shale-sandstone units of equal rank. Where applicable, names from Kansas section have been used, but rank of these names in Kansas classification has been discarded. In Pawnee County, includes (ascending) Foraker limestone with Americus limestone, Hughes Creek shale, and Long Creek limestone members, Johnson shale, Red Eagle limestone, Roca shale, Neva limestone, Eskridge shale, Cottonwood limestone, and Garrison shale. Wolfcamp series.

Named for Council Grove, Morris County, Kans.

Council Spring Limestone (in Veredas Group)

Pennsylvanian (Missouri series) : Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 58 (fig. 6), 59, 62–63. Proposed for uppermost formation of Veredas group (new). Overlies Adobe formation and underlies Burrego formation (both new). Limestone is light gray to white, coarsely crystalline to fine grained, and massive to massively bedded. Thickness at type locality 18 feet.

Type locality: Northwest face of Oscura Mountains in eastern part of SE¼ sec. 36, T. 5 S., 5 E., Socorro County. Name derived from Council Spring near top of Oscura Mountains, about 5 miles south of north end of mountains.

†Courtland Quartzite[1]

Precambrian (Huronian) : Central southern Minnesota.

Original reference: C. W. Hall, 1899, U.S. Geol. Survey Bull. 157. p. 20–25.

Redstone, in Courtland Township, midway between towns of New Ulm and Courtland, Nicollet County.

Courtney Granite[1]

Mesozoic: Northern California.

Original reference: O. H. Hershey, 1900, Science, new ser., v. 11, p. 130–132.

Mount Courtney batholith, Trinity County.

†Coutchiching Series[1]

Precambrian: Northern Minnesota, and Ontario, Canada.

Original reference: A. C. Lawson, 1887, Am. Jour. Sci., 3d ser., v. 33, p. 473–480.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1020–1022. No Coutchiching recognized in Minnesota.

Rainy Lake region, Minnesota.

Covada Group[1]

Probably Devonian, Carboniferous, or Mesozoic: Northeastern Washington.

Original reference: C. E. Weaver, 1913, Washington Geol. Survey Bull. 16, p. 20–30.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 75a), Correlation chart shows age Mississippian to Permian.

Washington [State] Division of Mines and Geology, 1960, Washington Div. Mines and Geology Rept. Inv. 20, p. 5. Intruded by Scatter Creek rhyodacite (new). Has been mapped as greenstone and limestone. Greenstone includes greenstone, graywacke, graywacke conglomerate, quartzite, argillite, chert, and phyllite; limestone is lenticular; some is Permian in age and some Triassic.

Named for Covada, Ferry County.

†Cove Limestone[1]

Ordovician: Appalachian region.

Original reference: H. D. Rogers, 1836, Pennsylvania Geol. Survey 1st Ann. Rept., p. 12–22.

Name probably derived from Cove Mountain, Franklin County, Pa.

Cove Quartz Monzonite

Jurassic: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

†Cove Slate[1]

Ordovician: Appalachian region.

Original reference: H. D. Rogers, 1836, Pennsylvania Geol. Survey 1st Ann. Rept., p. 12–22.

Name probably derived from Cove Mountain, Franklin County, Pa.

†Cove Creek Limestone[1]

Mississippian: Southwestern Virginia.

Original reference: C. Butts, 1927, Virginia Geol. Survey Bull. 27, p. 16.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Abandoned on basis of this report. Replaced by Bluefield formation.

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1911. Butts (1927) ignored Reger's 1926 terminology and used names "Cove Creek" limestone and "Fido" sandstone for certain stages of the Mauch Chunk and assigned everything between the Gasper (Upper Union) and St. Louis (Hillsdale) to the Ste. Genevieve. This assignment of certain lower rocks to the Ste. Genevieve was merely an avoidance of Pickaway, Taggard, Patton, and Sinks Grove. Continued use of Butts' illogical Ste. Genevieve column has led to confusion. [See Denmar formation.]

Well exposed along Cove Creek, Scott County.

Cove Fort Quartzite

Upper Devonian(?): Southwestern Utah.

G. W. Crosby, 1959, Brigham Young Univ. Research Studies, Geology Ser., v. 6, no. 3, p. 20–21, 52, pl. 11. Proposed for cream-colored vitreous quartzite formation unconformably overlying Guilmette formation. Consists of three units: lower, which is thickest, is white to cream, highly indurated, clean quartz sand; middle, gray limestone intraformational breccia with large amount of sand; upper, reddish-gray poorly sorted quartzite with calcareous cement. Thickness about 85 feet. Disconformably underlies Redwall limestone.

Occurs in south end of Pavant Mountains. Measured section is in sec. 16, T. 24 S., R. 6 W., [Millard County] at southeast corner of White Sage Flat. Exposed in overturned limb of asymmetrial syncline resting in thrust relationship on Triassic beds. Cove Fort is in southeastern corner Millard County.

Covel Conglomerate Member (of Carbondale Formation)

Covel Conglomerate (in Carbondale Group)

Pennsylvanian: Northern Illinois.

H. B. Willman, 1939, Illinois Acad. Sci. Trans., v. 32, no. 2, p. 174–176. Proposed for a thin limestone conglomerate that occurs at top of Summum cyclothem a short distance below No. 5 coal in overlying St. David cyclothem. Notably lenticular so that it is discontinuous in almost every outcrop. Thickness varies from a trace to about 1 foot but is usually ½ to 2 inches thick. In upper Illinois Valley, underlain by a light-greenish-gray calcareous clay and overlain by 4 to 6 inches of dark-gray thin-bedded shale.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), pl. 1. Rank reduced to member status in Carbondale formation (redefined). Stratigraphically above Hanover limestone member and below Springfield (No. 5) coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: SE¼SW¼ sec. 26, T. 33 N., R. 3 E., La Salle County. Named for exposures along Covel Creek south of Ottawa.

Cove Mountain Formation

Tertiary: Eastern Nevada and southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 44, maps 1 and 2. Consists of four members (ascending) Willow Spring, Racer Canyon tuff, Pilot Creek basalt, and Cedar Spring. Thickness as much as 2,000 feet. Stratigraphically above Maple Ridge porphyry (new). Underlies Ox Valley tuff (new). Name credited to H. R. Blank (unpub. thesis).

Type locality and derivation of name not stated. Cove Mountain is in Bull Valley area, Washington County, Utah.

Cove Mountain Member (of Pocono Formation)

Lower Mississippian: Central Pennsylvania.

Bradford Willard, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 18. Name proposed for uppermost division of formation in south-central Pennsylvania. Consists of gray sandstone and pebble beds; lithologically similar to Second Mountain member at base of formation, but distinguished by presence of several coal beds. Conformably overlies Peters Mountain member; underlies Mauch Chunk red beds. Has been termed Burgoon, but question of precise correlation with that unit occurring in areas to the west warrants introduction of new name.

Type locality: In highway cuts at Cove Mountain, Perry County, south of Duncannon.

Coventry Conglomerate[1]

Lower Ordovician: Northeastern Vermont.

Original reference: C. H. Richardson, 1919, Vermont State Geologist 11th Rept., p. 47.

Located about 10 miles north of Craftsbury, and on main road from Newport to South Troy, and crosses northern part of Coventry Township, Orleans County.

Coventry Limestone[1]

Coventry phase (of Waits River Limestone)[1]

Ordovician: Northeastern Vermont.

Original reference: C. H. Richardson, 1908, Vermont State Geologist 6th Rept., p. 265-291.

Type locality: Coventry, Irasburg quadrangle, Orleans County.

†Covington Group[1]

Covington Subseries

Upper Ordovician (Cincinnatian Series): North-central Kentucky and southwestern Ohio.

Original reference: R. S. Bassler, 1906, U.S. Natl. Mus. Proc., v. 30, p. 9.

R. H. Flower, 1946, Bulls. Am. Paleontology, v. 29, no. 116, p. 107-112. Referred to as Covington subseries of Cincinnatian series. Below Richmond subseries. Includes Eden and Maysville groups.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1029-1032. Group comprises (ascending) Eden, Fairview, and McMillan formations. Cincinnatian series. Group contains standard sections of Eden and Maysville stages.

Named for Covington, Ky.

Cowaselon Clay[1]

Pleistocene: Southeastern New York.

Original reference: B. Smith, 1914, Am. Jour. Sci., 4th, v. 38, p. 463.

Named for Cowaselon Creek, Madison County.

Cow Bayou Formation (in Wilcox Group)

Cow Bayou Member (of Logansport Formation)

Paleocene: Northwestern Louisiana and northeastern Texas.

D. P. Meagher and L. C. Aycock, 1942, Louisiana Dept. Conserv. Geol. Pamph. 3, p. 13, 14. Named in a stratigraphic summary of Louisiana lignite district. Name credited to G. Murray, Jr.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Pertoleum Geologists Bull., v. 29, no. 1, p. 48 (fig. 2), 57. Consists of carbonaceous to lignitic shale of a cyclic pattern; typical facies best developed in and around type locality. Average thickness 75 to 100 feet. Underlies Lime Hill member; overlies Dolet Hills member; both upper and lower contacts are transitional, the transition taking place through 5 to 15 feet of section. Paleocene. Type locality designated.

G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 110-116, pl. 10. Consists of two facies Benson (lower) and Lulu. Geographically extended into Panola County, Tex.

H. V. Andersen, 1960, Louisiana Dept. Conserv. Geol. Bull. 34, p. 54-55. Formation, in Sabine Parish [this report], consists of interbedded silts, shales, and fine-grained sands. Present only in subsurface. Overlies Dolet Hills formation. Underlies Converse formation (new) which includes sand occupying valleys of Pleasant Hill oil field mapped by Murray (1948) as Cow Bayou member of Logansport. Term Logansport eliminated as members are given formational rank. Wilcox group.

Type locality: Along Cow Bayou in SE¼ sec. 9 and NW¼ sec. 16, T. 10 N., R. 14 W., De Soto Parish, La., approximately 3 miles southeast of Hunter on road to Converse.

Cow Creek Granodiorite

Jurassic–Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 11, pl. 1. Leucocratic granodiorite; light gray and finer grained than rocks of Giant Forest pluton. Relation to other named plutonic rocks in area not determined.

Named from exposures along Cow Creek along west side of mapped area, Sequoia National Park.

Cow Creek Limestone Member (of Pearsall Formation)

Cow Creek Limestone Member (of Travis Peak Formation)

Cow Creek Beds (in Travis Peak Formation)[1]

Cow Creek Formation

Lower Cretaceous: Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Rept., pt. 7, p. 141–143.

R. H. Cuyler, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 5, p. 632–633. Referred to as member of Travis Peak formation.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Middle member at type section of Pearsall formation (new) in subsurface. Thickness about 85 feet. Consists of black, gray, and light-brown hard dense to finely crystalline limestone. Overlies Pine Island member; underlies Hensell shale member. Occupies same stratigraphic position as Cow Creek limestone member of Travis Peak formation of outcrop and as James limestone of Arkansas-Louisiana-east Texas area.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 318, 319 [1946]. In outcrops, overlies Sycamore sand member and underlies Hensell sand member. Overlaps top of Honeycut formation and all of Carboniferous within map area of this report. A fossil coquina in which fossils are bonded into massive limestone bed.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 5, 6–7 (fig. 1), 8. Upper member of Travis Peak formation (restricted). Thickness 10 to 30 feet. Underlies Hensell sand member reallocated to member status in Shingle Hills formation (new).

F. E. Lozo and F. L. Stricklin, Jr., 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 69, 70, figs. In subsurface and outcrop, formation overlies Hammett shale (new). Hammet was originally included in Hill's Cow Creek beds.

Named for Cow Creek, Burnet County.

Cowdren Anhydrite Member (of Salado Formation)

Permian (Ochoa): Subsurface in West Texas and southeastern New Mexico.

G. A. Kroenlein, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1689. Anhydrite bed at base of a 200-foot zone of alternating halite and anhydrite beds. Above a basal 150-foot halite zone. Name credited to Giesey and Fulk (unpub. ms.).

S. G. Giesey and F. F. Fulk, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 4, p. 603. Mainly white crystalline anhydrite in type locality well, whereas 70 miles to north bed is composed of brown earthy dolomitic anhydrite. Also becomes considerably dolomitic southward.

Thickness in type section 15 feet; in other localtities 10 to 50 feet. Lowermost anhydrite bed in Salado, occurring from 150 to 200 feet above base of formation. Type section designated.

Type locality well: Between depths of 2,590 and 2,605 feet in Southern Crude Oil Purchasing Co. J. M. Cowden No. 1, located 2,310 feet from north and 330 feet from west lines of sec. 26, Blk. 43, T. 1 N., T. & P., Ector County, Tex.

Cowesett Granite (in East Greenwich Group)

Mississippian(?): Central Rhode Island.

A. W. Quinn, 1952, Bedrock geology of the East Greenwich quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad. Map [GQ–17]. Gray to pink medium-grained granite which is subporphyritic, mostly massive, and foliated near the contacts. Underlies Pennsylvanian sedimentary rocks unconformably. Intrusive into Westboro(?) quartzite, Spencer Hill volcanics (new), an unnamed metadiorite, and Maskerchugg granite (new). Intruded by a dark fine-grained granite dike. Included in East Greenwich group.

Named for typical exposures along Cowesett Road one-half mile west of Hardig Road, Kent County.

Cowiche Gravel[1]

Pleistocene: Central Washington.

Original reference: G. O. Smith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 86.

Occurs in broad terrace in valley of Cowiche Creek, Ellensburg quadrangle.

Cow Island Beds[1]

Upper Cretaceous: Central northern Montana.

Original reference: C. H. Sternberg, 1914, Science, new ser., v. 40, p. 134–135.

At Dog Creek, east of Judith River and in Fergus County.

Cowles Member (of Tererro Formation)

Lower Mississippian: Northern New Mexico.

E. H. Baltz and C. B. Read, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1754–1756, 1760, 1763–1768, 1769, 1770–1771, 1772, 1773. Consists of lower unit of calcarenite and upper unit, present locally, of marly quartz siltstone and intercalated limestone beds. Thickness 26 to 50 feet. Overlies Manuelitas member (new); underlies Sandia formation. Because of its unconformable relation with Manuelitas member, the Cowles may be of Late Mississippian age.

Typical section: Abandoned quarry on road to Winsor Ranch, 0.2 mile above junction with State Highway 63, 1.4 miles south of Cowles, San Miguel County. East side of Pecos River Canyon.

Cowley Formation

Upper Mississippian: Kansas (subsurface).

Wallace Lee *in* G. E. Abernathy, R. P. Keroher, and Wallace Lee, 1940, Kansas Geol. Survey Bull. 31, p. 15. Consists of silty and cherty gray or dark-gray or buff to almost black dolomite or dark dolomitic silty shale; contains glauconite, particularly in a zone a few inches to 30 or more feet thick, which forms a transgressive deposit at base of formation. Thickness as much as 300 feet. Conformably underlies Warsaw limestone; unconformably overlies rocks of Osage age.

Wallace Lee, 1940, Kansas Geol. Survey Bull. 33, p. 66–79, pl. 2. In different areas, base is in contact with Keokuk, Burlington, Reeds Spring, and St. Joe limestones of Osage age; in some areas, rests on Northview shale, Compton limestone, Chattanooga shale, and even on pre-Chattanooga rocks; at most places, unconformably overlain by Pennsylvanian rocks, but, in some places, conformably overlain by the Warsaw. Deriviation of name given.

Named for Cowley County, where in most wells, except in north-central part of county, there is a good development of the formation.

Cowley Canyon Member (of Wasatch Group)

Paleocene or Eocene, lower: Northern Utah.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1144–1145. Ooidal, stromatolitic ,pisolitic, or algal limestone at most outcrops with army-brown stromatolites in brownish-gray matrix of compact limestone. Locally stromatolites are missing, and rock is compact cream-colored limestone. Thickness 0 to 83 feet. Basal member of Wasatch group. Unconformably overlies Paleozoic rocks.

Good exposure on east side of Cowley Canyon in sec. 21, T. 12 N., R. 3 E., 0.9 mile above junction of Cowley Canyon and Right Fork Roads. Base of section at elevation 5,880 feet, about 100 feet above road, Logan quadrangle.

Cowlitz Formation[1]

Eocene, upper: Southwestern Washington and northwestern Oregon.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 15, p. 10–22.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 90–97. At type section, consists of massive stratified medium- to coarse-grained brownish-gray marine sandstones, shaly sandstnoes, sandy shales, and clay shales, with estuarine and fresh-water members near middle and intercalated basaltic flows near base; extreme lower part not exposed. Thickness at type section 3,745 feet.

R. S. Beck, 1943, Jour. Paleontology, v. 17, no. 6, p. 584–614. Approximately 200 feet of Eocene beds are exposed 1½ miles east of Vader, Lewis County, Wash., along west bank of Cowlitz River in E½SE¼ sec. 28, T. 11 N., R. 2 W. Weaver (1912) proposed name Cowlitz formation for the beds containing molluscan fauna at this locality. Weaver (1937) expanded type Cowlitz to include strata exposed along Olequa Creek between towns of Winlock and Vader. This emendation is undesirable because Olequa Creek section was not included in original definition and the addition would necessitate two type localities for the Cowlitz. In this report, type Cowlitz is limited to beds exposed along Cowlitz River. Foraminifera described. [Report also refers to Cowlitz River beds.]

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 44, no. 5, p. 593, chart 11. Formation composed of about 8,000 feet of marine grayish-brown sandstone and sandy shale containing well-preserved molluscan fossils. Type section is in banks of Olequah Creek and not in banks of Cowlitz River. Best known fauna does occur in about 200 feet of strata exposed in bluffs of Cowlitz River, 1½ miles east of Vader, and corresponds to strata in middle of type section on Olequah Creek.

W. C. Warren, Hans Norbisrath, and R. M. Grivetti, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 42. West of Willamette River, unconformably overlies Tillamook volcanic series (new); interfingers with basal part of Goble volcanic series (new).

W. C. Warren and Hans Norbisrath, 1946, Am Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 220 (table 1), 221–225. Described in upper Nehalem River basin where it is 950 feet thick, overlies Tillamook volcanic series, and underlies Keasey formation. Upper Eocene.

D. A. Henriksen, 1954, Dissert. Abs., v. 12, p. 2315–2316; 1956, Washington Div. Mines and Geology Bull. 43, p. 16 (fig. 5), 36–66, pl. 1. Weaver's 1937 type section expanded to include strata along Stillwater Creek from its confluence with Olequa Creek westward to contact with uppermost basalt flows of Metchosin volcanic series 3 miles west of Ryderwood. Type Cowlitz, as redefined herein, consists of more than 8,000 feet of upper Eocene sediments and subordinate volcanic rocks exposed along Stillwater and Olequa Creeks as far south as Cowlitz River. Subdivided into (ascending) Stillwater Creek, Pe Ell volcanics, Olequa Creek (all new), and Goble volcanics members. Underlies undifferentiated Oligocene.

M. L. Steere, 1955, Geol. Soc. Oregon Country News Letter, v. 21, no. 10, p. 85. In Sunset Tunnel area, Columbia County, Oreg., underlies Nehalem formation (new).

M. H. Pease, Jr., and Linn Hoover, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–188. Underlies Hatchet Mountain formation (new).

A. E. Roberts, 1958, U.S. Geol. Survey Bull. 1062, p. 12 (table), 14–19, pl. 1. In Toledo-Castle Rock coal district, Washington, unconformably overlies Northcraft formation and underlies Hatchet Mountain formation. Thickness about 2,600 feet.

Type section (Weaver, 1937): In canyon of Olequa [also spelled Olequah] Creek between towns of Winlock and Olequa, Lewis and Cowlitz Counties, Wash. Well exposed between Winlock and junction of Olequa Creek and Cowlitz River, a distance of about 14 miles.

Cowlitz River Beds

See **Cowlitz Formation.**

Cow Run Sandstone (in Conemaugh Formation)[1]

Cow Run sandstone and shale member

Pennsylvanian (Conemaugh Series): Eastern Ohio and western West Virginia.

Original reference: J. J. Stevenson, 1906, Geol. Soc. America Bull., v. 17, p. 154.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 68. 70, table 1. Member of Barton cyclothem in report on Perry County. Includes about 30 feet of shale and sandstone lying between Portersville member of Anderson cyclothem and Ewing limestone member of Barton cyclothem. Dominantly interval contains brick-red or buff shale or interbedded sandstone and shale, but massive coarse-grained sandstone is locally present. Conemaugh series.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 42–45. Name Cow Run has been applied to almost any massive sandstone in middle part of Conemaugh series. Member, as defined by Condit (1912, Ohio Geol. Survey, 4th ser., Bull. 17) and as adopted by Geological Survey of Ohio, includes an erratic sequence of sandstones and shales between the Portersville shale and limestone member below and Ewing limestone above; these latter units are not developed in many areas; hence, boundaries of Cow Run member usually are indefinite. Lithologically member varies from a massive sandstone to a series of sandstones and shales or to a sandy shale or clay shale section; facies changes are rapid. Thickness in Morgan County 30 feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 124–127. Sandstone member of Upper Bakerstown cyclothem in report on Athens County. Name Cow Run was originally applied to an oil-bearing sandstone in shallow wells in Lawrence Township, Washington County, Ohio. Name has been used and misused for various Pennsylvanian sandstones, and today a First Cow Run sandstone (to which name was first given and one under consideration here), lying in interval between Ames and Cambridge limestone, and a deeper Second Cow Run sandstone (Lower Freeport), lying above Middle Kittanning coal, are recognized. Cow Run member under discussion here is commonly considered to be the local massive thick sandstone lying just above Anderson cyclothem and at some places cutting out and replacing members of that cycle. Here, Cow Run will be used not only for massive sandstone but also for bedded sandstone and shale lying between Portersville and Ewing members. Average thickness about 26 feet. Conemaugh series.

Named for stream in eastern Washington County, Ohio.

Cow Springs Sandstone

Upper Jurassic: Northeastern Arizona, southwestern Colorado, northwestern New Mexico, and southeastern Utah.

E. D. McKee *in* C. R. Longwell, 1949, Geol. Soc. America Mem. 39, p. 46 (fig. 6). Name appears on cross section of north side of Black Mesa, Ariz. Name credited to J. W. Harshbarger.

J. W. Harshbarger, C. A. Repenning, and R. L. Jackson, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 97–98. In Navajo country, Summerville formation, Bluff sandstone member, and Recapture shale member of Morrison grade laterally southwestward into district sand facies here named Cow Springs sandstone. Consists of greenish-gray to light-yellowish-gray fine-grained well-sorted cross-stratified well-cemented sandstone. Thickness at type locality 342 feet. Separated from overlying Dakota sandstone by erosional unconformity; thins southward to 112 feet at Coal Canyon and remains relatively thin eastward to Hopi Buttes area; 420 feet at Steamboat, Ariz.; 240 feet at Lupton, Ariz. Overlies Entrada sandstone.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 48–51. Because of its intertonguing relationships with Summerville formation and lower members of Morrison formation, Cow Springs cannot be considered either a formation in San Rafael group or a member of Morrison formation. Bluff sandstone is believed to be a tongue of Cow Springs, but, because of its homogeneous and mappable character and its areal extent, it is considered a separate formation and assigned to San Rafael group.

Type locality: In cliff along north face of Black Mesa, Ariz., 4 miles east of Cow Springs along Reservation Highway 3. Section is 1¼ miles west of long 110°45′ W., and 6 miles south of lat 36°30′ N.

Cox Sandstone

Cox Sandstone (in Trinity Group)[1]

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 47.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 1003. Described in northern Quitman Mountains where it is about 704 feet thick, overlies Bluff formation, and underlies Finlay formation.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 21–22. Described in Eagle Mountains, where it is 1,300 feet thick, underlies Finlay limestone, and overlies Bluff Mesa formation (name replaces preoccupied Bluff formation).

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 374 (fig. 2), 376–378. In Kent quadrangle, disconformably overlies Yearwood formation (new); underlies Finlay formation, here included in Sixshooter group (new). In eastern and northeastern parts of quadrangle, the Cox oversteps Permian Castile, Rustler, and Pierce Canyon formations. Thickness 130 feet.

R. K. DeFord and L. W. Bridges, 1959, Texas Jour. Sci., v. 11, no. 3, p. 291. In northern Rim Rock country, underlies Tarantula gravel (new).

Named for Cox Mountain, El Paso County.

Coxcomb Granodiorite

Upper Jurassic(?): Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 64, pl. 3. Light gray; uniform in composition, structure, and texture. Cuts steeply dipping beds of McCoy Mountains formation (new).

Named for typical occurrence in middle part of Coxcomb Mountains, Riverside County, where it comprises an area of approximately 20 square miles.

Coxville Sandstone[1]

Coxville Sandstone Member (of Linton Formation)

Middle Pennsylvanian: Central western Indiana.

Original reference: G. H. Ashley, 1899, Indiana Dept. Geol. and Natl. Res. 23d Ann. Rept., p. 300–303, 385.

S. A. Friedman, 1960, Indiana Geol. Survey Prog. Rept. 23, p. 7, 23–28. Rank reduced to member status in Linton formation (Allegheny series). Thickness about 60 feet. Occurs at or near base of formation. Conformably overlain by (ascending) underclay, Coal IIIa, dark-gray and black shale, and thin limestone; underlain disconformably by shale above Coal III, by Coal III, or, where this coal has been completely eroded, by underclay or gray shale.

Named for outcrops north and east of Coxville, Parke County, approximately 15 miles north-northeast of Terre Haute.

Coyote Formation[1]

Eocene(?) : Central southern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Type locality: Coyote Hills, near Plush, Lake County.

Coyote Sandstone Member (of Madera Limestone)[1]

Pennsylvanian: Central northern New Mexico.

Original references: C. L. Herrick, 1900, Jour. Geology, v. 8, p. 115; 1900, Am. Geologist, v. 25, p. 234–237; 1900, New Mexico Univ. Bull., v. 2, pt. 3, p. 1–14.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 21. Term poorly defined. Not possible to determine exact position of Coyote sandstone. Term should not be used.

Named for Coyote Springs, Sandia Mountains.

Coyote Butte Formation

Permian: Central Oregon.

C. W. Merriam, 1942, Jour. Paleontology, v. 16, no. 3, p. 372. Fusulinid-bearing limestones, sandy limestones, and sandstones, 900 feet thick. Unconformably underlies Triassic sandstones and conglomerates; unconformably overlies Pennsylvanian Spotted Ridge formation (new).

C. W. Merriam and S. A. Berthiaume, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 156–158. At type section, lower part of formation is light-olive-gray commonly crinoidal limestone, locally containing abundant fusulinids; higher in section, limestones become purer, finer grained, deep olive gray, and more distinctly bedded, and fusulinids become less common, brachiopods more abundant.

Type locality: Steeply dipping strata forming crest of Coyote Butte, near Paulina, Crook County.

†Coyote Mountain Clays (in Imperial Formation)[1]

Miocene, lower: Southern California.

Original reference: G. D. Hanna, 1926, California Acad. Sci. Proc., 4th ser., v. 14, no. 18, p. 435.

Type locality: In foothills bordering southeastern slopes of Coyote Mountains, Imperial County.

Coys Hill Granite[1]

Late Carboniferous or post-Carboniferous: Western central Massachusetts and southwestern New Hampshire.

Original reference: B. K. Emerson, 1898, U. S. Geol. Survey Mon. 29, p. 319–320, pl. 34, map.

Composes mass of Coys Hill, western central Massachusetts.

Cozy Dell Formation

Cozy Dell Shale Member[1] (of Tejon Formation)

Eocene, or Eocene, upper: Southern California.

Original reference: P. F. Kerr and H. G. Schenck, 1928, Geol. Soc. America Bull., v. 39, p. 1090.

T. L. Bailey, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1931. Upper Eocene.

T. W. Dibblee, Jr., 1950, California Div. Mines. Bull. 150, p. 27–28, 38 (fig. 2), pls. 1–6. Formation described in Santa Ynez Mountains, Santa Barbara County, as well-bedded brown clay shale lying conformably on the Matilija sandstone and grading upward through a series of thin sandstone interbeds into the overlying Sacate sandstone. Thickness 700 to 2,000 feet.

Typically exposed in Cozy Dell Canyon, on east side of Ventura River, Ventura County.

Cozzette Member (of Price River Formation)

Upper Cretaceous (Montana): Central western Colorado.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 188, 191, fig. 2. In Neslen facies. Littoral marine sandstone and associated coal-bearing rocks which overlie Corcoran member (new) and are separated from it by tongue of Mancos shale which rests disconformably on coal-bearing rocks of Corcoran member. The basal sandstone grades downward into the Mancos tongue and is composed of two units with combined thickness of about 130 feet. This massive-bedded buff sandstone begins near Hunter Canyon and extends into Grand Mesa. Upper limit of member drawn at disconformity between coal-bearing rocks and overlying tongue of Mancos shale which, in turn, underlies Cameo member (new).

Named for exposures near old Cozzette mine north of Palisade, Mesa County. In Book Cliffs.

Crabbottom Sandstone

Silurian: Northwestern Virginia, western Maryland, and eastern West Virginia.

C. K. Swartz and F. M. Swartz, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2008. Proposed for a thick-bedded, whitish sandstone at base of Wills Creek formation. Overlies McKenzie formation near Driscol and Frost, W. Va. Widespread and apparently intertongues northward with Bloomsburg beds at base of Wills Creek in western Maryland.

Well exposed near Crabbottom, Va., 6½ miles northeast of Monterey, Highland County, along road leading from Strait Creek to Crabbottom.

Crab Creek Formation

Tertiary: North-central Utah.

R. E. Metter, 1955, Dissert. Abs., v. 15, no. 6, p. 1047. A piedmont deposit which may be lateral facies of Flagstaff and Colton formations. Younger than North Horn formation.

In area of southern Wasatch Mountains and northern Cedar Hills bounded by Spanish Fork Canyon, Utah Valley, Santaquin Canyon, Gardner Hollow, and Thistle Creek.

Crab Orchard cyclothem (in Carbondale Group)

Pennsyvalnian: Southern Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 16, 17 (fig. 3). In list of cyclothems in southern Illinois, Crab Orchard occurs between Brereton above and St. David below. Includes coal No. 5A.

C. C. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 12, 16 (fig. 2). Craborchard limestone shown on correlation chart below Herrin limestone and above Absher limestone. Text states that "Craborchard" limestone is part of a cyclothem which includes the so-called No. 5A coal; name "Craborchard" is a field term which is not proposed as a permanent stratigraphic name.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 43, 54 (table 3). Replaced by Briar Hill cyclothem (new).

Type locality and derivation of name not given.

Crab Orchard Formation

Crab Orchard Clay Shales

Crab Orchard Shale[1]

Lower and Middle Silurian: Central Kentucky and southwestern Ohio.

Original reference: W. M. Linney, 1882, Kentucky Geol. Survey Repts. on Garrard and Lincoln Counties.

J. K. Rogers, 1936, Ohio Geol. Survey, 4th ser., Bull. 38, p. 69–71, geol. map. Described in Highland County, Ohio, where it is from 30 to 95 feet thick, base not exposed. Occurs below Bisher and Lilley dolomites and above Brassfield and Dayton limestones.

Kentucky Geological Society, 1955, Kentucky Geol. Soc. Field Trip, p. 31 (fig. 11). Shown on generalized section of Serpent Mound region. Adams and Highland Counties, Ohio, as Crab Orchard clay shales; includes Estill member below and Ribolt member above. Thickness about 120 feet. Occurs below Bisher formation and above Dayton limestone.

U.S. Geological Survey currently classifies the Crab Orchard as a formation and designates the ages Lower and Middle Silurian on the basis of a study now in progress.

Named for Crab Orchard, Lincoln County, Ky.

Crab Orchard Sandstone

Pennsylvanian: Eastern Tennessee.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 36–37 An interval of evenly bedded hard sandstone younger than the Rockcastle. This sandstone, which has been extensively quarried near Crossville, is known commercially as Crab Orchard sandstone. It is proposed that it be called Crossville sandstone member of Duskin Creek formation since name Crab Orchard has been previously applied to a Silurian shale in Kentucky.

Occurs in syncline in Cumberland County west of Crab Orchard Mountains. Exposed on Pigeon Ridge Road, northwest of Byrd Creek, near Cumberland Homesteads CCC camp, about 6 miles south of Crossville.

Crab Orchard Mountains Formation

Crab Orchard Mountains Group

Lower Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [Folio], p. 1, 4, pls. 3, 4, 6. Includes all strata from top of Gizzard group to base of Crooked Fork group (new). At type section, approximately 640 feet thick; 300 feet in vicinity of Jamestown; 900 feet along eastern edge of Walden Ridge. Includes (ascending) Sewanee conglomerate, Whitewell shale, Newton sandstone, Vandever formation, and Rockcastle conglomerate.

U.S. Geological Survey currently classifies the Crab Orchard Mountains as a formation on the basis of a study now in progress.

Type section: (Composite) along U.S. Highway 70N and the tracks of the Tennessee Central Railway Company where they cut across the Crab Orchard Mountains of Cumberland County.

Crack Canyon Formation

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Listed as underlying Little Valley formation (new) and overlying Sulfur Creek formation (new). Comprises Grizzly Creek member above and Blue Ridge member (both new). The Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Craddock Clay Member (of Harpersville Formation)

Pennsylvanian (Cisco): North-central Texas.

F. B. Plummer and H. B. Bradley, 1949, Texas Univ. Bur. Econ. Geology Pub. 4915, p. 21–23, pl. 3. Black or very dark gray hard compact joint clay weathering gray and in most places oxidizing upon exposure to pink, red, or maroon. Average thickness about 8 feet. Occurs as an under clay just below the Newcastle coal bed, which is below Belknap limestone. [Member of Harpersville formation.]

Named from the Craddock Farm and Craddock Lake, 1 mile northwest of Cisco, Eastland County.

Craftsbury Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Probably named for Craftsbury Township or one of villages of that name within that Township, in unnamed quadrangle in southern part of Orleans County.

Craggy Gneiss[1]

Triassic to Cretaceous: Southwestern Oregon.

Original reference: G. M. Butler and G. J. Mitchell, 1916, Min. Res. Oregon, v. 2, no. 2.

Hewitt Wilson and R. C. Treasher, 1938, Oregon Dept. Geology and Mineral Industries Bull. 6, p. 11 (fig. 3). Triassic to Cretaceous.

Composes West Craggy, Curry County.

†Craghead Creek Shale[1]

Upper Devonian: North-central Missouri.

Original reference: D. K. Greger, 1909, Am. Jour. Sci., 4th, v. 27, p. 375.

Named for Craghead Creek, 6 miles south of Fulton, Callaway County.

Crag Mountain Formation

Middle Paleozoic: North-central Massachusetts.

Robert Balk, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–92; Map GQ–93. Name proposed for formation consisting of four unnamed members.

Basal member is coarse-grained white or yellowish hard glassy quartzite; locally conglomeratic, containing abundant quartz pebbles and fragments of black cherty rocks and schist. The quartzite is irregularly distributed along the borders of the formation and is overlain by and locally interbedded with mica schist. Mica schist member is typically dark-gray, silvery, or black lustrous phyllitic schist; beds are isoclinally folded. Metagraywacke member overlying the mica schist is a succsesion of thick-bedded gray or greenish rocks; quartzose beds are separated by thin chloritic phyllite, fine-grained dark-green amphibolite, or by layers composed of quartz, garnet, epidote, hornblende and chlorite. Youngest member is a dark-green or greenish-gray well-foliated amphibolite; thin veins of quartz, albite, and epidote are common. Base of amphibolite member generally rests conformably on metagraywacke; locally, lenses of one occur in the other. This amphibolite occurring near village of Erving in the Millers Falls quadrangle was called Erving hornblende schist by Emerson (1917). Quartzite member overlies Poplar Mountain gneiss on west slopes of Brush and Crag Mountains.

Named for Crag Mountain in south-central part of Massachusetts part of the Northfield quadrangle, Massachusetts-New Hampshire-Vermont.

Craig Limestone Member (of Rogersville Shale)

Middle Cambrian: Eastern Tennessee.

John Rodgers, 1943, Geologic map of Copper Ridge district, Hancock and Grainger Counties, Tennessee (1:24,000): U.S. Geol. Survey Strategic Minerals Inv. Prelim. Map. Named on map legend.

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 10–11. Formally proposed for members near top of Rogersville. Thickness at Craig quarry 85 feet; here member is separated from overlying Maryville limestone by 17 feet of green shale; in general, member thins to west and northwest and thickens to east and southeast; a few miles east-northeast of Lee Valley section, overlying shale thins to disappearance, and the Craig merges with the lithologically similar Maryville. Name credited to Josiah Bridge.

Named from Craig quarry in southern part of village of Rutledge, Grainger County. Quarry is about 0.15 mile south of junction of U.S. Highway 11W and State Highway 92, near sharp turn of latter.

Craig Shale[1]

Pennsylvanian: North-central Oklahoma.

Original reference: G. C. Clark and C. L. Cooper, 1927, Oklahoma Geol. Survey Bull. 40H, fig. 3.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey. Approximates pre-Warner Pennsylvanian in Craig County.

Craigsville Limestone[1]

Lower Devonian: Central western Virginia.

Original reference: R. J. Holden, 1920, Geol. Soc. America Bull., v. 31, p. 137.

Probably named for Craigsville, Augusta County.

†Crainesville horizon (in Midway Group)[1]

Eocene, lower: Southwestern Tennessee and northeastern Mississippi.

Original reference: G. D. Harris, 1896, Bulls. Am. Paleontology, v. 1, no. 4, p. 18–25.

Exposed in vicinity of Crainesville, Hardeman County, Tenn., and also identified in northern Mississippi.

Cramer Limestone Member (of Modesto Formation)

Pennsylvanian: Western and northern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38, 49 (table 1), pl. 1. Proposed for unit formerly called Trivoli limestone. Name Turner limestone, informally used in northern Illinois, is discontinued because it is believed to be equivalent to the Cramer. Stratigraphically above Chapel (No. 8) coal member (new). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: SW¼ sec. 3, T. 8 N., R. 5 E., Peoria County. Named for village of Cramer about 1⅓ miles southwest of type locality.

Cram Hill Formation

Middle Ordovician: Central Vermont.

L. W. Currier and R. H. Jahns, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1492, 1493–1496. Gray to black slate and phyllite grading downward into quartz-chlorite-sericite schist; thin to massive quartzite beds at bottom, herein named Harlow Bridge quartzite member. Siliceous volcanics at top; greenstone dikes locally abundant. Thickness from 1,500 to 2,600 feet. Underlies Shaw Mountain formation (new); overlies unnamed Ordovician(?) schists. Equivalent to upper part of "Missisquoi" schists of Richardson (1919).

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116. Lower Cambrian to Lower Ordovician.

W. M. Cady, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–79. Subdivision of the Missisquoi group of Richardson (1924, Vermont State Geologist Rept. 1923–1924).

Named for and well exposed on east slope of Cram Hill 3½ miles south-southeast of Roxbury, Barre quadrangle. Traced from Randolph about 27 miles north to point 2½ miles north of Montpelier.

Cranberry Gneiss

Cranberry Granite[1]

Cranberry Granite Gneiss

Precambrian: Western North Carolina and eastern Tennessee.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 3.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 17–18; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. As mapped, Cranberry granite gneiss consists essentially of Cranberry granite as named by Keith (1903) and further described by him [see bibliography of this reference]. Keith considered the Cranberry granite as igneous in origin, Archean in age, and intrusive into older formations. As considered here, the unit, whatever its origin, is essentially gneiss which grades at places into schist. Near Linville Falls, McDowell

County, it is in contact with Henderson granite gneiss, and the two units are considered to be stratigraphically equivalent. Precambrian(?).

Named for development at Cranberry in Mitchell, now Avery County, N.C. In North Carolina, occurs as strips and patches in the mountain region along northwestern border of State from near Asheville to Virginia line.

Cranberry Island Series[1]

Cranberry Island volcanic facies (of Frenchmans Bay Series)

Silurian: Southeastern Maine.

Original reference: N. S. Shaler, 1889, U.S. Geol. Survey 8th Ann. Rept., pt. 2, p. 1037, 1042–1047, 1059, 1061, and map.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1797. Considered a facies of the Frenchmans Bay series (new). Interfingers with and is of same age as Bar Harbor detrital facies. Silurian.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 173. Volcanic facies consists of felsite (and porphyry) flows and ash beds with tuffs and amygdaloids. Developed extensively in the southern part of Mount Desert Island.

C. A. Chapman and P. S. Wingard, 1958, Geol. Soc. America Bull., v. 69, no. 9, p. 1194 (table 1). Middle or Upper Silurian.

Named for development in Great Cranberry and Little Cranberry Islands, south of Mount Desert Island, Hancock County.

Crandall Conglomerate

Eocene: Northwestern Wyoming.

W. G. Pierce, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 4, p. 592–593 (fig. 1), 609–613. Stream-channel deposit of coarse conglomerate. At northwestern end of deposits the Crandall rests on Upper Cambrian; just south of Squaw Creek, conglomerate in middle part of channel rests on Pilgrim limestone, and toward sides of channel contact rises stratigraphically until conglomerate rests on Grove Creek formation. South of Squaw Creek, maximum thickness about 350 feet.

Type locality: South side of Squaw Creek about 2 miles above its junction with Clarks Fork, Park County. Fourteen areas of outcrop are spread over a linear distance of 20 miles.

Crane Member (of Mount Simon Formation)

Upper Cambrian: Northern Illinois (subsurface).

J. S. Templeton, Jr., 1950, Illinois Acad. Sci. Trans., v. 43 p. 153 (fig. 2), 154. Name proposed for the relatively fine-grained basal member of the formation. Type section extends from depths of 3,105 to 3,845 feet. Thickness 620 to 740 feet. Overlies a 245-foot arkosic zone above Precambrian granite; underlies Kenyon member (new).

Type well: Wyman No. 1 (well 7), in NE¼NE¼SE¼ sec. 35, T. 41 N., R. 5 E., DeKalb County. Name derived from Crane School, 4 miles south of type well.

Crane Creek Gravel

Pleistocene (Yarmouth): Northeastern Montana and northwestern North Dakota.

A. D. Howard, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 580–581. Characterized by distinctive brown water-worn pebbles. Contains many glacial pebbles of northeastern origin. Caps a broad strath terrace, the Crane terrace, within the major valleys.

A. D. Howard, 1960, U. S. Geol. Survey Prof. Paper 326, p. 19 (table 3), 20 (fig. 9), 21–23, pl. 1. Gravel and interbedded sand on Missouri Plateau peneplain. Thickness about 30 feet; average 10 to 15 feet. Similar to older and higher Flaxville and Cartwright gravels.

Named after Crane Creek, a tributary of the Yellowstone River near town of Crane in southern Richland County, Mont.

Cranesville Dolomite or Formation

Lower Ordovician (Upper Canadian): East-central New York.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76 (fig. 2), 77, 92–93. Name proposed for thin- to thick-bedded grayish-brown dolomites alternating with sandy and silty dolomites and dolomitic siltstone. Thin seams of sandy shale rare. Basal stratum invariably a feldspathic sandstone (or subgraywacke). Lower part of formation coarse-grained blue-gray variegated silty dolomite. Upper part characterized by coarse light-tan dolomarenites and dolomitic siltstone. Maximum thickness 70 feet; thins rapidly eastward and westward. Unconformably overlies Chuctanunda Creek dolomite (new).

Type locality: Along Swartztown Creek 0.6 mile east of Cushing quarry which is just east of the Niagara-Mohawk power station at Cranesville, Montgomery County.

Cranktown Sandstone[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures at a small group of prospectors' cabins, locally called Cranktown, on Silver Creek about 1 mile below Mogollon, Catron County.

Cranston Beds[1]

Pennsylvanian: Eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 159–164.

Occur in southwestern part of Cranston Township, Providence County.

Crater Creek Basalt

Pleistocene or Recent: Southwestern Alaska.

F. M. Byers, Jr., and others, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 3, p. 25–26, pl. 3. Series of basalt flows with beds of tuff and tuff-breccia, the products of explosive eruptions, making up small part of unit. Most flows massive, but a few blocky and brecciated. Top and bottom of individual flows commonly flow breccias, 5 to 20 feet thick, consisting of red oxidized lava fragments. Individual basalt flows from 10 to 70 feet thick. Flow rocks are fine-grained basalt containing few or no phenocrysts. Youngest flows display well-developed flow structure. Tuff and tuff-breccia are medium gray on fresh surfaces and weather light reddish yellow. Maximum thickness 1,300 feet. Basalt thickens away from Okmok caldera in northern part of mapped area, indicating that many flows probably emitted from vents well down the flanks of Mount Okmok. Overlies Tulik and Ashishik basalts (new); underlies Tanak volcanics (new). Mapped as Tertiary and Quaternary.

F. M. Byers, Jr., 1959, U.S. Geol. Survey Bull. 1028–L, p. 313–314, pl. 41. Youngest unit of precaldera age. Originally defined to include uppermost aphyric basalt flows on outer slopes of Okmok Volcano, but is herein restricted to sequence of basalt flows exposed in Crater Creek Gorge and in north wall of Okmok Caldera to west. Fault separates the Crater Creek in north wall from Ashishik basalt where north arcuate ridge intersects Okmok Caldera. Separated from Ashishik basalt by erosional surface. Consists of at least 15 separate flows with total exposed thickness of 500 feet. Older than Okmok volcanics. Latest Pleistocene or early Recent.

Crater Creek Gorge, on north wall of Okmok Caldera, Umnak Island.

Crater Lake dacites, lavas, flows, series.

General terms applied to rocks of Crater Lake region.

Crater Lake Pumice.

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 68–98, 115. Map shows distribution and thickness of Crater Lake pumice. The pumice is of two kinds, pumice flows and pumice fall. Main pumice fall was part of culminating activity of Mount Mazama. Finely divided dacite pumice which was projected high above summit of volcano drifted afar and was winnowed by winds. Earlier pumice fall was followed by explosions in which pumice escaped from crater in too large a volume and too rapidly to be thrown far into air but fell en masse on upper slopes of volcano and swept downward into the canyons and across surrounding flats as glowing avalanches. Some of these flows are: Annie Creek, Sun Creek, Sand Creek, Rogue River, and Castle Creek.

I. S. Allison, 1945, Geol. Soc. America Bull., v. 56, no. 8, p. 789–808. Discussion of pumice beds at Summer Lake, Oreg. Here, section shows six beds of pumice. Four of these appear to record eruptions of Mount Mazama. On basis of lacustrine sedimentation, the first layer of Mount Mazama pumice would be a little more than 14,000 years old, and age of main Crater Lake pumice layer about 500 years less than that. These are older than eruption of Newberry pumice.

H. P. Hansen, 1946, Am. Jour. Sci., v. 244, no. 10, p. 710–734. Discussion of postglacial succession and climate in Oregon Cascades. Figure 1 is map showing distribution of Mount Mazama pumice. [This is adapted from Williams' (1942) map (fig. 16) which shows distribution and thickness of Crater Lake pumice.]

Covers area around Crater Lake.

Crater Peak Basalt Flow

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 33–34. Name applied to basalt flow on Crater Peak. [See Timber Crater Basalt Flow].

Crater Peak is south of Crater Lake.

Cravatt Formation (in Kite Group)

Cravatt Member (of Bois d'Arc Limestone)

Silurian and Devonian: South-central Oklahoma.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132, 134. Defined as upper part of Kite group (new). Consists of hard cherty lithographic and argillaceous limestones and slates. Average thickness 60 to 75 feet. Conformably underlies Bois d'Arc limestone; conformably, overlies Haragan formation.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 4 (fig. 3), 7, 41–45, fig. 4. Rank reduced to member of Bois d'Arc formation. Overlies Haragan formation; base of Cravatt arbitrarily placed at base of lowest cherty bed of any appreciable thickness. Underlies Fittstown member (new) of Bois d'Arc limestone. Silurian and Devonian. Type locality given.

Type locality: NE¼SW¼SW¼ sec. 2, T. 2 S., R. 7 E., Pontotoc County. Name taken from original allotment owner, Katy Cravatt.

Crawford Series[1] or Subseries[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 40–46.

†Crawford Shale[1]

Devonian(?) and Mississippian: Northwestern Pennsylvania.

Original reference: J. F. Carll, 1879, Pennsylvania 2d Geol. Survey Rept. I_3 Atlas, pl. 11.

Named for occurrence in Crawford County.

Crazy Hollow Formation

Eocene, upper, or Oligocene, lower: Central Utah.

E. M. Spieker, 1949, Utah Geol. Soc. Guidebook 4, p. 36–37, [pl. 1]. Red and orange sandstone, siltstone, and shale, white sandstone, and pepper-and-salt sandstone. Thickness about 600 feet in Crazy Hollow. Overlies Green River formation and underlies Gray Gulch formation (new) with disconformable contacts. Age not known, but probably Eocene and may be late Eocene.

W. N. Gilliland, 1952, American Assoc. Petroleum Geologists Bull., v. 36, no. 7, p. 1461, 1464. Of late Eocene or early Oligocene age.

C. T. Hardy, 1952, Utah Geol. and Mineralog. Survey Bull. 43, p. 41 (table 1). Eocene.

Type locality: In Crazy Hollow, where it forms lower walls of the gulch beginning a short distance above its mouth and is more completely exposed than anywhere else as far as known. Crazy Hollow gulch is on south side of Salina Canyon next west of mouth of Soldier Canyon, about 2½ miles from Salina [Sevier County].

Crazy Johnson Member (of Chadron Formation)

Oligocene, lower: Southwestern South Dakota.

John Clark, 1954, Carnegie Mus. Annals, v. 33, art. 11, p. 197. Designated as middle member of formation. Underlies Peanut Peak member (new); overlies Ahearn member (new). Author previously described unit as "Middle Member" of Chadron.

Type locality: At standard section of Chadron formation in Big Badlands on south fork of Indian Creek, Pennington County, from sec. 34, T. 3 S.,

R. 12 E., to sec. 10, T. 4 S., R. 12 E. Named from prominent butte in southern part of sec. 10, T. 4 S., R. 12 E.

†Crazy Mountain Beds[1]

Upper Cretaceous and Paleocene: Montana.

Original reference: G. H. Eldridge, 1886, U.S. Tenth Census, v. 15, maps 50 to 54.

In Crazy Mountains, Little Belt Mountains quadrangle.

Crazy Mountain Granite[1]

Eocene: Central southern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 56.

Occurs over considerable area in Crazy Mountains, Little Belt Mountains quadrangle.

Creal Springs Limestone Member (of Spoon Formation)

Pennsylvanian: Southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32–33, 45 (table 1), 65, pl. 1. Proposed for limestone previously correlated with Curlew limestone but now considered to be younger. Weathers reddish buff, dense, hard, fossiliferous; thins to north. Thickness about 1½ feet. Stratigraphically above Granger sandstone member (new) and below Mount Rorah coal member (new). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼SE¼SE¼ sec. 25, T. 10 S., R. 3 E., Williamson County. Exposed just above top of sandstone quarried east of Creal Springs.

Creal Springs Sandstone (in Tradewater Group)

Pennsylvanian: Southern Illinois.

W. H. Smith, 1957, Illinois Geol. Survey Circ. 228, p. 8 (fig. 2), 9. Sandstone overlying Upper New Burnside coal and immediately underlying Curlew limestone. Name credited to P. E. Potter (1957, unpub. ms.).

Exposed in vicinity of Creal Springs, T. 10 S., R. 3 E., Johnson County.

Creede Formation[1]

Tertiary, middle or upper: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull 718.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13, 167–172, pl. 1. Comprises two members: lower, made up entirely of fragmental material, greater part of which was deposited by water; much of material is thinly laminated white shaly tuff, part is sandy and part is breccia and conglomerate; interbedded with tuff of lower member are beds of travertine; upper member coarser than lower member and made up mainly of well-bedded breccia. No satisfactory estimate of thickness made; structure is uncertain; top of formation nowhere preserved; and base exposed only on steep sides of basin. About 500 feet of lower member exposed on both sides of Willow Creek below Creede; neither top nor base shown; east of

Creede, where top of lower member is preserved, about 900 feet are present; about 1,000 feet of upper member exposed east of Windy Gulch. Cut by and underlies Fisher quartz latite. Overlies Potosi volcanic series (Piedra rhyolite). Upper Miocene.

U.S. Geological Survey tentatively considers the Creede formation to be middle or late Tertiary in age.

Named for development on slopes of both sides of Willow Creek about town of Creede, Mineral County.

Crekola Sandstone Member (of Boggy Shale)[1]

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 52–53. Bedded brownish sandstone, 4 to 10 feet thick. Lies about 10 feet below Inola limestone and about 6 feet above Secor or Upper Witteville coal.

Named for village of Crekola, in E½ sec. 10, T. 14 N., R. 17 E., Muskogee County.

Creola Member (of Yegua Formation)

Eocene (Claiborne): Central Louisiana, eastern Mississippi, and eastern Texas.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3945, pt. 2, p. 879 (fig. 133), 881. Name applied to beds of upper Yegua which contain unmistakable marine indicators, such as marine fossils, glauconite, limestone layers, or fucoids. This part of the Yegua has been referred to as a "transition zone" between the typical Yegua and typical Jackson. Thickness varies from 10 feet at Garland's Creek, Clarke County, Miss., to 40 feet at Pineland, Tex.; at type locality 32.4 feet. Bounded at top by a widespread clear-cut sharp disconformity on which the lower Jackson rests; at base, grades into typical nonmarine Yegua beds; west of Pineland, Creola outcrops become more and more nonmarine and fade into uppermost Yegua beds.

Type locality: Creole Bluff, near Montgomery, Grand Parish, La. Old town of Creola was built on the bluff in 1850.

Cresaptown Iron Sandstone[1] (in Rose Hill Formation)

Cresaptown Sandstone Member (of Clinton Shale)

Silurian (Niagaran): Western Maryland.

Original reference: C. K. Swartz, 1923, Maryland Geol. Survey, Silurian Volume, p. 28–31.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 73. Referred to as Cresaptown iron sandstone member of Clinton shale or formation.

Well exposed at Cresaptown 6 miles southwest of Cumberland, Allegany County.

Crescent Formation[1]

Eocene, lower(?) and middle: Northwestern Washington.

Original reference: R. Arnold, 1906, Geol. Soc. America Bull., v. 17, p. 451–468, map.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 25 (table), 40–45. At time of first investigation, the occurrence of Metchosin volcanics on Vancouver Island was unknown, and stratigraphic and structural relationships of the lavas and tuff at Crescent Bay to those along north side of Lake Crescent were not understood; in original description, these basaltic lavas together with the water-laid tuff were considered as a single formation. Recent studies indicate that the marine tuffs, shales, and sandstones which rest stratigraphically upon strictly volcanic part of formation and beneath Lyre conglomerates (new) should be segregated. Contact between underlying lava flows referred to as Metchosin volcanics and overlying marine phase in which volcanic products are mainly represented by tuffs is sharp and clearly defined. It is proposed to include within Crescent formation these upper tuffs and sedimentary deposits. Thickness about 1,000 feet. Includes Boundary shale (new) in uppermost part. Unit confined to northern border of Olympic Peninsula where it is represented in northern and southern limbs of Clallam syncline.

R. D. Brown, Jr., H. D. Gower, and P. D. Snavely, Jr., 1960, U.S. Geol. Survey Oil and Gas Inv. Map OM–203. As used in this report [Port Angeles-Lake Crescent area], name Crescent formation is extended to include entire sequence of volcanic rocks of which Arnold's type locality is small but generally typical part. Volcanic rocks of formation form belt from 2 to 5 miles wide, trending about N. 80° W., that extends from near Mount Muller southeastward to Round Mountain and form high ridges along south limb of Clallam syncline. Thickness difficult to estimate; more than 10,000 feet near east end of Lake Crescent. Underlies and interfingers with Aldwell formation (new). Overlies and interfingers with argillite and graywacke. Middle and possibly early Eocene.

Named for occurrence in vicinity of Port Crescent.

Crescent City Beds[1]

Crescent City facies (of St. George Formation)[1]

Miocene and Pliocene: Northwestern California.

Original reference: J. S. Diller, 1902, U.S. Geol. Survey Bull. 196, p. 31–35.

William Back, 1957, U.S. Geol. Survey Water-Supply Paper 1254, p. 21. Facies of St. George Formation. Outcrop of Crescent City beds no longer above sand and water level.

Occurs from Smith River to 3 miles south of Crescent City, Del Norte County.

Crescent Cliffs Flow, Lava, Dacite

Cenozoic: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 309–310, geol. map. Discussed under general heading pre-Lassen dacite flows which include Manzanita dacites, Loomis Peak flow, Black Butte flow, and other similar units.

Mapped in vicinity of Crescent Cliffs on western side of Mount Lassen.

Crescent Crater Dacites[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 675. Cenozoic.

Occur in Lassen National Park.

Crescent Hill Basalt

Miocene and (or) Pliocene: Northwestern Wyoming.

A. D. Howard, 1937, Geol. Soc. America Spec. Paper 6, p. 17–19, 78 (table 9), pl. 4. Coarse olivine basalt. Much of the olivine has changed to serpentine, and much of the pyroxene to uralite. Varies from brown to gray, although some exposures are colored brilliant red or yellow by surface growths of minute plants. Rock is massive to platy Platy character due to closely spaced shear surfaces. Most fractures are healed with silica, which also forms regular and irregular nodules and geodes many of which contain well-developed quartz crystals. Black color of fresh surfaces and coarse texture are in contrast to color and texture of Geode Creek basalt (new). Maximum thickness of 60 to 80 feet.

Typically exposed on summit of Crescent Hill from which it takes its name; Yellowstone National Park.

Cresswell Limestone Member (of Winfield Limestone)

Cresswell Limestone (in Chase Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 51.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44. Consists of limestone and locally shale in upper and middle parts and massive fossiliferous limestone in lower part; upper part, which has been called "Luta limestone" is thinner bedded and more shaly. Throughout a considerable distance, the lower massive ledge is almost constantly 3 feet thick. Total thickness of member commonly about 17 feet. Overlies Grant shale member; underlies Odell shale. Wolfcamp series.

Type locality: East side of golf course, in NE¼ sec. 18, T. 34 S., R. 4 E., on north side of Arkansas City, Cowley County, Kans.

Crest Hill Granite

Precambrian: Northern Virginia.

L. R. Thiesmeyer, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1963. Four major Precambrian granitic bodies, representing extensive batholiths of the western Piedmont, have been delineated; in order of intrusion, these are Lovingston gneiss, hypersthene granodiorite, Crest Hill granite, and Marshall granite (redefined).

Occurs in western Piedmont in Fauquier County.

Creston Formation

Creston Quartzite[1]

Precambrian (Belt Series): Northwestern Montana and northern Idaho, and southeastern British Columbia, Canada.

Original references: R. A. Daly, 1905, Canada Geol. Survey Summ. Rept. 1904, p. 96–100; 1905, Am. Jour. Sci., 4th ser., v. 20, p. 186.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 6 (fig. 4). Formation shown on correlation chart for the Belt series in northern Idaho.

Named for station on Canadian Pacific Railway (in Kootenay Province, southeastern British Columbia). Occurs at international boundary, 49th parallel, in section from Port Hill, Idaho, to Gateway, Mont.

Creston [Formation]

Eocene, upper: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

Creston Red Shale

Creston Shale (in Washington Formation)[1]

Permian (Dunkard Series): Western West Virginia and southeastern Ohio.

Original reference: R. V. Hennen, 1911, West Virginia Geol. Survey Rept. Wirt, Roane, and Calhoun Counties, p. 154.

J. B. McCue and others, 1948, West Virginia Geol. Survey [Rept.], v. 18, p. 9. Creston red shale, maximum thickness 60 feet, occurs between upper and lower Marietta sandstones, about 300 feet above base of Dunkard series. Commonly contains limestone nodules and locally interstratified with sandstone.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 18 (table 2). Creston shale, in Washington formation, listed in stratigraphic summary of Dunkard group in Harrison County. Thickness 30 to 65 feet. Above Middle Washington limestone and below Washington "A" coal and (or) fire clay and black carbonaceous shale.

Named for occurrence at Creston Flats, 1 mile east of Creston, Wirt County, W. Va.

Crestone Conglomerate Member (of Maroon Formation)

Crestone Conglomerate Member (of Sangre de Cristo Formation)

Crestone conglomerate phase[1] (of upper Sangre de Cristo Conglomerate)

Pennsylvanian or Permian: Southern central Colorado.

Original reference: F. A. Melton, 1925, Jour. Geology, v. 33, p. 812.

John Chronic, 1958, Rocky Mountain Assoc. Geologists Symposium on Pennsylvanian rocks of Colorado and adjacent areas, p. 63. Proposed that name Sangre de Cristo be dropped and that prior name Maroon be applied to equivalent coarse redbeds, at least as far south as La Veta Pass. Conglomeratic unit in upper part of formation is about 6,000 feet thick in vicinity of Crestone, where it has been called Crestone conglomerate "phase," more appropriately member, of Sangre de Cristo formation (now Maroon formation). Very local in occurrence, disappearing both southward and northward within a distance of about 10 miles.

D. W. Bolyard, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1903 (fig. 5), 1923, 1924–1925, 1933. Referred to as member of Sangre de Cristo formation. Overlies lower unnamed member. Formation considered to be late Pennsylvanian(?) and probably Permian (Wolfcamp).

Well exposed near Crestone, Sangre de Cristo Range.

Creta Dolomite (in Blaine Formation)[1]

Permian: Southwestern Oklahoma.

Original reference: G. G. Suffel, 1930, Oklahoma Geol. Survey Bull. 49, p. 29–40, 42, 47, 48, 63.

Named for station of Creta, in western part of Jackson County.

Crete Formation

Crete Formation (in Sanborn Group)

Crete Member (of Sanborn Formation)

Pleistocene: Nebraska and Kansas.

G. E. Condra, E. C. Reed, and E. D. Gordon, 1947, Nebraska Geol. Survey Bull. 15, p. 24–25 Name applied to unit which Lugn (1935) [1934] classified as "valley phase" of Loveland formation. A channel fill deposit which rests unconformably upon Upland formation or older Pleistocene deposits and is believed to be Illinois in age. Consists of sand, light-pinkish-brown in upper part, brownish-gray in middle, light-brownish-gray in lower part; grading from medium- to coarse-grained sand with fairly common fine to medium gravel in lower part, to fine to medium sand with rare fine gravel and fairly common silt in upper part; thin zone (1 to 2 inches) of red-brown iron-stained sand at base. Thickness 8 to 9½ feet. At type locality, underlies Loveland formation.

J. C. Frye and A. B. Leonard, 1949, Kansas Geol. Survey Bull. 81, p. 42–43; 1952, Kansas Geol. Survey Bull. 99, p. 52 (fig. 2), 110–115. Extended into Kansas where it is basal member of Sanborn formation. Underlies Loveland member.

G. E. Condra and E. C. Reed, 1950, Nebraska Geol. Survey Bull. 15–A, p. 24–25. Overlies Sappa formation which name replaces Upland formation of Lugn.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, p. 55 (fig. 1). Formation at base of Sanborn group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on correlation chart as Crete formation. [Kansas does not use term Sanborn group.]

Type locality: In roadcuts along State Highway 33 about 1½ miles west of main intersection at Crete, Saline County, Nebr., in NE¼ sec. 32, T. 8 N., R. 4 E.

Crevasse Canyon Formation (in Mesaverde Group)

Upper Cretaceous: Northwestern New Mexico.

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 91–92, pls. 1, 11. Name applied to sedimentary units which lie between top of Gallup sandstone and base of Point Lookout sandstone. Thickness 420 to 620 feet in northern sections; thickens to south of Crevasse Canyon, as it replaces rapidly thinning Point Lookout, to about 700 feet at type section. Includes three members: Dilco, Dalton sandstone (tongue), and lower Gibson.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2149, 2156–2157. In revised nomenclature of Mesaverde group in San Juan Basin, Crevasse Canyon formation is accepted for that part of group between Gallup and Point Lookout sandstones, with Gibson coal member (restricted) at its top; also includes Dilco coal, Dalton sandstone, and Bartlett barren members. For purposes of New Mexico State geologic map and other regional geologic maps now in preparation, contact between Crevasse Canyon and Menefee formations is arbitrarily shown at top of undivided Gibson and Cleary coal members in area of outcrop in which Point Lookout sandstone is missing.

C. H. Dane, A. A. Wanek, and J. B. Reeside, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 181, 188 (fig. 2), 191, 195. Winchester's (1920) Bell Mountain sandstone member at top of his Miguel formation in Alamosa Creek Valley area, Socorro and Catron Counties, is upfaulted duplication of his Gallego sandstone member, from which it had been supposed to be separated by nearly 1,000 feet of beds. Winchester's names Miguel formation, Chamiso formation, and Bell Mountain sandstone are abandoned and stratigraphic names in use in San Juan Basin are extended to units recognized in Alamosa Creek area. Winchester's Chamiso formation was properly defined and as it included only that part of the Mesaverde rocks above his Bell Mountain sandstone, it was not involved in duplication of section that requires abandonment of Miguel formation. Most of it, however, represents the Crevasse Canyon formation, including Dilco coal member at base and representatives or equivalents of Mulatto tongue of Mancos, overlying Dalton sandstone member, and Gibson coal member. Chamiso is abandoned in favor of Crevasse Canyon for Alamosa Creek area even though overlying Point Lookout sandstone or its equivalent has not been positively identified.

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 7 (fig. 2), 18, 20, 22, 23, pl. 1. In Puertecito quadrangle, overlies La Cruz Peak formation (new) and underlies Baca formation.

Type locality: Exposures north of Catron Creek, about 3 miles southwest of mouth of Crevasse Canyon, Tohatchi quadrangle.

Crill terrane[1]

Upper Cretaceous: Northwestern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 148, 150.

Named for old site of Crill mill, on Sioux River, Sioux City, Woodbury County.

Criner Formation[1]

Middle Ordovician: Central southern Oklahoma.

Original reference: E. O. Ulrich, 1930, U.S. Nat. Mus. Proc., v. 76, art. 21, p. 73.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey. Unit may be the Corbin Ranch formation of Harris (1957) and may include the Pooleville member of the Bromide formation (Cooper, 1956).

Named for exposures at south end of Criner Hills, south of Overbrook, Love County.

Crinerville Limestone (in Hoxbar Group)

Crinerville Limestone Member (of Hoxbar Formation)[1]

Pennsylvanian (Missouri Series): Southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p 15.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Shown on chart as limestone in Hoxbar group.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 41–42. Crinerville beds (or member) of Hoxbar group comprise a basal buff sandstone, a calcareous shale, and a limestone at top, each with maximum thickness of at least 30 feet. Crinerville beds are 400 to 500 feet above base of Hoxbar group and 400 to 500 feet below Anadarche beds or member. Confederate limestone is at base of Hoxbar.

Type locality: Near center of W½ sec. 28, T. 5 S., R. 1 E., near Crinerville Schoolhouse, Carter County.

†Cripple Creek Breccia[1]

Tertiary: Central Colorado.

Original reference: W. Cross, 1896, Colorado Sci. Soc. Proc., v. 5, p. 30.

Cripple Creek district, Teller County.

Cripple Creek Granite[1]

Precambrian: Eastern Colorado.

Original reference: E. B. Mathews, 1900, Jour. Geology, v. 8, p. 214–240.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 29. As used in this report, Cripple Creek granite of Pikes Peak quadrangle is included in Silver Plume granite.

Characteristically developed in area to west of line drawn from Lake George to town of Cripple Creek and thence in a somewhat sinuous line to waters of Oil Creek, Pikes Peak region.

Cripple Deer Sandstone Member (of Alsobrook Formation)[1]

Upper Mississippian: Northwestern Alabama and northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Included in Tanyard Branch member of Pride Mountain formation (both new). Alsobrook stratigraphically restricted above and reduced to member status in Pride Mountain formation.

Type locality: Along highway on north side of Cripple Deer Valley, Colbert County, Ala.

Crisfield Sandstone Member (of Salt Plain Formation)

Permian: Southern Kansas.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1788; R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 159. Sandstone about 29 feet thick occurring about 115 feet below top of formation. Name credited to G. L. Knight.

Outcrops in Harper and Barber Counties.

Cristobal limestone[1]

Ordovician: Southern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 6.

In Franklin, Caballos, Fra Cristobal, and Mimbres Ranges.

Critzer Limestone[1] (in Swope Limestone)

Critzer Limestone Member (of Hertha Limestone)

Pennsylvanian (Missouri Series): Eastern Kansas and western Missouri.

Original references: J. M. Jewett, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 99, 100, 103; R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 90, 97.

J. M. Jewett, 1940, Kansas Geol. Survey Bull. 30, p. 9. Reallocated to member status in Hertha limestone.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11. The Hertha differs from previous usage of Missouri Survey by inclusion of Critzer limestone and Mound City shale members.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 90. Consists of massive brownish-gray granular partly algal limestone and thin wavy-bedded gray limestone. Thickness ranges from featheredge to about 11 feet. Basal member of Hertha. Underlies Mound City shale member; overlies Pleasanton group.

Type locality: In sec. 17, T. 22 S., R. 23 E., south of Critzer, Linn County, Kans.

Croasdale Quartzite[1]

Silurian: Northeastern Pennsylvania.

Original reference: A. W. Grabau, 1913, Geol. Soc. America Bull., v. 24, p. 479.

Kittatinny Valley, Delaware Water Gap region.

Croatan Sand[1]

Croatan Formation

Pliocene, lower: Eastern North Carolina.

Original reference: W. H. Dall, 1892, Wagner Free Inst. Sci. Trans., v. 3, pt. 2, p. 209, 213–216.

F. S. MacNeil, 1938, U.S. Geol. Survey Prof. Paper 189–A, p. 19. Croatan sand of U.S. Geological Survey usage is of Pliocene age. Dall's original material from "Croatan beds" is mixture of Pliocene and Pleistocene and was probably collected along river for a distance of several miles. No Pliocene is exposed in bluffs of Neuse River nearest Croatan itself, so that type section for Croatan sand cannot be recognized there. Best section of Pliocene in region is exposed on property of Mr. Hastings on right bank of Neuse River, 2 miles below James City, Craven County, and this might be regarded as type section of Croatan sand.

R. F. Flint, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 543. In places along coast from the Carolinas to Florida are marine deposits of undoubted Pliocene date, with faunas that imply relatively warm water temperatures. These include the Croatan, Waccamaw, Charlton, and Caloosahatchie formations.

Type section (MacNeil): On property of Mr. Hastings on right bank of Neuse River, 2 miles below James City, Craven County. Named for exposures around Croatan. near Neuse River, Craven County.

Crockett Formation (in Claiborne group)

Crockett Member (of Claiborne Formation)[1]

Eocene: Eastern Texas and northwestern Louisiana.

Original reference: A. C. Ellisor, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 1339–1346.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 124–158 [1939]. Formation described in Leon County where it includes (ascending) Wheelock marl, Landrum shale, Spiller sand, and Mount Tabor members (all new). Overlies Stone City formation; underlies Yegua formation. Thickness about 385 feet. Middle Eocene.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ Geology Pub. 3945, p. 847–904. Yegua-Crockett boundary discussed.

H. B. Stenzel, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 9, p. 1663. Crockett formation replaced by term Cook Mountain formation.

G. D. Harris, 1941, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 33, p. 13–20. In Leon County, formation includes (ascending) Stone City, Wheelock, Two Mile (new), and [Mount] Tabor members.

Type locality: Vicinity of Crockett, Houston County, Tex.

Croghan Syenite Granite Complex[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1919, New York State Mus. Bull. 207, 208, p. 102–110, map.

Probably named for village of Croghan, Lewis County.

Croixan[1] or Croixian[1] Series
See **St. Croixan Series.**

Crook Formation

Upper Devonian: Central Arizona.

E. N. Harshman *in* M. N. Short and others, 1943, Arizona Bur. Mines Bull. 151, Geol. Ser. 16, p. 27. As originally described by Ransome, Martin limestone in Bisbee area contained a fauna similar to that of Hackberry shale of Iowa. Stoyanow noted that in Superior area a section of Upper Devonian limestone with interbedded clastic sediments is present below the true Martin limestone. These beds contain invertebrate fauna similar to that of Cedar Valley limestone. This lower part of Martin limestone section is here termed Crook formation.

Named after its locality in the Crook National Forest, Superior mining area.

Crooked Creek Chert Bed (in Cotter Dolomite)

Lower Ordovician: Northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 35, pls. 2, 9. Interbedded chert and dolomite; chert is very dark bluish gray, almost black, and occurs in three layers. Occurs near top of lower half of formation and stratigraphically below Jenkins Branch chert bed (new).

Well exposed on Arkansas State Highway 101 just above the north approach to the bridge at Crooked Creek, 2½ miles southwest of Cotter, Baxter County.

Crooked Creek Formation

Lower Cretaceous: Central southern Montana and central northern Wyoming.

R. M. Moberly, Jr., 1958, Dissert. Abs., v. 18, no. 1, p. 198. Sandstones and thinly interbedded rusty-brown-weathering siltstones, dark shales, and ironstones. Disconformably overlies Lovell member (new) of Cloverly formation; gradationally underlies Thermopolis shale.

In Bighorn Basin.

Crooked Creek Formation (in Meade Group)

Pleistocene: Southwestern Kansas and northwestern Oklahoma.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no. 4, p. 69 (fig. 1), 70–73. Proposed for sediments laid down during cycle of deposition which followed Meade formation; includes the following succession (ascending): (1) sands and gravels, (2) silt, (3) Pearlette ash, and (4) overlying deposits up to and including a well-developed caliche; as thus defined, includes Stump Arroyo member (new) at base. Type locality for the Crooked Creek is the same locality that was designated by Frye and Hibbard (1941) as type locality of Meade formation; it is now known that beds to which Cragin (1896) applied name Meade formation do not occur in this sequence of Pleistocene deposits but belong to an older series of Pleistocene beds.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1), 56, 57, 58. Top formation in Meade group. Comprises (ascending) Stump Arroyo member, Pearlette ash lentil, and Atwater member (new). Thickness as much as 60 feet. Overlies Ballard formation (new); underlies Kingsdown formation.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 57–58, pl. 2. Name Crooked Creek formation is applied in Harper County to gravels, sand, silt, and Pearlette volcanic ash lentils which unconformably overlie Ogalalla formation and Whitehorse group and are generally blanketed by post-Crooked Creek sand dune. Pearlette ash, which is only recognizable unit, forms a 13-foot lenticular bed in NW¼ sec. 10, T. 28 N., R. 26 W., but is absent elsewhere in county. Thickness 0 to 70 feet.

Type locality: S½ sec. 16, W½ sec. 15, and N½ sec. 21, T. 33 S., R. 28 W., on east side of Crooked Creek, Meade County, Kans.

Crooked Fork Group

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 6, pls. 3, 4, 6. Includes all strata between top of Crab Orchard Mountains group (new) and base of Slatestone group (new). Consists of alternating sequence of three sandstones and three shales. Northwest of type area, upper and lower sandstones converge so that in northern part of Barthell Southwest quadrangle group is essentially thick conglomerate overlying Rockcastle conglomerate. Thickness at type locality 360 feet; on Cumberland block 150 to 330 feet. Includes (ascending) Dorton shale (new), Crossville sandstone, Burnt Mill shale (new), Coalfield sandstone (new), Glenmary shale (new), and Wartburg sandstone. Rex coal present near base and Poplar Creek coal at top.

Type section: Southeastward from Wartburg and along Crooked Fork, Morgan County.

Crooked Lake Granite Pebble Conglomerates

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1615. Name applied to coarse granite pebble conglomerates that were deposited on the arkosites and graywackes which rest directly on the Saganaga granite. Some 12-inch Saganaga granite boulders are common in the middle or top of the conglomerate as well as at the bottom. Conglomerates reach a thickness of nearly three-fourths of a mile, or one-half that much where isoclinally folded over their width in sec. 36, T. 66 N., R. 6 W. Conglomerate is limited by a fault on western margin. In this report, Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Crooked Lake conglomerate as unit 15 occurring above Ester Lake graywackes and below an unnamed lower slate pebble conglomerate.

Report covers a belt in eastern Vermilion district more or less parallel to international boundary.

Crooked River Formation[1]

Recent(?): Central northern Oregon.

Original reference: E. T. Hodge, 1927, Geol. Soc. America Bull., v. 38, p. 163.

Cascade Mountains.

Crooks Complex[1]

Precambrian: Central Arizona.

Original reference: T. A. Jaggard, Jr., and C. Palache, 1905, U.S. Geol. Survey Geol. Atlas, Folio 126.

Named for exposures in Crooks Canyon in northwestern part of Bradshaw Mountain quadrangle.

Cropsey Drift

Pleistocene (Wisconsin): Northern Illinois.

H. B. Willman and others, 1942, Illinois Geol. Survey Bull. 66, p. 145 (fig. 85), 146 (fig. 86), 159–161. Largely till, locally both overlain and underlain by outwash deposits of gravel and sand. Maximum thickness about 50 feet; commonly less than 15 feet. Overlies Bloomington drift; underlies Farm Ridge drift. [Report lists six drifts in the Tazewell; for sequence see under Shelbyville.]

Named for morainic ridge at Cropsey, McLean County.

Crosby Lentil (in Starkey Tongue of Sherburne Formation)

Crosby Sandstone[1] Member (of Standish Formation)

Upper Devonian: West-central New York.

Original reference: I. W. Fox, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 7, p. 677, 681, 687.

P. D. Torrey and others, 1932, Am. Petroleum Inst. Div. Production Paper 826–4A, figs. 6, 7. Crosby sandstone in Standish shale and flags below Bluff Point flagstone.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 67, pl. 1. Reallocated. Lentil lies at base of Starkey tongue of Sherburne formation. Further described as heavy-bedded crinoidal very fine calcareous sandstone.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2824–2825. In area between Gorham and Penn Yan, Genundewa limestone member of Genesee grades laterally into Crosby sandstone of Torrey. In vicinity of Keuka Lake and Keuka Lake Outlet, Torrey's Crosby sandstone forms basal part of eastward-thickening wedge of Ithaca member of Genesee. East of Seneca Lake, Crosby sandstone of Torrey is in lower part of Ithaca. At Williams Brook, the Williams Brook coquinite of Caster (1933) is apparently at horizon of Crosby sandstone—the horizon of Genundewa limestone member. Interval between top of Geneseo shale member of Genesee and Torrey's Crosby is 170 feet near Keuka Lake, 200 feet at Seneca Lake, and 385 feet in vicinity of Ithaca.

Named from exposures at Crosby on east shore of Lake Keuka.

Crossen Trachyte (in Buck Hill Volcanic Series)

Crossen Trachyte (in Pruett Formation)

Eocene, upper: Western Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Lava flows intercalated in Pruett formation are (ascending) Crossen trachyte, Sheep Canyon basalts, and Potato Hill andesite.

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1144 (fig. 3), 1151–1153, 1171 (fig. 6), 1178, pl. 1. Porphyritic flows, 115 to 150 feet thick. Rests on tuff and fresh-water limestone of the Pruett. In vicinity of Potato Hill underlies tuff beds which are succeeded by Potato Hill andesite. Near northern boundary of Buck Hill quadrangle, Sheep Canyon basalt overlies the trachyte. In Alpine quadrangle, trachyte was eroded by stream and channel subsequently filled by Sheep Canyon basalt; small erosional remnants of trachyte now appear as inliers in the Sheep Canyon.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 546–547, pl. 1. Described in Cathedral Mountain quadrangle. Rank raised to formation in Buck Hill volcanic series. Average thickness approximately 200 feet; maximum thickness 265 feet at Mount Ord. Top of Eocene is placed at prominent disconformity between Crossen trachyte and Sheep Canyon basalt.

Named for the fact that it caps Crossen Mesa in north-central part of Buck Hill quadrangle, Brewster County.

Cross Mountain Group

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 11, 19, pls. 2, 3, 4, 6, 8. Includes all strata between top of Frozen Head sandstone of Vowell Mountain group (new) and the top of Cross Mountain. Thickness at type section 554 feet. Includes (ascending) shale interval, Low Gap sandstone (new), shale interval, Tub Spring sandstone (new), and shale unit.

Type locality: Cross Mountain, Lake City quadrangle, Anderson County. Section is on road leading to top of Cross Mountain. Group includes youngest Pennsylvanian beds in Tennessee and is preserved only on the higher peaks and ridges in the Cumberland Mountains.

Cross Plains Sandstone[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Derivation of name not stated.

Crossville Sandstone (in Crooked Fork Group)

Crossville Sandstone Member (of Duskin Creek Formation)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 37, 44 (table 3), 139. Light-gray fine- to medium-grained even-bedded sandstone; iron-stained, giving bands of pink, yellow, brown, and gray both on and across the bedding. Thickness about 39 feet. Occurs at top of Duskin Creek formation about 75 feet above Rockcastle sandstone. Known commercially as Crab Orchard sandstone, but name Crab Orchard preoccupied; hence, Crossville proposed.

C. W. Wilson, Jr., J. W. Jewell and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Rank raised to formation in Crooked Fork group (new). Thickness as much as 130 feet. In Morgan County, unit varies from a single thin sandstone to a bipartite or tripartite sandstone; only lower bench believed to represent the Crossville of the type area. Underlies Burnt Mill shale (new); overlies Dorton shale (new).

Well exposed on Pigeon Ridge Road, northwest of Byrd Creek, near Cumberland Homesteads CCC Camp, about 6 miles south of Crossville, Cumberland County.

Crosswicks Clay[1] (in Matawan Group)

Upper Cretaceous: New Jersey, northern Delaware, and eastern Maryland.

Original reference: T. A. Conrad, 1869, Am. Jour. Sci., 2d, v. 47, p. 359–360.

C. W. Carter, 1937, Maryland Geol. Survey, v. 13, p. 251–256. In banks of Chesapeake and Delaware Canal, conformably underlies Englishtown sand; unconformably overlies Magothy formation. Thickness about 50 feet.

R. A. Schmidt, 1948, Jour. Paleontology, v. 22, no. 4, p. 392 (table 1). Shown in Matawan group in northern Delaware.

Named for village of Crosswicks, on Crosswicks Creek, Burlington County, N.J.

Croton Gypsum[1]

Permian: Central northern Texas.

Original reference: A. M. Lloyd and W. C. Thompson, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, pl. 9.

Mapped in Stonewall County. Derivation of name not stated.

Croton Limestone (in St. Louis Limestone)[1]

Mississippian: Southeastern Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 231.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 813. About 30 feet of compact buff dolomitic limestone which grades into or is interbedded with dense gray nondolomitic limestone. Underlies Verdi member.

Named for exposures in vicinity of Croton, Lee County.

Croton Falls Diorite

Croton Falls Hornblendite[1]

Upper Ordovician(?): Southeastern New York.

Original reference: C. R. Fettke, 1914, New York Acad. Sci. Annals, v. 23, p. 228.

T. W. Fluhr, 1948, Rocks and Minerals Mag., v. 23, no. 8, p. 699. Referred to as diorite in map legend. Age shown as probably Upper Ordovician.

Occurs at Croton Falls and extends northeastward along east side of Croton River, Westchester County.

Crouse Limestone (in Council Grove Group)

Crouse Limestone Member (of Garrison Shale)[1]

Permian: Oklahoma, Kansas, and Nebraska.

Original reference: K. C. Heald, 1916, U.S. Geol. Survey Bull. 641–B, p. 21, 22.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 50 (fig. 12). In diagram showing comparison of old and revised classification of beds referred to lower part of Big Blue series of "Permian" age, Garrison shale is replaced by ascending) Beattie limestone (includes Florena and Morrill limestone members), Stearns shale, Bader limestone (includes Eiss limestone, Hooser shale, and Middleburg limestone members), Easly Creek shale, Bigelow limestone (includes Crouse limestone, Blue Rapids shale, and Funston limestone members), and Speiser shale.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 64–65. Condra (1935) employed term Bigelow limestone as comprising (ascending) Sabetha limestone (Crouse limestone), Blue Rapids shale, and Funston limestone. The Bigelow thus included strata between the Easly Creek shale and Speiser shale. To be consistent with classification applied to strata above and below them, these beds should be divided into formations. Proposed that Bigelow be dropped as stratigraphic term and that Crouse limestone, Blue Rapids shale, and Funston limestone be recognized as formations. In Council Grove group, Wolfcamp series.

Named for Crouse Hill, Foraker quadrangle, Osage County, Okla.

Croweburg Formation (in Cabaniss Group)

Croweburg Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas, southwestern Missouri, and northeastern Oklahoma.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 195. Cherokee group is divided into 15 cyclic formational units. The Croweburg, 12th in sequence (ascending), overlies the Coalvale and underlies the Ardmore. Average thickness 18 feet. Contains coal here referred to as Tebo. [For complete sequence see Cherokee group.]

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on midcontinent composite stratigraphic section as Croweburg formation in Cabaniss group. Underlies Verdigris formation; overlies Fleming formation.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as a coal cycle in Senora formation, Cabaniss group, in Oklahoma.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 25, 34. Exposed in Vernon County, Mo., where it is about 6 feet thick. Derivation of name given.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 68–72. Formation in Cabaniss subgroup of Cherokee. Includes beds above Fleming coal and extends to top of Croweburg coal. From base upward, succession includes massive dark lenticular limestone and dark-gray calcareous shale (cap-rock of Fleming coal), dark-gray to black shale containing clay-ironstone concretions, lenticular sandstone and underlimestone, underclay, and Croweburg coal. Each division, except Croweburg coal, is extremely variable in thickness, lithology, and distribution.

Named for association with Croweburg coal type locality of which is in strip pits about 1 mile east of Croweburg, Crawford County, Kans.

Crow Creek Member (of Pierre Shale)

Crow Creek zone (in Sully Member of Pierre Shale)

Upper Cretaceous: Central South Dakota.

J. P. Gries and E. P. Rothrock, 1941, South Dakota Geol. Survey Rept. Inv. 38, p. 14–18, pl. 1. Sand and marl zone at base of Sully member (new) of Pierre shale. Name replaces term Gregory marl of previous reports.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 1), 2343, 2346. Rank raised to member of Pierre shale. Defined to include sandstone and calcareous shale and marl beds lying between noncalcareous shales of Gregory member below and DeGrey member (new) above. Thickness ranges from a few feet to 15 feet. Type locality designated.

Type locality: At mouth of Crow Creek, Buffalo County.

Crow Hill Member (of Waits River Formation)

Silurian and (or) Devonian: Northeastern Vermont.

L. M. Hall, 1959, Vermont Geol. Survey Bull. 13, p. 21–23, 26, pl. 4. Series of interbedded quartzites, micaeous quartzites, gray quartz-mica schists, quartz-feldspar granulites, and minor calcareous rocks distinct from typical Waits River. Member closely resembles Gile Mountain formation and may be continuous with it, but continuity cannot be proved due to lack of outcrops.

Name derived from Crow Hill, southwest of village of St. Johnsbury, St. Johnsbury quadrangle.

Crowleyan series[1]

Tertiary, lower: Missouri and Illinois.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 252.

Derivation of name not stated.

Crow Mountain Sandstone Member (of Chugwater Formation)

Crow Mountain Formation (in Chugwater Group)

Triassic: Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 12, 43, 44. Predominantly sandstone with minor amount of shale; nonfossiliferous. Thickness 202 feet. Overlies Red Peak member (new); underlies Popo Agie member. Not recognized in any localities to west or in Wind River Mountains.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 135. Referred to as Crow Mountain formation in

Chugwater group. In Wind River Mountains, overlies Alcova dolomite and underlies Popo Agie formation.

T. C. Woodward, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 231–232. In Deadman Butte area, Natrona County, restricted use of name Crow Mountain sandstone member is applied to Triassic Chugwater interval between the Alcova below and Popo Agie members. Thickness 165 to 185 feet. In area where Love defined the Crow Mountain, the Alcova is absent; he probably included as part of the Crow Mountain the 20 to 80 feet of sandstone at top of Red Peak member.

Name derived from Crow Mountain, near southeastern end of Washakie Range.

Crown Conglomerate[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 66–67.

Named for Crown Peak, Brewster County.

Crownian Stage

Ordovician (Chazyan): North America.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 91, 94 (table 2). Chazy has long been divided into three lithologic and faunal zones (Brainerd and Seely, 1888, Am. Geologist, v. 2), which were given "substage" names Day Point, Crown Point, and Valcour (Cushing, 1905, New York State Mus. Bull. 95). As stages, these have been called Dayan, Crownian, and Valcourian by Oxley (unpub. ms.).

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 830, 838, 840. In Champlain Valley, Chazy series is separable into Dayan, Crownian, and Valcourian stages, distinguished by faunal criteria. Each stage has several lithologic facies. Reefs are prevalent. *Maclurites magnus* Lesueur considered guide to Crown Point limestone.

Crown Point Lava Member (of Troutdale Formation)

Pliocene, upper(?): Northwestern Oregon.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 10. Name applied to 30-foot flow of Boring lava interbedded in Troutdale formation.

Occurs in vicinity of Crown Point, east of Portland.

Crown Point Limestone[1]

Middle Ordovician: Eastern New York and west-central Vermont.

Original reference: H. P. Cushing, 1905, New York State Mus. Bull. 95.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524 (table), 548–550. Chazyan succession (Chazy group) in west-central Vermont comprises (ascending) Crown Point limestone, Beldens limestone with Weybridge member (both new), and Middlebury limestone (new). Crown Point limestone consists of lead-gray compact massive rock that weathers to gray surface. Thickness 0 to 150 feet. Overlies upper Beekmantown Bridport dolomite (new) at the meridian of Shoreham and west. Lies on Bascom formation (new) and is gradationally overlain by Beldens formation east of meridian of Cornwall.

Marshall Kay and W. M. Cady, 1947, Science, v. 105, no. 2736, p. 601. Inasmuch as Crown Point limestone (Cady, 1945) is structurally separated from Crown Point limestone of type locality and other outcrops in New York and is succeeded by Beldens formation rather than Valcour limestone, it is proposed here that "Crown Point" formation east of Champlain thrust in west-central Vermont be designated Burchards limestone.

Philip Oxley, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12 pt. 2, p. 1492. Discussion of Chazyan stratigraphy west of Champlain thrust, New York and Vermont. Lower Middle Ordovician sequence is Day Point (oldest), Crown Point and Valcour limestones. Day Point basal quartz sands and succeeding crosslaminated, locally reefy calcarenites and shallow water deposits of transgressing sea. Southward-lapping Crown Point limestones are preponderately deeper water argillicalcisiltites, but locally, and particularly toward top, are *Stromatocerium* reefs. Lower limestones of offlapping Valcour tend to match facies of underlying Crown Point. Upper Crown Point reefs are most widespread, forming roughly linear, discontinuous trend from near Isle La Motte, Vt., south of Essex, N.Y.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 820, 825 (fig. 4), 828 (fig. 6), 830–833, measured sections. Discussion of Ordovician Chazyan series of Champlain Valley, N.Y. and Vt. Series is divided into three stages: Dayan, Crownian, and Valcourian. Crown Point substage (Cushing, 1905) was division B of Brainerd and Seely (1888, Am. Geologist, v. 2) originally described southwest of Chazy, N.Y., from exposure of original Chazy limestone (Emmons, 1842). Sequence is 250 feet of dark-blue-gray massive argillicalcisiltites, gray-weathering, with buff silty crenulated laminae at intervals up to 4 inches; a 20-foot zone of lighter gray medium to coarse calcarenite lies about 50 feet above base. The Crown Point becomes more argillaceous and thinner bedded toward top. Calcarenites of Fleury member (new) of Day Point underlie with slight disconformity and succeeding is a 2-foot light-yellowish-gray fine-textured dolomite, the base of Hero member (new) of Valcour formation. Has normal or basinal facies and reef facies.

Probably named for exposures at or near Crown Point, Essex County, N.Y.

†Crow Ridge Series[1]

Jurassic and Cretaceous: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 399–455.

Named for southwest spur of Crow Peak, Elkhorn region.

Crows Mill Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1915, Illinois Geol. Survey Bull. 20, p. 99–107.

Sangamon County.

Crow Wing Formation[1]

Precambrian (Animikie): Central Minnesota.

Original reference: C. Zapffe, 1930, Lake Superior Min. Inst. Proc., v. 28, p. 101–106.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1002. Listed in geologic succession of central Minnesota as presumably Animikie in age.

Apparently named for extensive outcrops in northern part of Crow Wing County.

Croydon Group

Middle Devonian(?): South-central New Hampshire.

C. A. Chapman and others, 1938, Geologic map and structure sections of the Mascoma quadrangle, New Hampshire (1:62,500): New Hampshire Highway Dept. Described as fine-grained white to gray weakly foliated quartz diorite and granodiorite. Composed of oligoclase, quartz, biotite, and microcline. Belongs to Oliverian magma series whose age is post-Lower Devonian and probably Upper Devonian.

C. A. Chapman, 1952, Geol. Soc. America Bull., v. 63, no. 4, p. 391–392, pl. 1. Middle Devonian(?). Outcrop area largely in Sunapee quadrangle.

Confined to Croydon dome immediately east of Croydon Mountain in Grantham and Croydon Townships, Sullivan County.

†Crusher Hill (alternating) Shales and Limestones (in Council Grove Group)[1]

Permian: Central Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas, p. 9.

Derivation of name not stated.

Crystal Gray Quartz Monzonite (in Stearns Magma Series)

Precambrian (middle Keweenawan): Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1002, 1008–1009, pl. 1. Pinkish gray; granitoid; seriate; phenocrysts 1 to 2 centimeters, grains of ground mass 1 to 5 millimeters; appears to have been heavily contaminated by St. Cloud gray granodiorite (new) and then attacked by deuteric reactions.

Exposed in quarry in NE¼ sec. 27, T. 124 N., R. 29 W., Stearns County. Derivation of name not given.

†Crystal City Sandstone[1]

Lower Ordovician: Eastern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 352, 358.

Named for exposures at Crystal City, Jefferson County.

Crystal Falls Formation[1]

Precambrian (Upper Huronian): Northern Michigan.

Original reference: J. Zinn, 1933, Michigan Acad. Sci., Arts., and Letters, v. 18, p. 446–448, 454.

Has been traced almost continuously to Iron River district to west and to Florence district to south, Crystal Falls district.

Crystal Falls Limestone Member (of Thrifty Formation)

Crystal Falls Limestone (in Thrifty Group)

Crystal Falls Limestone Member (of Harpersville Formation)[1]

Upper Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 161–164; 1922, Jour. Geology, v. 30, p. 24, 31, 39.

Wallace Lee, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 64–65, 66–67. Member of Harpersville formation. Consists of lower limestone, gray, finely crystalline, 1 foot thick; shale, 1½ feet; and light-yellowish to buff limestone, 1 foot thick. Overlies shale and limestone in lower part of formation; separated by shale interval from limestone referred to by some writers as "Upper Crystal Falls limestone."

F. B. Plummer and H. B. Bradley, 1949, Texas Univ. Bur. Econ. Geology Pub. 4915, p. 6–20, figs. pls. Lower Crystal Falls limestone overlies Quinn clay (new). Curry clay (new) occurs between the lower and upper Crystal Falls limestone layers, just above Quinn clay in areas where sandstone deposits of Park Mountain and its probable equivalent, the Cisco Lake sandstone, do not occur.

John Kay, 1956, *in* North Texas Geol. Soc. Field Guidebook May 25–26, p. [13], fig. 4. Shown on columnar section as limestone in Thrifty group.

L. F. Brown, Jr., 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 41, p. 7 (fig. 2), 8 (fig. 3), 23–26, pls. 1, 3. Plummer and Moore (1921) stated that the Crystal Falls limestone "occurs 40 to 80 feet above the base of the Harpersville formation," which is top of Breckenridge limestone. The Crystal Falls was described as "yellow or gray limestone, weathering locally red or purple, with an average thickness of 2 or 3 feet." A section accompanying type description (idem, p. 163) was measured along Clear Fork of Brazos River west of Crystal Falls, Stephens County. However, this section does not include an unnamed limestone 23 feet above the Breckenridge designated "C1" by Bradish (1937, Geologic map of Stephens County, revised) and discussed by Lee (1938, Texas Univ. Bull. 3801). Crystal Falls limestone has been called "Lower Crystal Falls" by Bradish (1937) and some other writers. Plummer and others (1949, Texas Univ. Pub. 4915) showed sections of Crystal Falls type area. Difference in interpretation may be noted by comparing section by Plummer and others (fig. 18) at Crystal Falls type locality (fig. 6 of present report) and their sections 23, 24, and 25, with sections 9, 10, and 11, respectively, of present report. In general, present report agrees with Lee's stratigraphic description for section between the Breckenridge and "Upper Crystal Falls" limestones in northern Stephens County. Type section of Crystal Falls herein redescribed. Type Crystal Falls composed of an upper 1-foot limestone bed separated by about 1 foot of shale from a lower limestone bed that is 1 to 3½ feet thick. Limestone weathers from gray to yellowish orange; upper surface is ferruginous, commonly dark red or purple. Upper surface uneven and has wave or "moundlike" undulations with amplitudes up to 5 feet. Overlies Quinn clay member; underlies Curry clay member which in turn underlies unit termed "Upper Crystal Falls member." Area of report is northern Stephens County.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 72, 74, pl. 27. Bed here correlated with Breckenridge is shown on geologic map of Coleman County (Hudnall and Pirtle, 1929) as Lower Crystal Falls limestone. The generally persistent upper part of Chaffin limestone member of Thrifty formation has been variously called Breckenridge limestone (Plummer and Moore, 1921; Bullard and Cuyler, 1935, Texas Univ. Bull. 3501), Upper Crystal Falls limestone (Hudnall and Pirtle, 1929), Crystal Falls limestone (Cheney, 1950, Abilene Geol. Soc

Guidebook Nov. 2–4), and Chaffin limestone (Sellards, 1933, Texas Univ. Bull. 3232; Nickell, 1938; Cheney and Eargle, 1951, Geologic map of Brown County).

Type section (Brown): Measured from the shale beneath Breckenridge limestone to top of "Upper Crystal Falls" limestone. Beds 1–4 of section (fig. 6 and pl. 2, A) crop out on State land and beds 4–14 on property of Truman Robertson of Crystal Falls. Breckenridge limestone crops out in bed of Clear Fork of Brazos River from dam beneath bridge on Farm Road 578, down stream to first bend. Lower part of section (fig. 6, beds 1–7C) was measured southwestward from first bend below dam (pl. 2, A), across the dam and old bridge road to good exposure of bed 4 (pl. 1, bed c), and upward to exposure of the Crystal Falls in railroad cut no. 1; upper part of Quinn clay (bed 5) is well exposed at clay exposure no. 1. The interval from the top of Crystal Falls limestone to coal in Curry clay was described at clay exposure no. 2 (beds 7C–11), about 25 yards southwest of railroad cut no. 1; the offset is along bed 7C. Upper part of section (beds 11–14D) was described in railroad cut no. 2 to west; offset correlated with coal (bed 11). Named from Crystal Falls, Stephens County.

Crystal Mountain Sandstone[1]

Ordovician(?): Southwestern Arkansas and southeastern Oklahoma.

Original reference: A. H. Purdue, 1909, Geol. Soc. America Bull., v. 19, p. 557; 1909, Slates of Arkansas: Arkansas Geol. Survey, p. 30, 32.

August Goldstein, Jr., and T. A. Hendricks, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 424 (fig. 2). Shown on columnar section as massive light-gray calcareous to quartzitic sandstone; chert conglomerate at base in McCurtain County, Okla. Thickness 500 to 850 feet. Underlies Mazarn formation; unconformably overlies Collier formation. Cambrian-Ordovician.

H. D. Miser and others, 1954, Geologic Map of Oklahoma (1:500,000), U.S. Geol. Survey. Ordovician(?).

W. D. Pitt, 1955, Oklahoma Geol. Survey Circ. 34, p. 18–22. Outcrop area in Oklahoma small. Thickness estimated from 5 to 100 feet. Honess (1923, Oklahoma Geol. Survey Bull. 32) estimated 500 feet. Comprises a basal conglomerate and a massive sandstone member. Overlies Collier limestone; underlies Mazarn shale.

Named for Crystal Mountains, Montgomery County, Ark.

Crystal Pass Limestone Member (of Sultan Limestone)[1]

Middle and Upper Devonian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 15.

J. C. Hazzard, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881, 884 (fig. 3). Geographically extended into Nopah Range, Inyo County, Calif., where it is 140 feet thick, overlies Valentine limestone member of Sultan, and underlies Dawn limestone member of Monte Cristo limestone. Herein suggested that name Stewart Valley limestone be abandoned and that Devonian beds ascribed to it be assigned to Crystal Pass and Valentine members of Sultan. Middle Devonian.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 41. Because no fossils have been found in Crystal Pass limestone and there are no unconformities under or over the limestone, its age must be open to debate. Age of Sultan limestone is considered to be Middle or early Late Devonian.

U.S. Geol. Survey currently considers the Sultan limestone and its members to be Middle and Upper Devonian in age.

Named for Crystal Pass, sec. 2, T. 25 S., R. 58 E., Clark County, Nev.

Crystal Peak Dolomite

Middle Ordovician: Western Utah and eastern Nevada.

G. W. Webb, 1956, Utah Geol. and Mineralog. Survey Bull. 57, p. 12–13, 42–43 (fig. 11). Name applied to dolomite separating Watson Ranch tongue (new) of Swan Peak quartzite from overlying Eureka quartzite. Dolomites are closely parted by reddish or yellow silt seams and are gray or black and fine or medium in grain. Thickness about 85 feet.

Named for occurrences at Crystal Peak, near Ibex, Millard County, Utah.

Crystal River Formation (in Ocala Group)

Eocene (Jackson): Northern and western Florida.

H. S. Puri, 1953, (abs.) Jour. Sed. Petrology, v. 23, no. 2, p. 130. Proposed for the 108 feet of limestone exposed in Crystal River Rock quarry in Citrus County. Includes all calcareous sediments of upper Eocene age lying stratigraphically between the Williston formation and the overlying Oligocene limestones.

W. E. Moore, 1955, Florida Geol. Survey Bull. 37, p. 30–36. In this report, includes all limestones containing Jackson Eocene orbitoid and camerinid faunas that underlie the Marianna limestone or younger beds and overlie beds of Cook Mountain (lower middle Eocene) age with *Operculinoides sabinensis*. White to cream-colored soft granular permeable limestone. Thickness in Jackson County about 200 feet including Bumpnose member (new).

H. S. Puri, 1957, Florida Geol. Survey Bull. 38, p. 31–38. Moore (1955) erroneously included in the unit all upper Eocene beds overlying the *Operculinoides sabinensis* faunizones of the Lisbon formation (Claiborne). Bumpnose member is not considered a valid stratigraphic unit. Type locality stated.

Type locality: Crystal River Rock Co. quarry, NE¼SW¼ sec. 6, T. 19 S., R. 18 E, Citrus County.

Crystal Spring Formation

Precambrian (Pahrump Series): Southern California.

D. F. Hewett, 1940, Washington Acad. Sci. Jour., v. 30, no. 6, p. 240; 1956, U.S. Geol. Survey Prof. Paper 275, p. 26, 28, 29, pl. 1. Comprises about 2,000 feet of quartzite, arkose, shale, and limestone, intruded by sills of diorite and syenite, with beds of dolomite and chert at top and thick coarse conglomerate at base. Base of series; underlies Beck Spring dolomite (new); unconformably overlies Precambrian granite gneiss. Base of formation observed at only one locality, on west end of ridge 2 miles east of Horse Springs; here conglomeratic quartzite rests on Precambrian gneissic granite.

L. A. Wright, 1952, California Div. Mines Spec. Rept. 20, p. 7 (fig. 3), 9–12, 13. Described in Superior talc area, Death Valley region, where it consists of lower 800 feet of conglomerate, quartzite, and shale, middle 600 feet of dolomite, and upper 200 feet of alternating quartzite, shale, and dolomite layers; a diabase sill, 200 to 600 feet thick, lies at or near the base of the massive dolomite; below sill is alternation zone which contains commercial talc deposit. Underlies Beck Spring dolomite; overlies Archean quartzite, gneiss, and schist.

Crops out in belt that extends for 5 miles around north slope of Kingston Range and in two areas on eastern slope of range, Ivanpah quadrangle. Name derived from Crystal Spring on north slope of Kingston Range.

Cuba Formation (in Canadaway Group)

Cuba Member (of Canadaway Formation)

Cuba Sandstone[1]

Upper Devonian: Western New York.

Original reference: J. M. Clarke, 1902, New York State Mus. Bull. 52, p. 524–528.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 14, 16–18, 23–27. Referred to as Cuba formation in Canadaway group. Thickness about 40 feet in Wellsville quadrangle. Overlies Machias formation; underlies Wellsville formation (new) of Conneaut group.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 12–14. Rank reduced to member status in Canadaway formation.

Well exposed in quarry east of Erie depot at Cuba, Allegany County.

Cuba Sandstone (in Carbondale Formation)[1]

Cuba Sandstone (in Carbondale Group)

Pennsylvanian: Western and central Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 107–108, 195, 196, 204, 206, 207. Light brownish gray and spotted with bright brown specks; commonly thin bedded and shaly in upper part, the beds thickening downward. Thickness 3 to more than 80 feet; through most of Glasford quadrangle and east of Cuba in Havana and Canton quadrangles, ranges from 30 to 80 feet and varies inversely with underlying St. David beds. Underlies Big Creek shale near base of Brereton cyclothem, Carbondale group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35. Replaced by Vermilionville sandstone member of Carbondale formation. Name Cuba preempted.

Named from exposures north of Cuba in sec. 8, T. 6 N., R. 3 E., Havana quadrangle, Fulton County.

Cubierto Shale (in Puente Formation)

Miocene, upper: Southern California.

M. L. Krueger, 1943, California Div. Mines Bull. 118, p. 363. Shown on structural section as underlying Hunter sandstone and conglomerate (new) and overlying Blanco shale (new).

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 521. Thin-bedded gray micaceous clay shale and fine- and medium-grained sandstone. Thickness 864 feet. Upper part of Puente. Measured section noted.

Exposed in Slaughter Canyon in southeastern Puente Hills, between Chino and Santa Ana River, San Bernardino County.

Cub Mountain Formation

Eocene: Central New Mexico.

M. W. Bodine, Jr., 1956, New Mexico Bur. Mines Min. Res. Circ. 35, p. 1, 8–11, figs. 2, 3. Consists of beds of pale-yellow to gray coarse-grained quartzose sandstones, with lenses of quartzite and chert-pebble conglomerate. Color not at all reliable because it changes drastically, both vertically and horizontally. Thickness at least 500 feet. Underlies Tertiary rocks with unconformity and overlies Mesaverde group with apparent unconformity. May be as old as latest Cretaceous or as young as Miocene.

G. B. Griswold, 1959, New Mexico Bur. Mines Mineral Resources Bull. 67, p. 7 (table 2), 12, pl. 2. Thickness about 2,000 feet. Mapped as Eocene.

Named for isolated peak located 7 miles due south of Carrizozo and 18 miles due west of Capitan, Lincoln County. Exposed in southwest flank of the mountain.

Cucamonga Complex

Pre-Upper Cretaceous: Southern California.

R. M. Alf, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1104 (fig. 2), 1107–1108, pl. 6. Characterized by discontinuous bands of pale and graphitic limestone, complex gneiss, and quartz monzonite mylonite. Aggregate thickness of the two sections sampled 231 feet.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 259–274, geol. map. Name replaced by Cucamonga Canyon group.

Occurs in San Gabriel Mountains southeast of Los Angeles.

Cucamonga fan deposits

Recent: Southern California.

E. M. Mackevett, 1951, California Div. Mines Spec. Rept. 5, p. 11. Contains a wide assemblage of clastic materials; some of constituent boulders exceed 2 feet in diameter. Distributaries have cut as much as 40 feet into the fan.

Almost surrounds Jurupa Mountains, western San Bernardino and Riverside Counties.

Cucamonga Canyon Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 259–272, geol. map. Divided into two subgroups on basis of textural criteria: layered plutonics and cataclastic plutonics. Distinction between the two is in many places difficult because all gradations of textures from typically granoblastic to ultracataclastic are represented. Group forms an east-northeast-trending belt south of Aurela Ridge group (new); the two are separated by Cucamonga Canyon thrust. Alf (1948) described these rocks as "Cucamonga complex" and considered them a heterogeneous aggregation of rocks of different origins. Present study indicates that most Cucamonga Canyon rocks were derived from Aurela Ridge granulites under conditions represented by the amphibolite facies.

Exposed in lower Cucamonga Canyon, San Bernardino County.

Cucaracha Formation[1]

Miocene, lower: Panamá.

Original references: D. F. MacDonald, 1913, Canal Records, v. 6, p. 214; 1913, Geol. Soc. America Bull., v. 24, p. 709.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 240–241, 246 (fig. 2). Chiefly massive generally greenish-gray waxy highly slickensided bentonitic clay. Bed of agglomeratic andesitic tuff, 10 to 35 feet thick, occurs about 200 feet below top of formation. Maximum thickness about 625 feet. Overlies Culebra formation; underlies La Boca formation. Early Miocene.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 39, 51 (fig. 4), pl. 1. Underlies La Boca member of Panamá formation. Assigned to early Miocene because both underlying Culebra formation and overlying Panama formation are considered to be of that age.

Type region: Along Gaillard Cut south of Continental Divide where village of Cucaracha was located near site of Cucaracha slide.

Cuchara Formation[1]

Eocene: Southern Colorado and northern New Mexico.

Original reference: R. C. Hills, 1893?, Colorado Sci. Soc. Proc., v. 4, p. 9; paper read Feb. 2, 1891.

W. S. Burbank and E. N. Goddard, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 947. Overlies Poison Canyon beds, with marked unconformity at northern end of Huerfano Park, and entirely overlaps formation locally; because the Cuchara is, in turn, overlapped along western side of park by Huerfano beds, it is assigned questionably to lower Eocene (Wasatch).

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map. OM–146. Described in La Veta area, Huerfano County, where it unconformably overlies Poison Canyon formation; unconformably underlies Huerfano formation. Composed of thin to massive red, pink, and white sandstone beds and thin red and tan shale beds. Estimated thickness more than 5,000 feet in center of Raton Basin on northern flank of West Spanish Peak; probably not more than 2,500 feet present in La Veta area. Eocene.

Named for exposures along Cuchara River north and south of La Veta, Huerfano County, Colo.

Cuchillo Formation[1] (in Trinity Group)

Lower Cretaceous (Comanche Series): Southwestern Texas, and northern Mexico.

Original references: R. H. Burrows, 1909, Min. and Sci. Press, v. 99, p. 324; 1910, Soc. geol. Mexicana Bol., t. 7, p. 95.

Gayle Scott, 1939, Texas Univ. Bur. Econ. Geol. Pub. 3945, p. 969–1077. Overlies Las Vigas formation; underlies Glen Rose in Sierra Blanca-Quitman Mountain area. Ammonite zone of *Sonneratia trinitensis* and *Douvilleiceras mammillatum* of Trinity group.

Named from Conchos Valley section north of Kansas City, Mexico & Orient Railroad, a short distance north of Presidio, Presidio County, Tex. Fossil collection made near Aurora mine, 5 kilometers south of Cuchillo Parado.

Cuchillo Negro Formation (in Mud Springs Group)

Pennsylvanian (Derry Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 31 (fig. 2), 37, 39. Name proposed for all strata between top of Mud Springs [Hot Springs] formation below and base of Des Moines series above. At type locality, formation is composed almost entirely of medium- to light-gray massive to nodular cherty limestone. Calcareous algae are abundant in some parts of formation and make up more than 50 percent of some strata. Two thin beds of greenish to brownish coarse-grained sandstones to granule conglomerates occur in lower part of formation in some areas of the Mud Springs Mountains; one of these sandstones occurs at the base and the other occurs about 15 feet above base of formation. Thickness at type locality about 28 feet.

M. L. Thompson, 1948, Kansas Univ. Paleont. Contr. 4, Protozoa, art. 1, p. 73 (fig. 8), 74. Overlies Fra Cristobal formation (new) which name replaces preoccupied Hot Springs formation.

Type locality: Near west end of Whiskey Canyon in northern part of Mud Springs Mountain, just west of westernmost box canyon, in southwestern part of sec. 1, T. 13 S., R. 5 W., Sierra County. Name derived from Cuchillo Negro Peak where formation is well exposed.

Cucuracha Formation

See **Cucaracha Formation,** correct spelling.

Cuerbio Basalt

Pleistocene(?): North-central New Mexico.

C. E. Stearns, 1943, Jour. Geology, v. 51, no. 5, fig. 2. Mapped in Galisteo-Tonque area. Pleistocene. Younger than Santa Fe formation.

C. E. Stearns, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 476, 477, pl. 1. Basalt flows interbedded with Tuerto gravel (new) are tentatively correlated with Cuerbio basalt.

A. E. Disbrow and W. C. Stoll, 1957, New Mexico Bur. Mines Mineral Resources Bull. 48, p. 5 (table 1), 29–30, pl. 1. In this report [Cerrillos area], basalt flows that are interbedded with and overlie upper part of Ancha formation, together with an associated cinder cone, are placed in Cuerbio basalt. Two flows mapped; each about 20 feet thick. Pleistocene(?). Name credited to Kirk Bryan (unpub. ms.).

Type locality and derivation of name not stated.

Cuero Formation (in Fleming Group)

Miocene, upper: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists 26th Ann. Mtg. Program, p. 20. Name appears on a chart; occurs below Lapara member of Goliad formation and above Oakville formation.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1724–1726. Proposed for the predominantly red, pink, green, and gray section of clays and sandstones lying above the Oakville formation and below the Goliad formation. Thickness about 350 feet. In Bee, Karnes, and DeWitt Counties, formation is identical with the section assigned to the Lower Lagarto by Weeks (1933, Am. Assoc. Petroleum

Geologists Bull., v. 17, no. 5) and is part of section assigned to Lagarto (emended) by Plummer (1933, Texas Univ. Bull. 3232).

Name taken from a city in DeWitt County.

Cuesta Diabase[1]

Lower Cretaceous: Southern California.

Original reference: H. W. Fairbanks, 1904, U.S. Geol. Survey. Geol. Atlas, Folio 101.

Extends from near Cuesta Pass on south to northern edge of San Luis quadrangle. Named for exposures near Cuesta and Cuesta Pass, San Luis Obispo County.

Cueva Rhyolite[1]

Eocene: Southern New Mexico.

Original reference: K. C. Dunham, 1935, New Mexico School Mines Bull. 11, p. 53, 55.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 114 (fig. 14). Age shown on correlation chart as Eocene.

Type locality: La Cueva, west of mouth of Fillmore Canyon, Organ Mountains, Dona Ana County.

Cuivre Shale

Mississippian (Kinderhook): Northeastern Missouri.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 98–100. Proposed to designate stratigraphic unit between Hannibal shale and Louisiana limestone. Predominantly very dark gray to blue-black somewhat fissile clay shale; in some places massive and shows blocky weathering; sandy at base with lenses of hard gray sandstone with calcareous and pyritiferous cement. Thickness 12 feet at type locality. Unconformable below, resting on Louisiana or Bowling Green limestone; unconformable beneath the Hannibal.

Type locality: SE¼NE¼SE¼ sec. 35, T. 54 N., R. 3 W., Pike County, about 4½ miles north of Bowling Green. Here, in one of head branches of Grassy Creek, entire thickness of unit is exposed. Named from Cuivre Township, near northeastern corner of which the type locality is located.

Culberson series[1]

Permian: Western Texas.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 57, p. 350, 351, 354.

Occurs on Wiley Ridge, Wiley Mountains.

Culbert Breccia

Pleistocene(?): Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 39. Composed of angular to subangular blocks of monzonite porphyry, as much as 5 feet in diameter, in a poorly cemented matrix. Considerable differences in color and density. Of mudflow origin and cited also as mudflow fanglomerate. Of probable Pleistocene age according to text; shown as Pliocene(?) age on fig. 2a. Generalized section of formations in area shows breccia stratigraphically above Pine Valley latite (new).

Exposed in small patches on east side of Culbert Canyon and in the Comanche Creek drainage, Pine Valley Mountains, Washington and Iron Counties.

Culebra Dolomite Member (of Rustler Formation)

Permian: Southeastern New Mexico and western Texas.

J. E. Adams, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 11, p. 1600 (fig. 2), 1614. Name applied to 35-foot dolomite in upper part of Rustler. Name suggested by W. B. Lang 1938, New Mexico State Engineer 12th and 13th Bienn. Rept.), who divided Rustler into 11 units; Culebra member is unit 6 (descending) in this classification. Member is also good marker in subsurface where it extends into western Texas.

Exposed east of Pecos River, central Eddy County, N. Mex.

Culebra Formation[1]

Culebra Clays or Beds

Miocene, lower: Panamá.

Original reference (Culebra clays): R. T. Hill, 1898, Harvard Coll. Mus. Comp. Zoology Bull., v. 28, no. 5, p. 192–195.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 239. Referred to as Culebra beds. Upper Oligocene.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 236–240, 246 (fig. 2). Formation includes Emperador limestone member. Estimated maximum thickness about 500 feet. Conformably overlies Las Cascadas agglomerate; underlies Cucaracha formation. Upper Oligocene and lower Miocene. First named Culebra clays by Hill (1898).

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 34–39, 51 (fig. 4), pl. 1. Lower Miocene.

Type region: Central Gaillard Cut area, where town of Culebra was located on west side of canal during construction.

Culebra Lake Clay

Late Cenozoic: North-central New Mexico.

V. C. Kelley, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p 111–112. Accumulated in waters impounded by lava flows to the south. Some of the lavas poured into the lake, and, with the clay, formed subaqueous pudding-stone and pillow structure. Deposited in late Santa Fe time.

In Rio Grande depression between Taos and Santa Fe.

Cullom Limestone[1]

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 7, 11, 20, 35.

G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 57. Condra (1927, Nebraska Geol. Survey Bull. 1, 2d ser.) wrongly correlated Beil limestone as Cullom. At Cullom Station, the bed so named is part of Westerville limestone.

Named for Cullom Station, Cass County, Nebr.

774–954—vol. 1—66——64

Cultus Formation[1]

Triassic: Southern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 16 and 17.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 17. In extreme western part of Cascades just south of Canadian boundary are outcrops of dark-gray to black argillite, together with intercalated bands of greenish-gray sandstone, grit, and conglomerate which have been described as Cultus formation.

Mapped around south shore of Cultus Lake, British Columbia.

Culver Springs Shale Member (of Brodhead Formation)

Lower Mississippian: Northwestern Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 147. Basal member of Brodhead formation, Pilot Knob facies (new). Thickness 40 feet. Underlies Lebanon Junction siltstone member (new); overlies New Providence formation, Keith Knob facies (new).

Good exposure on slope along northern side of Belmont-Pitts Point Road, 2 miles west of Culver Springs School, 3½ miles west of Belmont, southwestern Bullitt County.

Cumberland facies (of Clinton Formation)

Silurian (Niagaran): Western Maryland and western Virginia.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 238, 242–244. Clinton formation in Virginia is composed almost entirely of shale and sandstone and varies geographically in character and proportions of its constituents. At northeast and southwest ends of Appalachian Valley (in Virginia), formation comprises a rather homogeneous body of shale and thin layers of sandstone. It is proposed to designate this lithologic expression of formation the Cumberland facies. Merges laterally into Iron Gate facies (new). Facies is well displayed at north end of Rose Hill, Cumberland, Md., where approximately 600 feet of section is exposed.

Type locality not stated.

†Cumberland Quartzite[1]

Precambrian: Northeastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 106–107.

Crops out on south side of Sneech Pond, along to main street southeastward for 1½ miles in village of Cumberland Hill, Providence County.

Cumberland Sandstone[1]

Upper Ordovician (Richmond): Southern Kentucky.

Original reference: N. S. Shaler, 1877, Kentucky Geol. Survey, 2d ser., v. 3, p. 152, 153, 155, 159–160. 387.

W. R. Jillson, 1951, Geology of the McFarland Creek oil pool; Frankfort, Ky., Roberts Printing Co., p. 13. In Monroe County, 40 to 50 feet of Cumberland sandstone (Richmond-Upper Ordovician) is exposed beneath Chattanooga shale.

Named for exposures along Cumberland River in Cumberland and adjoining counties.

Cumberland Gap Shale Member (of Chattanooga Shale)[1]

Devonian and (or) Mississippian: Southern Tennessee and southwestern Virginia.

Original reference: J. H. Swartz, 1927, Am. Jour. Sci., 5th, v. 14, p. 485–499.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on Devonian correlation chart as Devonian or Mississippian.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 167, chart 5 (columns 93, 94, 97). Shown on Mississippian correlation chart as Kinderhook. Age of Cumberland Gap shale has not been determined, but may include strata of early as well as middle New Albany age.

Well exposed along Lee Highway on north edge of town of Cumberland Gap, Tenn.

Cumberland Head Shale[1] or Formation

Middle Ordovician: Northwestern Vermont and eastern New York.

Original reference: H. P. Cushing, 1905, New York State Mus. Bull. 95, map forming pl. 13.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 274–275, pl. 2. Redescribed as formation including argillaceous limestones and limestone-bearing black shales overlying lowest Sherman Fall Shoreham limestone and underlying Stony Point black shale in type region. Thickness typically about 150 feet. Assigned to Trenton group. Geographically extended to Vermont. Type region mentioned.

R. B. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 32–37, 74–75, 77–80, 82, pl. 1. Described on Isle la Motte and in several fault blocks on South Hero Island in Lake Champlain.

Type region: [South] Hero Island, Grand Isle County, Vt., 2 miles southeast of Cumberland Head. Named for Cumberland Head near Plattsburgh, Clinton County, N.Y.

Cumberland River Sandstone[1]

Upper Ordovician: Southern Kentucky.

Original reference: A. M. Miller, 1919, Kentucky Dept. Geol. and Forestry, ser. 5, Bull. 2.

Named for exposures along Cumberland River in Cumberland and adjoining counties.

Cummingsville Member (of Galena Formation)

Middle Ordovician: Southeastern Minnesota and northwestern Iowa.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 764–766; 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1036–1037. Proposed for interbedded limestones and shaly limestones at base of Galena formation that were formerly included in overlying Prosser member. Unit is an argillaceous limestone, yellowish-gray to pale-yellowish-brown, generally microgranular, and thin and crinkly bedded, with conspicuous to thick shaly partings. Thin beds are typically grouped into massive units that are separated by smoother more prominent shaly partings. Thickness at type locality 63 feet; essentially uniform throughout its extent. Overlies Decorah formation; base is the level at which the green shales of the Decorah are succeeded by rock that is predominantly limestone, usually beds of lumpy or nodular limestone in a shale matrix.

Type section: One-half mile north of Cummingsville, on east edge of SE¼ sec. 21, T. 105 N., R. 12 W. Name derived from hamlet of Cummingsville, Olmsted County, Minn., on State Highway 30, 3½ miles west of Chatfield.

Cummins Station Shale Member (of Muldraugh Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 212–214. Shale, slightly silty, blue-gray to olive-gray, with thin siltstone ribs. Forms basal unit of Maretburg facies (new) of formation. Thickness 12 to 18 feet. Overlies Floyds Knob formation.

Type section: Along Louisville and Nashville Railroad and nearby hillsides midway between Maretburg and Brodhead, one-half mile west of Cummins Station, Rockcastle County. Named for station on railroad.

Cumnock Formation (in Newark Group)[1]

Upper Triassic: Central North Carolina.

Original reference: M. R. Campbell and K. K. Kimball, 1923, North Carolina Geol. and Econ. Survey Bull. 33, p. 20, 25–43.

J. A. Reinemund, 1955, U.S. Geol. Survey Prof. Paper 246, p. 31–35, pl. 1. Conformably overlies Pekin formation; conformably underlies Sanford formation; in Colon, cross structure grades laterally into conglomerate and sandstone beds that are indistinguishable from strata in the Pekin and Sanford. Includes two coal beds, the Cumnock and Gulf, 200 to 260 feet above base of formation. Strata below coal beds consist mainly of light-gray, medium-dark-gray, and dark-greenish-gray siltstone and fine-grained sandstone and contain small amounts of claystone and shale; strata above coal beds consist mainly of medium-light-gray to black shale and include small amounts of claystone, siltstone, and sandstone; shale is irregularly calcareous and carbonaceous. Thickness 750 to 800 feet in north-central part of Sanford basin, northwest of Deep River fault.

Named for section exposed in mine shaft at Cumnock, Lee County. Crops out in narrow belt along center and northwestern side of Sanford basin, is duplicated four times by longitudinal faulting in western part of basin, and is present locally at southern end of Durham basin.

Cundiff Limestone (in Caddo Creek Formation[1]

Pennsylvanian: Central northern Texas.

Original reference: J. M. Armstrong, 1929, Texas Bur. Econ. Geology, geol, map of Jack County.

Crops out near Cundiff in eastern part of Jack County. Named for village of Cundiff.

Cunningham Granite

Precambrian: Central western Georgia.

D. F. Hewett and G. W. Crickmay, 1937, U.S. Geol. Survey Water-Supply Paper 819, p. 30, pl. 1. Commonly massive coarse-grained rock dark in color in contrast to other igneous and metamorphic rocks of region. Boundaries locally cut across lamination of Woodland gneiss (new) and the Cunningham is believed to be intrusive into the Woodland.

Named for Cunningham Crossroads in Talbot County, southeast of Manchester, where central part of the largest mass of the rock is exposed; area is south of Towaliga fault.

Curdsville Limestone[1] (in Lexington Group)

Curdsville Limestone Member (of Hermitage Formation)

Middle Ordovician: Central Kentucky and central Tennessee.

Original reference: A. M. Miller, 1905, Kentucky Geol. Survey Bull. 2, p. 9, 18.

C. W. Wilson, Jr., 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1993; 1949, Tennessee Div. Geology Bull. 56, p. 84 (fig. 15), 85–88. member at base of Hermitage formation in Tennessee. Consists of thin beds of medium-grained to coarsely crystalline blue to gray limestone interbedded with partings of gray shale. Maximum thickness 15 feet. Overlies Carters limestone of Stones River group.

D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 41. Basal formation in Lexington group in Kentucky. Consists of cherty coarsely crystalline gray-blue limestone, about 20 feet thick. Underlies Hermitage formation; overlies Tyrone limestone of Highbridge group.

Named for Curdsville Station, Mercer County, Ky.

Curecanti Quartz Monzonite

Curecanti Granite[1]

Precambrian: Central western Colorado.

Original reference: J. F. Hunter, 1925, U.S. Geol. Survey Bull. 777.

Exposed for 3½ miles along Black Canyon, from a point 1½ miles east of Curecanti Creek to Nelson Gulch, Gunnison River region.

†Curl Formation[1]

Pennsylvanian: Northeastern Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 26.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey.

Named for Curl Creek, Nowata County.

Curlew Limestone Member (of Spoon Formation)

Curlew Limestone Member (of Tradewater Formation)[1]

Curlew Limestone (in Macedonia Formation)

Curlew Limestone (in Tradewater Group)

Middle Pennsylvanian: Western Kentucky and southern Illinois.

Original references: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, pl. showing section of Lower Coal Measures; 1857, Kentucky Geol. Survey, v. 3, p. 13, 23.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 40. Curlew limestone occurs in Macedonia formation about 20 or 30 feet above a more or less local sandstone that lies above the Murray Bluff sandstone. Light gray, compact, and generally 3 to 4 feet thick; contains chert; and locally weathers to a porous cherty residium.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, *in* C. O. Dunbar and L. G. Henbest, Illinois Geol. Survey Bull. 67, p. 15 (fig. 2), 18, 20–21

[1943]. Curlew limestone included in Tradewater group. Occurs in Macedonia cyclothem above Murray Bluff sandstone and below Curlew coal and Curlew sandstone in Stonefort cyclothem. Light-colored limestone, very siliceous and cherty, and locally grades into a bed of solid chert. Thickness variable, maximum 5 to 6 feet. Known from Williamson County, Ill., to Butler County, Ky.

W. H. Smith, 1957, Illinois Geol. Survey Circ. 228, p. 8 (fig. 2), 9. Overlies Creal Springs sandstone (new) in vicinity of Creal Springs.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 45. Reallocated to member status in Spoon formation (new). Overlies New Burnside coal member; underlies O'Nan coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

U. S. Geological Survey has discontinued the use of the name Tradewater in Illinois.

Type locality: South side of Indian Hill, near Curlew, Shawneetown quadrangle, Union County, Ky.

Curlew Sandstone (in Stonefort Formation)

†Curlew Sandstone (in Tradewater Formation)[1]

Curlew Sandstone (in Tradewater Group)

Pennsylvanian: Western Kentucky and southern Illinois.

Original references: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, pl. showing section of Lower Coal Measures; 1857, Kentucky Geol. Survey, v. 3, p. 13, 23.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 41. Basal sandstone in Stonefort formation. Massive micaceous crossbedded more or less friable member that unconformably overlies Macedonia formation (new).

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 15 (fig. 2) [1943]. Included in Stonefort cyclothem, Tradewater group. Occurs above Curlew coal and below Bald Knob coal which is below Stonefort limestone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32. Replaced by Granger sandstone member of Spoon formation (both new).

Apparently named for Curlew, Union County, Ky.

Curley bed

Curley limestone member (of Gardner Dolomite)

Mississippian: Central Utah.

T. S. Lovering and others, 1949, Econ. Geology Mon. 1, p. 6 (table 1). A 2-foot bed of light-gray fine-grained wavy-bedded limestone in Gardner dolomite. Underlain by 6 feet of pink lithographic dolomite; overlain by thin-bedded blue limestone.

P. D. Procter and D. L. Clark, 1956, Jour. Sed. Petrology, v. 26, no. 4, p. 313–321. Referred to as member of Gardner. An unusual biostrome. Described in detail and distribution noted.

Crops out over area of at least 600 square miles west of Provo. Type locality and derivation of name not stated.

Currant Tuff

Miocene, upper, or Pliocene, lower: Eastern Nevada.

G. T. Faust and Eugene Callaghan, 1948, Geol. Soc. America Bull., v. 59, no. 1, p. 33–40. Contains a wide variety of tuffs—crystal tuff, crystal-vitric tuff, vitric-crystal tuff, and vitric tuffs. Thickness ranges from a few feet to over 400 feet. Occurs between two groups of volcanic flows here referred to as lower volcanics and upper volcanics.

C. J. Vitaliano, 1951, U.S. Geol. Survey Bull. 978–A, p. 1, 7–9, pl. 2. Considered to be late Miocene or early Pliocene.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 140 (fig. 4). In Grant Range, overlies Stone Cabin tuff (new) and underlies Windous Butte tuff (new). Windous Butte tuff has K–A age of 34 million years.

Named for Currant Creek area, in White Pine and Nye Counties, 29 miles southwest of Ely. Tuff is the host rock for magnesite in district.

Currant Creek Formation

Currant Creek Formation (in Wasatch Group)

Upper Cretaceous(?): Northeastern Utah.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 117–120, pls. 1, 2, 3. Proposed for sequence of conglomerates, sandstones, and variegated shales, which, in western part of Uinta Basin, transect Mesaverde Niobraran beds and unconformably underlie Eocene strata of probable Uinta age. Thickness along Red Creek 4,550 feet. Tentatively referred to Upper Cretaceous but probably represents transitional strata deposited from late Upper Cretaceous to Eocene during early phases of Laramide folding.

M. D. Williams, 1950, Utah Geol. Soc. Guidebook 5, p. 106–107. Possibilities of Cretaceous age for Currant Creek and of correlation with conglomerates of Price River formation (as mapped by Spieker) must be considered. In many parts of Wasatch Mountains, thick conglomerates presently and formerly considered as Wasatch unconformably overlie strata of varying ages. Until relationship between these conglomerates and those of Price River formation is understood, seems best to assign Currant Creek to Wasatch group (redefined); considered Paleocene-lower Eocene.

Exposed from Currant Creek to a few miles east of Duchesne River, Wasatch and Duchesne Counties.

Curry Clay Member (of Harpersville Formation)

Pennsylvanian (Cisco): North-central Texas.

F. B. Plummer *in* M. G. Cheney, 1948, Abilene Geol. soc. [Guidebook] Spring Field Trip, June 11–12, p. 8. Named in road log.

F. B. Plummer and H. B. Bradley, 1949, Texas Univ. Bur. Econ. Geology Pub. 4915, p. 17–21, pl. 3. Purplish red and greenish red, grading in places into deep maroon. Thickness varies from a few feet to 32 feet depending upon thickness of sand in section above it. Occurs between upper and lower Crystal Falls limestone layers, just above Quinn clay in areas where thick sandstone deposits of Parks Mountain and its probable equivalent, Cisco Lake sandstone, do not occur. [Member of Harpersville formation].

L. F. Brown, Jr., 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 41, p. 7 (fig. 2), measured sections. Member of Harpersville formation in report on Stephens County. Thickness 1 to more than 15 feet. Overlies Crystal Falls limestone member; underlies unit referred to as "Upper Crystal Falls" limestone member.

Named for Curry Farm, 5 miles south and 2¼ miles west of Breckenridge, Stephens County.

Curry Iron-Bearing Member (of Vulcan Iron-Formation)[1]

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1900, U.S. Geol. Survey Geol. Atlas, Folio 62.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Referred to as iron-bearing member of Vulcan iron-formation. Underlies Loretto slate member; overlies Brier slate member.

Named for exposures north of Curry mine, Menominee district, [Dickinson County].

Curry Mountain Shale (in Panoche Formation or Group)

Upper Cretaceous: Central western California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2), 993. Panoche group (or formation) is subdivided into 10 units. Curry Mountain shale is lowermost in sequence (ascending). Underlies Long Canyon sandstone (new). Curry Mountain shale is assigned to Delevanian stage (new). Name credited to J. Q. Anderson.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull., v. 71, no. 10, chart 10e (column 15). Shown on correlation chart as member of Panoche formation. Overlies Center Peak conglomerate member (new).

Occurs in Alcalde Hills, Coalinga-Ortigalito area, San Joaquin Valley.

Curtin Limestone (in Black River Group)

Curtin Limestone (in Hunter Group)

Curtin limestone facies (of Oak Hall Member of Nealmont Limestone)

Middle Ordovician (Trentonian): Central Pennsylvania.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 194, 197–203. Named as upper unit in Black River group in central Pennsylvania. Consists of impure and relatively pure limestone. Contains five metabentonites, A–E. Subdivided to include Valley View member (new) below and redefined Valentine member above. Thickness about 143 feet at type locality. Thins from 100–150 feet along northwest side of Nittany Valley to extinction along line from Tyrone to north of Lemont, Oak Hall and Spring Mills and south of Millheim. Unconformably underlies Nealmont limestone; overlies Stover member of Benner limestone.

Marshall Kay, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1199. Assigned to upper Bolarian (Hunterian) series.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. [1402], 1409. Uppermost unit in Hunter group and Hunter subseries (Bolarian series).

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 78, 95, 102. Described as a calcilutite facies of the Oak Hall member of Nealmont limestone. Age changed to Trentonian.

Type section: In quarry wall south of headframe of Bell mine of America Lime and Stone Co. at Bellefonte, Centre County. Named from Curtin Gap 3 miles northeast of Bellefonte.

Curtis Formation (in San Rafael Group)[1]

Upper Jurassic: Southeastern and central Utah and western Colorado.

Original reference: J. Gilluly and J. B. Reeside, Jr., 1926, U.S. Geol. Survey Press Bull. 6064, March 30.

James Gilluly and J. B. Reeside, Jr., 1928, U.S. Geol. Survey Prof. Paper 150–D, p. 78–79. In San Rafael Swell, an erosional unconformity displaying irregularities of as much as 50 feet in height occurs at top of Entrada sandstone (new). Resting on this channeled surface is Curtis formation. Consists of series of greenish-gray glauconitic conglomerates, sandstones, and shales, and contains Upper Jurassic fossils. Thickness 193 feet at type locality; 252 feet at Summerville Point, at north end of the Swell; 50 feet near mouth of San Rafael River. Underlies Summerville formation (new) with boundary gradational. San Rafael group.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, p. 1278–1279. Discussion of stratigraphy of Uinta Mountains, Utah. Name Stump is used in Weber River, Duchesne River, and Lake Fork areas so that southeastern Idaho Jurassic terminology is uniform in all western sections. East of Lake Fork, name Curtis is used and along eastern part of mountains, the lithologic character is somewhat different than that on west. In general, the Curtis is made up of basal medium-grained to coarse-grained crossbedded sandstone which rests with sharp contact on subjacent beds [Entrada]. Middle part of formation is greenish-gray shale with intercalated fossiliferous sandstones, limestones, and coquinal limestones. At Whiterocks Canyon and near Vernal and Manila, formation has conspicuous limestone member at top which is characterized by brachiopod genus *Kallirhynchia*. Twin Creek limestone of Sears' (1924, U.S. Geol. Survey Bull. 751–G) Vermilion Creek section is the Curtis.

H. E. Gregory, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 235; 1950, U.S. Geol. Survey Prof. Paper 220, p. 49 (fig. 25), 51 (table), 96, pl. 5. Described in Zion Park region where it is 40 to 50 feet thick; consists of gray roughly bedded limestone and thick gypsum; unconformably overlies Entrada sandstone and unconformably underlies Winsor formation (new).

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 599–600. In Strawberry Valley quadrangle, Utah, 725 feet thick; overlies Entrada sandstone, and underlies Morrison formation.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 38 (table), 72–73, strat. sections. Described in Henry Mountains region where it is as much as 175 feet thick and consists of evenly bedded gray sandstone and shaly sandstone, glauconitic(?), numerous siliceous geodes and concretions at some places; local thin basal conglomerate. Underlies Summerville formation, unconformably overlies Entrada sandstone.

D. M. Kinney, 1955, U.S. Geol. Survey Bull. 1007, p. 85–89, pls. 1, 2, 6. Described in Uinta River-Brush Creek area, Utah, where it is 144 to 270 feet thick. Unconformably overlies Entrada formation; underlies Morrison formation.

Named for exposures on Curtis Point, near head of Cottonwood Springs Wash, on northeastern side of San Rafael Swell, southeastern Utah.

Curzon Limestone Member (of Topeka Limestone)

Curzon Limestone (in Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Northwestern Missouri, southwestern Iowa, northeastern Kansas, and southeastern Nebraska.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 57.

G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 20, 46, 50–51. Reallocated to member status in Topeka limestone; underlies Jones Point shale member; overlies Iowa Point shale member. Iowa occurrences noted. Type locality designated. [Name spelled Curzen.]

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035; G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 21; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Member of Topeka formation. Overlies Iowa Point shale member; underlies Jones Point shale member. This is a classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 16, fig. 5. Variable in texture; commonly divided into two or three units by thin shale partings. Near Thurman, Fremont County, a fine-grained sublithographic brecciated bed that contains soft green shale within the fractures is common near top of member; in Mills County, to the north, upper beds are thicker and contain dark-brown chert; near Howe, Adair County, to the northeast, it is made up of light-gray *Osagia*-bearing bed overlying fine-grained massive fossil-bearing limestone; west of Macedonia, Pottawattamie County, it is composed of alternating shales and limestones. Thins northeastward; thickness 9 feet near Thurman; 6 feet near Macedonia; about 3 feet near Howe. Member of Topeka limestone. Underlies Jones Point shale member; overlies Iowa Point shale member.

Type locality: East of Curzon Station, southeast of Forest City, Holt County, Mo. Reason for change in spelling of name of station since Gallaher's time not known.

Cushing Granodiorite[1]

Late Carboniferous(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, U.S. Geol. Survey Prof. Paper 108, p. 176.

Named for exposures on Cushing Island, in Casco Bay.

†Cushing Limestone Member (of Elmdale Formation)[1]

Pennsylvanian: Central northern Oklahoma.

Original reference: C. N. Gould, 1925, Oklahoma Geol. Survey Bull. 35, p. 80.

Exposed about one-half mile west of Cushing, Payne County.

Cusseta Sand

Cusseta Sand Member (of Ripley Formation)[1]

Upper Cretaceous: Western Georgia and eastern Alabama.

Original reference: J. O. Veatch, 1909, Georgia Geol. Survey Bull. 18, p. 86–89.

C. W. Cooke and A. C. Munyan, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 790–791. Rank raised to formation. In western

Georgia, overlaps Blufftown and Eutaw formations in Marion County and extends eastward on the Tuscaloosa as far as Peach County, where it is overlain by basal Eocene Clayton formation. Above the Cusseta is more than 100 feet of dark-gray micaceous sand representing the Ripley formation.

L. W. Stephenson and W. H. Monroe, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1643 (fig. 2), 1649–1650. Geographically extended into eastern Alabama where it merges into Selma chalk; merging takes place in an east-west stretch of 15 or 20 miles in region south of Montgomery; intertonguing consists of two main westward extending tongues of sand, one below and one above an eastward extending tongue of chalk. In its westward continuation through Alabama, the updip near-shore facies of Cusseta becomes a coarse sand with fine-gravel lenses in basal part. North-facing escarpment known as Chunnenuggee Ridge, which extends from Union Springs eastward toward Chattahoochee River, is physiographic expression of the Cusseta. Underlies Ripley formation; presence of unconformity separating the two not established.

D. H. Eargle, 1948, Southeastern Geol. Soc. 6th Field Trip [Guidebook]. p. 44, 45. In this report [Cretaceous of east-central Alabama], the Cusseta is considered a member of Ripley formation.

Named for exposures in vicinity of Cusseta, Chattahoochee County, Ga.

Cussewago Limestone[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 202.

Cussewago Sandstone[1]

Cussewago Stage

Mississippian: Northwestern Pennsylvania and eastern Ohio.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. Q_4, p. 91–98, 202, 203, 204, 205 (fig. 63).

W. M. Laird, 1941, Pennsylvania Geol. Survey Prog. Rept. 126, p. 12–16. Discussed as Cussewago stage in lower part of Oil Lake series. Includes interval between Berea stage above and Riceville stage below.

Wallace de Witt, Jr., 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 21. Discussion of relationship of Berea, Corry, and Cussewago sandstones in Ohio and Pennsylvania. Bedford shale has been traced eastward across Ohio into Pennsylvania where it lies below Berea and above the Cussewago sandstone. In Pennsylvania, name Cussewago was first applied to this shale by White, and later name Hayfield was substituted by Chadwick (1925, Geol. Soc. America Bull., v. 36, no. 3). Cussewago limestone of White, renamed Hayfield by Chadwick and redefined as Littles Corners by Caster (1934, Bulls. Am. Paleontology, v. 21, no. 71) is described as occurring in this shale in Bartholomew quarry (outcrops 55 of this report). Name Cussewago as originally applied by White included sandstone and shale below Berea in outcrop at Bartholomew quarry. Because of lack of formal description, name has been redefined by later workers and extended beyond areal limits of the sandstone. However, Cussewago sandstone forms a mappable lithologic unit and is best horizon marker in its outcrop area. Cussewago sandstone merits rank of formation and is here defined as the typical friable greenish-brown medium-grained quartz sandstone below Bedford shale at Bartholomew quarry. Here, top of Cussewago lies 37 feet below graphic siltstone layer at base of Orangeville shale and 29 feet below top of Berea sandstone. This section is on a tributary of Cussewago Creek, which is type locality of Cussewago as cited by White. Cussewago sandstone has been designated by Caster (1934) as western facies of Cobham conglomerate of Warren, Pa., region. The two are separated horizontally by shales and cannot be traced into one another. Recognition of Cussewago as independent unit lying below Berea sandstone, and separated by Bedford shale from that sandstone, has not been general. Inclusion of Cussewago and Bedford in Berea in Ohio is largely responsible for introduction of hypothetical threefold Berea formation in Ohio. Mississippian.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1351 (fig. 3), 1353–1354, 1362. In Crawford County, Pa., underlies Shellhammer Hollow formation (new). Underlies Riceville shale.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. As mapped, Pocono group includes, in Appalachian Plateau, Burgoon, Shenango, Cuyahoga, Cussewago, Corry, and Knapp formations.

Named for exposures in Cussewago Valley, Crawford County, Pa. Exposed in Bartholomew quarry, Hayfield Township.

†Cussewago Shales[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. Q_4, p. 94–96.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1356, 1366. In Bartholomew section, Hayfield Township, White reported 35 feet of Cussewago shale, including 2 feet of limestone near the top, between his Cussewago sandstone and his Corry sandstone. Bedford shale has been traced into this outcrop, where it lies between Cussewago sandstone and White's Corry. Bedford has priority; recommended that name Cussewago shale be dropped from literature.

Named for exposures in Cussewago Valley, Crawford County.

Cussewago Slate[1] or monothem[1]

Mississippian: Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 53, 103, table opposite p. 61.

Custards shale member[1] (of Meadville Stage)

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 137.

Well exposed at Peterson's Falls, on Rocky Creek, 2 miles west of Custards, Crawford County.

Custer Formation[1] or Group

Triassic, (?): Oklahoma, Kansas, and Texas.

Original reference: R. Roth, 1932, Jour. Geology, v. 40, no. 8, p. 688–725.

Robert Roth, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 421–474. Trace of unconformity at base of Custer mapped from Wheeler County southward to Coke County, Tex. Suggested that beds occupying interval between base of Dockum and the unconformity mapped be given one formation name, Custer, and that names now in usage be confined to the facies which they represent. In Collingsworth and Wheeler Counties, contact between base of Custer and older beds is one of sandstone resting on shale or gypsum. In Collingsworth and Hall Counties, includes Dozier Mounds dolomite member. In Childress and Cottle Counties, Childress dolomite is 3 to 20 feet above base of Custer. In King and Stonewall Counties, base is sandstone or gypsum. In Fisher, Nolan, and Coke Counties, base is marked by sandstone or anhydrite and a fine quartz conglomerate. In these counties, Eskota dolomite is from a few feet to 20 feet above base. Sediments below are shale, sandstones, or gypsum, or the "Blaine of Texas." In Nolan and Coke Counties, pre-Custer erosion has removed most of "Blaine of Texas," and the Custer rests on upper sandstone facies of the San Angelo. Terms Cloud Chief, Quartermaster, and Whitehorse have been very loosely applied to sediments of Custer age in Texas.

Ira Cram, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 474. In Andarko basin, Oklahoma, Roth's Custer formation would include sediments between base of Marlow formation and the Tertiary. In this area, there are unconformities which separate Marlow formation from Rush Springs formation and the Rush Springs from higher sediments. These mechanical changes may or may not be recognizable in other areas, but their presence over several counties in Oklahoma satisfied requirements for dividing Custer unit into formations. Custer cannot be correctly termed a formation because it contains within its boundaries good formations. Term Custer is an Oklahoma term, and Oklahoma conditions are important. Custer unit is correctly classified as a group.

Robert Roth, N. D. Newell, and B. H. Burma, 1941, Jour. Paleontology, v. 15, no. 3, p. 313. Table shows Custer group comprises (ascending) Whitehorse formation, Day Creek dolomite, and Quartermaster formation.

Robert Roth, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1412, 1413. Overlies Pease River group (new).

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey. Roth grouped the Whitehorse, Cloud Chief, and Quartermaster and considered them of Triassic age. Grouping is not recognized, and name is not used.

Named for Custer County, Okla., where almost whole formation is exposed.

Custer Granite Gneiss[1]

Jurassic(?): Southwestern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 15.

Forms Custer Ridge, British Columbia.

Custerian series[1]

Early Cretacic: South Dakota.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 43. p. 109, 125, 126.

Well exposed in Black Hills. Named for exposures in Custer County, S. Dak.

Cutalossa Member (of Stockton Formation)

[Upper Triassic]: East-central New Jersey.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 52–53 (table). Medium to coarse thick-bedded arkose with interbeds of red-brown fine sandstone. Thickness 232 feet. May or may not include overlying 787 feet of red and gray sandstone and red shale and underlying 373 feet of red and brown sandstone [see Stockton formation]. Older than Raven Rock member (new); younger than Prallsville member (new).

In area along Delaware River from Stockton northward to 3 miles west of Milford, Hunterdon County.

Cutbank Sand'

Cut Bank Sandstone

Jurassic or Lower Cretaceous: Northwestern Montana (subsurface and surface).

Compiler unable to locate original reference.

R. J. Weimer, 1959, Billings Geol. Soc. Guidebook 10th Ann. Field Conf., p. 88. Surface section of Cut Bank sandstone shows an intertonguing in the lower 10 feet of gray medium- to coarse-grained sandstone (Cut Bank) and laminated glauconitic sandstone and siltstone (Swift). Jurassic. Editors note states that Weimer's correlations of the Cretaceous Jurassic section differ radically from those in other articles of the guidebook.

Surface section measured in NE¼ sec. 34, T. 30 N., R. 11 W., in Cut Bank area.

Cutler cyclothem (in McLeansboro Group)

Pennsylvanian: Southern Illinois.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, pl. 1. Shown on correlation chart as underlying Gimlet cyclothem and overlying Bankston cyclothem. Includes Cutler limestone and Cutler coal.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 43. Strata of cycle now referred to Sparland cyclothem, but strata included in cycle in southern and southwestern Illinois do not include all strata included in Sparland. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: Secs. 2 and 3, T. 6 S., R. 4 W., Perry County.

Cutler Formation[1]

Cutler Group

Permian: Southwestern Colorado, northeastern Arizona, northwestern New Mexico, and southeastern Utah.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 120.

A. A. Baker and J. B. Reeside, Jr., 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 11, p. 1423, 1425, 1436, 1444, 1445, 1446. Includes (ascending) Halgaito tongue, Cedar Mesa sandstone tongue (new), Organ Rock tongue (new), White Rim sandstone member (new), DeChelly sandstone member, and Hoskinnini tongue (new).

L. G. Henbest, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1330. On basis of fossil evidence, at least part of redbeds of Cutler at type locality are believed to be of Pennsylvanian age.

C. B. Hunt, Paul Averitt, and Ralph Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 39–45, pls. 1, 15. Formation includes all Permian rocks exposed in canyons east of Henry Mountains. Divided into three members (ascending) : Cedar Mesa sandstone, Organ Rock tongue, and White River sandstone. In Monument Valley, southeastern Utah and northeastern Arizona, comprises (ascending) Halgaito tongue, Cedar Mesa sandstone member, Organ Rock tongue, DeChelly sandstone member, and Hoskinnini tongue.

S. A. Wengerd and J. W. Strickland, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2174. Includes Rico basal member. Overlies Hermosa formation. [See Hermosa formation for explanation of "R" datum.]

George Herman and S. L. Sharps, 1956, Intermountain Assoc. Petroleum Geologists [Guidebook] 7th Ann. Field Conf., p. 81. Rico should not be considered basal unit of Cutler.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2054, 2055 (fig. 3). Rank raised to group. Includes (ascending) Rico transition facies, Halgaito formation, and Cedar Mesa formation. Overlies Hermosa group.

J. H. Stewart, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1854–1856, 1857 (fig. 3). In most of southeastern Utah and southwestern Colorado, Cutler formation of Permian age overlies Rico formation of Pennsylvanian and Permian(?) age and underlies Moenkopi formation of Triassic(?) and Early and Middle(?) Triassic age. In salt anticline region, the Cutler is absent over crests of some anticlines and pinches out northeast along southwestern edge of Uncompahgre Plateau. In southwestern Utah, consists of reddish-brown horizontally bedded siltstone and sandstone redbed tongues with light-colored very fine- to fine-grained cross-stratified sandstone members. In Monument Valley, members, as recognized in this report, are (ascending) Halgaito tongue, about 400 feet thick; Cedar Mesa sandstone member, about 800 feet; Organ Rock tongue, about 500 feet; and DeChelly sandstone member, about 300 feet. Formation is stratigraphically restricted above to exclude Hoskinnini member which is reallocated to Moenkopi formation. Thickness about 2,000 feet in southern part of southeastern Utah; thins irregularly northward to about 700 feet in some parts of east-central Utah; zero to several thousand feet in salt anticline region; maximum thickness not known.

R. O. Lewis, Sr., and R. H. Campbell, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–194. Mapped in Elk Ridge 3 NE quadrangle, San Juan County, Utah. Includes Cedar Mesa sandstone member, Organ Rock tongue, and Hoskinnini tongue. Overlies Rico formation; underlies Moenkopi formation.

Named for exposures on Cutler Creek, which enters Uncompahgre River about 4 miles north of Ouray, Ouray County, Colo.

Cutler Limestone (in McLeansboro Group)

Cutler Limestone Member (of McLeansboro Formation)[1]

Pennsylvanian: Southern Illinois.

Original reference: A. H. Bell, C. Ball, and L. McCabe, 1931, Illinois Geol. Survey Press Bull. 19.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 17 (fig. 3), 25–26. Columnar section shows Cutler limestone in McLeansboro group. In St. Clair, Perry, and Randolph Counties, the Cutler is a light-gray bed about 5 feet thick which lies about 15 feet above Bankston Fork limestone. Included in Gimlet cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. Correlation chart shows Cutler limestone in Cutler cyclothem (new) and in Sparland cyclothem. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37. Replaced by Piasa limestone member of Modesto formation (new).

Type locality: Secs. 2 and 3, T. 6 S., R. 4 W., Perry County. Named for exposures in vicinity of Cutler.

Cutoff Shaly Member (of Bone Spring Limestone)

Permian (Leonard Series): Southern New Mexico and western Texas.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 569–570, pl. 2. Consists of several hundred feet of buff, dove-gray, or black thin-bedded limestones and siliceous shales at top of formation. Assigned to the Bone Spring because, 2 miles north of Bone Spring, the beds are truncated and overlain unconformably by Delaware Mountain group. At type locality, overlies Victorio Peak gray member. In some areas, lies between the Victorio Peak gray member and the sandstone tongue of the Cherry Canyon formation; in other areas, underlies Brushy Canyon formation.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 16, 18, 24, pl. 3 [1949]. Name Cutoff shaly member given to discontinuous sets of beds at top of Bone Spring limestone exposed in three general districts: area from which it is named; Shumard Canyon, where it is separable into two divisions; and along base of Delaware Mountains. Mapped in New Mexico.

Type exposure: On west face of Cutoff Mountain near Texas-New Mexico line.

Cutright Sandstone Member[1] (of Edwardsville Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 118, 181, 182, 189, 212, 250.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 74. Cutright sandstone, Weed Patch, and Mount Ebel sandstone members included in Allens Creek facies of Edwardsville. Lower Mississippian.

Named derived from Cutright Bridge across Salt Creek, center sec. 4, T. N., R. 1 E., from Cutright Ridge to the south, and from the Cutright community, Monroe County.

Cutter Member (of Montoya Formation)

Cutter Formation or Dolomite (in Montoya Group)

Upper Ordovician: Southern New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs, in Geology 4, p. 57, 62–64, fig. 4. Thin sequence of light-gray-weathering generally unfossiliferous claystone, limestone, calcitic dolomite, and dolomite in

Caballo Mountains. Limestone is medium gray to dark gray on fresh surfaces and weathers blue gray. Dolomite is light gray to dark gray and along with the calcitic dolomite weathers light gray or light tan. Both limestone and dolomite are generally microgranular or sublithographic. Chert present as occasional bands parallel to bedding or as rounded nodules; it is dark gray to black on fresh exposure and weathers black. Thickness 121 to 162 feet in Mud Springs Mountains, from 50 to 115 feet from Palomas Gap south, and 130 feet at Granite Wash. Conformably overlies Aleman formation (new). Underlies Percha formation at north end of San Andres Mountains. Unit here named Cutter was called Fusselman(?) by Darton (1917, U.S. Geol. Survey Prof. Paper 108–C; 1928, U.S. Geol. Survey Bull. 794). Montoya group.

L. C. Pray, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1907 (footnote). Cutter formation (name pub. by Kelley and Silver after submission of ms. for present rept.) is probably correlative with Valmont dolomite (new) of Sacramento Mountains.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 1, 26. Term Cutter, as applied by Kelley and Silver (1952) to lower part of Richardson's (1909) Fusselman, has priority over Pray's (1953) term Valmont, but agewise should yield to Entwhistle's (1944) term Raven. Where not eroded by pre-Onate erosion, the Cutter is relatively uniform in thickness beneath Fusselman dolomite, being 168 feet in Ash Canyon and 182 feet in Hembrillo Canyon. In Rhodes Canyon, only lower beds are present, and thickness varies from 26 to 75 feet. Cutter, however, has been used more often in south central New Mexico. Overlies Aleman dolomite. Unconformably underlies Fusselman dolomite in Ash and Hembrillo Canyons, and Onate formation in Rhodes Canyon. Montoya group.

Dorothy Hill, 1959, New Mexico Bur. Mines Mineral Resources Bull. 64, p. 3. Cutter formation (uppermost Montoya) is Upper Ordovician or Lower or Middle Silurian. Determination based on study of corals.

Type locality: Cable Canyon section opposite Sierrite mine in NW¼ sec. 10, T. 16 S., R. 4 W., Caballo Mountains.

Cutting Dolomite

Cutting Dolomite (in Beekmantown Group)

Lower Ordovician: West-central Vermont.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524, 539–540, 541–542, 543. Sequence of dolomite beds averaging 1 or 2 feet in thickness. At base is thinly laminated sandstone that bears worm boring "*Scolithus.*" Nodules of black chert occur in upper part of the dolomite. Thickness about 350 feet. Underlies Bascom formation (new); overlies Shelburne marble. Corresponds to Division C of the "Calciferous" of Brainerd and Seely (1890, Am. Mus. Nat. History Bull., v. 3). Beekmantown group (Beekmantownian).

Type locality: On eastern dip slope of Cutting Hill in southeastern Shoreham Township, Addison County.

Cuyahoga Group[1] or Formation[1]

Cuyahoga Formation (in Pocono Group)

Mississippian: Ohio and western Pennsylvania.

Original reference: J. S. Newberry, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 21.

J. E. Hyde, 1915, Jour. Geology, v. 23, p. 655–682. Formation includes five facies: Toboso conglomerate, Hocking Valley conglomerate, Granville shale, Scioto Valley shale, and Vanceburg sandstone. Named members: Berne, Black Hand, Buena Vista, Churn Creek, Fairfield, Henley, Lithopolis, Raccoon, and Rarden.

H. P. Cushing, Frank Leverett, and F. R. Van Horn, 1931, U.S. Geol. Survey Bull. 818, p. 48–54, pl. 20. Cuyahoga, in its typical area, is elevated to rank of group. Comprises (ascending) Orangeville shale, Sharpsville sandstone, and Meadville shale. Thickness 165 to 425 feet. As generally recognized in Ohio, overlies Sunbury shale, a thin representative of which is present in basal part of Orangeville shale. Unconformable below Sharon conglomerate.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942 Jour. Geology, v. 50, no. 1, p. 34–67. Seven lithologic facies, each subdivided into a varying number of members and submembers are recognized in Cuyahoga formation: Tinkers Creek shale (new), River Styx conglomerate (new), Killbuck shale (new), Toboso conglomerate, Granville shale, Hocking Valley conglomerate, and Henley shale. Facies named in progressive order from northeastern Ohio to south-central Ohio. Cuyahoga directly underlies Logan formation. Named members: Meadville shale, Sharpsville sandstone, Orangeville, Black Hand conglomerate, Armstrong sandstone, Black Hand shale, Burbank, Pleasant Valley Black Hand siltstone, Raccoon shale, Fairfield sandstone, Lithopolis siltstone, and Henley shale. Sunbury shale not recognized as distinct formation in area of this report; all black shale immediately overlying Berea sandstone is included in Orangeville member of Cuyahoga.

P. A. Dickey, 1941, Pennsylvania Geol. Survey, 4th ser., Bull. M–22, p. 5. Group, in Titusville quadrangle, is 130 to 150 feet thick. Not subdivided in this area. Overlies Corry sandstone; underlies Shenango group.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Formation, as shown on generalized section, comprises (ascending) Henley, Buena Vista, Portsmouth, Black Hand, and Berne members. Overlies Sunbury; underlies Logan.

P. A. Dickey, R. E. Sherrell, and L. S. Matteson, 1943, Pennsylvania Geol. Survey, 4th ser., Bull. M–25, p. 18–20, map. Cuyahoga group, in Oil City quadrangle, includes strata between basal member (A) of Shenango formation and Corry sandstone of Berea group. Thickness about 140 feet. Consists of alternating beds of shale and sandstone. Group not subdivided.

J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 10 (fig. 4), 13. Group comprises (ascending) Sunbury shale, Orangeville shale, Sharpsville sandstone, and Meadville shale. Overlies Berea sandstone.

J. F. Hall, 1958, Dissert. Abs., v. 18, no. 2, p. 559. Southern Hocking County, Ohio, contains strata ranging in age from Kinderhook-Osage series of Mississippian to Conemaugh series of Pennsylvanian. Oldest outcropping unit, the Cuyahoga shale member of Cuyahoga formation, consists of about 75 feet of interbedded shales and sandstones. Overlying and grading into shale member in a facies relationship is Black Hand member, composed of 175 feet of coarse-grained sandstone and lenses of conglomerate. Disconformably underlies Logan formation of Osage series.

E. J. Szmuc, 1958, Dissert, Abs., v. 18, no. 6, p. 2109. Cuyahoga rocks are marine clastic deposits, which include fine-grained shelf sediments and coarse-grained deltaic or bar sediments. Maximum thickness about 600 feet in northern Ohio. Formation comprises (ascending) Orangeville, Sharpsville, Strongsville (new), Meadville, Rittman, Armstrong, Wooster (new), and Black Hand. Cuyahoga-Shenango contact in northwestern Pennsylvania and northeastern Ohio is conformable. Cuyahoga-Logan contact in Wayne and Ashland Counties, Ohio, locally is surface of minor disconformity. In most of northern Ohio, a major unconformity separates Cuyahoga strata from Lower Pennsylvanian rocks.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped in Pocono group.

Named for exposures along Cuyahoga River, between Akron and Cleveland, Ohio.

Cuyama Formation[1]

Cuyama Beds

Pliocene(?): Southern California.

Original reference: W. A. English, 1916, U.S. Geol. Survey Bull. 621, p. 191–215.

Chester Stock, 1947, Southern California Acad. Sci., v. 46, pt. 2, p. 84–85. New faunal evidence indicates Miocene age for Cuyama beds.

Crops out in Cuyama Valley, Ventura County.

Cuyamaca Gabbro

Cuyamaca basin intrusive[1]

Upper Cretaceous: Southern California.

Original reference: F. S. Hudson, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 6, 181, 192–207.

S. C. Creasey, 1946, California Jour. Mines and Geology, v. 42, no. 1, p. 18, 19–21, pl. 3. Described in Julian-Cuyamaca area as Cuyamaca gabbro. Youngest rock in area; intrusive into Julian schist and Stonewall quartz diorite.

Richard Merriam, 1946, Geol. Soc. America Bull., v. 57, no. 3, p. 234. Mapping in Ramona area has shown that Cuyamaca basic intrusive (Hudson, 1922) and San Marcos gabbro (Miller, 1937) are probably the same. In this area, name San Marcos gabbro is applied.

D. L. Everhart, 1951, California Div. Mines Bull., 159, p. 66–74, pls. 3, 4, 5. Described in Cuyamaca Peak quadrangle. Writer followed Creasey (1946) in referring to rocks as Cuyamaca gabbro, thereby retaining original locality name given by Hudson, but substituting more appropriate gabbro for term basic intrusive. Considered older than Green Valley tonalite.

Named for the three peaks of Cuyamaca Mountains, Ramona and Cuyamaca quadrangles, San Diego County.

Cuyuna Member (of Crow Wing Formation)[1]

Precambrian (Huronian): Central Minnesota.

Original reference: C. Zapffe, 1930, Lake Superior Min. Inst. Proc., v. 28, p. 101–106.

Cuyuna district, Crow Wing County.

†Cuyuna Series[1]

Cuyuna Slates

Precambrian (Huronian): Central Minnesota.

Original reference: C. K. Leith, 1907, Econ. Geology, v. 2, p. 145–152.

G. M. Schwartz, 1951, Geology of the Cuyuna Range: Minnesota Univ. Center for Continuation Study Mining [Geology] Symposium [No. 2], p. 3. For the most part, the Cuyuna slates have been considered to belong to the Virginia slate. This correlation has very little evidence to support it.

Occurs in Cuyuna Range, Crow Wing County.

Cygnian Substage

Pennsylvanian (Desmoinesian): Missouri, Iowa, Kansas, Nebraska, and Oklahoma.

W. V. Searight *in* W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. Named on a stratigraphic column of Carroll and Livingston Counties, Mo. Comprises Cabaniss and Marmaton groups.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1), 2749. Shown on a northern midcontinent composite stratigraphic column. Cygnian substage together with underlying Venteran substage (new) make up the Desmoinesian stage.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 22. Type area stated.

Type area: Along Marais des Cygnes River (Little Osage) in Vernon County, Mo., and to west in Bourbon and Lynn Counties, Kans.

Cynthia Falls Sandstone (in Tuxedni Group)

Cynthia Falls Sandstone Member (of Tuxedni Formation)

Middle Jurassic: Central southern Alaska.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1). Medium-grained gray sandstone grading horizontally into alternating sandstone and conglomerate. Thickness 800 feet.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Thick-bedded to massive, medium- to coarse-grained sandstone. Dark gray green; weathers light gray. Contains many lenticular layers of subrounded pebbles. Bed of arenaceous siltstone, from 50 to at least 100 feet thick, present near middle of member. Member 600 to 900 feet thick. Underlies Bowser member (new); overlies unnamed siltstone member. Derivation of name and geographic distribution given.

U.S. Geological Survey currently classifies the Cynthia Falls Sandstone as a formation in Tuxedni Group on the basis of a study now in progress.

Named for conspicuous waterfall on Hardy Creek. Forms hogback ridges along flanks of Tonnie syncline and Fitz Creek anticline and well exposed in nearly all creeks tributary to Fitz Creek from the west; in **Iniskin Peninsula.**

Cynthiana Formation[1]

Middle Ordovician: East-central Kentucky, southern Indiana, and southwestern Ohio.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 10, 13, 14, 211–212.

A. C. McFarlan, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 992–995. Several names have been applied to different members of the Cynthiana. There is confusion in the literature in regard to the relationships, due both to regional variation in lithology and fauna, and to overlap. Formation as defined herein comprises following members: Rogers Gap, Greendale, Millersburg, Nicholas limestone, Bromley, and Gratz; in southern and western Bluegrass are other pre-Greendale beds that are characterized by a fauna not known elsewhere in central Kentucky. Thickness 38 to 125 feet. Marked unconformity at base; formation rests at different places on all formations from top of Perryville (Cornishville) to Jessamine formation (in Lexington limestone). Underlies Eden.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky, Univ., p. 11 (footnote), 19–23. Name Sulphur Well member proposed for beds below Greendale member.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1641–1645. Lexington-Cynthiana-Eden is probably a conformable succession. Cynthiana consists of fossiliferous limestone and shale 40 to 100 feet thick varying in character in different parts of area. Following divisions discussed: Greendale, Millersburg, Nicholas limestone, Rogers Gap beds, Bromley shale, Gratz shale, and *Allonychia* zone. Facies of divisions change from place to place. Unit formerly termed Sulfur [Sulphur] Well member is herein considered facies of upper Lexington. Pre-Cincinnatian.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 18. All subdivisions of interval between top of Benson limestone and base of Eden formation should be referred to as members of Cynthiana. This would include as members the lithologic and paleontologic units heretofore defined as Brannon, Woodburn, Greendale, Millersburg, Nicholas, Rogers Gap, Bromley, and Gratz.

L. H. Lattman, 1954, Am. Jour. Sci., v. 252, p. 257–276. Rogers Gap [member of Cynthiana] formation, uppermost member of the Mohawkian, and overlying Fulton shale, lowermost member of the Cincinnatian, are faunally indistinguishable in area of this report [Ohio Valley around Cincinnati]. They appear to be lithologic facies of same time-rock unit. Evidence indicates advisability of extending Cincinnatian series downward to embrace Cynthiana formation, rather than including it in the Mohawkian as has been common practice.

F. R. Hall and W. N. Palmquist, Jr., 1960, U.S. Geol. Survey Hydrol. Inv. Atlas HA–25. Generalized columnar section of rocks in Carroll, Gallatin, Henry, Owen, and Trimble Counties, Ky., shows Cynthiana formation, 80 to 173 feet thick, above Benson limestone member of Lexington and below Eden formation. Includes Woodburn limestone member at base, and Devils Hollow facies above; upper part formation unnamed. Middle Ordovician.

Named for Cynthiana, Harrison County, Ky.

Cypress Sandstone[1]

Cypress Sandstone (in Homberg Group)

Upper Mississippian (Chester Series): Southern Illinois, northwestern Alabama, southern Indiana, western Kentucky, and Tennessee.

Original reference: H. Engelmann, 1868, St. Louis Acad. Sci. Trans., v. 2, p. 189–190; paper read in 1862.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 135; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 830. Assigned to Homberg group (new). In standard Mississippian section, underlies Golconda formation and overlies Paint Creek formation.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 27, pl. 1. In Indiana, Cypress sandstone is 25 to at least 40 feet thick. Typically cream-white to light-tan fine-grained subangular well-sorted sandstone in which thinner beds are laminated locally; in some places, massive and crossbedded. Sandstone herein referred to as Cypress can be traced into the thick-bedded Big Clifty sandstone. Correlation of the Beech Creek limestone of Indiana with the Chester section of Illinois is uncertain at this date. If future investigations show that Beech Creek is equivalent to the lower part of Golconda formation of southern Illinois, beds herein termed Cypress should be designated Big Clifty.

S. W. Welch, 1958, U.S. Geol, Survey Oil and Gas Inv. Chart OC–58. In northwestern Alabama, Mynot sandstone member of Pride Mountain formation (both new) is equivalent to strata referred to by Butts (1926, Alabama Geol. Survey Spec. Rept. 14) as Cypress sandstone.

Named for exposures on Cypress Creek, southeastern Union County, Ill.

Cypress Creek Chert[1]

Lower Devonian: Southwestern Tennessee.

Original reference: C. O. Dunbar, 1917, Geol. Soc. America Bull., v. 28, p. 207.

Cyprian Sandstone Member (of Thermopolis Shale)

Lower Cretaceous: Northeastern Montana.

M. M. Knechtel, 1959, U.S. Geol. Survey Bull. 1072–N, p. 739–740, pls. 52, 53. Name applied to prominent sandy unit near middle of Thermopolis. Thickness about 25 feet. Unit has been referred to as Muddy sand.

Typically exposed in Cyprian Creek on southwest side of road that crosses NE¼NW¼ sec. 31, T. 25 N., R. 24 E., 2 miles southwest of Landusky, Phillips County, Little Rocky Mountains.

Cyrene Member (of Edgewood Limestone)[1]

Silurian (Albion Series): Northeastern Missouri and southwestern Illinois.

Original reference: T. E. Savage, 1913, Geol. Soc. America Bull., v. 24, p. 361, 376.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 16, 17, 18, 19. Described in Bowling Green quadrangle where it is typically a light-gray to dusky brown finely crystalline limestone. Includes Noix oolitic facies, which. at Clinton Springs, is about 7 feet 2 inches thick; maximum thickness of Cyrene 17 feet. Underlies Bowling Green member.

Named for exposures at Cyrene, Pike County, Mo.

†Cyril Gypsum Member[1] (of Greer Formation)

Permian: Central Oklahoma.

Original reference: F. G. Clapp, 1920, Mining and Metall., Am. Inst. Mining and Metall. Engineers, no. 158, sec. 27, Feb. 1920.

Named for exposures near Cyril, Caddo County.

Dadina Schist[1]

Mississippian: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 27, map.

Occurs along south side of a tributary of Dadina River that drains from flanks of Snider Peak.

Dagger Flat Sandstone[1]

Dagger Flat Formation

Upper Cambrian: Southwestern Texas.

Original reference: P. B. King, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 9, p. 1064–1066.

J. L. Wilson, 1954, Jour. Paleontology, v. 28, no. 3, p. 251–252; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 12, p. 2465. Dagger Flat formation subdivided at type locality into Buttrill Ranch member (new) below and Roberts Ranch member (new) above.

Type locality: South side of Dagger Flat northeast of Buttrill Ranch, Brewster County. Exposed in long narrow belts in center of anticlines in both Marathon and Dagger Flat anticlinoria.

Dagmar Dolomite

Dagmar Limestone[1]

Middle Cambrian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 5 (fig. 2), 6–7. In East Tintic Mountains, consists of dense medium- to light-gray laminated dolomitic limestone that weathers creamy white. Thickness 75 to 100 feet. Underlies Herkimer limestone, contact sharp; overlies Teutonic limestone, contact commonly gradational through 10 feet or more, base placed at base of lowermost laminated bed. Type locality indicated.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 14 (fig. 3), 16–17. In Stansbury Mountains, commonly less than 20 feet thick and consists of light-medium-gray finely crystalline dolomite; distinctly laminated. Overlies Teutonic limestone; underlies Herkimer limestone.

Type locality: Near Dagmar mine, 1 mile west-northwest of Eureka, Juab County.

Dagmar Limestone Member (of Ute Formation)

Middle Cambrian: Southeastern Idaho and northern Utah.

G. B. Maxey, 1955, Dissert. Abs., v. 15, no. 4, p. 558. Incidental mention.

Dake Quartzite[1]

Precambrian: Central southern Wisconsin.

Original reference: A. Leith, 1935, Kansas Geol. Soc. Rept. 9th Ann. Field Conf., p. 329–330, fig. 216.

Well exposed on south bank of Baraboo River, near west Baraboo, and on a low ridge 2 miles east of Baraboo on north side of main highway from Baraboo to Portage, Sauk County.

Dakin Hill Member (of Littleton Formation)

Lower Devonian: Southwestern New Hampshire.

M. T. Heald, 1950, Geol. Soc. America Bull., v. 61, no. 1, p. 45 (fig. 2), 54–55, pl. 1. Uppermost part of Littleton formation in Lovewell Mountain quadrangle. Consists of porphyproblastic orthoclase gneiss, biotite-quartz gneiss, biotite-sillimanite gneiss and pyritiferous gneiss. Evidence of bedding rare and foliation poorly developed. Thickness undetermined, the breath of outcrop may mean that the thickness is of the order of 10,000 feet. Overlies May Pond member (new). Occupies a large area extending from southern boundary to northern boundary of quadrangle.

C. A. Chapman, 1952, Geol. Soc. America Bull., v. 63, no. 4, p. 387, 390–391, pl. 1. In Sunapee quadrangle where May Pond member is absent, Dakin Hill member overlies Hubbard Hill member and is separated from it by a mass of Kinsman quartz monzonite. Thickness from knife edge to 2,500 feet.

Dakin Hill is in Cheshire County.

Dakota Sandstone,[1] **Formation, Quartzite,** or **Group**

Dakota Stage

Lower and Upper Cretaceous: Nebraska, eastern Colorado, Kansas, Minnesota, southeastern Montana, northeastern New Mexico, North Dakota, western Oklahoma, and eastern Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1862, Philadelphia Acad. Nat. Sci. Proc., v. 13, p. 419, 420.

N. H. Winchell, 1875, *in* William Ludlow, Report of a reconnaissance of the Black Hills of South Dakota, made in the summer of 1874, U.S. Engineer Dept., U.S. Army: Washington, U.S. Govt. Printing Office, p. 32, 60, 64. Report mentions the light-colored sandstones of the Dakota group of the Cretaceous. Thickness about 500 feet.

Henry Newton and W. P. Jenney, 1880, U.S. Geog. and Geol. Survey Rocky Mountain Region, p. 151–180. Group described in Black Hills region where it is prominently developed, forming capping rock to foothills that surround the Hills on all sides. Appears with its characteristic composition—coarse yellow or red sandstones with discontinuous variegated clays. At places, considerable thickness of very soft and fine white sandstone appears at base. Elsewhere considerable portions are hard dense quartzite. No animal fossils, but many remnants of plants—in no case more than mere coaly fragments. Lower Cretaceous. Thickness 250 to 400 feet.

G. H. Eldridge, 1896, U.S. Geol. Survey Mon. 27, p. 62–65. In Denver basin, formation is from 225 to 350 feet thick and commonly consists of two or three nearly equal benches of massive sandstone separated by narrow bands of shale which locally become fire clays. Characteristic conglomerate occurs at base of formation; at summit, a zone of hard white slaty shales, 10 to 30 feet thick, transitional to Benton shale of Colorado group. Fossil flora found throughout. Overlies Morrison formation (new).

W. P. Jenney, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 568–593. Newton's Dakota group of Black Hills is subdivided into five divisions 1 to 5, descending. Proposed names for the divisions, No. 5, Beulah clays, Upper Jurassic; No. 4, Hay Creek coal formation; No. 3, Barrett shales; No. 2, Oak Creek beds; and No. 1, Dakota sandstone. Dakota sandstone is Upper Cretaceous, the other units Lower Cretaceous. Dakota sandstone divided into two units, lower 30 to 45 feet thick and upper 35 to 45 feet. Unconformably underlies Fort Benton.

N. H. Darton, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 4, p. 489–599. In Black Hills, Dakota sandstone (formation), 35 to 150 feet thick, overlies Fuson formation. Underlies Graneros shale of Benton group.

G. W. Stose, 1912, U.S. Geol. Survey Geol. Atlas, Folio 186. Dakota sandstone described in Apishapa quadrangle, Colorado. Consists of massive gray sandstone, weathering rusty brown, generally in two ledges with variable thin dark shale parting. Thickness 63 to 83 feet. Overlies Purgatoire formation (new); underlies Graneros shale of Benton group. Purgatoire formation was formerly considered part of Dakota sandstone and is so mapped in Walsenburg and Pueblo folios. Upper Cretaceous.

G. I. Finlay, 1916, U.S. Geol. Survey Geol. Atlas, Folio 203. Dakota sandstone (formation) consists of light-colored quartz sandstone having average thickness in Colorado Springs quadrangle of 100 feet. Unconformably overlies Glencairn member (new) of Purgatoire formation, although unconformity is probably not extensive. Commonly conformably overlain by Graneros shale of Benton age, but near north side of quadrangle intervening formations are overlapped by Dawson arkose, which there lies unconformably on the Dakota. Upper Cretaceous.

W. T. Lee, 1923, U.S. Geol. Survey Bull. 751–A, p. 1–22. Dakota group is divided into five informally named formations (ascending): Lower sandstone, Lower shale, Middle sandstone, Middle shale, and Upper sandstone. Group is well exposed about 2 miles north of Bellvue, Colo., and section measured here, about 325 feet thick, may be regarded as type section of group. Lower sandstone (40 feet at Bellvue) is a gray massive coarse-grained usually crossbedded and conglomeratic sandstone, variable in thickness but everywhere present and readily identified; unconformably overlies Morrison formation. Lower shale (40 feet at Bellvue) consists of variable beds of sandy shale and thin layers of hard sandstone; commonly, but not invariably, highly colored—red, purple, green, blue. In Wyoming, this shale has been called middle member of Cloverly. It may prove to be age equivalent of Fuson formation of Black Hills and is probably included in Kootenai of Montana. Middle sandstone (10 feet at Bellvue) is gray, hard, quartzose, evenly bedded, and strongly ripple marked at many localities; variable in thickness, and, where the variegated underlying shale is absent or not distinctive, it cannot be differentiated from the lower sandstone. This middle sandstone has been called upper Cloverly, true Dakota, and second Muddy and probably is included in Purgatoire formation by different workers. Middle shale (200 feet at Bellvue) is thickest formation of group. It is dark-colored bituminous marine shale. In many areas in northern Colorado between Morrison and Boulder, it contains fossil plants which Knowlton refers to the Dakota flora. North of Boulder it has yielded fossil invertebrates which Reeside tentatively places in Kiowa fauna of Kansas and Purgatoire fauna of southeastern Colorado. Near Colorado Springs, this shale is called Glencairn member of Purgatoire formation. In southern Wyoming, it has been included in Graneros shale or lower part of the Benton. It is equivalent to upper part of Thermopolis shale of northern Wyoming. Upper sandstone (35 feet at Bellvue) is variable in character and thickness and in some places thins out entirely. Contains fossil plants, fragments of charcoal, streaks of coal and markings resembling fillings of worm borings. This sandstone is the upper Dakota of northern Colorado but is known in oil industry as Muddy sand. It is herein emphasized that there is no single definite persistent and easily recognized sandstone such as was formerly supposed to exist and was termed the Dakota sandstone. The group as a whole is interpreted as the result of accumulation of sediments near the strand line of the advancing Cretaceous sea, and as such it differs in age from place to place by length of time consumed by advance of strand line across the intervening distance. Whether this advance marks the beginning of Upper Cretaceous time remains to be determined. Area of report extends from Perry Park, Colo., about 35 miles south of Denver, northward along foothills east of Rocky Mountains to Douglas, Wyo., thence northwestward to Thermopolis, and includes section at Lander and Rawlins.

W. W. Rubey and N. W. Bass, 1925, Kansas Geol. Survey Bull. 10, p. 16, 57–65. Dakota sandstone, in Russell County, includes Rocktown channel sandstone member (new).

W. T. Lee, 1927, U.S. Geol. Survey Prof. Paper 149, p. 17–23. Name Dakota group, applied by writer [Lee] (1923) to beds as far west as Lander and as far north as Greybull, Wyo., is accepted by the U.S. Geological Survey only for section at Bellvue, Colo., with understanding that if rocks of Comanche age are proved to be present in Dakota group of that section, they are to be excluded from group. The rocks to which the writer thus applied term Dakota group are described in present report according to their position. They are (ascending) lower conglomeratic sandstone; a variable division of sand shale separable toward north into a highly colored lower shale and sandstone that becomes the middle sandstone of the group where three sandstones are present; upper shale, which was called middle shale in 1923 publication, but which in many sections is the higher of two shales and is therefore designated the upper shale of this group; an upper sandstone which is the upper Dakota of northern Colorado and the Muddy sand of many Wyoming localities and is probably equivalent to Newcastle sandstone of eastern Wyoming. Writer believes that group is well defined from Colorado Springs, Colo., northward nearly to southern boundary of Montana. According to this interpretation, it includes Cloverly formation of Wyoming and some rocks usually included in Benton shale.

W. L. Russell, 1928, Econ. Geology, v. 23, no. 2, p. 134–137. Term Fall River formation replaces Dakota sandstone in Black Hills region.

A. C. Tester, 1931, Iowa Geol. Survey, v. 35, p. 199–322. Discussion of Dakota stage of type locality. Meek and Hayden used term group. Other writers have used series, stage, formation, or sandstone. Lithology of the Dakota, distribution of the various zones, stratigraphic range and interpretations made in present study, all suggest that term stage be used to designate the sandstones, shales, and clays exposed near Dakota City, Nebr., and described by Meek and Hayden as Dakota group. Dakota age is used for time. Best exposures are at Sioux City, Iowa, and its suburbs. This includes Prospect Hill section; exposures at Sioux City Brick Company pits, at Riverside; bluffs along Big Sioux River south of west entrance to Stone Park; Sergeant Bluff, south of Sioux City; Crill Mill section south of Westfield, Iowa; and several sections in vicinity of Homer, Nebr.

R. C. Moore and K. K. Landes, 1937, Geologic map of Kansas (1:500,000): Kansas Geol. Survey. Dakota group as mapped includes Solomon and Ellsworth formations of Late Cretaceous age, and Belvidere formation and Cheyenne sandstone of Early Cretaceous age. Comanche series.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9, 99–104. In southeastern Minnesota, Dakota formation includes Ostrander member (new). Geological column shows Dakota formation of Dakota series stratigraphically below Coleraine (Benton) formation of Colorado series and above Devonian Senecan series.

B. F. Latta, 1941, Kansas Geol. Survey Bull. 37, p. 68–79. Group includes all strata from base of Cheyenne sandstone to base of Graneros shale. All Cretaceous strata in Stanton County [this report] belong to Dakota group. They comprise (ascending) Cheyenne sandstone, Kiowa shale, and an upper sandstone (formerly called Dakota) that is here named Cockrum sandstone.

A. R. Edwards, 1941, Wyoming Geol. Survey Bull. 32, p. 10. Term Dakota group, in Platte and Laramie Counties, Wyo., includes sequence of sandstones and shales which rest disconformably upon Morrison formation. Consists of five members (ascending): dark-gray coarse-grained sandstone; dark shale; buff hard ripple-marked sandstone; dark carbonaceous shale; and massive hard sandstone. Thickness 250 to 375 feet. Underlies Benton group.

Norman Plummer and J. F. Romary, 1942, Kansas Geol. Survey Bull. 41, p. 315–348. Dakota formation of Kansas, as here defined, has been called variously "Dakota group," "Dakota formation," Ellsworth and Solomon formations, Rocktown channel sandstone member, and "Dakota sandstone." Dakota formation is here defined to include Cretaceous strata from top of Kiowa shale below to top of Graneros shale above. Subdivided into (ascending) Terra Cotta clay and Janssen clay (new) members.

Norval Ballard, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1562. Strata of Dakota group crop out as hogbacks completely surrounding the Black Hills and are present throughout the Dakotas in subsurface. Group comprises an upper unnamed sandstone member, middle or Fuson shale member, and lower or Lakota sandstone member. Maximum thickness 725 feet.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7), 18–20. Group was named by Meek and Hayden in 1862. Since that time it has been separated as three formations, the upper one of which is yet called Dakota sandstone, a usage conflicting with name of the group. Lee (1927) correlates the subdivisions of Dakota group at east side of Laramie Range in Wyoming, in a section near Greenacre ranch, as follows (ascending): Lakota sandstone, Fuson shale, Fall River sandstone, Skull Creek shale, and Newcastle sandstone. Studies reveal that Newcastle sandstone, Skull Creek shale, and Fall River sandstone correlate collectively with the so-called Dakota sandstone or top formation of Dakota group in eastern Nebraska. Name Omadi sandstone proposed for the so-called Dakota formation, to include section lying between Fuson and Graneros shales. Dakota group then includes (ascending) Lakota, Fuson, and Omadi. Meek and Hayden did not locate a very definite type locality; hence, type locality is herein designated. Thickness at proposed type locality 392 feet.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153–154, 155 (fig. 3). Formation consists of clay, shale, siltstone, and sandstone, interbedded and lenticular; contains carbonaceous material, lignite, concretions of hematite and limonite, and locally quartzitic sandstone. Average thickness 215 feet. Contains stratigraphic units formerly called Rocktown channel sandstone, Ellsworth formation, Solomon formation, Reeder sandstone, Marquette sandstone, Spring Creek clay, and others. Comprises (ascending) Terra Cotta clay and Janssen clay members. Underlies Graneros shale; overlies Kiowa shale. Cockrum sandstone of southwestern Kansas is equivalent in age to part of Dakota formation. Gulfian series.

C. B. Hunt and R. L. Miller, 1946, Utah Geol. Soc. Guidebook 1, p. 8. Generalized section of exposed sedimentary rocks in Henry Mountains structural basin shows that Dakota sandstone, 0 to 50 feet thick, overlies Morrison formation and underlies Tununk shale member of Mancos shale.

J. W. Huddle and F. T. McCann, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 75. Dakota sandstone, in Duchesne and Wasatch Counties, Utah, includes lower sandstone, 30 to 40 feet thick, a middle shale, 160 feet thick, and an upper sandstone, 5 to 26 feet thick. Lower sandstone and shale tentatively considered to be of Lower Cretaceous age, and upper sandstone to be of Upper Cretaceous age. Overlies Morrison; contact concealed. Underlies Mancos shale.

W. L. Stokes and D. A. Phoenix, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 93. Term Dakota sandstone, as used in this report [Egnar-Gypsum Valley area, San Miguel and Montrose Counties, Colo.], includes the impure coal, carbonaceous beds, and lenticular, yellow, fluvial sandstones above Burro Canyon formation (new) and below Mancos shale. Average thickness about 125 feet. Upper Cretaceous.

K. M. Waagé, 1952, Colorado Sci. Soc. Proc., v. 15, no. 9, p. 375 (fig. 1). Discussion of clay deposits of Denver-Golden area. Generalized stratigraphic section shows Dakota sandstone, 80 feet thick, overlies Purgatoire formation and underlies Benton shale.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. Dakota sandstone in Mora County, N. Mex., is about 180 feet thick; overlies Morrison formation and underlies Benton formation.

G. H. Wood, Jr., S. A. Northrop, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–141. Dakota sandstone in Colfax County, N. Mex., conformably overlies Purgatoire formation and conformably underlies Graneros shale.

K. M. Waagé, 1953, U.S. Geol. Survey Bull. 993, p. 6 (fig. 2), 11–26, pls. 1, 2, 4, 5. Throughout large part of southeastern Colorado, Dakota sandstone is prominent cliff-forming unit averaging about 100 feet in thickness and consisting largely of fine- and medium-grained cross-laminated sandstone. Consists of lower unnamed sandstone unit, Dry

Creek Canyon member (new), and upper sandstone unit. Overlies Glencairn shale member of Purgatoire formation; underlies Graneros shale.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Dakota sandstone mapped in northwestern Oklahoma.

K. M. Waagé, 1955, U.S. Geol. Survey Prof. Paper 274–B, p. 15–49. Discussion of Dakota group in northern Front Range foothills, Colorado. Area includes narrow belt of pre-Benton Cretaceous exposures extending from 2 miles south of Wyoming State line, in Larimer County, where beds emerge from under Cenozoic cover, to fault-terminated end of Dakota hogback just south of Indian Creek in Kassler quadrangle, Douglas County. Northern foothills area corresponds with area in which Lee (1923) applied name Dakota group to pre-Benton Cretaceous rocks of Colorado and divided it into five informal subdivisions. Terminology presented in this report is revision of Lee's (1923) Dakota group and is intended to apply only to northern foothills area. Name Lytle formation is applied to lower part of sequence and South Platte formation (new) to upper part of sequence. Overlies Morrison formation [see Morrison formation, this reference for discussion of Morrison-Lytle contact]; underlies Benton shale. First formal subdivision of Dakota formation was made by Stose (1912) in Apishapa quadrangle. He named lower sandstone and middle shale of the threefold sequence the Purgatoire formation and retained name Dakota sandstone for upper sandstone. Finlay (1916), in Colorado Springs quadrangle, named the sandstone and shale units in the Purgatoire the Lytle sandstone and Glencairn shale members, respectively. With exception of addition to Dakota sandstone of a local refractory shale unit, Dry Creek Canyon member (Waagé, 1953), the subdivision and nomenclature have remained as designated by Stose and Finlay. Names Dakota sandstone, in restricted sense, and Purgatoire formation have been used throughout southeastern and central Colorado and as far north along Front Range foothills as Perry Park in Castle Rock quadrangle. Lee's work in northern foothills led to fivefold rather than threefold subdivision of the Dakota in this area. Lee used his terminology throughout Front Range foothills and correlated his subunits with subdivisions of Stose and Finlay to the south and with Wyoming terminology to the north. No formal changes have been made in nomenclature or subdivision of Lee's Dakota group since it was proposed, and it has existed side by side with southern classification of Stose and Finlay. Terminologies other than that of Lee have been used in northern Front Range foothills presumably because Lee's Dakota group is too broad a unit for detailed work and because some of his subdivisions lack lateral continuity and are difficult to apply. Stose and Finlay's terminology was used in Denver-Golden area by Waagé (1952), but subsequent work leading to present report has shown that it was incorrectly applied and that it is equally as unsatisfactory as Lee's in providing a logical subdivision of pre-Benton Cretaceous strata. George (1927, Colorado Univ. Semicentennial Pub.) called Early Cretaceous rocks throughout eastern Colorado the Purgatoire and incorrectly used names Lakota and Fuson in northern foothills for members of the Purgatoire that he considered equivalent, respectively, for Finlay's Lytle and Glencairn members in Colorado Springs area. This usage, based on incorrect correlation with

Black Hills area, is still used in Colorado by some workers. Others have extended the Cloverly-Thermopolis-Muddy terminology southward from Wyoming, and some still use term Dakota formation in sense in which it was used in early reports of Geological Survey. Several sources of confusion in usage of pre-Benton Cretaceous terminology are apparent in the history of subdivision and nomenclature of the Dakota. First source is taxonomic change from use of terms formation and group as synonyms to their use as terms for separate ranks of rock units. More critical source was tendency to separate the Early Cretaceous from the Late Cretaceous parts of the pre-Benton Cretaceous sequence, a tendency that influenced, and is reflected in, Stose's formal subdivision of Dakota formation. Use of age as criterion for subdivision of rock units, a practice at the root of many nomenclatural problems, can lead only to confusion in correlation and to ambiguity in terminology when applied to complex transgressive deposits like the pre-Benton Cretaceous sequence. Much of the confusion associated with name Dakota stems from this cause. An unfortunate nomenclatural practice, that of retaining name Dakota for Late Cretaceous part of sequence in those areas where Early Cretaceous rocks can be identified and separated, has served to crystallize the confusion. This practice has been applied in Kansas and in Colorado, making it impossible to use name Dakota in a single sense for physical correlation between areas in which Early Cretaceous strata are separated from the Dakota and areas in which occurrence of Early Cretaceous rocks has not been sufficiently well established to permit their separation from the Dakota. Introduction of terminologies from other areas is a recent source of confusion in Colorado pre-Benton Cretaceous classification. Usage of Dakota in present report follows that of Meek and Hayden (1862) inasmuch as it includes all pre-Benton Cretaceous strata. In type area along Missouri River in Nebraska, the Dakota rests on Paleozoic rocks so its lower contact is unequivocal. The characteristic twofold lithogenetic division is present in type area where sharp break separates sandstone with variegated clay below from sandstone with dark-gray clay, carbonaceous clay, and lignite above. In light of previous attempts to make name Dakota reflect opinion on age of rock that it includes, it is emphasized that Dakota group, as used herein, is strictly a rock term, and whether or not the group contains both Lower and Upper Cretaceous rocks, is entirely Lower Cretaceous, or varies in age from region to region is irrelevant to this definition. Because of indefinite nature of Morrison-Lytle contact in parts of northern foothills, it may not be convenient in some places to use Dakota group as a unit for small-scale mapping; in such places, best map units would be Morrison and Lytle formations, undifferentiated, and South Platte formation.

C. A. Repenning and H. G. Page, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 259–263. Dakota sandstone is basal Cretaceous formation of Black Mesa, Navajo, and Hopi Indian Reservations, Ariz. Consists of a lower sandstone member, middle carbonaceous member, and upper sandstone member. Average thickness about 80 feet; maximum thickness 119 feet. Underlies Mancos shale. Believed to be entirely of Late Cretaceous in this area, although presence of Lower Cretaceous beds at base cannot be ruled out.

K. M. Waagé, 1959, U.S. Geol. Survey Bull. 1081–B, p. 13–26. A persistent disconformity separating continental deposits of varied facies from overlying marginal marine deposits and marine deposits was recognized in Dakota group of northern Colorado Front Range (Waagé, 1955), where this twofold lithogenetic pattern was used as basis for subdivision of the group. Earlier (Waagé, 1953) the same disconformity, whose regional significance was not recognized at the time, was used as contact between Lytle and Glencairn members of Purgatoire formation in south-central Colorado. Reconnaissance studies supplemental to those in Front Range and additional studies as yet unpublished reveal the disconformity and the two gross lithogenetic units it separates in the Purgatoire-Dakota sequence of southeastern Colorado and southwestern Kansas, in the Cloverly-Thermopolis-Muddy sequence of Bighorn Basin area and eastern Wyoming, in type area of original Dakota formation along the Missouri River in Iowa and Nebraska, and in Inyan Kara-Skull Creek-Newcastle sequence of Black Hills region. Within the broad twofold lithogenetic framework, the Dakota group and its equivalents vary considerably from place to place. Changes in type of rock, sequence of rocks, and thickness of individual subunits locally obscure basic pattern. Many environments of deposition represented in the two parts of sequence account for much of the variation. Deposits of lower sequence are, in general, typified by fine- to coarse-grained buff to white lenses of sandstone and conglomeratic sandstone, irregularly interbedded with variegated red, green, yellow, gray, and black claystones; shale is rare and commonly limited to local lacustrine deposits; most of the coarser material is chert, quartzite, and quartz, obviously many cycles removed from parent rock. In some areas, such as south-central and southeastern Colorado, lower part of sequence is dominantly sandy, and variegated claystones are rare; in other areas such as the Bighorn Basin, variegated claystone and argillaceous siltstone predominate. Fossils not common in lower part, but plant remains include coniferous wood, cycadeoids, charophytes, and other algae and foliage of ferns and cycods; animal remains include dinosaur bones, fresh-water mollusks, ostracodes, and branchiopods. Lower part of sequence is more closely related lithogenetically to underlying Morrison than to upper part of sequence. No obvious stratigraphic break marks contact with the Morrison, and at many places it is impossible to separate the two units except on some arbitrarily selected local feature. Upper part of Dakota sequence consists chiefly of fine-grained commonly thin-bedded laminated to tabular cross-laminated buff- to brown-weathering sandstone interbedded with gray to black shale and siltstone. Thin bedding and lamination characterize this part of sequence. In some areas, such as central Wyoming, that lay within central part of basin of deposition, nearly the entire sequence is shale and silty shale (Thermopolis) except for some sandy shale and local sandstone at top (Muddy) and base (Rusty beds). Fossils in marginal marine beds include dicotyledonous leaves, wood, false trunks of *Tempskya*, some fresh-water clams, linguloid brachiopods, and Foraminifera. Marine beds contain pelecypods, gastropods, linguloid brachiopods. Foraminifera, bones of fish, crocodiles, and plesiosaurs. Contact of the two parts of sequence is, in many places, a relatively plane surface of disconformity marking an abrupt lithic change. The gross twofold subdivision affords only consistent means of orientation within the varied local Dakota sequences. Whether or not this disconformity transgresses time, it is an excellent datum to use in working out equivalency of lithogenetic units in Dakota sequence, and, if local terminologies can be adjusted to it, many of the Dakota nomenclatural problems will resolve themselves. Many problems of stratigraphy of Dakota and equivalent rocks have their roots in the nomenclature. Report gives historical summary of usage of term Dakota in Black Hills area and points out, among other things, the fact that Darton (1901) miscorrelated these beds with the Dakota of eastern Colorado. He became convinced that the Fort Benton of the Black Hills was the "precise equivalent" of Gilbert's (1896) Graneros shale in eastern Colorado and introduced name Graneros into Black Hills terminology. This miscorrelation has had lasting effect. Name Fuson is still misapplied by some geologists to black shale of Glencairn member of Purgatoire formation, the Skull Creek equivalent in southern part of Colorado Front Range. Name Graneros is still used locally by most geologists in spite of the fact that it is a hangover from miscorrelation by Darton and is misleading in regional correlation. It is used both as a formation and group to include beds between Fall River formation and Greenhorn limestone. Black Hills area is one of several that have followed similar pattern in development of the terminology applied to its pre-Benton (Dakota equivalents) Cretaceous beds. In much of the central and northern Great Plains and Rocky Mountains, these beds vary in stratigraphic detail from place to place, but their sequence is uniform in its major lithogenetic features. This uniformity is obscured by complex and conflicting terminology that has resulted largely from the unfortunate practice of distinguishing stratigraphic units on the basis of their supposed age. Soon after name Dakota was introduced, it came to be used synonymously with sandy basal Upper Cretaceous rocks. Subsequent discovery of Early Cretaceous fossils in these rocks resulted in their subdivision, generally with name Dakota for that part of sequence still considered Upper Cretaceous. Division between Lower and Upper Cretaceous rocks in northern part of interior region has been placed higher and higher in the sequence. In Black Hills, each shift of this time boundary has resulted in change in nomenclature. For Black Hills, where name Dakota has passed from nomenclature, the principal subunits, Lakota, Fuson, and Fall River formations, have not proved to be satisfactory mappable units. This is the problem with which present report is concerned. In Black Hills, the transgressive disconformity discussed above falls within Inyan Kara group. Subdivision and nomenclature of Inyan Kara group is adjusted to conform to this twofold lithogenetic division.

R. G. Young, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 154–194. Basal Cretaceous deposits of Colorado Plateau can be subdivided into two formations on basis of carbonaceous content. The lower noncarbonaceous unit, Cedar Mountain formation, consists of mudstones and persistent conglomeratic sandstones which were deposited in an inland floodplain environment. The upper carbonaceous unit, Naturita formation (new), consists of carbonaceous mudstone, coal, persistent conglomeratic sandstones, and beach sandstones deposited on or adjacent to shore of Mancos sea. Naturita deposits can be traced landward into Cedar Mountain deposits, indicating that they are facies of a larger unit, the Dakota group. Upper part of Naturita intertongues with and passes laterally into basal part of Mancos shale throughout much of Colorado Plateau. Group is unconformable above Morrison formation. Lower and Upper Cretaceous.

Type locality (Condra and Reed): In Missouri River bluffs of Dakota County, located 1 mile southeast of Homer, Nebr., in NE¼ sec. 13, T. 27 N., R. 4 E.

Type locality of group (Lee): About 2 miles north of Bellevue, Larimer County, Colo.

Dale quartzites[1]

Lower Cambrian: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 38.

Derivation of name not stated.

Dallas deposits[1]

Pleistocene: Central southern Iowa.

Original references: J. L. Tilton, 1913, Science, new ser., v. 38, p. 241; 1913, Iowa Acad. Sci. Proc., v. 20, p. 218.

Named for Dallas, Marion County.

†Dallas Limestone[1]

Upper Cretaceous (Gulf Series): Northern Texas.

Original reference: R. T. Hill, 1887, Am. Jour. Sci., 3d, v. 33, p. 298.

Named for occurrence at Dallas, Marion County.

Dallas Limestone Bed

Dallas Limestone Member (of Yamhill Formation)

Eocene, upper: Eastern Oregon.

J. E. Allen, 1946, Oregon Dept. Geology and Mineral Industries G.M.I. Short Paper 15, p. 2–5. Dallas limestone crops out as dark-gray massive rock, which weathers first to light-buff color and then to deeper shades of iron oxide. Thickness 50 to 75 feet. Occurs at base of marine series of Cowlitz age and above basalt believed to be equivalent of Tillamook volcanics. May occupy stratigraphic position similar to Buell limestone (new).

E. M. Baldwin, 1959, Geology of Oregon: Ann Arbor, Mich., Edwards Brothers, Inc., p. 13. Dallas limestone member of Yamhill formation. Present at base of formation. Composed of fragments of shells, Foraminifera, and calcareous algae intermixed with tuffaceous material derived from underlying volcanic rocks.

Crops out in northeast part of T. 8 S., R. 6 W., from 2 to 4 miles southwest of Dallas, Polk County, on western edge of Willamette Valley. Extensively quarried.

Dalles Formation[1]

Pliocene: Central northern Oregon and central southern Washington.

Original reference: E. D. Cope, 1880, Am. Philos. Soc. Proc., v. 19, p. 61; 1880, Am. Nat., v. 14, p. 458.

R. W. Chaney, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1945. Mammalian remains suggest an early Pliocene or late Miocene age. Plant fossils indicate an age not earlier than lower Pliocene. When these are compared with larger flora from Ellensburg formation in which mammalian remains are well represented, contemporaneity of Dalles is established, and age of both formations may be indicated as Pliocene.

C. R. Warren, 1941, Am Jour. Sci., v. 239, no. 2, p. 106–126. Hood River conglomerate is of contemporaneous origin with the Dalles and Ellensburg formations, both of late Miocene or early Pliocene.

E. T. Hodge, 1942, Oregon State Coll. Studies in Geology Mon. 3, p. 23–26. Hodge (1928, Pan-Am. Geologist, v. 49, no. 5) gave name Madras formation to beds in vicinity of Madras. Present study has shown that the Dalles and Madras are one formation; hence the older name, Dalles, takes precedence. Consists of lava flows and water-spread materials. Lavas vary from 15 to 200 feet and average 75 feet in thickness. Unconformably overlies all older formations. Rhododendron formation extends eastward and becomes Dalles formation. To east and north of Kloan, the Dalles grades into Shutler formation.

R. W. Chaney, 1944, Carnegie Inst. Washington Pub. 553, p. 285–321, pls. Discussion of the Dalles flora. Age of Dalles formation, as indicated by fossil flora, is lower Pliocene.

Dalton Formation[1]

Lower Cambrian: Western Massachusetts and southwestern Vermont.

Original reference: B. K. Emerson, 1899, U.S. Geol. Survey Bull. 159.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Correlation chart for Vermont shows Dalton formation in southwestern part of State below Cheshire quartzite.

Best exposed at site of former Dalton clubhouse, on high hill south of Dalton Station, in open pasture farther south and on southeastward to lookout tower, Berkshire County, Mass.

Dalton Gneiss[1]

Precambrian: Northwestern Connecticut.

Original reference: W. M. Agar, 1932, Am. Jour. Sci., 5th, v. 23, p. 35.

Dalton Sandstone Member (of Crevasse Canyon Formation)

Dalton Sandstone Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears 1934, U.S. Geol. Survey Bull. 860–A.

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 90, 92–93, pl. 1. Reallocated to member status in Crevasse Canyon formation (new). Overlies Dilco member; underlies lower Gibson member. In area of this report [Fort Defiance-Tohatchi quadrangles], comprises two sandstone units from 20 to 45 feet thick, occupying an interval from 40 to 72 feet; lower unit disappears toward southern edge of mapped area, and upper unit thins markedly.

Named for exposures at Dalton Pass, Gallup region, McKinley County.

Dam Breccia

Tertiary: Northwestern Arizona and southeastern Nevada.

U.S. Bureau of Reclamation, 1950, U.S. Bur. Reclamation, Boulder Canyon Proj. Final Repts., pt. 3, Preparatory Exams., Geol. Inv., Bull. 1, p. 80 (fig. 28), 89–92, fig. 34 (geol. map). Dark-red cemented sedimentary breccia. Roughly and indefinitely bedded. No complete section exposed. Based on average dip of 30° and an exposure of 3,500 feet along canyon, estimated thickness is about 1,700 feet. Overlain by latite flow breccia. Older than Spillway breccia (new). Included in older volcanic series of area. Name credited to F. L. Ransome (unpub. rept.).

Named for occurrence at site of Hoover Dam in Black Canyon of Colorado River. Forms floor and lower part of walls of the canyon.

Damascus Red Shale[1]

Upper Devonian: Northeastern Pennsylvania and southern New York.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 571, 584–585.

L. V. Rickard *in* W. H. Young, Jr., and W. L. Kreidler, 1957, New York State Geol. Assoc. Guidebook 29th Ann. Meeting, fig. 2, [p. 23]. Geographically extended to New York.

Well exposed near Damascus, Wayne County, Pa.

Dam Lake Quartzite[1]

Precambrian: Minnesota.

Original reference: H. B. Ayers, 1911, Science, new ser., v. 33, p. 465.

Dam Lake, Aitkin County.

Damnation Limestone[1]

Middle Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 35.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1086–1087, 1089, 1090 (fig. 2). Redefined to include former Damnation and Nannie Basin limestones, and name Nannie Basin dropped. Thickness at type locality, herein stated, 149 feet; at Pentagon Mountain, 191 feet. Overlies Gordon shale; underlies Dearborn limestone.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 213 (table 1), 220. Described in southwest Saypo quadrangle where it is 150 feet thick, overlies Gordon shale, and underlies Dearborn limestone.

Type locality: At west end of Scapegoat basin in S½ sec. 6 SW¼ sec. 5, and N½ sec. 8, T. 18 N., R. 10 W. Named from Damnation Creek on west side of Pagoda Mountain, Flathead Range.

Dana Diorite[1]

Upper Carboniferous or post-Carboniferous: Central Massachusetts and southwestern New Hampshire.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 244–247, and map.

J. B. Hadley, 1949, Bedrock geology of the Mount Grace quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–3]. Name based upon an erroneous interpretation by Emerson (1917). Part of unit is represented by Ammonoosuc volcanics in the Mount Grace quadrangle, Massachusetts.

Well developed in Dana and Ware, Mass.

Danbury Granite Gneiss or Augen Granite

Danbury Granodiorite Gneiss[1]

Pre-Triassic: Southwestern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 104, 108, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Redescribed as a granite gneiss. Consists of gray to pink gneissic augen granite or augen gneiss. Pre-Triassic. Derivation of name stated.

J. W. Clarke, 1958, Connecticut Geol. Nat. History Quad. Rept. 7, p. 12–15, geol. map. Porphyrite gneissic augen granite characterized by large microcline megacrysts. In this report [Danbury quadrangle], much of area mapped as Danbury granodiorite on State geological map of 1906, including Shelter Rock area, is assigned to Brookfield plutonic series. Name Danbury augen granite is retained for granites that crop out along western shore of Lake Candlewood in towns of Danbury and New Fairfield.

Named for town of Danbury, Fairfield County.

Danby Formation[1]

Lower Cambrian: West-central Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 396.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 525, 535–536. Stratigraphically extended to include overlying beds, formerly the Wallingford formation, as Wallingford member. Thickness 400 to 800 feet. Underlies Clarendon Springs dolomite.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 22–23. Described in Castleton area. Crops out in narrow belt extending from boundary of Castleton and Brandon quadranges through Florence and Procter to western slopes of Pine Hill. Southern exposures cover area extending from boundary of quadrangle southwest of Chippenhook northward to western slope of Boardman Hill. Includes Wallingford member in upper part. Overlies Winooski dolomite; underlies Clarendon Springs dolomite. Thickness about 700 feet. Upper Cambrian.

Named for town of Danby, Rutland County.

Dane Member (of Pecatonica Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 41, figs. 3, 10, 12, 16. Dolomite, thin- to thick-bedded, with weak argillaceous streaks and some shale films. Thickness varies from 3 to 14 feet. Shown on columnar section as underlying New Glarus member (new) and overlying Chana member (new).

Occurs in the Dixon-Oregon area.

Danforth Formation[1]

Pliocene: Southeastern Oregon.

A. M. Piper, 1936, Geol. Soc. Oregon County News Letter, v. 2, no. 8, p. 10. Unconformably overlies Steens basalt; unconformably underlies Harney formation (new). Thickness 20 to 800 feet. In southern part of area, consists of four facies: tuff-breccia and associated stratified rocks; basaltic breccia and associated siltstone, sandstone, conglomerate, and two intercalated sheets of basalt; stratified siltstone, sandstone, and ash; and spherulitic rhyolite. In northwestern part of area, formation comprises, in upper part, stratified siltstone, sandstone, tuff, and volcanic ash with intercalated layers of glassy perlitic rhyolite and one rhyolitic tuff-breccia layer; lower part massive rhyolite.

A. M. Piper, T. W. Robinson, and C. F. Park, Jr., 1939, U.S. Geol. Survey Water-Supply Paper 841, p. 43–49, pl. 2. Detailed description. [This is report cited in Wilmarth Lexicon as "in press."]

Name derived from Danforth Ranch in T. 22 S., R. 32½ E., where section is exposed along Cow Creek, Harney County.

Dangkulo Limestone

See Dankuro Limestone.

Daniels Conglomerate

Tertiary, middle (?) : Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 15 (table 1), 46–47, pl. 1; 1946, U.S. Geol. Survey Prof. Paper 209, p. 42–44, pl. 3 [1947]. Coarse stream gravel, partly cemented; includes a little interbedded quartz latite. Carries boulders 4 feet in diameter, but most of the pebbles are less than 3 inches through. As much as 250 feet thick in Chico Shunie Hills, but thinner elsewhere. Unconformably overlies Cornelia quartz monzonite (new), Cardigan gneiss (new), and Chico Shunie quartz monzonite in southern part of quadrangle and Sneed andesite (new) and Childs latite (new) in the Childs Mountain localities. Conglomerate seems more likely to be early Pliocene or even older rather than a correlative of the Gila conglomerate of southeast Arizona.

Poorly exposed in hills just north of Daniels Arroyo, from which it is named, Ajo quadrangle, Pima County. Principal exposure is in southwestern part of Chico Shunie Hills, just north of Daniels Arroyo, where it forms a belt about 1½ miles wide practically from west edge of T. 13 S., R. 6 W., to west boundary of the quadrangle northwest of Teepee Butte.

Dankuro (Dangkulo) Limestone

Recent (early Holocene) : Mariana Islands (Tinian).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 58, table 4 [English translation in library of U.S. Geol. Survey, p. 69]. Named on correlation chart. Correlated with Tanapag limestone on Saipan, Mirikattan limestone on Rota, and Garukijokku limestone on Palau. A raised coral reef. Recent.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 27. Dangkula limestone, a raised coral reef; younger than Sonson limestone. Early Holocene. Name credited to M. Kodaira (unpub. ms.).

Danley Ranch Tongue (of Abo Sandstone)

Lower Permian (Wolfcamp Series) : Central southern New Mexico.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 690 (fig. 1), 692–695, 698 (fig. 5). Predominantly soft red shale, reddish-brown cross-laminated shaly siltstone, and very fine grained sandstone; thin ledges of thin-bedded tannish-weathering light-olive-gray limestone, which probably represent minor tongues of Hueco limestone, present in most places; conglomerate of four types present in most localities in lower part of tongue. Maximum thickness about

200 feet; average thickness 100 feet; thickness varies widely as result of intertonguing with Hueco limestone and from marked relief of erosional surface on which Abo was deposited. In most areas, rests with sharp angular unconformity on limestone and shale beds of Pennsylvanian sequence; most commonly these rocks belong to upper unit of Magdalena group.

Type section: Exposed in SW¼ sec. 35, T. 19 S., R. 11 E., about 1 mile west of Danley Ranch headquarters, Otero County. Crops out in Sand Canyon area in narrow, discontinuous band from northeast edge of area to north fork of Culp Canyon.

†Dannemora Formation[1]

Precambrian: Northeastern New York.

Original reference: H. P. Cushing, 1901, New York State Mus. 53d Ann. Rept., pt. 1, p. r36–r69, map.

Well exposed all over Dannemora Mountain and throughout Dannemora Township, Clinton County.

†Dan River Series[1]

Upper Triassic: Central northern North Carolina.

Original reference: E. Emmons, 1856, Geological report of Midland Counties of North Carolina: North Carolina Geol. Survey.

Dan River region.

Dantzler Formation

Cretaceous (Comanche): Subsurface in Mississippi and Louisiana.

R. T. Hazzard, B. N. Blanpied, and W. C. Spooner, 1947, Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 477 (table), 478. Defined as the sand and gray and red-mottled shale section, with fossiliferous zones, which intervenes between base of lower Tuscaloosa and top of Washita limestone. Occurs between 8,905 and 9,910 feet in type well.

Type well: Humble Oil Co.'s B–1 Dantzler well, Jackson County, Miss. Recognized in wells in Forest, Jefferson Davis, Lamar, Lawrence, Marion, and Stone Counties, Miss., and in Washington Parish, La.

Danville Coal Member (of Carbondale Formation)

Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 36, 48 (table 1), 65, pl. 1. Uppermost member of Carbondale formation (redefined). In southern area, occurs above Galum limestone member; in western and northern areas, occurs above Copperas Creek sandstone member; in eastern area, occurs above Herrin (No. 6) coal member. Thickness about 1⅔ feet. Danville (No. 7) coal is extended to No. 7 coal throughout Illinois. In southern Illinois, replaces name Cutler (No. 7) coal; in northern and western areas, replaces name Sparland (No. 7) coal. Coal named by Bradley (1870, Geology and Paleontology, v. 4, Illinois Geol. Survey). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: E½ sec. 7, T. 19 N., R. 11 W., Vermilion County.

Danville Injection Gneiss

Middle Silurian: Southwestern Maine.

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. In Lewiston area are seven formations (ascending): Danville injection gneiss, Androscoggin gneiss, Bates crystalline limestone, Deer Rips lime-silicate gneiss (new), Thorncrag biotite-sillimanite gneiss, Tacoma lime-silicate series, and Sabbatus quartz-sillimanite-biotite schist.

Occurs in Lewiston area, Androscoggin County.

Danville Stage[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Probably named for Danville, Yell County, Ark.

Danville Landing Beds or Group[1]

Danville Landing Formation or Beds (in Jackson Group)

Eocene: Central Louisiana.

Original reference: M. A. Hanna, Donald Gravell, and James McGuirt, 1934, Shreveport Geol. Soc. 11th Ann. Field Trip [Guidebook], p. 35–37, table opposite p. 30.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 106. Danville Landing beds present in Grant and La Salle Parishes as a 40-foot series of interbedded sands and clays. Grade vertically into underlying Verda member (new) of Yazoo formation and into overlying gypsiferous clays of Vicksburg group.

H. N. Fisk, 1944, U.S. Mississippi River Comm., p. 13 (table 2), 14, 15. Jackson group divided into three formations (ascending): Moodys Branch marl, Yazoo clay, and Danville Landing beds.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1838 (fig. 6), 1839. Danville Landing formation present above Yazoo clay in central Louisiana. In Jackson group.

G. E. Murray, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 702 (fig. 1), 703, 704, 705. Formation (beds) underlies Mosley Hill formation (new).

Named for occurrence in vicinity of Danville Landing, reported to be on Ouachita River, Catahoula Parish.

Darby Formation[1]

Middle and Upper Devonian: Northwestern Wyoming.

Original reference: E. Blackwelder, 1918, Washington Acad. Sci. Jour., v. 8, p. 420.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Upper Devonian.

W. W. Rubey, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–109. In Bedford quadrangle, formation consists of alternating thick beds of (1) dark-gray buff-weathering massive dolomitic limestone; and (2) black, yellow, and red sandy calcareous siltstone. Thickness 450 to 550 feet. Overlies Bighorn dolomite; underlies Madison and Brazer limestone (mapped together).

Named for canyon of Darby Creek, on western slope of Teton Range.

Dardanelle Flow or Latite

Miocene and Pliocene: Central California.

F. L. Ransome, 1898, U.S. Geol. Survey Bull. 89, p. 14, 46–52. Discussion of lava flows on western slope of the Sierra Nevada in region drained by Stanislaus River. Latites belong to at least three distinct flows. The youngest, Dardanelle flow (or facies), consists of dark very compact augite-latite, with small scattered phenocrysts of labradorite and augite. Similar to oldest flow, herein named Table Mountain.

Named for occurrence on extreme summit of the West Dardanelle, Tuolumne County.

Darling Creek Glaciation

Pleistocene: East-central Alaska.

T. L. Péwé, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1289; T. L. Péwé *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 9, 13 (table 1). At least three major Quaternary glaciations recorded at north end of Delta River valley. Darling Creek, the earliest glacial advance, preceded Delta glaciation (new). Maximum extent of Darling Creek glaciers not known, but in immediate area of Big Delta they probably abutted against Yukon-Tanana upland and deflected down Tanana River valley perhaps as far as Richardson. Only isolated remnants of till occur on flat interfluves 2,000 to 3,000 feet above floor of Delta River valley.

Delta River valley in Big Delta area.

Darlington (plant) Bed (in Allegheny Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 308–316.

Beaver County.

Darlington Shale (in Allegheny Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 308–316.

Beaver County.

Darlington Underclay (in Allegheny Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 308–316.

Beaver County.

Darrough Felsite

Permian(?): South-central Nevada.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–40. Masses of fine-grained felsitic rocks largely intrusive into older rocks, chiefly the Pablo formation (new); also probably flows. The rocks are mostly rhyolitic in appearance and are fine grained and procelainlike in texture, commonly with well-defined flow banding. Contains abundant inclusions, particularly near contacts. Locally, in central parts of larger masses, the texture is coarser, resembling a fine-grained granitic rock.

Type locality: East front of Toyabe [Toiyabe] Range, west of Darrough's Hot Springs.

Darty Limestone

Mississippian (Kinderhookian): Illinois.

J. M. Weller, 1948, (abs.) Am. Jour. Sci., v. 246, no. 3, p. 150; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 153, chart 5. Name proposed for a thin glauconitic limestone occurring in one or two layers and formerly included in basal part of Springville shale of Union County, Ill. Underlies restricted Springville shale; overlies Mountain Glen shale.

Charles Collinson and A. J. Scott, 1958, Illinois Geol. Survey Circ. 254, p. 511. Limestone near base of Springville shale is accepted as Chouteau and name Darty is no longer needed.

Name derived from tributary of Caney Creek, west of Jonesboro, Union County.

Darwin Quartz Diorite

Upper Mesozoic: Southern California.

V. C. Kelley, 1937, Econ. Geology, v. 32, no. 8, p. 992, 996 (fig. 4). Typically a white or light-grayish-green rock; the average or normal phase of the Darwin stock.

V. C. Kelley, 1938, California Jour. Mines and Geology, v. 34, no. 4, p. 514–516, pl. 7. Formation name Darwin quartz diorite is applied to the elongated stock which occupies center of Darwin Hills. Mapped as Darwin quartz diorite.

Occurs in Darwin silver-lead district in Coso Range, Inyo County.

Darwin Sandstone Member (of Amsden Formation)[1]

Pennsylvanian: Northwestern Wyoming.

Original reference (Dorwin): E. Blackwelder, 1918, Washington Acad. Sci. Jour., v. 8, p. 422.

C. A. Burk, 1954, Jour. Paleontology, v. 28, no. 1, p. 1–16. Discussion of faunas and age of Amsden. Faunal evidence confirms Pennsylvanian age of Amsden. [Hence Darwin sandstone is Pennsylvanian.] Fossils used in present report were collected by Biggs (unpub. thesis). Biggs revisited localities at Bull Lake Canyon and Cherry Creek where Branson and Greger (1918, Geol. Soc. America Bull., v. 29, no. 2) collected from what they believed to be Amsden formation. Biggs demonstrated that Branson's and Greger's collection from Bull Lake Canyon was taken from Mississippian Madison limestone but that it was possible that part of their collection from Cherry Creek was taken from the Amsden. This cannot be established because beds are poorly exposed, and Biggs points out that fossils could apparently be obtained only from slope wash. Because the Branson and Greger collections were the only ones figured, they became a standard reference for later geologists; on this basis, the apparent Mississippian age of Amsden was generally accepted by geologists.

J. D. Love, 1954, Tentative diagrammatic correlation of Tensleep, Amsden, Casper, and Hartville formations in Wyoming: Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf. Correlation chart shows Darwin sandstone member at base of Amsden formation. Stratigraphic, structural, and paleontologic data suggest that base of Darwin is contact between Pennsylvanian and Mississippian rocks. At Bull Lake, Darwin sandstone member overlies Sacajawea formation (this is, at type section of Sacajawea).

A. B. Shaw and W. G. Bell, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 3, p. 333–337. New fossil collections made from lower part of Amsden at Cherry Creek, Wind River Mountains. Mississippian-Pennsylvanian boundary placed more than 48 feet and less than 63 feet above Madison limestone. Lower faunas are Chesteran, and upper faunas tentatively dated Atokan. Presence of two sandstones in the Amsden, both of which have been called "Darwin" is inferred. Since basal sandstone of Amsden at Cherry Creek lies below Mississippian fauna, it cannot be same lithic unit as that identified as Darwin sandstone by Biggs, as quoted by Burk (1954) and Love (1954), elsewhere in Wind River Mountains. Thus there are two sandstones, both lying at base of red-bed sequence, that have been confused as one. Systemic boundary may lie below the upper sandstone, but it cannot lie below the lower sandstone. Love's correlations suggest that the upper sandstone is correlative of type Darwin. Use of name Sacajawea formation at Cherry Creek is not justified.

J. W. Strickland, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 51–57. Discussion of Mississippian stratigraphy of western Wyoming and Mississippian-Pennsylvanian contact. Recommended that Darwin sandstone should mark base of Amsden formation and term Sacajawea be applied to all strata below Darwin and above Madison group. Darwin sandstone is not present in Cherry Creek section of Shaw and Bell (1955) but a Darwin zone, depicted by conglomerate between 68 and 73 feet above top of Madison, marks base of Amsden.

Name derived from Darwin Peak, in Gros Ventre Range.

Dashner Limestone[1] Member (of Topeka Limestone)

Pennsylvanian: Northeastern Kansas.

Original references: R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita, Kans., [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]; 1936, Kansas Geol. Soc. Guidebook 10th Ann. Field Conf., Sept. 4–7, p. 41.

Derivation of name not stated.

Datil Formation[1]

Datil Volcanics

Tertiary: Southwestern New Mexico.

Original reference: D. E. Winchester, 1920, U.S. Geol. Survey Bull. 716–A.

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 61. Restricted to exclude unit here named Baca formation, which as defined includes the lower 694 feet of Winchester's stratigraphic section. Restricted Datil in that area is 1,140 feet and consists of latite, rhyolites, and andesite flows, agglomerate, tuff, conglomerate, and sandstone. Thickness in area of this report [La Joya area, Los Pinos Mountains, and northern Chupadera Mesa] estimated about 2,000 feet. Truncates several formations; in Socorro Mountains, rests on Madera limestone, the Baca being absent. Age of formation in doubt; if Baca is Eocene, Datil may be Eocene or younger. Mapped as Miocene(?).

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 6 (table 1), 7 (fig. 2), 26–32, pl. 1. Referred to as Datil volcanics. Winchester failed to measure complete section of Datil in Bear Mountains because above his uppermost 120 feet of quartz rhyolite there is at least 150 feet of vitric and welded rhyolitic tuff and a minimum of 1,200 feet of basalt and basaltic andesitic lava flows. He mapped about 500 feet of the Popotosa-Santa Fe unit as Datil, but did not include it in his measured section. In area of this report [Puertecito quadrangle], the Datil rests on strata of Cretaceous age as well as on Baca formation. Subdivided into (ascending) Spears, Hells Mesa, and La Jara Peak members. Thickness 2,740 to 2,990 feet. Underlies Santa Fe group. Upper Miocene(?).

M. E. Willard, 1959, New Mexico Geol. Soc. Guidebook 10th Field Conf., p. 95–98. Use of Datil formation in restricted sense by some authors and in very broad sense by others (as Tonking) has caused misunderstanding and confusion. On basis of reconnaissance study in Catron County, redefinition of Datil is suggested. Typically, a latite facies makes up lower parts of formation and is commonly gradational into an overlying rhyolite facies of tuff, welded tuff, and flows; rhyolite facies is overlain by, or interfingers with, an andesite facies consisting of flows, dikes, sills, and pyroclastics; conglomerate, sandstone, and siltstone from various sources may be present at any stratigraphic position but are only locally of sufficient thickness to warrant their being designated as facies. At only few places is whole assemblage of facies present; commonly one or two make up bulk of formation. Overlies nonvolcanic (Baca) sediments; underlies basalt and basaltic andesite.

Named for fact it is mountain-forming series of Datil Mountains. Winchester's section measured at north end of Bear Mountains in secs. 4, 5, 8, and 9, T. 1 N., R. 4 W., Socorro County.

Daube Limestone (in Hoxbar Group)

Daube Member (of Hoxbar Formation)[1]

Pennsylvanian (Missouri Series): Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 16.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6. Shown on chart as formation in the Hoxbar here considered a group.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 42–43. Referred to as member of Hoxbar group. Thickness 10 feet. Lies about 400 feet above Anadarche member and about 500 feet below Zuckerman member. Missourian.

Named for occurrence at abandoned coal mine of Daube, Westheimer, Munzesheimer, and Zuckerman, in SE¼ sec. 8, T. 5 S., R. 2 E., Carter County.

Dauphin Shale (in Martinsburg Group)

Ordovician: South-central and east-central Pennsylvania and northwestern New Jersey.

Bradford Willard, 1943, Geol. Soc. America Bull., v. 54, no. 8, p. 1069 (footnote), 1070, 1118. Name proposed for lower shaly part of group. Underlies Fairview sandstone or Shochary sandstone; overlies Chambersburg limestone or Jacksonburg limestone. Table 1 shows upper part included in interval of Jonestown red beds in Susquehanna Valley and Lehigh and Berks Counties, Pa.

M. E. Johnson and Bradford Willard, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 129. Mostly black shale west of Delaware Valley and black slate in Delaware Valley. Thickness at least 3,500 feet. Geographically extended to New Jersey.

Named from good exposures in Dauphin County, Pa.

Davenport Beds[1]

Davenport Member (of Wapsipinicon Formation)

Middle Devonian: Eastern Iowa.

Original reference: W. H. Norton, 1894, Iowa Acad. Sci. Proc., v. 1, pt. 4, p. 24.

E. H. Scobey, 1940, Jour. Sed. Petrology, v. 10, no. 1, p. 38 (fig. 1), 42–43. Uppermost member of formation. Overlies Spring Grove member; underlies Cedar Valley formation. Typically gray sublithographic dense unfossiliferous pure limestone, which is commonly highly brecciated; a shaly zone just below the Cedar Valley is referred to as Vinton phase. Average thickness between 10 and 30 feet; may be more than 50 feet thick in Scott County where lower boundary cannot be delimited.

Named for occurrence in vicinity of Davenport, Scott County.

David Formation

Eocene, upper: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no. 29, p. 131, 134 (correlation chart). Upper Eocene limestone. Below Majagua formation.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, Geol. Sci., p. 234 (chart), 236. David formation applied in broad sense to the younger upper Eocene rocks of Panamá, consisting generally of foraminiferal limestones in their entirety or of shale and sandstone formations in which the limestones may be entirely missing or restricted to reeflike masses. In vicinity of David and Brenon, occurs above Bucarú formation; in Veraguas and Los Santos area occurs below Tonosi limestones.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 334. Poorly defined name. Eocene.

In Chiriqui Province.

David City Formation[1]

Pleistocene (Nebraskan): Eastern Nebraska and northeastern Kansas.

Original reference: A. L. Lugn and G. E. Condra, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 190.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 52 (fig. 2), 53–55. In Kansas, term David City formation is applied only to water-laid deposits occurring below and genetically related to Nebraska glacial till; its distribution, therefore, is restricted to Doniphan, Atchison, and Brown Counties. In NE¼SE¼ sec. 6, T. 2 S., R. 20 E., Doniphan County, measured section includes 10 feet of sand, gravel, and cobbles which rest directly on Pennsylvanian limestone (Deer Creek limestone and Calhoun shale) and are conformably overlain by Nebraska till.

Type area: David City, Butler County, Nebr.

Davidson Granodiorite

Davidson Diorite

Miocene(?): Western Nevada.

V. P. Gianella, 1934, Mining and Metallurgy, v. 15, no. 331, p. 299. Davidson diorite is clearly intrusive but its precise place in geological events of area is undetermined.

V. P. Gianella, 1936, Nevada Univ. Bull., v. 30, no. 9, p. 64–68. Described as medium-grained granular rock of light-gray color. Contains many andesite inclusions. Intruded the Alta andesites, probably about middle Miocene.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 52–54, pl. 3. Gianella's (1934) Davidson diorite renamed Davidson granodiorite. Intrudes Alta formation. May be contemporaneous with parts of Kate Peak formation; cannot be younger than all of Kate Peak because it is cut by a few dikes of andesite porphyry of Kate Peak formation. Miocene(?).

Makes up bulk of Mount Davidson, Virginia City quadrangle.

Davidson Granophyre[1]

Precambrian: Southwestern Oklahoma.

Original reference: M. G. Hoffman, 1930, Oklahoma Geol. Survey Bull. 52, p. 39–48.

Crops out in west half of Davidson Hill and northwest along Little Medicine Creek for about one-half mile.

†Davion rock[1]

Miocene: Southern Mississippi.

Original reference: B. L. C. Wailes, 1854, Mississippi Agric. and Geol. Rept., p. 214–216.

Davis Coal Member (of Spoon Formation)

Pennsylvanian: Southeastern and southwestern Illinois and western Kentucky.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 33, 46 (table 1), 64, pl. 1. Assigned member status in Spoon formation (new). Occurs above Stonefort limestone member and below DeKoven coal member. Thickness about 3½ feet. Coal named by Lee (1916, Kentucky Geol. Survey, ser. 4, v. 4, pt. 2); reference of Owen (1856, Kentucky Geol. Survey Bull., v. 1, ser. 1) incorrect. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Davis mine. one-half mile east of DeKoven, Shawneetown quadrangle, Union County, Ky.

Davis cyclothem (in Tradewater Group)

Pennsylvanian: Southern Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 16 (fig. 2) [1943]. Shown on columnar section as Davis cyclothem. Occurs below DeKoven cyclothem and above Stonefort cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol, Survey Circ. 217, p. 5. Name Colbert cyclothem substituted for preempted name Davis.

Type locality of Davis cyclothem not given, but type locality of Colbert is one-half mile west of Colbert School in SE¼SW¼ sec. 23, T. 10 S., R. 7 E., Saline County.

Davis Formation (in Elvins Group)[1]

Davis Member (of Elvins Formation)

Upper Cambrian: Southeastern Missouri.

Original reference: E. R. Buckley, 1907, Missouri Bur. Geology and Mines, v. 10, 2d ser., separate.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 234 (table 1). Table shows Davis as basal formation of Elvins group. Underlies Derby dolomite; overlies Bonneterre dolomite.

V. E. Kurtz, 1960, Dissert. Abs., v. 21, no. 3, p. 595. Referred to as member of Elvins formation. Sharp lithologic change of wide areal extent divided member into a lower dominantly carbonate section and an upper dominantly shale unit. Underlies Derby member; disconformably overlies Bonneterre dolomite.

Named for outcrops on Davis Creek, St. Francois County.

Davis Formation (in Tradewater Group)

Pennsylvanian: Southern Illinois.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 39, 41. Uppermost formation in Tradewater group. Overlies Stonefort formation. Represents a single cycle of deposition. Basal sandstone, Davis, has maximum thickness of 30 feet or more but thins and pinches out to west; Davis coal is persistent seam about 3 feet thick.

Type locality and derivation of name not given.

Davis Creek Beds[1]

Miocene: Northwestern Nevada.

Original reference: R. W. Chaney, 1924, Geol. Soc. America Bull., v. 35, p. 162–163.

Washoe County.

Davis Creek Formation

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Shown in list as underlying Brophy Canyon formation and overlying Little Valley formation (both new). Comprises Buck Island member above and Baldy Mountain member (both new). The Upper Jurassic and Cretaceous section, about 40,000 feet, consists of sequence of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Davistown Sandstone (in Washington Group)

Permian: Western Pennsylvania and West Virginia.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 151. Medium- to heavy-bedded, medium-grained brown shaly sandstone. Thickness 10 to 30 feet. Lies 320 feet above Waynesburg coal and a short distance between Jollytown coal. Probable that in parts of West Virginia where Middle Washington limestone is lacking, this sandstone may have been included in Upper Marietta, but from type section given by Hennen, the Upper Marietta is confined to sandstone lying below a calcareous shale which is probable equivalent of Middle Washington limestone rather than bed so called in Hennen's (1909, West Virginia Geol. Survey County Rept. Marshall, Tyler, and Wetzel Counties) section. Therefore, in section where Middle Washington limestone is well developed, it seems prefrable that Upper Marietta be confined to sandstone strata below this limestone, and that sandstone above it be given another name.

A. T. Cross and M. P. Schemel, 1956, West Virgina Geol. Survey, v. 22, pt. 1, p. 53 (fig. 1–141). Columnar section of Lower Dunkard (Washington series) in Ohio River valley, West Virginia, shows Davistown sandstone above Upper Marietta sandstone and below Upper Washington limestone.

Named for quarry in the sandstone just north of National Pike at Davistown, Greene County, Pa.

Dawes Sandstone (in Clinton Group)

Middle Silurian: Central New York.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 13, 99–100, 170. Name proposed for light-gray slightly calcareous sandstone. Very cross-bedded and unfossiliferous. Few thin layers of arenaceous shales in basal part. Upper part stained red. Thickness about 8 feet. Unconformably underlies Kirkland iron ore; unconformably overlies Willowvale shale.

Type locality: On small stream known locally as Dawes Quarry Creek flowing west into Oriskany Valley within limits of village of Clinton; section is east of main part of Clinton in town of Kirkland, Oneida County. Outcrop area bounded on west by College Hill Creek on west side of Oriskany Valley and on east by Dawes Quarry Creek.

Dawn Limestone Member (of Monte Cristo Limestone)[1]

Dawn Member (of Monte Cristo Dolomite)

Lower Mississippian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 17.

J. C. Hazzard, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1503; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 880, 881, 883 (fig. 2). Geographically extended into Nopah Range, Inyo County, Calif., where it is predominantly limestone 350 feet thick, underlies Anchor limestone member and overlies Sultan limestone (Crystal Pass member). Name Stewart Valley is abandoned, and Mississippian beds previously ascribed to it are assigned to Dawn limestone.

Charles Deiss, 1952, U.S. Geol. Survey Bull. 973–C, p. 114–115, pl. 13. Member described in Sloan district, Nevada, where it is approximately 175 feet thick, and consists of two lithologic units. Lower, which comprises four-fifths of the formation, is dull chocolate gray, tan gray, light gray, or white and consists of a medium to coarsely crystalline, thick-bedded dolomite; upper unit consists of thinner bedded (2 to 18 inches) tan-buff medium crystalline dolomite. Underlies Anchor member; contact arbitrarily drawn at base of lowest bed containing chert.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 42. Described in Ivanpah quadrangle (California-Nevada) where it is made largely up of beds of blue-gray to dark-gray limestone, 2 to 10 feet thick, but is widely altered to dolomite. Underlies Anchor limestone member.

Well exposed west of Dawn mine, SW¼ sec. 15, T. 23, S., R. 58 E., Goodsprings quadrangle, Nevada.

Dawson Arkose[1] or **Formation**

Upper Cretaceous and Paleocene: Eastern Colorado.

Original reference: G. B. Richardson, 1912, Geol. Soc. America Bull., v. 23, p. 267–276.

C. H. Dane and W. G. Pierce, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 10, p. 1309–1312, 1314–1315 (fig. 3), 1320–1328. More than 2,000 feet thick; consists of arkosic conglomerate and sands. Merges northward into Arapahoe and Denver formations along foothills of Front Range, where beds stand vertically or dip steeply eastward on west flank of Denver basin. Dawson and Arapahoe along this belt overlie, with erosional irregularity, Laramie formation. In plains region—on east side of basin—where beds dip gently westward into basin, upper part of Dawson is coarsely conglomeratic, but lower consists chiefly of arkosic sands and dark shales, contains beds of lignite, and is not much different than underlying Laramie upon which it rests with apparent conformity. Identifiable remains of *Triceratops* present in lower part, but upper part has not yielded fossils of diagnostic age. Underlies Castle Rock conglomerate.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 65–86. New fossil evidence places basal part of Dawson arkose and Denver formation in Upper Cretaceous sequence. Proposed that Dawson arkose be restricted to Tertiary strata and that lower part be included in redefined Laramie.

S. O. Reichert, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 107–111, pls. 1, 2. Arapahoe and Denver formations can be mapped throughout Denver basin, and these names should replace term "lower" Dawson of Dane and Pierce (1936). Dawson formation (type section at Dawson Butte) should designate only "upper" Dawson of Dane and Pierce. Name Green Mountain conglomerate should be abandoned because it is only partial representative of Dawson formation as here restricted.

Named for Dawson Butte, about 6 miles southwest of Castle Rock, Douglas County.

Dawson Bay Formation

Dawson Bay Formation (in Manitoba Group)

Middle Devonian: Surface and subsurface in Manitoba, Canada, and subsurface in northeastern Montana, western North Dakota, and northwestern South Dakota.

A. D. Baillie, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 2, p. 444–452; 1953, Manitoba Dept. Mines and Nat. Resources Mines Br. Pub. 52–5, p. 26–27. Term proposed for lowest sequence of strata of Manitoba group. Lower limit is taken at base of red and green argillaceous zone that overlies Elk Point group. Upper limit marked by top of widespread reefoid and stromatoporid zone. Thickness 100 to 200 feet. In outcrop overlies Winnipegosis formation. Underlies unnamed strata of group.

W. M. Laird, 1953, Interstate Oil Compact Quart. Bull., v. 12, no. 2, p. 74. Underlies Souris River formation (new). Included in Beaver Hill Lake group.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2299 (fig. 2), 2302–2304 (fig. 4), 2307–2308, 2309 (fig. 5). Baillie placed Dawson Bay formation and overlying unnamed beds that are approximately equivalent to Souris River formation of present report in Manitoba group. This grouping is not recommended for United States part of Williston basin because Dawson Bay and Souris River formations are readily separable. In Birdbear well, Dunn County, N. Dak., formation lies between depths of 11,052 and 11,170 feet. Ranges in thickness from fraction of foot to 185 feet; thickest along international boundary and in north-central North Dakota. Underlies approximately same area as Elk Point group in Williston basin and northeastern Montana but extends slightly beyond limit of Winnipegosis formation. Overlies Prairie formation of Elk Point group; underlies Souris River formation. Does not outcrop in United States.

Named for exposures along shores of Dawson Bay at northern end of Lake Winnipegosis, Manitoba, Canada.

Dayan Stage

Ordovician (Chazyan): North America.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 91, 94 (table 2). Chazy has long been divided into three lithologic and faunal zones (Brainerd and Seely, 1888, Am. Geologist, v. 2) which were given "substage" names Day Point, Crown Point, and Valcour (Cushing, 1905, New York State Mus. Bull. 95). These stages have been called Dayan, Crownian, and Valcourian by Oxley (unpub. ms.).

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 820–829. In Champlain Valley Chazy series is separable into Dayan, Crownian, and Valcourian stages, distinguished by faunal criteria. Each stage has several lithologic facies. Reefs are prevalent.

Marshall Kay, 1960, Internat. Geol. Cong. 21st, Copenhagen, pt. 7, p. 28–33. Chazyan series has Whiterockian, Dayan, Crownian, and Valcourian stages.

Day Creek Dolomite

Day Creek Dolomite Member (of Cloud Chief Formation)

Day Creek Dolomite (in Cimarron Group or Woodward Group)[1]

Permian: Southern Kansas, eastern Colorado, and northwestern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 44.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 37. Fine-grained dense dolomite about 2 feet thick in Kansas. Crops out in western Clark County; seemingly absent between northern part of T. 33 S., R. 24 W., and a point in Oklahoma near center of T. 25 N., R. 25 W., (Indian meridian). Overlies Whitehorse sandstone; underlies Taloga formation of Quartermaster group.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as member of Cloud Chief formation.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 81, 82 (fig. 23). Day Creek dolomite exposed in Baca County, Colo., where it underlies Taloga formation.

Named for Day Creek, Clark County, Kans.

Day Point Limestone[1]

Middle Ordovician: Eastern New York and western Vermont.

Original reference: H. P. Cushing, 1905, New York State Mus. Bull. 95.

F. M. Swartz, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1402 (fig. 2). Shown on correlation chart as Chazyan. Below Crown Point formation.

Marshall Kay, 1950, (abs.) Geol. Soc. America Bull. 61, no. 12, pt. 2, p. 1476. Bridport dolomite underlies Chazy Day Point formation within and west of Lake Champlain in Vermont and New York.

R. E. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 11–20, 63, 65, pls. 1, 2. Described on South Hero Island and Isle La Motte, where it overlies Providence Island dolomite and underlies Crown Point limestone. Thickness about 233 feet on Isle La Motte; 237½ feet on South Hero Island.

Philip Oxley and Marshall Kay, 1959, Am. Asoc. Petroleum Geologists Bull., v. 43, no. 4, p. 820–829. Included in Dayan stage (new). Comprises (ascending) Head, Scott, Wait, and Fleury members (all new). Chazyan.

Well exposed at Day Point, Peru Township, Clinton County, N.Y.

Days Creek Formation (in Myrtle Group)

Lower Cretaceous: Southwestern Oregon.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2775 (fig. 2), 2777 (fig. 3), 2781 (table 1), 2782–2784. Name applied to early Cretaceous clastic sedimentary rocks that concordantly overlie Riddle formation (new). Consists of alternating units of greenish-gray, fine-grained, even-grained sandstone and medium-gray to greenish siltstone; divisible into two members of which lower is distinguished from upper by presence of limestone lenses, by its siltstone units being medium gray instead of greenish gray, by its sandstone units being less massive, and by containing pelecypod *Buchia crassicollis* (Keyserling). Thickness at type section 809 feet. Rests directly on Riddle formation at many places in Douglas County; appears to rest normally on Galice formation at bridge across Illinois River west of O'Brien, Josephine County, but actual plane of contact not visible; in Port Orford area, basal beds containing *Buchia crassicollis* (Keyserling) rest generally on the Riddle but locally overlap onto Colebrooke schist. Contact with Galice and Colebrooke interpreted as angular unconformity. Name Days Creek replaces Horsetown formation and Cretaceous part of Knoxville as used by Diller and Kay (1924, U.S. Geol. Survey Geol. Atlas, Folio 218) in southwestern Oregon.

Type section: Along South Umpqua River in NW¼ sec. 15, SW¼ sec. 47, and E½ sec. 9. T. 30 N., R. 4 W., Douglas County. Named for village of Days Creek.

Daysville Formation (in Ancell Group)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 21, figs. 3, 12. Dolomite, impure, greenish-gray, chalky, thin-bedded. Thickness about 4½ feet. Shown on columnar section as underlying Loughridge formation (new) and overlying Kingdom formation (new).

Occurs in Dixon-Oregon area.

Dayton Limestone[1]

Middle Silurian: Southwestern Ohio.

Original reference: E. Orton, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 143; 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 271, 297, 299–301, 309, fig. 1 facing p. 310.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart below Estill clay and above Waco limestone. Niagaran series.

R. J. Bernhagen, chm., 1960, Ohio Acad. Sci. Sec. Geology Guidebook 35th Ann. Field Conf., p. 17, 21. Silurian section exposed in Yellow Springs region shows Dayton limestone, 5 to 8 feet thick, above Brassfield limestone and below Osgood shale. Clinton group.

Typically exposed in vicinity of Dayton, Montgomery County.

Dayville Member (of Coeymans Limestone)

Lower Devonian: Central New York.

L. V. Rickard, 1956, Dissert. Abs., v. 16, no. 1, p. 102. When traced westward from the Helderbergs, the Coeymans formation thickens to nearly 100 feet at Cherry Valley. Slightly further west, this greatly thickened Coeymans splits into three parts. Lower part, for which name Dayville limestone is proposed, grades laterally into Olney limestone of Syracuse area.

Type locality and derivation of name not stated.

D-Cross Tongue (of Mancos Shale)

Upper Cretaceous: Southwestern New Mexico.

C. H. Dane, A. A. Wanek, and J. B. Reeside, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 187, 188 (fig. 2). A marine shale unit ranging from 90 to 191 feet in thickness and decreasing consistently in thickness from south to north. Underlies Gallego sandstone member of Gallup sandstone and overlies lower part of Gallup sandstone. Unit formerly correlated with Pescado tongue but now believed to be a distinct and higher tongue.

Named for exposures at D-Cross Mountains in secs. 17 and 18, T. 3 N., R. 8 W., Socorro County.

Dead Horse Conglomerate Member (of Manitou Formation)

Lower Ordovician: Central northwestern Colorado.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 892 (fig. 2), 893, 905–906. Consists largely of thin beds of gray flat-pebble limestone conglomerate. Thickness about 108 feet. Underlies Tie Gulch dolomite member (new); overlies Clinetop algal limestone member (new) of Dotsero formation.

Type section: Spur on north side of U.S. Highway 6, one-half mile northeast of bridge over French Creek. Named for exposures along Dead Horse Creek which enters Glenwood Canyon from northwest near NE cor. sec. 30, T. 5 S., R. 87 W., Garfield County.

Dead Horse Tuff

Eocene, upper: Northeastern Nevada.

R. R. Coats, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI–690, Book 2, p. 304–305. Massive dull-green to reddish- and pinkish-gray biotite quartz latite welded tuff. Thickness about 5,000 feet. Grades upward into coarse conglomerate which is overlain by Jarbidge rhyolite (new). Rests on Paleozoic limestone.

U.S. Geological Survey currently considers the Dead Horse Tuff to be upper Eocene in age.

Present in Jarbidge quadrangle.

Deadman Limestone[1]

Upper Triassic: Southeastern Idaho and northwestern Wyoming.

Original reference: G. R. Mansfield, 1915, Washington Acad. Sci. Jour., v. 5, p. 492.

C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1801 (table 1). Age shown on table as Upper(?) Triassic.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 34–35, pl. 1. Mapped in Ammon and Paradise Valley quadrangles. Type locality designated.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 180–181. Mansfield (1927, U.S. Geol. Survey Prof. Paper 152) recognized following sequence of beds between Thaynes and Nugget formations: Timothy sandstone, Higham grit, Deadman limestone, and Wood shale. These units are distinct lithologically and are equivalent to Ankareh formation of Wasatch and Uinta Mountains of western Wyoming. In present report, Timothy sandstone is considered uppermost member of Thaynes. Higham grit and Deadman limestone are recognized as independent formations and Wood shale is considered westward extending tongue of Ankareh formation. At type area, the Deadman is 150 feet thick and directly overlies Higham grit.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 46. Geographically extended into Snake River Range, Wyo.

Type locality: Deadman Creek in northeastern part of T. 4 S., R. 38 E., Paradise Valley quadrangle, Idaho, where formation is crossed by the creek and extends northwestward along the ridge parallel to and northeast of prominent band of Higham grit. Named from Deadman Creek.

Deadman Quartzite

Precambrian: Central Arizona.

E. D. Wilson, 1938, *in* Arizona Bur. Mines Bull. 145, Geol. Ser. 12, pl. 3; 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1118, 1123. Hard fine- to medium-grained thinly stratified crossbedded cliff-forming quartzite, together with some thin conglomerate and hematitic shale members and an irregular basal conglomerate. In general, upper third weathers grayish brown to white, in contrast to reddish-brown tint of lower part. Thickness ranges from 90 to 110 feet except in a thrust block at the southeast where it is approximately 800 feet. Thins out northward; removed by erosion southward. Unconformably overlies Red Rock rhyolite; conformably underlies Maverick shale (new).

Named from typical occurrence on North Fork of Deadman Creek. Found only within northern half of Mazatzal Range.

Deadman Island Beds[1] (in San Pedro Formation)

Pleistocene: Southern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, chart opposite p. 217.

Deadman Island no longer exists. Was an island formerly located in San Pedro Harbor but has now been entirely removed by steam shovels.

Deadwood Formation[1]

Upper Cambrian and Lower Ordovician: Western South Dakota, southeastern Montana, and eastern Wyoming.

Original reference: N. H. Darton, 1901, U.S. Survey 21st Ann. Rept., pt. 4, p. 505.

M. R. McCoy, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 45 (chart), 47. In northern Black Hills, conformably underlies Aladdin sandstone (new).

M. R. McCoy, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 21. In Powder River Basin, term Deadwood is used to include a series of sandstone, shale, and limestone-dolomites which are Upper Cambrian and Lower Ordovician in age. At type section in Black Hills, Deadwood is 350 to 400 feet thick. Sandstone or conglomerate, often auriferous, marks base of formation; this unit, which rests on beveled schists or quartzites, is erratic in thickness, varying from 2 to 95 feet. Above basal sandstone is series of interbedded blue-gray shales, with 2 or 3 horizons, 10 to 70 feet thick. In upper part, a massive sandstone unit is commonly present, often dolomitic, and sometimes ferruginous. Deadwood thins southward to zero edge.

Type locality: Whitewood Canyon, just below Deadwood, Lawence County, S. Dak.

Deadwood Gulch Rhyolite Tuff[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures in upper part of Deadwood Gulch, Mogollon district.

Dean Formation (in Great Smoky Group)

Precambrian: Central northern Georgia.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 9, 40–45, pl. 1, map. Staurolite-mica schists, X-biotite schists, quartzites, metaconglomerates, and "pseudo-diorite" beds; interbedded lesser amounts of gray slate, phyllite, and sericite schist; shows marked horizontal variations, abrupt vertical variations, and many breaks in lithologic sequence. Thickness 2,500 to 3,500 feet. Overlies Hothouse formation (new), hybrid character of rocks between the two makes position of boundary largely interpretative; underlies Nantahala slate, formations appear to be gradational through a zone less than 20 feet thick, and concordant; staurolite schist and metaconglomerate formerly included in basal Nantahala are here included in the Dean, and the Dean-Nantahala boundary is drawn at base of dark slate.

Crops out in a one-half-mile wide belt on each limb of Murphy syncline; western belt extends along west side of Dean Ridge, after which formation is named, through Windy Ridge, and along upper course of Sugar Creek; eastern belt lies to west of Lake Toccoa, Mineral Bluff quadrangle, Fannin County.

Dean Sandstone

Permian (Wolfcamp): Western Texas (subsurface).

Lamar McLennan, Jr., and H. W. Bradley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 4, p. 899, 903, 904, 908. Name was first applied by Seaboard geologists to a sandstone in Gulf Oil Corp.'s Dean No. 1, from 7,990 to 8,190 feet. Type section for Dean as used in this report occurs between depths of 7,550 to 7,660 feet in the Seaboard's Robison 6–A. In type locality, consists of approximately 120 feet of gray-white to brown fine sandstone with thin streaks of tan to brown dense limestone and black shale. Occurs below Spraberry sandstone.

Type well: Seaboard's Robison 6–A, a Spraberry field well in sec. 37, Black 34, T. 5 N., Texas and Pacific Railway Survey, Dawson County.

Deanefield Shale (in Pottsville Formation)[1]

Pennsylvanian: Western Kentucky.

Original reference: J. H. Gardner, 1927, Kentucky Geol. Survey, ser. 6, v. 26, p. 135, 137, 153.

Extends throughout territory from Butler to Daviess Counties and is well exposed around Deanefield and Fordsville, Hartford quadrangle.

Dean Lake Chert

Dean Lake Chert (in Hannan Limestone)

Dean Lake Chert Member[1] (of Madison Limestone)

Mississippian (Kinderhookian and Osagean): Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 47.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 2 (column 38). Underlies Rooney chert and overlies Saypo limestone, all in Hannan limestone. Kinderhookian and Osagean.

J. M. Andrichuk, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 89. Hall (1952, unpub. thesis) proposed that Deiss' Dean Lake be recognized as a formation. Deiss gave thickness of 60 feet at type section. Hall redefined type section of 105-foot thickness to include about 45 feet of overlying similar beds separated by 11 feet of chert-free limestone. Kinderhook.

Type locality: Southeast side of Pentagon Mountain in SW¼ sec. 14 T. 25 N., R. 14 W. Named for small cirque lake lying at foot of cliffs that form upper part of east side of the mountain.

Deansboro Member (of Coeymans Limestone)

Lower Devonian: Central New York.

L. V. Rickard, 1955, New York Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7, 9 (strat. column); 1956, Dissert Abs., v. 16, no. 1, p. 102. Coeymans limestone of central New York, overlying Jamesville member of the Manlius, is entirely younger than the Coeymans of eastern New York.

Name Deansboro is proposed for this part of the Coeymans. Consists of massive gray or blue coarse-grained limestone, 30 to 60 feet thick, characterized by *Gypidula coeymanensis, Brachyprion varistriata, Atrypa "reticularis", Camarothoechia semiplicata, Leptostrophia planulata,* and *Uncinulus mutabilis.* Contains at least four coral reefs. Underlies Onondaga. The "Bishop Brook" is merely a reappearance of the Deansboro at Manlius beneath the pre-Onondaga unconformity.

Type locality and derivation of name not stated.

Dearborn Limestone[1]

Middle Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 36.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1075, 1081–1082, 1086, 1089, 1090 (fig. 2); 1939, Geol. Soc. America Spec. Paper 18, p. 26, 30, 33, 40, 54 (fig. 6). As herein defined, conformably overlies Damnation limestone (redefined) and conformably underlies Pagoda limestone. Steamboat limestone, as used in 1933 sequence, has proved to be part of massive upper Dearborn which was repeated in the Dearborn section by low angle overthrust. Steamboat as now used refers to limestone underlying Switchback limestone and overlying Pentagon shale. Thickness at type locality 354 feet. Consists of lower shaly interval and a much thicker upper limestone interval. Middle Cambrian.

Type locality: On north side of valley of North Fork of Dearborn River, in W½ sec. 6, T. 17 N., R. 7 W., south-central part of Lewis and Clark Range, Lewis and Clark County.

Death Canyon Member (of Gros Ventre Formation)[1]

Death Canyon Limestone (in Gros Ventre Group)

Cambrian: Western Wyoming.

Original reference: B. M. Miller, 1936, Jour. Geology, v. 44, no. 2, p. 119.

A. B. Shaw and P. O. McGraw, 1954, Wyoming Geol, Assoc. Guidebook 9th Ann. Field Conf., chart 2; A. B. Shaw and C. R. LeLand, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 38, 39. Gros Ventre formation of earlier workers is raised to group status in western Wyoming where it contains three mappable formations: Wolsey shale, Death Canyon limestone, and Park shale.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 12, 13. In Gros Ventre, southern Teton, northern Hoback, and Snake River Ranges, considered middle member of formation; overlies Wolsey shale member; underlies Park shale member. Consists of massive dull-blue-gray limestone in two beds of unequal thickness with an intervening fossiliferous shale. Thickness 207 to 368 feet.

Type section: Along divide between Death and Teton Canyons in Teton Range.

Death Valley Formation[1]

Precambrian: Southeastern California.

Original reference: F. M. Murphy, 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Pub. Geol. Sci., v. 30, no. 5, p. 355, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible the correlation of formations defined by Murphy (1930, Econ. Geology, v. 25; 1932 [1933]) in Telescope Peak quadrangle with formations now commonly used in Death Valley. Death Valley formation is correlated with Stirling quartzite here assigned to Precambrian as defined in this report.

Mapped over a wide area to west of Death Valley, Panamint Mountains, Inyo County.

Deaton Formation,[1] Series,[1] or Iron-Ore Series[1]

Middle Ordovician: Northwestern Georgia.

Original reference: J. W. Spencer, 1893, Georgia Geol. Survey, Paleozoic group, p. 46, 83.

Named for exposures at Deaton mine, Polk County.

DeBeque Formation

Paleocene, upper, and Eocene, lower: Western Colorado.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 18, pl. 1. Late Paleocene and Wasatchian of western Colorado, to be named and described by Patterson.

J. A. Dorr, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 1, pl. 2 facing p. 64. Correlation chart shows age to be Paleocene (Tiffanian and Clarkforkian) and early Eocene (Wasatchian).

D. B. Kitts, 1956, Am. Mus. Nat. History Bull., v. 110, p. 47, 49, 51. Includes Rifle member (new).

C. L. Gazin, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 134 (fig. 1), 135. Comprises (ascending) Plateau Valley beds, Lysite equivalent, and Lost Cabin equivalents. Tiffanian, Clarkforkian, and Wasatchian.

Town of De Beque is in Mesa County.

Debris Dam Sandstone

Upper Cretaceous: Southern California.

B. M. Page, J. G. Marks, and G. W. Walker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1730 (fig. 2), 1734 (fig. 4), 1739–1743. Lower 750 feet of type section consists of sandstone members 60 to 330 feet thick alternating with shale members 50 to 150 feet thick; middle 850 feet is massive cliff-forming sandstone that is predominantly light gray; upper 600 feet is alternating shales and sandstones, members averaging about 150 feet in thickness. South of Santa Ynez fault, includes Romero conglomerate lentils (new). In type area, underlies Pendola shale (new); southwest of type section, Pendola is cut out and the Debris Dam is unconformably overlain by middle Eocene Juncal formation. Gradationally overlies unnamed Cretaceous shale unit; base of Debris Dam arbitrarily selected where sandstone first predominates over shale in the transitional sequence.

Type locality: Small canyon that drains westward to Agua Caliente Canyon about 1½ miles northeast of Pendola Guard Station and 1⅛ miles south of Big Caliente Debris Dam, Santa Barbara County. Base of section 6,200 feet S. 1° E. of Big Caliente Dam, and top is 6,700 feet S. of 23° E. of dam. Formation forms part of Auga Caliente anticline. To northwest of type section, beds extend past Big Caliente Debris Dam to northern limit of area; southwestward, they extend approximately 1 mile where they disappear beneath Juncal formation; seemingly they reappear south of Santa Ynez fault in an elongate east-west-trending belt; however, correlation here is uncertain because of lack of fossils and occurrence of Romero conglomerate lentils.

Decathon Dolomite

Silurian: Eastern Nevada and western Utah.

R. W. Rush, 1956, Utah Geol. and Mineralog. Survey Bull. 53, p. 12 (fig. 3), 23 (fig. 5), 25–26, 30–31 (fig. 6), 34–35 (fig. 7), 36–37 (fig. 8), 40–41 (fig. 9), 52–53 (fig. 11), 60. Proposed for light-gray coarsely crystalline, dense dolomite 350 feet thick lying above Roberts Mountain and below Kings Canyon dolomite (new) at Big Springs, Nev. Locally overlies Jack Valley dolomite (new).

Name taken from Decathon Canyon, one of principal drainage channels of southern part of Snake Range, Nev., west of Big Springs Ranch.

Decatur Limestone[1]

Decatur Limestone (in Brownsport Group)

Upper Silurian: Western and central Tennessee.

Original reference: W. F. Pate and R. S. Bassler, 1908, U.S. Natl. Mus. Proc., v. 34, p. 410–432.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Age shown on correlation chart as Niagaran [Middle Silurian].

T. W. Amsden, 1949, Yale Univ., Peabody Mus. Nat. History Bull. 5, p. 10–12, fig. 6. Conformably overlies Brownsport formation. A post- Decatur unconformity is present throughout area [western Tennessee]; Decatur may be overlain by beds ranging in age from Devonian to Cretaceous; as result of this post-Silurian erosion, thickness of Decatur varies greatly within short distances—as near Sewell's Spring, Clifton quadrangle, where thickness ranges from 18 to 70 feet; here, too, some Devonian may be present in upper part.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 266–269, fig. 2. Included in Brownsport group. Everywhere overlain unconformably by formations of the Devonian or by Chattanooga shale. Locally is an overlapping unit; transgresses westward across beveled Lobelville and Bob formations and part of Beech River formation. Believed to be Niagaran in age.

Type section: At Tuck's Mill, 1½ miles north of Decaturville. Named for Decatur Country.

†Decatur Sand (in Claiborne Group)[1]

Eocene, middle: Southeastern Mississippi.

Original reference: E. N. Lowe, 1919, Mississippi Geol. Survey Bull. 14, p. 78.

Crops out mainly near Enterprise, Wautubbee, and Decatur. Named for exposures near Decatur, Newton County.

Decaturville Chert[1]

Upper Ordovician (Richmond): Central Missouri.

Original reference: G. H. Scherer, 1905, Bradley Geol. Field Sta. Drury Coll. Bull., v. 1, pt. 2, p. 67.

Probably named for exposures at Decaturville, Camden County.

Decaturville Chert[1]

Decaturville Chert (in Linden Group)

Decaturville chert zone (in Ross Formation)

Lower Devonian: Western and central Tennessee.

Original reference: C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 744.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., 53, no. 12, pt. 1, chart 4. Shown on correlation chart as uppermost formation in Linden group. Occurs above Birdsong shale and below Quall limestone.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 280, 290–292, 295–296, 301–302. Considered a zone conformably interbedded with beds of Ross limestone member, Bear Branch facies, and Birdsong shale member of Ross formation (new). Term Decaturville zone is applied to the porous fossiliferous gray chert that is developed by chertification of limestone zone that carries large specimens of brachiopods and overlies the Bryozoan zone.

Well exposed in vicinity of Decaturville, Decatur County.

†Decaturville Limestone[1]

Upper Cambrian: Central Missouri.

Original reference: E. M. Shepard, 1904, Bradley Geol. Field Sta. Drury Coll. Bull., v. 1, pt. 1, p. 42.

Named for exposures at Decaturville, Camden County.

Deception Rhyolite (in Ash Creek Group)

Deception Porphyry[1]

Precambrian (Yavapai Series): Central Arizona.

Original reference: L. E. Reber, Jr., 1922, Am. Inst. Mining and Metall. Engineers Trans., v. 66, p. 12.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308. p. 15–17, pl. 1. As exposed in Deception Gulch and in part of Mescal Gulch, unit is a hydrothermally altered facies of rhyolitic flows and fragmental rocks. Name therefore modified to Deception rhyolite to include all rhyolitic rocks older than Grapevine Gulch formation (new) and younger than Shea basalt, dacite of Burnt Canyon, Brindle Pup andesite (new), and Buzzard rhyolite (new). A jasper-bearing facies of rhyolite present at top of unit in drainage basin of Ash Creek and in Hull Canyon. A minor facies in Mescal Gulch area contains sericitized plagioclase phenocrysts in microcystalline groundmass. Near Jerome, outcrops are reddish hue, changing to buff and cream in Mescal Gulch, and are pale colored near Ash Creek. Most complete section exposed between Ash Creek and Black Canyon, where rhyolite is about 3,000 feet thick.

Well exposed in drainage basins of Mescal Gulch and Deception Gulch, which is the name for the deep rugged part of Hull Canyon south of Jerome, Yavapai County. Also exposed south of Mingus Mountain between Ash Creek and Black Canyon.

Decew Dolomite

DeCew Limestone[1]

Middle Silurian: Ontario, Canada, and western New York.

Original reference: E. M. Kindle, 1914, Science, new ser., v. 39, p. 918.

D. W. Fisher, 1959, New York State Mus. Sci., Service Geol. Survey Map and Chart Ser. 1. There is variance of opinion as to whether time break exists between Lockport group and underlying Rochester shale. There seems to be physical break between Decew dolomite and Gasport in western New York, but no physical break can be seen from Rochester eastward. The Rochester grades imperceptibly upward into Decew. Decew dolomite is placed in Tonawandan stage (new) because it contains *Arctinurus boltoni* and *Trimerus delphinocephalus* which are unknown in Lockportian stage (new). Middle Silurian.

Well exposed at DeCew Falls, Ontario.

†Decewsville Formation[1]

Decewville Formation[1]

Middle Devonian: Southeastern Ontario, Canada, and western New York.

Original reference: E. O. Ulrich and C. Schuchert, 1902, New York State Mus. Bull. 52, p. 653, chart opposite p. 659.

Named for exposures near village of Decewsville, Ontario.

De Chelly Sandstone

De Chelly Sandstone Member (of Cutler Formation)[1]

Permian: Northeastern Arizona and southeastern Utah.

Original reference: H. E. Gregory, 1915, Am. Jour. Sci., 4th, v. 40, p. 102.

J. A. Momper, 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 90. Rank raised to formation. Eolian De Chelly grades into continental fluvial deposits overlying differentiated Cutler in southeastern Utah; along northeast margin of southern and western San Juan Basin, loses its identity as it grades into arkosic facies of Cutler. In Arizona, overlies Supai formation; in New Mexico, overlies Yeso formation along its lateral boundary with the Glorieta. Includes Hoskinnini as member.

J. H. Stewart, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1855 (fig. 2), 1857 (fig. 3), 1862. In and near Monument Valley, De Chelly member of Cutler underlies Hoskinnini (herein reallocated to member status in Moenkopi formation). Thickness about 300 feet.

Gregory (1916) mapped sandstone along Canyon de Chelly, Apache County, Ariz.

Decie Member (of Duff Formation)

Oligocene and younger(?): Southwestern Texas.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 553–554, pl. 1. Northern facies of Duff differs from southern facies in that the effusive rocks are predominantly rhyolite, trachyte, and trachyandesite, whereas flows in southern part are chiefly trachybasalts. A succession that appears to constitute more than half of the formation in Paisana Peak quadrangle is herein named Decie member. Southernmost tongue, a trachyte porphyry, is about 60 feet above base of the Duff and is 60 to 110 feet thick west of Haley Mountain and along west side of McIntyre Peak intrusive mass. A second rhyolite porphyry tongue crops out around east and north sides of McIntyre Peak. Base of the rhyolite is about 150 feet above base of the Duff and has maximum thickness of 237 feet.

Named for exposures on Decie Ranch near McIntyre Peak, Cathedral Mountain quadrangle.

Decker Limestone[1]

Upper Silurian: Northern New Jersey, southeastern New York, and northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 76–77, 137–141.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart at base of Keyser group below Rondout limestone and above Bossardville limestone. Cayugan series.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Keyser formation passes into Manlius, Rondout, and Decker formations.

Well exposed near Decker's Ferry below Flatbrookville, Sussex County, N.J.

Decker Ferry Limestone[1] or Formation[1]

Silurian: Northern New Jersey, southeastern New York, and northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 76–77, 137–141.

Named for exposures near Decker's Ferry below Flatbrookville, Sussex County, N.J.

Decker Ferry Sandstone[1]

Silurian: Northwestern New Jersey and northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 77, 140–141.

Well exposed near Decker's Ferry below Flatbrookville, Sussex County, N.J.

Decker Ferry Shales[1]

Silurian: Northwestern New Jersey and northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 77, 141.

Well exposed at Decker's Ferry, Sussex County, N.J.

Decorah Shale[1] or **Formation**

Decorah Shale Member (of Galena Formation)

Middle Ordovician: Northeastern Iowa, western Illinois, southern Minnesota, northern Missouri, and southwestern Wisconsin.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 84.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9 (geol. column), 72, 81, 82–86. Considered member of Galena formation in southeastern Minnesota. Underlies Prosser member; overlies Spechts Ferry member of Platteville formation. Includes Guttenberg and Ion submembers. Thickness 27 to 46 feet.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2064–2066. In southeastern Missouri, underlies Kimmswick limestone and overlies Macy formation (new) of Plattin group. Spechts Ferry member traced from type locality into Missouri where it is lower shale-bearing part of formation. Thicknesses: 25 feet in Lincoln County; 18 feet in St. Louis County; 15 feet in Jefferson County; and 20 feet in Perry County, Spechts Ferry member absent.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 759–763. Overlies Carimona member (new) of Platteville formation and underlies Cummingsville member (new) of Galena formation. Thickens from about 20 feet at Iowa line to nearly 90 feet at Twin Cities. Spechts Ferry, Guttenberg, and Ion members not recognizable units in Minnesota.

A. F. Agnew, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 49–50. Carimona limestone reallocated to member status in Decorah formation in Minnesota for following reasons: lithology is similar to that of limestone bands in Spechts Ferry member; Carimona and Spechts Ferry members wedge out eastward, and Guttenberg member thins eastward, whereas Quimbys Mill member of Platteville wedges out to west and McGregor member of Platteville thins westward; there is disconformity in Platteville at top of Quimbys Mill member.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1029 (fig. 1), 1033–1036, pl. 1. Formation described in Fillmore County, Minn., where it is not differentiated into members. Here, and in adjacent exposures, formation is a shale, grayish yellow green to greenish gray, calcareous, generally fissile, but more massive and blocky where coquinoid layers are absent or sparse. Numerous limestone layers concentrated near base and top and subordinately near middle. A 1- to 2-inch bentonite present near base; this seam is the "putty layer" of Twin City section and is continuous with Spechts Ferry bentonite. Thickens northwestward across county from 22 to 46 feet. Underlies Galena formation, Cummingsville member; overlies Platteville formation, Carimona member. Most fossiliferous unit in Minnesota Ordovician.

A. V. Heyl, Jr., and others, 1959, U.S. Geol. Survey Prof. Paper 309, p. 8 (fig. 2), 11 (fig. 3), 14–17. Formation described in upper Mississippi Valley zinc-lead district (Wisconsin, Illinois, Iowa) where it is about 40 feet thick; includes three members: a basal green-shale member (Spechts Ferry) that thickens toward northwest, a thin-bedded pinkish-buff sublithographic limestone and interbedded carbonaceous brown-shale member (Guttenberg), and a medium-bedded gray dolomite or limestone member (Ion) that has thin greenish-shale partings. Disconformably overlies Platteville formation and grades upward into Galena dolomite.

First described in city and vicinity of Decorah, Winneshiek County, Iowa.

Decota Sandstone (in Kanawha Formation)[1]

Pennsylvanian: West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1914, West Virginia Geol. Survey Rept. Kanawha County, p. 292.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 81. In lower Kanawha between Eagle (above) and little Eagle coals.

Named for Decota, Kanawha County.

Dederick Shale Member[1] (of Cherokee Formation)

Dederick Subgroup (of Cherokee Group)

Pennsylvanian (Des Moines Series): Western Missouri.

Original reference: F. C. Greene and W. F. Pond, 1926, Missouri Bur. Geology and Mines, v. 19, 2d ser., p. 38–44.

T. R. Beveridge, 1951, Missouri Geol. Survey and Water Resources, 2d ser., v. 32, p. 51–53, pl. 11. Rank raised to subgroup of Cherokee group; regional correlations are insufficient to determine the position of the Weaubleau area (this report) Dederick within the subgroup. In

Weaubleau quadrangle, unit is undifferentiated and consists of dark-colored shale, in some localities carbonaceous to coal bearing, in others micaceous and silty. Maximum exposed thickness 6 feet; base not exposed. Unconformable on deeply eroded Mississippian rocks [Burlington]; relations of contact with overlying Graydon formation not known.

Named for exposures along railroad in northern part of sec. 26, T. 36 N., R. 29 W., and NE¼SE¼ sec. 36, T. 36 N., R. 29 W., in vicinity of Dederick, Vernon County.

Dedham Granodiorite[1]

Devonian(?): Eastern Massachusetts and southeastern New Hampshire.

Original reference: W. O. Crosby, 1880, Boston Soc. Nat. History Occasional Papers 3, map.

N. E. Chute, 1940, Massachusetts Dept. Public Works Bull. 1, p. 4, 11, pls. 2–A, 2–B. Ordovician(?) or Silurian(?).

N. E. Chute, 1950, Bedrock geology of the Brockton quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad Map [GQ–5]. Three rock types described in Brockton quadrangle, Massachusetts. Usual Dedham is pale-pink massive fairly homogeneous medium- to coarse-grained rock. Other varieties are white or light-gray granodiorite and porphyritic granodiorite with pink feldspar phenocrysts. Few dikes of fine-grained albite granite intrude the pink and light-gray varieties. Intrudes Salem gabbro-diorite. Lower Paleozoic(?).

A. W. Quinn and G. H. Springer, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–42. Restricted from Bristol quadrangle and vicinity, Rhode Island-Massachusetts. Pre-Carboniferous rocks of area assigned to Metacom granite gneiss (new) and two unnamed units.

Named for typical exposures about Dedham, Mass.

Deep Canyon Fanglomerate[1]

Quaternary: Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 384–385, map.

Named for Deep Canyon, Riverside County.

Deep Creek Andesite

Pliocene(?): Southwestern Washington.

R. V. Fisher, 1957, Dissert, Abs., v. 17, no. 9, p. 1981. Named and age given as Pliocene(?).

Exposed along Bumping River, Mount Aix quadrangle.

†Deep Creek Beds[1]

Miocene, middle: Central southern Montana.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 287.

East of Fort Ellis along Deep Creek, Little Belt Mountains region.

Deep Creek division[1]

Lower Ordovician: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. 302–306, pl. 3.

Named for Deep Creek, San Saba County.

Deepian series

Precambrian (Protozoic) : Eastern California.

[C. R.] Keyes, 1942, Pan-Am. Geologist, v. 77, no. 4, p. 307 (chart). Listed as a series consisting of 2,100 feet of shales. Unconformable below Campitoan series and above Reedian series.

Occurs in Death Valley region.

Deepkill Shale[1]

Lower and Middle Ordovician: Eastern New York and west-central Vermont, and Canada.

Original reference: R. Ruedemann, 1902, New York State Mus. Bull. 52, p. 546–575.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Correlation chart for Vermont shows Deepkill shale in Taconic sequence above Schaghticoke shale and below Bald Mountain limestone. Lower Ordovician.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65. no. 3, chart 2 (columns 8, 14). Correlation chart shows Deepkill shale present in Taconic area, New York and Vermont. Canadian and Chazyan. Overlies Schaghticoke shale; underlies Normanskill shale. Also present in Gaspe and New Brunswick.

W. B. N. Berry, 1959, (abs.) Geol. Soc. America Bull., v. 70, no. 12, pt. 2, p. 1568–1569. Graptolite and zonal sequence in Deepkill shale worked out by Ruedemann nearly 60 years ago, and faunas that constitute the zones have been considered standard of comparison for all Early Ordovician graptolites in North America. Also, term "Deepkill" has acquired time-stratigraphic significance in some publications. Reinvestigation and reinterpretation of formation and its faunas reveal that four zones based on graptolite assemblages may be delimited within it. Three of the zones are in the continuous exposure (Ruedemann's beds 1 through 5) in lower part of Deepkill Gorge. The two older zones are latest Early Ordovician, and the third zone is earliest Middle Ordovician. Rocks of fourth zone, which comprise Ruedemann's beds 6 and 7, are in fault contact with Normanskill shale. This zone is Middle Ordovician. One zone is missing between it and next youngest zone in Deepkill shale. Missing zone, although widely represented in other parts of country, has not been found anywhere in New York.

Named from typical exposure in Rensselaer County, N.Y., along Deepkill River, a tributary of the Hudson from the east.

Deep Lake Argillite[1] (in Stevens Series)

Cambrian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 80, map.

C. D. Campbell, 1947, Geol. Soc. America Bull., v. 58, no. 7, p. 602 (table 4), 611. Remapping of northeastern Stevens County and discovery of Cambrian and Ordovician fossils are thought to justify adoption there of formation names established by Parker and Cannon (1943) for Metaline quadrangle. Part of Deep Lake argillite is considered correlative with Metaline limestone, part correlative with Maitlen phyllite.

Exposed along east shore of Deep Lake, Stevens County.

Deep Lake Metaquartzite[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference. E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 623, 625.

J. J. Runner, 1928, Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included at base of Snowy Range series (new); overlies Centennial series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 130. Precambrian metamorphics consist of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

Crops out around Deep Lake, Medicine Bow Mountains.

Deep River Beds[1].

Miocene, middle: Central southern Montana.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 287.

W. T. Thom, Jr., 1957, Billings Geol. Soc. Guidebook 8th Ann Field Conf., p. 11 (table 1). Name appears on generalized stratigraphic section for Crazy Mountain Basin and nearby areas. Overlies Fort Logan beds and together the units dated as middle and upper Miocene.

Deposits occur east of Fort Ellis along Deep Creek (also called Deep River and Smith River); Little Belt Mountains region and Meagher County.

†Deep River Formation[1] or Series[1]

Upper Triassic: Central North Carolina.

Original reference: E. Emmons, 1856, North Carolina Geol. Survey Rept. of Midland Counties, p. 255, 273.

Named for exposures along Deep River.

Deep Run Formation

Deep Run Member (of Ludlowville Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 218, 226, 227.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, no. 5–6, p. 371–372, pl. 1. Member is 55 feet thick at type locality; thins rapidly westward until it wedges out in Batavia quadrangle. Corps out in eastern part of Batavia quadrangle, three-quarters mile southeast of Pavilion Center. Here is consists of 3.6 feet of calcareous shale and is overlain by Menteth limestone 0.6 foot thick.

T. B. Coley, 1954, Jour. Paleontology, v. 28, no. 4, p. 453, 454, 455 (fig. 2). Referred to as Deep Run formation. Thickness 10 feet. Overlies Tichenor formation; underlies Menteth formation. Ostracodes discussed.

Type locality: Ravine, about 1 mile north of Cottage City, on east side of Canandaigua Lake, Ontario County.

Deep Spring Formation[1]

Precambrian(?): Eastern California.

Original reference: E. Kirk, 1918, U.S. Geol. Survey Prof. Paper 110.

C. R. Longwell, 1950, Geol. Soc. America Bull., v. 61, no. 5, pl. 1. Underlies Campito sandstone; overlies Reed dolomite.

U.S. Geological Survey currently designates the age of the Deep Spring Formation as Precambrian(?) on the basis of a study now in progress.

Named for exposures along west side of Deep Spring Valley in canyons north of Antelope Spring, Inyo Range.

Deer Diorite

Pre-Upper Cretaceous: Southern California.

R. M. Alf, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1104 (fig. 2), 1109–1110, pl. 6. Medium- to coarse-grained plutonic rock with small to large crystals of hornblende up to 1 inch or more in length. Occurs as a lenticular mass in what is termed Black Belt (nongeographic name) mylonites.

Well exposed in Deer Canyon, San Gabriel Mountains, southeast of Los Angeles.

Deer Creek Formation

Pennsylvanian: South-central Colorado.

D. W. Bolyard, 1956, Rocky Mountain Assoc. Geologists Guidebook to geology of the Raton Basin, Colorado, p. 52–53; 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1903 (fig. 5), 1904–1910. Proposed for beds previously called Clastic member of Sandia formation by Brill (1952) from Huerfano River south to New Mexico border. Consists of grayish, reddish, and greenish sandstones, siltstone, conglomerates, and shales, interbedded in upper part with gray sandy to argillaceous limestones; crossbedding and cut-and-fill stratification common in sandstones and conglomerates. Thickness at type section 1,119 feet. Unconformably overlies Precambrian at Huerfano River and La Veta Pass; gradationally underlies Madera formation with contact placed at top of highest redbeds. Name Clastic member of Sandia refers to a basal transgressive suite of gray sandstone, shale, and conglomerate, with a few coal beds, underlying Madera formation in central New Mexico (Read and Andrews, 1944). Abandonment of this term in south-central Colorado proposed because in this area red beds included in member bear impress of a different depositional sequence; furthermore, red coloration provides lithologic basis for separating these beds from Madera, whereas, if Brill's nomenclature were followed, separation would be based on paleontology. Assigned to upper Atokan on basis of fusulinids.

Type section: Along Huerfano River, beginning at unconformable contact with Precambrian in E½ sec. 23, crossing Deer Creek and extending to SW¼ sec. 24, all in T. 27 S., R. 72 W., Sangre de Cristo Mountains, between La Veta Pass and Westcliffe.

Deer Creek Limestone (in Shawnee Group)

Deer Creek Limestone Member (of Pawhuska Formation)

Deer Creek Limestone Member (of Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Southwestern Iowa, eastern Kansas, northwestern Missouri, southeastern Nebraska, and central northern Oklahoma.

Original reference: J. Bennett, 1896, Kansas Univ. Geol. Survey, v. 1, p. 117.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 142 (fig. 29), 156. Deer Creek formation, in Shawnee group, underlies Calhoun formation and overlies Tecumseh formation; includes (ascending) Ozawkie limestone, Oskaloosa shale, Rock Bluff limestone, Larsh shale, Haynies limestone, Burroak shale, and Ervine Creek limestone members. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma. In Kansas, the shale between the Rock Bluff and Ervine Creek limestones is called the Larsh-Burroak because it seems to be exactly equivalent to the Larsh shale, Haynies limestone, and Burroak shale as described in Nebraska. The Deer Creek is a member of the Pawhuska formation as defined in Oklahoma.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17–18. In Missouri, the interval between the Rock Bluff limestone member and the uppermost limestone of the Deer Creek is occupied by shale; this shale has been treated by Missouri Geological Survey as occupying the Rock Bluff-Ervine Creek interval, with implication that intervening Haynies limestone is absent in Missouri. Missouri follows Kansas practice, and the shale is called Larsh-Burroak; the Missouri Survey recognizes the possibility that Burroak shale member may be absent in Missouri and that the uppermost limestone of the Deer Creek may include the Haynies and Ervine Creek limestone members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 17–18, fig. 5. Comprises (ascending) Ozawkie limestone, Oskaloosa shale, Rock Bluff limestone Larsh shale, Haynies limestone, Burroak shale, and Ervine Creek limestone members. Lower two members not differentiated everywhere. Underlies Calhoun shale; overlies Tecumseh shale. Shawnee group.

Named for exposures on Deer Creek, east of Topeka, Shawnee County, Kans.

Deer Creek Quartzite[1]

Precambrian (Glenarm Series): Northern Maryland.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Rept., v. 1, p 130–132.

Occurs in center of Harford County, marking a sharp, narrow ridge 300 feet high, 4 miles long, and less than 1 mile wide.

Deerfield Diabase[1] (in Newark Group)

Upper Triassic: Central Massachusetts.

Original reference: B. K. Emerson, 1891, Geol. Soc. America Bull., v. 2, p. 451–456.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Revived and described in Mount Toby quadrangle as fine-grained black effusive diabase or trap rock, reddish-brown to nearly yellow on weathered surfaces. Generally massive in thicker parts; upper surface is somewhat vesicular. Locally a flow breccia. Maximum thickness 100 feet. Underlies Turners Falls sandstone (new); overlies Sugarloaf formation. No longer considered a unit of the Holyoke diabase because no direct connection can be traced and source and age of the two may differ. Triassic. Outcrop area described.

Crops out in Greenfield and Mount Toby quadrangles on western and southern slopes of the Mount Toby highland and west of the Connecticut River in the Pocumtuck Range.

Deer Isle Granite

Lower Devonian: South-central Maine.

H. W. Fairbairn and P. M. Hurley, 1957, Am. Geophys. Union Trans., v. 38, no. 1, p. 104 (table 7), 106 (table 9). Incidental mention. Probably comagmatic with Vinalhaven granite.

Occurs on Deer Isle, Hancock County.

Deer Lake Argillite[1]

Paleozoic: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 54, map.

Exposed along shores of Deer Lake, Stevens County.

†Deer Lake Conglomerates[1]

Precambrian (Keewatin): Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 490, 492, 496.

Exposed on Kitchi Hills, in vicinity of Deer Lake, Marquette district.

Deer Mountain Red Shale Member (of Hueco Limestone)[1]

Permian (Wolfcamp Series): Western Texa.

Original reference: P. B. King and R. E. King, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 925.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 695, 697. Lee Ranch tongue (new) of Abo sandstone is believed to be stratigraphically lower than Deer Mountain red shale member of type Hueco. The herein named Otero Mesa member of Yeso formation is believed to occupy an intermediate stratigraphic position between Lee Ranch tongue and Deer Mountain red shale.

Named from exposures on Deer Mountain, 4 miles southeast of Cerro Alto [Mountain], Hudspeth County.

Deerpark Stage or Group

Lower Devonian (Ulsterian): North America.

G. A. Cooper and others, 1952, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1733, chart 4. The Devonian is subdivided into 10 stages of which the Deerpark is second in sequence (ascending). [For complete sequence see Helderberg stage, this reference.] Follows Helderberg stage and is succeeded by Onesquethaw stage (new). Includes Oriskany and its correlates.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv. Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 35 (table 1). Referred to as group in Mackinac Straits region, Michigan. Underlies Onesquethaw group; overlies Bass Island[s] group. Includes Garden Island formation (new).

Type section (stage): Southeastern Deerpark Township on west slope of Shawangunk Mountains facing Port Jervis, Sullivan County, N.Y.

Deer Plain Formation

Pleistocene (Wisconsin): Central western Illinois and eastern Missouri.

W. M. Rubey, 1952, U.S. Geol. Survey Prof. Paper 218, p. 12 (chart), 90–96, pl. 1. A variable series of gravel, sand, and clay; along Mississippi River and near mouth of Illinois River, consists largely of gravel; up valley of Illinois River, becomes finer grained and passes within only a few miles through sand into silt and clay; at all exposures, material becomes progressively finer grained upward. True maximum thickness unknown; near Deer Plain at least 50 feet; in many smaller remnants 5 to 20 feet. Stratigraphic and physiographic evidence shows that Deer Plain formation is younger than Brussels formation and loess; physiographic relations demonstrate that Deer Plain terrace is younger than Metz Creek terrace and the scattered pebbles of igneous and metamorphic rocks that lie upon it; also evidence shows that Deer Plain formation is too old to be included within the latest or Recent stage of earth history.

Named for exposures near village of Deer Plain, sec. 16, T. 13 S., R. 1 W., Calhoun County, Ill. Deposits occur as a wide terrace in lowlands west of Illinois River and as small terrace remnants along Illinois and Mississippi Rivers; some terrace and deposits are well developed in lowlands west of Mississippi River from Winfield to Old Monroe in Lincoln County, Mo.

Deer Rips Lime-Silicate Gneiss (in Androscoggin Series)

Middle Silurian: Southwestern Maine.

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. In Lewiston area are seven formations (ascending): Danville injection gneiss (new), Androscoggin gneiss, Bates crystalline limestone, Deer Rips lime-silicate gneiss, Thorncrag biotite-sillimanite gneiss, Tacoma lime-silicate series, and Sabbatus quartz-sillimanite schist. Middle Silurian.

L. W. Fisher, 1938 (abs.) Geol. Soc. America Proc. 1937, p. 81. Deer Rips lime-silicate gneiss and Bates limestone included in Androscoggin series.

Occurs in Lewiston area, Androscoggin County.

Deer River Shale[1]

Middle Ordovician: Northern New York, and southern Ontario, Canada.

Original reference: Rudolf Ruedemann, 1921, New York State Mus. Bulls. 227, 228, p. 124–126, 130.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 284–285. Derivation of name. Middle Ordovician (Mohawkian).

Named for Deer River, northern Lewis County, N.Y.

Deer Trail Group

Deer Trail Argillite[1] (in Stevens Series)

Precambrian (Belt Series): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 59, map.

W. A. G. Bennett, 1941, Washington Div. Geology Rept. Inv. 5, p. 7–8. Referred to as a group including Stensgar dolomite.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Described as a group consisting of a series of metasediments, probably of Beltian age, composed dominantly of fine-grained clastics with minor amounts of quartzite and dolomite. Thickness 5,000 feet. Includes (ascending) Togo formation, Edna dolomite, McHale slate (all new), Stensgar dolomite, and Buffalo Hump formation (new). Unconformably underlies Huckleberry group (new).

Present in Stevens County.

Deerwood Iron-Formation Member (of Virginia Slate)[1]

Precambrian: Northeastern Minnesota.

Original reference: C. R. Van Hise and C. K. Leith, 1911, U.S. Geol. Survey Mon. 52, p. 212–215.

G. M. Schwartz, 1951, Geology of the Cuyuna Range: Minnesota Univ. Center for Continuation Study, Mining [Geology] Symposium [No. 2], p. 3. For most part, Deerwood iron-formation and Cuyuna slates have been considered to belong to the Virginia slate. This correlation has very little evidence to support it. General stratigraphy of Deerwood suggests a fourfold subdivision somewhat analogous to subdivisions of Biwabik formation.

Named for development at and near Deerwood, Crow Wing County.

Deese Formation[1]

Deese Group

Pennsylvanian (Des Moines Series): Central southern Oklahoma.

Original reference: W. L. Goldston, Jr., 1922, Am. Assoc. Petroleum Geologists Bull., v. 6, no. 1.

W. E. Ham, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2040–2044. The four principal conglomerates in the Arbuckle Mountains region are divisible into two general groups, an older consisting of "Franks" and Deese and a younger consisting of Collings Ranch (new) and Vanoss. All but Vanoss (youngest) are preserved in synclinal grabens and are moderately to strongly folded and faulted. In vicinity of Mill Creek, sec. 7, T. 2 S., R. 5 E., the Deese is about 1,950 feet thick (top eroded) and consists of pebble-cobble limestone conglomerates interstratified with red and gray shales and a few thin limestones. Conglomerate sequence rests disconformably on Atoka formation. In Buckhorn area south of Sulphur, sec. 26, T. 1 S., R. 3 E., the Deese rests disconformably on Springer shale (Lower Pennsylvanian) and underlies Vanoss conglomerate. In Lake Classen area, conglomeratic Deese rocks rest disconformably on Caney shale (Mississippian); they are steeply dipping to locally overturned and structurally conformable with older folded rocks of Arbuckle anticline.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. p. 697, chart 6 (column 37). Shown on correlation chart as Deese group. Occurs below Hoxbar group and above Dornick Hills group. Includes (ascending) Devils Kitchen, Arnold limestone, Rocky Point conglomerate, and Confederate limestone. Base of Hoxbar group is here drawn above Confederate limestone, rather than below it, inasmuch as boundary between Desmoinesian and Missourian deposits preferably should correspond with Deese-Hoxbar contact.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 28–36. Group constitutes bulk of Desmoinesian section in Ardmore basin. Top of series was placed by Moore and others (1944) at top of Confederate limestone, basal member of overlying Hoxbar group, but base of Confederate is probably to be preferred in light of reclassification by Thompson and others, (1956, Jour. Paleontology, v. 30, no. 4) of abundant fusulinid in that limestone as *Wedekindellina ardmorensis.* Includes named units (ascending) Devils Kitchen sandstone and conglomerate, Arnold limestone, Rocky Point conglomerate and associated beds, Camp Ground member, Warren Ranch conglomerate facies (new), Williams member, and Natsy member. Overlies Pumpkin Creek limestone member of Big Branch formation of Dornick Hills group.

B. H. Harlton, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 213 (fig. 3), 200–221. Term Deese group is used in this report [Cement Pool area] for a succession of rocks comparable in lithologic character and fauna with rocks in Ardmore area. Melton zone formerly assigned to basal Hoxbar is designated to mark top of Deese and is included in West Arm formation (new). Tussy zone, with its Tussy limestone, is well developed at Cement Pool. It is given formational status in this report. Overlies Dornick Hills group.

Type locality: Sec. 33, T. 3. S., R. 1 E., adjoining village of Deese, Carter County.

Degonia Sandstone[1]

Degonia Sandstone (in Elvira Group)

Upper Mississippian (Chester Series): Western Illinois and western Kentucky.

Original references: S. Weller, 1920, Jour. Geology, v. 28, no. 4, p. 281–290; no. 5, p. 395–416; 1920, Illinois Geol. Survey Bull. 41.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131. 136, 137; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 839. Included in Elvira group (new). Underlies Kinkaid limestone; overlies Clore limestone. Thickness as much as 100 feet; thickest at type locality; thins progressively eastward; in Kentucky, maximum thickness about 18 feet. In southwestern Indiana, probably represented by Mount Pleasant sandstone.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 6. Name Degonia sandstone extended into southern Indiana where it replaces term Mount Pleasant sandstone. Local Indiana names of upper Chester are dropped and formations given names of standard Chester column.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, pl. 2. Shown on stratigraphic column of upper Chester in Indiana as hard massive sandstone that weathers blocky. Thickness 10 to 35 feet. Term Elvira not used in Indiana.

Named for Degonia Township, Jackson County, Ill. Forms conspicuous cliffs in bluffs of the Mississippi and sides of the tributary valleys.

DeGraff Coal Member (of Modesto Formation)

Pennsylvanian: Southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 48 (table 1), pl. 1. Name applied to coal member in lower part of formation. Stratigraphically above Piasa limestone member and below Pond Creek coal member (new). Has been referred to as "1st Cutler Rider coal." Name credited to Cady (unpub. ms.). Piasa limestone and DeGraff, Pond Creek, and Lake coals may be included in the complex West Franklin member in eastern part of area. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: SE cor. NE¼SW¼ sec. 21, T. 5 S., R. 4 E., Perry County. Name derived from DeGraff School about 1 mile northeast of exposure.

DeGrey Member (of Pierre Shale)

Upper Cretaceous: Central South Dakota.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 1), 2341, 2343, 2345–2346. Defined to include Agency-Oacoma zones of previous reports. Consists of clay, shale, and bentonite beds. Underlies Verendrye member (new); overlies Crow Creek member (new); contacts gradational. Thickness at type locality about 82 feet; thickness increases toward Pierre to about 160 feet and decreases toward Chamberlain to about 40 feet.

Type locality: West edge of NW¼ sec. 8, T. 109 N., R. 75 W., Hughes County. Named for DeGrey post office and store. Type section is 2 miles southeast of DeGrey in cut-bank of Missouri River.

DeKalb Granite[1]

Precambrian: Northern New York.

Original reference: H. P. Cushing, 1916, New York State Mus. Bull. 191, p. 13, 17, 19, 23.

Occurs in DeKalb, St. Lawrence County.

DeKalb Limestone Member (of Kansas City Formation)[1]

Pennsylvanian: Iowa, eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: H. F. Bain, 1898, Am. Jour. Sci., 4th, v. 5, p. 437–439. Named for DeKalb, Decatur County, Iowa.

Dekkas Andesite[1]

Dekkas Formation (in Bollibokka Group)

Permian: Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Survey Geol. Atlas, Folio 138.

H. E. Wheeler, 1939, 6th Pacific Sci. Cong. Proc., p. 369–376. Assigned to late Anthrocolithic (Permian) on basis of regional correlation.

J. P. Albers and J. F. Robertson, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1319. Age designated as Permian on basis of paleontological evidence and data obtained from geologic mapping. Dekkas andesite, composed chiefly of andesitic tuffs, andesitic flows, and mudstone lenses, is at least 3,500 feet thick. Underlies Bully Hill rhyolite; substructural divergence suggests unconformable relationship.

A. H. Coogan, 1957, (abs.) Geol. Soc. America Bull., v. 68, no. 12, pt. 2, p. 1821. Formation, at type locality of Nosoni along Nosoni Creek, is restricted to the 3,840 feet of green massive tuff breccia, tuffaceous conglomerate and sandstone, minor basic flows, black cherty shale, and chert conformably overlying Nosoni formation. Basal contact drawn at top of highest black shale below a thick sequence of massive green tuff breccia. Conformably underlies Pit shale. As originally mapped much of type Dekkas at Dekkas Creek is lateral equivalent of type Nosoni. Fossils show formation to be early Guadalupian age.

A. H. Coogan, 1960, California Univ. Pubs. Geol. Sci., v. 36, no. 5, p. 243–255. Described in Bollibokka area. Included in Bollibokka group (new). Name changed to formation because unit is of varied character. Consists of massive green andesite tuff breccia, green tuffaceous sedimentary rocks, lithic lapilli tuff, gray to purple chloritized basalt and olivine basalt, and scattered beds of red chert, medium-bedded black shale, light-gray cherty shale, red mudstone, and tuffaceous calcareous shale. Formation is herein restricted to the green tuff breccia, tuffaceous sedimentary rocks, and basic flows overlying topmost black shale unit of Member Four of type Nosoni formation. Formation redefined to resolve confusion which resulted from definition of unit on basis of fusulinids. At Dekkas Creek, type locality of Dekkas, Members Three and Four of Nosoni underlie the basalt green tuff breccia of the Dekkas as it is exposed in Nosoni Creek. Diller (1906) mapped all these rocks as Dekkas andesite although more than half are lateral equivalents of type Nosoni. Thickness about 3,840 feet at Nosoni Creek. Underlies Pit shale. No fossils found in Dekkas along Nosoni, Chatterdown, or Dekkas Creeks. Fossils were collected from a tuffaceous limy shale bed on ridge at elevation of 2,700 feet between Horse and Town Mountains in sec. 8, T. 24 N., R. 3 W., Bollibokka Mountain quadrangle. Bed contains *Parafusulina* of type described by Diller as characteristic of Nosoni formation and dates fossiliferous horizon as early Guadalupian. Diller (1906) believed that the Dekkas and Nosoni were separated by an unconformity. He referred the Dekkas to the Triassic because of its conformable relationship with the overlying Pitt and supposed unconformity separating it from overlying Nosoni.

Named for exposures along Dekkas Creek, Redding quadrangle.

DeKoven Coal Member (of Spoon Formation)

Pennsylvanian: Western Kentucky and southwestern and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 33, 46 (table 1), 63, pl. 1. Assigned member status in Spoon formation (new). In southeastern area, occurs below Palzo sandstone member and above Davis coal member; in southwestern area, occurs below Cheltenham clay member and above Davis coal member. Thickness about 3 feet. Coal named by Lee (1916, Kentucky Geol. Survey, ser. 4, v. 4, pt. 2). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Near DeKoven Station, Shawneetown quadrangle, Union County, Ky.

DeKoven cyclothem (in Spoon Formation)

DeKoven cyclothem (in Tradewater Group.)

Pennsylvanian: Northern Kentucky and southern Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). In list of cyclothems in southern Illinois, the DeKoven occurs at top of Tradewater group and overlies Davis cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 5, 10, pl. 1. Includes DeKoven coal. Stratigraphically below Liverpool cyclothem; overlies Colbert cyclothem (formerly termed Davis). Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 54 (table 3). Included in Spoon formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclothemic classification retained but is independent of rock-stratigraphic classification.

Type locality: Near DeKoven Station, Union County, Ky.

DeKoven Formation[1]

Pennsylvanian (Allegheny): Western Kentucky.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 27.

Probably named for DeKoven, Union County.

Delaney Gravel

[Quaternary]: Central Texas.

R. W. Mathis, 1944, Jour. Sed. Petrology, v. 14, no. 2, p. 87–88. Scattered gravel deposit consisting of flint, chert, quartz, and some feldspar pebbles. Lower than Uvalde formation.

A. W. Weeks, 1945, Am. Assoc. Petrolem Geologists Bull., v. 29, no. 12, p. 1705. Mathis described Delaney gravel, located west of Austin and occupying a level between the Uvalde and Asylum deposits. Since abundant limestone material is present in Uvalde and younger deposits, Mathis' omission of limestone pebbles in discussion of the Delaney suggests that either he failed to see them or that the Delaney came down from higher levels as erosion progressed and therefore is not in place.

Tops a hill 245 feet above Colorado River level on Delaney Ranch, along Bee Caves Road, 3 miles east of Austin, Travis County. Also occurs along ridge between Barton Creek and Fredericksburg Road and southeast of mouth of Bull Creek.

Delaneys Creek facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 169–172.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 2. Mississippian facies nomenclature discussed. Correlation chart lists Delaneys Creek facies of Carwood formation.

Name derived from Delaneys Creek which flows north across east-central T. 3 N., R. 4 E., Washington County.

Delano Peak Latite Member (of Bullion Canyon Volcanics)

Miocene(?): Southwest-central Utah.

Eugene Callaghan, 1939, Am. Geophys. Union Trans. 20th Ann. Mtg., pt. 3, p. 439 (fig. 2), 440 (fig. 3), 442, 443, 445. Brownish red with abundant phenocrysts of oligoclase, hornblende, and biotite, and minor quartz and magnetite in glassy base with fluidal structure. Forms lenticular mass in Bullion Canyon volcanics. Thickness over 800 feet in center of lens; no separate flows distinguished, although upper part has appearance of flow-breccia. Early Tertiary.

U.S. Geological Survey currently considers the Delano Peak Latite to be Miocene(?) in age. This designation is made on the basis of a restudy of Bullion Canyon Volcanics, now considered to be Miocene(?).

Named for occurrence in vicinity of Delano Peak, Marysvale region.

Delassus formation

Cambrian (Cambric) : Southeastern Missouri.

[C. R.] Keyes, 1941, Pan-Am. Geologist, v. 75, no. 3, p. 239. Proposed as a substitute for Buckley's Doe Run dolomite.

Name taken from railroad station near Doe Run, St. Francois County.

Delaware Flags[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 73, 76, 77, 80.

†Delaware Limestone[1]

Silurian (Niagaran) : Central eastern Iowa.

Original references: S. Calvin, 1885, Iowa Univ. State Lab. Nat. Sci. Bull., v. 3, p. 183–189; 1896, Iowa Geol. Survey, v. 5, p. 49–50.

Named for development in Delaware County.

Delaware Limestone[1]

Middle Devonian: Central and northern Ohio.

Original reference: N. H. Winchell, 1874, Ohio Geol. Survey, v. 2, p. 290–302.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1754, chart 4. At type section, several zones can be recognized, one of the most important, the *Hadrophyllum d'orbignyi* zone, near top. Chart shows the Delaware limestone below Plum Brook shale.

G. A. Stewart, 1955, Ohio Jour. Sci., v. 55, no. 3, p. 147–180. Upper of the two Middle Devonian limestones of central and north-central Ohio. Average thickness about 36 feet in central Ohio; maximum thickness in type area about 45 feet. Overlies Columbus limestone; underlies Olentangy shale. Review of terminology.

Named for exposures at Delaware, Delaware County.

Delaware Creek Member (of Caney Shale)

Mississippian (Meramecian and Chesterian) : South-central Oklahoma.

M. K. Elias, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 62–65, 69–71. Gray to dark-gray noncalcareous to slightly calcareous, finely laminated to flaky, partly bituminous shale, locally rotten (shattered), with large amount of finely crystalline gypsum along bedding planes; gray to light-gray to light-buff limestone concretions common, some as much as 12 feet in diameter. Thickness at type locality about 270 feet, dip of beds N. 18° E. 25°. Overlies Ahloso member (new), boundary taken as first or lowest occurrence of softer shale above harder calcareous shale of Ahloso and almost immediate occurrence in it of concretions 3 to 12 feet across; underlies Sand Branch member (new), and boundary is lithologic change from medium-soft-gray shale to dark-gray or nearly black shale of the Sand Branch.

M. K. Elias and C. C. Branson, 1959, Oklahoma Geol. Survey Circ. 52, p. 7, 17–18. Type section redesignated. Thickness 164.8 feet.

Type section: Beds 38 to 97, measured section C, sec. 14, T. 2 S., R. 7 E., Johnston County. Name derived from Delaware Creek which flows eastward in Bromide-Wapanucka area.

Delaware Mountain Group

Delaware Mountain Formation[1]

Permian (Guadalupe Series): Western Texas.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 38.

R. K. DeFord and E. R. Lloyd, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 8. Rank raised to group. Subdivisions heretofore referred to as lower, middle, and upper are designated by formational names, Brushy Canyon, Cherry Canyon, and Bell Canyon respectively. New names credited to P. B. King.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 576–592, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 27–28, pl. 3, strat. sections. Group is about 2,700 feet thick and consists largely of sandstone. Separable into (ascending) Brushy Canyon, Cherry Canyon, and Bell Canyon formations. Northwestward away from basin, lower formation overlaps older rocks along Bone Spring flexure and is absent beyond. Lower part of Cherry Canyon formation persists northwestward as thin sandstone tongue, but upper part changes into Goat Seep limestone. Upper formation changes northwestward into Capitan limestone. Overlies Bone Spring formation; underlies Castile formation.

P. T. Hayes and R. L. Koogle, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–112. Bell Canyon formation of group mapped in Carlsbad Caverns West quadrangle, New Mexico.

Named for exposures in Delaware Mountains, El Paso County, Tex.

Delaware River Flags[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. G_6, p. 94, 99–101.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Assigned to Catskill facies group.

Type region: Along Delaware River north of Hawks Nest, N.Y.

†Delaware River Gravels and Clays[1]

Pleistocene: Northern Delaware and southeastern Pennsylvania.

Original reference: C. E. Hall, 1881, Pennsylvania 2d Geol. Survey Rept. C_6.

Named for development along west side of Delaware River in northern Delaware.

Del Cuerto Formation (in Keller Group)

Pennsylvanian (Virgil Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 70 (fig. 7), 71–72. Term proposed for rocks of lower part of Keller group (new) between top of Story formation (new) and base of Moya formation (new). At type locality, formation is 81 feet thick and composed of irregularly bedded to nodular limestone, highly arkosic sandstone, limestone conglomerate, and gray and red shale. In other areas, formation generally is more highly clastic and thicker.

Type locality: Northeast side of Oscura Mountains in NE¼ sec. 31, T. 5 S., R. 6 E., and west-central part of sec 32, Socorro County. Name derived from Del Cuerto Spring on east slope of Oscura Mountains.

De Leon Formation (in Big Saline Group)

Pennsylvanian (Lampasas Series): North-central Texas (subsurface).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 84 (fig. 5), 85. Sequence of limestone and shale. Lies at a depth of 3,870–4,130 feet in type well. Underlies Sipe Springs formation (new); overlies Comyn formation (new).

Type well: Roxana Petroleum Co. Seaman No. 1, northwest Palo Pinto County. Name derived from town in northern Comanche County.

Delevanian Stage

Late Cretaceous: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 993–994, 1006. Lowermost of six stages, based on foraminiferal assemblages, in Upper Cretaceous column between top of Moreno and base of Panoche, as defined by Anderson and Pack (1915).

Stage embraces lower part of Yolo and whole thickness of Venado formations of Kirby (1943) and the lowest 14,000 feet of the Moreno surface section. Occurs below Cachenian stage (new).

Occurs in Great Valley in both surface and subsurface. Named after town of Delevan near Funks Creek, sec. 23, T. 17 N., R. 3 W., Colusa County.

Delhi Formation[1]

Mississippian: Northern California.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey Geol. Atlas, Folio 66.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 15). Shown on correlation chart above Cape Horn slate and below Clipper Gap formation.

Typical exposures near Delhi mine, Nevada County.

Delhi Limestone[1] Member (of Columbus Limestone)

Middle Devonian: Central Ohio.

Original reference: N. H. Winchell, 1874, Ohio Geol. Survey, v. 2, p. 296–301.

J. W. Wells, 1947, Ohio Jour. Sci., v. 47, no. 3, p. 121 (fig. 3). Chart shows Delhi (Klondike) as uppermost member of Columbus.

R. C. Moore, 1948, Geol. Soc. America Bull., v. 59, no. 4, p. 309 (fig. 2). Shown on columnar section as uppermost member of Columbus formation; overlies Bellepoint member; underlies Delaware formation.

Named for exposures at Delhi, the old name for Radnor, Delaware County.

Delight Sand (in Trinity Group)

Lower Cretaceous (Comanche Series): Southwestern Arkansas.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Proposed for sand lying between the Pike gravel and the Dierks limestone in Sevier, Howard, and Pike Counties. Sand is gray, generally fine grained and crossbedded, thick bedded, and interbedded with some clay and locally impregnated with asphalt. Attains thickness of at least 200 feet in area between Delight and Pike and thins westward.

Type locality: Asphalt quarry just west of Wolf Creek and about 3¾ miles northwest of Delight, Pike County.

Delleker Formation

Miocene, middle(?): Northeastern California.

Cordell Durrell, 1957, Pacific Petroleum Geologist, v. 11, no. 3, p. 3. Welded rhyolite tuff with gravel at base. About 350 feet thick; thickens to east and is probably equivalent to identical tuffs of early Miocene age, west of Pyramid Lake, Nev. Unconformable below Bonta formation (new); rests unconformably on Clover formation (new) and all older rocks; unconformities marked by faulting.

Cordell Durrell, 1959, California Univ. Pubs. Geol. Sci., v. 34, no. 3, p. 165 (fig. 1), 170–172. Consists mostly of biotite sanidine rhyolite tuff, but contains some gravel, mostly near base. Thickness 350 feet. Overlies Ingalls formation (new); in some areas, rests on both Ingalls and Lovejoy formations; underlies Bonta formation. Probably lower or middle Miocene; chart shows middle Miocene(?).

Named for recently abandoned sawmill community of Delleker which is partly on Blairsden and partly on Portola quadrangles; name appears only on the latter, edition of 1950. Most representative section is in Blairsden quadrangle in sec. 32, T. 23 N., R. 13 E., 2½ miles west of Delleker on east side of Willow Creek.

Dellet Sand Member (of Moodys Branch Marl)

Eocene (Jackson): Southwestern Alabama.

H. B. Stenzel, 1952, Mississippi Geol. Soc. [Guidebook] 9th Field Trip, p. 41, 58 (fig. 1), 59. Friable and slightly tough, light-greenish-gray when wet and fresh, for most part weathered to light grayish rust-brown, massive, argillaceous, glauconitic, fossiliferous, fine-grained sand at base of the Jackson. Thickness 2.2 feet. Disconformably overlies Gosport formation.

Name derived from Dellet mansion, a well-known landmark in old town of Claiborne, Monroe County.

Dellvale Ash Bed (in Ash Hollow Member of Ogallala Formation)

Pliocene: Northwestern Kansas.

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 254. Name applied to volcanic ash bed. Thickness at type locality 9½ feet; occurs within silts and sandy silts which overlie a thick fossiliferous sand and gravel bed. Lies stratigraphically above Fort Wallace ash bed (new) and below Reager ash bed.

Named from exposures in NW¼NW¼ sec. 2, T. 4 S., R. 24 W., southeast of Dellvale, Norton County.

Dellville Sandstone,[1] Shale, or Beds

Upper Devonian: Central Pennsylvania.

Original reference: E. W. Claypole, 1885, Pennsylvania 2d Geol. Survey Rept. F–2, p. 77–78, 394.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 33. Del[l]ville beds are a marine unit intercalated with Catskill continental facies in Perry County.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 17 (table 5). Dellville shale and Kings Mill sandstone included in Damascus red beds of Catskill facies group.

Exposed at Dellville, Perry County.

Delmar Sand[1]

Delmar Sand Member (of La Jolla Formation)

Eocene or Eocene, middle: Southern California.

Original reference: M. A. Hanna, 1926, California Univ. Pub., Geol. Sci. Bull., v. 16, no. 7, p. 187–246.

L. G. Hertlein and U. S. Grant 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 65. Lowest member of La Jolla. Underlies Torrey sand member. Maximum thickness about 100 feet, base not exposed.

M. A. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Listed on chart as member of La Jolla. Middle Eocene.

G. B. Oakeshott, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 254 (table). Table lists Delmar sand (formation); underlies Torrey sand.

Named for exposures in sea cliff at town of Delmar, San Diego County.

Delmontian Stage[1]

Miocene, upper: California.

Original reference: R. M. Kleinpell, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 3, p. 376–378.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 131–135, figs. 4, 14 (correlation chart). Superjacent to Mohnian stage. Subjacent to "Lower Pliocene" stage. Contains *Bolivina obliqua* zone in lower part. Systematic catalogue.

Manley Natland, 1953, Pacific Petroleum Geologist, v. 7, no. 2, p. 2. Subjacent to Pliocene Repettian stage (new).

Type locality: At head of Canyon Segundo, south of Del Monte, Monterey County.

Delmore Formation

Pliocene, middle: Central Kansas.

C. C. Williams and S. W. Lohman, 1949, Kansas Geol. Survey Bull. 79, p. 56–59, pl. 1. Proposed for Pliocene sediments underlying area north and northwest of Canton and Galva, Delmore Township, McPherson County; beds were originally assigned to Emma Creek formation, type beds of which were considered to be Pliocene; on the basis of present study, beds at type locality of Emma Creek are assigned to Pleistocene and Emma Creek abandoned; the Delmore does not extend into type area selected for Emma Creek. Formation consists of calcareous gray to buff silt and clay, fine- to coarse-grained sand, and some gravel; locally the calcium carbonate has been concentrated and forms irregularly shaped nodules and thin layers within the silt. Maximum thickness about 75 feet as shown by test drilling. Underlies McPherson formation.

Type area: Secs. 24, 25, and 26, T. 18 S., R. 2 W., and along ravines in sec. 31, T. 18 S., R. 1 W., McPherson County.

DeLong Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 45 (table 1), 63, pl. 1. Name applied to thin unit formerly designated as Upper DeLong coal. Stratigraphically above Brush coal member (new), formerly designated as Middle DeLong coal, and below Seahorne limestone member. Presentation of new rock-stratigraphic classification of Pensylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: Along Brush Creek in secs. 6 and 8, T. 9 N., R. 2 E., Knox County. Named for village of DeLong about 1½ miles northeast of type outcrop.

DeLong cyclothem (in Spoon Formation)

DeLong cyclothems (in Tradewater Group)

Pennsylvanian: Northern, western, and southwestern Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 188, 192.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 63, 73–76, 191, 192, 198, 199, 200, 201, 202, 203, 204, 205. Occupies interval between Seville cyclothem below and Seahorne cyclothem above. Sequence includes three rudimentary cyclothems referred to as Lower, Middle, and Upper Delong cyclothems. Consists principally of underclay, with soft shale and from one to four coaly streaks or thin coals; locally one or two thin sandstones are present but no limestone. Type exposure and derivation of name.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 52 (table 2), pl. 1. Name applied to cyclothem formerly called Upper DeLong. Above Brush cyclothem (new) and below Seahorne cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type exposure: Along Brush Creek in secs. 5 and 8, T. 9 N., R. 2 E., Galesburg quadrangle, Knox County. Named for town of DeLong which is about 2½ miles northeast of type exposure.

†Delphi Black Shale[1]

Upper Devonian: Northern central Indiana.

Original reference: R. T. Brown, 1883, Indiana Dept. Geology and Nat. History 12th Ann. Rept., p. 84.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1754, chart 4. Assigned to the Naples and Chemung because of presence of three species of *Manticoceras*.

Named for Delphi, Carroll County.

†Delphi Dolomite[1]

Permian: Southwestern Oklahoma and northern Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d. Bienn. Rept., p. 42, 56.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 107. Gould spelled his member name Delphi although he named it for village of Delhi, Beckham County. Name Delphi is preoccupied. If corrected to correspond with name of town, Delhi is also preoccupied. The unit is the Mangum dolomite.

Named for Delhi, Beckham County, Okla.

†Delphi Member (of Skaneateles Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 219.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180. Name abandoned. Replaced by Delphi Station member.

Type section: Knights Falls, 1 mile east of Delphi.

Delphi Station Member (of Skaneateles Formation)

Middle Devonian: Central New York.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180. Proposed to replace Delphi shale of Cooper, 1930 (not Brown, 1883, or Gould, 1902).

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Correlation chart shows Delphi Station shale and sandstone below Pompey shale and sandstone and above Mottville sandstone and limestone. Middle Devonian.

[G. A. Cooper], 1955, *in* New York State Geol. Assoc. [Guidebook] 27th Ann. Mtg., p. 10, 11. Basal member of formation. Dark shale grading upward into sandy mudstone and calcareous sandstone. Thickness 80 feet.

Type section: Knights Falls. Name is derived from Delphi Station, Cazenovia quadrangle, which is about 1½ miles northwest of Knights Falls.

†Del Rio Clay (in Washita Group)[1]

Upper Cretaceous (Comanche Series): Southern Texas.

Original references: R. T. Hill and T. W. Vaughan, 1898, U.S. Geol. Survey Geol. Atlas, Folio 42, p. 2; 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 236–237.

W. S. Adkins, 1933 [1932], Texas Univ. Bull. 3232, p. 387. Considered synonym of Grayson formation.

L. W. Stephenson, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 10, p. 1538–1541. Discussion of fossils from limestone of Buda age in Denton County. If it is admitted that this limestone is a facies of Buda age in upper part of Grayson marl, then the Grayson is not exact equivalent of Del Rio but includes equivalents of both Del Rio and Buda.

A. P. Noyes, Jr., and Keith Young, 1960, Texas Jour. Sci., v. 12, nos. 1–2, p. 74 (fig. 5), 89–90. Described in Purgatory Creek area where it is as much as 30 feet thick, overlies Georgetown limestone and underlies Buda limestone. Upper Cretaceous.

Type locality: Low conical butte, Loma de la Cruz, and surrounding clay lowlands, 2 miles south of Del Rio, Valverde County.

Delta Glaciation

Pleistocene: East-central Alaska.

T. L. Péwé, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1289; T. L. Péwé *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 9, 13 (table 1). At least three major Quaternary glaciations recorded at north end of Delta River valley. Delta succeeded Darling Creek glaciation (new); preceded Donnelly glaciation (new). Trunk glacier in Delta Valley coalesced with smaller northward-flowing glaciers to form piedmont lobe spreading about 30 miles beyond front of Alaska Range. Moraines dissected and considerably subdued.

Named from Delta River, along the valley of which the glacier coursed; Big Delta area.

Del Valle Formation

Upper Cretaceous: Northern California.

C. A. Hall, Jr., 1956, Dissert. Abs., v. 16, no. 12, p. 2426. Incidental mention as overlying Niles Canyon formation (new).

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 11–14, fig. 2, geol map. Proposed by Funkhouser (1948, unpub. thesis) for Upper Cretaceous rocks in Arroyo del Valle-Rocky Ridge area of northeastern part of La Costa Valley quadrangle, Alameda County. Name Del Valle formation is applied in this report to rocks along Sunol Ridge in northern part of Niles quadrangle and along western edge of Dublin quadrangle. Rocks along Sunol Ridge cannot be traced into type locality of formation, but they are similar to type section in lithology and age. Thickness along Sunol Ridge, where beds are commonly overturned, may be 3,500 feet; formation thins to the south along ridge. Characteristic lithology is a brown massive soft to hard occasionally concretionary sandstone interbedded with thinly bedded brown siltstone or shale; conglomerate along Sunol Ridge resembles conglomerate of type locality but occurs at top instead of middle of formation. At type locality, brown to reddish-brown hard concretions occur within the sandstone, and crossbedding and flow structures are common; individual sandstone beds at some localities are massive, whereas elsewhere they are 1 to 10 feet thick, interbedded with 1-inch to 4-foot layers of gray, greenish-gray, or brown shale; lenticular conglomerate near middle of formation is approximately 700 feet thick, thinning to the east. Conglomerate along west side of Sunol Ridge is approximately 600 feet thick; thickness is divided into 50- and 100-foot beds of alternating conglomerate and sandstone; this conglomerate unit was traced into Hayward quadrangle where it occurs below Upper Cretaceous rocks. Conformably overlies Niles Canyon formation; underlies Tolman formation. At type area, where maximum thickness is approximately 9,000 feet, formation is faulted against Franciscan group and Cierbo sandstone and is overlapped by Cierbo sandstone and Livermore gravels. Huey (1948) mapped rocks between Rocky Ridge and Arroyo del Valle as Panoche formation. Funkhouser renamed rocks Del Valle because type locality of Panoche is in Panoche Hills of Fresno County, nearly 100 miles from Arroyo del Valle; also Panoche is not a well-defined unit at its type locality.

774–954—vol. 1—66——69

Type locality: Arroyo del Valle-Rocky Ridge area of northeastern La Costa Valley quadrangle, Alameda County, where it covers approximately 4 square miles; extends into Tesla quadrangle.

Delwood Coal Member (of Abbott Formation)

Pennsylvanian: Southern Ilinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1), 62, pl. 1. Assigned to member status in Abbott formation (new). Occurs below Murray Bluff sandstone member and above Finnie sandstone member. Thickness 3 feet in type section of formation. Term Finnie sandstone is applied to unit formerly termed Delwood sandstone in order to retain name Delwood for the coal. Name Delwood coal credited to J. M. Weller (1940, Illinois Geol. Survey Rept. Inv. 71). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: NW¼NW¼ sec. 3, T. 11 S., R. 6 E., Pope County.

Delwood cyclothem (in Abbott Formation)

Delwood cyclothem (in Tradewater Group)

Pennsylvanian: Southern Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). Underlies Macedonia cyclothem and overlies Grindstaff cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 9. Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), 54 (table 3). In Abbott formation (new).

Type locality: Sec. 5, T. 11 S., R. 6 E., Pope County. Name derived from a crossroads village in northern part of county.

Delwood Formation or Sandstone (in Tradewater Group)

Pennsylvanian: Southern Illinois.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 16 (table), 39, 40, 41. Formation contains only one important sandstone and one coal and is considered to represent a single cycle of deposition. Basal sandstone is about 50 feet thick, generally massive and crossbedded and conspicuously micaceous; above the coal, formation consists of a succession of sandy shales and shaly to thin-bedded sandstones with a probable maximum thickness of 50 feet. Underlies Macedonia formation; overlies Grindstaff formation.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 9. Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31. Replaced by Finnie sandstone.

Type locality: Sec. 5, T. 11 S., R. 6 E., Pope County. Name derived from a crossroads village in northern part of county.

Dement Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 10, 16. Limestone, dolomitic, medium bedded, and nonshaly. Thickness about 7 feet. Shown on columnar section as underlying Walgreen member (new) of Grand Detour formation and overlying Briton member (new) of Mifflin formation.

Occurs in Dixon-Oregon area.

Demingian Series or Stage

Ordovician (Canadian): North America.

R. H. Flower, 1957, New Mexico Bur. Mines Mineral Resources Mem. 2, p. 18. Divisions within Canadian system favor natural division into four major units: Gasconadian, Demingian, Jeffersonian, and Cassinian. Demingian (Middle Canadian) beds in east are restricted and confined largely to *Lecanospira fauna*. In the west, a definite succession is known comprising the first endoceroid zone, first piloceroid zone, the oolite and succeeding gastropod beds of El Paso section in New Mexico, and F and lower G of Garden City sections.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–32. Canadian series includes Gasconadian, Demingian, Jeffersonian, and Cassinian stages.

Interval well developed in Cooks Range, Florida Mountains, N. Mex. Name derived from city of Deming, N. Mex.

†Demopolis (broad sense)[1]

Upper Cretaceous: Alabama.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–1888, geographic map of Alabama.

Probably named for exposures at Demopolis, Marengo County.

Demopolis Chalk or **Formation** (in Selma Group)

Demopolis Chalk Member (of Selma Chalk)

†Demopolis division (narrow sense)[1]

Upper Cretaceous: Western Alabama and eastern Mississippi.

Original reference: E. A. Smith, 1903, 58th Cong., 1st sess., S. Ex. Doc. 19, p. 12–20, map.

W. H. Monroe, 1941, Alabama Geol. Survey Bull. 48, p. 64–73. Smith (1903) divided Selma chalk into three divisions: upper, or Portland; middle, or Demopolis; and lower, or Selma. Later workers did not follow Smith in his threefold division of Selma, but recent works show that subdivision of Selma is not only practicable but desirable. In present paper, Smith's Selma division is represented almost exactly by the unnamed lower marly member of Selma chalk, but because name Selma chalk has long been established for formation as a whole, its additional use to designate member of same formation would be confusing. Smith's Demopolis division is represented by Arcola limestone member and lower part of Demopolis member. Smith's Portland division is represented in western Alabama by upper part of Demopolis member, Ripley formation, and Prairie Bluff chalk, and in central Alabama by upper part of Demopolis member and lower part of Ripley formation. Specifically, in this report, Demopolis member of Selma chalk includes all chalky and marly beds between diastem above Arcola limestone member below and Ripley formation above. Estimated thickness about 490 feet (estimates from wells). In Montgomery County, member is split into two eastward-extending tongues by westward-extending tongue of Cusseta sand. Type locality stated.

H. R. Bergquist, 1943, Mississippi Geol. Survey Bull. 53, p. 15 (table), 26–31. Demopolis chalk member geographically extended into Mississippi. Thickness is about 410 feet in Clay County. Overlies Arcola member; underlies Ripley formation.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Rank raised to formation in Selma group.

W. H. Monroe and D. H. Eargle, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 50. In southwestern part of Eutaw quadrangle, Alabama, overlies Arcola limestone member of Mooreville chalk.

W. H. Monroe, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2740–2742. Subdivided to include Bluffport marl member (new).

R. H. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 46–59, pls. 1, 5, 6, 10. Demopolis chalk described in Kemper County where it includes Bluffport marl member at top. Thickness about 260 feet. Underlies Ripley formation; oldest deposit exposed in county. In east-central Mississippi, the Demopolis lies between Ripley formation above and Mooreville chalk below; in northern part of state, overlain by Owl Creek tongue of Ripley and underlain by Tupelo tongue of Coffee sand.

W. S. Parks, 1960, Mississippi Geol. Survey Bull. 87, p. 22 (table 2), 26 (fig. 4), 52–61, pl. 4. In this report [Prentiss County], Demopolis formation refers to those chalk beds between Coffee sand below and transitional clay of Ripley formation above. Thickness 230 to 235 feet.

Type locality: Bluff of chalk on Tombigbee River at Webb and Sons cotton warehouse in Demopolis, Marengo County, Ala.

Dempsey Marble[1] (in Talladega Series)

Pennsylvanian: Northeastern Alabama.

Original reference: G. I. Adams, 1933, Jour. Geology, v. 41, no. 2, p. 163.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 20. Present in upper part of Talladega series. Pennsylvanian.

Present in Clay County.

DeNay Limestone Member (of Francis Formation)[1]

DeNay Limestone Member (of Coffeyville Formation)

Pennsylvanian (Missouri Series): Central southern Oklahoma.

Original references: G. D. Morgan, 1922, Oklahoma Geol. Survey Circ. 12, p. 9, 10; 1924, [Oklahoma] Bur. Geology Bull. 2, p. 110–115.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as basal member of formation.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 62, 63, 64. Reallocated to member status in Coffeyville formation. Interval designated by Morgan (1924) as Francis formation is herein described under headings Coffeyville and Nellie Bly.

Named for typical development on side of an eastward-facing bluff in sec. 5, T. 4 N., R. 7 E., about one-fourth mile west of DeNay School, in Stonewall quadrangle, Pontotoc County.

†Denison Formation (in Washita Group)[1]

Lower Cretaceous (Comanche Series): Northeastern Texas and southern Oklahoma.

Original reference: R. T. Hill, 1889, Am. Jour. Sci., 3d, v. 37, p. 290.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 29–41, pl. 1. Formation described in Fort Worth-Weatherford area, Texas, where it comprises (ascending) Denton marl, Weno marly limestone, Pawpaw shale, Main Street limestone, and Grayson marl members. Thickness about 245 feet. Overlies Fort Worth limestone; underlies Buda limestone. Washita group.

U.S. Geological Survey has abandoned the term Denison Formation and raised the members to formational status.

Named for exposures at Denison, Grayson County, Tex.

Denmar Formation

Middle Mississippian (Meramecian) : Southwestern West Virginia.

Dana Wells, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 5, p. 902–918. Proposed for sequence of gray slightly cherty calcarenite and calcilutite beds that are younger than top of Hillsdale in its type section and older than the Taggard in its type section; this stratigraphic and lithologic unit includes beds defined by Reger (1926) as Sinks Grove and Patton limestones. Thickness at type section 214 feet. Conformably overlies Hillsdale limestone from southern Mercer County to northern end of Pocahontas County; across remaining distance of latter county and for approximately 5½ miles into Randolph County, near Monterville, unconformably overlies thinning Maccrady; 1½ miles south of Monterville, the Maccrady disappears and the Denmar rests on the Pocono; throughout area investigated the Denmar underlies Reger's (1926) Taggard formation [shale]. Middle Mississippian (Meramecian series).

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1910–1912. The Patton and Sinks Grove do not represent a single stratigraphic and lithologic unit; in Monroe County, where they were named, they are separated by 10 to 20 feet of plant bearing shale [Patton shale]; use of term Denmar for these two formations is without merit.

Type locality: On eastern slope of Droop Mountain along County Road 20 in Locust Creek valley, 0.7 mile south of junction with U.S. Highway 219, Little Levels district, Pocahontas County. Named for village of Denmar about 2½ miles southeast on Greenbrier River.

Denmark Formation

Denmark Member (of Sherman Fall Formation)

Middle Ordovician (Mohawkian) : Central and northern New York.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 267–268, pl. 4. Named as a member and defined as alternating shaly and coarse-textured limestones constituting larger part of the formation. Calcareous fucoidal claystones present in higher part. Thickness about 170 feet. Base tends to be more resistant than more shaly Shoreham member (new) below, but contact is indistinct; contact with overlying Cobourg formation poorly defined lithologically.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 599, 605. Rank raised to formation. Subdivided to include three new members in West Canada Creek area, in ascending order: Rathbun limestone, Poland limestone, and Russia limestone. Contains several metabentonites. Grades into Canajoharie black shale southeastward. Underlies Rust limestone member (new) of Cobourg formation; disconformably overlies Shoreham limestone.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p. 527–530. Stratigraphically restricted by reallocation of basal Rathbun member to underlying Shoreham formation. In northwestern New York, lower part is subdivided to include Camp member below and Glendale member above. In Black River valley, consists primarily of coarse-textured fossiliferous calcarenites, few intercalated finer grained calcisiltites, and calcilutites of the Glendale member. Poland and Russia members not recognizable in sections north of Trenton Falls.

Named for Denmark Township, Lewis County. Well displayed in Trenton Falls Gorge.

Denmarkian (Denmark) Stage or Substage

Middle Ordovician: Eastern North America.

Referred to as Denmark time. G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 603.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1414–1415. Middle Trentonian includes rocks equivalent to Shoreham and Denmark limestones of New York, or undivided Sherman Fall limestone. Denmarkian commonly has abundance of *Sinuites cancellatus* (Hall), but upper limit has been established only in New York and Ontario, where succeeded by late Trentonian Cobourg limestone; in central Pennsylvania, the Salona is overlain by Coburn limestone, the contact approximating top of Denmarkian. The Denmarkian has limestones west of Adirondack line, which have been shown to change through a succession of facies into Canajoharie black shale as they thicken and approach Adirondack line in New York.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30. Suggested that term Shermanian stage be applied to Shorehamian and Denmarkian substages.

Name derived from Denmark Township, Lewis County, N.Y., for which Denmark formation was named.

Dennis Limestone[1] (in Kansas City Group)

Dennis Limestone (in Bronson Group)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. I. Adams, 1903, U.S. Geol. Survey Bull. 211, p. 36.

M. C. Oakes, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 723–724. Abandoned in Oklahoma in favor of Hogshooter limestone.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 191–192. Included in Bronson group. Comprises (ascending) Canville limestone, Stark shale, and Winterset limestone members. Overlies Galesburg shale; underlies Fontana shale.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Formation included in Bronson subgroup of Kansas City group. Comprises Canville limestone, Stark shale, and Winterset limestone members. Overlies Galesburg formation; underlies Cherryvale formation.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11–12. Formation redefined for Missouri to include Canville, Stark, and Winterset members.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 421. Thickness of formation in Madison County, Iowa, about 23 feet. Includes Canville, Stark, and Winterset members. Overlies Galesburg shale; underlies Cherryvale formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Comprises (ascending) Canville limestone, Stark shale, and Winterset limestone members. Canville usually missing in Iowa sections. Underlies Cherryvale shale; overlies Galesburg shale. Kansas City group.

Named for exposures at railroad station at Dennis, Labette County, Kans.

Dennis Bridge Limestone Bed (in Hill Creek Member of Lazy Bend Formation)

Dennis Bridge Limestone Member (of Lazy Bend Formation)

Dennis Bridge Limestone (in Millsap Lake Formation)[1]

Dennis Bridge Limestone (in Rayville Formation)

Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to member of Lazy Bend formation. Occurs between Brannon Bridge limestone member (above) and Kickapoo Falls member (below).

M. G. Cheney, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 210. Reallocated to Rayville formation (new).

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 14, fig. 3. Rank reduced to bed in Hill Creek member of Lazy Bend formation. Occurs at base of member. At type locality, overlain by 3 feet of shale; along strike, bed is covered by alluvium and Cretaceous rocks. Type locality established.

Type locality: Outcrops at end of bridge over Brazos River at Dennis in southwestern part of Parker County. Exposure extends westward along the Brazos for one-fourth mile to valley of tributary; basal 3 feet is exposed in small outcrop in stream bank one-half mile east of south end of bridge at Dennis; these are the only surface occurrences of the limestone.

Denny Formation

Pre-Tertiary: Central Washington.

R. J. Foster, 1957, Dissert. Abs., v. 17, no. 9, p. 1982; 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 111, pl. 1. At type locality, consists of medium- to coarse-crystalline marbles interbedded with fine-grained hornfels. Thickness not estimated; deformation and metamorphism that accompanied emplacement of Snoqualmie granodiorite has obscured structure. Rocks were included in Guye formation by Smith and Calkins (1906). Field relationships show Denny to be pre-Snoqualmie granodiorite and probably in fault contact with other rocks. Probably pre-Tertiary.

Type locality: Snoqualmie Mountain saddle, central Cascades Mountains. Confined to two small areas on Denny and Snoqualmie Mountains with total extent of less than 2 square miles.

Dennys Formation[1]

Silurian: Southeastern Maine.

Original references: E. S. Bastin and H. S. Williams, 1913, Maine Water Storage Comm. 3d Ann. Rept., p. 168; 1913, Geol. Soc. America Bull., v. 24, p. 378, 379.

C. K. Swartz and others, 1942. Geol. Soc. America Bull., v. 53, no. 4, chart 3. Assigned to Niagaran series [Middle Silurian].

Named for exposures near Dennysville, Washington County.

Densinyama Formation

Densinyama Beds

Eocene, upper: Mariana Islands (Saipan).

Risaburo Tayama, 1938, Geomorphology, geology, and coral reefs of Saipan Island. Tropical Industry Inst., Palau, South Sea Islands, Bull. 1 [English translation in library of U.S. Geol. Survey, p. 53–56]. Beds comprise four units (ascending): conglomerate containing felsite and limestone blocks with intercalated clays; conglomerate consisting largely of felsite pebbles with minor amounts of medium-sized limestone, liparite, andesite, and quartz pebbles; fine-grained conglomerate of felsite pebbles, sandstone, and tuff with two thin beds of yellow and pink clay (fuller's earth); well-stratified arenaceous limestone or calcareous sandstone. Thickness varies, about 60 to 100 meters at Densinyama; thins southward. Commonly in contact with Hagman andesite, with no intermediate Mantansya beds. Oligocene.

Josiah Bridge *in* W. S. Cole and Josiah Bridge, 1953, U.S. Geol. Survey Prof. Paper 253, p. 8–9. Referred to as formation. Miocene (Aquitanian).

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 51–56, pl. 2, chart 2. Formation, as herein described, comprises three facies (ascending): breccia, conglomerate-sandstone, and limestone-conglomerate. The conglomerate sandstone is subdivided into quartz-rich and quartz-poor facies. Thickness varies; aggregate at type section 730 feet; may exceed 800 feet in places; thins to disappearance. Upper Eocene. Type section designated. Difficult to distinguish some parts of Densinyama from Machegit conglomerate member (new) of Tagpochau limestone and from parts of Hagman formation.

Type section: Succession exposed along Talofofo Road that runs west and east from crest of Talofofo Ridge in north-central Saipan. Tayama gave as type locality ridge called Densinyama (radio hill) by Japanese, correct geographic name of which is Ogso Talofofo, or Talofofo Ridge.

Denton Clay (in Washita Group)

Denton Clay Member (of Denison Formation)[1]

Denton Formation (in Washita Group)

Denton Marl Member (of Denison Formation)

Denton Shale Member (of Georgetown Limestone)

Lower Cretaceous (Comanche Series): Central and northeastern Texas and central southern Oklahoma.

Original reference: J. A. Taff, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 272.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Chart shows Denton clay in Washita group. Occurs below Weno limestone and above Fort Worth limestone. [Term Denison abandoned.] Lower Cretaceous.

D. L. Frizzell, 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 27, table 4. Foraminifera of Denton formation described.

W. J. Fox and O. N. Hopkins, Jr., 1960, Baylor Geol. Soc. Guidebook 5th Field Trip, p. 88, 91. In central Texas, referred to as shale member of Georgetown limestone. Overlies Fort Worth limestone member; underlies Weno limestone. Thickness 3 to 5 feet. Predominantly marly shales containing two thin coquinoid limestone beds which are separated by about 1 foot of shelly marl.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 30–32, 33 (fig. 13). In this report [Fort Worth-Weatherford area], Denton marl is used in sense intended by Taff; that is, member of Denison formation. In Tarrant County, consists of about 35 feet of gray marly limestone, gray marl, and weakly consolidated shell beds near top of member. Underlies Weno marly limestone member; overlies Fort Worth limestone.

Named for Denton Creek, Denton County, Tex.

Denver Formation[1]

Upper Cretaceous and Paleocene: Eastern Colorado.

Original reference: W. Cross, 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 119–133.

C. H. Dane and W. G. Pierce, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 10, p. 1310 (fig. 2). Underlies Castle Rock conglomerate; overlies Arapahoe formation; southward merges into Dawson arkose.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 71, 78 (table 2), 84. Denver formation has yielded invertebrates found only in Laramie formation in Denver basin. Proposed that Laramie be redefined to include Arapahoe formation as a member, basal part of Denver formation, and basal part of Dawson arkose. Paleocene.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 34 (table 7), 57–61, 62, pl. 1. Described in South Park area where it consists of gravel, conglomerate, sandstone, and sandy shale with interbedded agglomerate and tuff. Thickness as much as 8,000 feet, but it is possible that the formation or a part of it may have been repeated by step faulting, now hidden, or small-scale faulting. Unconformably overlies Laramie formation; underlies Balfour formation, but relation to Balfour nowhere exposed; hence, Balfour, as here defined, may prove to be topmost part of Denver; in southern part of the area, overlies Fox Hills formation, and along eastern side of Trout Creek valley, overlies Pierre shale; locally overlies Precambrian and Permian deposits. Eocene.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 2, 40, 41, 42. Upper Cretaceous and Paleocene.

S. O. Reichert, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 107–112, pl. 1. Proposed that Arapahoe-Denver contact be placed at widespread erosional disconformity at base of lowest, thickest, and most prominent basalt-andesite pebble conglomerate bed in Denver area instead of at first appearance of andesitic debris as proposed by Emmons, Cross, and Eldridge (1896, U.S. Geol. Survey Mon. 27); also proposed that Denver formation be extended throughout Denver basin to include all dark clastic sediments derived from erosion of basic lavas as indicated by their mineral content. Denver formation (and Arapahoe herein also extended) would replace the "lower" Dawson of Dane and Pierce. Paleocene.

Named for exposures about city of Denver.

Denver Basin Group

See Basin Ridge Group.

Denzer Diorite[1]

Precambrian: South-central Wisconsin.

Original reference: J. T. Stark, 1932, Jour. Geology, v. 40, no. 2, p. 120, 121, 137.

Occurs in secs. 9 and 10, T. 10 N., R. 5 E., north and northwest of Denzer, Baraboo district.

Denzer Tuff[1]

Precambrian: South-central Wisconsin.

Original reference: J. T. Stark, 1932, Jour. Geology, v. 40, no. 2, p. 120, 121, 132.

Exposed in a ledge nearly 200 feet long and 5 to 10 feet wide on north bank of a small stream in SE¼ sec. 11, T. 10 N., R. 5 E., about 1½ miles northeast of Denzer, Honey Creek Township, Baraboo district.

Depass Formation[1]

Middle Cambrian: Western Wyoming.

Original reference: B. M. Miller, 1935, Geol. Soc. America Proc. 1934, p. 352.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1096–1101, 1102–1104. Redefined to include all beds in type locality between Cambrian-Precambrian contact and base of Upper Cambrian Boysen formation (new). Middle-Upper Cambrian boundary cannot be drawn upon evidence of fossils. Top of Depass is arbitrarily placed at top of two thick beds of intraformational conglomerate, which lie upon a 14-inch shale zone containing new genera of Middle Cambrian trilobites, and 12 feet below lowest horizon containing *Arapahoia?* sp. and *Dicellomus?* sp. On basis of lithology, divided into basal Flathead sandstone member and upper Gros Ventre member. Thickness emended section 580 feet.

Type section: Wind River Canyon at eastern end of Owl Creek Range. Name is taken from "D" Pass (now spelled Depass) near eastern end of Bridger Range.

†Depauville (Depeauville) Waterlime[1]

Lower Ordovician: Central New York.

Original reference: E. Emmons, 1840, New York Geol. Survey, 4th Rept., p. 324.

The village name is spelled Depauville, Jefferson County.

Deputy Formation (in Hamilton Group)

Middle Devonian: Southeastern Indiana.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1060–1061. Blue to gray limestone weathering light gray; in fresh material difficult to distinguish from the Speeds formation except by fossils; has been included with the Speeds as a part of the Jeffersonville or Sellersburg. Underlies Silver Creek formation; overlies Speeds formation; at type section occurs between Speeds and Swanville formations.

J. B. Patton and T. A. Dawson *in* H. H. Murray. 1955, Indiana Geol. Survey Field Conf. Guidebook 9, p. 42, pl. 1. Deputy and Swanville "formations" appear to be only faunal facies of units previously recognized and names, or combinations of such units; they might better be called "zones" or "faunal facies" of Sellersburg (North Vernon) limestone.

Type section: On secondary road one-half mile east of its intersection with Highway 3, three-quarters mile south of Deputy, Jefferson County.

De Queen Limestone (in Trinity Group)

De Queen Limestone Member (of Trinity Formation)[1]

Lower Cretaceous (Comanche Series): Southwestern Arkansas and southeastern Oklahoma.

Original reference: H. D. Miser and A. H. Purdue, 1918, U.S. Geol. Survey Bull. 690, p. 19, 22.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Rank raised to formation in Trinity group. Table shows unit as cropping out in Arkansas below the Paluxy sand and above the Holly Creek formation. Subsurface equivalents discussed.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 16 (table 5), 22–26, pl. 1. Crops out in McCurtain County just south of Holly Creek formation in narrow band ranging in width from several feet to more than half a mile. Outcrop extends from sec. 1, T. 6 S., R. 23 E., eastward to Arkansas State line. Thickness 38 feet in eastern part of outcrop; less than 1 foot in western extremity. Downdip attains maximum thickness of 190 feet at southeastern edge of county. Conformable to overlying Paluxy sand and to underlying Holly Creek formation. Unconformable to underlying Paleozoic rocks where Holly Creek is absent. Trinity group; Comanche series. Early Cretaceous.

Named for occurrence at De Queen, Sevier County, Ark.

Derby Dolomite (in Elvins Group)[1]

Derby Dolomite Member (of Elvins Formation)

Upper Cambrian: Eastern Missouri.

Original references: E. R. Buckley, 1907, Missouri Bur. Geology and Mines, v. 10, 2d ser., separate; H. A. Buehler, 1907, Missouri Bur. Geology and Mines, v. 6, 2d ser., p. 231.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 234 (table 1). Middle formation in Elvins group. Overlies Davis formation; underlies Doe Run dolomite. Upper Cambrian.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 27–30. Missouri Geological Survey uses compound term, Derby-Doe Run. Because Doe

Run was used as formation named by Frazer (1883) [for unit in Pennsylvania], it seems good usage to discontinue it as compound term. Term Derby formation is used in this report. Dominantly dolomite noncherty, gray to buff. Exposures of entire formation nowhere identified. Thicknesses of 75 feet near Potosi and 110 feet near St. Joe Lead Company mine are maximums that have been identified. Overlies Davis formation; underlies Potosi formation. Term Elvins group not recognized as valid in this report.

V. E. Kurtz, 1960, Dissert. Abs., v. 21, no. 3, p. 595. Referred to as member of Elvins formation. Overlies Davis member; underlies Doerun member. Derby and Doerun members become indistinguishable a short distance from their type localities.

Named for Derby mine (now Federal mine) near Elvins, St. Francois County.

Derry Series

Pennsylvanian: Central and southern New Mexico and western Texas.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 26–31. Term proposed for all rocks in the central to the extreme south-central areas of New Mexico between base of Pennsylvanian system and the basal part of Des Moines series. Composed largely of marine limestones, shales, conglomerates, and coarse sandstones; locally contains, especially in lower part, dark shales, sandstones, and thin coal beds. About 130 feet thick at type locality; thickens southward to slightly more than 600 feet in the Hueco Mountains of western Texas where it is composed almost entirely of marine limestones. Subdivided into two groups, Green Canyon below and Mud Springs (both new). At type locality, unconformably overlies Devonian Percha shale; elsewhere unconformably overlies rocks of Mississippian, Devonian, Cambrian(?), or Precambrian age. Overlain by Des Moines sediments referred to Armendaris group (new).

Type locality: West slope of hill about three-fourths mile east of center of Derry, near center of sec. 32, T. 17 S., R. 4 W. Named for village of Derry in Sierra County, N. Mex.

Descanso Granodiorite[1]

Late Mesozoic: Southern California.

Original reference: W. J. Miller, 1935, California Jour. Mines and Geology, v. 31, no. 2, p. 115–141, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 486, 487, table 4. Discussed under Late Mesozoic plutonics. Shown on table as older than La Posta quartz diorite and younger than Harbison quartz diorite.

Type occurrence in general vicinity of Descanso, southern Peninsular Range, San Diego and Imperial Counties.

†Deschutes Formation[1]

Pliocene, lower to middle: Central northern Oregon.

Original reference: I. C. Russell, 1905, U.S. Geol. Survey Bull. 252, p. 90–91.

R. W. Chaney, 1938, Carnegie Inst. Washington Pub. 476, p. 187–216. Flora and fauna indicate a lower to middle Pliocene age.

U.S. Geological Survey has abandoned the term Deschutes Formation.

Well exposed in wall of Deschutes River for at least 25 miles up stream from Crooked River.

Desecheo Stage[1]

Recent: Puerto Rico and Desecheo Island.

Original reference: B. Hubbard, 1923, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 1, p. 97.

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 324–325. Hubbard introduced term for post-Pleistocene beach sands and gravels in northern Puerto Rico and Desecheo Island. He recognized an Upper and Lower Desecheo stage in terms of elevation above sea level.

Deseret Limestone[1]

Lower and Upper Mississippian: Central northern Utah.

Original reference: J. Gilluly, 1932, U.S. Geol. Survey Prof. Paper 173.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 15 (fig. 4), 18–19. Described in East Tintic Mountains where it replaces Pine Canyon limestone of Loughlin (1919). Consists of three members: basal phosphatic shale, lower limestone member, and an upper limestone member. Total thickness 900 to 1,200 feet. Overlies Madison limestone; underlies Humbug formation.

A. E. Disbrow, 1957, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–131. Mapped in Fivemile Pass quadrangle where it is predominantly medium-gray cherty limestone interbedded with buff to brown sandy or shaly limestone and dolomite; beds of black carbonaceous phosphatic shale at base. Thickness about 700 feet. Overlies Madison limestone equivalents; underlies Humbug formation.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 49–52, pl. 1. Gilluly (1932) assigned 650 feet of limestone to Deseret limestone. In this report [southern Oquirrh Mountains], the upper 350 feet of Gilluly's section are referred to the Deseret, and lower strata are included in Pine Canyon formation, largely the upper member. Restricted Deseret is mapped in Ophir Canyon and on crest of Ophir anticline where it crosses Mercur Canyon. Conformably underlies Humbug formation.

M. D. Crittenden, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 63, 65–66, 69 (fig. 3), 70–71. Conformably overlies Gardison limestone (new) in Cottonwood, Provo, and Oquirrh Mountains areas.

Named for exposures at Deseret mine, Dry Canyon, Stockton quadrangle.

Desert Member (of Blackhawk Formation)

Upper Cretaceous (Montana): Central eastern Utah.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, 186, figs. 2, 3, pl. 3. Comprises a sandstone tongue and the overlying coal-bearing rocks which separate it from the Castlegate member of the Price River formation above. Basal unit of member is medium-grained buff sandstone with maximum thickness of about 70 feet; massive near top but grades downward into thinner beds and finally into Mancos shale which in turn disconformably overlies Grassy member (new) of Blackhawk formation; disappears eastward into Mancos shale at Saleratus Canyon.

About 50 feet of coal-bearing rocks is present at Desert, and it thins rapidly to southeast and is absent at Green River, where basal sandstone of the Castlegate rests directly on basal sandstone of Desert member.

Named for exposures in nearly vertical cliffs of Mount Elliot east of Desert, a siding of the D. & R. G. W. Railroad, Emery County.

Desert Cone Basalt Flow

Pliocene to Pleistocene, lower: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 32. Name applied to basalt flow on Desert Cone. [See Timber Crater Basalt Flow.]

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 27. Here considered to be pre-Mazama.

Desert Cone is in northwestern part of Crater Lake National Park.

Desert Peak Formation

Pliocene, lower: Western Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci. v. 33, p. 97–99, 139–141, figs. 5, 6, 8. Consists of two unnamed members: Lower member described as thick yellow-brown to tan shales, yellow-green basalt tuffs, thin basalt flows, and dense olive-gray basalt; thickness 850 feet; upper member described as white, creamy thin siliceous shales, chiefly opalized diatomite, some horizons breaking into conchoidal chips; higher parts grade northeastward to diatomite locally; basalt tuffs locally interbedded in section; thickness from 1,600 to 2,200 feet. Higher parts of formation grade upward into Truckee formation. Conformably overlies Chloropagus formation (new).

Type region at northern end of Hot Springs Range surrounding Desert Peak. Occurs also on far side of Carson Sink Basin in hills southwest of Fallon, as well as in Stillwater Range southeast of Stillwater.

De Smet Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. and Min. Journal-Press, v. 115, p. 793, 799, 836–843, maps.

J. A. Noble and J. O. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 945. Does not maintain constant position; may be absent or occur at one or several positions. Name De Smet dropped as separate formation; unit included in Poorman formation.

Named for exposures around north end of main opencut southwest of De Smet shaft, Lead district, Lawrence County.

†De Smet Formation[1]

Upper Cretaceous to Eocene, lower(?): Northern Wyoming.

Original reference: N. H. Darton, 1906, U.S. Geol. Survey Prof. Paper 51, p. 13, 62–67.

R. L. Nace, 1936, Wyoming Geol. Survey Bull. 26, p. 26. Originally defined as formation. Has since been shown to be terrane and subdivided into more natural divisions.

Typically exposed at Lake De Smet, Fort McKinney quadrangle.

Des Moines Series

Des Moines Group[1]

Middle Pennsylvanian: Iowa, Arkansas, Kansas, Missouri, Nebraska, and Oklahoma.

Original reference: C. R. Keyes, 1893, Iowa Geol. Survey, v. 1, p. 86–114.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 19 (table 1). Group, in Muskogee-Porum district, comprises (ascending) Atoka formation, Hartshorne sandstone, McAlester shale, Savannah formation, and Boggy formation. Overlies Morrow group.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 657–706, chart 6. In upward order, Midcontinent time-rock divisions of the Pennsylvanian are designated as Morrowan, Lampasan, Desmoinesian, Missourian, and Virgilian.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 140 (chart 2). Chart shows classification and correlation of type Pennsylvanian section of eastern and western Pennsylvania with costandard sections of Appalachian and Midcontinent regions. Midcontinent region section comprises (ascending) Springer, Morrow, Lampasas, Des Moines, Missouri, and Virgil series. Des Moines series is equivalent to Allegheny series in Appalachian region and Allegheny River valley, western Pennsylvania. Costandard section shown as east-central Oklahoma and reference section as south Ardmore basin, Oklahoma.

R. C. Spivey and T. G. Roberts, 1946, Am. Assoc. Petroleum Geologists Bull., v .30, no. 2, p. 185. Atoka formation is elevated to Atoka series and defined to include all beds from top of Wapanucka limestone, Morrow series, to base of Hartshorne sandstone, Des Moines series. Term Atoka series replaces term Lampasas series.

C. A. Moore, 1947, Oklahoma Geol. Survey Bull. 66, p. 50. In present classification of Pennsylvanian rocks of Oklahoma, all strata between top of Morrow series and base of Missouri series are referred to Des Moines series. This classification places Atoka formation in Des Moines series.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2020, 2021 (fig. 1). In some parts of northern Midcontinent states, Desmoinesian deposits are separable from underlying pre-Desmoinesian Pennsylvanian rocks, but in large areas, especially in subsurface of northern Oklahoma and Kansas along Nemaha Ridge and bordering central Kansas uplift, Desmoinesian beds rest on pre-Pennsylvanian formations with angular unconformity. Upper boundary of series is defined by disconformity which is inconspicuous in most places but, on basis of paleontological changes, is judged to be division line of first-rank intra-systemic magnitude. Series designated paleontologically as zone of *Fusulina*. Comprises Cherokee and Marmaton groups. Spans interval between Atokan series and Missourian series. Oklahoma uses Des Moines series as extending downward to top of Morrowan beds.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 286. Oklan series (new) comprises rocks assigned to Atokan and Desmoinesian stages.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1523–1526. Lower and middle part of Des Moines series in Oklahoma includes Krebs and Cabaniss groups (both new). These groups together are nearly but not quite the same, stratigraphically, as Cherokee rocks of southeastern Kansas.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2747–2749. In classification adopted in northern Midcontinent, Desmoinesian stage is subdivided into Venteran substage below and Cygnian substage above. Desmoinesian comprises Krebs, Cabaniss, and Marmaton groups. Middle Pennsylvanian. Iowa does not fully concur in this classification.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 20–21, 22 (fig. 5). Term Cherokee revived for basal group of Des Moines. Terms Krebs and Cabaniss reduced to rank of subgroups within the Cherokee.

W. H. Bradley, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2284–2285. In Midcontinent region (including Arkansas, Iowa, Kansas, Nebraska, and Oklahoma), U.S. Geological Survey uses following series subdivision of the Pennsylvanian: Morrow, Atoka, Des Moines, Missouri, and Virgil. The Des Moines is Middle Pennsylvanian.

Named for exposures on Des Moines River, Iowa.

Desmoinesian Series or Stage

See **Des Moines Series.**

†De Soto Beds[1]

Pliocene, lower: Southern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 126, 133, 141, 157, 158, 324.

Dessau Formation

Upper Cretaceous: South-central Texas.

C. L. Durham, Jr., 1955, Corpus Christi Geol. Soc. [Guidebook] Ann. Field Trip, Mar. 11–12, [p. 57], pl. 16. Consists of a basal glauconitic calcarenite which grades upward into a white calcilutite sequence. Approximately 70 to 90 feet thick in Travis County. Includes Pilot Knob tuff (new). Underlies Burditt marl (chalk); overlies disconformity at top of undifferentiated Austin. Name credited to Durham and Roux (unpub. ms.).

Type locality: On branch of Big Walnut Creek 7.6 miles north-northeast of State Capitol, Austin, Travis County.

Detonti Sand (in Wilcox Group)

Eocene: Central Arkansas.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 11 (fig. 4), 55–58, plates. Homogeneous sand unit containing some interbedded gray clay lenses and a prominent lignite bed at base. Best known from drill holes; as interpreted from logs thickness ranges from 207 to 412 feet. Unconformably overlies Saline formation (new); covered at many localities by deposits of gravel of late Tertiary age.

Type section: On east bank of first prominent gully west of Detonti on Detonti-Tull Road near center of NW¼NW¼NW¼ sec. 4, T. 3 S., R. 14 W., Saline County. Named for settlement of Detonti. Crops out in irregular northwestward-trending belt up to 3 miles wide and is probably continuous across bauxite region. Cut off at northeast by overlap of sediments higher in section and by Quaternary alluvial sediments of Arkansas River flood plain.

Detroit Glacial Stage

Detroit Till

Pleistocene: Northwestern Oregon.

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 20, 23–24. Stage defined as time during which Detroit till was deposited. All exposures of till are small.

Till crops out in North Santiam River just above bridge and on Quartzville Trail, in a roadcut one-half mile southwest of Berry, where highway crosses Breitenbush River southwest of Detroit, Marion County.

Detroit River Group

Detroit River Dolomite[1]

Middle Devonian: Southeastern Michigan and northern Ohio, and western Ontario, Canada.

Original reference: A. C. Lane and others, 1909, Geol. Soc. America Bull., v. 19, p. 555.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1754–1755, chart 4. Group, as now understood, includes Sylvania sandstone at base. Maximum thickness 1,000 feet in wells in central part of Southern Peninsula of Michigan; outcrop thickness commonly less than 200 feet. Wherever base of Sylvania is exposed, its contact with underlying rock is disconformable, and disconformity widens on leaving Michigan basin. In western Lake Erie region, the Sylvania lies on Bass Island[s] (Upper Silurian) beds, but unconformity includes at least part of Lower Devonian as indicated by Lower Devonian ostracoderms in pre-Sylvania stream deposit. If this disconformity is followed to farthest limits of Michigan basin province, the base of the "Sylvania" basal sand will rise in the column. This far-out "Sylvania" sand is probably to be found in Pendleton of Indiana, Hillsboro sandstone of southern Ohio, and Springvale sandstone in region around Cayuga, Ont. In first two cases, unconformity is so wide that it rests upon Niagaran limestones. Beds covering Detroit River vary in age from place to place, indicating disconformity at top, but not as great as one at base. Overlying rock at Sibley, Mich., northwestern Ohio, and Amherstburg, Ont., are of Dundee age; in Bruce and Huron Counties, Ont., overlying rock is lower Onondaga; on Mill Creek, Cheboygan County, Mich., group is said to contain a Schoharie fauna and is overlain by *Amphigenia*-bearing Mackinac breccia.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 127–128. Group, in Ohio, comprises Amherstburg and Lucas formations. Underlies Columbus formation; overlies Oriskany.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv., Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 35 (table 1), 109–120. Discussion of geology of Mackinac Straits region. Detroit River strata are regarded as a group but not differentiated into formations. In southeastern Michigan, southwestern Ohio, and northwestern Ohio, Detroit River dolomites and Sylvania sandstone are underlain by Middle Devonian Dundee limestone. In Mackinac Straits area, the group is underlain by Bois Blanc formation (new). In Rogers City area and apparently elsewhere in northern part of Southern Peninsula, the group is overlain by Dundee limestone. Most of the rocks of the group in northern part of Southern Peninsula are covered with Pleistocene gravel several hundreds of feet thick. Thickness of group difficult to determine. Well records indicate thickness of about 700 feet in northern part of Southern Peninsula.

G. M. Ehlers, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1455–1456. Succession of Detroit River formations above Sylvania sandstone as given by Lane and others (1909) has been doubtful matter in mind of several geologists for many years. No evidence has been obtained to prove that Lane and his associates were incorrect in believing that the Sylvania is succeeded respectively by Flat Rock dolomite, Anderdon limestone, Amherstburg dolomite, and Lucas dolomite. Present studies indicate that oldest unit of the group, the Sylvania sandstone, is succeeded respectively by Amherstburg dolomite, Lucas dolomite, and Anderdon limestone. Flat Rock dolomite cannot be distinguished in outcrop or in well borings as distinct formation. Strata of this dolomite are part of Amherstburg dolomite. Term Flat Rock should be dropped from stratigraphic nomenclature. Middle Devonian.

K. K. Landes, 1951, U.S. Geol. Survey Circ. 133, p. 1–23. Correlation of outcropping rocks in type locality of Detroit River group with thick sequence of rocks in subsurface Michigan Basin. Surface nomenclature as revised by Ehlers (1950) is suggested for subsurface section in place of heterogeneous collection of names now used. Sylvania sandstone is placed in Detroit River group and reduced to member status in Amherstburg formation. Group comprises Amherstburg formation below and Lucas formation above. In subsurface, the group is overlain by Dundee formation except in southwestern Michigan where Dundee is absent. Overlies Bois Blanc formation except in western and southern Michigan where it overlies rocks of Silurian age. Anderdon limestone not identified in subsurface.

Named from exposures along Detroit River, Mich.

Devils Flow

Devils Hill Obsidian Flow

Recent: Southwestern Oregon.

E. T. Hodge, 1925, Oregon Univ. Pub., v. 2, no. 10, p. 56, 60 (fig. 44). Discussion of Mount Multnomah ancient ancestor of the Three Sisters. Name Devils flow applied to flow that extends eastward from Devils Hill and covers about one-fourth square mile.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, no. 3, p. 58. Referred to as Devils Hill obsidian flow in report on volcanoes of Three Sisters region. May be among youngest rocks of region.

Devils Hill is south of South Sister Mountain and between Le Conte and Cayuse Craters.

Devils Canyon Member (of Modin Formation)

Upper Triassic: Northern California.

A. F. Sanborn, [1953], Stanford Univ. Abs. Dissert, v. 27, p. 436. Middle member of formation. Underlies Kosk member (new); overlies Hawkins Creek member (new).

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6, 10–11, pl. 1. Formal proposal of name. Composed principally of massive dark-gray tuffaceous limestone, calcareous tuff, fine- to medium-grained calcareous sandstone, and nearly pure limestone lenses. Thickness 430 to about 1,000 feet. Overlies Hawkins Creek member; underlies Kosk member.

Type section: Devils Canyon, Big Bend quadrangle, Shasta County. Upper contact about one-half mile west of confluence of Devils Canyon and Alder Creek; lower contact three-quarters mile west.

Devils Den Limestone (in Graford Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: E. Böse, 1918, Texas Univ. Bull. 1758, p. 17.
Covers west side of Jim Ned Mountains, Wise County. Probably named for occurrence in Devils Den.

Devils Den Sandstone[1]

Upper Devonian or Mississippian: Northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1935, Geol. Soc. America Bull., v. 46, no. 2, p. 332, 333 (footnote), 335, 336, 339.

Type locality not stated.

Devils Gate Limestone

Middle and Upper Devonian: Eastern Nevada.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 16–17. Name applied to upper 2,065 feet of Devonian strata exposed at Devils Gate and Modoc Ridge east of Yahoo Canyon. Overlies Nevada formation (restricted and redefined); underlies unit referred to as Diamond Peak series (includes Diamond Peak quartzite and White Pine shale).

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 48–52. Described in vicinity of Eureka where it consists largely of thick-bedded gray to blue-gray limestone that is cliff forming in most places. Thickness ranges from about 675 feet east of Phillipsburg mine in Diamond Mountains to 2,065 feet in combined sections at Devils Gate and Modoc Peak. On Newark Mountains and in southern end of Diamond Mountains, two members distinguished: Meister limestone below and Hayes Canyon limestone above. Overlies Nevada formation (Bay State member, new); underlies Pilot shale. In original description, formation was defined almost wholly on basis of faunas, lower boundary placed at top of zone containing *Stringocephalus*, and upper one marked by disappearance of *Crytospirifer* ("*Spirifer disjunctus*") fauna. Results of present study indicate there is adequate lithologic basis for establishing limestone as separate stratigraphic unit consistent with paleontologic definition. Middle and Late Devonian, time boundary apparently lies in upper half of Hayes Canyon limestone member.

Donald Carlisle and others, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2181 (fig. 3), 2184. In Sulphur Springs and Pinyon Ranges, overlies Telegraph Canyon member (new) of Nevada formation.

Type section: At Devils Gate, 8 miles northwest of Eureka, Eureka County.

Devils Glen Dolomite[1]

Upper Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 40.

Charles Deiss, 1939, Geol. Soc. America Spec. Paper 18, p. 30, 46–47, 54 (fig. 6). Top of Middle Cambrian in area. Conformably overlies and is transitional into Switchback shale; underlies White Ridge limestone. Thickness at type locality 565 feet.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 8, p. 1131 (table 1), 1133–1134. In Sawtooth Range, consists of white-gray to pale-buff-gray, finely crystalline thick- and some thin-bedded dolomite; mottled salmon pink and coarser grained in upper part. Thickness 200 to 250 feet. Overlies Switchback shale. Unconformable below unnamed Devonian formations. Upper Cambrian.

Type locality: Northern spur of Monitor Mountain, south of North Fork of Dearborn River, in SW¼ sec. 6, NW¼ sec. 7, T. 17 N., R. 7 W., Lewis and Clark Range. Named from narrow and partly boulder filled section of North Fork of Dearborn River known as Devils Glen.

Devils Grave Sandstone (in Mancos Shale)

Upper Cretaceous: Northwestern Colorado.

R. E. Kucera, 1959, Rocky Mountain Assoc. Geologists [Guidebook] 11th Field Conf., Symposium, p. 41, 43, figs. 3, 4. Sequence of alternating yellowish-brown fine-grained sandstone and dark-brown sandy shale. Zone is 50 feet thick and lies 1,350 feet below top of Mancos shale.

Forms Devil's Grave, a conspicuous escarpment and mesa 3½ miles northwest of Yampa.

Devils Gulch Beds[1]

Miocene and Pliocene: Northwestern Nebraska.

Original reference: E. H. Barbour and H. J. Cook, 1917, Nebraska Geol. Survey, v. 7, pt. 19, p. 173.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 18, 35. Although this term has been less used, it precedes Valentine and was adequately defined, stratigraphically, from the first, in terms of what was then known; if redefined, it is available to replace Valentine formation, if the latter be considered preoccupied or unduly ambiguous.

Present in Brown County.

Devils Hill Pumice

Pleistocene to Recent: Southwestern Oregon.

B. N. Moore, 1934, Jour. Geology, v. 42, no. 4, p. 360 (fig. 1). Devil Hill pumice shown on map showing distribution of pumice sheets of Crater Lake region.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 70 (fig. 16). Devils Hill pumice shown on map showing distribution and thickness of Crater Lake pumice.

Devils Hill is north of Crater Lake.

Devils Hole Dolomite

Middle Silurian (Lockportian): Western New York.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser., no. 1. Eastwardly thinning wedge of dolomite carrying Guelph fauna. Underlies Oakfield limestone (new); overlies Eramosa dolomite. Replaces preoccupied Lower Shelby of Clarke (1903).

Type section: Devils Hole State Park, in Niagara Gorge.

Devils Hole Formation

Miocene(?): Southeastern Colorado.

E. H. Baltz, Jr., 1955, U.S. Atomic Energy Comm. Trace Elements Mem. Rept. TEM-929, p. 31. Incidental mention.

R. B. Johnson and G. H. Wood, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 719, fig. 2. Sequence of water-laid volcanic rocks; mainly of beds of light-gray conglomeratic tuff. Matrix is tuffaceous. Coarse material is poorly sorted mixture of pebbles and cobbles of pumice, perlite, gneiss, and schist. Beds generally lenticular and cross stratified. May be thin to massive bedded. Thickness ranges from 25 to 1,300 feet. Intertongues westward with red conglomeratic sandstone. Unconformably overlaps Farisita conglomerate (new) and older rocks of Cenozoic, Mesozoic, and Paleozoic age.

Named from exposures in Devil's Hole in north-central part of Huerfano Park. No type section described because of scarcity of and discontinuity of outcrops.

Devils Hollow Member (of Cynthiana Formation)

Devils Hollow division of (Lexington Limestone)

Devils Hollow facies (of Cynthiana Formation)

Middle Ordovician: North-central Kentucky.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1640. Name proposed for the post-Woodburn "Perryville" of the upper Lexington limestone in the Frankfort-Versailles area. Term Perryville formerly applied to these beds is now considered a synonym of Benson. The 25 feet at type section includes 15 feet of the "Faulconer" rock and 10 feet of the "Salvisa." Regarded as a facies of the upper Woodburn and probably also lowermost Cynthiana.

F. H. Hall and W. N. Palmquist, Jr., 1960, U.S. Geol. Survey Hydrol. Inv. Atlas HA-23. Referred to as Devils Hollow facies of Cynthiana formation.

U.S. Geological Survey currently classifies the Devils Hollow as a member of Cynthiana Formation on basis of a study now in progress.

Type locality: Devils Hollow Road, a few miles west of Frankfort, Franklin County.

Devils Island Sandstone (in Bayfield Group)[1]

Precambrian: Northwestern Wisconsin.

Original reference: F. T. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 38.

G. O. Raasch, 1950, Illinois Acad. Sci. Trans., v. 43, p. 147. Thwaites' Chequamegon is considered to be Port Wing brownstone member of Orienta repeated by faulting. Contact of Chequamegon formation with supposedly underlying Devils Island formation is reported by Thwaites only from type locality, Devils Island. Beds here that Thwaites considered to be basal Chequamegon are believed to be part of the Devils Island.

Named for exposures on Devils Island, Ashland County.

Devils Kitchen Member (of Deese Formation[1] or Group)

Pennsylvanian (Desmoinesian) : Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40-Z, p. 14-15.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum Geology of southern Oklahoma—a symposium, v. 2: Tulsa, Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 31. Devils Kitchen member of Deese group, is about 500 feet thick. At base is medium-grained buff sandstone about 100 feet thick, locally split into two members separated by shale. Above this is shale interval from 100 to 200 feet thick, containing toward top 10 feet or more of fossiliferous impure limestone and calcareous shale. Above this is 200-foot sandstone which, near Ardmore, contains chert grains, and southeastward from Ardmore develops into a coarse conglomerate of angular to subangular chert pebbles. Overlies unnamed sandstone and shale below Arnold limestone. Desmoinesian.

Named for glen in sec. 10, T. 6 S., R. 2 E., Carter County.

Devils Lake Sandstone[1]

Upper Cambrian: Central southern Wisconsin.

Original reference: E. O. Ulrich, 1920, Washington Acad. Sci. Jour., v. 10, p. 74, 75.

F. T. Thwaites, 1943, Michigan Acad. Sci., Arts, and Letters, Papers, v. 28, p. 487. Reaffirms abandonment of name by Wanenmacher, Twenhofel, and Raasch (1934).

First described in vicinity of Devils Lake, Sauk County.

Devils Pocket Formation (in Big Snowy Group)

Pennnsylvanian: Central Montana.

H. D. Hadley and P. J. Lewis, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 143. Dolomite and limestone, partly sandy to siliceous, commonly red stained. Thickness ranges from 0 to 150 feet. Overlies Alaska Bench formation. Name credited to L. S. Gardner.

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 332 (fig. 2), 334 (fig. 3), 336 (fig. 4), 347-348. Included in Big Snowy group. Conformably succeeds Alaska Bench limestone; overlain with probable unconformity by rocks of unknown late Paleozoic or post-Paleozoic age. Formation was removed by pre-Ellis erosion nearly everywhere in central Montana, and has been recognized in outcrop only by vicinity of Stonehouse Ranch, sec. 32, T. 11 N., R. 21 E., where entire formation, 143 feet thick, is exposed, and at Durfee Creek dome where lower 71 feet remain. Type section designated.

Type section: In Road Canyon, sec. 31, T. 11 N., R. 21 E., about one-half mile west of Stonehouse Ranch. Name derived from Devils Pocket, an anticlinal valley on a long anticlinal nose breached by erosion in southeastern Big Snowy Mountains (T. 10 N., R. 21 E.), where formation is 141 feet thick.

Devils River Limestone[1]

Lower Cretaceous (Comanche Series) : Southwestern Texas.

Original reference: J. A. Udden, 1907, Augustana Lib. Pub. 6, p. 56.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol Survey Prof. Paper 312, p. 8-9, pl. 1. Oldest rock exposed in Terlingua district. Consists of sequence of medium- to thick-bedded fine-grained limestone, light to dark gray on fresh surface and gray on weathered surface. Thickness more than 1,500 feet in cliffs of Mesa de Anguila, base not exposed. Conformably underlies Grayson formation. In rim of the Solitario where base is exposed, conformably overlies impure limestone containing Glen Rose fossils.

Named for exposures along entire length of Devil's River, Valverde County, from Camp Hudson down to the Rio Grande.

Devils Slide Syenite

Mississippian(?): Northern New Hampshire.

H. W. Jaffe, H. T. Evans, Jr., and R. W. Chapman, 1956, Am. Mineralogist, v. 41, no. 5–6, p. 474, 475–476, 485. Described as typically coarse-grained syenite. Includes a medium-grained subporphyritic greenish-gray to bluish-gray fayalite-quartz syenite. One of the major components of the Devil's Slide ring dike. Belongs to the White Mountain plutonic volcanic series.

Occurs northwest of the village of Stark, Percy quadrangle.

Devilwater Silt Member (of Monterey Formation)

Miocene, middle: Central California (subsurface and surface).

W. C. Bailey, 1939, California Oil Fields, v. 24, no. 3, p. 67. Devilwater silt shown on composite columnar section of Wasco oil field. Overlies Gould shale; underlies McDonald shale.

R. R. Simonson and M. L. Krueger, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1611 (fig. 2), 1616. Monterey shale in southern part of Temblor can be subdivided into three lithologic and faunal units, lowest of which is Devilwater-Gould member. At type area of Temblor formation, in vicinity of Chico Martinez Creek, the Devilwater silt, Gould shale, and "Buttonbed" sandstone lens are distinct faunal and lithologic units characterized, respectively, by the *Valvulineria californica*, *Valvulineria robusta*, and "*Scutella*" *merriami* faunal zones. In Recruit Pass area [this report], an interval of 1,850 feet of well-bedded siliceous light-brown shale, with minor amount of interbedded tan silt and lentils of massive buff limestone, comprise a single lithologic unit from which have been collected faunules common to both Gould shale and Devilwater silt as they are defined on Chico-Martinez Creek. This unit is referred to as Devilwater-Gould member of Monterey. Underlies McDonald shale; overlies Temblor-Vaqueros.

L. B. McMichael, chm., 1959, San Joaquin Geol. Soc. Guidebook Field Trip, May 9, Road log, topog. profile, chart, map. Devilwater silt member underlies McDonald shale member and overlies Gould shale member in Chico Martinez Creek area. Thickness about 1,180 feet.

Shown on stratigraphic column of Wasco oil field, Kern County, at depths of 11,300 to 11,500 feet.

Dewdney Formation[1]

Precambrian: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Survey Mines Mem. 38, map 7.

Named for Dewdney Trail, British Columbia.

Dewdney Creek Formation or Group

Dewdney Creek Series[1]

Jurassic and Cretaceous: Southern British Columbia, Canada, and northeastern Washington.

Original reference: C. E. Cairnes, 1923, Canada Geol. Survey Summ. Rept. 1922, pt. A, p. 97, 111.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map 1–175, p. 5 (table 2). Termed a formation; geographically extended into northeastern Washington.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull. 71, no. 10, p. 1534, chart 10e (column 58). Formation was listed by McKee and others (1956) as partly of Jurassic age. In Princeton area of British Columbia (Rice, 1947, Canada Geol. Survey Mem. 243), the upper 7,200 feet of Dewdney Creek group contains fossils definitely of Early Cretaceous age.

First described in British Columbia.

Dewey Limestone[1] (in Skiatook Group)

Dewey Limestone Member (of Drum Limestone)

Pennsylvanian (Missouri Series): Northeastern, central, and central northern Oklahoma and eastern Kansas.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 30, 37.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 51–56; 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 720 (table 1), 725. Included in Skiatook group. Underlies Chanute formation; overlies Nellie Bly formation.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030. Northward tracing proves that Dewey member of Drum is the same as limestone called Cement City in Kansas City area. Dewey has priority over Cement City and is recognized as a formational unit in Oklahoma. Kansas Geological Survey proposes to use Dewey in place of Cement City for lower member of the Drum. Other State surveys will continue Cement City until question of stratigraphic identity of the type of this unit (near Kansas City) and the Dewey is removed.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 68–72. Described in Okfuskee County where it consists of a lower limestone or arenaceous limestone member and an overlying shale. Base is about 40 feet above uppermost Nellie Bly sandstone. Type locality stated.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 25–28. In a study of gas and oil fields of Indian Territory, the Drum limestone was traversed by G. I. Adams from outcrop west of Coffeyville to Bartlesville. It occurs on divide between the Verdigris and Caney, extending southward to Hogshooter Creek, thence northwestward to Bartlesville (Adams, Girty, and White, 1903, U.S. Geol. Survey Bull. 211). It is evident from text and map that Adams was following Hogshooter limestone from Kansas-Oklahoma line to SE cor. T. 26 N., R. 13 E., where he stepped up to the Dewey and followed it to Bartlesville. Sandstone and limestone conglomerate were erroneously shown on geologic map of Oklahoma (1926) as Dewey limestone from sec. 13, T. 28 N., R. 14 E., northeastward to Kansas-Oklahoma line across an area in which the Dewey was removed by pre-Chanute erosion. Thickness 20 to 50 feet in Creek County. Overlies Nellie Bly formation; underlies Chanute limestone. Skiatook group.

Type locality: In old quarry of Dewey Portland Cement Co., sec. 26, T. 27 N., R. 13 E., near Dewey, Washington County, Okla.

Dewey Bridge Dolomite

Upper Cambrian: East-central New York.

John Rodgers *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., 1952, Geol. Soc. America Guidebook for Field Trips in New England, p. 35 (table 2), 53 (road log). Dark-gray crystalline and sandy dolomite; cryptozoon layers in upper part and thin sandstone at top. Thickness 200 feet. Underlies Whitehall formation; overlies Potsdam sandstone. Refers to R. H. Flower (unpub. ms.).

Occurs in Fort Ann quadrangle.

Dewey Lake Redbeds

Dewey Lake Formation

Permian: Subsurface and surface in western Texas and southeastern New Mexico.

L. R. Page, 1938, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1709. Incidental mention as Dewey Lake redbeds.

L. R. Page and J. E. Adams, 1940, Am. Asoc. Petroleum Geologists Bull., v. 24, no. 1, p. 62–63. Formation consists of orange-red sandstones and silts. Overlies Rustler formation; underlies Tecovas silts. Occurs between depths of 1,155 feet and 1,407 feet in type well. No complete section found in outcrops hence named from subsurface. Triassic-Permian boundary occurs at top of formation.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 91–92, 101 (fig. 12). Referred to as Dewey Lake red beds. Ochoa series.

G. E. Hendrickson and R. S. Jones, 1952, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 3, p. 23. In Eddy County, redbeds and sandstones correlated with Dewey Lake redbeds overlie Rustler formation.

Type section: In Penn's Habenstreit No. 1 well, near center sec. 47, Block 36, T. 3 S., Texas and Pacific Railroad Survey, Glasscock County, Tex. Name derived from Dewey Lake.

Dewitt Formation[1]

Miocene and Pliocene: Eastern Texas.

Original reference: A. Deussen, 1914, U.S. Geol. Survey Water-Supply Paper 335, p. 28, 74–76.

Named for Dewitt County.

Dexter Member (of Woodbine Formation)

Dexter Member (of Euless Formation)

Dexter Sand Member (of Woodbine Sand)[1]

Upper Cretaceous: Northeastern Texas.

Original reference: J. A. Taff, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 285–298.

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 475, 476, 477. Dexter sand is basal member of newly defined Euless formation.

H. R. Bergquist, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 98. Termed Dexter member of Woodbine formation. In Cooke, Grayson, and Fannin Counties, stratigraphically restricted above to exclude 60 to 70 feet of sandstone and shale herein named Red Branch member. As restricted and redefined, Dexter member consists of 100 to 130 or 140 feet of nonmarine beds of white to ferruginous and siliceous sandstone with silty clay lenses, some carbonaceous clays at base, some scattered leaf and wood prints, and at top a persistent bed of varicolored clay. Overlies Grayson marl.

Named for exposures at Dexter, Cooke County.

Dexterville Shale Member[1] (of Chadakoin Formation)

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 63–66, table opp. p. 61.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 14. Gray sandstones and siltstones that underlie Ellicott member of Chadakoin and overlie Northeast shale member of Canadaway formation. Thickness in Cherry Creek quadrangle about 150 feet. Volusia shale, described by Chadwick (1923), bearing *Pugnoides duplicatus* is here included in the Dexterville. Lillibridge sandstone (Caster, 1934) member of Chadakoin is not a distinct lithologic unit and is abandoned.

Named for brick quarries, south of Chadakoin River in East Jamestown, a district formerly known as Dexterville, Chautaqua County, N.Y.

Deza Formation

Tertiary: Northwestern New Mexico and northeastern Arizona.

H. E. Wright, Jr., 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1830, 1831–1833, figs. 1, 2. Consists largely of sands with some layers of shale and clay and marked by a basal conglomerate. Color mostly white to buff and light green with a few beds of chocolate red clay. Appears to be largely an alluvial deposit. Thickness 250 feet in type area. Overlies Mesaverde group with angular unconformity and underlies Chuska sandstone.

Named for exposures 3 miles north of Tohatchi on south-facing scarp (Deza Bluffs) which lead up to the landslide-covered east foot-slope of Chuska Mountains, N. Mex.

Diablo Formation

Permian: Southwestern Nevada.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1953, Geology of the Coaldale quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-23]; 1954, U.S. Geol. Survey Geol. Quad. Map. 45. Dolomite with varying amounts of basal conglomerate and locally fanglomerate. Along western border, largely dolomite, but conglomerate and grit form isolated hill southeast of Redlich; in Monte Cristo Range, basal conglomerate overlain by interbedded dolomite, grit, and conglomerate. To west, in Mina quadrangle, dolomite grades into sandstone and grit. Thickness in Monte Cristo Range probably about 500 feet. Elsewhere not over 300 feet; missing in places: unconformable contacts with Palmetto formation below and Candelaria formation above.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ-40. Described and mapped in Round Mountain quadrangle where it is more than 3,000 feet thick in Toyabe Range. Underlies Pablo formation (new).

B. M. Page, 1959, Nevada Bur. Mines Bull. 56, p. 18–21, pl. 1. In Candelaria mining district, Mineral County, a thin grit bed, the Diablo formation, unconformably overlies Palmetto formation, angular unconformity ranging from 5° to 90°. Underlies Candelaria formation. Thickness as much as 30 feet.

Type locality: For sandstone, crest and west slope of Mount Diablo, 1 mile west of Candelaria, Mina quadrangle; for dolomite facies, 1 mile north of Columbus, Mina quadrangle.

Diablo Formation

Pliocene, lower: Northern California.

B. L. Clark, 1944, *in* C. E. Weaver and others, Geol. Soc. America Bull., v. 55, no. 5, p. 585, chart 11. Consists of coarse arkosic sandstones; a heavy conglomerate at base composed mostly of andesitic boulders with lenses of conglomerate higher up; also thin layers of shale carrying abundant leaf impressions. Thickness about 1,000 feet. Shown on chart as underlying Green Valley formation and overlying Neroly formation. Replaces name Alamo formation.

D. I. Axelrod, 1944, Carnegie Inst. Washington Pub. 553, p. 213. Derivation of name given.

Name derived from Diablo post office, Mount Diablo region.

†Diabolo Sandstone[1]

Precambrian: Western Texas.

Original reference: W. H. Von Streeruwitz, 1891, Texas Geol. Survey, v. 2, p. 682, 683.

Occurs along foot of southern cliffs of Sierra Diabolo, Sierra Diablo region.

Diamond Formation[1]

Pleistocene, upper, or Recent: Southeastern Oregon.

Original reference. W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Typically exposed at Diamond Craters, Harney County.

Diamond Creek Sandstone

Permian: Northeastern Utah.

A. A. Baker and J. S. Williams, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 623 (fig. 4), 625. Gray or buff to red, fine- to coarse-grained cross-bedded sandstone, in large part lime-cemented and friable but locally silica-cemented. Thickness 600 to 1,000 feet. Conformably underlies Park City formation; conformably overlies Kirkman limestone (new).

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 589. Described in Strawberry Valley quadrangle. Traced as almost continuous outcrop from southern Wasatch Mountains northward where it passes beneath Tertiary sediments in Strawberry Ridge; reappears in North Strawberry Valley as thin outcrop band and extends almost due northeast of and overlying Kirkman limestone from Willow Creek

Canyon to point near mouth of Right Fork of Strawberry River. From known maximum thickness of 1,140 feet in Spanish Fork Canyon near Castilla, thins northward to 165 feet in North Strawberry Valley.

Named for outcrops in sec. 22, T. 8 S., R. 4 E., near head of Little Diamond Creek, Utah County.

Diamond Head Black Ash

Recent: Oahu Island, Hawaii.

C. K. Wentworth, 1937, Jour. Sed. Petrology, v. 7, no. 3, p. 91–103. Black sandy vitric ash, pisolitic. Typical mantle bedding; very small proportion of bedding of clear, wind-produced or dune characteristics.

H. T. Stearns, 1940, Hawaii Div. Hydrog. Bull. 5, p. 53. Five distinct eruptions occurred along Kaimuki-Diamond Head rift, namely Mauumae basalt, Diamond Head ash, Kaimuki basalt, Black Point basalt, and Black Point ash. Eruption must have taken place in Recent time while sea was practically at its present level.

Type locality: On slopes and near base of Diamond Head. Crops out only in small area at southeast foot of Diamond Head tuff cone and on Black Point.

Diamond Head Talus Breccia[1]

Recent: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 40, 43.

G. A. Macdonald and D. A. Davis, 1956, *in* Jacques Avias and others, Lexique Strat. Internat., v. 6 Océanie, fasc. 2, p. 80. Talus breccia composed of angular fragments of Diamond Head tuff cemented by calcareous cement into a porous fairly compact mass. Thickness commonly 5 to 25 feet, exceptionally up to 50 feet. Rests against and on Diamond Head tuff. No fossils. Some of it is older than Diamond Head black ash, but some of it is still forming.

Named for occurrence on slopes of Diamond Head.

Diamond Head Tuff[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 40, 42.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 80–81. Palagonitized subaerial brown tuff containing many accessory and accidental ejecta including many fragments of reef limestone and some of Koolau basalt. Magma is nepheline basalt. Thickness about 900 feet. Rests on reef limestone believed to have been formed during plus 95-foot (Kaena) stand of sea; overlain locally by beach limestone of plus 25-foot (Waimanalo) stand. Overlain by Kaimuki and Black Point basalts.

Type locality: Diamond Head. Covers about 1.3 square miles on south coast of Oahu about 10 miles west of Makapuu Head.

Diamond Hill Felsite[1]

Carboniferous: Northeastern Rhode Island.

Original reference: C. H. Warren and S. Powers, 1914, Geol. Soc. America Bull., v. 25, p. 461.

Diamond Island Slate (in Casco Bay Group)[1]

Pennsylvanian(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour. v. 7, p. 198.

Named for exposures on Great Diamond Island and Little Diamond Island in Casco Bay.

Diamond King Member (of Esmeralda Formation)[1]

Miocene, upper, and Pliocene, lower: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

Prominent on Diamond King Hill, Manhattan district.

Diamond Peak Formation

Diamond Peak Quartzite[1]

Diamond Peak Series or Beds

Upper Mississippian: Northern Nevada and eastern California.

Original reference: Arnold Hague, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 28; 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 268.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 8 (table 1), 43–46. Diamond Peak series used to apply to post-Devils Gate sedimentary rocks in Roberts Mountains region. Used in preference to extending Hague's White Pine shale and Diamond Peak quartzite into area. Further work in post-Devils Gate deposits may lead to redefinition of Diamond Peak formation and necessitate revised terminology for beds in Devils Gate area.

C. W. Merriam and C. A. Anderson, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1690–1691. Term Diamond Peak beds used to include not only original Diamond Peak quartzite of Diamond Peak (Eureka district) but also underlying black shales and sandy interbeds referred by Hague (1892, U.S. Geol. Survey Mon. 20) to White Pine shale. "Diamond Peak quartzite" included large percentage of conglomerate at Diamond Peak; hence, lithologic term is misleading. Because stratigraphic relations of true White Pine formation in White Pine district are not well understood, it appears undesirable to use this term for dark shale in Eureka and Roberts Mountains area.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 57, 60–61. Proposed to use term Diamond Peak formation, in Eureka district, for the coarse clastic part of upper Mississippian sequence where it can be satisfactorily separated from underlying black shales and to adopt Spencer's name of Chainman shale for lower unit where it can be mapped separately. Hague characterized Diamond Peak as quartzite, but even at this type locality, unit contains large proportion of shale, conglomerate, and limestone; hence, term formation seems more appropriate. Formation mapped separately only south of Eureka, elsewhere equivalent beds are included in Chainman and Diamond Peak undifferentiated sequence. Thickness as much as 420 feet. Underlies Ely limestone. Discussion of problems of nomenclature and correlation of upper Mississippian sedimentary rocks in area.

Walter Sadlick, 1960, Intermountain Assoc. Petroleum Geologists 11th Ann. Field Conf., p. 84. Discussion of aspects of Chainman stratigraphy. The Chainman is recognized as valid stratigraphic unit. Diamond

Peak and Scotty Wash are referred to as facies within the Chainman. Term Illipah suppressed as synonymous with the Diamond Peak.

Named for exposures on flanks of Diamond Peak, Eureka district, Nevada.

Diamond Rock Quartzite[1]

Diamond Rock Quartzite Member (of Schodack Formation)

Lower Cambrian: Eastern New York.

Original reference: R. Ruedemann, 1914, New York State Mus. Bull. 169, p. 67–70.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 64. Schodack formation, in Troy and Cohoes quadrangles, includes as members (ascending) Bomoseen grit, Diamond Rock quartzite, Troy shale and limestone, and Schodack shale and limestone.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 331. Dale's (1904, U.S. Geol. Survey Bull. 242) division G in Rensselaer County, was named by Ruedemann (1914) from type locality at Diamond Rock overlooking North Troy. Ruedemann states that formation occurs only at this locality, but Dale (1904) reported it farther east and west. In type area, the Diamond Rock is variable: hard quartzite with infrequent quartzite pebbles, lenses of a breccia of quartz pebbles in dark-gray matrix, rare thin beds of dolomite, a reddish- to orange-weathering sandstone with well-rounded frosted quartz grains in calcic or dolomite cement, and a yellow-stained calcareous sandstone with poorly preserved fauna tentatively identified as *Hyolithes*, *Paterina*, *Rustella*, *Microdiscus*, and olenellid fragments. Possibly beds are repeated due to faulting and (or) folding, so true thickness in indeterminable; probably no more than 50 feet. Whether Diamond Rock is correlate of Eddy Hill grit is conjecture.

Named for exposures at the "Diamond Rock," Lansingburgh (North Troy, N.Y.).

Diamond Valley Complex

Paleozoic and (or) Mesozoic: Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 477–479. Series of strongly metamorphosed sediments, with associated metatuffs, commonly injected lit-par-lit with granitic material. In type area, dips are steep, and strike is northwesterly over ridge; exposed thickness not accurately known, but is some thousands of feet.

Type area: Ridge 4 miles in length east and southeast of Winchester, Riverside County. Named for exposures on north side of Diamond Valley.

Diana Complex

Diana Syenite Complex[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1919, New York State Mus. Bull. 207, 208, p. 102–110, map.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 73–109. Diana quartz syenitic complex consists of eight facies. In this report, they are discussed in detail in order of their occurrence from northwest to southeast, and which, on their interpretation as parts of a stratiform sheet, would be from bottom to top. Pitcairn gneiss (new) and Grenville limestone border main complex on northeast. Pyroxene quartz syenite outcropping in southeast part of Lowville quadrangle, and for an unknown distance to southeast, is mapped as part of the Diana, though it may belong with Santa Clara complex or may be a separate sheet.

Named from Diana Township, Lake Bonaparte quadrangle, within which the central part of the complex lies. Forms northwest border of Adirondack highlands, from Carthage to South Edwards.

Diana Formation

Silurian: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). Named on cross section and structure section in report on Paleozoic continental margin of central Nevada. Underlies Masket formation (new); overlies Antelope Valley formation.

Toquima Range, Nye County.

Diana Granite (in Cerbat Complex)

Precambrian: Northwestern Arizona.

B. E. Thomas, 1949, Econ. Geology, v. 44, no. 8, p. 666, fig. 2. Coarsely porphyritic granite which occupies core of a distinctive anticline preserved in schists of Cerbat complex (new).

B. E. Thomas, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 400–401, pl. 1. Rock is medium gray on fresh fracture and weathers light to moderate brown. Many outcrops show weak foliation, and some exposures are highly gneissic or mylonitic. Porphyritic texture with medium-grained groundmass. Body is roughly circular, with diameter of about 1¾ miles.

Named from Diana (Arizona Magma) mine, which is approximately in center of the exposure, in western half of Chloride district, Cerbat Mountains, Mohave County.

Diboll Member[1] (of Jackson Formation)

Eocene: Southeastern Texas.

Original reference: I. R. Sheldon, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 7, p. 819, 820, 822.

In Driscoll pool, Duval County.

Dick Rhyolite

Precambrian: West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 12, pl. 3. Porphyritic rock containing quartz phenocrysts in microcrystalline groundmass. Forms intrusive masses. Locally is foliated, becoming a quartz-sericite schist. Distinguished from King Peak rhyolite (new) by presence of phenocrysts in Dick rhyolite. Probably younger than King Peak rhyolite. Intrudes Bridle formation and Butte Falls tuff (both new). Pattern of outcrops indicates that it also intrudes King Peak rhyolite.

Large mass is exposed on Dick Peak, for which the rock has been named, in south-central part of Bagdad area, Yavapai County. This mass, more than 2,000 feet wide, has been mapped for distance of 1 mile. and extends southward beyond the mapped area.

Dickerson Formation (in Millsap Lake Group)

Dickerson Member (of Millsap Lake Formation)[1]

Pennsylvanian (Strawn Series): North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation. Basal formation of group. Underlies Kickapoo Falls member of Lazy Bend formation; overlies unnamed subsurface units.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 45 ,no. 2, p. 163. Kickapoo Falls limestone may well be classified as top member of Dickerson formation in harmony with common practice in this region [Texas] of placing an important limestone at top of formation.

Exposed in Brazos River valley.

Dickinson Group

Precambrian: Northern Michigan.

R. W. Bailey, 1956, Dissert, Abs., v. 16, no. 8, p. 1426. Name used in discussion of lower Precambrian rocks of Lake Mary quadrangle, Iron County. Composed chiefly of metavolcanic schist. Underlies core area of Holmes Lake anticline, which is flanked by steeply dipping Middle Precambrian (Huronian) formations. Major unconformity separates Dickinson group from overlying Middle Precambrian rocks.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 27 (table 1), 31. Name applied to a sequence of lower Precambrian rocks—Archean of older reports—consisting of metamorphosed sedimentary and volcanic rocks. Strata unconformably overlie older granite gneiss and have been invaded by granitic rocks of batholithic dimensions. In central Dickinson County, group is divided into three formations: East Branch arkose (oldest), Solberg schist, and Six-Mile Lake amphibolite. Rocks are steeply dipping or vertical and sequence is believed to be conformable. Separated by covered interval from strata of group is newly defined Hardwood gneiss, which may be in part or wholly equivalent in group.

Named for Dickinson County where group occurs in an easterly trending belt about 4 miles wide in central part of T. 42 N., R. 28, 29, and 30 W.

Dicksburg Hills Sandstone

Upper Pennsylvanian: Southwestern Indiana.

C. A. Malott, 1939, (abs.) Indiana Acad. Sci. Proc., v. 48, p. 114. Overlies Hazleton Bridge formation (new).

C. A. Malott, 1947, Indiana Acad. Sci. Proc., v. 57, p. 131, 133 (fig. 2), 134 [1948]. Massive coarse-grained micaceous friable crossbedded sandstone. Thickness at type locality 50 feet. Unconformably overlies Hazelton Bridge formation; underlies Parkers formation. To the south, the sandstone was mapped as a part of Fuller's Inglefield formation (Ditney and Patoka folios of U.S. Geological Survey). Type locality designated.

Type locality: In "The Rock Bluffs," SW¼ sec. 18, T. 1 N., R. 10 W., in northeastern part of the western hill of the Dicksburg Hills, Knox County.

Dicks River facies (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 117–119. Predominantly shale with a middle zone of massive cliff-forming siltstone, Gum Sulphur siltstone member (new), up to 40 or more feet thick. Average thickness of facies about 125 feet. Merges with Junction City facies (new) on west and with Boone Gap facies (new) on east. Underlies Brodhead formation (new) [Irvine facies]; overlies New Albany black shale.

Typical section: Along steep slope at north side of Dicks River valley, immediately west of confluence with East Fork, half a mile north of Brodhead, Rockcastle County. Named for Dicks River in northwestern part of county.

Dierks Limestone (in Trinity Group)

Dierks Limestone Lentil (of Trinity Formation)[1]

Lower Cretaceous (Comanche): Southwestern Arkansas.

Original reference: H. D. Miser and A. H. Purdue, 1918, U.S. Geol. Survey Bull. 690–B.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Rank raised to formation in Trinity group. Underlies Holly Creek formation; overlies Delight sand (new). Subsurface equivalents discussed.

Named for exposures near Dierks, Howard County.

Difficulty Creek Latite[1]

Miocene or Pliocene: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1907, U.S. Geol. Survey Geol. Atlas, Folio 153.

Cut by wild canyon of Difficulty Creek, Ouray region.

Dighton Conglomerate[1]

Pennsylvanian or Permian(?): Southeastern Massachusetts and Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 184–187, pl. 17.

N. E. Chute, 1950, Bedrock geology of the Brockton quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–5]. Permian(?).

Named for occurrence in Dighton, Mass.

Dike Lake Slate

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1034, 1038 (fig. 4). Finely banded and laminated slate containing numerous beds of graywacke and lenses of black cherty slate. Thickness about 1,000 feet. Overlies Saddlebag Lake conglomerate [table and map show Moose Lake conglomerate at this horizon]; unconformable below rocks of Ogishke group.

Occurs in vicinity of Dike Lake, Kekequabic-Ogishkemuncie area.

Dilco Coal Member (of Crevasse Canyon Formation)

Dilco Coal Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1925, U.S. Geol. Survey Bull. 767.

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 90, 92, pl. 1. Reallocated to member status in Crevasse Canyon formation (new). Underlies Dalton sandstone member. Overlies Gallup sandstone. In area of this report [Fort Defiance-Tohatchi quadrangle], consists of 240 feet of silty shale, laminated siltstone, thin coal, and thin- to medium-bedded fine-grained sandstone, the latter being more abundant toward top. Thins toward south to about 81 feet.

Named for Dilco, McKinley County.

Dillard Limestone Member (of Chimneyhill Limestone)

Lower Silurian: South-central Oklahoma.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132, 133. Defined as uppermost unit of Chimneyhill. Consists of two lithologic units, a basal shale, 1 to 2 feet thick, and an upper limestone unit 15 to 18 feet thick. Overlies Cochrane limestone member (new); underlies Henryhouse formation.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 19. Replaced by Clarita member; name Dillard preoccupied. States Maxwell's type locality for Dillard.

Type locality: E½W½SW¼ sec. 8, T. 1 S., R. 8 E. [Coal County.].

†Dillard Series[1] or Formation

Jurassic: Southwestern Oregon.

Original reference: G. D. Louderback, 1905, Jour. Geology, v. 13, p. 522–555.

N. L. Taliaferro, 1941, Geol. Soc. America Bull., v. 52, no. 12, p. 1957. Dillard, as originally defined, includes Knoxville (Upper Jurassic) sediments and possibly infolded Lower Cretaceous, but most of unit is to be correlated with Franciscan.

N. L. Taliaferro, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 71–112. Generally accepted correlations of Jurassic of southwestern Oregon and California are: Galice and Mariposa, Dothan and Franciscan, Myrtle and Shasta. Dothan is stated to be younger than Galice. Has been stated that the Dillard, the lower part of the original Myrtle, is the equivalent of the Franciscan. Since the Dillard unconformably overlies the Dothan and Galice, it is clear that one or other of these correlations must be erroneous. Evidence is presented in present report to show that the Dothan is older than the Galice and cannot be same age as the Franciscan. Dillard, as originally defined, includes Knoxville (Upper Jurassic) sediments and possibly infolded Lower Cretaceous, but bulk of Dillard is to be correlated with Franciscan. It would be unsafe to state that the beds in vicinity of Dillard, Oreg., were Lower Cretaceous on basis of *Aucella "crassicollis."* Lower Cretaceous beds may be present in area covered by Louderback's (1905) Dillard group, but unquestionably the great bulk of Dillard series and that part of Diller's (1907, Am. Jour. Sci., 4th, v. 23) Myrtle in this locality are lithologically identical with Franciscan of Coast Ranges of

California. Discovery of fossils, nearly all species of *Aucella* formerly regarded as indicative of Lower Cretaceous, is not sufficient justification for including beds in vicinity of Dillard, Oreg., (Louderback's Dillard series) in the Myrtle and regarding them as Lower Cretaceous. The Myrtle as mapped and defined, includes beds of both Upper Jurassic and Lower Cretaceous and at least one important unconformity; the Myrtle either should be redefined and restricted or the name abandoned.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, chart 8C (column 97). Shown on correlation chart as Upper Jurassic.

Named for village of Dillard in Roseburg quadrangle.

Dillon Granite Gneiss

Precambrian (pre-Beltian): Southwestern Montana.

E. W. Heinrich, 1953, (abs.) Geol. Soc. America Bull., v. 64, no. 12, pt. 2, p. 1432. A number of post-Cherry Creek intrusives, all of which show varying degrees of metamorphism, include, among others, the Dillion granite gneiss, widespread in Beaverhead and Madison Counties.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 351–352, pl. 1. Introduced by Heinrich (1953) to replace term Blacktail previously used for same unit (Heinrich, 1950) because latter term is preoccupied. A plutonic complex of granite gneisses, pegmatites, aplites, quartz masses, and hybrid gneisses. Most common rock type is a reddish-brown feldspar-quartz gneiss in which bands of pink feldspar and quartz alternate with dark bands of mafic minerals. Complex is most widespread of the pre-Beltian metamorphic rocks. Intrudes rocks of both Pony and Cherry Creek groups.

Crops out over large areas of Blacktail and Tendoy Ranges and of the mountain north of Armstead, Beaverhead, and Madison Counties.

Dilworth Sandstone Member (of McElroy Formation)

Dilworth Sand[1]

Eocene, upper: Southeastern Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1311.

W. L. Russell, 1955, Gulf Coast Assoc. Geol. Soc. Trans., v. 5, p. 166–171. In Grimes and Manning Counties, unit termed Dilworth by Renick (1936, Texas Univ. Bull. 3619) on assumption that it was equivalent to Dilworth of Gonzales County, is here named Tuttle sandstone member of Manning formation.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2626 (table 1), 2630–2631. Termed sandstone and reallocated to member status in McElroy formation (redefined). Overlies Manning clay member; underlies Conquista clay member (new).

Named for exposures about 1 mile east of Dilworth, Gonzales County.

Dime Box Member (of Yegua Formation)

Eocene (Claiborne): Southern Texas.

H. D. McCallum, 1947, South Texas [Geol. Soc. Guidebook] 14th Ann. Mtg. Field Trip, p. 4. Consists of red sand. Basal member of formation; underlies Cistern member (new).

Named after Dime Box, a small settlement in Lee County.

Dimple Limestone

Pennsylvanian: Southwestern Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 46.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 289 (fig. 1). Included in Morrowan stage of Ardian series (new).

T. S. Jones, 1953, Stratigraphy of the Permian basin of West Texas: West Texas Geol. Soc., p. 23. Here included in Bend (Atoka) series.

Named for exposures in and near Dimple Hills, Pecos County.

Dingess Limestone (in Kanawha Formation[1] or group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 165.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 12). Shown on correlation chart in Kanawha group.

Named for Dingess, Mingo County.

Dingess Sandstone (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. D. Teets, Jr., 1919, West Virginia Geol. Survey Rept. Fayette County, p. 926–928.

At Dingess, Mingo County.

Dingess Shale (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia and Kentucky.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties.

Occurs in Kanawha, Fayette, Nicholas, Boone, Logan, and Mingo Counties, W. Va., and in Kentucky.

Dingus Limestone (in Pottsville Formation)[1]

Pennsylvanian: Northeastern Kentucky.

Original reference: L. C. Robinson, 1927, Kentucky Geol. Survey, ser. 6, v. 26, p. 239.

Probably named for Dingus, Morgan County.

Dinosaur Canyon Sandstone Member (of Moenave Formation)

Dinosaur Canyon Sandstone

Upper Triassic(?): Northeastern Arizona and southern Utah.

E. H. Colbert and C. C. Mook, 1951, Am. Mus. Nat. History Bull., v. 97, art. 3, p. 151–153. Proposed for the orange-red sandstone, about 200 feet thick, that overlies the Chinle and underlies about 140 feet of the so-called Wingate below the Kayenta. Contains *Protosuchus*.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2517, 2519. Rank reduced to member status in Moenave formation. Basal member of formation; underlies Springdale sandstone member. Geographically extended into southern Utah.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 13–16, 63. At type locality, consists of sequence of lenticular units predominantly of fluvial origin but which also include large amount of eolian sandstone. Thickness at type locality 202 feet; 307 feet at Moenave; 321 feet at Kachina Point; thins northeast from type locality to 110 feet at Navajo Creek, 28 feet at Piute Canyon, and 47 feet at Steamboat Canyon. At type locality, unconformably overlies Chinle formation; in Navajo Creek area, Arizona, overlies Lukachukai member of Wingate sandstone.

Type locality: Dinosaur Canyon, which joins valley of Little Colorado to east of Cameron, Ariz. Completely exposed in cliffs of Kachina Point, 40 miles northwest of Winslow, Navajo County, Ariz.

†Dinsmore Limestone Bed (in Monongahela Formation)[1]

Pennsylvanian: Southwestern Pennsylvania and southeastern Ohio.

Original reference: W. T. Griswold and M. J. Munn, 1907, U.S. Geol. Survey Bull. 318, p. 69–70.

Named for town of Dinsmore, Washington County, Pa.

Dinwoody Formation[1]

Dinwoody Formation (in Chugwater Group)

Lower Triassic: Western Wyoming, southeastern Idaho, southwestern Montana, and northeastern Utah.

Original reference: D. D. Condit, 1916, U.S. Geol. Survey Prof. Paper 98, p. 263.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 134. Lowermost formation in Chugwater group. Underlies Red Peak formation.

N. D. Newell and Bernhard Kummel, 1942, Geol. Soc. America Bull., v. 53, no. 6, p. 940–945, pl. 1, strat. sections. As originally defined [authors refer to Blackwelder, 1918, Washington Acad. Sci. Jour., v. 8], formation comprised 200 feet of gray and olive-gray shaly siltstones and shales, with thin brown limestones near base. Limits of formation were defined by Phosphoria limestone below and bright red shales and siltstones of Chugwater formation above. Present study reveals that change from gray to red beds does not follow stratigraphic plane but varies in position from place to place, even within a few hundred yards in Dinwoody Canyon. Since color boundary between Dinwoody and Chugwater is not useful or natural boundary, it is proposed to restrict Dinwoody at type locality to include only dominantly silty strata between Phosphoria and top of resistant siltstones about half way toward summit of original Dinwoody. Restricted Dinwoody is 90 feet thick at type locality. Thickness: less than 40 feet southwest of Lander to 120 feet at northwest end of Wind River Mountains; 650 to 700 feet in deeper parts of geosyncline near Afton and Cokeville, Wyo., and Montpelier, Idaho. Three major divisions recognized: basal siltstone; *Lingula* zone, characterized by thin dense limestone and dark-olive shales; and *Claria* zone, characterized by calcareous olive-buff siltstones, with some interbedded hard gray limestones. Successively higher divisions of Dinwoody are progressively more extensive toward north and east across southwestern Wyoming. If upper part of *Claria* zone corresponds to Thomas' (1934) Little Medicine tongue, equivalents of *Claria* zone can be recognized as far to east as southeastern Wyoming. Dinwoody is probably time equivalent of lower part of red-beds section in type area of the Woodside. In much of western Wyoming, Dinwoody is overlain by several hundred feet of red shaly siltstones and sandstone, variously called lower Chugwater, Red Peak, and red Woodside; these red beds belong to same facies as type Woodside but apparently correspond stratigraphically only to about upper half of typical Woodside as defined in Park City area. These red beds between the Dinwoody and Thaynes are regarded as northeastern tongue of Woodside.

W. R. Lowell and M. R. Klepper, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 241. Beaverhead formation (new) unconformably overlies Cretaceous Kootenai, Triassic Dinwoody, and Permian Phosphoria.

H. A. Tourtelot, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM-124. In Badwater area, is 10 to 80 feet thick; overlies Phosphoria formation; underlies Chugwater formation. Little Medicine tongue extends eastward into Big Horn Mountains.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254-H, p. 166 (fig. 18), 167–170. Discussion of Triassic stratigraphy of southeastern Idaho and adjacent areas. In southeastern Idaho, Dinwoody is 700 to 2,400 feet thick and includes beds both older and younger than those at type locality. In southeastern Idaho, southwestern Montana, and western Wyoming, Dinwoody is bounded below by Phosphoria and above by Woodside or Thaynes. Relationship of Dinwoody and Woodside to Phosphoria not completely understood. Areas discussed in detail.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2836–2837 (fig. 4). Chart shows Dinwoody overlies Ervay member of Park City formation, and Retort phosphatic shale and Tosi members (both new) of Phosphoria formation. Column 15 shows Dinwoody in Crawford Mountains, Utah.

Named for Dinwoody Canyon in Wind River Mountains near Dubois, Wyo.

Dip Creek Formation

Paleocene: West-central California.

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 450, 512–517. Name proposed for Paleocene beds in central and south Santa Lucia Range. Consists of coarse cobble and boulder conglomerates and coarse to fine-grained arkose sandstones, commonly filled with carbonized plant remains. Thickness about 1,320 feet. Unconformably underlies pre-Vaqueros landlaid redbeds and marine Vaqueros sandstones; overlies Asuncion formation [group].

Type locality: In west part of sec. 30, T. 25 S., R. 10 E., Adelaida quadrangle, Santa Lucia Range.

Dipping Vat Formation

Eocene: Central Utah.

D. P. McGookey, 1959, Dissert, Abs., v. 19, no. 12, p. 3278; 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 5, p. 591, 592–593 (fig. 2), 594, 607, 608–610. Proposed for light-gray to white coarse tuffaceous sandstone that rests conformably on, and is possibly gradational with, beds of Bald Knoll formation and is overlain disconformably by Bullion Canyon volcanics. Thickness about 208 feet.

Type section: Upper 208 feet of section measured along line starting in cutbank on west side of Lost Creek in sec. 1, T. 23 S., R. 1 W., and ending in NE¼ sec. 11, T. 23 S., R. 1 W., Sevier County. Named from exposures in canyon of Dipping Vat Creek just above confluence with Little Lost Creek in sec. 30, T. 23 S., R. 1 E.

Dirty Creek Sandstone Member (of Atoka Formation)[1]

Middle Pennsylvanian: Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 29–30. Thickness 5 to 20 feet in type area. Separated by unnamed shale intervals from overlying Webbers Falls sandstone member and underlying Georges Fork sandstone member.

Named for exposures west of Dirty Creek in secs. 11 and 14, T. 12 N., R. 19 E., Muskogee County.

Disappointment Mountain Greenstone Conglomerate

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1592. Name applied to a conglomerate consisting mostly of fragments of greenstone with a few fragments of jasper. Average thickness at Disappointment Mountain about 1,200 feet; south of Moose Lake, only a few feet to 300 feet thick and grades into graywacke and slate. Overlies or surrounds Ely greenstone. In this report, the Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Disappointment Mountain and Moose Lake greenstone as unit 3 occurring above unnamed flinty slates and below Jasper Lake greenstone conglomerate or agglomerate.

Report covers a belt in eastern part of Vermilion district more or less parallel to international boundary.

Dismal Conglomerate Lentil (in Dismal Formation)[1]

Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44.

Named for exposures on Dismal Creek, Buchanan County, Va.

Dismal Formation[1]

Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio, 44.

Named for exposures on Dismal Creek, Buchanan County, Va.

†Dismal Swamp Formation[1]

Pleistocene: North Carolina and Virginia.

Original reference: C. K. Wentworth, 1930, Virginia Geol. Survey Bull. 32, p. 691.

Dismal Swamp area.

Ditney Formation[1]

Upper Pennsylvanian: Southwestern Indiana.

Original reference: M. L. Fuller and G. H. Ashley, 1902, U.S. Geol. Survey Geol. Atlas, Folio 84.

C. A. Malott, 1948, Indiana Acad. Sci. Proc., v. 57, p. 126 (fig. 1), 128–129, Ditney formation (restored) underlies Merom sandstone and overlies West Franklin limestone.

Caps Big Ditney and Little Ditney Hills, Warren County.

Divide Andesite[1]

Miocene, upper(?): Southwestern Nevada.

Original reference: A. Knopf, 1921, U.S. Geol. Survey Bull. 715, p. 151, 155.

Occurs southeast of Tonopah Divide mine. Forms main bulk of largest and highest mountainous area in district and is well exposed at highest point on Tonopah-Goldfield Road, Divide district.

Divide cyclothem

Pennsylvanian: Southern Illinois.

J. R. Ball, 1943, Illinois Acad. Sci. Trans., v. 36, no. 2, p. 147, 150. Named in list of cyclothems in the late Pennsylvanian (McLeansboro) rocks in Carlinville quadrangle. Approximate thickness 9 feet. Occurs above Livingston cyclothem. Text (p. 150) refers to the Divide(?) cyclothem and states that this is probably a channel sandstone because it includes only sandstone and shale.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 13. Studies by E. S. Ekblaw in south-central Illinois led to tentative recognition of six cyclothems, of which the Divide is second in sequence (ascending). Occurs above the LaSalle and below the Effingham (new). If the Greenup and Omega limestones are not equivalent, a single standard reference section would include 14 cyclothems; the Divide would be seventh in sequence (ascending) and would occur below the Effingham and above the Cohn.

Present in Carlinville quadrangle, northeast corner of which is about one-half mile east of Virden and 20 miles south of Springfield.

Divide Peak Andesite[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 5, p. 71 (map).

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 676. Cenozoic.

Occurs in Mount Lassen region.

Divine Limestone[1]

Upper Ordovician: Northeastern Illinois.

Original reference: J. E. Lamar and H. B. Willman, 1931, Illinois Geol. Survey Rept. Inv. 23, passim.

E. P. Du Bois, 1945, Illinois Geol. Survey Rept. Inv. 105, p. 7. Specific names, such as Fernvale limestone, Divine limestone, and Thebes sandstone, have been applied locally to parts of the Maquoketa formation, but it appears that none of these, except possibly the Divine limestone, are consistent stratigraphic units.

Named for exposures in vicinity of Divine Station, on Elgin, Joliet & Eastern Railroad, Grundy County.

Dixie shale[1]

Lower Cretaceous: Southeastern Arizona.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 64, no. 2, p. 129, 138, 139.

Named for Dixie Canyon, near Bisbee, Cochise County.

Dixie Valley Formation

Lower Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]. Conglomerate grading locally to fanglomerate, sandstone and shaly limestones and dolomites. Forms massive steplike ledges, prevailingly yellowish to brownish red or maroon. Maximum thickness about 600 feet; 280 to 300 feet at south end of Tobin Range. Underlies Favret formation (new), contact gradational; overlies Tobin formation (new).

Type locality: Northwest part of Augusta Mountain, north end of Dixie Valley.

†Dixon chalk or limestone[1]

Upper Cretaceous: Nebraska and western Iowa.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44, p. 147–149.

Dixon Earthy Limestone Member (of Wayne Formation)[1]

Dixon Formation (in Wayne Group)

Middle Silurian: West-central Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 566, 578–582, 681, 694.

H. D. Miser, 1921, Tennessee Div. Geology Bull. 26, p. 20. Referred to as Dixon earthy limestone member of Wayne formation.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 244, 253–256, figs. 2, 76, 80. Dixon formation included in Wayne group. Consists of an alternation of several lithologic types, all of which are argillaceous; these include beds of calcareous shale as much as 5 feet thick, massive calcareous mudstone averaging about 5 feet in thickness but being locally as much as 10 or 15 feet thick, earthy limestone, and uniformly bedded, argillaceous limestone containing disseminated silt; this latter type is ordinarily concentrated near base of formation and represents the gradation between the Lego and Dixon. Western part of formation (fig. 76) is usually brick red; the eastern part is usually gray, commonly greenish gray; color change is commonly quite rapid and may locally occur with distance of 1 mile. Thickness varies owing to gradation into underlying Lego; average thickness about 38 feet where overlain by Beech River formation. Locally overlain unconformably by Pegram formation or Chattanooga shale.

T. W. Amsden, 1949, Yale Univ. Peabody Mus. Nat. History Bull. 5, p. 10. Discussed as Dixon formation underlying Brownsport formation.

Named for Dixon Spring, Decatur County.

†Dixon Formation[1]

Pennsylvanian: Western Kentucky.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 26.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 81. Highest Pennsylvanian formation in western Kentucky. Includes beds younger than Lisman formation. Consists of (descending) Mount Gilead sandstone, Mount Gilead shale, Vanderburg sandstone, Bald Hill shale, and Dixon sandstone.

Named for exposures east of Dixon, Webster County.

Dixon Granite

Precambrian (Proterozoic): Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 24–25, 45, pl. 2. Typically is fairly coarse grained but varies a good deal in both texture and composition from place to place. In gorge of Rio Pueblo, it is mainly even-grained pink and gray biotite granite. Intrudes all older Proterozoic rocks in area. Intruded during Pueblo revolution.

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 37. Preoccupied name Dixon replaced by term Embudo granite.

Conspicuous in hills to west and south of Harding mine and exposed along Rio Pueblo from Dixon almost to Picuris. Also occurs in belt extending from foot of mountain slope northeast of Picuris nearly to Talpa and other smaller outcrops in Picuris area, Rio Arriba County.

Dixon Sandstone

Ordovician: Oklahoma.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 100. Abandoned by Oklahoma Geological Survey. Eldridge (1901, U.S. Geol. Survey 22d Ann. Rept., pt. 1, p. 227) states that he named unit for the Indian upon whose allotment the rock occurs. Sandstone is probably in Oil Creek formation. If restored, name would invalidate well known Dixon limestone, Silurian, of Tennessee, named in 1903. Name has also been used for a Kentucky Pennsylvanian sandstone, a schist in New York, and an Upper Cretaceous chalk in Nebraska.

†Dixon Sandstone (in Henshaw Formation)[1]

Dixon Sandstone Member (of Dixon Formation)

Pennsylvanian: Western Kentucky.

L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 26. Fine-grained sandstone of variable character, 10 to 25 feet thick; locally 50 to 60 feet; forms basal member of Dixon formation.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 81. Basal member of Dixon formation.

Named for exposures near Dixon, Webster County.

Dixon Schist[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Hague gneiss and below Faxon limestone.

Type locality: Dixon mine, Hague Township, Warren County.

Dixon Mountain Member (of Wilhite Formation)

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 962. Dominantly siltstone, mostly micaceous and sandy, containing much carbonate that is mainly concentrated along certain laminae; some interbedded sandstone. About 1,500 feet thick. Underlies Yellow Breeches member (new).

Named for Dixon Mountain west of Jones Cove, Sevier County.

†Dixons Group[1]

Upper Cretaceous: Eastern Nebraska and western Iowa.

Original reference: I. N. Nicollet, 1843, Rept. intended to illustrate map of hydrographical basin of Upper Mississippi River: 26th Cong., 2d sess., S. Ex. Doc. 237, p. 35, 37.

Named for the fact that divisions A, B, and C compose Dixon's bluff, in Dixon County, Nebr., about 12 miles above Sioux City, Iowa.

Dobbs Valley Sandstone (in Millsap Lake Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer and J. Hornberger, Jr., 1936, Texas Univ. Bull. 3534, p. 163.

Crops out north of Dobbs Valley, Brazos River region.

Dock Street Clay Member (of Four Mile Dam Formation)

Dock Street Clay[1]

Middle Devonian: Northeastern Michigan.

Original reference: A. W. Grabow, 1902, Rept. Michigan State Board of Geol. Survey for 1901, p. 178, 192.

A. S. Warthin and G. A. Cooper, 1942, *in* G. A. Cooper and others, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1744. Above Alpena (restricted) are 8 feet of blue clay shale, the Dock Street clay of Grabau, a lens confined to east side of Alpena, and classified with the Alpena limestone.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 588. Considered member of Four Mile Dam. At type section of Four Mile Dam, consists of bluish-gray calcareous mudstone about 7½ feet thick; near base of formation. Contains well-preserved echinoderms.

First described from test well on Dock Street, Alpena. Well exposed at type section of Four Mile Dam, Thunder Bay quarries, SE¼ sec. 14, T. 31 N., R. 8 E., Alpena County.

Dockum Group[1] or Formation

Upper Triassic: Western Texas, Colorado, Kansas, Oklahoma, and New Mexico.

Original reference: W. F. Cummings, 1890, Texas Geol. Survey 1st Ann. Rept., p. 189.

J. W. Stovall and D. E. Savage, 1939, Jour. Geology, v. 47, no. 7, p. 759–766. Skull of phytosaur *Machaeroprosopus* discovered in Sloan Canyon formation, confirms Triassic age of rocks lying beneath Exeter (Jurassic) in valley of dry Cimarron River in Union County, N. Mex., and Cimarron County, Okla. Underlying red beds, the Sloan Canyon formation, and Sheep Pen Canyon formation form continuous and conformable succession of strata. These three units should be included in Dockum group.

R. E. King and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 556. Upper Triassic red shales and sandstones of terrestrial origin overlie

Permian throughout much of South Permian basin. They are placed in Dockum group and divided into (ascending) Tecovas shale, Santa Rosa sandstone, and Chinle shale.

G. E. Hendrickson and R. S. Jones, 1952, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 3, p. 23–24. Group, in Eddy County, overlies Rustler formation. Consists of redbeds and sandstones. Lower part of these beds has been considered Permian and correlated with Dewey Lake redbeds by some geologists. Total thickness of group east of Artesia is about 1,000 feet. Formations exposed are Pierce Canyon redbeds, Santa Rose sandstone, and redbeds that possibly represent the Chinle formation. Triassic.

C. E. Stearns, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 463 (fig. 2), 467. Glorieta sandstone, in Galisteo-Tonque area, New Mexico, is overlain by about 800 feet of red and variegated sandstone and shale. These beds are generally correlated with Dockum group of eastern New Mexico.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in Cimarron County.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 34–42, pl. 1d. Group, as used in this report, includes all beds of Triassic age exposed in Union County. With only one or two exceptions, exposures of the Dockum are restricted to drainage area of Dry Cimarron, where group is divided into four formations (ascending): Baldy Hill (new), Travesser (new), Sloan Canyon, and Sheep Pen. Unconformably underlies Exeter sandstone. Thickness about 900 feet.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Dockum group shown on chart with statement that some part of Triassic section is believed to crop out in small area in Morton County.

Named for Dockum, Dickens County, Tex.

Dodds Creek Sandstone Member (of Coffeyville Shale)

Dodds Creek Sandstone[1] Member (of Galesburg Shale)

Pennsylvanian (Missouri Series): Eastern Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 97.

R. C. Moore and others, 1937, Kansas Geol. Soc. 11th Ann. Field Conf. Guidebook, p. 40 (table), 42. Included in Coffeyville shale (restricted) in northeastern Oklahoma.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 83, 87. Massive to thin-bedded sandstone, seemingly of deltaic origin; thickness as much as 40 feet.

Occurs in Galesburg shale in southern Kansas.

Named for Dodds Creek, Labette County, Kans.

Dodge gypsum[1]

Upper Cretaceous or Miocene(?): Iowa.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 219, pls. 25, 26, fig. 3.

Fort Dodge, Webster County.

Dodge shale[1]

Upper Cretaceous or Miocene(?): Western Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 148, 154.

Probably named for Fort Dodge, Webster County.

Dodson Member (of Cook Mountain Formation)

Eocene (Claiborne): Central Louisiana.

J. Huner, Jr., 1939, Louisiana Dept. Conserv. Geol. Bull. 15, p. 87–91, 92, pl. 3. Term proposed for the basal fossiliferous glauconitic, clayey sands which underlie the Milams member and overlie the Sparta sands. As defined, the Dodson includes the lower 17 feet of the Milams member as defined by Ellisor (1929). Thickness 4 to 25 feet.

Name derived from town of Dodson in sec. 27, T. 13 N., R. 3 W., north-central Winn Parish. This is nearest geographical name to any of the typical localities described.

Doe Creek Sandstone Member (of Marlow Formation)

Permian: Northwestern Oklahoma.

O. F. Evans, 1954, Oklahoma Acad. Sci. Proc., v. 33, p. 196–197. Name applied to a sandstone, 6 to 36 feet thick, exposed in a line of disconnected hills that extend southwest from about 15 miles west of Alva, to near Woodward, a distance of about 40 miles. Sandstone is hard, highly cemented, fossiliferous. Considered younger than Verden sandstone although some workers have suggested that it is an extension of the Verden; both units are included in the Whitehorse [group].

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as sandstone member of Marlow formation.

C. C. Branson, 1955, Hopper, v. 15, no. 12, p. 137. Doe Creek lies within the Marlow formation at a higher level than the Verden sandstone. The original Whitehorse sandstone of the Whitehorse Springs locality is the Doe Creek; name Whitehorse has been applied to the group consisting of the Marlow formation and Rush Springs sandstone. Derivation of name given.

Named for Doe Creek in T. 25 N., R. 18 W., Woodward County. Type section not designated; perhaps in Doe Creek mounds, which are buttes along valley of Doe Creek. Occurs in Cleveland Hills, Whitehorse mounds, Wildcat mounds, Woods County; Doe Creek mounds and vicinity of Woodward, Woodward County.

Doe Run Dolomite (in Elvins Group)[1]

Doe Run Member (of Elvins Formation)

Upper Cambrian: Eastern Missouri.

Original references: E. R. Buckley, 1907, Missouri Bur. Geology and Mines, v. 10, 2d ser., separate; H. A. Buehler, 1907, Missouri Bur. Mines, v. 6, 2d ser., p. 231.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 234 (table 1). Uppermost formation in Elvins group. Overlies Derby dolomite; underlies Potosi dolomite. Upper Cambrian.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 27–30. Missouri Geological Survey uses compound term Derby-Doe Run. Because

Doe Run was used as formation name by Frazer (1883) [for unit in Pennsylvania], is seems good usage to discontinue it as compound term with Derby. Term Derby formation is used in this report. Term Elvins not recognized as valid in this report.

V. E. Kurtz, 1960, Dissert. Abs., v. 21, no. 3, p. 595. Doerun referred to as member of Elvins formation.

Named for Doe Run Lead Co., which owns land in St. Francois County, upon which type section occurs.

Doe Run Limestone[1]

Precambrian: Southeastern Pennsylvania.

Original reference: P. Frazer, 1883, Pennsylvania 2d Geol. Survey Rept. C_4, p. 70, 304, 307.

Extends more than 1 mile in southwest direction parallel to valley of Doe Run, from near Doe Run village to vicinity of Passmore's mill, Chester County.

Dog Bend Limestone (in Mineral Wells Formation)[1]

Dog Bend Limestone Bed (in Salesville Formation)

Dog Bend Limestone Member (of Salesville Formation)

Pennsylvanian (Canyon): Central northern Texas.

Original reference: F. B. Plummer, 1929, Texas Bur. Econ. Geology, geol. map of Palo Pinto County.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Salesville is raised to formation rank and expanded below to base of Lake Pinto sandstone. Chart shows Dog Bend limestone member above Lake Pinto member; underlies unnamed sandstones and limestone below Turkey Creek sandstone member of Keechi Creek formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 24, pl. 1. Referred to as limestone bed in Salesville formation. As used in this report [Parker County], it is lower part of unnamed shale member that overlies Lake Pinto sandstone member. Bed is continuous with bed mapped and named Dog Bend in Palo Pinto County.

Probably named from exposures in the Dog Bend of Brazos River 5 miles west of Mineral Wells, Palo Pinto County.

†Dog Canyon Limestone[1]

Permian: Southeastern New Mexico.

Original reference: W. B. Lang, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 588 (footnote). Abandoned in favor of Goat Seep limestone (new).

Exposed on western flank of Guadalupe Mountains, in Dog Canyon.

Dog Creek Shale (in Nippewalla, El Reno, or Pease River Group)

Dog Creek Shale (in Cimarron Group)[1]

Dog Creek Shale (in Double Mountain Group)

Permian: Central southern Kansas, western Oklahoma, and western Texas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 39.

D. A. Green, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1469. In central and west-central Oklahoma, in areas where Blaine formation can be identified, Dog Creek shale lies between it and Marlow formation. Thickness about 150 feet at Mountain View; more than 200 feet in Canadian County where it contains several continuous thin dolomites in basal 50 feet.

N. H. Darton, L. W. Stephenson, and Julia Gardner, 1937, Geologic map of Texas (1:500,000): U.S. Geol. Survey. Mapped in Double Mountain group in northwestern Texas. Includes Childress dolomite member at top.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 98. Top formation of El Reno group on east side of Permian basin. Overlies Blaine gypsum; underlies Whitehorse group. El Reno appears to be better term than recently suggested San Andres group. Leonard series.

R. L. Clifton, 1942, Jour. Paleontology, v. 16, no. 6, p. 685–699. Includes (ascending) unnamed shales, Guthrie member, unnamed shales, Aspermont member, unnamed shales and gypsums, and Childress member. Overlies Blaine; underlies Whitehorse. Faunas discussed.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Included in El Reno group. Double Mountain group abandoned.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 158, 161 (fig. 4). Uppermost formation in Nippewalla group. Consists of maroon shale, sandstone, thin layers of dolomite, dolomitic sandstone, and gypsum. Thickness 14 to 53 feet; average 35 feet. Overlies Blaine formation. Underlies Whitehorse sandstone. In Kiowa County overlapped by Cretaceous sandstone (Cheyenne).

Robert Roth, 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 893–907. Pease River group includes San Angelo, Flowerpot, Blaine, and Dog Creek formations as exposed in Texas. Chart shows Pease River group as Guadalupe.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 17 (fig. 3), 19 (fig. 4), 28–30, pl. 1. As classified in this report [Carter area], Dog Creek overlies Van Vacter gypsum member (new) of Blaine formation and underlies Marlow formation of Whitehorse group. Thickness 80 feet. In El Reno group.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 24 (fig. 6), 34–36, pl. 1. Described in Harper County where it conformably overlies Blaine formation and is unconformable below Whitehorse formation. Consists of reddish-buff gypsiferous shale with thin beds of red sandstone and gypsum. Thickness 25 to 50 feet. Uppermost formation of El Reno group; Guadalupian. [Page 36 refers to El Reno group, Leonardian series.]

Named for Dog Creek, Barber County, Kans.

Dog Gulch Formation[1]

Tertiary: Southwestern New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures in upper part of Dog Gulch, Mogollon district.

Dogs Head Andesites

Quaternary: Southwestern Washington.

Jean Verhoogen, 1937, California Univ. Dept. Geol. Sci. Bull., v. 24, no. 9, p. 286. Dark reddish tough andesite which carries abundant gabbroic inclusions. Overlain by succession of thin sheets of basalt separated by clinkery layers of cinders and thin beds of ash.

Occurs in vicinity of Mount St. Helens on western slope of Cascade Range, 40 miles north of Columbia River. Dogs Head is prominent escarpment that rises over east end of Forsythe glacier.

Dolet Hills Formation (in Wilcox Group)

Dolet Hills Member (of Logansport Formation)

Paleocene: Northwestern Louisiana.

D. P. Meagher and L. C. Aycock, 1942, Louisiana Dept. Conserv. Geol. Pamph. 3, p. 13. Named in a stratigraphic summary of Louisiana lignite district. Name credited to G. Murray, Jr.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 48 (fig. 2), 57. In type area, consists of about 100 feet of rather massive sand; lithologically cannot be differentiated from other sands in Midway-Wilcox complex. Interfingers along strike with overlying and partially equivalent Cow Bayou member and is gradational from underlying Naborton formation.

G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 105–110. Overlies Chemard Lake lignite lentil of Naborton formaton. Midway group.

H. V. Andersen, 1960, Louisiana Dept. Conserv. Geol. Bull. 34, p. 53–54. Rank raised to formation in report on Sabine Parish. Term Logansport discontinued. Overlies Naborton formation; underlies Cow Bayou formation. Wilcox group. Subsurface.

Type area: Dolet Hills south of Naborton, especially exposures along road from Grove Hill Church and Cemetery to Naborton and adjacent ravines in sec. 6, T. 11 N., R. 11 W., in sec. 1, T. 11 N., R. 12 W., and sec. 36, T. 12 N., R. 12 W., De Soto Parish.

Dolgeville Shale[1]

Dolgeville facies (of Denmark Formation)

Dolgeville facies (of Sherman Fall Formation)

Middle Ordovician: Eastern New York.

Original reference: H. P. Cushing, 1909, New York State Mus. Bull. 126, p. 20.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 271. Facies of Sherman Fall formation.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 57. Name Dolgeville was proposed for interbedded rather than barren limestones and dark shales that lie between fossiliferous Trenton limestones and black shales near Dolgeville. In type locality, these overlie Shoreham limestone and underlie uppermost Canajoharie (Fort Plain zone of Fairfield member). Rocks of this lithology grade into Poland member of Denmark formation along lower West Canada Creek, and in southeastern exposures at Stony Creek there is limited representation of typical Poland lithology. Thus, it is certain that lower part of type Dolgeville corresponds to Poland limestone. Rocks having stratigraphic position of Russia member of Denmark in vicinity of Middleville are wholly of

Dolgeville facies and are succeeded by black shales bearing same fauna as type Dolgeville. It is probable that the higher type Dolgeville is equivalent to most of the Russia. Thus, typical Dolgeville is equivalent to near the whole of the Denmark.

Well exposed in banks of East Canada Creek, just below Dolgeville, Herkimer County.

Dolls Run Sandstone (in Washington Formation)[1]

Permian: Northern West Virginia.

Original reference: E. L. Core, 1929, West Virginia Acad. Sci. Proc., v. 3, p. 204.

Occurs in region near Core, Monongalia County.

Dolores Formation[1]

Upper Triassic: Southwestern Colorado.

Original reference: W. Cross, 1899, U.S. Geol. Survey Geol. Atlas, Folio 57.

A. L. Bush, C. S. Bromfield, and C. T. Pierson, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–96. Mapped as Upper Triassic. In Placerville quadrangle, consists of red siltstone, sandstone, shale, and a few thin limestone-pebble conglomerate layers; quartz-pebble conglomerate or grit at base; locally includes thin Wingate sandstone equivalent of Triassic age at top. Unconformable above Cutler formation and below Entrada sandstone.

Named for typical exposures in valley of Dolores River.

†Doloresian series[1]

Upper Triassic: Colorado, Arizona, New Mexico, and Utah.

Original reference: C. R. Keyes, 1924, Pan-Am, Geologist, v. 41.

Dome Limestone

Dome Formation[1]

Dome Limestone (in Ophir Group)

Middle Cambrian: Western Utah and southeastern Nevada.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 9, 11.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1134–1135, 1141 (fig. 5), 1145. At emended section formation is 310 feet thick and consists of black and dark-gray thick- and thin-bedded fine-grained limestone which contains drab-tan and maroon clay flakes, laminae, and nodules in lower two-thirds and dull-gray argillaceous pure limestone in upper third. Conformably overlies Howell limestone (emended); underlies Swasey limestone (emended). Forms part of continuous emended Cambrian section for region.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 38–39, fig. 5. Geographically extended into Nevada where it is same as units D-E of Highland Peak limestone as described by Wheeler and Lemmon (1939). Unconformably overlies Burnt Canyon limestone (new); unconformably underlies Condor member (new) of Swasey limestone.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 35, 45–46, pl. 1, measured sections. Included in Ophir group in Sheeprock

Mountains, where it overlies Burnt Canyon limestone and underlies Condor formation. Thickness 37 to 81 feet.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 49, 50 (fig. 4), 51. Wheeler's terminology in House Range revised. Term Burnt Canyon replaced by Chisholm formation, and Condor member of Swasey limestone replaced by Whirlwind formation (new). Hence, Dome overlies the Chisholm and underlies the Whirlwind. In Wah Wah Range, the Dome lies between the Chisholm and the Whirlwind.

Type locality: Head of Dome Canyon, House Range, Millard County, Utah. Emended section measured on north side of Marjum Canyon, House Range.

Dome Canyon Limestone[1]

Middle Cambrian: Western Utah.

Original reference: C. D. Walcott, 1912, U.S. Geol. Survey Mon. 51, p. 157.

U.S. Geological Survey has abandoned the term Dome Canyon limestone in favor of Dome limestone, the more widely used term.

Type locality: Dome Canyon, House Range, Utah.

Domengine Formation[1] or Sandstone

Domengine Stage

Eocene, middle: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 3, p. 167–168.

B. L. Clark and H. E. Vokes, 1936, Geol. Soc. America Bull., v. 47, no. 6, p. 853 (fig. 1), 861–863. West Coast Eocene comprises (ascending) Martinez, Meganos, Capay, Domengine, Transition, and Tejon stages. For the Martinez, Capay, and Domengine, there is fairly good faunal evidence for general correlation.

R. T. White, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 256–257. Domengine formation in Tumey Hills overlies Lodo formation (new).

H. E. Vokes, 1939, New York Acad. Sci. Annals, v. 38, p. 13 (table 1), 15–16. Name Domengine was first used (as Domijean) by Anderson (1905) to designate a sandstone member in Eocene north of Coalinga, the upper part of which included Domengine formation as recognized in this report but lower part of which included the white sandstones of Arroyo Hondo formation (new). Formation is described in areas designated as follows: type section of Domengine, including region from Oil City north to Cantua Creek; Vallecitos section, including Vallecitos syncline; Coal Mines section between the overlaps north of Alcade Creek and south of Los Gatos Creek; and Reef Ridge section, including area from Garza Creek to point about 2 miles south of Big Tar Canyon. Domengine (restricted) occurs as almost continuous line of outcrop throughout entire area included in this report. Only interruptions of any extent occur between north end of Reef Ridge section near Zapato Creek and southern part of Coal Mine section and southern part of type section in vicinity of Los Gatos Creek. In both areas, the Domengine is overlapped by Etchegoin formation. Thickness about 140 feet in type area. In some areas, overlies Cantua sandstone member of Arroyo Hondo formation; underlies Kreyenhagen formation. Domengine stage is younger than Capay stage.

Boris Laiming, 1940, 6th Pacific Sci. Cong., v. 2, p. 535–568. Discussion of character and distribution of smaller foraminifera in marine Eocene deposits of California and correlation of foraminiferal zones with faunal "stages" already established by paleontologists on basis of mollusca. Correlation chart shows 12 foraminiferal zones in Eocene as compared to 6 stages on basis of mollusca. Foraminiferal zones (ascending) B–1 and B–1A correlate with Domengine stage of Clark and Vokes (1936).

R. T. White, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 10, p. 1747–1750. Domengine sandstone, as redefined by Clark (1926, California Univ. Pub. Bull. Geol. Sci., v. 16, no. 5), is well-defined mappable unit, and north of Coalinga overlies Yokut sandstone (new); underlies Kreyenhagen shale.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 209–210. In San Benito quadrangle, Domengine sandstone occurs on both sides of Butts Ranch syncline, from eastern edge of quadrangle to Salt Creek, where it is overlapped by Etchegoin group and San Benito gravels. Thickness about 200 feet. On south side of syncline, rests on Yokut sandstone; on north side of syncline, rests alternately upon Butts Ranch shale and Call sandstone member (both new) of Panoche group. Middle Eocene.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 56–59, pls. Domengine sandstone widely distributed in all quadrangles mapped in this report [Coast Ranges immediately north of San Francisco Bay region] except Point Reyes, Petaluma, and Santa Rosa. Exposed in eight areas and attains maximum thickness of 2,200 feet; average thickness less than 200. Overlies Capay shale; underlies Markley sandstone.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Overlies Hawkhill formation (new).

M. B. Payne, 1951, California Div. Mines Spec. Rept. 9, p. 6 (fig. 2), 8 (fig. 4), 12 (fig. 6), 13, 15, 16 (fig. 9). Formation is defined in this paper [area of type Moreno] as beds stratigraphically below glauconite at base of Kreyenhagen shale and above Lodo formation. Includes gray foraminiferal shale and underlying gray sands down to base of Panoche bed which rests unconformably on Lodo formation in southeastern part of Panoche Hills. This is sequence of sediments except for the restricted area where Chaney Ranch sandstone (new) is found in outcrop and another area just north of Cantua Creek where basal Kreyenhagen glauconitic sand lies directly on Yokut sand. Comprises (ascending) Nonada sand and Capita shale members (both new). In some areas, overlies Laguna Seca formation (new). Name Domengine is undesirable in time stratigraphic sense.

J. E. Schoellhamer and D. M. Kinney, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–128. As used in this report [Panoche Hills, Fresno County], Domengine sandstone includes fossiliferous sandstone that directly overlies Lodo formaiton or White's Yokut sandstone, where it is present, and underlies Kreyenhagen shale. Crops out discontinuously from Tumey Gulch northward until it is overlapped by Tulare(?) formation in NW¼ sec. 5, T. 15 S., R. 12 E., at north edge of area. Thickness 125 to 250 feet.

G. B. Oakeshott, 1958, California Div. Mines Bull, 172, p. 22 (fig. 2), 58–59, pl. 1. In current usage, Domengine is stage name applied to rocks of middle Eocene age. It is also commonly used in many parts of California for mappable units in which middle Eocene microfauna or megafauna has been recognized. Formation crops out in San Fernando quadrangle south of San Gabriel fault and covers area of about 0.1 square mile in Elsmere Canyon. Exposed thickness about 650 feet, but beds are cut off by Whitney fault. Unconformable below Elsmere sandstone member of Repetto.

Named for exposures in vicinity of Domijean or Domengine Ranch, in NE¼ sec. 17, north of Coalinga, Fresno County.

Domenigoni Granodiorite

See **Domenigoni Valley Granodiorite.**

Domenigoni Valley Granodiorite

Cretaceous: Southern California.

E. S. Larsen, Jr., and N. B. Keevil, 1947, Geol. Soc. America Bull., v. 58, no. 6, p. 488. Named Domenigoni granodiorite in a report on a study of the batholith of southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 69, pl. 1. Described as several bodies of rock that range from tonalite to granodiorite. Crops out as light-colored boulders of disintegration. Derivation of name given.

Well exposed on both sides of Domenigoni Valley, southeastern part Elsinore quadrangle.

†Domijean Sands[1]

Eocene, middle: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 3, p. 167–168.

Named for development in vicinity of Domijean or Domengine Ranch, in NE¼ sec. 17, north of Coalinga, Fresno County.

Don Limestone[1]

A name applied by geologists of mining companies, in their company reports, to upper 260 feet of Syrena Formation (Pennsylvanian) of Santa Rita district, New Mexico.

See Humboldt Formation, New Mexico.

Dona Ana Member (of Lake Valley Formation)

Mississippian (Osage): Central southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1941 (abs.) Tulsa Geol. Soc. Digest, v. 9, p. 73–75; 1941, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 25, no. 5, p. 935; no. 12, p. 2116, 2136–2138, fig. 8. Thin- to massive-bedded gray to brown coarsely crystalline very cherty crinoidal limestone. Normally interbedded with dark crinoidal marl beds. Normal even bedding complicated by local small bioherm masses. Basal part contains more soft marly material than central part. Upper part filled with large masses of light-colored chert. In some sections, uppermost 10 feet of member made up almost entirely of chert. Thickness of 60 feet in type section; thins northward and is missing entirely in northern part of Sacramento Mountains. Maximum thickness of 175 feet in San Andreas Canyon; thins abruptly to south and is absent in southern part of range. Thickness dependent to great extent on amount of pre-Pennsylvanian erosion in area where section is being measured. Upper member of formation. Conformably overlies Arcente member (new); unconformably underlies widely varying members of Pennsylvanian formations.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 11 (fig. 4), 15. Geographic distribution given.

Type section: At head of Deadman Canyon, Sacramento Mountains, in south center sec. 3, T. 17 S., R. 10 E., Otero County. Named from Dona Ana County. Occurs only in Sacramento Mountains and in central part of San Andres Mountains.

Donaher sandstones[1]

Precambrian (Belt Series): Central western Montana.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44, p. 215.

Mission Range.

Donald quartzites[1]

Precambian: Montana.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44, p. 217.

Derivation of name not stated.

Donegal Limestone (in Sumner Group)[1]

Permian: Northeastern Kansas.

Original reference: R. C. Moore, 1936, Jour. Geology, v. 44, no. 1, p. 5–9.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 30. Term Wellington is used for the section between top of Herington limestone and base of Ninnescah formation. Of the 10 subdivisions listed, the Strickler limestone and Newbern shale members of the Donegal limestone (Moore, 1936) are not very persistent; name Donegal limestone is not well founded.

Type locality and derivation of name not stated.

Doneley Limestone Member (of Savanna Formation)

Pennsylvanian (Des Moines Series): Northeastern Oklahoma and southeastern Kansas.

C. C. Branson, 1954, Oklahoma Acad. Sci. Proc., v. 33, p. 192, 193 (table 1); C. C. Branson, 1955, *in* E. W. Reed, S. L. Schoff, and C. C. Branson, Oklahoma Geol. Survey Bull. 72, p. 67–68. Defined as the uppermost of three persistent "brown limes" of Savanna formation. At type section, calcareous clay ironstone 3 inches thick, lying 8 inches above a thin coal and its underclay. Lies 70 feet below base of Bluejacket sandstone; overlies Rowe coal, which is above Sam Creek limestone. Name credited to L. P. Chrisman (unpub. thesis).

Type section: One mile north of school building in NW¼ sec. 16, T. 26 N., R. 20 E., Craig County, Okla., in south bank of creek which crosses north-south section line road. Exposure is about 100 feet east of road. Name derived from Doneley School, which is shown on U.S. Geological Survey topographic map of Vinita quadrangle in NW¼ sec. 27, T. 26 N., R. 20 E. This school has been replaced by Pleasant Hill School which is at same location.

Doniphan Shale Member (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 44, 47.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22),

153. Doniphan shale member of Lecompton formation; underlies Big Springs limestone member; overlies Spring Branch limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24. Thickness 4 to 5 feet in Iowa and Nebraska and 5 to 10 feet in Kansas. Type locality stated.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 66. Notes thickness in Kansas as 5 to 34 feet. Contains some red shale and prominent sandstone beds in southern Kansas.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 20, fig. 5. Dark-gray to buff, calcareous shale with beds of fossiliferous nodular limestone. Thickness 3 to 6 feet. Underlies Big Springs limestone member; overlies Spring Branch limestone member.

Type locality: In Missouri River bluffs, northeastern Doniphan County, Kans.

Donkey Fanglomerate

Pliocene(?) : Southern central Idaho.

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1095, 1122–1123, pl. 1. Defined to include partially cemented material of alluvial character which is older than the alluvium of the modern valleys. Composed almost exclusively of rounded to subangular poorly sorted gravel in an abundant cemented matrix composed largely of angular pebbles, sand, and dirt held in a mixture of quartz and calcite. Locally porous calcareous material so predominates in cement that material resembles caliche. Forms hills and spurs in and on sides of valleys, and recent alluvium laps up against it. Attains thicknesses upward of 1,000 feet. Rests on and contains pebbles of Challis volcanics.

Named for Donkey Hills where it is exceptionally well displayed. Principal exposure is west of Donkey Creek in western part of T. 11 N., R. 24 E., Borah Peak quadrangle.

Donkey Creek Glaciation or **Drift**

Pleistocene, upper: South-central Utah.

R. F. Flint and C. S. Denny, 1958, U.S. Geol. Survey Bull. 1061–D, p. 117 (fig. 25), 125, pl. 6. Southern part of Fish Creek-Grover drift lobe composed of drift assigned to Donkey Creek and Blind Lake (new) glaciations. Near Hickman Pasture, Donkey Creek drift narrows to width of less than 1,200 feet, probably because of massive slumping on eastern side of valley. Eastern lateral moraine of the drift is cut by an earthflow near Hickman Pasture. Pinedale(?) stage.

Mapped on flanks of Boulder Mountain, including the course of Donkey Creek on north flank of Boulder Mountain; Wayne and Garfield Counties.

Donley Limestone Member (of Greene Formation)[1]

Permian: Southwestern Pennsylvania and eastern Ohio.

Original reference: W. T. Griswold and M. J. Munn, 1907, U.S. Geol. Survey Bull. 318, p. 77.

Exposed in vicinity of Donley, Donegal Township, Washington County, Pa.

Donnay (Donny)

See **Donni Sandstone Member** (of Tagpochau Limestone).

Donnelly Glaciation

Pleistocene: East-central Alaska.

T. L. Péwé, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1289; T. L. Péwé *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 9, 13 (table 1) At least three major Quaternary glaciations recorded at north end of Delta River valley. Donnelly succeeded Delta glaciation (new). Extended about 15 miles north of Alaska Range. Distinct terminal bulbs spread northward onto plain from Little Delta River, Delta Creek, Granite Creek, Gerstle River, and Johnson River. Well-preserved end moraines with many lakes and fresh knob-and-kettle topography at base of range. Glacier split into major and minor lobe near Donnelly Dome and partially surrounded the dome.

Named after Donnelly Dome, a prominent rock knob 25 miles south of Big Delta.

Donnelly iron ore[1]

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Donni Sandstone Member (of Tagpochau Limestone)

Donni Tuff

Miocene, lower: Mariana Islands (Saipan).

Risaburo Tayama, 1938, Geomorphology, geology, and coral reefs of Saipan Island: Tropical Industry Inst., Palau, South Sea Islands, Bull. 1 [English translation in library of U.S. Geol. Survey, p. 61–63]. Donny beds include alternating tuff, sandstone, and shale beds. Lower part consists of alternating fine-grained conglomerate, sandstone, shale, and tuff with limestone blocks and lenses; middle part, alternating sandstone, sandy shale, and shale; upper, alternating shale, arenaceous shale, and marl. Well stratified. Thickness appropriate 100 to 200 meters at Donny and Tarohoho; 30 centimeters on sea-cliff of Naftan Peninsula. On north wall of valley east of Saipan Institute, exposed in thin calcareous seam between Laulau limestone and Tappocho limestone.

Josiah Bridge *in* W. S. Cole and Josiah Bridge, 1953, U.S. Geol. Survey Prof. Paper 253, p. 10–11. Donni tuff is brilliantly colored and well-stratified formation consisting of beds of conglomerate, tuff, sandstone, and shale. Rests unconformably on Sankakuyama rhyolite, Hagman andesite, and tuffs of Densinyama formation, and grades laterally into Laulau and Tagpochau limestones; disconformably overlain by Naftan and Mariana limestones. Miocene (Aquitanian).

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 68–71, pl. 2, chart 2. Reduced to member status in Tagpochau limestone. Comprises thinly bedded and well-bedded, soft, tuffaceous, marine sandstone, siltstone, marl and shaly beds, and pebble and granule conglomerates. Average thickness 100 feet; may be as much as 200 feet. Although at any given place the Donni may lie relatively above, below, or within the local Tagpochau succession, its general distribution pattern suggests that it properly occupies a position near middle of formation. Type section designated.

Type section: Between I Hasngot Ravine and I Pitot Ravine. Its base is west of junction of Cross-Island Connecting Highway and East Coast Highway and its top along East Coast Highway about 800 feet east-southeast of junction.

Donny Sandy Tuff

See **Donni Sandstone Member** (of Tagpochau Limestone).

Donovan Formation

Lower Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229–235. Consists principally of hard green and gray noncalcareous sandstone, sandy shale, red sandstone, and yellowish calcareous sandstone. Thickness 2,241 to 2,500 feet. Underlies Mowich group; appears to be oldest Jurassic formation in central Oregon; Jurassic sequence lies with high-angle discordance upon a basement of highly folded strata which are in part of Mississippian and Upper Triassic age.

Exposures occupy less than one-half square mile in secs. 5, 6, 7, and 8, T. 20 S., R. 30 E., 19 miles north of Burns and 10 miles west of Crow Flat Ranger Station. Named for Tim Donovan Ranch, in sec. 7, T. 20 S., R. 30 E., Crook County.

Dooley Rhyolite Breccia[1]

Miocene(?): Northeastern Oregon.

Original reference: J. Gilluly, 1937, U.S. Geol. Survey Bull. 879.

Named for exposures on Dooley Mountain and in Stices Gulch and Mill Creek, Baker quadrangle.

Dora Dolomite Member (of Bluebell Formation)

Silurian: Central Utah.

Paul Billingsley, 1933, *in* J. M. Boutwell, Internat. Geol. Cong. 16th, [United States] Guidebook 17, Excursion C–1, p. 110 (fig. 14). Name appears on stratigraphic column of Tintic district. Overlies Beecher member (new); underlies Noah member (new).

T. S. Lovering and others, 1949, Econ. Geology Mon 1, p. 7 (table 1). Upper 10 feet gray wavy thin-bedded ("Curley") dolomite; remainder of unit dominantly fine-grained blue-gray dolomite containing a few light-gray nearly lithographic dolomite beds. Thickness 212 feet.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 144. Dora dolomite (in part at least) should be termed Sevy.

Type locality and derivation of name not stated.

Dorado Basalt (in Hinsdale Series)

Pliocene: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 3, 38, 51, 53, pl. 1. Flows of olivine basalt, basalt, and quartz basalt. Appears partly to wholly crystalline, fine grained, and porphyritic in thin section. Thickness from at least 40 to about 100 feet. Younger than Cisneros basalt (new); unconformably overlies Cordito member (new) of Los Pinos formation. Name credited to Butler (unpub. dissert.).

Name applied to basalt that caps Petaca Mesas. Particularly well exposed in Dorado Canyon, northeast of Petaca.

Dorans Cove Sandstone[1]

Mississippian: Northeastern Alabama.

Original reference: J. J. Stevenson, 1903, Geol. Soc. America Bull., v. 14, p. 76.

Well exposed in Madison, just west from Jackson. Named for Dorans Cove, Jackson County.

Dorcheat Member (of Schuler Formation)

Upper Jurassic: Subsurface in Arkansas, northern Louisiana, and eastern Texas.

F. M. Swain, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 578 (table 1), 597, 602–609. Upper member of formation. Defined as including the nearshore pastel, varicolored shales, and sandstones, and the equivalent offshore dark-gray fossiliferous shales, sandstone, and limestones between the base of the Hosston formation and the top of the red-green shales, sandstones (nearshore facies), and marine rocks (offshore facies) of the Shongaloo member (new). Locally, dark-gray, glauconitic, fossiliferous shale, herein named the Wesson tongue, occurs near the top of the nearshore facies of the member. Occurs between depths of 6,420 to 7,510 feet in type well. Attains its greatest thickness of 1,200 feet or more near Arkansas-Louisiana State line and on the Monroe uplift, in Morehouse Parish, La., south of which it thins gradually. In most areas, the Dorcheat is overlain with regional conformity by the Hosston formation; in central part of Monroe uplift, overlain by late Upper Cretaceous chalk; in East Texas basin, the contact is unconformable; generally the Dorcheat conformably overlies the Shongaloo; in Nevada County, Ark., it overlaps the Shongaloo and rests directly on the Smackover limestone; in Bowie County, Tex., it overlaps the Shongaloo and rests on Paleozoic sandstone.

Type section: Atlantic Refining Co.'s Pinewoods Lumber Company No. 1, C., NE¼NE¼ sec. 16, T. 18 S., R. 22 W., Columbia County, Ark.:; Dorcheat Field discovery well.

Dorchester Slate Member (of Roxbury Conglomerate)[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. W. Dodge, 1881 and 1882, Boston Soc. Nat. History Proc., v. 21, p. 208–210.

Named for Dorchester district of Boston, where it is exposed at several places.

Dorena Welded Tuff

Tertiary: Western Oregon.

D. M. Hausen, [1954], Mississippi Acad., Sci. Jour., v. 5, p. 212–216. Consists, locally, of five mappable units ascending): crystal and vitric tuff, pumice tuff, dacite tuff, pumice tuff, and crystal and vitric tuffs. Overlies and underlies pumice tuff units.

Type locality: Near Dorena, Lane County.

Dornick Hills Formation[1]

Dornick Hills Group

Pennsylvanian: Central southern Oklahoma.

Original reference: J. A. Waters, 1927, Jour. Paleontology, v. 1, p. 129.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Dornick Hills group comprises (ascending) Jolliff, Otterville, Bostwick, Lester, and Frensley limestones, and Pumpkin Creek beds. Overlies Springer group; underlies Deese group. Morrow-Lampasas series.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 138–143. Group redefined and subdivided into three formations (ascending): Golf Course (new), Lake Murray (new), and Big Branch. Golf Course formation includes the Primrose at base and the Otterville at top. Primrose sandstone and shale between the Primrose and Otterville are transferred from Springer group to Dornick Hills. Overlies Springer group; underlies Deese group. Pennsylvanian (Morrow, Atoka, Des Moines).

Named for Dornick Hills north of Ardmore, Carter County.

Dorothy Limestone and Shale (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original references: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Raleigh and western Mercer and Summers Counties, p. 353.

Exposed at Dorothy, Raleigh County.

Dorr Run Shale Member (of Allegheny Formation)

Pennsylvanian: Eastern Ohio.

M. T. Sturgeon and W. M. Merrill, 1949, Ohio Jour. Sci., v. 49, no. 1, p. 1–11. Proposed for fossiliferous shale overlying the Lower Freeport coal in an exposure on southwest side of Dorr Run valley 1.6 miles northwest of junction of road along Dorr Run with Logan-Nelsonville road. Typically gray to dark-gray or even black argillaceous carbonaceous fossiliferous marine shale; in vicinity of Downhour School in Ward Township, member is light gray and argillaceous. Average thickness 17 inches.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 83–84. Member of Lower Freeport cyclothem in report on Athens County. Allegheny series.

Type section: In abandoned strip mine in SW¼NW¼ sec. 31, Ward Township, Hocking County; entire section includes strata exposed along side road in SE¼NW¼ sec. 31.

Dorset Limestone[1]

Cambrian and Ordovician: Southwestern Vermont.

Original reference: C. H. Hitchcock, 1860, Boston Soc. Nat. History Proc., v. 7, p. 237.

Dorset Mountain, Rutland and Bennington Counties.

Dorton Shale (in Crooked Fork Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4–6, pls. 2, 3. Name applied to shale between top of Rockcastle conglomerate and base of Crossville sandstone. Thickness commonly 50 to 80 feet; at type locality approximately 35 feet; in Crooked Fork section 42 feet; maximum thickness 115 feet occurs on Cumberland block. Contains Rex coal near base and thin Potters Falls coal near top. Name Duskin Creek was previously used for beds presumably overlying the Rockcastle, and including Dorton shale of this report. Type section of Duskin Creek consists of beds of the Vandever formation that actually underlie the Rockcastle. This error is believed due to failure to identify the Rockcastle because of its local shaly character.

Named from exposure near Dorton, Dorton quadrangle, Cumberland County.

Dorwin Sandstone Member (of Amsden Formation)[1]

See **Darwin Sandstone Member** (of Amsden Formation), correct spelling.

Dosados Sand and Shale Member (of Moreno Formation)

Upper Cretaceous: Southern California.

M. B. Payne, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1954; 1951, California Div. Mines Spec. Rept. 9, p. 6 (fig. 2), 8 (fig. 4), 9, 22, pls. 2, 3. Thickness about 200 feet. Underlies Tierra Loma shale member (new); unconformably overlies Panoche formation. On basis of this mapping it is concluded that Anderson and Pack (1915) show base of Moreno formation in Ortigalita Creek some 1,800 feet stratigraphically lower than their type Moreno in Moreno Gulch.

Type locality: Escarpado Canyon, Panoche Hills, Fresno County. Name is contraction of Spanish dos a dos. Escarpado Canyon is 6 miles south of Moreno Gulch and 2 miles north of Panoche Creek.

†Dos Alamos Gypsum Member (of Delaware Mountain Formation)[1]

Permian: Western Texas.

Original reference: P. B. King and R. E. King, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 922, 925.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 570 (footnote). Term Dos Alamos gypsum abandoned because the gypsum layers are included in the newly defined Cutoff shaly member of Bone Spring limestone.

Named for exposures near Dos Alamos, or Cottonwood Wells, due west of Guadalupe Point, on west side of Salt Flat, Hudspeth County.

Dos Palmas Rhyolite

Miocene(?): Southern California.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 24, 25 (fig. 3), pl. 2. Thickness as much as 400 feet. Rests directly on much older crystalline rocks. Southeast of Box Canyon, underlies Canebrake conglomerate (new).

Crops out in Mecca Hills, Imperial County, 8 miles S. 30° E. of Mecca.

Dos Palos Shale Member (of Moreno Formation)

Upper Cretaceous and Paleocene(?): Southern California.

M. B. Payne, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1953; 1951, California Div. Mines Spec. Rept. 9, p. 6 (fig. 2), 8 (fig. 4), 9, 22, pls. 2, 3, 4, 5. Consists principally of brown shale. Thickness 900 to 1,045 feet; includes the 60-foot Cima sandstone lens (new) 185 feet below its top. Discomformably underlies Paleocene glauconitic sandstone; overlies Marca shale (new). On basis of this mapping, it is concluded that Anderson and Pack (1915) show base of Moreno formation in Ortegalita Creek some 1,800 feet stratigraphically lower than in their type Moreno in Moreno Gulch.

Type locality: Escarpado Canyon, secs. 7 and 8, T. 15 S., R. 12 E., Panoche Hills, Fresno County. Named for town of Dos Palos. Escarpado Canyon is 6 miles south of Moreno Gulch and 2 miles north of Panoche Creek.

Dos Picachos Gravels

Pleistocene and Recent: West-central California.

N. L. Taliaferro, [1946?], Geologic map of the Hollister quadrangle, California (1:62,500): California Div. Mines Bull. 143, pl. 1 [preprint?]. Shown on map legend as coarse cemented gravels.

Exposed along Dos Picachos Creek, northeast Hollister.

Dot Limestone, Dolomite, or **Formation**

Middle Ordovician: Southwestern Virginia.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104 (2 sheets). Dolomitic limestone weathering yellow or red and with characteristic rounded surfaces in lower part; tan dense fine-grained limestone in upper part; normally contains no zones of chert nodules, but locally one or more zones of chert nodules are present near top; prominent conglomeratic zone of chert and dolomite pebbles at base. Thickness 120 to 193 feet. Unconformably underlies Poteet limestone (new); unconformably overlies Mascot dolomite. Dot limestone and Poteet limestone shown as Murfreesboro limestone (after Butts) on U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 76.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table 1), 33–37, 93, 96, 100–102, pl. 1. Further described and type section given. Dot seems to correlate with zones 1 and 2 of Blackford formation as used by Cooper (1944) in Burkes Garden quadrangle. Summary of conflicts in nomenclature of Middle Ordovician formations in Lee County.

Type section: In cut of Louisville and Nashville Railroad spur at Hagan, Lee County. Name derived from settlement of Dot, which is at junction of U. S. No. 58 and State Route 66 in eastern part of Jonesville district. Limestone crops out in two continuous belts on opposite sides of main anticlinal axis of Jonesville district.

Dothan Formation[1]

Upper Jurassic: Southwestern Oregon and northern California.

Original reference: J. S. Diller, 1907, Am. Jour. Sci., 4th, v. 23, p. 401–421.

N. L. Taliaferro, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 81–83. Diller (1907) concluded that the Dothan was younger than the Galice and believed that the entire section, Galice, volcanics, and Dothan, was overturned. Present study indicates that Dothan sediments in type section are not overturned, except locally on drag folds; Dothan is older than the Galice and, at type section at least, is separated from it by volcanics which grade downward into the former and upward into the latter.

F. G. Wells and G. W. Walker, 1953, Geology of the Galice quadrangle, Oregon: U.S. Geol. Survey Geol. Quad. Map [GQ–25]. Consists largely of sandstone, siltstone, and shale, with a few chert lenses, lenticular beds of conglomerate, and layers of volcanic rocks. Crops out in western part of quadrangle; distance across strike is 12 miles, 7 within and 5 without the quadrangle. Thickness difficult to determine due to thickening by folding and repetition of beds; stratigraphic thickness may be 10,000 to 18,000 feet. Present study shows Dothan is right side up and stratigraphically below volcanic rocks of Rogue formation (new). Dothan is assumed to be older than Galice.

F. W. Cater, Jr., and F. G. Wells, 1953, U.S. Geol. Survey Bull. 995–C, p. 84–86, pl. 11. Geographically extended into Gasquet quadrangle, California, where it consists of about 15,000 feet of graywacke, sandstone, shale, chert, and conglomerate. In northwest corner of quadrangle, Dothan rocks plunge southward under, and are generally conformable with, the peridotite sheet of Josephine Mountains; to the south, on Middle Fork of Smith River, the peridotite in turn underlies southward-plunging metavolcanic rocks of Galice formation that are known to be in normal position; hence, it is assumed Dothan underlies Galice, and although older than Galice, is still probably no older than Late Jurassic.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2778. Myrtle formation in southwestern Oregon is herein rank raised to group and subdivided into Riddle and Days Creek formations. Some of Myrtle formation as mapped by Diller is excluded from Myrtle group and reassigned to Dothan formation. Riddle formation rests on Rogue formation near Days Creek and in valley of Myrtle Creek, Douglas County; on Dothan formation in Dutchman Butte quadrangle and in southwestern part of Roseburg quadrangle in Douglas County; on Dothan formation in Dutchman Foggy Creek area of Bone Mountain quadrangle in Coos County. Contact with these underlying formation is angular unconformity.

Named for Dothan post office on Cow Creek, Douglas County, Oreg.

†Dothan Limestone (in Moran Formation)[1]

Dothan Limestone (in Moran Group)

Permian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in the Moran herein raised to group status. Underlies Horse Creek formation; overlies Camp Colorado formation in Pueblo group.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 5. Replaced by Ibex limestone (new). Term Dothan preoccupied.

Crops out near Dothan, Callahan County.

Dotsero Formation

Dotsero Dolomite

Upper Cambrian: Central northwestern Colorado.

C. F. Bassett, 1939, Geol. Soc. America Bull., v. 50, no. 12, pt. 1, p. 1855–1858. Dotsero dolomite consists of beds of gray dolomite and limestone with partings and thin beds of shale. Some beds intraformational conglomerates and breccias. In some beds, the included pebbles are gray, whereas in others they are red. Dolomites and limestones are of shallow-water origin as indicated by presence of ripple marks, rain prints, and other markings. Thickness in a bluff along road, 2.35 miles west of Garfield-Eagle County line, is 269 feet. Overlies Sawatch quartzite and underlies Parting quartzite member of Chaffee formation.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 896–904. Redefined as formation, which includes only the lower part (Late Cambrian) of the former Dotsero dolomite. Comprises the sequence of beds, 96 to 106 feet thick, directly above Sawatch quartzite. Contains considerable amounts of glauconite in many beds. Subdivided into two new members (ascending): Glenwood Canyon and Clinetop algal limestone. Underlies Dead Horse conglomerate member (new) of Manitou formation.

Named for good exposures in northeastern end of Glenwood Canyon near Dotsero, about 100 miles west of Denver.

Dotson Black (sheety) Shale[1]

Mississippian: Northwestern Arkansas.

Original reference: D. D. Owen, 1858, First Rept. Geol. Reconn. northern counties of Arkansas, p. 101–102.

Exposed on Wharton Creek at Dotson's Farm, Madison County.

Dotson Sandstone[1]

Dotson Sandstone (in Kanawha Group)

Pennsylvanian (Pottsville Series): Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 215, 221, 222. In Greenbrier County, Dotson sandstone (Campbell, 1897) is 20 to 65 feet thick. Underlies Gilbert coal; overlies Douglas coals. Lower Dotson sandstone (Hennen, 1919) is 10 to 25 feet thick. Overlies Douglas shale; separated from overlying Dotson sandstone by Douglas coals. Both sandstones included in Kanawha group, Pottsville series.

Named for occurrence at Dotson, McDowell County, W. Va.

Double Crater Volcanics

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, pl. 2. Agglomerate and interbedded lava flows. Name appears only on geologic map legend.

Mapped on summit of Double Crater in vicinity of Pavlof Volcano, Alaska Peninsula.

Doublehorn Shale Member (of Houy Formation)

Upper Devonian and Lower Mississippian(?) : Central Texas.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 807, 810, 811, pl. 3 (fig. 1). A black fissile radioactive spore-bearing shale from which, at places, large silicified pieces of wood of *Callixyon* have weathered free. Maximum thickness 15 feet; thins to disappearance. Principal unit of the Houy; overlies Ives breccia member; underlies unnamed phosphoritic member, or locally, Chappell limestone. Remnants of Doublehorn are found only along eastern side of Llano region.

Type section: Along Burnam Branch where it enters Doublehorn Creek and on Rubin Houy Ranch along Doublehorn Creek just down stream from Houy Branch, Burnet County.

Double Horseshoe cyclothem (in Carbondale Group)

Pennsylvanian: Eastern Illinois and western Indiana.

J. W. Alexander, 1943, Illinois Acad. Sci. Trans., v. 36, no. 2, p. 141–143. Composed of two limestones, both of which are thin and discontinuous. Upper is limestone conglomerate which has light-gray limestone matrix and contains black pebbles; maximum thickness 6 inches. Lower is light-gray lithographic slightly septarian limestone; maximum thickness 14 inches. Occurs below St. David limestone and above Summum cyclothem.

Well exposed in "Double Horseshoe" region on Little Vermilion River at Illinois-Indiana border.

†Double Mountain Formation[1] or Group

Permian: Central northern and central Texas.

Original reference: E. T. Dumble and W. F. Cummins, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxx, 187, 188, pl. 3.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 668. Name Double Mountain group abandoned; part of former unit now classed under Whitehorse group.

Named for Double Mountains, Stonewall County.

Double Point Dacite

Quaternary, middle: Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 177–180, pl. 23. Flows of light- to dark-gray glassy to lithoidal rocks containing many small plagioclase phenocrysts ordinarily visible in hand specimen. Rocks commonly irregularly vesicular, the vesicles commonly being lined with sugary-textured altered glass, tridymite, or both. Although classified as high-silica dacite, composition ranges into rhyodacite. Contains many round inclusions of miarolitic andesite. Flows form volcanic pile 3,000 feet high. Younger than Williwaw Cove (new), Sitkin Point (new), and East Point (new) formations. Underlies Patterson Point formation (new).

Named for exposures north of Double Point in southwest coast of Little Sitkin Island, in Rat Islands group of Aleutian Islands. Largest outcrop area extends from Double Point northeastward to drainage of Williwaw Cove stream and includes present caldera scarp.

Doublian series[1]

Permian: Texas.

Original reference: C. R. Keyes, 1929, Pan-Am. Geologist, v. 57, p. 337, 350–356.

Dough Hills Member (of Fleming Formation)

Miocene: Central Louisiana.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 118 (fig. 26), 158–161, geol. map. Consists primarily of a thick group of silty clays with calcareous beds near the center; lower beds are yellow silty clays carrying localized opaline nodules. Thickness 85 to 135 feet. Contact with underlying Carnahan Bayou member (new) arbitrarily taken as a tuffaceous clay bed which outcrops near center of NW¼ sec. 12, T. 4 N., R. 5 W.; contact with overlying Williamson Creek member (new) arbitrarily drawn on the appearance of numerous sand lentils in the clayey-silt sequence overlying the calcareous clay beds.

Crops out in Dough Hills, centrally located in T. 4 N., Rs. 4 and 5 W., Rapides Parish.

Doughnut Formation

Upper Mississippian: Central northern Utah.

M. D. Crittenden, Jr., B. J. Sharp, and F. C. Calkins, 1952, Utah Geol. Soc. Guidebook 8, p. 10–11, pl. 1. Includes parts of Morgan formation as defined by Calkins (1943, U.S. Geol. Survey Prof. Paper 201). Formation consists of dark rocks that are relatively unresistant. Lowest beds which are well exposed at south end of Doughnut Cliffs, are resistant, more or less sandy and siliceous, tawny-weathering rocks, in sharp contrast to the blue limestones of upper part of Humbug formation. Next 50 to 100 feet is black shale. Upper part consists of about 200 feet of thin-bedded limestone, blue black on fresh fractures but gray to buff on weathered surfaces. Underlies Morgan(?) formation.

M. D. Crittenden, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 69–70, 71–72, 73. Overlies Humbug formation. Underlies Round Valley limestone (called Morgan? by Calkins and Butler, 1943, U.S. Geol. Survey Prof. Paper 201). Thickness at type locality 400 feet. This unit [Doughnut] can be traced over much of Cottonwood area, from near Neff Canyon near Salt Lake, south to Charleston Thrust, and east to Park City. East of there, bedrocks are covered by volcanics and younger sediments, but they reappear about 2½ miles east of Kamas where this unit consists largely of black shale. It has been called Manning Canyon shale by Sadlick (1955, Wyoming Geol. Assoc. Guidebook 10th Field Conf.; 1956, Intermountain Assoc. Petroleum Geologists Guidebook 7th Ann. Field Conf.) but fauna is virtually identical with Doughnut formation. Proposed that black shale unit of western Uinta Mountains be called Doughnut formation.

Type sections: In Cliffs east of Doughnut Falls, in Mill D South Fork, a tributary of Big Cottonwood Canyon, in Wasatch Mountains, east of Salt Lake.

Douglas Amygdaloid[1] (in Central Mine Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, pl. 18.

Named for occurrence in Douglas mine, Houghton County.

Douglas Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Douglas Group[1]

Douglas Formation[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 93, 94.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2034, 2035 (fig. 5). As now recognized, group comprises strata. almost exclusively clastic occurring between disconformity at base of Virgilian series and base of Oread formation. Overlies Pedee group; underlies Shawnee group. Includes Stranger formation below and Lawrence formation above.

Named for Douglas County, Kans.

Douglas Shale (in Kanawha Formation[1] or Group)

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 183.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 215, 222. Underlies Lower Dotson sandstone; overlies Upper Nuttall sandstone. Thickness about 25 feet. Included in Kanawha group, Pottsville series.

Named for exposures at Douglas Railroad Station, McDowell County.

Douglas Canyon Formation[1]

Miocene, upper: Central Washington.

Original reference: A. D. Hoffman, 1932, Jour. Geology, v. 40, no. 8, p. 735–738.

Exposed in Douglas Canyon, one of side canyons of Moses Coulee, above and below waterfalls about one-half mile from canyon mouth, NW¼SW¼ sec. 30, T. 23 N., R. 24 E., Douglas County.

Douglas County traps[1]

Precambrian (Keweenawan): Northwestern Wisconsin.

Original reference: R. D. Irving, 1874, Am. Jour. Sci., 3d, v. 8, p. 46–56.

Douglas and Bayfield Counties.

Douglas Creek Member (of Green River Formation)[1]

Eocene: Northwestern Colorado and northeastern Utah.

Original reference: W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168.

D. C. Duncan and N. M. Denson, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 94. Described in Garfield County, Colo., where it is essentially brown sandstone and gray shale with a few thin beds of oolites and algae. Thickness 430 to 470 feet. Underlies Garden Gulch members; overlies Wasatch formation. Douglas Creek, Garden Gulch, and Parachute Creek members interfinger with a unit referred to as lower sandy member of Green River. Eocene.

F. M. Swain, 1956, Intermountain Assoc. Petroleum Geologists [Guidebook] 7th Ann. Field Conf., p. 128, 130. In this report, the shales, sandstones, and oolitic limestones which Bradley placed in Douglas Creek member are referred to the Colton-Green River transition beds.

C. W. Cline, 1957, Brigham Young Univ. Research Studies, Geology Ser., v. 4, no. 3, p. 1–46. Discussed in detail in Piceance Creek basin, Colorado. Age of Green River given as upper middle Eocene.

Well exposed at head of Douglas Creek in E½ of T. 5 S., R. 102 W., Garfield County, Colo.

Douglas Hills member (of Fleming Formation)

A lapsus for Dough Hills.

Douglas Island Volcanic Group[1]

Jurassic(?) to Lower Cretaceous(?): Southeastern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 255–256, chart opposite p. 247, p. 270.

T. G. Payne, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–84. Age shown on chart as Jurassic.

Fred Barker, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–100. On northeast limb of Shelter syncline. Thickness estimated to be at least 5,000 feet and probably 10,000 feet in Juneau (B–3) quadrangle. Jurassic(?) to Early Cretaceous(?).

Forms main mountain mass of Douglas Island, Juneau region.

Douglas Lake Member (of Lenoir Limestone)

Middle Ordovician: Eastern Tennessee.

Josiah Bridge, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 727–729. Proposed for beds overlying Mascot dolomite and underlying typical nodular member of the Lenoir in Douglas Lake area. Member is composed of several rock types including rubble conglomerate. chert conglomerate, and black dolomite; the chert conglomerate overlies the rubble conglomerate (that occurs in depressions or sinks on upper surface of the Mascot) and at other places forms the lower part of the member; the black fine-grained thick-bedded dolomite, as much as 30 feet thick at the two large sinks, grades upward almost imperceptibly into typical Lenoir limestone; the Douglas Lake, therefore, is regarded as a discontinuous member of the formation.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145 (table), 147. In Tellico-Sevier belt, eastern Tennessee, the Douglas Lake is basal member of the Lenoir. Underlies Mosheim member.

Type locality: On north shore of Douglas Lake, 1½ miles northeast of Douglas Dam, Jefferson County.

Douglass[1] (shales)

Lower Cretaceous: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Derivation of name not given.

†Douty Gravel[1]

Pleistocene (pre-Wisconsin?): Western Washington.

Original reference: B. Willis, 1898, Geol. Soc. America Bull., v. 9, p. 111.

D. R. Crandell, D. R. Mullineaux, and H. H. Waldron, 1958, Am. Jour. Sci., v. 256, no. 6, p. 395. According to Willis (1898), deposits of Vashon age include Vashon drift, Osceola till, Osceola clays, and Douty gravels. Osceola till of Willis is now known to be a postglacial mudflow deposit from Mount Rainier. Osceola clays and Douty gravels of Willis are glacial drift of Vashon age, and the two names are thereby abandoned.

Named for Douty Station, in canyon near Carbonado, Pierce County.

Dover Limestone Member (of Stotler Limestone)

Dover Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series) : Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 31.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 15. Consists of thin fossiliferous limestone and some shale. Thickness 2 to 4 feet in Nebraska, southeastern Iowa, and northwestern Missouri; thicker in southern Kansas. Underlies Dry formation; overlies Langdon formation.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Stotler limestone (new). Underlies Dry shale member; overlies Pillsbury shale (new).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12, fig. 5. Consists of two limestone beds separated by thin bed of gray shale. Upper limestone is dense, gray, unfossiliferous, and weathers buff; lower limestone is dark gray to black, weathering to nodular form with many white fragments of *Derbyia*, *Chonetes*, and *Crurithyris*. Thickness about 3 feet. Underlies Dry shale; overlies Table Creek shale. Wabaunsee group.

Named for exposures near Dover, Shawnee County, Kans.

Dover Shale and Sandstone (in Wabaunsee Group)[1]

Pennsylvanian: Northeastern Kansas.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 31.

Named for Dover, Shawnee County.

Dowell Hill facies[1] (of New Providence Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 95, 102–103.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Correction chart lists Dowell Hill as facies of New Providence formation.

Described in Brown and Bartholomew Counties. Name derived from Dowell Hill in NE¼ sec. 25, T. 9 N., R. 4 E., 5½ miles west of Columbus, Bartholomew County.

Dowelltown Member (of Chattanooga Shale)

Dowelltown Formation (in Chattanooga Shale)

Upper Devonian: Central Tennessee.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 883–884, 885. In type area and adjacent territory, consists of lower and upper member, each with a lower bed of fissile black shale and an upper bed with interbedded layers of gray and black shale; near crest of Nashville Dome, formation is a poorly fissile soft dull-black shale that shows a blending of the black and gray shale elements into a shale intermediate in character; lower member pinches out and is represented at Nashville only by a foot of sandstone. A layer of sandstone which is correlated with the Hardin sandstone occurs at base of Dowelltown at Celina. Thickness varies; 22 to 29 feet in type area; 8 to 12 feet in Macon and Clay Counties; 15 to 19 feet in Sumner County. Lies between Trousdale formation below and Gassaway shales (new) above and is basal part of the Chattanooga in most of central Tennessee. Devonian.

S. G. Conrad, R. T. Elmore, Jr., and S. W. Maher, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1358. Termed Dowelltown member of Chattanooga shale. Within Flynn Creek structure, Jackson County, maximum thickness of Dowelltown is 166.4 feet.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 12 (table 1), 16–20. In this report, considered a member of the Chattanooga shale. Underlies Gassaway member and in some areas overlies Hardin sandstone member. Where well developed, it is between 10 and 17½ feet thick and consists of two persistent units; lower one, which is predominantly black shale, and upper, which is primarily a grayish mudstone near the top of which is a bentonite bed about 0.1 foot thick. On west flank of Cincinnati anticline, Dowelltown is commonly a sandy black shale as much as 17 feet thick. Wedges out in Sequatchie Valley of eastern Tennessee and has not been recognized in south-central Tennessee or north-central Alabama.

Type sction: Outcrop 1½ miles east of Dowelltown, DeKalb County. Hass did not find Campbell's type section at designated distance but considered an exposure 3.1 miles east of Dowelltown on an abandoned part of Tennessee Highway 26 as Campbell's type locality.

Downeys Bluff Member (of Renault Formation)

Mississippian (Chester Series): Southern Illinois and northern Kentucky.

Elwood Atherton, 1947, Illinois Acad. Sci. Trans., v. 40, p. 129, 130 (fig. 7), 131 (fig. 8). Frank Tippie (unpub. ms.) correlated upper part of the Renault with the basal Paint Creek of western Illinois and proposed name Downeys Bluff for this member of the Paint Creek; remainder of the Renault is referred to as Shetlerville member. Thickness about 40 feet. At type locality, underlies Bethel sandstone.

J. M. Weller and others, 1952, Illinois Geol. Survey Bull. 76, p. 62–63. In fluorspar district, consists predominantly of limestone with small amounts of shale occurring as partings; limestones are commonly gray or bluish gray and crystalline to more or less fine grained. Thickness about 30 feet. Overlies Shetlerville member; at Downeys Bluff, contact is unconformable and at most places separation of the two units is difficult, especially where shale is not abundant in Shetlerville; underlies Bethel sandstone.

Type locality: Downeys Bluff, NW¼SE¼ sec. 5, T. 13 S., R. 8 E., Hardin County, Ill.

†Downs Limestone (in Greenhorn Limestone)[1]

Upper Cretaceous: North-central Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 50.

Quarried near Downs, Osborne County.

Dox Sandstone (in Unkar Group)[1]

Precambrian (Grand Canyon Series): Northern Arizona.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (table), 110. Top formation in Grand Canyon series. Thickness over 3,000 feet in Unkar Valley. Underlies Cardenas lava series (new).

Named for Dox Castle, in Shinumo quadrangle, underneath which a typical section is found below Tonto group, which makes the castle.

Doxey Member (of Quartermaster Formation)[1]

Permian: Western Oklahoma.

Original reference: H. L. Griley, 1933, Pan-Am. Geologist, v. 59, no. 3, p. 234.

D. A. Greene, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1473, 1474. Doxey shale is 160- to 200 feet thick in Washita and Beckman Counties; near middle of unit are several bench-forming beds of siltstone. Underlies Elk City member, contact irregular; overlies Cloud Chief member.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Quartermaster formation includes Doxey and Elk City members. Cloud Chief mapped as formation.

Quartermaster formation is noted as occurring in Beckham, Caddo, Custer, Grady, and Washita Counties.

Doyle Shale (in Chase Group)[1]

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: C. S. Prosser, 1902, Jour. Geology, v. 10, p. 715.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 80. Restored to formal nomenclature and considered as consisting of (ascending) Holmesville shale, Towanda limestone, and Gage shale members, which had heretofore been given formational rank. Overlies Barneston limestone; underlies Winfield limestone.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 115–116. Subdivided into (ascending) Holmesville shale, Towanda limestone, and Gage shale members. Members recognized in Kansas, southeastern Nebraska, and northern Oklahoma where they have been identified in Kay and Osage Counties. Members cannot be differentiated in Pawnee County. Thickness 103 to 118 feet in Kay County; 125 to 135 feet in Osage County. Thickness difficult to determine in Pawnee County; electric logs show about 150 feet. Overlies Fort Riley limestone; underlies Winfield limestone. Wolfcamp series.

Named for exposures on Doyle Creek, southwest of Florence, Marion County, Kans.

Doylesburg Member (of Shippensburg Formation)

Middle Ordovician (Bolarian): South-central Pennsylvania.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 715 (fig. 1), 727–731. Name proposed for uppermost member of formation. Described at type locality as massive-bedded white-weathering dove calcilutite with dark-gray fine-grained platy limestone at top. In western belts of outcrop, two locally intertonguing lithofacies recognized: calcilutite facies and platy limestone facies with heavy interbeds of medium-gray to dove limestone conglomerate. Facies variations distributed in northeast-trending belts. Thickness 6 to 40 feet. Conformably overlies Fannettsburg member (new); disconformably underlies Mercersburg formation.

Type section: Exposure on south side of U.S. Route 30, 1 mile southwest of St. Thomas, Franklin County. Named for exposure at Binkley and Ober quarry at Dry Run, 4 miles southwest of Doylesburg in Path Valley.

Dozier Sandstone Member (of Rush Springs Formation)

Dozier Sandstone Member (of Peacock Formation)[1]

Permian: Western Texas.

Original reference: J. W. Beede, 1907, Kansas Univ. Sci. Bull., v. 4, no. 3, p. 142.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Reallocated to member status in Rush Springs formation.

U.S. Geological Survey has abandoned the term Peacock Formation.

First described on western side of "Dozier Mountains," east of Mr. Caperton's place (then Dozier post office), 15 miles south or southwest of Shamrock, Collingsworth County.

Dozier Mounds Dolomite

Dozier Mounds Dolomite Member (of Custer Formation)

Triassic: Texas.

Robert Roth, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 422, 438, 439, 450–457. Referred to as Dozier Mounds dolomite and Dozier Mounds dolomite member of Custer formation. When Custer was originally defined (Roth, 1932), base of Dozier Mounds dolomite was chosen as base of Custer because Dozier Mounds dolomite [Roth did not use formal name Dozier Mounds in his 1932 report] and Verden channel dolomite of Oklahoma were considered the same. Present study shows that Dozier Mounds dolomite is not always at base of Custer. Interval between Dozier Mounds dolomite and base of Custer increases as section is traced southwestward from Collingsworth County. First description of unit credited to Gould (1906, U.S. Geol. Survey Water-Supply Paper 154), who described unit near middle of Quartermaster as ledge of rather hard red or pinkish more or less oolitic sandstone, which on weathering gives rise to a number of flat-topped buttes and ridges. One of most typical [buttes] is Dozier Mounds, near Dozier post office. [On plate 8, Gould showed a hill in Rocking Chair Mountains capped by Dozier sandstone.]

Type locality: NE¼NE¼NE¼ sec. 28, Blk. 16, H. and G. N. Survey, Collingsworth County. Named for Dozier Mounds.

Dracut Diorite[1]

Upper Carboniferous or post-Carboniferous: Northeastern Massachusetts and southeastern New Hampshire.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 221–223, map.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 66. Not mapped by name in New Hampshire.

Named for occurrence at Dracut, north of Lowell, Middlesex County, Mass.

Dracut Norite[1]

Post-Cambrian and pre-Carboniferous: Northeastern Massachusetts.

Original reference: E. E. Fairbanks, 1927, Boston Soc. Nat. History, v. 38, p. 397–407.

W. H. Dennen, 1943, Econ. Geology, v. 38, no. 1, p. 27, 29, 32–34, 35–41. Contains many inclusions of Merrimack quartzite which it intrudes. Typical texture is holocrystalline. Cut by Andover granite and a few diabase dikes. Post-Cambrian and pre-Carboniferous.

Occurs at Dracut, Middlesex County.

Dragonian Age

Paleocene: North America:

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 9, pl. 1. Provincial time term, based on Dragon local fauna in North Horn formation, Dragon Canyon, Emery County, Utah, principally from western half of sec. 8, T. 19 S., R. 6 E. Covers interval between Paleocene Puercan (older) and Torrejonian ages. Definition of 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

†Dragoon Quartzite[1]

Middle Cambrian: Southeastern Arizona.

Original reference: E. T. Dumble, 1902, Am. Inst. Mining Engineers Trans., v. 31, p. 696–715.

Dragoon Mountains.

Dragoonan series[1]

Cambrian: Arizona and New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico. Des Moines, Robert Henderson, State Printer, p. 4, 6.

Named for Dragoon Mountains, southeastern Arizona.

Draney Limestone (in Gannett Group)[1]

Lower Cretaceous: Southeastern Idaho and western Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 76, 83.

R. E. Peck, 1941, Jour. Paleontology, v. 15, no. 3, p. 285–286. Considered Lower Cretaceous on basis of faunal studies.

L. S. Gardner, 1944, U.S. Geol. Survey Bull. 944–A, p. 7. In Irvine quadrangle, Idaho, 245 feet thick; overlies Bechler shale and underlies Bear River formation.

A. Moritz, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 65 (table 1), 67 (fig. 2), 68. In Gannett Hills area, western Wyoming, overlies Bechler formation (shale or conglomerate); underlies a discontinuous unnamed red bed unit below Bear River formation. Tygee sandstone is here included in Bear River formation.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 56, pl. 21. Referred to as member of Gannett group in Jackson Hole area. Consists of about 55 feet of limestone. Underlies Tygee sandstone member; overlies Bechler conglomerate member.

Named for exposure on top of ridge about 1¼ miles east of Draney Ranch, on Tygee Creek, sec. 10, T. 8 S., R. 46 E., Boise meridian, Idaho.

Draper Dolomite Member (of Nittany Formation)

Lower Ordovician (Canadian): Western Virginia.

B. N. Cooper, 1939, Jour. Geology, v. 47, no. 5, p. 511 (footnote). Name applied to upper member of formation; overlies Oglesby member (new). Thickness approximately 350 feet.

B. N. Cooper, 1939, Virginia Geol. Survey Bull. 55, p. 19–20, pls. 1, 3. Formally proposed as Draper dolomite member. Composed of medium-bedded light-gray dolomitic limestone and dolomite; most beds are siliceous and slightly argillaceous; bedding is uniform in lower part of member but irregular in upper part. Thickness as much as 475 feet. Conformably underlies Bellefonte formation. Type locality stated.

Type locality: In Draper Mountain area, south of Lee Highway about three-fourths mile southwest of Draper School, near Draper, Pulaski County.

Draytonville Conglomerate Member (of Kings Mountain Quartzite)[1]

Ordovician to Mississippian: Northwestern South Carolina and southern North Carolina.

Original reference: A. Keith and D. B. Sterrett, 1931, U.S. Geol. Survey Geol. Atlas, Folio 222.

U.S. Geological Survey currently designates the age of Draytonville as Ordovician to Mississippian on the basis of a study now in progress.

Named for exposures on Draytonville Mountain, Cherokee County, S.C.

Dresbach Group

Dresbach Sandstone[1] or Formation

Upper Cambrian: Southern Minnesota, northwestern Illinois, northeastern Iowa, and western Wisconsin.

Original reference: N. H. Winchell, 1886, Minnesota Geol. Nat. History Survey 14th Ann. Rept. p. 334-337.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9, 28 (table 4), 29–35. Formation described in southeastern Minnesota where it includes (ascending) Mount Simon, Eau Claire, and Galesville members. Underlies Franconia formation. At type section, includes Galesville member, 24 feet, and Eau Claire member about 128 feet. St. Croixian series.

H. B. Willman and J. N. Payne, 1942, Illinois Geol. Survey Bull. 66, p. 54. Classified as group consisting of Mount Simon, Eau Claire, and Galesville formations.

R. R. Berg, 1953, Jour. Paleontology, v. 27, no. 4, p. 555. Underlies Woodhill member of Franconia formation.

R. R. Berg, C. A. Nelson, and W. C. Bell, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 6–8. No exhaustive study of Dresbach formation has been published, and distribution of its members and faunas is poorly known. Internally, Dresbach contains three distinguishable but genetically and gradationally related rock types: (1) medium- to coarse-grained quartzose sandstone that characterizes near-shore transgressive (Mount Simon member) and regressive (Galesville member) phases of cycle, (2) shaly sandstone and very fine grained quartzose sandstone that characterizes offshore (Eau Claire member) phase, and (3) red shale phase of Eau Claire identified in wells. Dresbach is topped by disconformity. At type section, uppermost 35 feet of Eau Claire member is composed of thin-bedded very fine grained sandstone, siltstone, and shale. Overlying 93 feet of Galesville member is massive- to crossbedded fine- to medium-grained sandstone. This subdivision of type section differs from previous descriptions in which most of Galesville sandstone was included in Eau Claire member.

U.S. Geological Survey currently classifies the Dresbach as a group on the basis of a study now in progress.

Named from town of Dresbach in Winona County, Minn.

†Dresbach Shale[1]

Upper Cambrian: Southeastern Minnesota.

Original reference: N. H. Winchell, 1888, Minnesota Geol. Nat. History Survey Final Rept., v. 2, p. 364.

At Dresbach, Winona County.

Dresbachian Stage

Upper Cambrian: North America.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Upper Cambrian comprises three stages (ascending): Dresbachian, Franconian, and Trempealeauan. The Dresbachian includes three faunal zones: *Cedaria*, *Crepicephalus*, and *Aphelaspis*.

C. A. Nelson, 1956, Internat. Geol. Cong. 20th Mexico, Cambrian symposium, pt. 2, p. 421–425. Dresbachian stage consists, by definition, of *Cedaria*, *Crepicephalus*, and *Aphelaspis* zones, which in turn occur within middle Eau Claire member of Dresbach formation. Hence, it is likely that Dresbach formation and Dresbachian stage will maintain nomenclatorially coincident boundaries in upper Mississippian Valley. However, *Cedaria* and *Aphelaspis* zones have their minimum expression in type Dresbachian area because of hiatuses associated with unconformities that bound Dresbach formation. Consequently, concept of Dresbachian will have to be expanded in area where sedimentary record is more complete and where its faunas mingle with earlier and later ones.

Named from town of Dresbach in Winona County, Minn.

Dresden Amphibolite[1]

Precambrian: Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

Type locality: Dresden Township, Washington County.

Dresden Sandstone (in Pottsville Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: E. Orton, 1884, Ohio Geol. Survey, v. 5, p. 919, 920, 991.

Probably named for Dresden, Muskingum County.

Drews Lake Granite[1]

Carboniferous(?): Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 106–107, 148–149.

Named for exposures near Drews Lake, west of Houlton, Aroostook County.

Drinkard Sandy Member (of Yeso Formation)

Permian: Southeastern New Mexico (subsurface).

R. E. King, 1945, New Mexico Bur. Mines Mineral Resources Bull. 23, p. 13–15, fig. 1. Name applied to widespread clastic zone in middle or lower part of Yeso formation. In eastern Lea County, member is 90 to 110 feet thick, and consists of very fine grained calcareous and argillaceous gray and brown sandstone and sandy shale, in part pyritic, interbedded with brown sandy dolomite. In type well, occurs between depths of 6,100 and 6,210 feet.

Type section: Penetrated in Texas Co. Blinebry 1, 660 feet from south line and 1,980 feet from east line sec. 19, T. 22 S., R. 38 E., Drinkard area, Lea County.

Drinker Creek sandstone member (of Lanesboro formational suite)

Upper Devonian (Chautauquan): Northeastern Pennsylvania.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7), 46, 47–49. Name proposed for member at base of formational suite. Described as micaceous, quartzose, usually gray or olive-greenish sandstone; varies from fine sand to thin layers of flat vein-quartz pebbles up to 1 inch in diameter. Whole unit more or less lenticular and locally broken into flags and shales. Thickness 25 feet. Basal unit of upper sandstone sequence of White's (1881) New Milford group.

Type locality: Old quarry pits near forks of Drinker Creek about 1½ miles south of Susquehanna, Susquehanna County.

Dripping Spring Quartzite (in Apache Group)[1]

Precambrian: Southeastern Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

M. N. Short and others, 1943, Arizona Bur. Mines Bull. 151, Geol. Ser. 16, p. 12, 21–22. Completely uninterrupted section crops out on east side of Potts Canyon just west of Prudential mine. Here thickness is 820 feet, which is average total thickness of formation in Superior area.

J. R. Cooper, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 31, 32 (fig. 13). Unconformably underlies Bolsa quartzite in Johnson Camp area, Little Dragoon Mountains, Cochise County.

H. C. Granger and R. B. Raup, 1959, U.S. Geol. Survey Bull. 1046–P, p. 422–424, pls. 46–48. An upper and a lower member recognizable throughout Gila County. Lower member typically feldspar-rich cross-stratified well-indurated sandstone; upper member mostly of thinly stratified arenaceous siltstone. Thickness ranges from 450 to 700 feet and averages about 600 feet in Sierra Ancha region and about 450 to 540 feet in Mescal Mountains. Overlies Barnes conglomerate; underlies Mescal limestone.

D. W. Peterson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–128. Three members recognized in Haunted Canyon quadrangle. Lower, 100 to 200 feet thick, medium- to coarse-grained quartzite, grayish yellow, light gray, white; middle, 10 to 15 feet, nearly pure white medium-grained quartzite; upper, 200 to 300 feet, fine-grained quartzite interbedded with layers of shale. Overlies Barnes conglomerate; underlies Mescal limestone.

U.S. Geological Survey currently classifies the Barnes Conglomerate as a member of the Dripping Spring Quartzite on the basis of a study now in progress.

Named for Dripping Spring Mountains, Globe quadrangle.

Dripping Springs Formation

Pleistocene: Southern California.

J. F. Mann, Jr., 1955, California Div. Mines Spec. Rept. 43, p. 3, 9, 14–15, pl. 1. Defined as the fanglomerates, in Temecula region, deposited with reference to a base level not greatly above present base level, as opposed to Pauba fanglomerates which were deposited at a much higher base level. Thickness about 30 feet. Unconformably underlies Recent terrace gravels; unconformably overlies Pauba formation (new).

Occurs in Elsinore fault zone in western Riverside and northern San Diego Counties. Well exposed in Dripping Springs alcove, Riverside County, especially in roadcuts along Highway 71.

Driscoll-Sevier Sand

Oligocene: Southern Texas (subsurface).

Alexander Deussen and K. D. Owen, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1630 (fig. 5), 1631 (fig. 6), 1632–1633, 1634. Name suggested for sand unit north and west of marine shale wedge [Old Ocean sand] and representing merged western representatives of both underlying [Van Vleck] and overlying [Pierce Estate or Flour Bluff] sand.

Typically developed in well No. 27 (Santa Clara, Driscoll-Sevier No. A–1), Nueces County.

Droop Sandstone (in Bluefield Formation[1] or Group)

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 415.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 225, 264. In Greenbrier County is grayish brown, massive, medium grained, and hard, commonly crossbedded, and ripple marked with carbonized plant remains. Thickness 50 to 100 feet. Underlies unnamed shale sections; overlies yellow, olive sandy shale above Reynolds limestone. Mauch Chunk series.

Type locality: On Droop Mountain, Pocahontas County, W. Va., in vicinity of Spice, Mt. Zion Church and West Droop School.

†Drum Group[1]

Pennsylvanian: Northeastern Oklahoma.

Original reference: C. N. Gould, 1925, Oklahoma Geol. Survey Bull. 35, p. 73–74.

Drum Limestone (in Kansas City Group)[1]

Drum Limestone (in Skiatook Group)

Drum Limestone Member (of Kansas City Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. I. Adams, 1903, U.S. Geol. Survey Bull. 211, p. 37, 63, 66.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40 (table), 42. Included in Skiatook group. Overlies Cherryvale shale; underlies Chanute shale of Ochelata group. Near Kansas-Oklahoma State line, the Drum is absent owing to erosion. Reappears a few miles south of State line and in Oklahoma has been known as Dewey limestone.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030–2032. Drum limestone, in type area, comprises two units classed as members. Upper unit, Corbin City, locally 40 feet or more in thickness, is not persistent. Corbin City disconformably overlies lower member which consists of fine-grained bluish limestone; this is identified unquestionably as Dewey limestone of northeastern Oklahoma. Northeastward tracing proves that Dewey member is same as limestone called Cement City in Kansas City area. Inasmuch as Dewey has priority over Cement City and has been widely used, it is recognized by Oklahoma Geological Survey as formational unit which is classed as uppermost division of Skiatook group. Kansas has used Cement City for lower member of Drum limestone, and Cement City was recognized by interstate conference. Kansas proposes to deviate from interstate classification by adopting Dewey, instead of Cement City.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 36–37. Formation comprises (ascending) Corbin City limestone (missing in Nebraska), Cement City limestone, Richfield Quarry shale (new), and P. W. A. Quarry limestone (new) members. Thicknesses: 12½ feet southwestern Iowa; 14 feet, Sarpy County, Nebr.; 3 to 18 feet, Kansas City, Mo.; 2 to 60 feet in Kansas. Underlies Chanute formation; overlies Quivera formation. Note on type locality.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. Thickness of formation 2 feet in Madison and Adair Counties; no members differentiated. Overlies Cherryvale formation; underlies Chanute formation. Kansas City group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. As shown on chart, Drum Limestone comprises (ascending) Cement City Limestone and Corbin City Limestone Members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Formation in Iowa is single conglomeratic, oolitic limestone bed characterized by tiny *Triticites*. Thickness 6 feet, Madison County; 14 feet, Pottawattamie County. Overlies Quivera shale; underlies Chanute shale. Kansas City group.

Type locality: Along highway east of Independence, Kans., and at cement plant in NW sec. 4, T. 33 S., R. 16 E. Named for Drum Creek, Montgomery County, Kans.

Drumheller Silts

Quaternary (post-Wisconsin): Central Washington.

[G. F. Beck], 1937, Central Washington Coll. Education Bull., v. 2, no. 7. Proposed for most recent valley fills occurring generally over Columbia Basin. Channel fills are 6 to 12 feet in depth. Bones showing relationship to modern buffalo are abundant in silts.

Well exposed in Drumheller section of Lower Crab Creek, Grant County.

Drumlummon Porphyry[1]

Tertiary, upper(?): Western central Montana.

Original reference: J. Barrell, 1907, U.S. Geol. Survey Prof. Paper 57.

Mapped on Drumlummon Hill, just south of Marysville, Lewis and Clark County.

Drummond[1] (clays)

Tertiary: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Derivation of name not stated.

Drury Shale Member (of Caseyville Formation)

Drury Shale Member (of Battery Rock Formation)

Drury Shale and Sandstone Member (of Pottsville Formation)[1]

Pennsylvanian: Southwestern Illinois.

Original reference: J. E. Lamar, 1925, Illinois Geol. Survey Bull. 48, p. 23, 91–95, map.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 37, 38. Reallocated to member status in Battery Rock formation. Principally sandy shale and shaly sandstone 50 to 100 feet thick. Upper part of formation; overlies Battery Rock sandstone in lower part of formation.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 29–30, 44 (table 1), 61, pl. 1. Reallocated to member status in Caseyville formation (redefined). Includes all strata between Battery Rock sandstone member below and Pounds sandstone member. Dominantly shale but includes some sandstone and two or more discontinuous coals. Thickness at type section of Caseyville, 98 feet. Name Drury not used in southeastern Illinois where Gentry coal and Sellers limestone are differentiated in this interval. Presentation of new rock-stratigraphic classification of Pennsylvanian strata of Illinois.

Type locality: Along Drury Creek, secs. 33 and 34, T. 10 S., R. 1 W., Jackson County. Named for exposures along Drury Creek, in bluffs south of Makanda, Jackson County.

Dry Shale Member (of Stotler Limestone)

Dry Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 22, 236.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 15. Consists of clay-shale, sandy shale, and fossiliferous limeseams. Thickness 14 feet in clay pits at Nebraska City. Areal extent noted.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Stotler limestone (new). Underlies Grandhaven limestone member; overlies Dover limestone member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12, fig. 5. Bluish-gray silty shale with thin interbedded gray limestone and siltstone; ferruginous concretions common in siltstone. Thickness about 20 feet. Underlies Grandhaven limestone; overlies Dover limestone. Wabaunsee group.

Type locality: Dry Creek, in sec. 5, T. 20 S., R. 11 E., southwest of Emporia, Lyon County, Kans.

Dry Camp Breccia

Tertiary: Northwestern Arizona.

U.S. Bureau of Reclamation, 1950, U.S. Bur. Reclamation, Boulder Canyon Proj. Final Repts., pt. 3, Preparatory Exams., Geol. Inv., Bull. 1, p. 99, fig. 34 (geol. map). An intervolcanic sedimentary breccia. Resembles Dam breccia (new) but more definitely bedded. Maximum thickness about 400 feet. Part of younger volcanic series of area. Underlain and overlain by basalt. Name credited to F. L. Ransome (unpub. rept.).

Occurs only on east side of Black Canyon, Hoover Dam area.

Dry Cimarron Flow (in Capulin Basalts)

Quaternary: Northeastern New Mexico.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1031. Black fine-grained vesicular olivine basalt with 4-mm olivine phenocrysts.

One long flow north and east 21 miles down Dry Cimarron Canyon, from Folsom, Union County.

Dry Creek Formation[1]

Eocene: Northern California.

Original reference: V. T. Allen, 1929, California Univ. Pub., Bull. Dept. Geol. Sci., v. 18, no. 14, p. 367–369, 400, 401, 403.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Used in quotational sense as a sandstone member of Ione formation. Name Dry Creek is preoccupied by Dry Creek shale of Montana.

Exposed in steep-walled valley formed by a tributary of Dry Creek, Chico quadrangle.

Dry Creek Glaciation

Pleistocene: Central southern Alaska.

Clyde Wahrhaftig 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 7, 13 (table 1); Clyde Wahrhaftig, 1958, U.S. Geol. Survey Prof. Paper 293–A, p. 17, 28–30, pls. 2, 3, 5.

Lake deposit at Dry Creek, 5 miles west of Healy; and drift between McKinley Park Railroad Station, 10 miles south of Healy, and Windy 20 miles further to the south, Nenana River valley area.

Dry Creek Sandstone Member[1] (of Edwardsville Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Geol. Pub. 98, p. 76, 238, 243, 246.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 74. Dry Creek sandstone and Brownstown Hills sandstone members included in Medora Knob facies of formation.

Named for prominence along Dry Creek, both east and west of Jackson-Lawrence County line.

Dry Creek Shale[1]

Dry Creek Shale Member (of Open Door Limestone)

Dry Creek Shale Member (of Red Lion Formation)

Dry Creek Shale Member (of Sage Limestone)

Dry Creek Shale Member (of Snowy Range Formation)

Upper Cambrian: Western Montana and northwestern Wyoming.

Original references: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110; 1896, U.S. Geol. Survey Geol. Atlas, Folio 24; W. H. Weed, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 286.

Charles Deiss, 1936, Geol. Soc. America Bull., v. 47, no. 8, p. 1284, 1335–1337, strat. sections. Weed's (1900) definition of Dry Creek shale emended. Dry Creek rests on Pilgrim limestone (emended) and is youngest Cambrian formation in any of measured sections. Underlies Devonian limestones; term Yogo limestone discarded. Characteristically bright-maroon and yellow-buff dolomitic sandy calcareous mudstones, interbedded with red and green shales and thin limestones. Average thickness 68 feet, exclusive of Checkerboard and Helena sections; from maximum thickness of 99 feet, on Belt Creek, formation thins eastward to 32 feet in Big Snowy Mountains, and westward to extinction in Beaver Creek area in Big Belt Mountains; thickness 50 feet at emended type section, herein designated Weed (1900) defined Dry Creek shale as lying "between the beds of the massive Pilgrim limestone and the dark chocolate-colored beds of the Jefferson formation." The statement gives exactly the actual conditions observable wherever these rocks are exposed and is concise in placing Cambrian-Devonian boundary at top of Dry Creek shale. Consequently, Yogo limestone or any other Cambrian rocks could not be present in Little Belt Mountains above Dry Creek. That Weed did not find Cambrian rocks in these mountains is implied in his statement. If Weed's statement had not been confused by the definition of the fictitious Yogo limestone, much confusion would have been avoided, and a more correct picture of Cambrian stratigraphy in central Montana would have resulted. Weed (1900) did not specify type section for Dry Creek shale, name of which he obviously took from Peale's (1893) Three Forks section, instead of from Little Belt Mountains. Type of Dry Creek shale (formation) must be in Little Belt Mountains province, or serious confusion will result. In section on north side of Dry Wolf Creek, Dry Creek shale is sharply defined at its top by *Spirifer* bed which marks base of Devonian. However, Dry Creek shale is better exposed in Yogo Gulch, and lower 13 feet contain only identifiable Dry Creek fossils in Montana known to writer. [See Flathead quartzite.]

Erling Dorf and Christina Lochman, 1940, Geol. Soc. America Bull., v. 5, no. 4, p. 551. Unit termed Dry Creek shale by Deiss (1936) apparently represents lower part of Snowy Range formation (new).

Christina Lochman and Donald Duncan, 1944, Geol. Soc. America Spec. Paper 54, p. 2–3, 4 (fig. 1), 6–12. Dry Creek shale is partly emended by restricting all limestone pebble conglomerates and gray-green shales to Pilgrim formation. This revision gives lithologic unity to both Dry Creek and Pilgrim in all sections and restricts fossil horizons to Pilgrim. As thus emended, contact between the two formations differs in most sections from that designated by Deiss (1936). Dry Creek-Jefferson boundary discussed.

L. L. Sloss and W. M. Laird, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 8, p. 1405–1406, 1407–1409, 1413, 1415. In central Montana, shales, mudstones, and argillaceous dolomites assigned to Devonian are apparently transitional with beds lithologically like Upper Cambrian Dry Creek shale. Weed (1900) and Deiss (1936) assigned all shales to Cambrian, although Deiss recognized difficulty of separating them from Devonian. It is believed that a variable proportion of the shale previously placed in Cambrian is Devonian in age. In Three Forks area, basal Devonian rocks are predominantly red shales, mudstones, and argillaceous dolomites. These beds are in apparent transition with underlying Cambrian strata and were formerly grouped with them in Dry Creek shale. For purposes of this report, the glauconitic, micaceous, and sandy shales associated with flat-pebble conglomerates, bearing trilobite fragments and phosphatic brachiopods, are assigned to the Cambrian Dry Creek shale; the nonmicaceous and less fissile shales and mudstones interbedded with rocks of Devonian type are placed in Devonian. At Logan, the Dry Creek is 45 feet thick; 34 feet, Yogo Creek section, Judith Basin County.

Christina Lochman, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2200–2222. Name Dry Creek shale was originally proposed by Peale for small nonfossiliferous unit in Gallatin formation in Upper Cambrian sequence in vicinity of Three Forks, Mont. Weed (1899, U.S. Geol. Survey Geol. Atlas, Folio 55) used same name for formation of brick-red shales and dolomites, a unit entirely different in age, lithology, and stratigraphic position from that of Peale. Subsequent usage of term, with or without definition, has been regarded by authors as implying that they were referring to beds which were wholly or in part the equivalent of original Dry Creek shale member of Peale. With exception of Knopf (1913, U.S. Geol. Survey Bull. 527), no author using Dry Creek shale as formational unit in Montana sections referred to beds which were lithologic or time equivalent of Peale's Dry Creek shales. Names should be used as originally defined by Peale, but strata involved do not constitute a mappable lithic unit by present mapping standards. Peale's Dry Creek shales constitute lower member of Snowy Range formation; name Sage pebble conglomerate is proposed for upper member of this formation. Weed's (1899) formation of brick-red shales and dolomites is mappable lithic unit of Devonian age; it is basal Devonian unit (unit C) of Sloss and Laird (1947) should be called Maywood formation, the name proposed by Emmons and Calkins (1913) for same lithologic unit in Philipsburg quadrangle.

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull. v. 35, no. 10, p. 2146. Term Red Lion is favored for beds formerly assigned to Dry Creek in southwestern Montana.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 12, 18, pl. 5. Lochman restricted term Dry Creek to Peale's original usage, and, as thus defined, the Dry Creek shale becomes lower shale member of Red Lion formation in southwestern Montana. Overlies Sage pebble conglomerate member. Thickness commonly 20 feet; locally absent.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. Lochman (1950) revised and redescribed Dry Creek shale and named what, in Wyoming, is called "upper Gallatin limestone" the Sage pebble conglomerates. This name seems applicable in Wyoming, but because of lithic changes it is better called Sage limestone. Dry Creek shale is thin and rarely mappable and most commonly should be regarded as member of Sage limestone. Gallatin is herein raised to rank of group with Sage limestone as upper member.

A. B. Shaw and C. R. DeLand, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 38, 39 (fig. 1), 40 (fig. 2), 41. Rank reduced to member status in Open Door limestone (new) in southwestern Wyoming. Forms basal part of formation; overlies Du Noir limestone.

P. W. Richards, 1957, U.S. Geol. Survey Bull. 1021–L, p. 400–401. Snowy Range formation is used in this report [area east and southeast of Livingston] because of inconsistencies in use of Dry Creek shale. Formation in this area apparently includes beds in stratigraphic position of Peale's Dry Creek shales and pebbly limestones and still younger beds.

Type locality (emended): North side of Yogo Gulch, on northeastern side of Little Belt Mountains, Judith Basin County, Mont. Section measured approximately one-eighth mile west of mouth of Bear Creek, in SE¼ sec. 1, T. 13 N., R. 10 E. Peale (1893) did not designate type locality but stated unit was best exposed on Dry Creek, northeast corner Three Forks quadrangle, Gallatin County.

Dry Creek Canyon Member (of Dakota Sandstone)

Lower Cretaceous: South-central Colorado.

K. M. Waagé, 1953, U.S. Geol. Survey Bull. 993, p. 12, 13–17, fig. 2, pls. 2, 4, 5. Consists of three lithologic zones (ascending): even-bedded white sandstone with some interbedded shale with average thickness in type area of about 6 feet; a middle zone composed commonly of upper bed of blue-gray to black plastic clay and lower bed of flint clay and sandy flint clay, thickness up to 18 feet; and roof-rock zone of fine-grained thin- to thick-bedded soft-white to hard-green sandstone, with intercalated sandy gray clay shale and blue-gray plastic clay, up to 27 feet thick. Member underlies upper sandstone unit of Dakota sandstone with local unconformity and overlies lower sandstone unit of Dakota.

Type area: Along Dry Creek Canyon in S½NW¼SE¼ sec. 26, T. 18 S., R. 67 W., Pueblo County.

Dryden Formation

Middle Ordovician (Mohawkian): Western Virginia and eastern Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 58, chart 1 (facing p. 130). Name used for combined Benbolt and Wardell formations when these two are not separated by Gratton formation. Consists mostly of limestone, but may contain conspicuous amounts of shale as at Rye Cove and Lone Mountain. Usually easy to identify Benbolt or Wardell parts of sequence in upper and lower parts, respectively, but boundary between two more difficult to find. Thickness 300 to 500 feet. Underlies Witten formation; overlies Surgener formation (new) in Tennessee sections and undivided Peery-Ward Cove sequence in Virginia. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: In fields on both sides of highway about 1 mile east of Dryden and less than 1,000 feet west of Stallard Ford Bridge across Powell River, Keokee (TVA 178–SW) quadrangle, Lee County, Va.

Dry Hill Granite Gneiss

Middle Paleozoic: North-central Massachusetts.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Described in Mount Toby quadrangle. Name credited to Robert Balk. Pre-Triassic.

Robert Balk, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–93. Described in its type area as medium-grained well-foliated granitoid gneiss with uniform pinkish or light-gray color. Layers and lenses of quartz and feldspar are separated by thin black films of biotite; large ellipsoidal crystalloblasts of microcline common. Includes border facies consisting of closely related finer grained siliceous gneiss which lacks feldspar crystalloblasts, has more evenly distributed biotite flakes, and has chalky-appearing feldspars. Both facies occur as sheets 2,500 feet or more in thickness; numerous thinner sheets penetrate Poplar Mountain gneiss. Represents igneous facies of domelike gneissic complex which Emerson (1917) termed Pelham granite. Border facies is stratigraphic equivalent of Joshua schist of Greenfield quadrangle. Middle Paleozoic.

Named for exposures on Dry Hill, 3 miles southeast of Millers Falls, Millers Falls quadrangle.

Dry Hollow Formation

Dry Hollow Latite

Pliocene(?): Southwest-central Utah.

Eugene Callaghan, 1939, Am. Geophys. Union Trans. 20th Ann. Mtg., pt. 3, p. 439 (fig. 2), 440 (fig. 3), 449. Individual latite flows are more than 200 feet thick in many places and aggregate thickness probably about 1,000 feet. Rests on earlier volcanic rocks and upon Mount Belknap rhyolite; interbedded with Joe Lott tuff (new); overlain by younger rocks including Sevier River formation and basalt flows. Tertiary.

U.S. Geological Survey has approved the name Dry Hollow formation for this unit. Age considered to be Pliocene(?). This designation is made on the basis of a restudy of units in this area.

Occurs in Marysvale region. Derivation of name not stated.

Dry Hollow Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 139 (fig. 1), 140, 141, 143 (fig. 2), 145 (fig. 3). Consists of basal conglomerate, a lower shaly interval 880 feet thick, 90 feet of carbonaceous coal-bearing rocks, and prominent white cliff-forming sandstone 200 feet thick. Aggregate thickness 1,000 to 1,220 feet. Underlies Grass Creek member (new); unconformably overlies rocks of early Carlile age [Oyster Ridge sandstone member.] Name credited to D. W. Trexler (unpub. thesis).

Typically exposed in Dry Hollow, a strike valley, 1½ miles northeast of Coalville, Summit County.

Drywood Formation (in Cherokee Group)

Drywood Formation or coal cycle (in Krebs Group)

Pennsylvanian (Des Moines Series): Southwestern Missouri, southeastern Kansas, and northeastern Oklahoma.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Dry Wood (Drywood) formation. Includes Dry Wood coal at top. Underlies Bluejacket sandstone; overlies Rowe formation (new). Included in Krebs group.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 6. Referred to as Dry Wood coal cycle in Savannah formation, Krebs group.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 14 (fig. 5), 18 (fig. 7), 20 (fig. 9), 35. At type section, Drywood (Dry Wood) consists of basal black shale, underclay, lenticular sandy shale, and thin coal horizon. Thickness about 5 feet. Overlies Rowe formation; underlies Bluejacket formation. Krebs group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 38–39. A formation in Krebs subgroup of Cherokee group. In southeastern Kansas, includes (ascending) basal dark shale containing lenticular limestone, thin irregular silty limestone and clay ironstone, underclay, and Dry Wood coal. Thickens from 6 to 8 feet in Crawford County to maximum of somewhat more than 15 feet in Cherokee County. Overlies Rowe formation; underlies Bluejacket formation.

Type locality: Below spillway of the artificial lake on a tributary of Dry Wood Creek in SE¼NE¼ sec. 4, T. 32 N., R. 33 W., 1½ miles west of Liberal, Barton, County, Mo.

Duarte Conglomerate

Pliocene(?): Southern California.

J. S. Shelton, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 63. Coarse unsorted sandy poorly consolidated conglomerate; conspicuously gray and light colored. Maximum exposed thickness at least 1,500 feet, due north of Duarte, where it either overlies or is faulted against sandstone of Topanga(?) formation, and is overlain by Quaternary deposits.

Exposed in steeply dipping, isolated outcrops, in foothills between Maddock and Sawpit Canyons, north and northwest of town of Duarte, east of Monrovia, Los Angeles County.

Dublin Blue Shale[1]

Middle Devonian: Central Ohio.

Original reference: E. Claypole, 1903, Am. Geologist, v. 32, p. 19, 20, 34, 35.

Named for exposures along Scioto River near Dublin, Franklin County.

Dubois Greenstone[1]

Precambrian (Gunnison River Series): Central western Colorado.

Original reference: J. F. Hunter, 1925, U.S. Geol. Survey Bull. 777.

Extends from Lake Fork of Gunnison River on west to beyond South Beaver Creek on east. Named for exposures at old mining camp of Dubois, on Goose Creek, Gunnison River region.

Du Bois Limestone[1] Member (of Topeka Limestone)

Pennsylvanian (Virgil Series) : Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 42, 52, 53.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5) ; 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 164; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Du Bois limestone member of Topeka formation; underlies Holt shale member; overlies Turner Creek shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 21. Type locality stated.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 15–16, fig. 5. Commonly single bluish-gray bed; locally divided into two limestone beds separated by shale; fossiliferous. Thickness seldom more than 1 foot; lenses out in some localities. Underlies Holt shale member; overlies Turner Creek shale member.

Type locality: About 4 miles southeast of Du Bois, Pawnee County, Nebr. Not definitely identified south of Topeka, Kans.

Dubose Member (of Whitsett Formation)

Dubose Sands and Clays[1]

Eocene, upper: South-central Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1314.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626 (table 1), 2632–2633. Here considered member of Whitsett; overlies Stones Switch member. Near Czestochowa, Karnes County, about 85 feet of Dubose is exposed; it is underlain by Stones Switch member and unconformably overlain by Catahoula tuff. Lower 100 feet of member exposed in Tordilla Hill in western Karnes County, hill is capped by sandstone locally called Tordilla sandstone bed; upper part of member is exposed in type section of Whitsett. In southeastern Atascosa County and southwest, Dubose is conformably overlain by Calliham sandstone member; northeast of Fashing, the Calliham is not traceable and Dubose, Calliham sandstone, and Fashing clay member become indistinguishable; northeast of Fashing, this part of section is truncated and overlapped by Catahoula; about 100 feet of Dubose is overlapped in vicinity of Fashing, and about 200 feet is overlapped in northern Karnes County.

Named for exposures in valley wall south of Sandies Creek near former Dubose Ranch, 2.5 miles by county road north-northeast of Sample in southern part of Gonzales County. Sample is on U.S. Highway 87, 7.8 miles south of Smiley.

Dubuque Formation[1]

Dubuque Shaly Member (of Galena Dolomite)

Dubuque Formation (in Galena Group)

Dubuque Member (of Maquoketa Formation)

Middle Ordovician: Eastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

Original reference: F. W. Sardeson, 1907, Geol. Soc. America Bull., v. 18, p. 193.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 90–92. Considered member of Maquoketa formation in Minnesota. Thickness about 30 feet. Underlies Wykoff member; overlies Stewartville member of Galena limestone.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, fig. 3. In Dixon-Oregon area, Illinois, considered uppermost formation in Galena group. Thickness about 30 feet. Overlies Wise Lake formation (new).

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 26, 297–299; A. V. Heyl, Jr., and others, 1959, U.S. Geol. Survey Prof. Paper 309, p. 17–18. Referred to as shaly member of Galena dolomite; overlies Stewartville massive member. In mining district member is light-gray to buff fine-grained sugary and silty dolomitic limestone that weathers to yellowish buff; medium to thin bedded and contains interbeds of platy dolomitic shale. Thickness 35 to 45 feet. Age of Galena, Middle Ordovician.

M. P. Weiss, 1957, Geol. Soc. America Bull., 68, no. 8, p. 1029 (fig. 1), 1040–1042, pl. 1. This report [Fillmore County, Minn.] follows Kay's (1935, Jour. Geology, v. 43, no. 5) concept of type section. At type section, interval of transition from Stewartville rock to Dubuque rock is thicker than it commonly is in Minnesota. The Dubuque is unit of interbedded limestone and shale and contains two feldspathized shale beds. Control on thickness of Dubuque in southeastern Minnesota and adjacent Iowa is meager, but it is about 34 feet thick at two outcrops; in Fillmore County, outcrops are close to eroded edge of formation. Overlies Stewartville member of Galena formation; underlies Maquoketa formation.

Named for Dubuque, Dubuque County, Iowa.

Dubuque terrane[1]

Quaternary: Iowa.

Original reference: C. R. Keyes, 1914, Iowa Acid. Sci. Proc., v. 21, p. 186.

Probably named for Dubuque or Dubuque County.

Duchesne Formation[1]

Oligocene: Northeastern Utah.

Original reference: O. A. Peterson, 1932, Carnegie Mus. Annals, v. 21, no. 2, p. 61–63, pl. 1.

Duchesne River, in Duchesne County, traverses these beds.

Duchesne limestone[1]

Upper Jurassic: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 300.

Derivation of name not stated.

Duchesnean Age

Eocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 10, pl .1. Provincial time term, based on Duchesne River formation of northeastern Utah. Covers interval between Uintan (Eocene) and Chadronian (Oligocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

Duchesne River Formation[1]

Eocene or Oligocene: Northeastern Utah and northwestern Colorado.

Original reference: J. L. Kay, 1934, Carnegie Mus. Annals, v. 23, p. 357–359, pls. 45, 46, map.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 97 (table 1), 99 (table 2), 122–123. Consists of buff and gray sandstone, red and pink sandy shale, and conglomerate; fluviatile. Thickness western part Uinta basin 1,500 feet; eastern part of basin, 1,372 feet. Unconformably underlies Bishop conglomerate; unconformably overlies Uinta and Uinta(?) formation. Oligocene.

W. B. Cashion and J. H. Brown, Jr., 1956, U.S. Geol. Survey Oil and Gas Inv. Map OM–153. Mapped in oil shale area, Uintah County, Utah, and Rio Blanco County, Colo. Only basal 50 feet of formation exposed. Along Raven Ridge, unconformably overlies both Uinta formation and Green River formation; near axis of basin, unconformably overlies Uinta formation. Eocene or Oligocene.

First described along Duchesne River, Duchesne County, Utah.

Duck Creek Formation[1] or **Limestone** (in Washita Group)

Duck Creek Limestone Member (of Georgetown Limestone)

Lower Cretaceous (Comanche Series): Central and northwestern Texas and south-central Oklahoma.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504, 516.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 25–26, table 4. Foraminifera of formation described.

W. J. Fox and O. N. Hopkins, Jr., 1960, Baylor Geol. Soc. Guidebook 5th Field Conf., p. 88, 90–91. In central Texas, considered member of Georgetown limestone. Overlies Kiamichi clay member; underlies Fort Worth limestone member. Thickness 120 feet at type section, thinning to 30 feet in McLennan County. Locally Kiamichi is missing, and Duck Creek rests on Edwards limestone.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 24–27, pl. 2. Formation described in Tarrant and Parker Counties, Tex., where it consists of lower thickly bedded fucoidal limestone and an upper marl with interbedded thin marly limestone. Thickness 50 to 60 feet. Overlies Kiamichi formation with possible unconformity; conformably underlies Fort Worth limestone. Washita group.

Named for Duck Creek, north of Denison, Grayson County, Tex.

†Duck Creek limestone,[1] marl,[1] or limy marl[1]

Lower Cretaceous (Comanche Series): Eastern Texas, southwestern Arkansas, and central southern and southeastern Oklahoma.

Original reference: W. M. Winton and W. S. Adkins, 1919, Texas Univ. Bull. 1931.

Duck Lake Formation

Pleistocene: South-central Louisiana (subsurface).

J. A. Doering, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 782–783. Name applied to interval between base of Lissie and top of Citronelle equivalent that occurs in type well between 880 feet and 1,470 feet.

Type well: Hunt Oil Co. State Lease 1392 No. 1, sec. 2, T. 15 S., R. 11 E., Duck Lake field, St. Martin Parish.

Duck Lake Stage

Miocene: Southeastern Louisiana (subsurface).

C. M. McLean, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 241, 242 (fig. 1), 243. Stage name, based on faunal assemblages occurring in sediments commonly referred to as "Middle" Miocene in subsurface of southeastern Louisiana. Clovelly and Napoleonville stages are proposed as replacements for "Lower" and "Upper" Miocene respectively. Names were selected arbitrarily only because denoted fields demonstrate representative sections for each; nothing in way of principal producing members is implied.

†Dudley Limestone[1] or Series[1]

Ordovician: New York.

Original reference: T. A. Conrad, 1839, New York Geol. Survey 3d Rept., p. 58–59.

Exposed at Dudley.

†Dudley Shale (in Pleasanton Group[1]

†Dudley Shale Member (of Pleasanton Formation)[1]

Pennsylvanian: Eastern Kansas, Missouri, and southeastern Nebraska.
Original reference: G. I. Adams, 1903, U.S. Geol. Survey Bull. 211, p. 34.

Named for Dudley, Neosho County, Kans.

Duff Formation or Tuff (in Buck Hills Volcanic Series)

Duff Tuff (in Green Valley Volcanic Series)

Oligocene and younger: Western Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Name applied to upper 1,000 feet of Green Valley volcanic series (new). Overlies Cottonwood Spring basalts (new). Underlies Mitchell Mesa rhyolite (new).

S. S. Goldich and C. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Oct. 29–31, p. 14 (table 1), 17 (fig. 3), 20–21; S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1144 (fig. 3), 1159–1161, pl. 1. Formation included in Buck Hill volcanic series (new). [Authors make no reference to use of term Green Valley volcanic series.] Chiefly rhyolitic tuff with minor breccia and conglomerate. Thickness at type section 1,015 feet. Overlies Cottonwood Spring basalt. Oligocene(?). Derivation of name stated.

R. L. Erickson, 1953, Geol. Soc. America Bull., v. 64, no. 12, pt. 1, p. 1362–1364. Formation described in Tascatol Mesa quadrangle where it is about 764 feet thick. Underlies Mitchell Mesa tuff flow; overlies Pruett formation.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 551–554. Includes Decie member (new) in Cathedral Mountain quadrangle. Northward across quadrangle, formation changes from dominantly rhyolite tuff to lava tuff, and conglomerate (Decie member). Thickness 1,400 to 1,500 feet. Overlies Cottonwood Spring basalt; underlies Mitchell Mesa welded tuff.

Named for Duff Spring in northwestern part of Buck Hill quadrangle, Brewster County.

Duffin Limestone[1]

Duffin limestone or dolomite facies (of Portwood Formation)

Middle Devonian: East-central Kentucky.

Original reference: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145.

G. A. Cooper and others, 1942, Geol. Soc. America Bull. v. 53, no. 12, pt. 1, chart 4. Middle Devonian.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 860 (fig. 4), 861, 862–863. Portwood formation (new) contains three coeval facies: Duffin limestone or dolomite, Harg shale (new), and Ravenna shale (new). Duffin layer is mottled gray to brownish dolomite which commonly presents brecciated appearance. Typically represented in Boyle, Lincoln, and Casey Counties, where it ranges from 3 to 8 feet thick, and eastward to Berea, thins to 1 foot at Crab Orchard. Harg replaces Duffin dolomite in area where former appears and is transitional between Duffin and Ravenna.

A. C. McFarlan and W. H. White, 1952, Kentucky Geol. Survey, ser. 9, Bull. 10, p. 5–16. Discussion of Boyle-Duffin-Ohio shale relationships.

Named for Duffin cut three-fourths mile north of Junction City, Boyle County.

Duffin Sandstone and Shale (in Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 36–37, pl. 2. Medium- to coarse-grained brick-red sandstones with interbedded purple shales. Crossbedding locally prominent. Near California, Barbee and Walker, and Thompson mines, a clay pebble conglomerate as much as 1 foot thick lies just above upper contact of Tecumseh sandstone (new). West of McNally mine, unit includes thin white lenticular sandstone 50 feet above lower contact. Total thickness 427 feet. Under lies Quaternary alluvium; overlies Silver Reef sandstone with local unconformities.

Section measured 500 feet south of Duffin mine, Silver Reef (Harrisburg) Mining District, Washington County.

Dufrene Slate (in Amador Group)

Middle or Upper Jurassic: East-central California.

G. R. Heyl and J. H. Eric, 1948, California Div. Mines Bull. 144, pt. 1, p. 51, 52, 53, pl. 7. A series of schists and greenstone in Newton mine area (near Jackson, Amador County), tentatively correlated with Jurassic Amador group described by Taliaferro (1942), is subdivided into four formations (descending): Mountain Spring volcanics, Dufrene slate, Newton Mine volcanics, and Sunnybrook volcanics. Dufrene consists of sequence of dark-blue-gray slates and fine-grained gray sandstone; some green chloritic feldspathic schist near base. Approximate thickness 745 feet. In absence of fossil evidence, wider regional studies will be necessary to determine definitely whether Dufrene slate and Mountain Spring volcanics should be considered uppermost Amador or part of Mariposa slate. Measured section, along Mountain Spring Creek from Mariposa slate eastward, dips steeply to east; relation of beds to Mariposa slate suggests section is overturned and is on west limb of overturned anticline or its faulted equivalent.

Name derived from Dufrene Ranch west of Newton mine, Amador County.

Dugger Formation

Middle Pennsylvanian: Southeastern Indiana.

C. E. Wier, 1950, U.S. Geol. Survey Coal Inv. Map C–1. Consists of (ascending) 55 feet of sandstone and shale locally containing two thin coal beds and massive conglomeratic limestone in places; Coal VI, which may be absent or as much as 6 feet thick; 40 to 50 feet of sandstone and shale containing thin limestone in places; Coal VII, which is generally 2½ feet thick; and 20 feet of gray shale in places. Overlies Alum Cave member of St. Petersburg formation; unconformably underlies sandstone of Shelburn formation.

C. E. Wier, 1951, U.S. Geol. Survey Coal Inv. Map C–9. Includes Universal limestone member (new) between Coal VI and Coal VII.

Named for exposures in secs, 31 and 32, T. 8 N., R. 7 W., and secs. 5 and 6, T. 7 N., R. 7 W., 2 miles northeast of Dugger, Sullivan County.

Dugout Beds[1]

Pennsylvanian: Texas.

Original reference: C. L. Baker and W. F. Bowman, 1917, Texas Univ. Bull. 1753, p. 104–105.

Exposed in vicinity of Dugout Creek at Payne's Ranch, Marathon Basin.

Dugout Clay and Gravel[1]

Miocene and Pliocene: Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 68.

Named for Dugout wells, near Boquillas, Brewster County.

Dukes Boulder Bed[1]

Pleistocene: Southeastern Massachusetts and southern Rhode Island.

Original reference: J. B. Woodworth and Edward Wigglesworth, 1934, Harvard Coll. Mus. Comp. Zool. Mem., v. 52, p. 163.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1715, chart 12. Pleistocene (Kansan).

Named for occurrence in Dukes County, Mass.

Duluth Gabbro[1]

Duluth Gabbro or Gabbro Complex (in Keweenawan Group)

Precambrian: Northeastern Minnesota, northern Michigan, and northern Wisconsin.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 124, 134.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1054–1057. Included in middle part of Keweenawan group, late Precambrian. Upper part of middle division of group is made up of acidic and basic intrusives: Logan intrusives, Beaver Bay complex, Duluth gabbro, and scattered granites. Detailed description of Duluth gabbro and its relation to other units.

F. F. Grout, R. P. Sharp, and G. M. Schwartz, 1959, Minnesota Geol. Survey Bull. 39, p. 13, 40–50. Described as Duluth gabbro complex in Cook County.

Named for development near Duluth, Minn.

†Duluth Group[1]

Precambrian (Keweenawan): Northeastern Minnesota.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 134, 142–146, 185, pl. 14.

Exposed along north side of St. Louis River up to Duluth, St. Louis County.

Dun Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: Robert Hay, 1887, Kansas Acad. Sci. Trans., v. 10, p. 7.

Named for Dun, Wilson County.

Duncan Chert[1]

Mississippian: Northern California.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey Geol. Atlas, Folio 66, p. 2.

Extends from Duncan Peak across North Fork of American River to vicinity of Monumental Hill, Colfax quadrangle.

Duncan Group

Miocene, upper: Southeastern Arizona.

A. A. Stoyanow, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 297 (table). Named on table. Lithology shown questionably as clay. Older than San Pedro group; younger than Sonoita group (new).

Duncan Sandstone[1] (in El Reno Group)

Permian: Central southern and southwestern Oklahoma.

Original reference: C. N. Gould, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, p. 324–341, map.

Henry Schweer *in* O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1553 (fig. 9). Included in El Reno group. Overlies Hennessey formation; underlies Chickasha formation.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 13–14, pl. 1. Described in Carter area where it is base of El Reno group. Underlies Flowerpot shale; overlies Hennessey shale. Thickness about 40 feet. Maximum thickness about 250 feet to southeast in Stephens County. Note on type locality.

Type locality: Duncan, county seat of Stephens County.

Dunchee Hill Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 124–126, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts is known but stratigraphic position of Dunchee Hill, Purvine Mesa, Sierra Grande, and Gaylord Mountain is not known.

Dunchee Hill, a low hill, 1 mile north of Des Moines, Union County, is eroded remnant of volcano.

Dundee Limestone[1] or **Formation**

Middle Devonian: Southern Michigan and northern Ohio, and Ontario, Canada.

Original references: A. C. Lane, as reported by M. C. Wadsworth, 1893, Michigan Geol. Survey Rept. 1891 and 1892, p. 66; A. C. Lane, 1895, Michigan Geol. Survey, v. 5, pt. 2.

G. M. Ehlers and R. E. Radabaugh, 1937, Michigan Acad. Sci., Arts, and Letters Sec. Geology and Mineralogy [Guidebook] 7th Ann. Field Excursion, [p. 8–9]; 1938, Michigan Acad. Sci. Arts, and Letters, Papers, v. 23, p. 441–445. Dundee limestone restricted to lower unit, about 140 feet thick at Rogers City, which contains characteristic Dundee limestone fauna. Upper unit with distinct fauna is herein named Rogers City limestone.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1756, chart 4. Bassett (1935, Geol. Soc. America Bull., v. 46, no. 3) shows that type Dundee exposed in Sibley quarry, southeastern Michigan, contains *Spirifer lucasensis* and is underlain by Anderdon limestone. He correlates this section with "Upper Columbus" of the Silica and Whitehouse quarries in northwestern Ohio where the Dundee overlies Lucas dolomite and underlies "Blue bed" of Silica shale. Thus, the Dundee lies between Onondaga dolomite and Hamilton shale. In Presque Isle County, Mich., the Dundee overlies Mackinac breccia of lower Onondaga (Schoharie) age and underlies Rogers City limestone which carries *Stringocephalus* fauna.

K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 35 (table 1), 52, 101, 111, 115, 118. Dundee limestone in northwestern Ohio is erroneously designated Columbus limestone. Columbus limestone contains upper Onondaga fauna and is older than Dundee limestone. Dundee limestone of so-called Anderdon quarry near Amherstburg, Ont., owned by Bruner Mond Canada Limited, is incorrectly called Onondaga limestone. Examination of several reports of Devonian of southwestern Ontario leads to belief that Dundee limestone underlies large areas of southwestern Ontario where it is incorrectly designated Onondaga. In Mackinac Straits area, Detroit River group is underlain by Bois Blanc formation (new), most if not all of which is correlative of typical Onondaga limestone of southwestern Ontario. In Rogers City area and apparently elsewhere in northern part of Southern Peninsula, Detroit River group is overlain by Dundee limestone. Table of rocks of Straits of Mackinac region shows Dundee limestone overlies Mackinac breccia. In northwestern Ohio, the Dundee disconformably overlies Lucas dolomite of Detroit River group; in southeastern Michigan and at Amherstburg Ont., unconformably overlies Anderdon limestone of Detroit River group.

G. M. Ehlers, E. C. Stumm, R. V. Kesling, 1951, Devonian rocks of southeastern Michigan and northeastern Ohio: Ann Arbor, Mich., Edwards Brothers, Inc., p. 17–18. Dundee limestone ("Columbus limestone" of Ohio geologists) is 61½ feet thick at Silica, Lucas County, Ohio. Underlies Silica formation.

Named for exposures at Dundee, Monroe County, Mich.

Dundee sandstone member

Pennsylvanian (Pottsville series): Northeastern Ohio.

R. E. Lamborn, 1956, Ohio Geol. Survey Bull. 55, p. 26–29, geol. map. Gray to yellowish brown, medium to coarse, heavy bedded to massive, bedding planes rare. Thickness 5 to 75 feet. Base occurs either below drainage or is obscured by alluvial deposits. Top of sandstone in massive development occurs about 10 feet below Lower Mercer limestone on north side of Walnut Creek in sec. 13, Walnut Township; rises stratigraphically down valley to northeast; where Lower Mercer limestone is absent, top of Dundee is about 20 feet below Upper Mercer limestone; where both Upper and Lower Mercer are absent, the sandstone is about 15 feet below Tionesta coal. Only upper half of Pottsville series occurs above drainage in area of this report.

Named for exposure at Dundee, Tuscarawas County. Forms prominent cliffs along valleys of Walnut Creek and South Fork.

Dunderberg Shale[1] or Formation

Upper Cambrian: Eastern Nevada and western Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1812, p. 184.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 18–19. Dunderberg shale was originally defined by Hague (1883) as Hamburg shale. In order to avoid use of name Hamburg for two formations in same district, Walcott (1908) proposed name Dunderberg for shale unit. Latter name is used in this report [vicinity of Eureka, Nev.]. It is not certain whether top of unit as mapped by Hague is exactly equal to one currently used. Hague writes of the shale as having, near the top, persistent layers of chert and sand. It is probable that these layers have been included within overlying Windfall formation (new), although all beds of flaky shale of any appreciable thickness have been included within Dunderberg of this report. Thickness 265 feet on ridge in Windfall Canyon. Overlies Hamburg formation. Underlies Catlin member (new) of Windfall formation. Late early Late Cambrian and early middle Late Cambrian, that is, late Dresbach and early Franconia age in standard Late Cambrian time scale.

R. H. Olson, 1956, Utah Geol. Soc. Guidebook 11, p. 47–48. Geographically extended into Promontory Range, Utah, where it is exposed along crest of Black Mountain and on both sides of North Fork of Little Valley. Thickness at least 378 feet. Overlies Marjum limestone; separated from Garden City formation by thick sequence of dolomites, limestones, and interbedded shales.

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 340, 342–343. In Nye and Clark Counties, Nev., Dunderberg shale, about 195 feet thick; overlies Yucca Flat formation (new). Underlies unnamed limestone and dolomite interval provisionally referred to as Upper Cambrian.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 24–25, 28 (fig. 4), geol. map. Described in Stansbury Mountains where it is 30 to 200 feet thick; overlies Opex formation and underlies Ajax limestone.

C. B. Bentley, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 6, p. 21–24, 39–40, 44, 48, 53, 58, 61, 62–63. Described in western Utah where it is 4 to 137 feet thick; overlies Orr formation (restricted) or Hicks formation (restricted); underlies Notch Peak formation. Dunderberg is basal Franconian and is equivalent to a sandstone, shale, and limestone unit about 600 feet above base of Mendha limestone at Pioche, Nev. Dunderberg shale is present in Snake Range, Nev., where Drewes and Palmer (1957) called it Corset Spring shale. Although they correlated it [Corset Spring] with Dunderberg shale at Eureka, Nev., and found basal Franconian fossils, they designated it as Trempealeauan (Drewes, 1958). Underlying Corset Spring shale is limestone which they designate Johns Wash limestone, supposedly of Upper Franconian and basal Trempealeauan age. Author [Bentley] does not agree with their dating nor with nomenclature employed and believes that their formation names, at least those for Upper Cambrian, should be suppressed and section renamed with either Eureka district or House Range terminology. Olson (1956) designated 378 feet of argillaceous siltstone and limestone in Promontory Range as Dunderberg. Formation as used by Olson is not equivalent to Dunderberg shale of Eureka and may not even by Upper Cambrian. Olson states that overlying his Dunderberg is 3,800 feet of Upper Cambrian (undifferentiated) dolomites and limestones, 1,160 feet below top of which is Worm Creek quartzite member [of St. Charles formation]. Haynie (1957, unpub. thesis) affirmed Olson's Worm Creek designation. Since Worm Creek is same age as Dunderberg shale of Eureka, Olson's Dunderberg shale is misnomer and should not be used.

A. R. Palmer, 1960, U.S. Geol. Survey Prof. Paper 334–C, p. 53–109, pls. Report describes trilobites of Dunderberg shale. Five local lithic units, designated by letters (ascending) A–E, are recognized. All but upper unit (E) contain thin fossiliferous limestones bearing generally distinctive trilobite assemblages. Fauna of units A–C belong to upper half of *Dunderbergia* zone of late Dresbach age. Fauna of unit D correlates with basal part of *Elvinia* zone of early Franconia age.

A. R. Palmer, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B289–B290. Previous to 1958, the Dunderberg shale or supposedly equivalent unit had been identified at many places in eastern half of Great Basin. Bentley (1958) described what he called "Dunderberg shale" as occurring at many localities in western Utah and has shown that it is shaly westward extension of Worm Creek quartzite member of St. Charles formation of northern Wasatch Range. Bentley has also shown that trilobite fauna of "Dunderberg shale" in western Utah is that of *Elvinia* zone. Recent studies of Dunderberg at its type locality reveal that trilobites of *Elvinia* zone are confined to upper 50 feet of formation. Bentley's "Dunderberg shale" is younger than almost all of Dunderberg shale at its type locality. In Eureka district, contact of Dunderberg with underlying Hamburg dolomite is zone of shearing. Until recently, only a few feet of beds were believed to be missing.

New evidence indicates that as much as 200 to 300 feet of lower part of Dunderberg may be faulted out at Eureka. Practically unfaulted exposure of Dunderberg, 600 feet thick, has now been recognized at Cherry Creek about 65 miles northeast of Eureka. In this section, upper 350 feet of beds contain trilobites of both *Elvinia* and *Dunderbergia* zones similar to those at Eureka. Lower 250 feet contains trilobites belonging to *Aphelaspis* zone. Below these beds, and above another shaly unit containing *Eldoradia*, there is about 1,000 feet of thick-bedded limestone which has not been named. As *Eldoradia* is found in upper beds of Secret Canyon shale, which underlies Hamburg dolomite at Eureka, unnamed limestone near Cherry Creek should probably be correlated with Hamburg dolomite. Hence, there is no indication of significant stratigraphic thinning of Dunderberg between Cherry Creek and Eureka. A 30-foot unit of interbedded limestone and shale at top of Hicks formation in Deep Creek Range, Utah, contains trilobites of *Elvinia* zone. This unit was identified by Bentley as "Dunderberg shale" and separated from underlying Hicks. Shaly unit in middle of Hicks formation, separated from Bentley's "Dunderberg shale" by 120 feet of dolomite, contains trilobites of *Dunderbergia* zone in its upper part and trilobites of the *Aphelaspis* zone in its lower part. This unit correlates with lower part of Dunderberg shale as exposed near Cherry Creek. Therefore, unit that has been called "Dunderberg shale" by Bentley and by those who have studied it at many localities in western Utah is not equivalent to whole of Dunderberg shale exposed near Eureka and Cherry Creek, Nev. Evidence indicates that name "Dunderberg shale" should no longer be used for thin unit of interbedded limestones and shales occurring in western Utah and containing *Elvinia* zone trilobites. This unit is better named Corset Spring shale.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field. Conf., p. 160. In Shell Creek Range, Nev., name Dunderberg formation is applied to sequence of shales and limestones which forms characteristic ledge above Raiff limestone (new) and below Windfall formation. Thickness about 600 feet.

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 10 (fig. 3), 14–15, pl. 1. Described in White Pine district. Average thickness about 350 feet. Overlies Secret Canyon shale, and although they appear to form continuous depositional sequence, they are apparently separated by disconformity. Underlies Goodwin formation of Mount Hamilton group (new). [Editor's note states that reexamination of Humphrey's collections from Secret Canyon and re-collection of trilobites in 1959 show that all known trilobites of Secret Canyon in Hamilton district are Upper Cambrian. Revision of age of Secret Canyon removes need for an unconformity between it and the Dunderberg. As far as can be determined, Cambrian section on west face of Mount Hamilton is without significant stratigraphic breaks.]

Named for exposures opposite Dunderberg mine, Eureka district, Nevada.

Dunderbergian series[1]

Upper Cambrian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53, 78.

Dun Glen Formation

Upper Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad Map [GQ–11]. Dark-gray to black massive dolomite, in part crossbedded, standing in bold relief; interbedded with limestone and shale in lower 100 feet. In Stillwater Range, principally nodular limestone with some quartzite near base. Thickness generally 500 to 600 feet but reaches 1,150 feet in northwestern part of Sonoma Range. Underlies Winnemucca formation with local unconformity; overlies Grass Valley formation.

Type locality: Dun Glen Peak, East Range, Winnemucca quadrangle.

Dunham Dolomite[1]

Lower Cambrian: Southern Quebec, Canada, and northwestern and west-central Vermont.

Original reference: T. H. Clark, 1934, Geol. Soc. America Bull., v. 45, no. 1, p. 6, 10.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137, 146–147. Dark gray, sometimes black, rock weathering brown. Crystalline throughout; stratification obscure. Thickness 30 to 120 feet. Underlies Oak Hill slate; overlies Gilman quartzite conformably. Type locality cited.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 525, 528–530. Extended into Vermont where it includes Mallett member in upper part. Thickness 1,700 to 2,000 feet. Overlies Cheshire quartzite; underlies Monkton quartzite.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 525–528, 532 (fig. 5), pl. 1. Described in St. Albans area, where it consists of sandy facies (Mallett member of Cady) and carbonate facies. Thickness 2,800 feet east of Highgate Springs; about 1,500 feet at southern boundary of area; 25 feet at international boundary. Overlies Gilman quartzite; underlies Parker slate. Lower Cambrian (Georgian series).

Type locality: At Oak Hill, Sutton quadrangle, Quebec. Named for nearby town of Dunham.

Dunkard Group[1]

Dunkard Series or Division

Pennsylvanian and Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio. and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 22.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 88. Permian strata in Ohio are grouped under term Dunkard which has been given rank of group by U.S. Geological Survey, and of series in earlier publications of Ohio Geological Survey. Washington and Greene subdivisions of Dunkard have been classified as formations. Latter are herein raised to series rank, thus making main subdivisions of strata in Permian the same stratigraphic rank as those in Pennsylvanian. Dunkard becomes a sort of superseries and is superfluous. Term in Ohio is synonymous with term Permian. In this report, term Dunkard division is used in order to keep term under consideration until decision is made as to its validity in current stratigraphic usage.

H. L. Berryhill *in* C. O. Dunbar and others, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, p. 1789–1790. West Virginia, Pennsylvania, and Ohio Geological Surveys and U.S. Geological Survey agreed (November, 1959) to designate age of Washington formation as Pennsylvanian-Permian and age of Greene formation as Early Permian. [Thus age of Dunkard group is Pennsylvanian and Permian.]

First described on Dunkard Creek, Greene County, Pa.

†Dunkard Creek Series[1]

Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 22.

On Dunkard Creek, Greene County, Pa.

Dunkirk Shale Member (of Perrysburg Formation)

Dunkirk Formation (in Canadaway Group)

Dunkirk Shale Member (of Canadaway Formation)

Dunkirk Shale or Sandstone[1]

Upper Devonian: Western and west-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 24, chart.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 17. In area of this report, Dunkirk sandstone is used in preference to Canaseraga sandstone.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 397. In Batavia quadrangle, considered a formation in Canadaway group. Youngest formation present in area of this report.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Rank reduced to member status in Perrysburg formation (new). Dunkirk shale member of this report is restricted to 19 feet of black and 20 feet of olive-black and brownish-black shale resting on Hanover shale in exposures on Walnut Creek south of town of Silver Creek, Chautauqua County. In some areas, overlies Wiscoy sandstone. Grades upward into South Wales member (new) through transition zone between very dark-gray and brown shales and gray shales containing some platy siltstones. Thickens eastward from 40 feet on Walnut Creek to maximum of about 120 feet in area between Big Indian Creek and Irish Gulf; thins to featheredge in Woodhull quadrangle and has not been identified to south in Pennsylvania. Name Canaseraga sandstone is reapplied to unit termed Dunkirk sandstone by Bradley and Pepper (1938).

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 14. Basal member of Canadaway formation. Underlies South Wales member; overlies Hanover or Wiscoy member of Chemung formation.

Named for Dunkirk, Chautauqua County.

Dunlap Formation[1]

Lower and Middle Jurassic: Southwestern Nevada.

Original reference: S. W. Muller and H. G. Ferguson, 1936, Geol. Soc. America Bull., v. 47, p. 241–252.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–45. Described in Mina quadrangle where five units are mapped. Formation deposited during folding and thrusting; consequently lithology varies from range to range. Usual sequence not everywhere complete. Upper part: conglomerate, with interbedded sandstone, pebbles derived from Luning formation; includes "thrust conglomerate" derived from upper plates of surface thrusts and overridden by same thrusts; greenstone and greenstone breccia with variable amounts of conglomerate and sandstone. Lower part: basal conglomerate overlain by interbedded sandstone and conglomerate in variable proportions; sandstones commonly reddish and crossbedded, locally interbedded shale; pebbles in conglomerates almost exclusively derived from Excelsior formation. In eastern Excelsior Mountains, basal unit is coarse breccia (fossil talus) of felsite fragments. Locally thin beds of moraine limestone and dolomite. Variable thickness, maximum about 5,000 feet in Pilot Mountains. Though locally conformable on Sunrise over most of area, it is unconformable on Luning and Excelsior formations.

N. J. Silberling, 1959, U.S. Geol. Survey Prof. Paper 322, p. 24 (fig. 3), 29–31, pls. 10, 11. Described in Union district, Shoshone Mountains, where it conformably overlies undifferentiated Gabbs and Sunrise formations. Consists mainly of noncalcareous, possibly nonmarine, sandstone including two relatively thin dolomitic carbonate units near top. Structure is for most part a syncline, which is partly overturned to west and divided into three dislocated segments of unequal size by two westerly trending high-angle faults; east limb of this syncline in middle one of its three faulted segments approaches anticlinal axis adjacent to Third Canyon thrust. On east, formation is bounded by thrust [Third Canyon] which has carried undifferentiated Gabbs and Sunrise formations to west over Dunlap. Southern limit of formation is intrusive contact with Tertiary volcanic rocks. Thickness about 800 feet. Unfossiliferous; might be assigned, at least in lower part, to lower Middle Jurassic.

Type locality: In ridge west of upper part of Dunlap Canyon, Pilot Mountains, Mina quadrangle.

†Dunlap Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: M. Z. Kirk, 1896, Kansas Univ. Geol. Survey, v. 1, p. 81, 82.

Named for Dunlap, Morris County.

Dunlap Sandstone (in Greene Group)

Permian (Dunkard Series): Southwestern Pennsylvania.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 152–153. Thin-bedded brown micaceous sandstone, with little crossbedding. Mica especially conspicuous along bedding planes. Individual beds ½ to 1 inch thick. Total thickness 10 to 35 feet, average about 20 feet. Overlying strata commonly obscured. Base of sandstone lies 5 to 15 feet (average 10 feet) above top of Upper Washington limestone of Washington group. Was noted by Stevenson (1876) in his Greene group section for Washington County but not named.

Named from Dunlap Creek just north of which it is well exposed on hill, 2 miles east of Republic, Fayette County.

Dunlap Sandstone Member (of Catahoula Formation)

See Dunlap Quarry Sandstone Member (of Catahoula Formation)

Dunlap Quarry Sandstone Member[1] (of Catahoula Formation)

Miocene, lower(?): Southeastern Texas.

Original reference: B. C. Renick, 1936, Texas Univ. Bull. 3619, p. 64, table facing p. 17.

W. L. Russell, 1957, Gulf Coast Assoc., Geol. Soc. Trans., v. 7, p. 68. Formation, in Grimes, Brazos, and Burleson Counties, includes Chita, Dunlap, and Corough (new) members.

Well exposed in large quarry on G. W. Dunlap 165-acre tract, in southeastern part of E. M. Millican survey, 2.4 miles S. 17° E. of Millican, Brazos County.

Dunleith Formation (in Galena Group)

Middle Ordovician; Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, 23–24, figs. 3, 9. Dolomite, pure and argillaceous in alternating units, cherty, medium crystalline, medium- to thick-bedded; green shale partings. Thickness up to 125 feet. Differentiated into 10 members (ascending) Buckhorn, St. James, Beecher, Eagle Point, Fairplay, Mortimer, Rivoli, Sherwood, Wall, and Wyota. Underlies Wise Lake formation (new); overlies Guttenberg formation.

In copy of guidebook used by compiler, in figures 3 and 9, name Buckhorn had been crossed out and name Red Oak written in.

Type area is extreme northwestern Illinois.

Dunn Creek Slate (in Paint River Group)

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 37–38. Basal formation of group. Consists of sequence of siltstones and slates; in type area contains one or more layers of slaty sideritic iron-formation; in uppermost part includes newly defined Wauseca pyritic member. Probable maximum thickness about 800 feet; probable minimum thickness about 400 feet. Underlies Riverton formation (new); overlies Badwater greenstone (new).

Type area: Eastern Iron County. Name derived from Dunn Creek, south of Crystal Falls.

†Dunnellon Formation[1]

Pliocene, lower: Northern Florida.

Original reference: E. H. Sellards, 1910, Florida Geol. Survey 3d Ann. Rept., p. 22–35.

Named for exposures at Dunnellon, Marion County.

Dunns Peak Sandstone

Eocene: Northern California.

Boris Laiming, 1940, 6th Pacific Sci. Cong. Proc., v. 2, p. 562 (fig. 8). Shown on stratigraphic column as sandstone 350 feet thick. Underlies Markley sandstone; overlies Capay formation ("Vacaville shales"). Occurs in Vaca Valley north of San Francisco.

Du Noir Limestone (in Gallatin Group)

Du Noir Member (of Gallatin Formation)[1]

Upper Cambrian: Western Wyoming.

Original reference: B. M. Miller, 1936, Jour. Geology, v. 44, no. 2, p. 124–127.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1104. Original nomenclature and definitions of formations in Wind River Canyon section is herein revised. Name Gallatin formation is replaced by Boysen formation (new). Because Upper-Middle Cambrian boundary is nearly 100 feet below base of Miller's Du Noir, member would have to be redefined to include many beds which Miller assigned to Middle Cambrian; hence, Du Noir member is not recognizable in Wind River Canyon, and lower member of Boysen is called Maurice member.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. Rank raised to formation in Gallatin group. Underlies Dry Creek shale; overlies Park shale. In Wind River basin, overlies Buck Spring formation (new).

Type section: Along Warm Springs Creek, 2 miles west of Du Noir, in nothwestern part of Wind River Mountains.

Du Page Limestone[1]

Upper Ordovician (Richmond): Northeastern Illinois.

Original reference: J. R. C. Evans, 1926, Chicago Univ., Abs. Theses, Sci. ser., v. 2, p. 199–200.

Type locality not stated.

Duperow Formation (in Jefferson Group)

Upper Devonian: Subsurface in North Dakota, northeastern Montana, and northwestern South Dakota, and Manitoba and Saskatchewan, Canada.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2299 (fig. 2), 2302–2304 (fig. 4), 2309 (fig. 5), 2315–2318, 2319 (fig. 6). Named by Powley (1951, unpub. thesis). He designated type subsurface section as interval between depths of 3,310 and 4,150 feet in Tidewater Oil Co.'s Duperow Crown Well 1 in southwestern Saskatchewan and considered the Duperow to be equivalent to all but basal section of Beaverhill Lake formation of Late Devonian age in Alberta. Through misunderstanding of Powley's definition, the Duperow came to be considered as an equivalent of Woodbend formation of Late Devonian age which overlies Beaverhill Lake formation in Alberta. In February 1953, Williston Basin Nomenclature Committee of American Association of Petroleum Geologists abandoned use of Duperow formation in sense in which Powley had originally intended and applied name to overlying lithologic unit. The Duperow as defined by the committee has been used widely in geologic literature and by geologists working in Williston basin. Standard subsurface section herein designated. Consists of medium- to brownish-gray dense to microcrystalline limestone, yellowish- to light-brownish-gray fine-grained argillaceous limestone and dolomitic limestone, brownish-gray finely crystalline dolomite, and white to brownish-gray anhydrite, interbedded with thinner beds of greenish-gray dolomitic shale, very fine-grained siltstone, and sandy argillaceous dolomite. Formation ranges in thickness from fraction of a foot to approximately 600 feet in north-central and northeastern Montana along international boundary. Overlies Souris River formation; underlies Birdbear formation (new). In Jefferson group.

Standard section: Interval between depths of 10,400 to 10,743 feet in Mobil Producing Co.'s Birdbear Well 1, center sec. 22, T. 149 N., R. 91 W., Dunn County, N. Dak.

Duplin Marl[1]

Miocene, upper: Eastern North Carolina, Florida, eastern Georgia, and eastern South Carolina.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 388; published in 1897, as 55th Cong., 2d sess. H. Doc. 5.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 180–195. Geographically extended into Florida where it includes *Ecphora* and *Cancellaria* zones formerly included in Choctawhatchee marl (abandoned). *Ecphora* zone, which lies near base of Duplin, is believed to be equivalent to deposit in South Carolina named Raysor marl (Cooke, 1936); recommended that use of Raysor marl be discontinued. Thickness at Alum Bluff 46 feet; in Georgia 5 to 16 feet; maximum thickness South Carolina 41 feet; North Carolina 100 feet. From North Carolina to Florida, unconformably overlies older beds—in Carolinas, underlying formations range in age from Upper Cretaceous Black Creek to middle Miocene Hawthorn; in Georgia and Florida east of the Apalachicola, underlying formation is Hawthorn; west of the Apalachicola, Chipola and Shoal River formations. Everywhere unconformably underlies Pliocene or Pleistocene deposits.

H. E. LeGrand and P. M. Brown, 1955, Carolina Geol. Soc. Guidebook of Excursion in Coastal Plain of North Carolina, Oct. 8–9, p. 11. In this report, the Duplin and Yorktown are considered one formation, the Yorktown.

H. E. Malde, 1959, U.S. Geol. Survey Bull. 1079, p. 28–34. Term Duplin marl, defined as the rocks deposited in this region [Carolinas and Georgia] during late Miocene time, denotes a stage, in time-stratigraphic sense. The Duplin has distinctive marine fauna but little lithologic uniformity; Duplin outcrops would be difficult to identify if adequate fossils were lacking. Many other time-stratigraphic units in Atlantic and Gulf Coastal Plain are similarly named, but with progress in detailed mapping, formations will be defined as rock units, not on basis of age. Term Duplin marl might then be abandoned. Base of Duplin is an unconformity. Along Pee Dee River, the Duplin rests on Cretaceous rocks (Peedee formation). Farther south, rests on Eocene rocks (probably Black Mingo formation), and in Charleston area [this report] on Oligocene rocks (Cooper marl). Along Savannah River, rests on middle Eocene (Hawthorn formation). Fossils indicate that the Duplin near present coast is younger than Duplin marl farther inland. Upper Miocene.

Named for exposures in Duplin County, N.C., especially in Natural Well, southwest of Magnolia.

Duquesne cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 141 (map 17), 143–147. Embraces interval between Gaysport cyclothem (new) below and Elk Lick cyclothem above. Includes (ascending) Lower Grafton shale and sandstone, Duquesne redbed, Duquesne limestone, Duquesne underclay, Duquesne coal, Skelley shale and sandstone, and Skelley limestone members. Except for Skelley marine limestone, members of cyclothem are inconspicuous and not well known in eastern Ohio; in Athens County it is rather thick with all members at least present but with several not well developed. Average thickness between 35 and 40 feet.

Most outcrops are in Alexander, Ames, Athens, Canaan, and Dover Townships, Athens County. Named for Duquesne coal. Name is taken from Duquesne, a locality in metropolitan district of Pittsburgh, Pa.

Duquesne Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Topog. and Geol. Survey Atlas 27, p. 31, 60, 61.

Well exposed in bluff on north side of Allegheny River which faces Herrs Island. Probably named for Duquesne, Allegheny County.

Durango Glaciation or Till

Durango Glacial Stage[1] or Till[1]

Pleistocene (pre-Wisconsin): Southwestern Colorado and northwestern New Mexico.

Original references: W. W. Atwood and K. F. Mather, 1915, U.S. Geol. Survey Prof. Paper 95, p. 14, map; 1924, Geol. Soc. America Bull., v. 35, p. 122; 1932, U.S. Geol. Survey Prof. Paper 166.

V. C. Kelley, 1949, New Mexico Univ. Pubs. in Geology 2, fig. 2, facing p. 2. Durango gravels shown on correlation chart of New Mexico formations as present in San Juan County.

Named for Durango, southwestern Colorado.

Durango Sand Member (of Taylor Marl)[1]

Upper Cretaceous (Gulf Series): Eastern Texas.

Original reference: C. H. Dane and L. W. Stephenson, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, p. 51.

Occurs 1.2 miles south of Chilton, Falls County, and extends southwest through Durango to Theo, on Bell-Falls County line.

Durbin Formation[1]

Durbin Group

Middle Silurian: Southwestern Ohio.

Original reference: A. F. Foerste, 1917, Ohio Jour. Sci., v. 17, p. 187.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown no correlation chart as group including (ascending) Euphemia dolomite, Springfield dolomite, and Cedarville dolomite. Underlies Peebles dolomite; overlies Lilley formation.

Named for exposures at Mills quarries, about 1 mile east of Durbin and 1 mile southwest of Springfield, Clark County.

Durgin Brook Member (of Littleton Formation)

Lower Devonian: Northern New Hampshire.

M. T. Heald, 1955, The geology of the Gilmanton quadrangle, New Hampshire: New Hampshire State Plan. Devel. Comm., p. 8, 9, 10 (table 1), geol. map. Uppermost part of Littleton formation in Gilmanton quadrangle. Composed of well-bedded schists, chiefly sillimanite schist, pseudosillimanite schist and mica schist. Overlies Jenness Pond member (new).

Good exposures near village of Belmont.

Durham Quartz Diorite[1]

Devonian(?): Southeastern New Hampshire.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 149.

Extends from 2 miles southwest of Exeter to within one-quarter mile of Rollingsford. Named for exposures through Durham Township, Strafford County.

Durkee Hill Greenstones

Upper Devonian or post-Devonian: East-central Vermont.

C. G. Doll, 1945, Vermont State Geologist 24th Rept., p. 16, 20. A complex of gray to green to black basic and ultrabasic intrusives and volcanics. Massive and schistose, fine grained to coarse grained. Chlorite schist prominent. Light-gray feldspathic gneiss occurs irregularly among the greenstones. Some volcanics may be of Middle Ordovician age.

Exposed in area between Monroe and Ammonoosuc faults, Strafford quadrangle. Named for good exposures on Durkee Hill.

Durst Group

Pennsylvanian-Permian: Northeastern Utah.

Walter Sadlick, 1957, Intermountain Assoc. Petroleum Geologists Guidebook 8th Ann. Field Conf., p. 62 (fig. 1), 70–76 Name proposed to include type Morgan and type Weber formations; group should also include Hells Canyon formation of eastern Uinta Mountains because this formation is facies of Morgan. Unconformable above Round Valley formation. Term probably can be applied within at least the following localities: North Rich County, where names Wells formation and Weber sandstone have been used; southward to just north of Charleston thrust; and eastward along flanks of Uinta Mountains to Juniper Mountain in eastern Moffatt County, Colo.

Walter Sadlick, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 83 (table 1), 84–85, 86–87. Includes Permian (mainly Wolfcamp) fusulinids in upper 150 to 180 feet.

Named after Durst Mountain, a prominent peak about 7 miles north of Morgan, Morgan County.

Durst Silts

Pleistocene (Wisconsin?): West-central Texas.

M. M. Leighton, 1936, Medallion Papers 24, p. 16, 39 (fig. 5). Compact pebbly silts unconformably underlying Elm Creek silts (new). Show evidence of human occupation.

Well exposed on the P. Durst Survey near Abilene, Taylor County.

Dushkin Basalt

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaska Volcano Inv. Rept. 2, pt. 2, p. 13–14, pl. 2; 1955, U.S. Geol. Survey Bull. 1028–A, p. 9–10, pl. 3. Youngest of three extensive lava-flow units filling old canyons and gullies carved in Belkofski tuff (new) and intrusive diorite stocks. Overlies Arch Point basalt (new). Locally, a single flow more than 200 feet thick makes up unit; elsewhere unit comprises many superimposed flows, each a few tens of feet thick, which in places aggregate several thousand feet, as in the cliffs south of "Emmons" Lake.

Well displayed on north margin of Dushkin Lagoon, vicinity of Pavlof Volcano, Alaska Peninsula.

Duskin Creek Formation[1] (in Lee Group)

Pennsylvanian: Eastern Tennessee and southern Kentucky.

Original reference: W. A. Nelson, 1925, Tennessee Dept. Ed., Div. Geol. Bull. 33A.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 37, 44 (table 3), 139. Extended to include strata between Rockcastle and Corbin sandstones in northern Tennessee and southern Kentucky. Includes Crossville sandstone member (new).

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [Folio], p. 4–5. Duskin Creek formation was used for beds presumably overlying Rockcastle, and including Dorton shale (new) of this report. Type section of Duskin Creek, which is along this tributary of Piney River, however, consists of beds of Vandever formation that actually underlie the Rockcastle. This error is believed to have been due to failure to identify the Rockcastle because of its local shaly character. For this reason, the name Duskin Creek is no longer used.

Well exposed on Duskin Creek, a tributary of Piney Creek, which flows by Spring City, Rhea County, Tenn.

Dutch Creek Sandstone[1]

Middle Devonian: Southwestern Illinois and eastern Missouri.

Original reference: T. E. Savage, 1920, Am. Jour. Sci., 4th, v. 49, p. 170–171, 175.

J. M. Weller and G. E. Ekblaw, 1940, Illinois Geol. Survey Rept. Inv. 70, p. 15–16; J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 24–25, 26. Further described in southwestern Illinois where it is included in Ulsterian group. Comparatively thin and highly characteristic formation. It is only restricted zone in Devonian succession that can be invariably recognized, but actual outcrops in places are not abundant. Massive sandstone 10 to 30 feet thick, composed almost exclusively of rounded grains of St. Peter type. Probably overlies Clear Creek chert with slight unconformity; grades upward into Grand Tower limestone through a few inches or feet of calcareous sandstone and sandy limestone. Strata intervening between Grand Tower limestone (or the Dutch Creek sandstone where Grand Tower is absent) and Mountain Glen shale (or Springville shale where Mountain Glen is absent) have been referred by Savage (1920) to Misenheimer shale and Lingle and Alto limestones. Restudy of the area suggests that recognition of these three formations may be neither stratigraphically logical nor practically feasible.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Lower or Middle Devonian.

Named for exposures along Dutch Creek, southwestern part Union County, Ill.

Dutchmans Conglomerate Lens[1] (in Amity Shale)

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am.'Paleontology, v. 21, no. 71, table opposite p. 61, 84.

I. H. Tesmer, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1651. Mentioned in proposed stratigraphic sequence of Cattaraugus formation.

Named for exposures along Dutchman's Run, a tributary of Allegany River in Mead Township, Warren County.

Dutch Peak Tillite (in Sheeprock Series)

Precambrian: Western Utah.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 19–25, 28, 131–133, 135, pl. 1. Proposed for tillite in Sheeprock series(new). Typically dark-green conglomeratic rock having a slate of quartzite matrix. Thickness 4,044 feet on Dutch Peak; 2,555 feet in Pole Canyon. Occurs in middle part of series.

R. E. Cohenour, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 37. Gradational character of upper and lower contacts and interfingering of tillite with quartzites and phyllites of Sheeprock series indicates that Dutch Peak is conformably included between strata represented by hiatuses above and below Mineral Fork tillite of Wasatch Range.

Type section: Dutch Peak, Tooele County. Crops out from head of South Oak Brush Canyon along crest of Sheeprock Mountains to Dutch Peak where it leaves divide and forms dip slope along north-facing slopes to Little Valley Creek. Present north of principal mining area in West Tintic mining district.

Dutchtown Formation

Middle Ordovician: Southeastern Missouri and northern Arkansas.

H. S. McQueen, 1937, Missouri Geol. Survey and Water Resources 59th Bienn. Rept., app. 1, p. 12–25. Name applied to rocks which intervene between St. Peter and Everton sandstones below and Joachim dolomite above. Lower member is light to dark, smoky-gray, dense to fine-grained, argillaceous limestone and dark-gray shale; middle member, referred to as Geiser Quarry member, consists of dark-brown to black, argillaceous limestone, calcareous, hard, platy and fissile shale, and calcareous siltstone; upper member contains dark-brown to black, dense, and occasionally very finely crystalline limestone, and calcareous shales and siltstones of same color. Thickness 5 to 170 feet (determined from wells). Lower Ordovician.

J. S. Cullison, 1938, Jour. Paleontology, v. 12, no. 3, p. 219–228. Formation belongs in Buffalo River group. Fauna described.

E. B. Branson and M. G. Mehl, 1943, Jour Paleontology, v. 17, no. 4, p. 375. Whether Dutchtown is Lower or Middle Ordovician depends on where line between two series is drawn. In this report boundary is placed below St. Peter sandstone; hence, Dutchtown is lower Middle Ordovician in age.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (columns 52, 53). Correlation chart shows Dutchtown limestone as Chazyan. In Missouri and Arkansas.

Name derived from village of Dutchtown, SE¼ sec. 24, T. 30 N., R. 12 E., Cape Girardeau County, Mo.

Duzel Formation

Upper Ordovician(?): Northern California.

F. G. Wells, G. W. Walker, and C. W. Merriam, 1959, Geol. Soc. America Bull., v. 70, no. 5, p. 645–646, 647 (fig. 1), pl. 1. Proposed for sequence of pale-gray-green phyllitic graywackes. Crumpled structure is most distinctive feature. The graywacke is thinly layered and fissile; in general, it is layered at 1- to 2-mm intervals, although occasional beds up to 3 inches occur, and some a foot to 18 inches thick crop out at stratigraphic intervals of 1 to several hundred feet. Such beds are hard in contrast to the fragile thin layers. Limestone and associated chert beds occur within the phyllite. Many are less than 2 feet thick, but others as much as 200 feet in outcrop width are conspicuous in Horseshoe Gulch and to northeast along the ridge. The largest is more than a mile long and several hundred feet thick. Attitudes of beds indicate that the Duzel is involved in northward-plunging synclinorium, the east limb of which has been thrust over beds of younger Gazelle formation (new). In southern part of area, the syncline has been cut off by steeply dipping northward-trending fault which has dropped beds of the Duzel against peridotite and quartz-mica schist. Because top of Duzel is not exposed and base is uncertain, total thickness cannot be determined; below Duzel Rock, 1,250 feet of crinkled phyllite and phyllitic graywacke is exposed, but structure of the formation indicates its total thickness must be many times this figure. Contains coral and brachiopod fauna and is oldest fossil-bearing formation in Klamath Mountains.

Occurs in two valleys south of Yreka, Siskiyou County. Crops out in drainage basin of Moffett Creek. Name is derived from Duzel Creek, a tributary of Moffett Creek, which is just east of Duzel Rock, conspicuous mass of white marble that caps highest peak in area.

Dwale Shale[1]

Pennsylvanian: Eastern Kentucky.

Original reference: W. C. Morse, 1931, Kentucky Geol. Survey, ser. 6, v. 36, p. 296.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 42, 43, 82. In lower part of Breathitt formation, forming roof of Prestonburg coal.

Exposed at Dwale, Floyd County.

Dyberry Glomerate[1] (in Cherry Ridge Red Beds)

Dyeberry Conglomerate

Upper Devonian: Northeastern Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 571, 578.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 279 (table 30), 284–285. Upper Devonian.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Listed as Dyeberry conglomerate.

Named from Dyberry Creek and Township, Wayne County.

Dyer Dolomite Member (of Chaffee Formation)[1]

Upper Devonian: Central Colorado.

Original reference: C. H. Behre, Jr., 1932, Colorado Sci. Soc. Proc., v. 13, no. 3, p. 60.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 174–177. Described in Pando area where it is 73 to 80 feet thick; overlies Parting quartzite member and uncomformably underlies Gilman sandstone member (new) of Leadville dolomite.

Typically exposed on West Dyer and Dyer Mountains, 5 miles east of Leadville.

Dyer Bay Dolomite Lentille (of Cabot Head Shale Member[1] of Cataract Formation)

Dyer Formation

Middle Silurian: Ontario, Canada, and Michigan.

Original reference: M. Y. Williams, 1919, Canada Geol. Survey Mem. 111, no. 191, geol. ser., p. 35, chart opposite p. 18.

T. E. Bolton, 1953, Canada Geol. Survey Paper 53–23, p. 3, 11. Rank raised to formation and geographically extended into northern Michigan. Formation is considered northern facies of Lower Clinton, rather than local phase of Cabot Head as postulated by Williams (1919). Overlies Cabot Head shales.

Type locality: Dyer Bay, Ontario, Canada.

Dyer Hill member (of Madrid Formation)

Age not stated: West-central Maine.

A. R. Cariani, 1959, Dissert. Abs., v. 19, no. 10, p. 2577. Composed of chloritoid-bearing black slates. Grades downward into quartzites of formation.

In Anson quadrangle.

†Dyestone Group[1]

Silurian: Tennessee.

Original reference: J. M. Safford, 1856, Geol. Reconn. Tenn., 1st Rept., p. 149, 156–158, map.

Dynneson Sand

Lower Cretaceous: Eastern Montana and western North Dakota.

G. R. Wulf, 1959, Dissert. Abs., v. 20, no. 5, p. 1747. Blanket-type sand much of which came from land areas to the east. Upper part deposited as series of northeasterly trending features resembling offshore bars. Underlies highly siliceous clays. Previously called Newcastle sand.

Type locality and derivation of name not given.

Dyson Hollow Limestone Member or zone (of Stoner Member of Stanton Formation)

Pennsylvanian (Missouri Series) : Eastern Nebraska.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32. Zone or member within Stoner limestone. Thickness 1½ to 2 feet. Underlies Kiewitz shale zone; overlies Eudora shale.

Type locality: Below upper water fall in Dyson Hollow, located about 1⅜ miles west of La Platte, Sarpy County.

Eager Formation

Upper Cretaceous-Paleocene: Northeastern Arizona.

G. K. Sirrine, 1959, Dissert. Abs., v. 19, no. 8, p. 2064. Incidental mention.

Springerville-St. Johns area, Apache County.

Eagle Bed[1]

Upper Cretaceous (Gulf Series) : Western Texas.

Original reference: J. A. Taff, 1891, Texas Geol. Survey 2d Ann. Rept., p. 733, 735.

Probably named for Eagle Spring, at northeast end of Eagle Mountain, El Paso County.

Eagle Dolomite Member (of Bluebell Formation)

Upper Ordovician: Central Utah.

Paul Billingsley *in* J. M. Boutwell, 1933, Internat. Geol. Cong., 16th, [United States] Guidebook 17, Excursion C–1, p. 110 (fig. 14). Name appears on stratigraphic column of Tintic district. Basal member of formation. Underlies Beecher member (new) ; overlies Opohonga formation.

T. S. Lovering and others, 1949, Econ. Geology Mon. 1, p. 7 (table 1). Light-gray fine-grained dolomite with dark-gray cherty bed at top, and 15-foot bed of dark-blue-gray fine-grained thin-bedded flaky dolomite at base. Thickness 180 feet.

T. S. Lovering and others, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1506. Entire lower part of Bluebell, known locally as Eagle dolomite, is Upper Ordovician. Thickness about 200 feet on Pinyon Peak.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 137, 139. What has been termed Eagle dolomite in Tintic district should be called Fish Haven dolomite.

Type locality and derivation of name not stated.

Eagle Greenschist (in Easton Group)

Paleocene or older: Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. Contains blue-amphibole schist intercalations.

Between central and eastern part of Skykomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

Eagle Limestone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southwestern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 140, 141, 177.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 82. Marine limestone in lower part of Kanawha group about 100 feet below Eagle coal, between Cedar above and Little Cedar coals, in Eagle shale.

Named for exposures in cuts of Chesapeake and Ohio Railroad at mining village of Eagle, Fayette County.

Eagle Sandstone (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 202.

Named for association with underlying Eagle coal.

Eagle Sandstone (in Montana Group)[1]

Upper Cretaceous: Montana and central northern Wyoming.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

R. M. Lindvall, 1953, U.S. Geol. Survey Geol. Quad. Map GQ-29. Exposed along Missouri River and along several faults in Eagleton quadrangle. Includes Virgelle sandstone member in lower 80 to 100 feet. Middle and upper members consist of 125 to 150 feet of alternating beds of gray to buff medium-grained sandstone, containing sandy limonitic concretions. Conformably underlies Claggett shale; overlies Colorado shale with contact transitional through series of alternating beds of sandstone and shale.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 108 (fig. 1), 114–115. On east side of Sweetgrass arch, the Eagle sandstone includes all strata between Telegraph Creek formation and Claggett shale. Divided into lower Virgelle sandstone member and upper unnamed member of mudstone, shale, siltstone, and sandstone.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 15, 16. Discussion of marine Cretaceous formations of Hardin district, Montana and Wyoming. Local nomenclature revised. Names Frontier and Eagle which appear on maps published by Thom and others (1935, U.S. Geol. Survey Bull. 856), Richards and Rogers (1951, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 111), and Knechtel and Patterson (1952, U.S. Geol. Survey Circ. 150) have been dropped from nomenclature adopted for this report. Rocks formerly called Eagle sandstone are assigned to unnamed sandy shale member in upper part of the Cody; they represent a shaly facies of strata that elsewhere in central Montana includes thick massive sandstone beds that are typical of Eagle sandstone.

Type exposures: Along Missouri River about mouth of Eagle Creek, 40 miles below Fort Benton, Chouteau County, Mont.

Eagle Shale (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 211–215.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 82. Widespread dark-gray to black marine shale including Eagle limestone; in lower part of Kanawha group.

Derivation of name not given but may be same as Eagle limestone.

Eagle Bridge Quartzite[1]

Lower Cambrian: Eastern New York.

Original reference: L. M. Prindle and E. B. Knopf, 1932, Am. Jour. Sci., 5th, v. 24, p. 277–278.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland, 1942, New York State Mus. Bull. 331, p. 65 [1946]. Mentioned in discussion of correlation of Schodack formation in geology of Catskill quadrangle.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 330–331. Named and originally described by Prindle and Knopf, the Eagle Bridge was assigned to Lower Cambrian. Basis for this age assignment appears unsound. Nomenclators state that its stratigraphic position below slate that carries Beekmantown graptolites and above Lower Cambrian limestone indicates that it is probably Lower Cambrian. It is equally as logical to assume Lower Ordovician age by virtue of such reasoning. Type locality restudied for present report. Here, bluish-gray slightly feldspathic calcitic and dolomitic orthoquartzite grades upward through alternating thin beds of argillaceous sandstone and sandy and silty shale into graptolite-bearing shales carrying *Dicellograptus*, *Dicranograptus*, and *Nemagraptus*. Thus, Eagle Bridge is transitionally overlain by Middle Ordovician Normanskill formation. At the base, Eagle Bridge is set off sharply but conformably from platy black pyritiferous, somewhat siliceous, shales with no fossils. They may be Lower Cambrian Schodack shales or Lower Ordovician Deepkill shales. Whatever the age of underlying unit, Eagle Bridge is intimately associated with the overlying unit, which is proved Middle Ordovician. Eagle Bridge is removed from Lower Cambrian and assigned to Ordovician.

Well exposed in vicinity of Eagle Bridge, on Hoosick River, Washington County.

Eagle City Beds[1] or Limestone

Eagle City Member (of Hampton Formation)

Mississippian (Kinderhook): Central northern Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 52, 92–94.

L. A. Thomas, 1960, Tri-State Geol. Soc. Guidebook 24th Ann. Field Conf., p. [3, 17–19]. Stratigraphic reconstruction of Lower Mississippian rocks across Iowa Falls area, when adjusted to orthodox system of classification, presents anomalous situation that is irreconcilable with stratigraphic relationships observed elsewhere in the State. Believed that this stems from miscorrelations resulting from misunderstanding of relationships of Gilmore City to Iowa Falls dolomite. Van Tuyl (1925) considered Eagle City limestone to be nearly 80 feet thick and to consist of two limestones separated by a thick dolomite and to be unconformable beneath Iowa Falls dolomite. Present evidence suggests that formation is essentially limestone, about 20 feet thick, and conformable with Iowa Falls and Maynes Creek dolomites. May be facies of Gilmore City.

Named for exposures in banks of Iowa River at Eagle City, Hardin County.

Eagle Cliff Porphyrite[1]

Permian and Cretaceous: Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington Univ. Pub. in Geology, v. 2, p. 142, 146–148.

W. R. Danner, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 2056. Volcanic rocks originally described as intrusive dikes of Eagle Cliff porphyrite appear to be composed largely of submarine pillow lavas of Permian and Cretaceous age.

Named for Eagle Cliff on north end of Cypress Island, San Juan Islands.

†Eagle Creek Formation[1]

Upper Triassic: Northeastern Oregon.

Original reference: W. D. Smith and E. L. Packard, 1919, Oregon Univ. Bull., v. 16, no. 7, p. 88, 105, 108.

Wallowa Mountains region.

Eagle Creek Formation[1]

Miocene: Central northern Oregon and southwestern Washington.

Original reference: I. A. Williams, 1916, Oregon Bur. Mines and Geol. Res. Oregon, v. 2, no. 3, p. 95–96.

W. M. Felts, 1939, Ohio Jour. Sci., v. 39, no. 6, p. 300–301, 304, 315 (fig. 4). Described in Skamania County, Wash., where it underlies Skamania andesites (new) and is intruded by Silver Star granodiorite (new).

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 7. Mehama volcanics are comparable in age to Warrendale or Eagle Creek formation in Columbia River Gorge. Oligocene.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 5. In Columbia River Gorge, Columbia River basalt lies on erosional surface cut in sediments of Eagle Creek formation. Chaney (1944, Carnegie Inst. Washington Pub. 553) assigned fossil flora of Eagle Creek formation to lower Miocene.

Exposed along Columbia River Gorge from Warrendale to Viento, on Oregon side, with corresponding distribution on north side of river.

Eagle Flats Formation

Quaternary or later: Western Texas.

R. T. Hill, 1890, (abs.) Am. Assoc. Adv. Sci. Proc., p. 242. Largest part of area west of Pecos River consists of extensive flats which are shown to be almost recent lakes, drained of their waters, except in rare instances where salt lakes still occupy limited parts of basin. Quaternary or later sediments of these former lakes are described as Eagle Flats formation.

Eagle Ford Shale,[1] Clay,[1] or Formation

Eagle Ford Formation (in Woodbine Group)

Eagle Ford Group

Upper Cretaceous (Gulf Series): Texas, western Louisiana, and southeastern Oklahoma.

Original reference: R. T. Hill, 1887, Am. Jour. Sci., 3d, v. 33, p. 298.

W. S. Adkins, 1932, Texas Univ. Bur. Econ. Geology Pub. 3232, p. 425–426. Group divided into (ascending) Tarrant, Britton, and Arcadia Park formations. Names credited to W. L. Moreman.

C. C. Albritton, Jr., and others, 1941, Field and Lab., v. 10, no. 1, p. 17–42, pls. 1, 3. Referred to as formation. Moreman's subdivisions not recognized in area of this report [Dallas County]. Underlies Austin formation. Chiefly clay-shale. Average thickness 475 feet.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Shown on correlation chart as Eagle Ford shale. Overlies Woodbine sand; underlies Austin chalk.

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 472, 473, 474, 475, 477, 480 (correlation chart). Formation in Woodbine group (surface and subsurface). Includes Tarrant member. Overlies Lewisville formation with unconformity; underlies Ector chalk of Austin group with unconformity.

L. W. Stephenson, 1953, U.S. Geol. Survey Prof. Paper 243–E, p. 58. Eagle Ford shale unconformably overlies Pepper shale member of Woodbine formation at type section of Pepper shale.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Eagle Ford shale.

Named for exposures at Eagle Ford, Dallas County, Tex.

Eagle Gulch Latite[1]

Tertiary: Southwestern Colorado.

Original reference: H. B. Patton, 1916, Colorado Geol. Survey Bull. 9, p. 21–63.

Forms county rock on both sides of Eagle Gulch, Bonanza district, Saguache County.

Eagle Hill Rhyolite[1]

Eocene(?): Central northern Utah.

Original refernece: J. E. Spurr, 1895, U.S. Geol. Survey 16th Ann. Rept., p. 377.

P. D. Procter, 1959, Utah Geol. Soc. Guidebook 14, p. 183–187. Discussed in report on igneous rocks of Mercur-Ophir area. Table lists Eagle Hill under heading probable late Eocene or early Oligocene(?).

Named for exposures in vicinity of Eagle Hill, just south of Mercur, Mercur district.

Eagle Mills Formation

Permian(?): Subsurface in Arkansas, Louisiana, Mississippi, and Texas.

H. K. Shearer, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 6, p. 724. Consists chiefly of red shale and sand that overlies Pennsylvanian and Mississippian beds and underlies Smackover limestone and also underlies, and evidently in part contemporaneous with, mass of rock salt. Age of salt and associated red beds unknown, but best estimate is early Mesozoic, probably Triassic or Jurassic, because Eagle Mills beds seem to be more nearly conformable and related to overlying Cretaceous than to underlying Paleozoic. Name approved by Shreveport Geological Society.

W. B. Weeks, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 8, p. 958–959 (fig. 2), 960 (fig. 3), 962–964. Thickness 1,190 feet in type well, herein designated. Underlies Smackover limestone; overlies Pennsylvanian and possibly Mississippian. Permian(?).

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 8–15, pl. 12. Southward from type locality, red beds pass abruptly into thick rock salt that contains minor amounts of anhydrite. Salt is bounded at top and bottom, in most sections in Arkansas, by red beds and associated anhydrite which constitute southward spreading tongues from main mass of red beds. Upper red beds are herein defined as Norphlet tongue and lower red beds, Louann tongue. Overlies Morehouse formation (new), apparently conformable and gradational; underlies Smackover, apparently conformable. Formation has been tentatively assigned by various authors to periods as removed as Permian, Upper Jurassic, and Lower Cretaceous. Herein considered Jurassic.

R. W. Imlay, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 11, p. 1422–1440. Described in Gulf Coast region. Upper Jurassic.

R. T. Hazzard, W. C. Spooner, and B. W. Blanpied, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 483, 484–486, cross sections. As used in this report, Eagle Mills is older than Morehouse formation. Term Louann tongue is synonymous with Werner formation (new); term Louann salt is proposed for formation overlying the Werner; term Norphlet tongue, as formerly used, is replaced by Norphlet formation. Thickness 500 to 4,500 feet; maximum thickness unknown. Permian.

F. M. Swain, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 7, p. 1207–1212. Formation, as used in this report [Upper Jurassic of northeastern Texas], includes (ascending) Werner formation, Louann salt, and Norphlet formation of Hazzard, Spooner, and Blanpied who believe that type Eagle Mills is older than their Werner formation. Upper Jurassic.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–175. If Louann and Werner formations are of Jurassic age, then Eagle Mills of this report is youngest pre-Jurassic formation in middle part of Gulf Coast region. Late Paleozoic age assigned to unfossiliferous Eagle Mills (restricted) is questionable. Validity of paleogeologic map in Gulf Coast region, as well as summary isopach and Interval B maps herein presented, depends on solution of these stratigraphic problems. Neither relation of Morehouse to overlying and underlying formations nor its position relative to Eagle Mills formation is clear. Three interpretations suggested: Eagle Mills older than Morehouse; Morehouse older than Eagle Mills; or unit separated by fault of unknown dip and displacement. Second interpretation followed in this report. Permian.

Type well: Amerada Petroleum Co. et al. No. 1 Eagle Mills Lumber Co. well in sec. 11, T. 12 S., R. 16 W., Ouachita County, Ark.

Eagle Mountain Quartzite[1]

Paleozoic: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 56, map.

Named for occurrence on Eagle Mountain, 5 miles northeast of Chewelah, Stevens County.

Eagle Mountains Sandstone Member (of Grayson Formation)

Eagle Mountains Sandstone

Upper Cretaceous: Southwestern Texas.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 11 (table 1), 27, 28, 31, pls. 1, 8, 16. Uppermost member of Grayson. About 70 feet of interbedded brown sandstones (some of which are quartzitic), brown shales, siltstones, and sandy limestones; dominantly brown; contrasts strongly with dominant blue gray of other formations of late Comanche age. Overlies 60-foot middle member informally referred to as reef-limestone. Conformably underlies Buda limestone.

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Quad. Map 23. Rank raised to formation. In Van Horn Mountains, overlies Loma Plata limestone, upper member of which is approximately correlative with San Martine member of Boracho limestone (Brand and De Ford, 1958); underlies Buda limestone.

Type locality: Carpenter Canyon at point about 1 mile above Carpenter Wells, Hudspeth County. Named for exposures on east side of Eagle Mountains.

Eagle Nest Formation

Pliocene(?): Central northern New Mexico.

L. L. Ray and J. F. Smith, Jr., 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 190–191, pl. 1. Reddish clay and white tuffs interbedded with coarse white to buff sand and gravel. Cobbles up to 8 inches in diameter not uncommon. In general, cobbles are smooth but subangular. A few small channel deposits of sand in thicker beds of clay. Thickness unknown since neither top nor base has been seen, but total thickness must have been over 1,000 feet. Probably represents great coalescing stream fans. Tentatively assigned to Pliocene and perhaps early Pleistocene.

Along U.S. Highway 64, north of Eagle Nest Lake, in Moreno Valley, Colfax County.

Eagle Pass Formation[1]

Upper Cretaceous (Gulf Series): Southwestern Texas.

Original reference: C. A. White, 1891, U.S. Geol. Survey Bull. 82, p. 116, 117, 124, 126, 127, 130, 138, 139.

Named for Eagle Pass, Maverick County.

Eagle Peak Syenite

Tertiary: Southwestern Texas.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 38, pl. 1. Proposed for brownish-gray medium-grained rock with large phenocrysts of feldspar, chiefly orthoclase, which occurs in central and highest part of Eagle Mountains and is exposed on Eagle Peak. Much of rock has been altered to "soda syenite". Crops out as roughly elliptical-shaped body, with, in the main, almost vertical contacts with surrounding rhyolite.

Altered syenite is well exposed on summit of Eagle Peak; unaltered syenite is well exposed on flanks of Eagle Peak and in Wind Canyon 1½ miles southeast of Eagle Peak, Hudspeth County.

Eagle Point Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 33, fig. 3. Shown on columnar section as underlying Fairplay member (new) and overlying Beecher member (new).

Occurs in Dixon-Oregon area.

Eagle River Group[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane and A. E. Seaman, 1907, Jour. Geology, v. 15, p. 680, 690.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Name Portage Lake lava series (new) proposed to include Eagle River, Ashbed, Central Mine, and Bohemian Range groups of old reports; these subdivisions are quite arbitrary and depend on continuity of individual flows or conglomerate beds for validity. They are not useful for purpose of this report.

Named for exposures on Eagle River, Keweenaw County.

Eagle River Porphyry[1]

Tertiary, lower: Central Colorado.

Original reference: S. F. Emmons and W. Cross, 1886, U.S. Geol. Survey Mon. 12, p. 80, 188, 193, 330, 591.

Ogden Tweto, 1951, Geol. Soc. America Bull., v. 62, no. 5, p. 510, 511, 512. Term Eagle River porphyry is used here for a quartz monzonite porphyry that is younger than Lincoln porphyry. Originally (Emmons and Cross, 1886) term included both this and later porphyry and Lincoln porphyry. Emmons and Cross used term only in Leadville monograph and made no mention of it in their later work on Tenmile district (U.S. Geol. Survey Geol. Atlas, Folio 48). Eagle River porphyry is similar to Johnson Gulch porphyry of Gray porphyry group at Leadville, and mapping now in progress may prove it to be equivalent. In this area [near Pando], four varieties of early Tertiary quartz monzonite and quartz latite porphyries: Elk Mountain, Lincoln, Eagle River, and Pando (new) form numerous sills in Pennsylvanian and Permian(?) clastic rocks of southern part of Gore Range.

Odgen Tweto, 1953, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-12. Mapped in Pando area, Summit and Eagle Counties, where early Tertiary sequence of porphyries includes (ascending) Pando, Elk Mountain, Quail, Lincoln, and Eagle River.

Named for occurrence at headwaters of Eagle River, Tenmile region, Eagle County.

Eagle Rock Flow or Basalt

Pliocene, lower(?): Southeastern Idaho.

H. T. Stearns and Andrei Isotoff, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 24, 30, 33–34, pl. 1. Basalt has red vesicular base and dense olive-black middle phase which grades into red scoriaceous basalt at top. Locally lenses of pyroclastic material intercalated between flow units. Basal part carries inclusions of basaltic cinders and quartz grains. Lower Pliocene(?).

Exposed on crest of Eagle Rock, a prominent hill on northwest bank of Snake River, 7½ miles downstream from American Falls, and on both sides of river in secs. 28 and 29, T. 8 S., R. 30 E., Power County.

Eagle Rock Tuff[1]

(?)Pliocene, lower: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 32 (table), 44–46, pls. 4–6. Thickness about 35 feet. Shown on stratigraphic column above Neeley lake beds and below Massacre volcanics. Type locality designated.

H. T. Stearns and Andrei Isotoff, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 23. Renamed Walcott welded tuff to avoid confusion with basaltic tuff that originated at locality of Eagle Rock.

Type locality: North bank of Snake River at America Falls, Power County.

†Eangua Limestone[1]

Upper Cambrian and Lower Ordovician(?): Central Missouri.

Original reference: H. King, 1844, Am. Jour. Sci., 1st, v. 47, p. 129.

In vicinity of Eangua River.

†Earlham Limestone (in Kansas City Formation)[1]

Pennsylvanian: Western Iowa, eastern Kansas, and Missouri.

Original reference: H. F. Bain, 1897, Iowa Geol. Survey, v. 7, p. 511–517.

Well exposed at Earlham, in sec. 22, Lincoln Township, Madison County, Iowa.

†Earlton Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 51, 103.

Well developed to west and northwest of Earlton, Neosho County.

Earp Formation (in Naco Group)

Upper Pennsylvanian and Permian: Southeastern Arizona and southwestern New Mexico.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 18–23. Base of formation arbitrarily taken where thin shaly limestones and reddish shales become dominant over more massive limestones characteristic of Horquilla formation (new). Much shale, a little sandstone, and a few beds of limestone and shale conglomerate occur somewhat higher in section and in turn give way upward to more massive limestone with a few conspicuous beds of dolomite, 1 to 5 or 6 feet thick, that weather to brilliant orange or red. Dolomites commonly crossbedded and somewhat cherty, and associated with a few thin sandstones. Topmost dolomite bed taken as top of formation. Underlies Colina limestone (new). Broken sequences exposed west of Dragoon Camp (Pearce quadrangle) suggest thickness of 600 feet. Formation may thicken abruptly toward north. Late Pennsylvanian and possibly Permian.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 35–38, tables 1 and 2, pl. 1. In Peloncillo Mountains, southwestern New Mexico, formation comprises lower dominantly clastic unit and upper dominantly carbonate section. As exposed near Silver Hill mine, lower unit of alternating beds of sandstone, siltstone, or shale and medium-grained gray limestone—399 feet thick; upper unit wholly of medium- to thick-bedded medium-grained gray limestone—432 feet thick. In Peloncillo Mountains, formation includes beds of Permian [Wolfcamp] age only.

Type section: Extends from saddle south of Earp Hill up to conspicuous mottled, pink and gray limestone, and then (to avoid faulting at this locality) is completed by exposed section above this mottled bed about one-half mile to east on the same slope. Named from Earp Hill in sec. 5, T. 21 S., R. 23 E., on whose slope lower part of formation is well exposed, central Cochise County. There is no continuous, unfaulted section of entire formation in area of northern Mule Mountains, Tombstone Hills, or Dragoon Mountains, included in Pearce and Benson quadrangles, Arizona.

Easley Group

Mississippian (Kinderhookian): Missouri, Illinois, Indiana, Iowa, and Kentucky.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 101, chart 5; J. M. Weller, 1948, (abs.) Am. Jour. Sci. v. 246, no. 3, p. 150. Proposed for Upper Kinderhook strata which are generally conceded to be of Mississippian age. In type area, in Mississippi Valley, group consists of Hannibal shale and Chouteau limestone and related formations or members. At least locally, these are separated by unconformities from underlying Fabius group (new) and overlying Osage series.

M. G. Mehl, 1960, Denison Univ. Jour. Lab., v. 45, art. 5, p. 94. Weller and others (1948) proposed that the Kinderhook be considered a series and divided into two groups, the Easley and Fabius. The Easley was to include all Kinderhookian strata which are almost universally recognized to be of Mississippian age, and the Fabius to include all those Kinderhookian strata which are believed by some to be Mississippian and by others to be Devonian. Position of the committee in establishing two Kinderhook groups based on above distinction does not appear tenable. Recommended that terms Easley and Fabius groups be dropped from list of stratigraphic designations in Missouri.

Name derived from Easley, Boone County, Mo., where Chouteau limestone and Sylamore sandstone are well exposed.

Easly Creek Shale (in Council Grove Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 229–237.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46. Consists of red, green, and gray shale, partly calcareous and containing local limestone beds; upper part is light colored and calcareous; lower part largely red shale; locally contains gypsum bed near base. Thickness approximately 15 to 20 feet. Underlies Crouse limestone; overlies Bader limestone.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 13 (table 2), 81–82. Easly Creek shale was named by Condra (1927) who described it as member of Garrison shale and defined it as beds from top of Eiss limestone to base of Crouse limestone. Condra and Upp (1931, Nebraska Geol. Survey Bull 6, 2d ser.) redefined Easly Creek to include beds between Middleburg limestone [member of Bader limestone] and Crouse limestone. This is classification followed in present report [Wabaunsee County, Kans.]. Thickness 10 to 18 feet.

Type locality: On Easly Creek, in NE¼ sec. 35, T. 1 N., R. 13 E., about 10 miles south and 1¼ miles east of Humboldt, Richardson County, Nebr.

East Berlin Formation (in Newark Group)

Upper Triassic: Central Connecticut.

E. P. Lehmann, 1959, Connecticut Geol. and Nat. History Survey Quad. Rept. 8, p. 7, 8 (table 1), 14–24, pl. 1. Proposed for sedimentary rocks that conformably overlie Holyoke basalt and conformably underlie Hampden basalt. This unit was designated as upper sedimentary division of Meriden formation by Krynine (1950). Principally fine-grained clastics—shale and mudstone—predominantly grayish red. On basis of calculations along three cross sections in three different fault blocks, thickness found to vary between 550 and 600 feet.

Type section: On Connecticut Highway 72, just northeast of town of Berlin and west of village of East Berlin, in northwest corner of Middletown quadrangle.

East Bluff Member (of Windrow Formation)

Cretaceous: Southwestern Wisconsin, northwestern Iowa, and southwestern Minnesota.

G. W. Andrews, 1958, Jour. Geology, v. 66, no. 6, p. 599, 606 (fig. 2), 607–610. Proposed to include coarser clastic deposits of formation which commonly rest conformably on older ferruginous deposits here named Iron Hill member. Term Ostrander member of Dakota formation has been applied to these deposits in southeastern Minnesota by Stauffer and Thiel (1941). Thwaites and Twenhofel (1921) refer these deposits to Windrow. Section in Fillmore County, Minn., consists of 20 feet of lensing units of gray clay, sand, and sandy clay, with beds of iron oxide near base; channel fillings of small well-sorted quartz and chert pebbles, granules, grit, and sand common; channel deposits occasionally show cross-lamination. Underlies Kansan drift.

Named for exposures on the East Bluff in Devil's Lake State Park, Sauk County, Wis.

East Branch Arkose (in Dickinson Group)

Precambrian: Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 31–32. Basal formation of group. Strata comprise arkose, arkosic conglomerate, and interbedded metamorphosed basalt flows and basic tuffs; beds are steeply dipping or vertical. Thickness in type area about 1,000 feet. Underlies Solberg schist (new); actual contact with older granitic gneiss not observed, though in some places the two rock units are exposed but a few feet apart. Strata have been referred to Sturgeon quartzite by earlier workers who assumed it to underlie Randville dolomite that is exposed a short distance to the north.

Well exposed in broad glacially polished outcrops in secs. 17 and 18, T. 42 N., R. 28 W., along East Branch of Sturgeon River, Dickinson County.

East Buffalo Creek Limestone Member (of Tyler Formation)

Carboniferous: Central Montana.

G. H. Norton, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 62, 63 (fig. 7). Limestone unit very much like Amsden in lithology; overlain by basal Amsden conglomerate.

Named from exposures on East Buffalo Creek, secs. 11 and 12, T. 12 N., R. 16 E.

East Cape Volcanics

Quaternary: Southwestern Alaska.

R. R. Coats, 1953, U.S. Geol. Survey Bull. 989-A, p. 8-9, 14-16, fig. 2. Rocks of East Cape Volcano include hypersthene-bearing hornblende basalts and basaltic andesites. All are dense medium-gray rocks, with 80 to 90 percent of plagioclase. Dome on flank of volcano also of pale-gray hypersthene-bearing hornblende basalt.

Associated with East Cape Volcano consisting of older and higher cone to the north and smaller volcanic dome on southeastern flank, which contributed largely to construction of northeastern part of Buldir Island, in western Aleutian Islands.

East Caroline Beds or Formation

Miocene. East Caroline Islands.

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 69-70, table 5 [English translation in library of U.S. Geol. Survey, p. 84; S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 29. Consist of agglomerate, tuff, conglomerate, and breccia; intruded by basalt dikes. Rest unconformably on base rocks of islands. Getsuyoto [Getuyoto] beds of Truk, Matalanim [Mataranium] formation of Ponape, and Maremu [Marem (Malam)] formation of Kusaie are included in this formation.

Type locality: East Caroline Islands.

Eastern Basalts[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, p. 230-235, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 676. Cenozoic. Overlie Juniper lavas.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta, v. 8, p. 78 (table 3). Listed on table accompanying report on uranium geochemistry of Lassen volcanic rocks.

Occurs in Lassen Volcanic National Park, near Butte Lake.

Easterwood Shales (in Yegua Group)

Eocene (Claiborne): East-central Texas.

A. A. L. Mathews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 3-4, geol. map. Name applied to dominantly shaly section of group; underlies Cockfield formation and overlies Byram sandstone.

Name derived from Easterwood Airport located on campus of A & M College of Texas, Brazos County.

Eastford Granite Gneiss[1]

Pre-Triassic: Northeastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 127, and map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 51. Mapped as Monson orthogneiss.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as a granitic gneiss.

Good exposure in southeastern corner of Eastford [Township], Windham County.

East Fork Formation[1]

Precambrian(?): Central Idaho.

Original reference: L. G. Westgate and C. P. Ross, 1930, U.S. Geol. Survey Bull. 814, p. 10–17.

C. P. Ross and J. D. Forrester, 1947, Geologic map of the State of Idaho (1:500,000): U.S. Geol. Survey. Mapped as Precambrian(?).

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 3. Precambrian(?) rocks in Pioneer Mountains include Hyndman formation, about 6,600 feet, and East Fork formation, at least 1,560 feet. East Fork consists largely of metamorphosed limestone but includes conspicuous interbedded quartzite masses. The two formations crop out over an area of about 20 square miles along southwestern border of a granite body. They are cut by many faults and separated from all other sedimentary rocks in vicinity by faults. Assumption that the Hyndman and East Fork are Precambrian is far from proved.

Forms a belt on west side of area of metamorphosed rocks as far south as divide between Hyndman Creek and East Fork of Big Wood River. Best exposed on east side of headwaters area of Hyndman Creek, Hailey quadrangle.

†East Gallatin Group[1]

Precambrian: Central southern Montana.

Original reference: F. V. Hayden, 1885, U.S. Geol. Survey 6th Ann, Rept., p. 50.

Exposed near mouth of East Gallatin River, Threeforks quadrangle.

East Greenwich Group[1]

Mississippian(?): Central Rhode Island.

Original reference: B. K. Emerson and J. K. Perry, 1907, U.S. Geol. Survey Bull. 311, p. 58–65, map.

A. W. Quinn, 1952, Bedrock geology of the East Greenwich quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad. May [GQ–17]. Revived as a group because intrusive and extrusive rocks in vicinity of East Greenwich form a natural group closely related in composition and age. Subdivided to include (ascending) Spencer Hill volcanics (new), unnamed metadiorite, Maskerchugg granite (new), unnamed granite porphyry, Cowesett granite (new), and unnamed dark fine-grained granite. Younger than Blackstone series and Esmond granite; older than Pennsylvanian rocks of the Narragansett Basin. Mississippian(?). Derivation of name.

Occurs in and west of village of East Greenwich, East Greenwich quadrangle.

East Haven Granite[1]

Precambrian: Central Connecticut.

Original reference: E. Hitchcock, 1823, Am. Jour. Sci., 1st, v. 6, p. 3–86.

In East Haven and Branford, New Haven County.

†East Iowan Formation[1]

Pleistocene: Iowa.

Original reference: T. C. Chamberlin, 1894, Great ice age, by James Geikie, 3d ed., p. 724–775.

†East Iowan stage of glaciation[1]

Pleistocene: Iowa.

Original references: James Geikie, 1894, Great ice age, 3d ed., p. 724–775; 1895, Jour. Geology, v. 3, p. 270–277.

East Kane shale member[1] (of Knapp formational suite)

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 61, 112, table opposite p. 61.

Well exposed in brick shale quarries at East Kane, McKean County.

Eastland Formation

Eastland Member (of Lee Formation)

†Eastland Shale Lentil (of Bon Air Sandstone)[1]

Lower Pennsylvanian: Central Tennessee.

Original reference: Charles Butts and W. A. Nelson, 1925, Tennessee Div. Geology Bull. 33–D, p. 4–12, pl. 4.

H. R. Wanless, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1941. Listed as member of Lee formation.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 17). Correlation chart shows Eastland formation underlying Newton sandstone and overlying Herbert sandstone.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4. Conglomeratic phase of Newton sandstone in southern Cumberland and northern Bledsoe Counties was type "Herbert conglomerate" erroneously considered by Nelson (1925) to be older than Newton. The shale thought to be between the sandstones and named "Eastland shale" by Nelson is actually Whitwell shale. Names "Herbert" and "Eastland" are here discarded.

Named for occurrence at mining town of Eastland, 1 mile west of Clifty, White County.

†Eastland Formation (in Canyon Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologist Bull., v. 3, p. 133–145.

Named for Eastland, Eastland County.

†Eastland Limestone Member (of Caddo Creek Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Well exposed in creek bed one-half mile east of Caddo and in Caddo oil field. Named for Eastland, Eastland County.

Eastland Sandstone (in Graham Formation)[1]

Pennsylvanian: Central Texas.

Original reference: F. B. Plummer and J. Hornberger, Jr., 1936, Texas Univ. Bull. 3534, p. 62.

Well exposed in railroad cut 1 mile northwest of Eastland, Eastland County.

Eastland Lake Formation (in Smithwick Group)

Pennsylvanian (Lampasas): North-central Texas (subsurface).

M. G. Cheney, 1940, Am. Asoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 84 (fig. 5), 86. Basal formation of group. Consists of sandstones in lower part and gray limestones in upper part. Occurs between depths of 3,960 and 4,225 feet in type well. Underlies Caddo Pool formation (new); overlies Sipe Springs formation (new).

Some reports place Eastland Lake in Kickapoo Group, Strawn Series.

Type well: Anzac Oil Corp. et al. E. S. Graham No. 1, in Allen Hines Survey, Abstract 135, central Young County. Named from Eastland Lake district of northwest Eastland County.

†East Lee Gneiss[1]

Precambrian: Western Massachusetts.

Original reference: B. K. Emerson, 1892, U.S. Geol. Survey Hawley sheet, that is, proof sheets of geologic maps and text intended for a geologic folio, but never completed and published in that form, although cited in U.S. Geol. Survey Bull. 191, 1902.

Named for exposures in hill overlooking East Lee on northeast.

†East Lee Limestone[1]

Precambrian: Massachusetts.

Original reference: B. K. Emerson, 1899, U.S. Geol. Survey Bull. 159, p. 50–51.

Exposed at East Lee, Berkshire County.

East Liberty Bone Bed (in Columbus Formation)

Middle Devonian: West-central Ohio.

J. W. Wells, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 280–282. Name applied to bone bed near top of formation. Consists of dolomitic sandstone containing phosphatic nodules, many of which are internal molds of small mollusks and other fossils; some fish remains also present. Thickness of bone bed commonly less than 1 foot but arenaceous character of bed extends downward for 10 feet or more, and lower boundary of bone is gradational in places. Disconformably overlain by Ohio black shale.

Well exposed in quarry of East Liberty Stone Co., 1 mile west of East Liberty, Logan County. Area is known as Bellefontaine Devonian outlier.

East Lynn Sandstone

East Lynn Sandstones (in Allegheny Formation)[1]

Pennsylvanian (Allegheny Series): Southern West Virginia and Eastern Kentucky.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1913, West Virginia Geol. Survey Rept. Cabell, Wayne, and Lincoln Counties, p. 183.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 45, 48, 82. In lower Allegheny between Middle Kittanning above and No. 5 Block (Lower Kittanning) coals.

Named for occurrences at East Lynn, Wayne County, W. Va., where it forms massive cliffs 40 to 60 feet high.

East Molokai Volcanic Series

Pliocene(?): Molokai Island, Hawaii.

H. T. Stearns 1946, Hawaii Div. Hydrography Bull. 8, p. 69 (table), 71–72; H. T. Stearns and G. A. Macdonald, 1947, Hawaii Div. Hydrography Bull. 11, p. 16–23; G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 81–82. Consists of caldera complex member, lower (basalt) member, and upper (andesite) member. Exposed thickness 4,900 feet; probably extends 12,000 feet or more to ocean floor. Separated from underlying West Molokai volcanic series (new) by erosional unconformity; separated from overlying Kalaupapa basalt (new) by erosional unconformity.

Type locality: Cliff south of Kalaupapa Peninsula. Covers area 26 miles long and 8 miles wide, comprising almost all of East Molokai.

East Mountain Schist[1]

Precambrian(?): Southwestern Vermont.

Original reference: E. J. Foyles, 1931, Vermont State Geologist 17th Rept., p. 249.

East Mountain, Mendon Township, Rutland County.

East Mountain Shale Member (of Mineral Wells Formation)[1]

East Mountain Formation (in Lone Camp Group)

Middle Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 25, 31; Texas Univ. Bull. 2132, p. 77, charts.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 87, 88, 92. Rank raised to formation in Lone Camp group (new). Includes (ascending) Hog Mountain sandstone, Capps limestone (upper part), and Village Bend limestone members. Overlies Garner formation; underlies Salesville formation of Whitt group (new). Name Mineral Wells dropped in this report.

R. J. Cordell and others, 1954, Abilene Geol. Soc. Guidebook Nov. 19–20, fig. 2 (strat. chart). Formation revised to include (ascending) Brazos River sandstone (in part) and conglomerate, Hog Mountain sandstone, conglomerate sandstone in East Mountain shale, Capps limestone, and Village Bend limestone. Revision based on faunal break in Brazos River sandstone.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 22–23, fig. 3, pl. 1. Formation in Parker County consists of shale, one sandstone body (Hog Mountain sandstone bed), and one conglomeratic sandstone. Thickness 330 feet in traverse located east of Lake Mineral Wells. Upper 35 to 40 feet exposed in scarp that crosses Wolters Military Base; beds are poorly laminated clay-shale; interval includes stratigraphic position of Village Bend limestone mapped in Palo Pinto County (Plummer and Hornberger, 1935 [1936]), but limestone cannot be traced into Parker County. Underlies Salesville formation; overlies Garner formation. Group terminology not used in this report.

Type locality: Extensive exposures on south end of East Mountain in Mineral Wells, Palo Pinto County.

Easton Schist[1]

Easton Group

Pre-Ordovician(?) or Carboniferous(?): Central Washington.

Original reference: G. O. Smith, 1903, U.S. Geol. Survey Prof. Paper 19.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4 p. 775. Easton group, in Skykomish area, subdivided into Eagle greenschist and Tonga formation (both new).

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 102, pl. 1. Easton schist forms pre-Tertiary basement west of Cle Elum Valley. In area of this report [northern parts of Mount Stuart and Snoqualmie folios], consists of blue amphibole schists and apparently interbedded greenschist and phyllite. Is apparently southern end of extensive but discontinuous unit that has been traced from near Canadian border to just north of Snoqualmie quadrangle. Schist is pre-Swauk and therefore pre-Tertiary. W. S. Smith (1915, Columbia Univ. School of Mines Quart., v. 36; 1916, Jour. Geology, v. 26, no. 6) reported Ordovician fossils north of Snoqualmie quadrangle in less metamorphosed rocks and used these to date Easton as pre-Ordovician. Recent workers have not found Ordovician fossils and original Ordovician collection has been lost.

Named for occurrence near Easton, Kittitas County. Exposed in cores of two anticlines between Kachess and Cle Elum Lakes.

East Point Formation

Quaternary: Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 177, pl. 23. Uninterrupted sequence of andesitic lava flows, over 500 feet thick. Two dozen separate flow units distinguished in 700-foot sea cliff on southeast side of East Point. Lavas are light- to dark-gray andesite and basalt locally containing plagioclase, pyroxene, and olivine phenocrysts. Probably younger than Sitkin Point formation (new).: conformably underlies Double Point dacite (new).

Named for exposures, at sea level, on either side of East Point, Little Sitkin Island, in Rat Islands group of Aleutian Islands.

Eastport Formation[1]

Upper Silurian: Southeastern Maine.

Original references: E. S. Bastin and H. S. Williams, 1913, Maine Water Storage Comm. 3d Ann. Rept., p. 168; 1913, Geol. Soc. America Bull., v. 24, p. 378, 379.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart above Pembroke formation. Underlies Devonian. Cayugan series.

Named for exposures at Eastport on Moose Island, Washington County.

East Ridge Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 278–283, geol. map. Dominantly ultramylonites with some layered plutonics interlayered. Occurs in an apparently homoclinal sequence. Separated from Aurela Ridge and West Ridge rocks (both new) by Marjo Canyon thrust. Contact relations with Sarac Ridge mylonite (new) not certain.

Exposed on East Ridge, San Bernardino County.

East Tioga Clay (in Golden Valley Formation)

Eocene: Western North Dakota.

Great Northern Railway Co. Mineral Research and Development Department, 1958, Great Northern Railway Co. Mineral Research and Devel. Dept. Rept. 5, p. 8, 22, map. A 10-foot bed of clean, buff-colored clay. White Earth, South Ross, and Lakeside clays occur in same general area.

On Great Northern mainline in center sec. 33, T. 157 N., R. 94 W., Mountrail County.

East Verde limestone

[Upper Devonian] (Jeromian): Arizona.

[C. R.] Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228. Upper part of Jeromian series (new). Thickness 350 feet. Older than Island Mesa limestone. Overlies Sycamore sandstone. Upper part of Jerome formation (of Stoyanow).

[In Jerome region.]

East Waterford Red Sandstone Member (of Juniata Formation)

Upper Ordovician: Central Pennsylvania.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geol. Contr. 3, 58p. Consists of red graywacke-type sandstones with interbeds of shale and siltstone. Basal member of Juniata from Tyrone Gap to Susquehanna Gap. Underlies Plummer Hollow red mudstone and sandstone member (new) of Juniata from Tyrone Gap eastward to about vicinity of Lost Creek Gap. Overlies Spring Mount sandstone member (new) of Bald Eagle sandstone; eastward overlies Lost Run conglomerate. [Swartz refers to his 1955 report *in* Pennsylvania Geologists Guidebook 21st Ann. Field Conf. Compiler was unable to locate a copy of this report.]

Type locality: East Waterford Narrows in Tucsarora Mountain, Juniata County.

East Waynesboro Formation

[Lower Cambrian]: Western Virginia.

W. A. Nelson, 1949, (abs.) Virginia Acad. Sci. Proc. 1948–1949, p. 139. Lower part of Unicoi up to top of 300-foot acid lava flow is named Swannanoa formation, and upper part of Unicoi is named East Waynesboro formation.

Report discusses structure and stratigraphy of Blue Ridge in Albemarle and adjacent counties. Main Blue Ridge mountain is overturned anticline, with axial plane dipping 28° SE., and thrust fault bordering it on its western edge.

†East Wisconsin Formation[1]

Pleistocene: Wisconsin.

Original reference: T. C. Chamberlin, 1895, Jour. Geology, v. 3, p. 270–277.

Named for thick development of drift in eastern Wisconsin.

†East Wisconsin stage of glaciation[1]

Pleistocene: Wisconsin.

Original reference: T. C. Chamberlain, 1894, Great ice age, by James Geikie, 3d ed., p. 724–775.

Named for thick development of drift in eastern Wisconsin.

Eaton Beds[1]

Middle Silurian: Ohio.

Original reference: A. F. Foerste, 1888, Denison Univ. Sci. Lab. Bull., v. 3, p. 8.

Eaton Greensand Lentil (in Claiborne Group)[1]

Eocene, middle: Eastern central Texas.

Original reference: B. C. Renick and H. G. Stenzel, 1931, Texas Univ. Bull. 3101, p. 78, 90–91.

Occurs south of Eaton, in vicinity of Shiloh School, in southern Robertson County.

Eaton Sandstone Member (of Saginaw Formation)

Eaton Sandstone (in Grand River Group or Formation)

Pennsylvanian: Southern Michigan.

W. A. Kelly, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 207, 211–214. Eaton sandstone (in newly defined Grand River group) proposed for uppermost sandstones forming bluffs or ledges along valley of Grand River and its tributaries in vicinity of Grand Ledge in northern part of Eaton County. Beds are post-Saginaw in age, but true stratigraphic relations to Woodville sandstone, Ionia sandstone, or other strata of Grand River group cannot be determined. Overlies Saginaw at type locality of that group. Thickness 50 feet in vicinity of Grand Ledge.

Michigan Geol. Soc., 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan; Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 28–29. Herein considered member of Grand River formation. Occupies channels cut into shale and sandstone of Saginaw formation. It is probable that future study will show that the Eaton is brown-weathering facies of the Ionia as exact stratigraphic position of Eaton and Ionia members in the Grand River is not known.

Name derived from Eaton County.

Eau Claire Grit[1]

Upper Cambrian: Southwestern Wisconsin.

Original reference: L. C. Wooster, 1878, Wisconsin Geol. Survey Ann. Rept. 1877, p. 37.

Exposed at mouth of Eau Claire River, Eau Claire County.

Eau Claire Sandstone[1] (in Dresbach Group)

Eau Claire Member (of Dresbach Formation)

Upper Cambrian: Western Wisconsin and southeastern Minnesota.

Original reference: C. D. Walcott, 1914, Smithsonian Misc. Colln., v. 57, p. 354.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 30, 32, 33, measured sections. Middle member of Dresbach formation. Commonly medium- to fine-grained gray to buff sandstone with beds and partings of gray shale; may include conglomerates, and over large areas its shales may be red. Thickness about 128 feet at type section of Dresbach. Overlies Mount Simon member; underlies Galesville member.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 255 (fig. 32), 371. Referred to as Eau Claire sandstone. Overlies Mount Simon sandstone; underlies Dresbach sandstone. Thickness 70 to 330 feet.

U.S. Geological Survey currently includes the Eau Claire Sandstone in the Dresbach Group.

Named for exposures at mouth of Eau Claire River, Eau Claire County, Wis.

Ebbetts Pass Granodiorite

Pre-Tertiary: Central eastern California.

H. G. Wilshire, 1957, California Univ. Dept. Geol. Sci. Bull., v. 32, no. 4, fig. 1. Named on map legend of Ebbetts Pass region.

Ebbetts Pass is in Alpine County.

†Ebensburg Sandstone Member (of Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: C. Butts, 1905, U.S. Geol. Survey Geol. Atlas, Folio 133.

Crops out in river bluff to east of Summerhill, and also on top of knoll just northwest of Summerhill. Probably named for town of Ebensburg, Cambria County.

Echo Granite[1]

Precambrian(?): Southern California.

Original reference: W. J. Miller, 1930, Geol. Soc. America Bull., v. 41, p. 149–150.

Comprises several square miles, extending from Millard Canyon to Eaton Canyon, including part of Echo Mountain, San Gabriel Mountains.

Echo limestone or formation (in Kwaguntan series)

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 113. Consists of three chief ledges of limestone separated by shales. Principal limestone formation of entire Protozoic section. Thickness 150 feet. Underlies Walhalla formation (new); overlies Carbon Butte shales (new).

Name derived from Echo Cliffs, at edge of Kaibab Plateau, on latitude of mouth of Little Colorado River; Grand Canyon region.

Echo Canyon Conglomerate

Upper Cretaceous: Northeastern Utah.

N. C. Williams and J. H. Madsen, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10, p. 123, 125. Proposed for sequence of red conglomerates, sandstones, and shaly sandstones exposed in Echo Canyon and adjacent areas. Thickness 3,100 feet. Overlies Wanship formation; unconformably underlies Knight formation. Fossils near base are considered to be late(?) Niobrara; upper part of unit may be Montanan in age. Relationship of Echo Canyon conglomerate to Hilliard formation, which contains Coloradoan-Montanan boundary in southwestern Wyoming not presently known.

Eardley (1944, Geol. Soc. America Bull., v. 55, no. 7) mentioned, but did not define, an Echo Canyon conglomerate which he stated (p. 844) occurred below Fowkes(?) formation. Table 1, p. 824, shows his newly defined middle Paleocene(?) Saw Mill conglomerate underlying upper Paleocene(?) Fowkes formation.

L. A. Hale, 1960, Wyoming Geol. Assoc' Guidebook 15th Ann. Field Conf., p. 142. Refers to Echo Canyon (formerly Pulpit) conglomerate.

Exposed in Echo Canyon and vicinity of Echo Junction, Coalville area, Summit County.

Echo Falls Shale

Eocene, upper: Southern California.

T. L. Bailey, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1920 (fig. 3). Shown on structure section as underlying Matilija sandstone and overlying Topatopa sandstone.

Section is 2 miles east of Santa Paula, Ventura County.

Echooka River Glaciation

Pleistocene: Central northern Alaska.

R. L. Detterman, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 12, 13 (table 1). Four Quaternary glacial advances recognized in Sagavanirktok-Anaktuvuk district. Echooka, the last recognizable advance, succeeded Itkillik glaciation (new). Relatively minor, covering less than 50 square miles. At its maximum extent, ice did not reach front of range and formed independent valley glaciers. Well-developed end moraines and kame terraces along valley wall. Knob and kettle topography of moraine relatively fresh. Till sheet 30 to 50 feet thick.

Named after Echooka River, major eastern tributary of Sagavanirktok River. Confined to major valleys of Sagavanirktok River drainage area.

Echo Pond Granitic Complex

Age not stated: Northeastern Vermont.

B. K. Goodwin, 1959, Dissert, Abs., v. 20, no. 5, p. 1740. Granitic rocks occupy about two-thirds of map area. Three major granitic bodies are present: Averill granite, Nulhegan quartz monzonite (new), and Echo Pond granitic complex. Rocks of Echo Pond range from granite to gabbro.

Report discusses geology of Island Pond area, located between Green Mountain anticlinorium and Connecticut River.

Eckman Sandstone (in Pottsville Group)[1]

Eckman Sandstone (in Pocahontas Group)

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 221.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 217, 245. Included in Pocahontas group, Pottsville series. In Greenbrier County is lenticular brown to gray sandstone. Thickness 20 to 40 feet. Underlies No. 6 Pocahontas coal and overlies No. 5 Pocahontas coal.

Named for exposures at Eckman, McDowell County.

Economy Formation or Shale (in Eden Group)

Economy Member (of Eden Formation)

Economy Member (of Latonia Shale)[1]

Upper Ordovician: North-central Kentucky, southeastern Indiana, and southwestern Ohio.

Original reference: R. S. Bassler, 1906, U.S. Natl. Mus. Proc., v. 30, p. 9.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Shown on correlation chart as basal formation in Eden group in Indiana. Underlies Southgate formation; overlies Cynthiana formation in Trenton group. Consists of shale 50 to 80 feet thick.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 66, no. 3, chart 2 (column 45). Shown on correlation chart as Economy shale in Eden group. Underlies Southgate shale; overlies Fulton shale.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030–1031. Basal member of Eden formation. Economy member (designated "Fulton-Economy" in this rept.) is 20 to 80 feet thick. Gradationally underlies Southgate member.

Economy was old name of village now known as West Covington, Kenton County, Ky.

Ector Tongue (of Austin Chalk)[1]

Upper Cretaceous (Gulf Series): Northeastern Texas.

Original reference: L. W. Stephenson, 1918, U.S. Geol. Survey Prof. Paper 120–H, p. 149.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Shown on correlation chart as underlying Bonham marl and overlying Eagle Ford shale.

Exposed near Ector, Fannin County.

Eddy sandstone[1]

Permian: Southern New Mexico.

Original reference: C. R. Keyes, 1906, Jour. Geology, v. 14, p. 147–154.

Derivation of name not stated, but probably named for Eddy, Lincoln County [now Eddy County].

Eddy Hill Grit[1]

Eddy Hill Grit Member (of Schodack Formation)

Eddy Hill lithofacies

Lower Cambrian: Southwestern Vermont and eastern New York.

Original reference: Rudolf Ruedemann, 1914, New York State Mus. Bull. 169, p. 67–70.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 64. Rank reduced to member of revised Schodack formation.

Christina Lochman, 1956, Geol. Soc. America Bull., v. 67, no. 10, p. 1335, 1336, 1339, pl. 9. Referred to as a lithofacies of third phase of Lower Cambrian sedimentation in Cambridge and Hoosick quadrangles, New York. Not considered time-stratigraphic unit. Contemporaneous with Mettawee and Schodack lithofacies.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 332. Dale's "Black patch grit" (1898, U.S. Geol. Survey Ann. Rept., v. 19, pt. 3B) was named the Eddy Hill grit by Ruedemann (1914) from type exposure at Eddy Hill, Vt., where unit is 40 feet thick. The Eddy Hill is dark-gray calcareous quartz grit with black shaly patches and calcareous sandstone nodules. Another variant is feldspathic sandstone or subgraywacke with calcareous and sericitic cement. Formation may be mistaken for Middle Ordovician Normanskill graywacke but lacks kaolinized inclusions and more pronounced bedding. Southward extension of Eddy Hill into Rensselaer County is unproved, and its correlation with Diamond Rock quartzite is speculative.

Named for exposures at Eddy Hill near Fairhaven, Vt.

Eden Beds[1]

Pliocene, lower: Southern California.

Original reference: C. Frick, 1921, California Univ. Pub., Dept. Geol. Bull., v. 12, p. 283–288.

Occur in Eden region, San Jacinto quadrangle, Riverside County.

Eden Group[1] **or Formation**

Eden Formation (in Covington Group)

Eden (Edenian) Stage

Upper Ordovician: Southwestern Ohio, southern Indiana, central northern Kentucky, central Tennessee, and West Virginia.

Original reference: J. S. Newberry, 1873, Ohio Geol. Survey, v. 1, table facing p. 89.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 2 (fig. 1), 175–179. Eden group geographically extended into central Tennessee. An intercalation of beds carrying an Eden fauna and lithologically different from Leipers and Catheys occurs low on southeastern flank of Nashville dome. This zone is here named Inman formation.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Generalized stratigraphic column of Ordovician rocks exposed in Jefferson and Switzerland Counties, Ind., shows Eden group comprising (ascending) Economy formation, 50 to 80 feet, Southgate formation, 70 to 120 feet, and McMicken, 60 to 80 feet. Underlies Maysville group; overlies Trenton group.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2; Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–33. Cincinnatian series comprises (ascending) Edenian, Maysvillian, Richmondian, and Gamachian stages.

W. C. Sweet and others, 1959, Jour. Palentology, v. 33, no. 6, p. 1029–1030. Basal formation in Covington group. Underlies Fairview formation; above Point Pleasant (Cynthiana) beds. Formation divided into three members (ascending); Economy (including basal Fulton beds), Southgate, and McMicken. Eden formation may be considered reference standard for early Cincinnatian Eden stage.

Named for Eden Park, Cincinnati, Ohio.

Edgecliff Member (of Onondaga Limestone)

Middle Devonian: New York.

W. A. Oliver, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 7, p. 626–627, 631 (fig. 2), 635–636, 641–642, pl. 1. Lowest member of Onondaga. Massive light-gray (in some places pink) very coarsely crystalline limestone characterized, in type area of Onondaga, by profusion of tabulates, large rugose corals, and crinoidal columnals. This is true coral biostrome and is Hall's (1879, New York Geol. Survey, Palentology, v. 5, pt. 2) "great coral bearing limestone" and the "Onondaga limestone" of early reports. Biostrome ranges in thickness from 8 feet at Split Rock to 25 feet at Chittenango Falls. Base of this unit is very sandy in most places; sandy zone (Springvale horizon) ranges in thickness from fraction of an inch with only widely scattered sand grains to 4 feet with high enough sand concentration at its lower limit to make it a sandstone; carries Onondaga fauna and is easily distinguished from true Oriskany sandstone. Whitish-gray chert nodules are characteristic of upper half of limestone but may occur in lower part also. Recognizable as far west as Buffalo; main changes are in thickness and amount of chert; near Buffalo contains large biohermal "reef" structure 35 feet thick and several hundred feet in diameter. Thickens eastward; 20 feet thick at Springfield Four Corners, where biostrome extends to top of member; 39 feet in Berne and Albany quadrangles, where biostrome occupies only lower 16 feet. Underlies Nedrow member (new). Onondaga in New York is generally considered lower Middle Devonian (Onesquethaw stage).

Named from exposures at Edgecliff Park, southwest of Syracuse and 1 mile northeast of Howlet Hill, Camillus quadrangle, Onondaga County. Member is most accessible at Split Rock, but this name is preoccupied.

†Edgehill Quartzite[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: C. E. Hall, 1881, Pennsylvania 2d Geol. Survey Rept. C_6, p. 14–47, map.

Probably named for Edge Hill, Montgomery County.

Edgewood Limestone[1] or Dolomite

Lower Silurian: Northeastern Missouri, western Illinois, and northeastern Iowa.

Original reference: T. E. Savage, 1909, Am. Jour. Sci., 4th, v. 28, p. 517–518.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 9 (fig. 2), 16–22, pl. 1. Formation described in Bowling Green quadrangle where it is 0 to 40 feet thick and includes Cyrene limestone member below and Bowling Green dolomite member above. Unconformably overlies Maquoketa formation of upper Ordovician age; unconformably underlies Grassy Creek formation of Mississippian or Devonian age. Reference section designated. Albion series.

C. E. Brown and J. W. Whitlow, 1960, U.S. Geol. Survey Bull. 1123–A, p. 34–40, pls. 1, 3. Geographically extended into Dubuque South quadrangle, Iowa-Illinois, where it consists chiefly of dolomite. Thickness 9 to 116 feet. Separable into (ascending) Mosalem and Tete des Morts members (both new). Unconformably overlies Neda member of Maquoketa shale; underlies Kankakee formation.

Reference section: On Higginbotham Farm in NW¼NE¼ sec. 28, T. 53 N., R. 1 W., Bowling Green quadrangle, about 1 mile north of Calumet, Pike County, Mo. Named for exposures 3 miles north of Edgewood, Pike County, Mo.

Edie School Rhyolites

Pliocene: East-central Idaho and southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4. p. 376–377, pl. 1. Named for slightly porous pale-lavender rhyolitic rocks that weather in shades of brown. Attain greatest thickness, estimated at 200 to 250 feet, in southeast corner of area and wedge out where they overlap on flanks of adjoining ranges. Overlie mid-Tertiary sediments of South Medicine Lodge Basin and are overlapped by Snake River basalts in southeast corner of region.

Described in Lima region, Clark County, Idaho, and Beaverhead County, Mont.

Edinburg Formation

Middle Ordovician: Western Virginia.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 78–86. Proposed for stratigraphic interval above Lincolnshire limestone and below *Reuschella "edsoni"* zone which characterizes Oranda formation (new). In Shenandoah Valley, underlies Collierstown limestone (new). Embraces two equivalent facies: one of cobbly to nodular buff-weathering limestone, Lantz Mills (new), and other of black limestone and shale, Liberty Hall facies (new). Thickness as much as 1,348 feet; at type locality 455 feet. Includes Botetourt limestone member (new) at base and St. Luke member (new) near top. Corresponds to substantial part of Chambersburg formation of Pennsylvania.

Type section: One and one-half miles N. 61° E., of Edinburg, Shenandoah County.

Edison Gneiss[1]

Precambrian: Northern New Jersey.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 439.

D. R. Baker, 1957, Dissert. Abs., v. 17, no. 3, p. 597–598. Edison gneiss, a major lithologic unit in Edison area, is divided into four unnamed subunits. Detailed petrographic description given.

Edison area is in New Jersey highlands 3 miles south of Franklin, Sussex County.

Edisto Marl[1]

Miocene, lower: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources in South Carolina, p. 12, 18, 19.

Extends from mouth of Wando River by Charleston, Church Flats, Port Royal, Parachucla, Givhams Ferry, Bacon's Bridge and thence back to head of Wando River, Colleton County.

Edmunds Formation[1]

Silurian: Southeastern Maine.

Original references: E. S. Bastin and H. S. Williams, 1913, Maine Water Storage Comm. 3d Ann. Rept., p. 168; 1913, Geol. Soc. America Bull., v. 24, p. 378, 379.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Assigned to Niagaran and Cayugan series [Middle and Upper Silurian].

Named for exposures near Edmunds, Washington County.

Edmunds Hill Andesite[1]

Devonian(?): Northeastern Maine.

Original reference: H. E. Gregory, 1899, Am. Jour. Sci., 4th, v. 8, p. 359-360.

Forms entire top of Edmund's Hill, Chapman Township, Aroostook County.

Edna Dolomite (in Deer Trail Group)

Precambrian (Belt Series) : Northeastern Washington.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Named as the second of five formations in group. Younger than Togo formation; older than McHale slate.

Report of discusses magnesite belt of Stevens County.

Edna Mountain Formation

Upper Permian: North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler Peak quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-10]. Gray to buff calcareous sandstone and shale with interbedded chert-pebble conglomerate and thin limestone beds. Thickness about 100 feet. Unconformably overlies Antler Peak limestone.

H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-15]. Thickness about 250 feet in Edna Mountain, about 100 feet in Battle Mountain.

Type locality: West slope of Edna Mountain, Golconda quadrangle.

Edray Sandstone (in Bluefield Formation)[1]

Edray Sandstone (in Lillydale Shale)

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 301, 443.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 265. Lenticular sandstone that may correspond to Edray sandstone of Reger (1926) is present in Lillydale shale. It is a thin poorly defined stratum.

Type locality: In Pocahontas County, W. Va., on mountain road 1.2 miles north of Edray.

Edson Beds (in Ash Hollow Formation)

Edson Beds (in Ogallala Formation)[1]

Pliocene, lower: Western Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7, p. 161-162.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 144. Included in Ash Hollow formation (Ogallala group). Consist of unconsolidated sands topographically a few tens of feet below Rhinoceros Hill beds. Contain vertebrate fauna.

Form an isolated outcrop near Edson, Sherman County.

Edwards Limestone (in Fredericksburg Group)[1]

Lower Cretaceous (Comanche Series) : Southern Texas.

Original references: R. T. Hill and T. W. Vaughan, 1898, U.S. Geol. Survey Geol. Atlas, Folio 42, p. 2; U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 227-235.

W. S. Adkins, 1932, Texas Univ. Bur. Econ. Geology Pub. 3232, p. 338-348.

Name Edwards replaced terms Caprina limestone (paleontological term) and Barton Creek limestone of Hill. From Fort Worth to south of Waco, Edwards gradually thickens, and is overlain, apparently unconformably by Kiamichi clay. South of Waco, Kiamichi is absent, and Edwards is overlain by Duck Creek limestone. Type locality stated.

F. E. Lozo and others, 1959, Texas Univ. Bur. Econ. Geology Pub. 5905, 235 p. Symposium on Edwards limestone. Based on outcrop sections, a southern complex of Edwards, Comanche Peak, and Walnut formations is indicated to pass northward into a complex composed of Goodland, Walnut, and Paluxy formations.

A. P. Noyes, Jr., and Keith Young, 1960, Texas Jour. Sci., v. 12, nos. 1, 2, p. 78–85, 99–104. Described in Purgatory Creek area where it is about 250 feet thick, overlies Walnut clay and underlies Georgetown limestone of Washita group.

Type locality (Adkins): Barton Creek, near Austin. Named for Edwards Plateau, Nueces and Uvalde quadrangles, southwestern Texas, of which it is chief component of scarps and mesas.

Edwardsville Formation (in Borden Group)[1]

Lower Mississippian: Southeastern Indiana.

Original reference: P. B. Stockdale, 1929, Ohio Jour. Sci., v. 29, no. 4, p. 170.

P. B. Stockdale, 1931, Indiana Div. Geology Pub. 98, p. 76, 220–300. Includes following facies: Stewarts Landing, Springler Knob, Medora Knob, Allens Creek, Bear Wallow, and Riverside sandstone. Named members (not in sequence): Dry Creek sandstone, Brownstown Hills, Cutright sandstone, Weed Patch, and Mount Ebel sandstone.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 74, 78. Indiana units, Locust Point, Carwood, Floyds Knob, and Edwardsville were proposed by writer [Stockdale] in 1931. In present report, the Floyds Knob is carried into the Kentucky classification; the Edwardsville and "Lower Harrodsburg" are combined in Muldraugh formation (new); the Locust Point and Carwood together make Brodhead formation (new) in Kentucky.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 799. Includes Floyds Knob member (rank reduced).

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 76). Shown on correlation chart in Borden group. Osage series; underlies Harrodsburg limestone; overlies Floyds Knob formation.

Named for village of Edwardsville, near center NE¼ sec. 1, T. 3 S., R. 5 E., 4½ miles west of New Albany, Floyd County.

Eel River Formation (in Wildcat Group)

Pliocene, lower: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 28–31, 105–107, pls. 1, 2. Massive dark gray-black siltstone and glauconitic sandstone 600 to 2,000 feet thick. Unconformably underlies Rio Dell formation (new); unconformably overlies Pullen formation (new).

Type section: West bank of Eel River near Scotia, Humboldt County. In southern part of area, unit forms northward-dipping belt of varying thickness which extends from coast southeastward to Eel River and beyond.

Effingham cyclothem

Pennsylvanian: Southeastern Illinois.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 13. Studies by Ekblaw led to tentative recognition of six cyclothems of which Effingham is third in sequence (ascending). Succeeds Divide cyclothem and is followed by Omega cyclothem. If Greenup and Omega limestones are not equivalent, a single standard reference section would include 14 cyclothems of which the Effingham would be eighth in sequence (ascending).

Type locality and derivation of name not given. However, type locality of Effingham beds is in sec. 33, T. 8 N., R. 6 E., on tributary to Salt Creek one-half mile south of Effingham, Effingham County.

Effingham Limestone Member (of Mattoon Formation)

Effingham Beds (in McLeansboro Group)

Pennsylvanian: Southeastern Illinois.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12. Referred to as Effingham beds in McLeansboro group. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 41, 51 (table 1), pl. 1. Effingham limestone member of Mattoon formation (new) proposed. Occurs above Shumway limestone member and below Bogota limestone member. Thickness about 11 feet at type outcrop. Name Effingham beds discontinued.

Type locality: In sec. 33, T. 8 N., R. 6 E. on Tributary to Salt Creek one-half mile south of Effingham, Effingham County.

Effingham terrane[1]

Pennsylvanian: Illinois.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 39, no. 4, p. 320.

Probably named for Effingham, Effingham County.

Effna Limestone (in Cliffield Group)

Middle Ordovician (Mohawkian): Southwestern Virginia.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 59–64, pl. 8. Proposed for beds overlying Lincolnshire limestone and underlying Whitesburg limestone along northwest base of Walker Mountain. Consists mainly of white to light-gray coarse-grained shell limestone, some beds of which are pinkish; pyrite occurs as nests and stringers in 15-foot zone about 70 feet above base of formation. Thickness at type section 221 feet; decreases to about 60 feet south of Ceres.

C. E. Prouty, 1946,, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 5, p. 1152. Effna limestone is below Whitesburg, Athens, and Peery limestones in sequence southeast of Saltville thrust and is thought to be partly equivalent to Thompson Valley limestone (new), but relationships of succeeding Whitesburg to the Thompson Valley and Ward Cove are uncertain; because of this indefinite relationship, use of both Effna and Thompson Valley appears advisable.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 60–61, chart 1 (facing p. 130). Underlies Rich Valley formation (new). At Porterfield quarry, rests on thin tongue [Fetzer (new)] of Arline formation (new). Older than Red Knobs formation (new).

Type section: In and near McNutt quarry, about 1½ miles southeast of Sharon Springs, Bland County, Va. Name derived from settlement on State Highway 42, about 2 miles east of Sharon Springs.

Egan limestone[1]

Lower Ordovician: Eastern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53, 78.

Named for Egan Range, Ely region.

Eggleston Limestone[1] or Formation

Middle Ordovician: Southwestern Virginia and eastern Tennessee.

Original reference: A. A. L. Mathews, 1934, Virginia Geol. Survey Bull. 40, p. 7, 11, 30.

R. R. Rosenkrans, 1936, Virginia Geol. Survey Bull. 46–I, p. 100. Not a valid formation name. Considered a facies of Black River age transitional between red Moccasin facies and overlying Trenton facies of the Martinsburg. Generally overlies red Moccasin facies but also replaces uppermost part of red Moccasin in more westerly belts.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76 (two sheets); 1954, Virginia Geol. Survey Bull. 71, p. 108 (table 6), 109–116. Overlies Hardy Creek member (new) of Moccasin limestone in Rose Hill Oil Field, Lee County. Underlies Trenton limestone. Consists of buff-weathering earthy calcareous siltstone at base and near top; rest of formation is thin-bedded fine-grained moderately fossiliferous limestone; two thick and several thin bentonite beds in upper part. Thickness 135 to 165 feet.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 61–66, 110–111, pl. 1. Mathews (1934) did not give type section, but sections at Narrows in Giles County that include beds assigned to Eggleston limestone have been published by Rosenkrans (1936) and Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1). Section along highway at Narrows has slumped and is less well exposed than when studied by Rosenkrans and Butts, but several bentonite beds listed in their sections are still visible. Base of Eggleston, as defined by Mathews, was clearly intended to begin with drab-green mudstones that overlie red mudstones typical of the Moccasin. Butts draws base of his Eggleston at this horizon. Top of Eggleston is less readily seen in this section, because the critical zone in which the contact was placed by Butts is now largely covered. Now lowest exposed beds of typical Trenton lithology and containing *Dalmanella* and *Sowerbyella* are 25 feet above place where Butts draws top of Eggleston. Drawing contact close below the lowest exposed *Dalmanella-Sowerbyella* beds would keep the two thick bentonites that should occur in this 25-foot covered interval within the the Eggleston, where they seem to belong according to evidence from other parts of southwest Virginia. However, it must be assumed that Butts' placing of the contact is correct unless the covered beds in the critical zone are reexcavated. Throughout Lee County and in adjacent Tennessee, the Eggleston is divisible into three unnamed members. Thickness 126 to 181 feet. Conformably overlies Hardy Creek limestone; underlies Trenton limestone; in both contacts, lithologic and faunal changes are abrupt and without evidence of erosion.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 61. Formation appears in western belts of southwestern Virginia and eastern Tennessee on northwest slope of Wallen Ridge from Tennessee nearly to Big Stone Gap, and throughout Russell and Giles Counties, Va.

Type locality: Along State Highway 8, 1 mile north of Narrows, Giles County, Va. Also well exposed 1.1 miles south of Eggleston.

Eggners Ferry Chert

Mississippian: Western Kentucky.

E. M. Luttrell and Ann Livesay, 1952, Kentucky Geol. Survey, ser. 9, Bull. 11, p. 5, 11–12. Dark-blue to black chert that weathers white and gray. Contains *Productus* and *Spiriferina*. Occurs above New Albany shale and below Warsaw chert and, therefore, of Fort Payne age. Near Eggners Ferry, beds are from a few inches to 1 foot thick. Chert has been mapped as undifferentiated Meramec, St. Louis member of Meramec, Fort Payne, Camden chert, or Clear Creek chert by various workers [see bibliography this report].

Exposed along and near Kentucky Lake in vicinity of Eggner's Ferry, near Aurora, Marshall County.

Egremont Limestone[1]

Cambrian and Ordovician: Southwestern Massachusetts and northwestern Connecticut.

Original reference: W. H. Hobbs, 1893, Jour. Geology, v. 1, p. 717–736, 780–802.

Named for its wide extent in Egremont Valley, Berkshire County, Mass.

Egypt sand[1]

Upper Cretaceous: Missouri.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 252. Derivation of name not stated.

Eidson Member (of Lincolnshire Formation)

Middle Ordovician (Mohawkian): Northeastern Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 61–62, chart 1 (facing p. 130). Name proposed for thinned part of Lincolnshire formation underlying Hogskin shale (new) in belts where that member is present. Consists of dark limestone containing black chert. Name credited to B. N. Cooper and G. A. Cooper.

Type section: Just north of Eidson, Kyles Ford (TVA 170–SE) quadrangle, Hawkins County. Present in Clinch, Hogskin, and Beaver Valleys.

Eighteenmile Creek Member (of Ludlowville Formation)

Middle Devonian: Western New York.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, no. 5–6, p. 366. Described as shale. Overlies Spring Brook shale member in Lake Erie sections. Name used by G. A. Cooper (unpub. thesis, 1929) who has since modified the stratigraphy by combining this unit and Spring Brook member to form Wanakah shale member.

Eight Mile Dacite

Pleistocene(?): Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 69. Consists of lower massive hard cliff-forming pale-brown dacite 50 to 100 feet thick, principally composed of glass tabulae; and upper denser, heavier porphyritic lithoidal dacite at least 200 feet thick. Of probable Pleistocene age according to text; shown as Pliocene(?) age on figure 2a. Generalized section shows dacite stratigraphically above Pine Valley latite (new).

Filled a valley which descended to south from Eight Mile Spring, northeast of present village of Central, Washington County.

Eileen Sandstone (in Oronto Group)[1]

Precambrian: Northwestern Wisconsin.

Original reference: F. W. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 50, 54.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1474–1479. Thwaites assumed that Eileen sandstone lay below Amnicon sandstone on basis of distribution of outcrops and strikes and dips. Eileen at type locality is not in contact with any other formation of Oronto series but is separated by unexposed interval of almost 1½ miles from Amnicon formation. Therefore, relation of the Eileen to the Amnicon is not definitely known at type locality, and sequence postulated by Thwaites is only one of several possible explanations of relation of these two sandstones. Lithological and heavy mineral evidence suggests that the Eileen belongs above the Amnicon and includes beds on Middle River and Fish Creek sections which Thwaites classes as lower Orienta (in Bayfield group). Eileen sandstone is probably basal Orienta, and Amnicon arkose is upper Freda. Thickness of the Amnicon as given by Thwaites—5,000 feet—is included in his estimate of thickness of Freda, and the 2,000 feet assigned to the Eileen is the Orienta. Hence, Oronto group is revised to exclude Eileen and Amnicon.

Type locality: South fork of Fish Creek in sec. 20 and 21, T. 47 N., R. 5 W., in town of Eileen, Bayfield County.

Einstine (Einstein) Sandstone[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow and F. Hawn, 1865, Kansas Geol. Survey Rept. on Miami County, p. 7.

At McFaddin's and Ward's mill, Miami County. Derivation of name not stated.

Eiss Limestone Member (of Bader Limestone)

Eiss Limestone (in Council Grove Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 229, 233, 234, 235, 237.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 61, 62. Rank reduced to member status in Bader limestone. Underlies Hooser shale member; overlies Stearns shale.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 78–79, pls. Thickness about 10.9 feet in Wabaunsee County, Kans. Generally, consists of two beds of limestone and thin bed of shale. Underlies Hooser shale member; overlies Stearns shale.

Type exposure: In SE¼ sec. 3, T. 1 N., R. 13 E., on Eiss Farm, 8 miles south of Humboldt, Richardson County, Nebr.

Ekker Formation (in Sheeprock Group)

Precambrian: West-central Utah.

DeVerle Harris, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 1, p. 6, 16–23, pl. 1. Includes phyllitic quartzites, quartzites, graywackes, feldspathic quartzites, and tillites which comprise autochthon of Sheeprock thrust. Total measured thickness 4,159 feet. Underlies Quaternary alluvium; overlies Auts Canyon formation (new).

The only location where complete succession of beds can be seen fairly well exposed and in their proper relation is on ridges east and west of Hard-To-Beat Canyon. In vicinity of Dutch Peak and Rick Ekker Ranch, Sheeprock Range, Tooele County.

Eklutna Glaciation

Pleistocene: Alaska.

T. N. V. Karlstrom, 1957, Science, v. 125, no. 3237, p. 74 (fig. 1). Named on correlation chart of glacial events. Recognized in Cook inlet area. Older than Knik glaciation.

R. D. Miller and Ernest Dobrovolny, 1959, U.S. Geol. Survey Bull. 1093, p. 11–12, 13 (fig. 2), pl. 3. Represented by till, outwash, and silt. Locally truncated surface of till is overlain by till and outwash of Knik glacier. Oldest pre-Wisconsin deposits in Anchorage area.

Exposed north of Eagle River Flats along bluff of Knik Arm, Anchorage area.

Elbert Formation[1]

Upper Devonian: Southwestern Colorado.

Original reference: W. Cross, 1904, Am. Jour. Sci., 4th, v. 18, p. 245–252.

Harley Barnes, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1780–1791. Heretofore, Ignacio quartzite has been thought to be Late Cambrian in age, disconformably overlain by Elbert formation of Late Devonian. Recent fieldwork suggests that Ignacio quartzite is Devonian in age and that it forms essentially continuous depositional sequence with overlying Elbert formation and Ouray limestone.

R. L. Knight and J. C. Cooper, 1955, Four Corners Geol. Soc. Guidebook [1], p. 56, 57. In subsurface in Four Corners area, overlies Aneth formation (new) and subdivided to include McCracken sandstone member at base.

F. H. T. Rhodes and J. H. Fisher, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 11, p. 2508–2518. Major unconformity exists between Ignacio quartzite and Elbert formation. This is contrary to conclusions of Barnes (1954). No explanation is offered for parallelism of bedding of Ignacio and Elbert, nor for seeming transition is lithology between the two units.

Named for exposures on Elbert Creek, a western tributary of Animas River, entering it just above Rockwood.

Elberton Granite

[Cambrian-Ordovician]: Western Georgia.

Felix Chayes, 1952, Am. Jour. Sci., v. 250, no. 4, p. 284–286. Fine-grained massive granite. Extensively quarried.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 31. Intrudes Little River series in Wilkes County.

Marc Grunenfelder and L. T. Silver, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1574. Age determinations by isotope-dilution methods on zircon concentrates from Elberton granite yielded ages of 375 to 490 million years. These data are in contrast with K/A and Rb/Sr ages of 250 to 290 million years reported from same rocks by previous workers. Older ages indicate a late Cambrian(?) plutonic episode which has not been recognized in region previously.

Occurs in vicinity of Elberton and crops out over wide area in Elbert and Oglethorpe Counties.

Elbow Ridge Sandstone Member (of Coeymans Limestone)

Devonian: Southern Pennsylvania.

F. M. Swartz, 1939, Pennsylvania Geol. Survey Bull. G-19, p. 86. Thick-bedded quartzitic sandstone, some crinoid stems. Thickness about 11 feet.

Section is on south side of Licking Creek where it bends southward across Maryland line, and across northeastern end of Elbow Ridge. It is several hundred feet west of bridge crossing creek about 1 mile east of Warren Point and 1½ miles southwest of Yeakle Mill, Franklin County.

Elbrook Limestone,[1] Dolomite, or Formation (in Conasauga Group)

Middle and Upper Cambrian: Central southern Pennsylvania, western Maryland, northwestern Virginia, and northeastern West Virginia.

Original reference: G. W. Stose, 1906, Jour. Geology, v. 14, p. 209.

H. P. Woodward, 1949, West Virginia Geol. Survey, v. 20, p. 155–169. Geographically extended into Jefferson and Berkeley Counties, W. Va., where it occurs in two separated belts of outcrop. Estimated thickness in Jefferson County 2,200 to 2,400 feet; in Berkeley County, 2,000 to 2,200 feet. Overlies Waynesboro formation, but contact poorly exposed, may be unconformable; conformably underlies Conococheague dolomite with sharp contact.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 32–33, pl. 1. Described in Elkton, Va., area where it consists mostly of thin-bedded light-gray fine-grained dolomite that contains laminae and partings a few inches apart; some blue-gray limestone is interbedded with the dolomite, especially in upper part; some dolomitic buff or pink shale forms partings between dolomite or limestone beds. In most outcrops, dips are varied and formation is crossed by many small faults. In Crooked River Valley, belt of outcrop is about 3,500 feet wide and beds stand nearly vertical, except for local folds near top. Estimated thickness about 3,000 feet. Overlies Waynesboro formation; underlies Conococheague.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 54, pl. 1. Conasauga group is interfingering complex of shale, limestone, and dolomite, of which Elbrook dolomite, Honaker dolomite and Nolichucky shale are representatives in northeasternmost Tennessee [this report]. Within this region, group is exposed in two areas—one to north, along southeast edge of Appalachian Valley, and other to southwest near Elizabethton, in trough of Stony Creek syncline. In northern occurrence, interval is all Elbrook dolomite, but to southwest, Nolichucky shale is at top and underlying dolomite is Honaker. Thickness of Elbrook about 2,000 feet in Denton Valley area, upper contact uncertain.

Named for outcrops near Elbrook, Franklin County, Pa.

El Capitan Granite[1]

Cretaceous: West-central California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 121–122, map.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2122, 2123 (fig. 1). Discussed in paper dealing with potassium-argon dating of igneous rocks. Age given as 92.2 millions of years. Younger than Gateway granodiorite and older than Sentinel granodiorite.

E. S. Larsen, Jr., and others, 1958, U.S. Geol. Survey Bull. 1070–B, p. 52 (table 9). Lead-alpha age 94 millions of years.

Named for fact that it forms greater part of El Capitan, Yosemite National Park.

Elco Gravel[1]

Mississippian: Southwestern Illinois.

Original reference: L. C. Glenn, 1906, U.S. Geol. Survey Water-Supply Paper 164, p. 22, 150–152.

Quarried near Elco, Alexander County.

Elden limestones[1]

Carbonic: Northern central Arizona.

Original reference: C. [R.] Keyes, 1922, Pan-Am. Geologist, v. 38, p. 243, 251, 336.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart). In Mississippian series. Overlies Truxton limestones; unconformably underlies Pierce shales. Of Carbonic age.

Name derived from Elden Mountain near Flagstaff.

Eldena Member (of Nachusa Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 15 C. Shown on columnar section as underlying Elm member (new) of Nachusa formation and overlying Forreston member (new) of Grand Detour formation. Thickness varies from 2 to 6 feet.

Occurs in Dixon-Oregon area.

Elder Sandstone

Age not stated: Northeastern Nevada.

James Gilluly, 1955, *in* Pacific Petroleum Geologist, v. 9, no. 8, p. 1. Thickness 3,000 to 5,000 feet. Arkosic sandstone dominant with beds of tan, pale, or buff chert. Overlies Ordovician Valmy formation; underlies Middle Devonian Slaven chert (new).

Occurs in Roberts Mountains area, Eureka district.

Elder Creek Group

Upper Jurassic (Knoxville): Northern California.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 184 (fig. 68) [preprint 1941]. Shown as lowermost group of Knoxville series. Underlies Grindstone group (new).

F. M. Anderson, 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 924, 925–926. Basal beds, as exposed near Redbank Creek, consist of dark-reddish-brown greatly indurated shale or thin-bedded cherty strata standing at a high angle and in part slightly overturned. In Bennett Creek area, a thick succession of alternating thin-bedded shales and calcareous sandstone layers constitute major part of group. Maximum thickness 6,600 feet. To the north, group is overlapped by early Shasta (Paskenta) beds; farther south, it is overlapped by conglomerates of Grindstone group. Lowest exposed beds rest upon or against pre-Knoxville metaandesite of Klamath complex.

Traceable northwest from Redbank Creek for a short distance and toward the south for more than 40 miles to latitude of Elder Creek village, Tehama County.

Eldora Sandstone[1]

Pennsylvanian: Central northern Iowa.

Original reference: S. W. Beyer, 1900, Iowa Geol. Survey, v. 10, p. 254.

Named for Eldora, Hardin County.

Eldoradan series[1]

Middle Cambrian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 51, 53, 78.

Eldorado Dolomite

Eldorado Limestone[1]

Middle Cambrian: Eastern Nevada.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1812, p. 184, footnote.

H. E. Wheeler and D. M. Lemmon, 1939, Nevada Univ. Bull., Geology and Mining Ser., no. 31, p. 18–20, fig. 3. Referred to as dolomite. Consists of thick-bedded dolomite, dolomitic limestone, and limestone. Thickness 2,000 feet south of Prospect Peak. Overlies Prospect Mountain quartzite; underlies Geddes limestone (new). In absence of fossils, dolomite is questionably assigned to Lower and Middle(?) Cambrian.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 9–11, pl. 2. Detailed description of Eldorado dolomite. Wheeler and Lemmon's (1939) definition accepted in this report. Restricted in outcrop area—confined to Prospect Ridge and southerly extension of the Ridge in Secret Canyon. North of Secret Canyon divide, exposures are discontinuous as result of two minor thrust zones, the Eldorado occurring in each of the three thrust blocks. Lowest of blocks includes type locality. In middle plate, Eldorado lies concordantly above and to east of main mass of Prospect Mountain quartzite and in several places overrides belts of Secret Canyon shale. In third and highest block, dolomite commonly overlies Prospect Mountain with thrust contact, but in a few places it appears to dip westward and rest in relative conformity on Pioche shale. Cannot be dated by enclosed fossils, but time range is limited by upper Lower Cambrian Pioche shale below and medial Middle Cambrian Geddes limestone above. Wheeler and Lemmon assign unit to Lower and Middle(?) Cambrian; in view of occurrence of Middle Cambrian fauna in Pioche shale at Pioche, assignment to early Middle Cambrian is probably more suitable.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 159, 160. Eldorado limestone is as much as 3,171 feet thick in north-central Schell Creek Range. Overlies Pioche formation; underlies Monte Neva formation (new).

Type locality: Eldorado Tunnel, which is near north end of Prospect Ridge and about 2,000 feet north of east from portal of Prospect Mountain Tunnel. Beds exposed here are near top of formation as it is now defined. Named for Eldorado mine, Eureka district.

El Dorado Ridge Gneissose Quartz Diorite

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 298–300, geol. map. Medium-grained gneissose biotite-hornblende quartz diorite. Occurs in east-northeast-trending El Dorado Ridge—Stoddard Canyon pluton and south of Rainbow Flat metamorphics (new).

Named from exposures on El Dorado Ridge in San Bernardino County. Also present in Los Angeles County.

Eldoran Epoch[1] or Series[1]

Quaternary (Wisconsin and Recent): Iowa and Illinois.

Original reference: G. F. Kay, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 449–452.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 38. In Iowa and Illinois, Pleistocene is classed as a Period (System) and four Epochs (Series) are used to include a glacial-interglacial pair each. These are Grandian (Nebraskan and Aftonian), Ottumwan (Kansas and Yarmouthian), Centralian (Illinoian and Sangamonian), and Eldoran (Wisconsinan and Recent). Of these units, each of first three essentially coincides with a glacial cycle; present data indicate that the youngest (Eldoran) includes two distinct cycles, each of which is complex within itself. These terms have not been adopted for official use in Kansas partly because of this inconsistency and partly because the retention of Quaternary as the System-Period with Pleistocene as its contained Series-Epoch would necessitate erection of new category of names to include these terms and thus produce further complication of classification system.

Named for Eldora, Hardin County, Iowa.

Eleana Formation

Mississippian to Lower Pennsylvanian: Southern Nevada.

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 357–360, pls. 32, 33. Lithologically most diverse unit in area. Generally consists of a conglomerate, quartzite, and shale facies in northern part of area. Southward, these grade into finer grained sediments. On Quartzite Ridge, where incomplete measured section is 2,810 feet thick, the Eleana is subdivided into three units. Lower unit consists of 1,000 feet or more of dark-brown to buff hard poorly bedded slope-forming argillite and shale. Middle is composed of about 1,050 feet of interbedded quartzite, conglomerate. Upper consists of about 760 feet of varicolored argillite. These three units traceable southward into Eleana Range where they grade laterally into finer grained sediments. Most noticeable facies change is in middle unit which is split by shale tongue which thickens southward where it also contains interbedded limestone beds and occupies about a third of middle unit. Remainder is conglomerate and quartzite. Similar changes occur in upper unit. In southern part of Eleana, upper unit consists of interbedded sequence of argillite and limestone. South of Eleana Range and in Mine Mountains, middle and upper units not recognizable as such owing to abrupt lithologic changes. In these areas, formation consists of interbedded conglomerate, quartzite, shale, and some limestone. Lower contact of formation not exposed in area. Underlies Tippipah limestone (new). Upper contact on margins of Syncline Ridge, placed at lithic break between interbedded quartzite, argillite, and overlying limestone and appears to be conformable.

Named for exposures in Eleana Range, Atomic Energy Commission Nevada proving grounds area, Nye County.

†Electric Intrusives[1]

Miocene: Yellowstone National Park.

Original reference: A. Hague and others, 1899, U.S. Geol. Survey Mon. 32, pt. 2, pl. 10.

Probably named for Electric Peak.

Electric Peak Intrusives[1]

Miocene: Yellowstone National Park.

Original reference: A. Hague and others, 1904, U.S. Geol. Survey Mon. 32, Atlas, Gallatin sheet.

Intrude sedimentary rocks of Electric Peak in Gallatin quadrangle, Yellowstone National Park.

Elephant Limestone[1]

Pennsylvanian: Southwestern Utah.

Original reference: B. S. Butler, 1913, U.S. Geol. Survey Prof. Paper 80.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 703, chart 6 (column 53a). Mainly Pennsylvanian but may be Permian in part.

Named for Elephant Canyon, southeast of Frisco district.

Elephant Butte Formation (in Armendaris Group)

Pennsylvanian (Des Moines Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 44 (fig. 3), 47–49. Term proposed for all rocks between top of Derry series (new) and base of Whiskey Canyon limestone (new). Formation is essentially limestone, with one thin bed of conglomeratic sandstone about 22 feet above base and several beds of calcareous gray silty and micaceous shale near middle. Includes Warmington limestone member (new) at base. Thickness at type locality about 82 feet. Overlies Cuchillo Negro formation (new).

Type locality: Western end of Whiskey Canyon, in norther part of Mud Springs Mountains in southwest part of sec. 1, T. 13 S., R. 5 W., Sierra County. Name derived from Elephant Butte in Rio Grande Valley at Elephant Butte Dam.

Elephant Hill Breccia (in Glendora Volcanics)

Miocene, middle or older: Southern California.

J. S. Shelton, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 56, pl 1. Breccia member of Glendora volcanics. Composed of angular fragments of laminated gray spherulitic glass in tuffaceous matrix. Most of the blocks are 1 inch or less across, but the largest are at least 2 feet long.

Occurs in steep-walled semicircular valley head 500 feet in diameter that penetrates east flank of Elephant Hill, in Spadra area near Pomona, Los Angeles County.

Elephant Mountain Flow

Miocene and Pliocene: South-central Washington.

A. C. Waters, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 673, pl. 1. Name applied to basalt flow interstratified in Ellensburg formation. Occurs at higher stratigraphic level than Selah Butte flow (new). Average thickness about 35 feet in area mapped; thickens eastward into widespread lava sheet in Black Rock Spring quadrangle. Map bracket shows Ellensburg and associated basalt flows as Miocene and Pliocene. Text states that much or all of the Ellensburg and its associated intercalated basalt flows are regarded as Pliocene.

Flow crops out on Elephant Mountain, eastern continuation of Rattlesnake Ridge, Yakima East quadrangle.

Eleventh Street Limestone

Pennsylvanian (Des Moines Series): Northern Oklahoma.

R. C. Moore, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 102. Limestone in upper part Des Moines subseries; occurs at or near horizon of Lenapah limestone.

R. H. Dott, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 8, p. 1593. Abandoned in favor of Lenapah limestone. Credits name to F. E. Greene. Gives area and derivation of name.

Crops out on East Eleventh Street (U.S. Highway 66), about one-half mile east of intersection of East Eleventh Street and Sheridan Road, NE¼ sec. 11, T. 19 N., R. 13 E., Tulsa, Tulsa County.

†Elgin Limestone (in Maquoketa Group)[1]

Elgin Shaly Limestone Member (of Maquoketa Formation)

Upper Ordovician: Northeastern Iowa and western Wisconsin.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 98.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 50). Shown on correlation chart as shaly limestone member of Maquoketa formation. Underlies Clermont shale member; overlies Dubuque dolomite.

Named for exposures near Elgin, Fayette County, Iowa.

Elgin Sandstone Member (of Vamoosa Formation)

Elgin Sandstone[1]

Pennsylvanian (Virgil Series): Southern Kansas and central northern and central Oklahoma.

Original reference: Erasmus Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 64.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 67. In southern Kansas, much of the interval between the Lecompton and Oread formations is occupied by sandstone, sandy shale, and red shale collectively called Elgin sandstone.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as sandstone member of Vamoosa formation.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 32–34. Elgin in Pawnee County consists of four sandstone beds and numerous sandstone lenses within Kanwaka shale member of Vamoosa.

Well exposed near Elgin, Chautauqua County, Kans.

Eliot Formation (in Merrimack Group)

Eliot Slate[1]

Probably Ordovician and Silurian: Southwestern Maine and southeastern New Hampshire.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

Jacob Freedman, 1950 Geol. Soc. America Bull., v. 61, no. 5, p. 450, 453 (fig. 2), 454–456, 488. Termed formation since slate not abundant in Mount Pawtuckaway quadrangle, New Hampshire. Includes light- and dark-gray phyllite, green phyllite, quartzite, and quartz-sericite schist. Calef member at top. Silurian(?).

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Included in Merrimack group in New Hampshire. Age designated as probably Ordovician and Silurian.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 40–41. Age tentatively considered Silurian, probably Middle Silurian.

Named for developmnet at Eliot, York County, Maine.

Elizabeth Gabbros[1]

Precambrian: Eastern New York.

Original reference: G. H. Chadwick, 1930, Geol. Soc. America Bull., v. 41, p. 82.

Named for development around Elizabethtown, Essex County.

Elizabeth Furnace Conglomerate Member (of Gettysburg Shale)[1]

Upper Triassic: Southeastern Pennsylvania.

Original reference: A. I. Jonas and G. W. Stose, 1930, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 168.

M. E. Kauffman, 1960, Pennsylvania Geologists Guidebook 25th Ann. Field Conf., Oct. 22 and 23, p. 23. Basal member of Gettysburg shale. Pebbly sandstone and conglomerate up to 2,500 feet thick. Underlies unnamed shale member.

Forms prominent ridge, Elizabeth Furnace Hill, northeast of Mount Hope, Lancaster County.

Elizabethtown Gabbro[1]

Precambrian: Northeastern New York.

Original reference: G. H. Chadwick, 1930, Geol. Soc. America Bull., v. 41, p. 82.

Occurs around Elizabethtown, Essex County.

Elizaville Shales

Upper Cambrian and Lower Ordovician(?): Southeastern New York.

J. D. Weaver, 1957, Geol. Soc. America Bull., v. 68, no. 6, p. 739–743, pl. 1. Mainly light gray but ranges from light greenish gray to dark gray approaching black. Coarse shaly or fine silty texture with all variations from fine phyllitic shale to coarse siltstone. Upper part contains horizon with many bands of brown quartzite ranging from 3 inches to 12 inches in thickness, at intervals of 2 or 3 feet. Also contains banding consisting of thin layers of ferruginous and dolomitic material an inch or so apart, and characterized by fine irregular crumpling, with crenulations of amplitude about one-half inch; this crumpling is somewhat similar to that in Pine Plains dolomites. Thickness about 90 feet.

Named from village of Elizaville, southeast corner of Catskill quadrangle. Described in Copake quadrangle.

Elk Fire Clay (in Conemaugh Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1914, West Virginia Geol. Survey Rept. Kanawha County, p. 179.

Named for Elk River, near Charleston, Kanawha County.

Elk Basin Sandstone Member (of Telegraph Creek Formation)[1]

Upper Cretaceous: Southern Montana and central northern Wyoming.

Original reference: C. J. Hares, 1917, Washington Acad. Sci. Jour., v. 7, p. 430.

Forms rims from Park City to Elk Basin and Shoshone River, Yellowstone and Bighorn Counties.

Elk Butte Member (of Pierre Shale)

Upper Cretaceous: Central South Dakota and northeastern Nebraska.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 50–55, pls. 2, 3. Includes all beds in South Dakota between top of Mobridge member (new) and base of Fox Hills formation. Essentially medium-gray flaky shale with small ferruginous concretions. Thickness 70 to 290 feet.

A. L. Moxon, O. E. Olson, and W. V. Searight, 1939, South Dakota State Coll. Agriculture and Mech. Arts Tech. Bull. 2, p. 20, 26. Overlies Interior member, used in this report in preference to Mobridge member.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 16. Geographically extended into northeastern Nebraska.

A. L. Moxon, O. E. Olson, and W. V. Searight, 1939, South Dakota State Coll. Agriculture and Mech. Arts Tech. Bull. 2 (revised), p. 20, 25. Overlies Mobridge member, which name is now accepted in place of Interior.

Type locality: Along U.S. Highway 12, near Elk Butte, Corson County, S. Dak. Section begins a little less than 1½ miles west and continues to 5 miles west of Wakpala.

Elk City Member (of Quartermaster Formation)

Elk City Sandstone Member (of Quartermaster Formation)[1]

Permian: Western Oklahoma.

Original reference: H. L. Griley, 1933, Pan-Am. Geologist, v. 59, no. 3, p. 234.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in western Oklahoma as Elk City member of formation; upper member of formation; overlies Doxey member.

Well exposed in SE¼ sec. 3, T. 11 N., R. 19 W., [Washita County].

Elk Creek Basalt

Miocene and (or) Pliocene: Northwestern Wyoming.

A. D. Howard, 1937, Geol. Soc. America Spec. Paper 6, p. 33-36, 78 (table 9), pl. 4. Highly porphyritic basalt; the phenocrysts of feldspar are tabular, and average about one-quarter inch in size. Normally blue black. Intensely altered locally. Color of altered phases is lighter and in some places is almost white. Younger than Crescent Hill basalt (new) and older than Lost Creek trachyte (new).

Well exposed at southeast base of Crescent Hill ,near mouth of Elk Creek where it forms a bench, Yellowstone National Park.

†Elk Creek Beds (in Cheyenne Sandstone)[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 361, 366.

Named for Elk Creek, Kiowa County.

Elk Creek Gabbro

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 11, pl. 1. Distinguished by extreme dark color, prominent hornblende, and marked variation in grain size; most striking feature is local development of poikilitic brown hornblende crystals as large as 6 inches across. Relation to other named plutonic rocks in area not determined.

Crops out in four small masses about a square mile in area along and near Elk Creek, an intermittent stream northwest of Ash Mountain Park headquarters, Sequoia National Park.

Elk Falls Limestone[1]

Pennsylvanian: Southern Kansas.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 65-66, 105.

Named for Elk Falls, Elk County.

†Elkgarden Formation[1]

Pennsylvanian: Northeastern West Virginia and western Maryland.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

Well exposed on Elkgarden Plateau, Mineral County, W. Va.

Elk Hill Complex[1]

Precambrian: Southeastern Virginia.

Original reference: S. Taber, 1913, Virginia Geol. Survey Bull. 7, p. 57.

C. B. Brown, 1937, Virginia Geol. Survey Bull. 48, p. 15, pl. 2. Precambrian.

Complex is from 1 to 1½ miles wide where it crosses James River at Elk Hill; well exposed in bluffs three-quarters mile below Elk Hill, Goochland County.

Elkhorn Basalt

Tertiary: Southwestern Wyoming.

R. E. Wilcox, 1944, Geol. Soc. America Bull., v. 55, no. 9, p. 1054, 1060, pl. 1. Oldest of three basalts in area—that is, older than Cataract basalt (new) and Sheepeaters basalt (new). Not included in Gardiner River rhyolite-basalt complex (new). Porphyritic rock, slightly reddish in some phases and locally carrying numerous amygdules of zeolite; dense in lower part; grades upward into scoriaceous and cindery basalt near contact with overlying Cataract basalt. Relationships indicate Elkhorn is intermediate in age between Castle rhyolite (new) and Cataract basalt.

Present near Sevenmile Bridge on Gardiner River, Yellowstone Park.

Elkhorn Formation (in Richmond Group)[1]

Elkhorn Limestone (in Richmond Group)

Elkhorn Shale (in Medina Group)

Upper Ordovician: Southern and eastern Indiana and western Ohio.

Original reference: E. R. Cumings, 1908, Indiana Dept. Geology and Nat. Resources 32d Ann. Rept., p. 678.

Wilber Stout, 1941, Ohio Geol. Survey, 4th ser., Bull. 42, p. 31, 32, table facing p. 46. Medina group as used here includes two members: Elkhorn shale and Clinton sandstone, which are correlatives respectively with Queenstown shale and Whirlpool sandstone of New York section.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 45). Correlation chart shows Elkhorn limestone at top of Richmond group above Whitewater-Saluda formations.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030. Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations define Richmond stage of Cincinnatian series.

Type locality: About 3½ miles southeast of Richmond, Wayne County, Ind.

Elkhorn Limestone

See **Milligen Formation.**

Elkhorn Shale[1] or Hornstone[1]

Upper Cambrian: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Report., pt. 2, p. 434, 437, map.

Well exposed in a hanging-wall crosscut of Elkhorn mine, Elkhorn mining district.

Elkhorn Volcanics

See **Elkhorn Mountains Volcanics.**

Elkhorn Mountains Volcanics

Upper Cretaceous: Southwestern Montana.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 4 (table), 26 (table), 31–41, pls. 1, 2, 3. Sequence of volcanic rocks that differs from place to place. In region east of Boulder batholith, volcanic rocks divisible into three unnamed members of which only lower and middle are present in area of this report [southern Elkhorn Mountains, Jefferson and Broadwater Counties]: lower member that consists mainly of andesitic fragmental rocks with a few andesitic and basaltic flows and a few thin welded ash flow tuffs of andesitic to calcic quartz latitic composition, thickness probably more than 3,000 feet; a middle member that consists essentially of units of welded tuff alternating with units of ash-fall crystal tuff and water-laid volcanic ejectamenta, thickness at least 2,500 feet; and third member that consists largely of water-laid andesitic volcanic sediments that is missing in mapped area. Total thickness of volcanics in excess of 10,000 feet. In area mapped, more than 5,000 feet. Overlie Slim Sam formation. Where Slim Sam formation is absent, Elkhorn Mountains volcanics rest with angular unconformity on beds as old as the Morrison. In lower parts of area, Elkhorn Mountains volcanics are overlain with strong angular unconformity by poorly consolidated sedimentary rocks of lower Oligocene or Quaternary age. Maximum original thickness probably nowhere preserved. Billingsley (1921, Geol. Soc. America Bull., v. 32, p. 465, fig. 7) considered volcanic rocks in and adjacent to mapped area a separate volcanic field and used name Elkhorn volcanics. Usage has not been followed by others and is not recommended here because name Elkhorn is preempted as formation name. Alexander (1951, unpub. thesis) extended name Livingston into Whitehall area and included in the formation more than 9,600 feet of andesitic flows and tuffs that are continuous with Elkhorn Mountains volcanics. These, he stated, are unconformable on folded and truncated Madison formation. These volcanic rocks in Whitehall area are assigned to Elkhorn Mountains volcanics. Adel Mountain volcanics (Lyons, 1944) are younger than Elkhorn Mountains volcanics. Although volcanic rocks of Elkhorn Mountains are partial age equivalents of and compositionally similar to Livingston formation of type area, their modes of origin are distinctly different, and separate formation names are needed.

No single section has been designated as type section. Widely distributed in and around Elkhorn Mountains in plateaulike accumulation, Broadwater and Jefferson Counties.

Elkhorn Ridge Argillite[1]

Lower Permian: Northeastern Oregon.

Original reference: James Gilluly, 1937, U.S. Geol. Survey Bull. 879.

C. W. Merriam and S. A. Berthiaume, 1943, Geol. Soc. America Bull. 54, no. 2, p. 162. Elkhorn Ridge argillite contains "Fusulina" and is apparently at least in part Pennsylvanian. May be comparable in age to Spotted Ridge formation of central Oregon.

A. J. Eardley, 1947, Jour. Geology, v. 55, no. 4, p. 322. Overlies Burnt River schist and underlies Clover Creek greenstone. Thickness about 5,000 feet. Pennsylvanian on basis of fusulinid fossils.

W. H. Taubeneck, 1955, Northwest Sci., v. 29, no. 3. p. 97–100. Age determination of fusilinids, in conjunction with regional Pacific Coast stratigraphic relations, are considered sufficient evidence to assign Permian age to all strata included by Gilluly (1937) in Elkhorn Ridge argillite. Permian age is somewhat less certain for part of formation that underlies the fossiliferous limestone. However, base of argillite has not been found nor have the strata been observed in contact with older formations. In areas bordering Pacific Coast of North America, Pennsylvanian marine formations are characteristically lacking, hence, Pennsylvanian age is improbable for any part of Elkhorn Ridge argillite stratigraphically below fusulinid limestone.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 195. Cut by Black Bear quartz gabbro (new) in area of Bald Mountain batholith.

Named for exposures on Elkhorn Ridge, Sumpter quadrangle, Baker County. Argillite can be traced almost continuously for 70 miles from vicinity of Lookout Mountain westward to Greenhorn Mountains.

Elkins Sandstone[1]

Upper Devonian: Eastern West Virginia.

Original reference: D. B. Reger, 1928, Am. Jour. Sci., 5th, v. 15, p. 50–57.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart below Valley Head sandstone and above "Portage" formation.

Well exposed on State road 3 miles northwest of Elkins, Randolph County.

Elkins Fork Shale[1] (in Breathitt Formation)

Pennsylvanian: Eastern Kentucky.

Original reference: W. C. Morse, 1931, Kentucky Geol. Survey, ser. 6, v. 36, p. 296, 297.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 82. Marine shale in Breathitt formation. Probably equivalent to marine Seth limestone, West Virginia.

Named for exposures opposite Elkins Fork School in northern Pike County.

Elkland parvafacies[1]

Devonian or Carboniferous: Northern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 31.

Probably named for Elkland, Tioga County.

Elk Lick Clay[1] (in Conemaugh Formation)

Elk Lick underclay member

Pennsylvanian: Pennsylvania, Ohio, and West Virginia.

[Original reference]: R. E. Lamborn, 1930, Ohio Geol. Survey, 4th ser. Bull. 35, p. 157–158.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 150. Member of Elk Lick cyclothem in report on Athens County. Average thickness about 2 feet. Conemaugh series.

Named from its overlying coal. Type area of coal is near Elk Lick, Somerset County, Pa.

Elk Lick cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958. Ohio Geol. Survey Bull. 57, p. 94 (table 11), 147–150. Embraces interval between Duquesne cyclothem (new) below and Little Clarksburg cyclothem (new) above. Includes (ascending) Birmingham redbed, Upper Grafton shale and sandstone, Elk Lick limestone, Elk Lick underclay, and Elk Lick coal members. Consists essentially of redbed and shale and sandstone members, the Elk Lick members being poorly represented. Intricate facies relationship exists between Birmingham redbed and Upper Grafton shale and sandstone, and their thicknesses may be represented largely or entirely by redbed, by bedded shale and sandstone, by massive sandstone, or by variable combination of redbed and bedded shale and sandstone. Thickness about 53 feet. In area of this report, Conemaugh series is discussed on cyclothemic basis; 15 cyclothems are named. [For sequence see Mahoning cyclothem.]

Outcrops of members of cycle occur in Alexander, Ames, Athens, Canaan, and Dover Townships, Athens County.

Elk Lick Limestone Member (of Conemaugh Formation)[1]

Elk Lick limestone member

Upper Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

Original reference: F. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. H_3, p. 60.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 33. Recognized only in Jefferson County. Where present on outcrop, maximum thickness does not exceed 2 feet and average is much less. Lies about 25 feet above Skelly limestone and 48 feet below Clarksburg coal. Conemaugh series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 148–150. Member of Elk Lick cyclothem in report on Athens County. Poorly exposed. Conemaugh series.

Named for relations to Elk Lick coal, which was named for Elk Lick, Somerset County, Pa.

Elkmont Sandstone (in Great Smoky Group)

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 958, 959 (fig. 4). Fine-grained feldspathic sandstone. First formation above Greenbrier fault, base not visible; variable thickness present under Thunderhead sandstone—a few thousand feet on east, about 5,000 feet near Elkmont, and as much as 9,000 feet south of Cades Cove. Intertongues laterally with Thunderhead so that its top in eastern exposures lies at least several thousand feet higher than in western; much of western section differs only slightly from overlying Thunderhead. In southeastern part of mountains where stratigraphic base of Great Smoky group emerges, the Elkmont has not been identified, and it is uncertain to what part of this sequence it is related.

Type locality: Along Little River from Tennessee Highway 73 southward past Elkmont to base of Thunderhead sandstone. Named for community of Elkmont, 5 miles southwest of Gatlinburg, Sevier County. Crops out on lower and northern spurs of Great Smoky Mountains, from Greenbrier Pinnacle on east to beyond Cades Cove on west.

Elk Mountain Porphyry[1]

Tertiary, lower: Central Colorado.

Original reference: S. F. Emmons, 1898, U.S. Geol. Survey Tenmile Spec. Folio 48.

Ogden Tweto, 1951, Geol. Soc. America Bull., v. 62, no. 5, p. 509, 510–511. Sills of Pando area comprise four types of quartz monzonitic porphyries (ascending): Pando (new), Elk Mountain, Lincoln, and Eagle River, all of early Tertiary age.

Ogden Tweto, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–34. Mapped as early Tertiary in Tennessee Pass area where sequence of porphyries is (ascending) Pando, Elk Mountain, Sacramento, Lincoln, and Eagle River.

Named for Elk Mountain.

Elk Mountain Sandstone[1] Member (of Catskill Formation)

Upper Devonian: Northeastern Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 57, no. 4, p. 561, 574–577.

Bradford Willard *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 283. Summary discussion. Included in Upper Devonian Catskill facies group.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3. Pennsylvania Geological Survey currently limits use of term Catskill to thick brownish- and grayish-red units which characterize middle and upper parts of Middle and Upper Devonian red-bed sequence. Light-colored sandstones, such as Honesdale and Elk Mountain members, known only in east, are included in Catskill only in those areas where they are underlain by thick all-red unit.

Named for Elk Mountains, Susquehanna County.

Elk Mountain transition group[1]

Upper Devonian or Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 235.

Crops out around slopes of North and South Knobs of Elk Mountains, southeastern Susquehanna County.

Elko Shale[1] or Group[1]

Eocene: Northeastern Nevada.

Original reference: S. F. Emmons, 1877, U.S. Geol. Expl. 40th Par., v. 2, p. 551–564.

Elko Prince Rhyolite[1]

Tertiary: Central northern Nevada.

Original reference: E. H. Rott, Jr., 1931, Nevada Univ. Bull., v. 25, no. 5.

Occurs in both east and west walls of Elko Prince vein in Gold Circle or Midas mining district, western Elko County.

Elk Peak Leucocratic Quartz Monzonite

Lower Cretaceous(?): Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 210–211, 235. Uniform-grained slightly pinkish rock. Intrudes Bald Mountain tonalite-Anthony Lake granodiorite transition zone.

Present on summit and southeast slopes of Elk Peak, in Elkhorn Mountains [Grant County]. Forms part of Bald Mountain batholith.

Elk Point Group

Elk Point Formation

Middle Devonian: Subsurface in Alberta and Saskatchewan, and surface and subsurface in Manitoba, Canada, and subsurface in northeastern Montana, northwestern North Dakota, and northwestern South Dakota.

J. R. McGehee, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 4, p. 603–613. Study based on sample determinations of 12 wells, one of which is in Saskatchewan and 11 in plains of Alberta, shows sequence of strata of questionable age that is herein referred to as Elk Point formation. Consists of two conspicuous red shales, anhydritic dolomites, and thin slightly fossiliferous argillaceous silty limestones, in addition to three salt members. Maximum thickness about 1,557 feet. Underlies Upper Devonian Waterways formation. Overlies Ordovician, Cambrian, or Precambrian rocks. Considered to be Silurian although upper part may be Middle Devonian.

J. R. McGehee, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 64. Geographically extended into Manitoba. Tentative Silurian age abandoned in favor of Middle Devonian.

H. R. Belyea, 1952, Canada Geol. Survey Paper 52–27, p. 7–12. Rank raised to group but subdivisions not named.

A. D. Baillie, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 2, p. 444–452; 1953, Manitoba Dept. Mines and Nat. Resources Mines Br. Pub. 52–5, p. 10–13, 18–21. Term Elk Point group is applied to basal major Devonian unit in Williston basin. Group is approximately equivalent to Elk Point formation in Alberta. In Williston basin, includes (ascending) Ashern, Elm Point, and Winnipegosis formations of outcrop area and their subsurface equivalents and also main Middle Devonian salt and anhydrite section for which name Prairie evaporite is proposed. Upper limit is top of evaporite section or top of Winnipegosis formation where the evaporites are not present. Underlies Manitoba group. Middle Devonian.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2299 (fig. 2), 2302–2303 (fig. 4), 2304–2307. In the U.S. part of the Williston basin and adjacent areas, Elk Point group consists of Winnipegosis formation and overlying Prairie formation. Underlies Dawson Bay formation.

First described from wells in Elk Point area, near North Saskatchewan River, Alberta, Canada.

Elk Ridge Limestone Member (of Minturn Formation)

Elk Ridge Limestone

Pennsylvanian: Northwestern Colorado.

A. H. Koschmann and F. G. Wells, 1946, Colorado Sci. Soc. Proc., v. 15, no. 2, p. 62 (table 1), 67. In Kokomo mining district, includes two limestone beds, separated by 200 to 225 feet of thin-bedded red sandstone and conglomerate; upper limestone is 5 to 7 feet thick, dark bluish gray, and overlain by 10 to 12 feet of black micaceous shale; lower limestone is 12 to 15 feet thick, upper 7 to 8 feet crystalline and light gray, lower 6 to 7 feet mottled dark bluish gray. Underlies unnamed sandstone 250 to 400 feet thick; overlies unnamed sandstone and shale 300 to 500 feet thick.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 202–203. Limestone, which in Pando area lies 275 feet above Robinson member of Minturn formation, or about 4,800 feet above Belden shale, is known as Elk Ridge limestone at Kokomo and is here designated Elk Ridge limestone member of Minturn formation. In Pando area, member is single limestone bed 7½ feet thick; where thickest, on Radio Ridge, consists of 3 feet of dark fine-grained thin-bedded dolomite, overlain by 10 feet of mottled gray and pink slightly sandy locally oolitic limestone. Lies 150 to 200 feet below White Quail limestone member.

Forms conspicuous outcrops on crest of Elk Ridge, near Kokomo, Summit County.

Elk River Beds[1]

Pleistocene, upper: Southwestern Oregon.

Original reference: J. S. Diller, 1902, U.S. Geol. Survey Bull. 196, p. 30–31.

E. M. Baldwin, 1945, Jour. Geology, v. 53, no. 1, p. 35, 42–43. Elk River beds of Cape Blanco region, as currently used, include deposits of late- to post-Pleistocene age and beds of middle Pliocene age which unconformably underly them. Name Elk River beds is restricted to terrace deposits in accordance with Diller's original definition. Name Port Orford formation is proposed for beds of middle Pliocene age; name Coquille formation is proposed for estuarine deposits that unconformably underlie Elk River beds (restricted) just north of mouth of Coquille River.

Named for occurrences at mouth of Elk River, near Cape Blanco, Curry County.

†Elk River Series[1]

Pennsylvanian: West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 70–98.

Ellenburger Group

Ellenburger Limestone[1]

Lower Ordovician: Central Texas.

Original reference: S. Paige, 1911, U.S. Geol. Survey Bull. 450, p. 24.

V. E. Barnes and P. E. Cloud, Jr., 1944, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 34, p. 1–2. Ellenburger group subdivided into (ascending) Tanyard, Gorman, and Honeycut formations.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 133, 139–148, 151–153, 156–159, pls. 5, 6 [1945]. Group of this report is derived by revision of Ellenburger limestone (Paige, 1911) which by subsequent usage had come to include not only all Lower Ordovician dolomites and limestones in Llano region and adjacent subsurface but the immediately subjacent carbonate rocks of Upper Cambrian as well. Term Ellenburger is here restricted to beds of Lower Ordovician age. Cambrian dolomites formerly included in Ellenburger are here named Pedernales dolomite member of Wilberns formation. Maximum thickness approximately 1,820 feet in vicinity of Johnson City, southeastern part of uplift; thins north and west by truncation of upper beds to 970 feet in Mason County and about 800 feet in McCulloch County; truncation was essentially pre-Middle Devonian and probably pre-Devonian. Overlapped by Devonian, Mississippian, and Cretaceous.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 473, plates [1946]. Type section, standard section, and local stratigraphy, including underlying Cambrian formations, described in detail.

Type section: Composite Tanyard-Gorman section adjoining the Ellenburger Hills. This section is relatively inaccessible. Combined Moore

Hollow and Warren Springs sections south of Llano, Llano County, are designated as standard section. Named for Ellenburger Hills, Burnet County.

Ellensburg Formation[1]

Pliocene, lower: Central Washington.

Original reference: I. C. Russell, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 2, p. 100–137, map.

J. H. Mackin, 1947, (abs.) Northwest Sci., v. 21, no. 1, p. 33. Includes Selah tuff member (new) which underlies Wenas basalt member.

A. C. Waters, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 671, 673–675, pl. 1. Described and mapped in Yakima East quadrangle where it interfingers with underlying Yakima basalt. Includes interstratified basalt flows (ascending) Wenas basalt, Selah Butte flow (new), and Elephant Mountain flow (new). Present mapping indicates that contact between any one basalt flow and an overlying sedimentary bed cannot serve as workable horizon for defining top of Yakima basalt and the base of Ellensburg; in some areas, exact position of contact is matter of arbitrary choice; at one locality, Ellensburg pinches out and Wenas basalt rests directly on Yakima. In a broad sense, entire lower part of Ellensburg can be considered marginal sedimentary facies of Yakima basalt flows. Much or all of Ellensburg and its associated intercalated basalt flows is regarded as Pliocene. Map bracket shows Miocene and Pliocene.

D. R. Mullineaux, L. M. Gard, and D. R. Crandell, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 3, pt. 1, p. 694–695. Formation is alluvial deposit of volcanic detritus at least 1,600 feet thick that was transported eastward into central Washington from position of present Cascades. Formation was first assigned late Miocene age by Smith (1903, U.S. Geol. Survey Geol. Atlas, Folio 86) on basis of fossil leaves and *Hipparion* remains. Waters (1955) considered formation to be lower Pliocene on basis of new finds of vertebrate fossils and freshwater gastropods, and suggested that base of Ellensburg is probably placed at different stratigraphic positions in different areas. Problem of age is further complicated by fact that paleobotanists and other paleontologists are not agreed upon placement of Miocene-Pliocene boundary. Hence, exact age of Ellensburg is uncertain but formation likely contains both upper Miocene and lower Pliocene strata.

Forms floor of Kittitas Valley, Kittitas County, in which town of Ellensbur is situated.

Ellerslie Fire Clay (in Allegheny Formation)[1]

Pennsylvanian: Western Maryland.

Original references: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 572.

Georges Creek Basin.

Ellerslie Sandstone (in Allegheny Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1918, Geol Soc. America Bull., v. 30, p. 572.

At Ellerslie, Allegany County.

Ellett Formation

Middle Ordovician (Mohawkian): Western Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 62, chart 1 (facing p. 130). Name proposed for dark-gray limestones between Knox [group] and Botetourt formation (above) in belt east of Roanoke Valley. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: In fields west of County Road 615, about 899 feet north of Virginian Railway, near Ellett Station, Blacksburg (15') quadrangle, Montgomery County.

Ellicott Shale Member[1] (of Chadakoin Formation)

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 66–70, table opp. p. 61.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 15. Lies above Dexterville member; underlies Panama conglomerate member of Cattaraugus formation. Thickness in Cherry Creek quadrangle about 270 feet.

Type occurrence: In roadside cuts along Hunt Road, between Ashville and Jamestown, N.Y. This is in town of Ellicott, Chautauqua County.

Ellicott City Granite[1]

Upper Devonian(?): Northeastern Maryland.

Original reference: E. B. Knopf and A. I. Jonas, 1929, Maryland Geol. Survey Baltimore County Rept., p. 134–135.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 42 (table 7), 63. At least three periods of granite formation are recognized in Maryland rocks. The oldest granites are the probable migmatites associated with Baltimore gneiss. Those of second period cut Glenarm series. Rocks of third period are represented by Woodstock, Ellicott City, and at least part of Sykesville granite. The Ellicott City is a biotite-quartz monzonite.

Named for exposures at Ellicott City, Baltimore County. Crops out in a narrow mass extending southwestward from Ellicott City to Orange Grove, Howard County.

Ellicottville Conglomerate[1]

Pennsylvanian: New York.

Original reference: J. P. Lesley, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 89, 96.

Occurs at Ellicottville, Cattaraugus County.

Elliott Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference; N .F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 376.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 73 Largely bluish-gray clays. Thickness 100 feet. Overlies Burnt Branch bed; underlies Shadrick Mills sandstone. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to base of Drake's Ricker bed.

Named for Elliott Creek, Lampasas County.

Ellis Formation[1] or Group

Middle and Upper Jurassic: Montana and northwestern Wyoming.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 100, map.

W. A. Cobban, R. W. Imlay, and J. B. Reeside, Jr., 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 4, p. 451–453. Thickness 297 feet at type section herein designated. Underlies Morrison formation; overlies Tensleep(?).

W. A. Cobban, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 9, p. 1262–1303. Rank raised to group and subdivided into (ascending) Sawtooth, Rierdon, and Swift formations (all new). Name is restricted to marine Jurassic beds. In Sweetgrass arch area, north-central Montana, unconformably overlies marine Mississippian beds and underlies Upper Jurassic continental deposits (Morrison) or Lower Cretaceous continental deposits (Kootenai). Middle and Upper Jurassic (Bathonian-Argovian).

R. W. Imlay and others, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart. 32. Group, in south-central Montana, comprises (ascending) Piper (new), Rierdon, and Swift formations.

J. D. Weir, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 4, p. 547–563. Three-fold division of Ellis group into Swift, Rierdon, and Sawtooth formations recognizable and applicable in Alberta. Known only in subsurface in southern Alberta Plains [area of this rept.].

J. D. Vine and W. J. Hall, Jr., 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 108. Group, in Hobson area, central Montana, consists of (ascending) Piper, Rierdon, and Swift formations. Entire group less than 100 feet thick, and commonly only Swift formation represented. Overlies Amsden formation; underlies Morrison formation.

C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1802–1810. Marine Jurassic rocks of southwestern Montana have heretofore been mapped as Ellis formation, but study of these beds indicates that subdivisions recognized by Cobban (1945) in Sweetgrass arch region are present in area considered in this report. Proposed that Ellis of this region be raised to group rank and that formation names of Sweetgrass arch region be used in southwestern Montana. Thickness 236 feet, Little Water Creek section, Beaverhead County. Overlies Lower Triassic Thaynes formation.

R. W. Edmund, 1951, Augustana Libr. Pub. 23, p. 8 (fig. 5). Stratigraphic section of northern end of Teton Range, Wyo., shows that Ellis formation, 400 feet thick, comprises (ascending) Nugget sandstone, Twin Creek limestone, and (?) Stump sandstone members. Overlies Chugwater formation; underlies Lower Cretaceous sandstones, shales, and siltstones.

J. A. Mann, 1954, Yellowstone-Bighorn Research Proj. Contr. 190, p. 25–30. Ellis, in Gravelly Range, is thin, 13 to 41 feet, and is not differentiated into formations. Underlies Morrison formation; overlies Thaynes(?).

Type section: On north side U.S. Highway 10 on north side of Rocky Creek Canyon about 3.7 miles southeast of site of Fort Ellis, or 7 miles southeast of Bozeman Court House, in sec. 19, T. 2 S., R. 7 E., Gallatin County, Mont.

Ellison Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. and Min. Jour. Press, v. 115, p. 793–799, 836–843, maps.

J. A. Noble and J. A. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 944, 947–948, 951. In Lead district, consists of phyllites, schists, and large amount of dark quartzites; thickness 3,000 to 5,000 feet. Overlies Homestake formation; underlies Northwestern formation. In Rochford district, where Northwestern formation is missing, underlies Flag Rock formation.

Named for exposures on road to Homestake mine office and Ellison shaft, Lead district, Lawrence County.

†Ellisville phase[1]

Oligocene(?) and Miocene: Southern Mississippi and southern Louisiana.

Original reference: L. C. Johnson, 1893, Science, v. 21, p. 90–91.

Named for Ellisville, Jones County, Miss.

Ellsworth Formation (in Dakota Group)

Cretaceous (Comanche Series): Central Kansas.

R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita, [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]. Yellow-brown sandstone and reddish or varicolored shale mostly non-marine. Thickness 25 to 200 feet. Includes Rocktown sandstone above and Terra Cotta shale below. Unconformable below Solomon formation (new) and above Belvidere formation.

R. C. Moore and K. K. Landes, 1937, Geologic map of Kansas (1:500,000): Kansas Geol. Survey. Mapped with Dakota group.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Dakota formation, as herein defined, contains stratigraphic units formerly called "Rocktown channel sandstone," "Ellsworth formation," "Solomon formation," "Reeder sandstone," "Marquette sandstone," "Spring Creek clay," and others.

Probably named for occurrences in vicinity of Ellsworth, Ellsworth County.

Ellsworth Schist[1]

Precambrian or Cambrian: South-central and southeastern Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 1–2.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 172. Name abandoned; it was incorrectly applied to unit earlier named Bartletts Island.

W. T. Forsyth, 1953, Maine State Geologist Rept. 1951–1952, p. 34–37, 41–46. Includes massive pyritiferous quartzite not previously reported. No direct evidence of age known.

L. A. Wing, 1957, Maine Geol. Survey GP. and G. Survey 1, sheet 1. In Hancock and Penobscot Counties, Knox gneiss and Copeland formation (new) appear to be older than surrounding formations but not necessarily equivalent to Ellsworth.

P. S. Wingard, 1958, Kansas Acad. Sci. Trans., v. 61, no. 3, p. 330–333. Ellsworth formation, previously designated as Precambrian (Smith, 1907) should now be considered pre-Middle Silurian. Underlies Castine formation.

Named for exposures near Ellsworth, Hancock County.

Ellsworth Shale[1]

Upper Devonian and Lower Mississippian: Central western Michigan.

Original reference: R. B. Newcomb, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 2, p. 159.

G. V. Cohee, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–41, sheet 5. Because upper part of Antrim shale is known to grade laterally westward into lower part of Ellsworth and upper part of Antrim shale is considered to be of lower Mississippian age (Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5), the Upper Devonian and Mississippian time boundary appears to be within Ellsworth shale in western Michigan and within Antrim in eastern Michigan.

Type section: Petoskey Portland Cement Co. quarry, NE¼NE¼ sec. 26, T. 32 N., R. 8 W., about 1½ miles south of Ellsworth, Banks Township, Antrim County.

El Luis Ridge Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 296–298, geol. map. Includes metasedimentary rocks that are enclosed in El Dorado Ridge gneissose quartz diorite (new). On El Luis Ridge and in Stoddard Canyon, rocks are predominantly calc-silicate and quartzitic; a thin layer of metamorphosed argillaceous rock is intercalated. In San Antonio Canyon, rocks are predominantly feldspathic and migmatitic. Relations of group to Aurela Ridge granulite (new) are not certain.

Exposed in Los Angeles and San Bernardino Counties.

Elm Member (of Nachusa Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 15B, 15C. Shown on columnar section as underlying Everett member (new) and overlying Eldena member (new). Thickness as much as 3 feet.

Occurs in Dixon-Oregon area.

Elm Branch Shale[1]

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 85, 90, 97.

Derivation of name not stated.

Elm Creek Limestone (in Canyon Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: E. Böse, 1918, Texas Univ. Bull. 1758, p. 18.

Occurs in middle part of Elm Creek, Wise County.

Elm Creek Limestone (in Cherokee Shale)[1]

Pennsylvanian: Northeastern Oklahoma and southeastern Kansas.

Original reference: S. Weidman, 1932, Oklahoma Geol. Survey Bull. 56, p. 25–26.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 107. Abandoned by Oklahoma Geological Survey. Name preoccupied. Weidman's name has not been replaced.

Named from occurrences along Elm Creek, south of road, in NW¼SE¼ sec. 10, T. 29, N., R. 22 E., Ottawa County, Okla. Also occurs a few miles north of Kansas State line.

Elm Creek Limestone Member (of Belle Plains Formation)

Elm Creek Limestone (in Belle Plains Group)

Elm Creek Limestone Member (of Admiral Formation)[1]

Lower Permian (Leonard Series) : Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 424.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 96. Rank raised to formation in Belle Plains group. Overlies Jim Ned shale (new); underlies Jagger Bend limestone. Leonard series.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80. Described in Colorado River valley where it is classified as member of Belle Plains formation. Overlies Jim Ned shale member; underlies Voss shale member (new). Consists of closely spaced beds of gray medium-grained partly foraminiferal limestone, that weather light brown. Beds range in thickness from 1 to 5 feet, and except locally, are noncherty. Thickness about 45 feet at Colorado River. Note on type exposure.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 273, pl. 11. Member of Belle Plains formation. Thickness 55 to 95 feet in Brazos River valley. Overlies Jim Ned shale member; underlies Voss shale member.

Type exposures: On lower Elm Creek near its confluence with Colorado River, south of Leaday, Coleman County. Forms prominent escarpment in western Coleman County. Named for Elm Creek, Brown County.

Elm Creek Silts

Pleistocene (Illinois? or Sangamon?) : West-central Texas.

M. M. Leighton, 1936, Medallion Papers 24, p. 8–11, 39 (fig. 5). Consists of series or regularly thick-bedded and nearly uniformly textured silts and sandy silts with minor amounts of sand and gravel. Unconformably overlie Durst silts (new). Show evidence of human occupation.

Extensively exposed along Elm Creek, which flows into Clear Fork of Brazos River and heads into Edwards Plateau about 12 miles southwest of Abilene, Taylor County.

†Elmdale Formation or Shale (in Wabaunsee Group)[1]

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and central northern and central Oklahoma.

Original reference: J. W. Beede, 1902, Kansas Univ. Sci. Bull., v. 1, p. 178.

U.S. Geological Survey has abandoned the terms Elmdale Shale and Formation.

Named for exposures east of Elmdale, Chase County, Kans.

Elm Grove cyclothem

Permian (Washington Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 204, 205 (map 26). Lowest recognized cyclothem in Washington series. Occurs below Waynesburg "A" cyclothem (new). Thickness 15½ feet. Normal sequence includes (ascending) shale and sandstone, redbed, Elm Grove limestone, underclay, Elm Grove coal, and Elm Grove roof shale, but in Athens County cycle is poorly developed. In area of this report, Washington series is discussed on a cyclothemic basis; the following cyclothems are named (ascending): Elm Grove, Waynesburg "A," Little Washington, and Washington.

Recognized in two measured sections in Troy and Carthage Townships, Athens County.

Elm Grove Limestone Member (of Washington Formation)[1]

Elm Grove Limestone (in Washington Group)

Elm Grove limestone member

Pennsylvanian: Northern West Virginia, southeastern Ohio, and southwestern Pennsylvania.

Original reference: G. P. Grimsley, 1907, West Virginia Geol. Survey Rept. Ohio, Brooke and Hancock Counties, p. 68.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 135–145. Elm Grove limestone occurs 13 feet above base of Washington group. Overlies Cassville shale; underlies Waynesburg sandstone. Thickness as much as 5 feet.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 90–91, geol. map. In Morgan County, Elm Grove limestone member of Washington series overlies Cassville shale member and underlies Waynesburg sandstone and shale member. Thickness about 4 feet.

Named from exposures in vicinity of Elm Grove, Ohio County, W. Va.

Elmo Limestone Member (in Sumner Group)[1]

Permian: Central Kansas.

Original reference: C. O. Dunbar, 1924, Am. Jour. Sci., 5th, v. 7, p. 176, 178–208.

Named for occurrence about 3 miles south and one-half mile east of village of Elmo, Dickinson County, where it caps Insect Hill.

El Modeno Volcanics

Miocene: Southern California.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–154. A series of volcanic rocks. Subdivided into three members: the oldest, an olivine basalt flow; the second, a palagonitic tuff and tuff breccia; and the upper, a calcic andesite flow and flow breccia. Locally one or more of members may be missing. Thickness ranges from about 100 feet to 750 feet; average thickness about 300 feet. Unconformably underlie La Vida member (new) of Puente formation;

overlie Topanga formation. Volcanics probably straddle boundary between middle and late Miocene.

R. F. Yerkes, 1957, U.S. Geol. Survey Prof. Paper 274–L, p. 313–324, pl. 46. Detailed description of unit. Maximum outcrop thickness 850 feet. Middle to early late Miocene. Tentatively correlated with Glendora volcanics 25 miles to northwest.

Exposed in hills just east of El Modeno, Orange County. Cover an area of approximately 4 square miles.

Elmont Limestone Member (of Emporia Limestone)

Elmont Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 30.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 17. Areai extent of formation noted.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276. Rank reduced to member status in Emporia limestone here recognizde and used as originally defined. Overlies Harveyville shale member; underlies Willard shale.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 58–60. Described in Pawnee County. As currently defined (Moore, 1949, Kansas Geol. Survey Bull. 83), the Elmont overlies Harveyville shale and underlies Willard shale. In Pawnee County, overlying shale is the Gano. Thickness 20 to 34 feet. Traced across Pawnee County into Payne County, but southern extent not known.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12–13, fig. 5. Formation in Wabaunsee group. Underlies Willard shale; overlies Harveyville shale. Consists of two limestone beds separated by fossiliferous gray shale. Upper bed nodular and argillaceous; lower bed, dark blue gray, sublithographic. Thickness about 2 feet.

First described from occurrence on hills near Elmont, Shawnee County, Kans. [Condra refers to this as type locality.]

Elmwood Member (of Manlius Limestone)

Elmwood Beds[1] (in Manlius Group)

Lower Devonian: Central New York.

Original reference: Burnett Smith, 1929, New York State Mus. Bull. 271, p. 26, 27–31.

G. H. Davis 3d, 1953, New York State Mus. and Sci. Ser. Circ. 35, p. 10. Discussion of contact between Manlius limestone and Coeymans limestone in upper New York State. In section measured at Perrysville, Madison County, members of Manlius proposed by Smith (1929) are distinguished (ascending): Olney, Elmwood, Clark Reservation, Jamesville, and Pools Brook limestone. Top of quarry lies stratigraphically in Onondaga limestone which rests on Coeymans, the Oriskany sandstone being absent.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Manlius formation subdivided into (ascending) Thacher (new), Olney, Elmwood, Clark Reservation, and Jamseville. Thacher is only member present in eastern New York. Higher limestone members, all named by Smith (1929), pass laterally into Coeymans limestone of eastern New York and, hence, are undoubtedly Devonian in age.

L. V. Rickard, 1956, Dissert, Abs., v. 16, no. 1, p. 102. West of Cherry Valley, Coeymans formation splits into three parts. Lower part, for which name Dayville is proposed, grades laterally into Olney limestone of Syracuse area. Middle part grades into Elmwood, Clark Reservation, and Jamesville members of Manlius.

Type section: At Sweet's quarry, about one-half mile northeast of Onondaga Hill and in belt between St. Agnes Cemetery and Elmwood Park, Onondaga County.

Elmwoods Limestone Member (of Manlius Limestone)

See Elmwood Limestone Member (of Manlius Limestone).

El Pasan series[1]

Ordovician: Southern New Mexico and western Texas.

Original reference: C. R. Keyes.

El Paso Limestone[1] **or Formation**

El Paso Group

Lower Ordovician: Western Texas, Arizona, and southern New Mexico.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 29.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pub. in Geology 4, p. 31 (table), 40–56. Rank raised to group. Comprises (ascending) Sierrite limestone and Bat Cave formation (both new). Overlies Bliss formation (sandstone); underlies Montoya group.

F. E. Kottlowski, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 7 (table 2), 16–23. Acceptance of group status for El Paso not predicated on discriminating Sierrite and Bat Cave subdivisions of Kelley and Silver (1952) but on succession of faunas and lithic units as outlined by Flower (1955, New Mexico Geol. Soc. Guidebook 6th Field Conf.). Group in New Mexico can be subdivided into three lithic units of probable formational rank which correspond closely with faunal zones. Thickness as much as 760 feet. Ordovician (Canadian).

F. F. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 472–475. Formation geographically extended into southeastern Arizona where it conformably overlies Bolsa quartzite and underlies Portal formation (new); contact is disconformity representing time interval from Middle Ordovician through Middle Devonian; no angular discordance at contact. Thickness 340 to 715 feet. Term formation used because in this area [Chiricahua-Dos Cabezas Mountains] El Paso beds are predominantly dolomite rather than limestone. Upper Cambrian-Lower Ordovician:

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 11 (table 2), 21–24, table 1. Limestone described in central Peloncillo Mountains where it is about 550 feet thick; overlies Bolsa quartzite and underlies Montoya limestone. Age of limestone in this area, based on fossils collected and correlation with Chiricahua section, is late Cambrian and early Ordovician; thus, it contains beds which are older than any heretofore included in the El Paso in New Mexico.

Named for exposures in Franklin and Hueco Mountains, El Paso quadrangle, Tex.

El Portal Glaciation

El Portal Stage[1]

Pleistocene: Eastern California.

Original reference: F. E. Matthes, 1929, Science, new ser., v. 70, p. 75–76.

Ernst Antevs, 1945, Am. Jour. Sci., v. 243A, table 2. Correlated with Sherwin glaciation.

Change of name from stage to glaciation made in accordance with adoption of Stratigraphic Code, June 1961.

Named for occurrence in vicinity of El Portal, entrance to Yosemite Park.

El Rayo Formation

El Rayo Volcanics (in Mayagüez Group)

Upper Cretaceous: Southwestern Puerto Rico.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, no. 1, p. 200. In Yauco area, a complex, more than 9,000 meters thick, of volcanic flows with interbedded marine limstones, mudstones, tuffs, and sedimentary rocks derived from the volcanic rocks, is divided into eight formations: Sabana Grande (new), El Rayo (new), Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara (new). El Rayo and Sabana Grande formations unconformably underlie Ensenada and Río Yauco formations. Complex ranges in age from Senonian to late Paleocene, possibly Eocene.

P. H. Mattson, 1958, Dissert, Abs., v. 18, no. 1, p. 197; 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 339–340, pl. 1. El Rayo volcanic rocks were defined by Slodowski as feldspathic olivine basalt porphyry (90 percent) with interbedded lenses (about 10 percent) of volcanic conglomerate and dark massive limestone. In Mayagüez area, the dark massive limestone has been named Melones limestone, and the El Rayo volcanic rocks are considered within the Mayagüez group. The El Rayo rocks include about 1,000 meters of basalt lava, andesite breccia, and lava, and minor conglomerate and wacke. Conformable with underlying Yauco mudstone. Within area of outcrop of El Rayo volcanics and bordering it on the west are volcanic rock and limestone of San Germán formation believed to unconformably overlie the El Rayo. Campanian to Maestrichtian.

Forms part of north limb of Tea syncline, Mayagüez area.

El Reno Group

El Reno Formation[1]

Permian: Western Oklahoma.

Original reference: C. M. Becker, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 955.

Henry Schweer *in* O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1553 (fig. 9). El Reno group used to include Duncan-Chickasha sequence from top of Hennessey formation to base of Whitehorse group. Duncan-Chickasha sequence grades laterally into Flower Pot shale, Blaine gypsum, and Dog Creek shale.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 97–98. Shown on correlation chart of north-central Texas as El Reno (San Andres) group. Includes (ascending) San Angelo sandstone, Flower Pot shale, Blaine gypsum, and Dog Creek shale. On east side of Permian basin, name El Reno group appears to have priority and to be more appropriate on a facies basis than recently proposed San Andres group for beds of Leonard age from base of San Angelo sandstone to top of Dog Creek shale.

F. E. Lewis, 1941, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 1, p. 80, 81, 83, 84. El Reno group extends across Red River and can be traced southward across Texas 250 miles before it is lost under Cretaceous rocks. Unconformably overlies Clear Fork group. Considered Guadalupe in age; boundary between Guadalupe and Leonard should be drawn at base of San Andres-El Reno groups.

Robert Roth, 1945, Geol. Soc. America Bull., v. 56. no. 10, p. 893–894. Pease River group includes San Angelo, Flowerpot, Blaine, and Dog Creek formations as exposed in Texas. Formations form natural group bounded by disconformities. However, formations change facies so rapidly that any group name becomes a facies name. Examples: Pease River group, evaporite facies; El Reno, clastic facies; San Andres of Sacramento Mountains, dolomite facies; and Cherry Canyon formation, clastic and limestone facies. All these appear to be variants of the Word.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 12–13, pl. 1. Group comprises (ascending) Duncan sandstone, Flowerpot shale, Blaine formation (redefined), and Dog Creek shale. Overlies Hennessy shale; underlies Whitehorse group. In Oklahoma, El Reno outcrop forms "V-shaped" pattern; one limb of group passes along north side of Wichita Mountains, including Carter area (this report), and the other limb swings northwestward through west-central Oklahoma into Kansas. This outcrop pattern results from synclinal folding of Anadarko basin. Within southeastern margin of basin is a pronounced facies change that has led to recognition of numerous stratigraphic problems [see bibliography this report]. It is now generally believed that the Chickasha-Duncan complex is near-shore coarse-clastic equivalent of the shale-gypsum-anhydrite-dolomite strata comprising the El Reno on both sides of the basin to the north and west. The fact that the two evaporite areas are separated by nonevaporite sediments has resulted in establishment of dual nomenclature, one set being applied to members of the Blaine, and another set in the Carter area and elsewhere in southwestern Oklahoma. This report follows classification used by Schweer (1937) and older stratigraphic concept of the Blaine is revised. [For outcrop pattern see Geologic map of Oklahoma (Miser, 1954).]

C. O. Dunbar and others, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, chart 6 (columns 75, 76, 77). Correlation chart uses Pease River group in Texas in preference to El Reno group. Group in Oklahoma comprises in southwestern part of State—Duncan sandstone and Chickasha formation; in west-central part—Flowerpot shale, Blaine formation, and Dog Creek shale; in north-central part—Cedar Hill sandstone, Flowerpot shale, Blaine formation, and Dog Creek shale. Overlies Hennessey shale; underlies Marlow formation of Whitehorse group.

Probably named for El Reno, Canadian County, Okla.

El Rito Formation

Tertiary (Eocene ?): North-central New Mexico.

H. T. U. Smith, 1938, Jour. Geology, v. 46, no. 7, p. 937 (fig. 4), 940–944, 958. Composed of sandstone, conglomerate, and breccia—all have a characteristic brick-red color. Well consolidated; commonly stands in steep cliffs. Maximum thickness about 200 feet. Underlies Abiquiu tuff. Rests on Precambrian to Jurassic rocks with angular unconformity.

A. J. Budding, C. W. Pitrat, and C. T. Smith, 1960, New Mexico Geol. Soc. Guidebook 11th Field Conf., p. 82–84. Described in southern part of Chama Basin. Estimated that at least a 400-foot thickness of formation is present east of Madera Canyon. Overlies older formations (Cutler, Agua Zarca, Chinle, Entrada, and Mancos shale) with angular unconformity. Underlies Abiquiu tuff member of Santa Fe formation. Age uncertain; likely early Tertiary, possibly Eocene.

Principal localities: Ortega Mountains along both branches of El Rito Creek; badland west of the Cerro de las Minas; north bank of the Chama about 5 miles west of Abiquiu.

Elsinore Metamorphic Series[1]

Triassic: Southern California.

Original reference: P. H. Dudley, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 223.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 480–481, table 4. Described as including metasediments and metavolcanics. Most of metasediments are dark-gray slates and phyllites, gray quartzites which lie mostly above the slates, and some chert, all representing generally uniform low-grade metamorphism. May be younger than Diamond Valley complex (new).

René Engel, 1959, California Div. Mines Bull. 146, p. 24. Proposed that name Santa Ana formation be continued to designate Upper(?) Triassic metasedimentary rocks in preference to name "Elsinore formation", as proposed by Dudley (1935, California Div. Mines Rept. 31).

Occurs in Riverside-Elsinore-Coahuila area, Riverside County.

Elsmere Member (of Repetto Formation)

Pliocene, lower: Southern California.

U. S. Grant, 4th and L. G. Hertlein, 1943, California Div. Mines Bull. 118, pt. 2, p. 202 (fig. 85) [preprint 1941]. Shown on correlation chart as lying within Pico and Repetto formations in Ventura basin.

G. B. Oakeshott, 1950, California Jour. Mines and Geology, v. 46, no. 1, p. 51 (table 1), 54 (fig. 2), 55. Consists of coarse marine sandstone, conglomerate, siltstone, and mudstone. The Elsmere dips off crystalline basement rocks on which it lies unconformably; overlaps on Modelo and Mint Canyon formations; underlies siltstone member of Repetto and may be in part contemporaneous with it. Maximum thickness about 100 feet. Type locality designated.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 22 (fig. 2). 75, 77, 79, pl. 1. Member reaches its maximum thickness of 1,400 feet, from its contact on pre-Tertiary crystalline rocks to overlying base of Pico formation, in upper Elsmere Canyon. Thins rapidly northward and is overlapped by Pico before reaching Whitney Canyon. Southeastward becomes folded and faulted in complexities of Santa Susana fault zone and is overlapped by Pacoima formation near Olive View. Unconformably overlies Domengine sandstone. Present only south of San Gabriel fault. "Towsley formation" (Winterer and Durham) includes "Elsmere member."

Type locality: Elsmere Canyon, Los Angeles County. Occurs to south and east around western border of San Gabriel Mountains.

†Elstone Formation[1]

Eocene: Southern Texas.

Original reference: R. A. Liddle, 1921, Texas Univ. Bull. 1860, p. 75, map, columnar section.

Typically exposed near Elstone, Media County.

Elves Chasm Tongue (of Mauv Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 87–88. Snuff-brown massive crystalline dolomite which passes down into beds of buff fine-grained crossbedded glauconitic sandstone in vicinity of Bass trail. Thickness at Bass Canyon 12 feet; at Fossil Rapids 35 feet; and at Gateway Canyon 50 feet. Older than Garnet Canyon tongue (new); younger than Meriwitica tongue (new).

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 513, 515 (fig. 2). Cited as tongue of Mauv formation.

Excellent horizon marker throughout most of east-central Grand Canyon. Can be traced eastward from Bass Canyon to and beyond Hermit Canyon. Named for canyon of same designation.

Elvins Group[1]

Elvins Formation

Upper Cambrian: Southeastern Missouri.

Original references: E. O. Ulrich and H. F. Bain, 1905, U.S. Geol. Survey Bull. 260, p. 234; Bull. 267, p. 12, 17, 23–26.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 234 (table 1). Rank raised to group. Includes (ascending) Davis formation, Derby dolomite, and Doe Run dolomite. Underlies Potosi dolomite; overlies Bonneterre dolomite.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 30. Term Elvins as introduced by Ulrich is not recognized as valid in this report. As a group it would include the Davis and Derby and probably part of the Potosi.

V. E. Kurtz, 1960, Dissert, Abs., v. 21, no. 3, p. 595. Referred to as Elvins formation comprising (ascending) Davis, Derby, and Docrun members. Separated from underlying Bonneterre dolomite by disconformity; shows facies relationships with underlying Potosi formation. Contains four faunal zones. Upper Cambrian.

Named for exposures at Elvins, St. Francois County.

Elvira Group

Mississippian (Chester Series): Southern Illinois and western Kentucky.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 136; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 835, 841. Includes eight alternating sandstone and limestone-shale formations of upper Chester series (descending): Kinkaid limestone, Degonia sandstone, Clore limestone, Palestine sandstone, Menard limestone, Waltersburg sandstone, Vienna limestone, and Tar Springs sandstone. Latter three are considered equivalent to Baldwin formation in some areas.

Name derived from Elvira township, Johnson County, Ill., where all formations of standard Mississippian section are well developed.

Elway Limestone

Elway Limestone Member (of Lurich Formation)

Middle Ordovician: Southwestern Virginia.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66, p. 42–43, 45 (fig. 8), pls. 9, 18, 23. Consists of dove-gray to dark-bluish-gray fine-grained argillaceous limestones containing chert which weathers into characteristic blocks. Average thickness 35 to 40 feet. Underlies Five Oaks limestone; overlies Blackford formation which is herein restricted to exclude zone of blocky chert here named Elway.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 61, 72. Rank reduced to member status in Lurich formation (new).

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad, Map GQ–111. As described in Duffield quadrangle, includes about 15 feet of limestone that may be equivalent to Five Oaks limestone as used by Cooper (1945) in Scott County. This uppermost unit is a medium-light-gray lutite textured limestone with interbedded medium light-gray calcareous shale and dark-gray lutite-textured limestone.

Type section: Along State Highway 80, near Blackford, Russell County. Name derived from settlement along U.S. Route 19 near Lebanon.

Elwren Formation (in West Baden Group)

Elwren Sandstone (in Chester Group)[1]

Elwren Sandstone Member (of Paint Creek Formation)

Mississippian (Chester Series): Southwestern Indiana and northern and central Kentucky.

Original reference: C. A. Malott, 1919, Indiana Univ. Studies, v. 6, no. 40, p. 7–20.

R. E. Stouder, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 3, p. 268 (fig. 1), 269, 270 (fig. 2), 274 (fig. 3), 276. Paint Creek is used here to include group of formations above Sample sandstone and below Cypress sandstone between Ohio River and southern end of Hardin and Breckinridge Counties, Ky. The three formations of the Paint Creek are correlative of three formations of Indiana (ascending); Reelsville limestone, Elwren sandstone and shale, and Beech Creek limestone. Names Reelsville and Elwren are here proposed for the two lower members of Kentucky formation; term *Productus inflatus* zone is used for upper member. Elwren is 40 feet thick near Seree, Breckinridge County, and 3 feet thick at Girkin.

J. M. Weller and A. H. Sutton, 1940 Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 828; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 76). Considered member of Paint Creek formation in Indiana.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7, 14. Paint Creek of standard Chester column has triple expression in southern Indiana (ascending): Reelsville limestone, Elwren sandstone, and Beech Creek limestone. Each of these is a distinct stratigraphic unit in parity with other formations of Chester and deserves a name in its own right. Elwren sandstones present through outcrop of lower Chester beneath Beech Creek limestone; continues northward as far as Reelsville, Putnam County, but locally is cut out in part or in entirety and overlapped by the Pennsylvanian northward from Lawrence County. Locally, cuts below level of Reelsville limestone.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 25, pl. 1. Elwren sandstone in Indiana ranges from 20 to 50 feet in thickness. Lower part of formation is typically light-gray to light-brown commonly rust-spotted thick-bedded to massive locally crossbedded sandstone; drab-gray soft shale is commonly more abundant than sandstone in upper part of formation. In many localities, Elwren beds immediately below Beech Creek limestone are characteristically green-gray thin-bedded soft shale, which contains thin discontinuous beds of brick-red shale. Field identification of Elwren normally is based upon its stratigraphic position between distinctive Reelsville and Beech Creek limestone. Type locality indicated.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 45, pl. 1. Uppermost formation in West Baden group (redefined). Thickness 37 to 52 feet. Overlies Reelsville limestone; underlies Beech Creek limestone of Stephensport group (redefined).

Type locality: Vicinity of Elwren, Monroe County, Ind., where exposures occur in cuts along Illinois Central Railroad within 1 mile of boundary between Greene and Monroe Counties.

Ely Greenstone[1]

Precambrian (Keewatin): Northeastern Minnesota, and Ontario, Canada.

Original reference: C. R. Van Hise and J. M. Clements, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 401–409, map.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1025–1027. Formation is not uniform, and various areas are not necessarily of same age. Some rocks are effusive, others intrusive, and others fragmental; nearly all are altered and green because of abundant secondary chlorite; ellipsoids common and are safest criterion for recognition of the greenstone. Thickness cannot be estimated unless some underlying formation is clearly recognized. Considered base of earlier division of Precambrian; there is a possibility of a formation below Ely in Canada, but in Minnesota base has not been observed. At many places lower contact is with intrusive granites and gabbro. Soudan iron-formation lies near top and partly within greenstone. Overlain at places by Ogishke conglomerate; Animikie (Gunflint or Biwabik) iron-formation lies directly on Ely east of sec. 27, T. 65 N., R. 4 W. Intruded by Saganaga granite, Duluth gabbro, and Algoman granites.

G. M. Schwartz and I. L. Reid, 1955, Mining Eng., v. 7, no. 3, p. 298. Soudan beds should be considered member of Ely greenstone.

F. F. Grout, R. P. Sharp, and G. M. Schwartz, 1959, Minnesota Geol. Survey Bull. 39, p. 12–15. Occurs only in northwestern part of Cook County as narrow belt across T. 65 N., Rs. 4 and 5 W. This is south of Alpine and Sea Gull Lakes and along north side of Gunflint iron-bearing district. Width of belt ranges from thin lens at east end in sec. 22, T. 65 N., R. 4 W. to maximum of 1¼ miles in secs. 19 and 30. Greenstone is bounded on north throughout most of its length by Saganaga granite which intruded and metamorphosed the greenstone.

Typical exposures are under and adjacent to town of Ely, St. Louis County, Minn. Principal exposures follow Vermilion iron-bearing district from Tower to Gunflint Lake; largest, including type locality, extends 40 miles from Vermilion Lake to Moose Lake; another extends northeast into Hunter's Island, Canada.

Ely Limestone[1]

Ely Group

Upper Mississippian and Lower and Middle Pennsylvanian: Eastern Nevada and western Utah.

Original references: A. C. Lawson, 1906, California Univ. Pub. Bull., Dept. Geol., v. 4, no. 4, p. 295; A. C. Spencer, 1917, U.S. Geol. Survey Prof. Paper 96, p. 26, 27.

E. N. Pennebaker, 1932, Mining and Metallurgy, v. 13, no. 304, p. 164. Ely limestone, in Robinson mining district, is lowermost Pennsylvanian formation. It is practically free from sandy admixture and carries abundant chert as bands, lenses, and nodules. Estimated thickness 1,500 to 3,200 feet. Overlain by series of sandstone and sandy limestone herein designated Rib Hill formation. Most of Rib Hill was formerly included in Ely.

R. H. Dott, Jr., 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 11, p. 2219 (fig. 2), 2234–2248. Rank raised to group in Elko area. Includes Moleen formation below and Tomera formation above (both new). Overlies Tonka formation (new); underlies Strathearn formation (new). Thickness about 3,200 feet. Lower and Middle Pennsylvanian.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 61–63. Described in vicinity of Eureka where it is as much as 1,500 feet thick; overlies Diamond Peak formation and underlies Carbon Ridge formation (new). As exposed in this area, belongs to lower half of Pennsylvanian.

W. M. Winfrey, Jr., 1958, Am. Assoc. Petroleum Geologists, Rocky Mountain Sec., 8th Ann. Mtg., p. 77, 79 (fig. 2). In Egan Range, Nev., unconformably underlies Eocene Sheep Pass formation (new).

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2170–2174. Geographically extended into Confusion Range, Utah, where it replaces term Bird Spring formation. Consists of 1,850 to 2,000 feet of alternating resistant thick-bedded limestone and slabby slope-forming limestone. Upper 100 to 350 feet contain early Permian fauna and is commonly more massive and less cherty than remainder of formation, which contains fauna characteristic of lower half of Pennsylvanian and locally Late Mississippian. Overlies Chainman shale; underlies Arcturus limestone.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). In Gold Hill district and Confusion Range, Utah, and Moorman Ranch area, Nevada, overlies Illipah formation.

J. S. Berge, April 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 5, p. 9–18, pl. 4. Ely limestone, in Ferguson Mountain area, unconformably overlies Chainman shale and underlies Ferguson Mountain formation (new). Thickness 1,411.4 feet, of this, basal 111.8 feet is Morrowan age, followed by 262.2 feet of Derryan, 120.4 feet of Desmoinesian, 745.6 feet of upper Missourian, and 171.4 feet of Virgilian. In White River valley overlies Butte formation (new). Overlies Ferguson Springs formation (new) at Ferguson Springs.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists 11th Ann. Field Conf., p. 93 (chart 1), 99–100, 101. Pennebaker (1932) redefined Ely by placing upper contact at base of yellow and tan sand sequence, formerly assigned to Arcturus limestone, which he named Rib Hill formation; lower contact remained at top of Chainman. Ely is herein restricted to those limestones lying stratigraphically above Chainman shale or Scotty Wash quartzite, whichever is present, and below regional Pennsylvanian unconformity—that is, to those limestones described by Pennebaker as having abundant bedded and nodular chert. Because of nature of unconformity, overlying unit may be South Ridge sandstone (new), or that part of the Ely taken away from the unit as restricted in this paper. Upper 300 feet of massive coralline limestones without chert above the unconformity, and removed from Ely, is here named Riepe Spring limestone. Thickness of Ely (restricted) varies from 2,500 feet at type area to less than 500 feet at north end of Pequop Range. At reference section, herein designated, Ely overlies Scotty Wash quartzite (Illipah sandstone) and underlies Riepe Spring limestone. Disconformably underlies Ferguson Springs formation (new) at type locality of that unit. On basis of fusulinids dated as Pennsylvanian (Morrowan-middle Desmoinesian). Name Rib Hill abandoned.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 160, 163–164. Underlies Kinsey Canyon formation (new).

Type area: Ely district, Ely quadrangle. Reference section: Along U.S. Highway 50, between Illipah Creek and Moorman Ranch, secs. 7 and 8, T. 17 N., R. 59 E., White Pine County, Nev. This is 30 miles west of type area.

Ely Springs Dolomite[1]

Middle and Upper Ordovician: Eastern Nevada and southeastern California.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 14 (fig. 6), 13–15, pls. 1, 2, 3. Described in Quartz Spring area, northern Panamint Range, Calif., where it conformably underlies Hidden Springs dolomite (new) and overlies Eureka quartzite. Thickness 740 to 940 feet. Upper Ordovician.

H. R. Wanless, 1960, Jour. Paleontology, v. 34, no. 5, p. 862. In Independence quadrangle, California, overlies Middle Ordovician Johnson Spring formation (new) of Eureka group.

U.S. Geological Survey currently designates the age of the Ely Springs as Middle and Upper Ordovician on the basis of a study now in progress.

Named for exposures in Ely Springs Range, Pioche region, Nevada.

†Embar Formation[1] or Group[1]

Permian and Triassic(?): Western and central Wyoming.

Original reference: N. H. Darton, June 1906, Geology Owl Creek Mountains, Wyoming: 59th Cong. 1st Sess., S. Doc. 219, p. 17.

P. T. Walton, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 8, p. 1441–1442. Embar limestone, in subsurface in Oregon basin field, Park County, Wyo., underlies Dinwoody formation and overlies Tensleep sandstone. Name Embar was given by Darton (1906) to all beds between base of Chugwater and top of Tensleep sandstone, which interval is now recognized as consisting of both Triassic and Permian strata. Herein suggested that term Embar is too well established to consider abolishing it when it is applied in its present usage, that is, when used to denote only characteristic limestone section usually correlated with Phosphoria formation of Idaho. Permian.

W. G. Pierce, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 77. Formation mapped in Basin-Greybull area, Big Horn County, Wyo., where it overlies Pennsylvanian Tensleep and underlies Triassic Chugwater formation.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 32–34, pl. 1. Embar and Chugwater formations mapped separately only in southwestern part of area [Bighorn Canyon-Hardin area, Montana and Wyoming] where Embar consists of 100 feet of dolomite, limestone, red siltstone, and sandstone. Elsewhere, a zone of redbeds, gypsum, and thin beds of limestone is seemingly the Embar equivalent. Overlies Tensleep sandstone.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, 2833, 2835. Name Embar, introduced for beds between Tensleep and Chugwater, has been used for redbeds of Permian and Triassic age in central Wyoming (Lee, 1927, U.S. Geol. Survey Prof. Paper 149). Embar has also been used for Permian rocks only (Andrews and others, 1945, U.S. Geol. Survey Prelim. Map 25; Richards, 1955), and in that sense is synonym for the Phosphoria as used by others in same area. In new nomenclature herein proposed, Darton's Embar formation is considered obsolete.

Named for Embar post office, Big Horn County, on Owl Creek, a short distance south of which formation is extensively developed.

Embarrass Granite[1]

Precambrian (post-Keweenawan): Northeastern Minnesota.

Original reference: C. K. Leith, 1903, U.S. Geol. Survey Mon. 43, p. 186.

Forms core of extreme east end of Giants Range. Named for its lithologic similarity to granite exposed at Embarrass Station on Duluth & Iron Range Railroad just north of Mesabi Range, Mesabi district.

Embudo Granite

Precambrian: Central northern New Mexico.

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 37–46, pl. 1. Name introduced to replace Dixon granite of Just (1937); name Dixon preoccupied. Three main granite types distinguished: coarse-grained partly porphyritic biotite granite, light-colored partly porphyritic gneissic granite, and flesh-colored coarse-grained to pegmatitic leucogranite. Has invaded all rocks of Ortega and Vadito (new) formations, and thus is of more recent age.

Borders the Picuris Range on south and on east, Taos County. Name taken from town of Embudo, located 2 miles west of Dixon and 4 miles west of extensive outcrops of the granite.

Emerald Dolomite Member (of Ajax Dolomite)[1]

Upper Cambrian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 9. Massive bed of medium-grained creamy- or grayish-white dolomite marked or mottled by irregular zones of coarse-grained gray to white dolomite. Thickness about 30 feet. Overlies lower member 90 to 180 feet thick, and underlies upper member that averages about 450 feet in thickness. Ajax has yielded fossils of Late Cambrian age.

Named for Emerald mine, Tintic district. Continuously exposed from Mammoth to Eureka.

†Emerald Limestone[1]

Middle or Upper Cambrian: Southeastern Arizona.

Original reference: J. A. Church, 1903, Am. Inst. Mining Engrs. Trans., v. 33, p. 3–37.

Tombstone district.

†Emerald Series[1]

Middle or Upper Cambrian: Southeastern Arizona.

Original reference: W. P. Blake, 1902, Tombstone and its mines.

Ajax Mountain, Tombstone district.

Emerson Formation

Middle and Upper Cambrian and Lower Ordovician(?): Central Montana.

M. M. Knechtel, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1994–1995. Name applied to sequence of shale, thin beds of limestone, and intraformational conglomerate overlying Flathead sandstone and underlying Bighorn dolomite. Thickness at type locality estimated not less than 950 feet and not more than 1,100 feet. Approximately lower half is Middle Cambrian in age. Upper part includes 538 feet of strata of Late Cambrian and probably Early Ordovician age.

Type locality: At and near mouth of Emerson Gulch, on Lodgepole Creek, in SW¼ sec. 20, T. 36 N., R. 25 E., Phillips County, and about 4½ miles south-southwest of Lodgepole Subagency of Fort Belknap Indian Reservation.

Emery Sandstone Member (of Mancos Shale)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, p. 439.

J. G. Bartram, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7, p. 908. Suggests that name Emery be abandoned and unit included in proposed Eagle group.

C. B. Hunt and R. L. Miller, 1946, Utah Geol. Soc. Guidebook 1, p. 8 (table). Generalized section of sedimentary rocks exposed in Henry Mountains shows Emery sandstone member above Blue Gate shale member and below Masuk shale member. Thickness 200 feet.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Paper 228, p. 36 (table), 84–85, pls. In southern part of Castle Valley (type area), the Emery is about 800 feet thick, at north end of valley thins to 100 feet and grades eastward into marine shale. In Henry Mountains structural basin, Emery is about 250 feet thick. Here it underlies Masuk member and overlies Blue Gate shale member. Between type locality and Henry Mountains region, the sandstone has been removed by erosion and cannot be traced into this region, but name as used in this report is applied to beds in same stratigraphic position, which are lithologically like type Emery and which overlie shale beds containing marine fauna equivalent to fauna in beds beneath type Emery. Name Bluegate sandstone was used by Gilbert (1877). Probably never extended very far east of Henry Mountains.

Named for exposures southwest of Emery, Emery County.

Emery Peak Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. H. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 115–118, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt area are named and mapped. Stratigraphic position of six of these basalts has been determined. Emery Peak is oldest in known sequence; followed by Big Hill basalt.

Emery Peak is in northwestern Union County.

Emigrant Formation[1]

Middle and Upper Cambrian: Southwestern Nevada.

Original reference: H. W. Turner, 1902, Am. Geologist, v. 29, p. 261–272.

U.S. Geological Survey currently designates the age of the Emigrant Formation as Middle and Late Cambrian on the basis of a study now in progress.

Well developed to south of Emigrant Pass, in northern part of Silver Peak Range, Esmeralda County.

Emigration Formation[1]

Middle Triassic: Central northern Utah.

Original reference: A. A. L. Mathews, 1931, Oberlin Coll. Lab. Bull., new ser., no. 1.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 28. Mathews separated the Thaynes, on the basis of fossil evidence, into two units to which he applied names Pinecrest and Emigration formations. He assigned the Emigration to Middle Triassic.

Bernhard Kummel, Jr., 1943, Am. Jour. Sci., v. 241, no. 5, p. 325. Fauna from Emigration formation has never been described or illustrated, therefore Mathews' age determination cannot be checked from the literature.

Named for Emigration Creek east of Salt Lake City.

Emily Member (of Crow Wing Formation)[1]

Precambrian: Central Minnesota.

Original reference: C. Zapffe, 1930, Lake Superior Min. Inst. Proc., v. 28, p. 101–106.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3). Table shows sequence (ascending) Ogishke, Agawa, Emily, and (Carlton). Units are marked with asterisk(*) which, according to footnote, means uncertain as to place.

Named for occurrence at village of Emily, Crow Wing County.

Eminence Dolomite[1]

Upper Cambrian: Southeastern Missouri.

Original reference: E. R. Buckley, 1908, Am. Min. Cong. Rept. Proc. 10th Ann. Sess., p. 286.

Josiah Bridge, 1930, Missouri Geol. Survey and Water Resources, 2d ser., v. 24, p. 75–97, table 2, geol. map. Described in Eminence and Cardareva quadrangles. Maximum thickness 250 feet; average about 200. Overlies Potosi dolomite or overlaps Potosi and rests on Precambrian; unconformably underlies Gunter sandstone member of Van Buren formation. Fauna described.

O. R. Grawe, 1945, Missouri Geol. Survey and Water Resources, 2d ser., v. 30, p. 53–55. Overlies Potosi, dolomite; underlies Gasconade formation. In this report, Gasconade is used in its earlier unrestricted sense to include all strata between the Eminence and the Roubidoux.

R. D. Knight, 1954, Missouri Geol. Survey and Water Resources Rept. Inv. 17, p. 57. Reprinted from Kansas Geol. Soc. Guidebook 17th Ann Field Conf., 1954. Underlies Gunter member of Gasconade formation.

Named for exposures at Eminence, Shannon County.

†Emma Creek Formation

Pliocene, middle and upper: Central Kansas.

S. W. Lohman and J. C. Frye, 1939, (abs.) Econ. Geology, v. 34, no. 8, p. 943. Sands, gravel, clays, and silts of middle and upper Pliocene age. Underlies McPherson formation (redefined). Deposits formerly referred to the McPherson formation.

S. W. Lohman and J. C. Frye, 1940, Econ. Geology, v. 35, no. 7, p. 849–851. Brown, buff, and gray channel sand and gravel, and floodplain sandy silt and clay. Thickness 10 to 180 feet. Interfingers with Ogallala formation to southwest. Derivation of name stated.

C. C. Williams and S. W. Lohman, 1949, Kansas Geol. Survey Bull. 79, p. 56. Name abandoned. Beds at type locality are Pleistocene. Some beds assigned to Emma Creek have proved to be of Pliocene age and are here designated Delmore formation.

Named from exposures along Emma Creek, southeastern McPherson County.

Emmett Formation[1]

Pleistocene: Southwestern Idaho.

Original reference: V. R. D. Kirkham, 1928, Idaho Bur. Mines and Geol. Pamph. 29, p. 1.

Probably named for town of Emmett, Gem County.

Emmitsburg facies[1]

Upper Triassic: Western Maryland.

Original reference: G. E. Dorsey, 1919, Geol. Soc. America Bull., v. 30, p. 155–156.

Probably named for occurrence at or near Emmitsburg or Emmitsburg Junction, Frederick County.

Emmons Peak Quartzite[1]

Precambrian: Northeastern Utah and northwestern Colorado.

Original reference: H. E. Wood 2d, 1934, Am. Mus. Nat. History Bull., v. 67, p. 244.

Probably named from Emmons Peak, Uinta Mountains, Utah.

†Emory Sandstone[1]

Pennsylvanian: Southeastern Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 153.

Forms top stratum of Tracy City Measures in water gaps of Big Emory River at Harriman, Roane County.

Emperador Limestone[1] Member (of La Boca Formation)

Emperador Limestone Member (of Culebra Formation)

Miocene, lower: Panamá.

Original reference: D. F. MacDonald, 1913, (abs.) Geol. Soc. America Bull., v. 24, p. 709.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 237, 238, 246 (fig. 2). Member of Culebra formation. Massive cream-colored limestone. Limestone is rare along the Panamá Canal and is so conspicuous in the predominantly tuffaceous rocks that such beds in different regions were formerly correlated with the Emperador. As a result of these correlations, limestones in Caimito and La Boca formations, and even in Gatuncillo formation in Madden basin, were designated Emperador limestone. Even when limestones in other formations are eliminated there remains residue of limestones in the Culebra, the relative stratigraphic position of which is uncertain. Early Miocene. Formerly exposed in shallow quarries at Empire. Unit was termed Empire limestone by Hill (1898).

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 34, 36–37, 39, 51. Limestone agreeing with descriptions of the Emperador is still exposed along canal. These beds of relatively pure coralliferous limestone probably are at different horizons in upper part of Culebra formation and probably grade southeastward into calcareous sandstone. Should it be demonstrated that the name is being used for limestone at different horizons, the name should be abandoned, except for limestone at type locality.

U.S. Geological Survey currently classifies the Emperador Limestone as a member of La Boca Formation on the basis of a study now in progress.

Type region: Quarries at Empire, now unrecognizable.

Empire Formation[1]

Pliocene(?): Southwestern Oregon.

Original reference: J. S. Diller, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 475.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 195–197. Consists of approximately 1,050 feet of brownish-gray massive concretionary medium- to coarse-grained moderately indurated sandstones which are involved in a northerly plunging synclinal fold situated on south side of Coos Bay. Sandstones rest with marked angular unconformity on Tunnel Point sandstones. Cannot be distinguished on faunal basis from Coos conglomerate. Pliocene.

W. P. Woodring, Ralph Stewart, and R. W. Richards, 1940, U.S. Geol. Survey Prof. Paper 195, p. 109–110. Empire fauna is more probably Pliocene than Miocene.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 590, chart 11. Coos conglomerate is lens in Empire.

J. W. Durham, 1953, (abs.) Geol. Soc. America Bull., v. 64, no. 12, pt. 2, p. 1504–1505. Examination of section of marine fossiliferous strata along south side of Cape Blanco, referred to Empire formation (Pliocene) by Diller (1903) and other workers, revealed unconformity dividing formation into two parts. The unconformity, marked by moderately coarse conglomerate, is exposed in sea cliff about one-half mile south of the Cape and a short distance stratigraphically above 25-foot tuff member noted by Diller. *Securella* [*Chione*] *securis-Anadara trilineata* fauna is restricted to beds above the conglomerate. Name Empire should be applied only to these upper beds.

Well exposed on beach 3 miles southwest of Empire City, between Pigeon Point and Fossil Point.

Empire Formation (in Missoula Group)

Empire Member (of Spokane Formation)

Empire Shale[1] or Formation (in Piegan Group)

Precambrian (Belt Series) : West-central Montana.

Original reference: C. D. Walcott, 1899, Geol. Soc. America Bull., v. 10, p. 199–215.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1898. Member of Spokane formation which is included in Meagher facies (new) of Belt series. Member consists of argillites, thickly bedded, siliceous, greenish-gray, with some sandstones and limestones. Thickness about 600 feet. Overlies Prickly Pear member (new).

Adolph Knopf, 1950, Am. Mineralogist, v. 35, nos. 9–10, p. 835–837. Marysville stock is surrounded by Precambrian rocks of Belt series (ascending) : Empire formation, Helena limestone (renamed dolomite), Marsh formation, and Greenhorn Mountain quartzite (new). Area contains type section of Empire "shale." Empire formation, or "shale" as Walcott (1899) called it, was named for exposure west of Empire mine, at head of Lost Horse Gulch in western part of Marysville district. Lowermost beds exposed here are intruded by granodiorite of Marysville stock. All rocks in type section are hornfelsed, dark weathering, and are crackle breccias ramified with tremolite veinlets and quartz veins. They are well within contact-metamorphic aureole of Marysville stock and are overlain conformably by white diopsidic hornfels of Helena dolomite. Walcott mentioned occurrence of Empire shale on Drumlummon Hill, in eastern part of district, but rock there is a superb scapolite-diopside hornfels. Barrell (1907, U.S. Geol. Survey Prof. Paper 57) in his account of Marysville district, ignored type section of Empire and described formation as exposed on Long Creek in north-central part of Marysville area, outside of contact aureole, where it consists of finely laminated, soft limy shale, grayish-green or buff-colored with a few reddish bands. As observed in present study, the Empire there consists of pale-green hard argillite alternating with mud-cracked rose or lavender argillites. Top of Empire is light colored and weathers pale buff and yellowish. Section at this locality is bottomed by fault; Barrell measured 520 feet of Empire and accepted Walcott's figure of 600 feet at total thickness. However, base of Walcott's section is an intrusive contact. In present work formation was found to be best exposed in section that extends east-west through U.S.G.S. bench mark 4450 in Scratchgravel Hills, northwest of Helena where it consists of pale-green argillite, deep-red argillites, and fine-grained light-green and white quartzite. Thickness about 1,000 feet. Conformable contacts with Spokane shale below, where first appearance of quartzite in section is taken to mark base of Empire. Transition to overlying Helena is abrupt, taking place within stratigraphic thickness of 20 feet.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Provisionally included in Piegan group.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 6, pls. 1, 2. Empire shale intertongues with and grades downward into Spokane shale and underlies Flathead quartzite in southern Elkhorn Mountains, Jefferson and Broadwater Counties. Thickness about 600 feet.

U.S. Geological Survey currently classifies the Empire as a formation in the Missoula Group on the basis of a study now in progress.

Type localities: On ridge north of Empire, between Lost Horse Gulch, and in canyon walls just below Marysville, Lewis and Clark County.

Empire Limestone[1]

Miocene: Panamá.

Original reference: R. T. Hill, 1898, Mus. Comp. Zool. Harvard College Bull., v. 28, no. 5, p. 195–196.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 335. Limestone in Gaillard Cut area now referred to lower Miocene. MacDonald (1913, Isthmian Canal Comm., Ann. Rept., app. S. p. 564–582) renamed unit Emperador limestone. Credits name to R. T. Hill.

Named for Empire, now abandoned, a village on original line of Panama Railroad near Culebra and about one-half mile west of Gaillard Cut.

Empire Gulch Rhyolite[1]

Tertiary: Colorado.

Original reference: W. Cross, 1886, U.S. Geol. Survey Mon. 12, p. 351.

Named for occurrence on south side of Empire Gulch, south of Leadville, Lake County.

†Emporia Blue Limestone[1]

Pennsylvanian: Northeastern Kansas.

Original reference: A. J. Smith, 1903, Kansas Acad. Sci. Trans., v. 18, p. 100.

Named for Emporia, Lyon County.

Emporia Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: M. Z. Kirk, 1896, Kansas Univ. Geol. Survey, v. 1, p. 72–85.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276. As originally defined and now again recognized, the Emporia comprises beds between Willard shale above and Auburn shale below. Thickness ranges from 7 to 40 feet. Includes (ascending) Reading limestone, Harveyville shale, and Elmont limestone members. Kirk did not define type section or locality; reference section given.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 55–60. Emporia limestone of Kansas comprises (ascending) Reading limestone, Harveyville shale, and Elmont limestone members. Moore (1949, Kansas Geol. Survey Bull. 83) correlated the Reading, Harveyville, and Elmont of Kansas with lower, middle, and upper units of Stonebreaker formation in Osage County, Okla. Name Stonebreaker has been discarded as formation name in north-central Oklahoma in favor of name Emporia. Kansas subdivisions of Emporia are recognizable in Pawnee County; southern extent is not known. Average thickness 90 feet in Pawnee County. Overlies Auburn shale; underlies Gano shale.

Reference section exposed in roadcut on Kansas Highway 10 in NW¼ sec. 31, T. 11 S., R. 14 E., Shawnee County, Kans.

†Emporia (reservoir) Shales[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905. The Carboniferous rock system of eastern Kansas.

Probably named for Emporia, Lyon County.

Endeavor Granite[1]

Precambrian: Wisconsin.

Original reference: C. C. Wang, 1932, Geol. Soc. China Bull., v. 11, no. 4, p. 426–428.

Endee shale[1]

Triassic(?): Northeastern New Mexico.

Original reference: C. R. Keyes, 1905, Am. Jour. Sci., 4th, v. 20, p. 424.

Derivation of name not stated.

Endicott Diorite[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1899–1901, pl. 1. Holocrystalline dark-colored fine- to coarse-textured pegmatitic diorite. Shown on map as diorite breccia. Brecciated and intruded by Conway granite and Cobble Hill phase of Belknap syenite. Older than Conway granite and Belknap syenite at Cobble Hill; younger than Gilford gabbro. Assigned to White Mountain magma series.

Typical exposures on Endicott Hill in Belknap Mountains.

Enebro Sandstone Lens (in Johnson Peak Formation)

See Johnson Peak Formation.

Enfield facies subgroup[1]

Upper Devonian: Southern central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 201.

Ithaca region.

Enfield Formation

†Enfield Shale Member (of Portage Formation)[1]

Upper Devonian: South-central New York.

Original reference: H. S. Williams, 1906, Science, new ser., v. 24, p. 365–372.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1758, chart 4. As represented on correlation chart, Enfield formation lies between the Ithaca below and the Chemung above and, according to Chadwick (1935, Am. Midland Nat., v. 16), is eastern representative of Rhinestreet-Hatch sequence. This correlation differs from that published by Caster (1933, Geol. Soc. America Bull., v. 44, pt. 1), which showed that Enfield of Ithaca region consisted of Van Etten and Hatch.

R. E. Stevenson, 1948, New York State Sci. Rept. Inv. 1, p. 2 (chart). Shown on chart as upper member of Naples formation. Overlies Ithaca formation.

J. W. Wells, 1952, Jour. Paleontology, v. 26, no. 1, p. 120–122. Referred to as formation. Starfish *Ptilonaster* collected from middle of formation about 400 feet below base of Chemung and about same distance above top of Ithaca formation.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2826. In area south of Cayuga Lake, the Sonyea formation occupies upper four-fifths of rock sequence that was designated Enfield shale member of Portage formation by Williams and others (1909, U.S. Geol. Survey Geol. Atlas, Folio 169).

Typically exposed at town of Enfield, west of Ithaca, Tompkins County.

Engadine Dolomite[1]

Middle Silurian (Niagara Series) : Northern Michigan.

Original reference: R. A. Smith, 1916, Michigan Geol. Survey Pub. 21, p. 151.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv., Geol. Survey Div. Pub. 44, Geol. Ser. 37,, p. 35, 36. In Straits of Mackinac region, underlies Pointe aux Chenes formation (new).

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Field Excursion, p. 2 (table), 23, 29. Youngest unit of Middle Silurian in Northern Peninsula. Thickness 200 to 250 feet. Overlies Cordell dolomite with contact sharply defined in some area; underlies Pointe aux Chenes shale with contact not exposed.

Named for exposures at and around Engadine, Mackinac County.

Engle coal group (in Vermejo Formation)[1]

Upper Cretaceous: Eastern Colorado.

Original reference: R. C. Hill, 1899, U.S. Geol. Survey Geol. Atlas, Folio 58.

Elmoro region.

Englevale Channel Sandstone[1]

Englevale Sandstone Member (of Labette Shale)

Pennsylvanian (Des Moines Series) : Southeastern Kansas and western Missouri.

Original reference: W. G. Pierce and W. H. Courtier, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 7, p. 1061–1064.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 197. Englevale sandstone member of Labette shale is one of several bodies of sandstone, collectively referred to as Warrensburg sandstone. Lies in middle and lower part of Labette shale.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 6. Geographically extended into southwestern Missouri, Bates County and probably elsewhere.

Well exposed in vicinity of Englevale, Crawford County, Kans., along north-south road on east side of town and along east-west road one-half mile north of town.

Englewood Formation

Englewood Limestone[1]

Devonian and Mississippian: Western South Dakota and northeastern Wyoming.

Original reference: N. H. Darton, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 4, p. 509.

E. P. Rothrock, 1955, North Dakota Geol. Soc. Guidebook Black Hills Field Conf., p. 76–77. Mississippian system is represented in South Dakota by formations of Madison group, called Englewood and Pahasapa, where they outcrop and Bakken, Lodgepole, Mission Canyon, and Charles where encountered in wells.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Mapped in northeastern Wyoming.

U.S. Geological Survey currently classifies the Englewood as a formation and designates the age as Devonian and Mississippian on the basis of a study now in progress.

Name derived from Englewood, Lawrence County, S. Dak.

English River Formation (in Hannibal Group)

English River Sandstone Member (of Hannibal Shale)[1]

English River Siltstone Member (of Hannibal Formation)

Lower Mississippian (Kinderhook): Western Illinois and southeastern Iowa.

Original reference: H. F. Bain, 1895, Am. Geologist, v. 15, p. 322.

L. A. Thomas, 1949, Geol. Soc. America Bull., v. 60, no. 3, p. 408–409. Referred to as siltstone member. In southeastern Iowa, overlies Maple Mill shale with apparent conformity; at Burlington, underlies McCraney (McKerney) limestone with boundary indicated by leached yellow part at top of English River; in western Louisa County, underlies Wassonville limestone, which overlies Maple Mill near Kalona, northern Washington County. Conodont assemblage indicates Lower Mississippian.

M. A. Stainbrook, 1950, Am. Jour. Sci., v. 248, no. 3, p. 209, 212. English River siltstone is not member of Hannibal formation. Kinderhook succession in upper Mississippi valley seems to be (ascending) Maple Mill shale, English River siltstone, Louisiana limestone, Hannibal shale and siltstone, and Chouteau limestone.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 27–28. Top formation in Hannibal group in Illinois. Conformably overlies Maple Mill shale; conformably underlies and is gradational into McCraney (McKerney) limestone. Present in western Illinois in north-south belt about 25 miles wide extending from Henderson to Pike Counties. Thickness 30 to 43 feet along middle of belt; less than 10 feet along western border of state; wedges out eastward.

Named for exposures along English River, Washington County, Iowa.

Englishtown Formation (in Matawan Group)

Englishtown Member (of Matawan Formation)

Englishtown Sand (in Matawan Group)[1]

Upper Cretaceous: New Jersey and Delaware.

Original reference: H. B. Kummel, 1907, New Jersey Geol. Survey Paleontology, v. 4, p. 17, footnote.

C. W. Carter, 1937, Maryland Geol. Survey, v. 13, pt. 6, p. 243 (fig. 22), 256–258. Geographically extended into Delaware where it is present along Chesapeake and Delaware Canal. Underlies Marshalltown formation; overlies Crosswicks clay.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 8, (fig. 4), 24, 28–30. Member of the Matawan which is here reduced to formational rank. Conformably overlies Woodbury member; conformably underlies Marshalltown member. It is believed that Carter's interpretation of stratigraphy in Chesapeake and Delaware Canal is in error and that beds referred to Englishtown by him are Wenonah.

M. E. Johnson and H. G. Richards, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2150–2160. Here considered of formational rank. Report is a discussion of paper by Spangler and Peterson (1950).

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184, B185. Formation in Matawan group. Overlies Woodbury clay; underlies Marshalltown formation. Average dip SE 38 feet per mile. Thickness 20 to 140 feet; thickens northeast in outcrop.

Named for development in vicinity of Englishtown, Monmouth County, N.J.

†Enid Formation[1]

Permian: Western Oklahoma, western Kansas, and western Texas.

Original reference: C. N. Gould, 1905, U.S. Geol. Survey Water-Supply Paper 148, p. 39–44, map.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 99. Listed with names abandoned by Oklahoma Geological Survey.

Named for Enid, Garfield County, Okla.

†Enochkin Formation[1]

Middle and Upper Jurassic: Southwestern Alaska.

Original reference: T. W. Stanton and G. C. Martin, 1905, Geol. Soc. America Bull., v. 16, p. 397.

Typically exposed on eastern shore of Enochkin [Iniskin] Bay.

Ensenada Shale[1] or Formation

Upper Cretaceous: Puerto Rico.

Original reference: G. J. Mitchell, 1922, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 3, p. 252.

J. D. Weaver, 1956, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 325. Limy shale about 650 feet thick. Contains fragments of *Radiolites* and foraminifera. Stratigraphical relations not known. Upper Cretaceous.

T. R. Slodowski, 1958, Dissert, Abs., v. 18, no. 1, p. 200–201. In Yauco area, the younger complex, more than 9,000 meters thick, has been divided into eight formations: Sabana Grande, El Rayo, Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara. Ensenada is considered to have been deposited in a southern basin penecontemporaneously with deposition of Río Yauco and Río Blanco formations in a northern basin. Ensenada and Río Yauco formations overlie Sebana Grande and El Rayo formations unconformably and are separated from overlying San Germán and Jicara formations, at least locally, by unconformities.

Named for exposures at Ensenada, on Guanica Bay.

Ensign Lake Green Slates, Tuffs, and Graywackes

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1605–1606. Name applied to green slates and tuffs that form a large part of Ensign Lake Basin and extend eastward to [Duluth] gabbro. Beds commonly only a fraction of an inch thick; bands are light and dark green and gray with some pink. Locally formation is injected by granite and pegmatite dikes. Quartz veins from paper thin to 10 feet in width permeate rock in places. Isoclinally folded. Thickness may be 4,000 feet or more. In this report, Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Ensign Lake green slates as unit 10 occurring above Amoeba Lake graywackes and below Kekekabic Lake tuffs, agglomerates, slates, and andesite porphyry.

Report covers a belt in eastern part of Vermilion district more or less parallel to international boundry.

Ensign-Snowbank Lake Agglomerate

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1593. Dark greenish gray on fresh surface and light gray on weathered surface; not uniform in texture and structure; appears homogeneous on fresh surface; when weathered may appear massive, fragmental, or banded; contains a number of "blow-outs" and dikes of feldspar porphyry; bedding indistinct; gradational bedding rare. Thickness variable; probably 4,000 feet maximum. In practically all occurrences, overlies slates and graywackes. In this report, Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Ensign-Snowbank Lake agglomerate as unit 12 occurring above Kekebabic Lake tuffs, agglomerates, slates, and andesite porphyry and below unnamed feldspar porphyry intrusions.

Occurs in vicinity of Snowbank and Ensign Lakes, Lake County.

†Enterprise Green Marl (in Claiborne Group)[1]

Eocene, middle: Southeastern Mississippi.

Original reference: O. Meyer, 1885, Am. Jour. Sci., 3d, v. 30, p. 435.

Wythe Cook, 1925, U.S. Geol. Survey Prof. Paper 141–E, p. 135. Because name Enterprise is preoccupied, Winona sand is here redefined to include typical "Winona sand" of Montgomery County and typical "Enterprise marl" of Clarke County, but to exclude sands at base of Tallahatta formation in Lauderdale County.

Named for exposures at town of Enterprise, Clarke County.

†Enterprise Sandstone (in Boggy Shale)[1]

Pennsylvanian: Central eastern Oklahoma.

Original reference: S. W. Lowman, 1932, Summaries and abstracts of technical papers presented before Tulsa Geological Society 1932, unpaged.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 107. Abandoned by Oklahoma Geological Survey. Name of the Haskell County village was given to unit now known as Bluejacket sandstone. Name preoccupied.

†Enterprise Shale (in Sumner Group)[1]

Permian: Central Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: J. W. Beede, 1909, Kansas Acad. Sci. Trans., v. 21, pt. 2, p. 253.

Name not used on Geologic map of Oklahoma (1954). The Enterprise or its equivalents transferred to Chase Group.

Named for Enterprise, Dickinson County, Kans.

Entrada Sandstone (in San Rafael Group)[1]

Upper Jurassic: Southern, southeastern, and northeastern Utah, northeastern Arizona, western, central, and southeastern Colorado, and northwestern New Mexico.

Original reference: J. Gilluly and J. B. Reeside, Jr., 1926, U.S. Geol. Survey Press Bull. 6064, March 30.

A. A. Baker and others, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, no. 8, p. 787, 799, 804, 805. In Moab region, Utah, includes Moab tongue (new).

James Gilluly and J. B. Reeside, Jr., 1928, U.S. Geol. Survey Prof. Paper 150–D, p. 76–78. A thick series of earthy sandstones and subordinate shales. Thickness 312 feet at type locality; 844 feet at Muddy River on west flank of San Rafael Swell; 405 feet at Black Dragon Canyon; 498 feet at mouth of San Rafael River. Overlies Carmel formation; underlies Curtis formation. Extends into Colorado.

A. A. Baker, 1933, U.S. Geol. Survey Bull. 841, p. 49–50, pls. In Moab region, the Entrada consists of massive crossbedded medium-grained sandstone. Moab tongue is white; remainder of formation is banded orange and white with rows of solution cavities parallel to normal bedding. Thickness 360 to 405 feet. Underlies Summerville formation; overlies Carmel formation.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U.S. Geol. Survey Prof. Paper 183, p. 7–8, pls. Summary of results of recent fieldwork in eastern Utah and adjacent parts of Arizona, New Mexico, and Colorado and revision of interpretations and correlations of Jurassic formations of area. The Entrada extends eastward from type area into, and in the north, across Rocky Mountain province in Colorado and a relatively short distance southward into New Mexico and Arizona. A sandy zone above the Carmel in southwestern Utah has position and lithology of the Entrada and is here correlated with it. The Entrada in San Rafael Swell is deep-red fine-grained earthy sandstone that weathers into small bosses, "stone babies," and other rounded forms and at many localities is not much more resistant than shale. This facies occurs also in southwestern Utah. Eastward from San Rafael Swell, this earthy facies passes into less earthy irregularly bedded sandstone. This, in turn, passes eastward into sandstone composed of clean fine- to medium-sized lime-cemented quartz grains, red, orange-red, or gray, banded at many places with zones of color in sharp distinction to uniform coloring of the Navajo and Wingate. Moab sandstone tongue present at top of Entrada in vicinity of Moab, Utah. Maximum thickness about 1,000 feet near Circle Cliffs, Utah; thins southward. Rests on Carmel formation as far east as Bush Canyon in Colorado. Farther east rests successively upon Navajo sandstone, Kayenta formation, and Wingate sandstone and upon Dolores formation where Wingate sandstone is not recognized. Lower boundary arbitrary where Carmel formation is present; elsewhere it is sharp. Contact with overlying Curtis formation in San Rafael Swell is erosional unconformity, but elsewhere upper boundary is only moderately sharp and probably not an unconformity. Lower member of La Plata sandstone of Cross (1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3) at many localities in southwestern Colorado is Entrada, and so also is entire La Plata of north-central Colorado. San Rafael group. Upper Jurassic.

R. L. Heaton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 8, p. 1153–1177. Results of this study show that basal sandstone of the "Jurassic" of northern Colorado is probably partly Entrada and partly Upper Triassic, that the latter grades into redbeds southward and the former continues into New Mexico where it is identical with the so-called Wingate; and that it does not extend westward to the Arizona line but can be correlated with lower La Plata of San Juan Mountains in Colorado. Further, the so-called Nugget of northwestern Colorado is Nugget and Entrada separated by thin remnant of Carmel formation.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, p. 1277–1278. In Uinta Mountains, Preuss red beds grade into crossbedded Entrada sandstone.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1664–1668. Report is revised correlation of Jurassic formations of parts of Utah, Arizona, New Mexico, and Colorado. Entrada sandstone, with more or less typical lithologic character and in normal sequence with underlying Carmel formation, and Navajo, Kayenta, and Wingate formations of Glen Canyon group are recognized at Navajo Mountain, Utah, Kayenta and Rough Rock, Ariz., Boundary Butte, Utah, and Beclabito dome, New Mexico. Overlying Todilto limestone is not recognized at Navajo Mountain, is absent at Boundary Butte, but crops out at Kayenta, Red Rock, Ariz., and Beclabito dome. Southward from Red Rock, the Todilto is present at Toadlena and at its type locality at Todilto Park. Underlying Entrada thickens southward from Red Rock to Toadlena and to Todilto Park, where it is the thick cliff-forming sandstone which all previous workers, including authors of present report, have correlated with Wingate sandstone of Fort Wingate region. This cliff-forming sandstone which crops out along Arizona-New Mexico State line at Todilto Park, Window Rock, Hunters Point, and Lupton and in cliffs north of Fort Wingate, N. Mex., is thus equivalent to sandstone called Entrada over most of Utah and Colorado. Evidence shows that the sandstone extends north ward to Chama Basin and is same sandstone that crops out at Mesa Alta, Navajo Canyon, El Rito, and Rio Canones in Chama Basin. These new conclusions as to correlation pose problem of stratigraphic nomenclature. Strict application of principles of priority would require that name Wingate sandstone now be applied to unit heretofore called Entrada and would require a new name to be applied to Wingate sandstone of Utah and adjacent regions. However, it is believed that abandonment of this nomenclature through application of principles of priority would be confusing. Hence, name Entrada is extended to include sandstone at type locality of the Wingate, and name Wingate is retained for the sandstone forming lower part of Glen Canyon group, with the understanding that original type locality of the Wingate has been abandoned.

W. L. Stokes and D. A. Phoenix, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 93. Entrada sandstone mapped in Egnar-Gypsum Valley area, San Miguel and Montrose Counties, Colo.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51 (table), 94–96, pls., strat. sections. In Zion Park region, light-red white-banded fine even-grained thin-bedded gypsiferous friable sandstone 70 to 220 feet thick. At type section, consists chiefly of thick-bedded red sandstones, among them several massive crossbedded sandstones 13 to 30 feet thick; no gypsum beds included; thickness 312 to 844 feet. Overlies Carmel formation; unconformably underlies Curtis formation.

W. B. Hoover, 1950, New Mexico Geol. Soc. Guidebook 1st Field Conf., p. 77–80. Entrada and its members may be considered as representing the whole of San Rafael group where the Carmel is absent. Entrada, at type locality, is overlain by Curtis and Summerville. The Curtis apparently grades into Summerville, and the Summerville, in part, grades into Moab tongue of Entrada. Farther south, the Entrada divides again into a lower bed, the Entrada proper, and Bluff sandstone member. Term Red Mesa is here introduced for sandstone beds, 100 feet thick, between Entrada proper and Bluff member. Crinkly beds of the Red Mesa are similar in appearance to the Carmel at Moab which led Stokes (1944) to conclude that the Bluff and Entrada were one and same bed.

H. E. Wright, Jr., and R. M. Becker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 3, p. 610 (fig. 2). Discussion of correlation of Jurassic formations along Defiance monocline, Arizona-New Mexico. Cross section shows Entrada overlying Carmel formation and underlying Summerville formation and Todilto limestone.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 38 (table), 70–72, pls., strat. sections. Described in Henry Mountains region where it overlies Carmel formation and unconformably underlies Curtis formation. Thick-bedded and crossbedded sandstone; thinner bedded earthy sandstone to north. Thickness 300 to 700 feet.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 88–92, pls. 1, 2. Extended into Baca County, southeastern Colorado. Disconformably overlies Dockum group; underlies Morrison. These beds have been referred to as Exeter sandstone. Thickness 0 to 380 feet.

F. W. Cater, Jr., 1955, U.S. Geol. Survey Geol. Quad. Map GQ–64. Mapped in Horse Range Mesa quadrangle, Colorado.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 35–38, strat. sections. In most of Navajo country comprises three members which represent two distinct depositional facies. Lower sandy member is a sandy crossbedded facies, in part eolian, present only in northwestern part of area;

medial silty member approximates lithology of type section and is present in central and eastern parts of area; upper sandy member, a cross-bedded facies, is present in eastern part of area. A thin (50-foot) eastward extension of medial silty member and a thick (253-foot) sequence of upper sandy member constitute upper half of original type section of Wingate sandstone. In southwestern area, it is difficult to differentiate from underlying Carmel formation. In some areas, underlies Cow Springs sandstone, in others Summerville formation or Todilto limestone. Thickness as much as 303 feet.

R. B. Johnson, 1959, U.S. Geol. Survey Bull. 1071–D, p. 94–95, pls. 4, 5, 6. Described in Huerfano and Custer Counties, Colo., where it is 70 to 100 feet thick; disconformably overlies Sangre de Cristo formation and disconformably underlies Morrison. In this area and adjacent parts of New Mexico, replaces names Exeter and Ocate sandstones.

E. B. Ekren and F. N. Houser, 1959, U.S. Geol. Survey Mineral Inv. Map MF–221. Mapped in Moqui SE quadrangle where it consists of two units: upper sandstone 70 to 80 feet thick, pale brown and light pink at top grading to white and finally to orange in lower part; and lower argillaceous fine-grained brick-red sandstone 25 to 35 feet thick. Underlies Summerville formation; overlies Navajo formation.

R. B. Johnson and E. H. Baltz, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1895, 1897, 1898 (fig. 2). In Sangre de Cristo Mountains, Colo., unconformably overlies Johnson Gap formation (new), Lykins(?), or Sangre de Cristo formations.

Named for exposures on Entrada Point, in northern part of San Rafael Swell, Utah.

Enumclaw Volcanic Series[1]

Miocene, upper: Western Washington.

Original reference: C. E. Weaver, 1916, Washington Geol. Survey Bull. 13, p. 84.

Well exposed from Enumclaw to Cedar Lake, in southwestern part of King County.

†Eolian Limestone[1]

Cambrian and Ordovician: Southwestern Vermont.

Original reference: E. Hitchcock, 1861, Vermont Geologist Rept., v. 1, p. 396–419.

Named for Mount Eolus (Dorset Mountain) in Pawlet quadrangle.

Eolian Limestone Member (of Pueblo Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Texas Univ. Bull. 2132, p. 24, 31, 171–173, pl. 2, table 2.

Named for exposures near Eolian, Stephens County.

Eoline Member (of Coker Formation)

Eoline Formation (in Tuscaloosa Group)

Upper Cretaceous: West-central Alabama.

L. C. Conant and W. H. Monroe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 37; W. H. Monroe, L. C. Conant, and D. H. Eargle, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 194–197. Formation includes the marine beds which lie between the apparently nonmarine Cottondale formation (new) and the Coker formation (new). Consists of glauconitic fine- to medium-grained sand and laminated gray clay; sand and clay beds are lenticular and of doubtful persistence, but upper part is commonly more clayey and lower part more sandy; *Halymenites* borings locally present, chiefly in upper half; weathered exposures commonly bright rusty red; updip exposures in Cottondale quadrangle chiefly purple and red sand with little or no glauconite and no *Halymenites*. Thickness 50 to 150 feet. In many places, upper contact is abrupt locally showing as much as 40 feet of channeling and in such places commonly overlain by nonglauconitic sand; at other places, contact is more obscure and laminated clay of Eoline is overlain by massive clay of Coker; at such places, contact is undulating surface having about 10 feet of relief. Lignitized logs and macerated plant remains near top have been determined as Upper Cretaceous.

C. W. Drennan, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 3, p. 528, 529. Rank reduced to member status in Coker formation (revised). Sediments heretofore designated Cottondale are included in Eoline member.

Named for exposures in cuts along Alabama Highway 6, about 30 miles southeast of Tuscaloosa, and 1½ miles east of community of Eoline, Bibb County.

Eolus Granite[1] (in Front Range Granite Group)

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe. 1905, U.S. Geol. Survey Geol. Atlas, Folio 131.

Composes Mount Eolus, Needle Mountain quadrangle.

Ephraim Conglomerate (in Gannett Group)[1]

Lower Cretaceous: Southeastern Idaho and western Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 76, 82.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 40–42, pl. 1. In Paradise Valley quadrangle, Idaho, is sole representative of group. Contained in small slice of rocks in zone between middle and east branches of Bannock overthrust. Thickness 1,025 feet. Overlies Stump sandstone. Upper Jurassic and Lower Cretaceous.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 55–56, pl. 21. Referred to as conglomerate member of Gannett group in Jackson Hole area. Underlies Peterson limestone member; overlies Stump formation. Lower Cretaceous.

W. W. Rubey, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–109. Described in Bedford quadrangle, Wyoming, where it is a conspicuous unit composed of sandy siltstone and shale; contains crossbedded coarse-grained sandstone and prominent conglomerate lentils. Thickness, where least disturbed by faulting or other deformation, 350 to 500 feet. Overlies Stump sandstone; underlies unit referred to as Draney-Peterson limestone. Lower Cretaceous.

Named for Ephraim Valley, sec. 36, T. 10 S., R. 45 E., Boise meridian, Crow Creek quadrangle, Idaho.

Epitaph Dolomite (in Naco Group)

Lower Permian: Southeastern Arizona.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 25–27, 41; James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 44–46, pl. 5. Lowest member of formation consists of about 200 feet of dolomite which ranges from medium to light gray on fresh fracture and weathers to various shades of gray—light to very dark. Characterized by presence of knots of silica, which are suggestive of being silicified fossils—weather to brown or tan. Toward the top of this part of formation, partings of red shale occur in dolomite; overlying beds generally poorly exposed sandy limestone or limy sandstone with higher porportion of maroon shale and much less dolomite. Uppermost part of formation is assemblage of dolomite, limestone, red shale, and thin sandy layers. Thickness at type locality 783 feet. Unconformably underlies Glance conglomerate or other rocks of Comanche age; overlies Colina limestone (new) with gradational contact.

Type locality: On dip slope of Colina Ridge, west of Epitaph Gulch (from which dolomite takes its name), 1 mile south of Horquilla Peak, central Cochise County.

Epler Formation (in Beekmantown Group)

Lower Ordovician: Southeastern Pennsylvania.

J. P. Hobson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 12, p. 2716 (fig. 3), 2718, 2719–2720, 2721. Proposed for interbedded limestone and dolomite overlying Rickenbach formation (new) and underlying dolomite beds here termed Ontelaunee formation. Divided into two unnamed members: upper characterized by large proportion of calcarenite with bioclastics and limestone pebbles, and lower in which calcilutite is common; both members contain interbedded dolomite with much larger percentage in lower member. Thickness 800 feet in type section. Contact with underlying Rickenbach transitional, and boundary set at base of first limestone above solid dolomite body of the Rickenbach; contact with overlying Ontelaunee is placed at top of first limestone bed beneath lowest chert bed of Ontelaunee, and in Berks County this contact is 100 feet below lowest chert bed; contact zone gradational.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Geologic map of the Richland quadrangle, Pennsylvania (1:24,000): Pennsylvania Geol. Survey, 4th ser., Atlas 167–D. Described in Lebanon County where it is approximately 1,000 feet thick.

Type section: Continuous with type section of upper member of Rickenbach formation, east of Epler School, near Reading, Berks County.

Epworth Gravel Member (of San Pedro Formation)

Pleistocene, lower: Southern California.

California State Water Resources Board, 1953 (revised 1956), California State Water Resources Board Bull. 12, v. 2, p. B–103, pls. B–1C, B–2. Consists of up to 300 feet of gravel, gravelly clay, and silt, grading westward and southward into silt and clay. Gravels occur near top of formation and have been folded and partly eroded.

Occurs in a limited area around Moorpark, Ventura County.

†Equity Quartz Latite (in Alboroto Group)

†Equity Quartz Latite (in Potosi Volcanic Series)[1]

Miocene: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull. 718.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 93 (table 18). Alboroto rhyolite described in San Juan district. Upper part is biotite-hornblende latitic rhyolite; includes Equity and Phoenix Park quartz latites [both part of Alboroto group] of Creede district.

U.S. Geological Survey has abandoned the term Equity Quartz Latite on the basis of a study now in progress.

Named for development near Equity mine. Creede district.

Eramosa Member[1] (of Lockport Dolomite)

Middle Silurian: Ontario, Canada and western New York.

Original reference: M. Y. Williams, 1915, Canada Geol. Survey Mus. Bull. 20, Geol. Ser. 29, p. 1–4.

E. R. Cummings, 1939, Geologie der Erde, North America, v. 1, p. 596 (fig. 7), 597. Uppermost member of Lockport dolomite. Thickness 15 feet. Overlies Suspension Bridge member (new). Underlies Guelph dolomite. Forms crest of Niagara Falls.

B. F. Howell and J. T. Sanford, 1947, Wagner Free Inst. Sci. Bull., v. 22, no. 4, p. 34. Member of Lockport formation. Underlies Oak Orchard member (new); overlies Goat Island member (new). Term Goat Island replaces preoccupied name Suspension Bridge.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Formation in Lockport group. Overlies Goat Island limestone; underlies Devils Hole dolomite (new). Lockportian stage. Middle Silurian.

Well exposed along banks of Eramosa River between Rockwood and Guelph, Ontario.

Erath Member (of Anahuac Formation)

Oligocene, upper, or Miocene, lower: Southern Louisiana (subsurface).

H. C. Goheen, 1959, Gulf Coast Assoc. Geol. Soc. Trans., v. 9, p. 91–97. Term proposed for so-called deep water facies of down-dip Anahuac formation, which is regarded as upper Oligocene or lower Miocene. Predominantly shale unit containing some sandstone. Characterized by two foraminiferal zones, *Planulina palmerae* and Abbieville. These biostratigraphic zones serve to define Erath member, the same way *Marginulina* and *Discorbis* zones are used to limit type Anahuac. No single well log at present satisfactorily includes entire member. Reference log designated.

Reference log: Texas Co. Erath Unit 38, No. 7, Erath field, Vermilion Parish. Near Erath townsite.

Ericson Sandstone[1] or **Formation** (in Mesaverde Group)

Upper Cretaceous: Southwestern Wyoming and northeastern Utah.

Original reference: J. D. Sears, 1926, U.S. Geol. Survey Bull. 781, p. 20, pl. 5.

W. R. Hansen and M. G. Bonilla, 1954, Colorado Sci. Soc. Proc., v. 17, no. 1, p. 4 (fig. 1), 9, 10. Geographically extended into Daggett County, Utah, where it is 290 feet thick in Flaming Gorge area, overlies Rock Springs formation and unconformably underlies Fort Union(?) formation; 800 feet thick in Clay Basin.

W. R. Hansen, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–101. Described as formation in Clay Basin quadrangle, where it is about 800 feet thick, and consists of three massive gray sandstone beds separated by earthy punky dark-gray shale; locally basal beds are shale. Underlies Fort Union formation.

Named for exposures near old Ericson Ranch, on Salt Wells Creek, sec. 31, T. 16 N., R. 102 W., Sweetwater County, Wyo.

Erie Clay[1]

Pleistocene: New York and Ohio, and Ontario, Canada.

Original reference: W. E. Logan, 1863, Canada Geol. Survey Repts. 1843–1863, p. 887, 896–907.

Occurs along north shore of Lake Erie from Long Point westward to Detroit River, and appears to underlie whole country between this part of lake and main body of Lake Huron. Also occurs at Owen Sound and along Nottawasaga River, along shores of Lake Ontario and east far as Brockville.

Erie Group[1]

Erie Series[1] or Erian Series

Middle Devonian. New York and West Virginia.

Original reference: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, geol. 2d dist., p. 100, 429.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 253, 254, 308–311. Erie group (Erian) of West Virginia contains two members, Marcellus black shale below and Hamilton formation above. Name, which is currently in use by New York State Museum but not by U.S. Geological Survey, is here adopted to resolve a difficulty which otherwise would call for erection of a new term or transfer of another term not yet known to be wholly appropriate. To serve as the name of the Marcellus-Hamilton group of this report (that is, the Hamilton group of Pennsylvania) recourse is had to Erie, or Erian, early used by Emmons (1842) and redefined by Clarke and Schuchert (1899 Science, new ser., v. 10) expressly for this service—namely, for the rocks between the Onondaga and Tully limestone.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1729–1794, chart 4. Erian series, Middle Devonian. Comprises (ascending) Cazenovia, Tioughnioga, and Taghanic (Taughannock) stages. Follows Ulsterian series and precedes Senecan series.

Named for Lake Erie.

†Erie Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 108, 118.

Named for Erie, Neosho County.

†Erie Shale[1]

Upper Devonian: Northern Ohio.

Original reference: J. S. Newberry, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 20.

Named for exposures on shores of Lake Erie from mouth of the Vermillion to Dunkirk.

Erin Shale[1]

Erin Slate Member (of Talledega Series)

Carboniferous (probably Early Pennsylvanian): Eastern Alabama.

Original reference: Charles Butts, 1926, Alabama Geol. Survey Special Rept. 14, p. 217.

R. H. Griffin, 1951, Alabama Geol. Survey Bull. 63, p. 28, 31. Described in Hillabee area where Talladega series is divided into Cheaha quartzite, Erin slate, and group of quartzites, phyllites, and slates lying below, between, and above the two members. Thickness at type locality 2,800 feet; true thickness cannot be measured since upper limit is determined by Whitestone fault.

Type locality: Vicinity of Erin, Clay County.

Ermont Formation[1]

Upper Devonian: Southwestern Montana.

Original reference: P. J. Shenon, 1931, Montana Bur. Mines and Geology Bull. 6.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1742. Upper Devonian.

In vicinity of Ermont mine, Argenta district, Beaverhead County.

Erna Member (of Wilberns Formation)

Upper Cambrian: Central Texas.

F. B. Plummer, [1942], Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 22, p. 1, 2, map. Medium- to coarse-grained well-sorted well-rounded friable poorly cemented sand, 10- to 25-feet thick, near middle part of formation. Due to complicated system of normal faults which occurs in region, outcrop is repeated three times so that three narrow belts of the sand can be traced across Cambrian area.

Best exposures are on middle belt along east bluff of Leon Creek, 2 miles southeast of Erna, Mason County.

Ervay Carbonate Rock Member or **Tongue** (of Park City Formation)

Ervay Member (of Goose Egg Formation)

Ervay Tongue or **Member** (of Phosphoria Formation)[1]

Upper Permian: Northwestern Wyoming.

Original reference: H. D. Thomas, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1664, 1666.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2832 (fig. 3), 2844; 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 3 (fig. 1), 19–20, pls. 2, 3. In this report, beds that Thomas (1934) called Phosphoria in Wind River Mountains are designated Park City formation; hence, Ervay is considered member of Park City. Extends to northern Wind River Mountains where it is 30 to 40 feet thick; north and west of this, grades into upper member of Shedhorn sandstone; west of Big Piney, grades into Tosi chert member of Phosphoria. Mostly limestone in its western area and dolomite in its eastern area. Underlies Dinwoody formation. [Members of Phosphoria, Park City, and Shedhorn formations are referred to as tongues in areas where they occur singly or are subordinate parts of the interval.]

U.S. Geological Survey also classifies the Ervay as a member of the Goose Egg Formation on the basis of a study now in progress.

Type section: Casper Creek, Natrona County. Crops out a few hundred feet west of Evray, a post office in Natrona County, near north end of Rattlesnake Hills.

Ervine Creek Limestone[1] Member (of Deer Creek Limestone)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 43, 49, 50.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5). Uppermost member of Deer Creek; overlies Burroak shale member; underlies Calhoun formation. Virgilian series. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 22. Member persists from Adair County, Iowa, to Oklahoma. Thickness 14 to 18 feet. Type exposures noted.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17–19, fig. 3. In Missouri, interval between Rock Bluff limestone member and uppermost limestone of the Deer Creek is occupied by shale. This shale has been treated by Missouri Geological Survey as occupying the Rock Bluff-Ervine Creek interval, with implication that intervening Haynies limestone is absent in Missouri. This shale interval is here termed Larsh-Burroak. Missouri Geological Survey recognizes the possibility that Burroak shale member may be absent in Missouri and that uppermost limestone of Deer Creek formation may include both Haynies and Ervine Creek limestone members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 17, fig. 5. Massive- to wavy-bedded fossiliferous light-gray limestone, often chert bearing; algal and oolitic beds near top. Thickness 10 to 14 feet. Overlies Burroak shale member; underlies Calhoun shale.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 46, pl. 1. Member, in Douglas County, is 13 to 17 feet thick. Overlies Larsh-Burroak shale member; underlies Calhoun shale.

Type exposures: On Ervine Creek about 5 miles northeast of Union, Cass County, Nebr.

Erving Hornblende Schist[1]

Pre-Triassic: Central Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 60, 72–74, map.

774–954—vol. 1—66——81

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Described in Mount Toby quadrangle as fine-grained hornblende schist with interbedded feldspathic quartzite. Thinly layered amphibolite grades into overlying Joshua schist through narrow zone of quartzitic mica schist which contains small widely separated layers of amphibolite. Overlies Poplar Mountain gneiss with gradational contact. Pre-Triassic.

Robert Balk, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–93. Restricted. Unit mapped as Erving by Emerson (1917) in Millers Falls quadrangle is considered amphibolite member at top of Crag Mountain formation. Relation of Erving to amphibolite lenses in Poplar Mountain gneiss not known.

Named for occurrence at Erving, Millers Falls quadrangle.

Erwin Quartzite[1] **or Formation**[1] (in Chilhowee Group)

Lower Cambrian(?): Eastern Tennessee, western North Carolina, and southwestern Virginia.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 5.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51–A, p. 7–22. In Great Valley of Virginia, Erwin quartzite underlies Shady dolomite. In vicinity of Austinville, Lower Cambrian dolomite overlies Erwin. Proposed to extend Pennsylvania names Vintage dolomite, Kinzers formation, and Ledger dolomite to this fossil-bearing series of beds, which although equivalent to Shady dolomite of Great Valley, is different sedimentary facies deposited to southeast of main Appalachian geosyncline, and has been carried northwestward by thrust faulting to rest on typical Shady dolomite.

P. B. King and others, 1944, Tennessee Div. Geology Bull. 52, p. 29–35. Formation in northeastern Tennessee consists of interbedded layers of white vitreous quartzite, ferruginous quartzite, siltstone, and shale. Formation extends from overlying Shady dolomite to base of widely traceable white quartzite bed that contains *Scolithus* in many places. As thus defined, it has rather uniform thickness of 1,200 to 1,400 feet throughout region. Includes Helenmode member (new) in Iron and Holston Mountains. The Helenmode consists of the so-called "transition beds" of earlier reports. Overlies Hampton formation; underlies Shady dolomite.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 12, 14–16. Formation, as mapped in this report [Hot Springs Window], includes upper part of Murray slate and Hesse quartzite as mapped by Keith (1904, U.S. Geol. Survey Geol. Atlas, Folio 116). Base of formation is placed beneath resistant ledge-forming white quartzite series of beds that overlie upper shale member of Hampton formation. *Scolithus* tubes not noted except at one locality. Except for Helenmode member at top, Erwin beds are not subdivided in this area. Overlies Hampton formation; underlies Shady dolomite. Two sets of formation names for Lower Cambrian clastic rocks are in current use in eastern Tennessee and western North Carolina. Northeast Tennessee names Unicoi, Hampton, and Erwin are used here for same rocks which Keith (1904) and Stose and Stose (1947, Am. Jour. Sci., v. 245, no. 10) named Cochran, Nichols, Nebo, Murray, and Hesse, all defined by Keith (1895) in Chilhowee Mountain area, Blount and Sevier Counties, Tenn.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28, 32, 41–45, pls. 1, 19. Uppermost unit of Chilhowee group. Consists of interbedded layers of white vitreous quartzite, dark ferruginous quartzite, siltstone, and shale. Thickness 1,220 feet at type locality; between 1,200 and 1,500 feet on Holston Mountain and Iron Mountain; 1,000 feet in Stone Mountains; about 600 feet on Nowhere Ridge. Includes (ascending) Nebo quartzite, Murray shale, Hesse quartzite, and Helenmode members. Overlies Hampton formation; underlies Shady dolomite. Lower Cambrian.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 19–20, pl. 1. In this report [Rockingham County], term Erwin quartzite is used in preference to Antietam sandstone. Consists almost entirely of thick beds of clean well-sorted grains of white quartz sand which are cemented with silicia. Thickness 800 to 1,000 feet. Overlies Hampton (Harpers) formation; underlies Shady (Tomstown) dolomite.

Type locality: On Nolichucky River, southeast of Unaka Springs. Named for exposures near Erwin, Unicoi County, Tenn.

Escabrosa Limestone[1]

Lower and Upper(?) Mississippian: Southeastern Arizona and southwestern New Mexico.

Original reference: F. L. Ransome, 1904, U.S. Geol. Survey Prof. Paper 21.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 2–13. Crops out in northwestern Mule Mountains, Tombstone Hills, in many fault blocks in southeastern end of Dragoon Mountains, and along main ridge of Dragoon Mountains and in parts of Little Dragoon Mountains, Gunnison Hills, and Johnny Lyon Hills. Overlies Martin limestone or Abrigo limestone; underlies Horquilla limestone (new), or Black Prince limestone. Thickness 585 to 755 feet. Lower Mississippian.

F. F. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 476 (fig. 6), 480–481. Described in Chiricahua and Dos Cabezas Mountains where it consists of cherty crinoidal limestone 630 to 730 feet thick. Overlies Upper Devonian Portal formation (new); underlies Upper Mississippian Paradise formation.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 11 (table 2), 28–29, table 1. In central Peloncillo Mountains, about 460 feet thick; overlies Percha shale and underlies Paradise formation. Unit resembles Escabrosa of Bisbee area much more closely than it does Lake Valley limestone; hence, term Escabrosa is used here even though it is at variance with nomenclature used throughout rest of New Mexico. Kinderhookian-Meramecian.

D. W. Peterson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–128. Thickness about 300 feet in Haunted Canyon quadrangle, Arizona. Overlies Martin limestone; underlies Naco limestone.

U.S. Geological Survey currently designates the age of Escabrosa Limestone as Lower and Upper(?) Mississippian.

Named for exposures on Escabrosa Ridge, Bisbee quadrangle, Ariz.

Escacado Limestone

Upper Devonian (Rockfordian): Southeastern Arizona.

[C. R.] Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 227, 228 (table). Name applied to lower 100 feet of Martin limestone of Ransome (1904).

Characterized by occurrence of Iowa Rockford fauna. Younger than Berenda formation; underlies Patagonia limestone (new).

In Bisbee region.

Escanaba Limestone[1]

Middle Ordovician: Michigan.

Original reference: A. C. Lane, 1909, Michigan Geol. Survey Rept. 1908, p. 47.

Escanaba and St. Mary's Rivers.

Escanaba River Group

Middle Ordovician: Northwestern Michigan.

R. C. Hussey, 1950, Michigan Geol. Soc. [Guidebook 14th] Ann. Geol. Excursion, introd. Proposed for Middle Ordovician rocks of Michigan.

Middle Ordovician rocks are well exposed along Escanaba River from hydroelectric power station at Bony Falls almost to mouth of stream, Upper Peninsula.

Escobar Sandstone

Eocene, upper: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 44–48, pls. 4A, 4B, 4C. Proposed for massive thick-bedded grayish and yellowish-brown medium-grained sandstones with subordinate amounts of interstratified brown silty shales which overlie Muir sandstone (new) and underlie Alhambra formation (new). Thickness at type section approximately 1,200 feet.

Type section: In west limb of Pacheco syncline in cut along Industrial Highway, east of Alhambra Valley, and in cuts along Santa Fe Railway, Contra Costa County. Forms crest of ridge in west limb from Martinez southward nearly to town of Walnut Creek. Also exposed in east limb of syncline.

Escondido Formation (in Navarro Group)[1]

Upper Cretaceous (Gulf Series): Southern Texas.

Original reference: E. T. Dumble, 1892, Geol. Soc. America Bull., v. 3, p. 227–229, 230.

L. W. Stephenson, 1937, U.S. Geol. Survey Prof. Paper 186–G, p. 137. In Medina County, Escondido formation (marl facies), 34 feet thick, unconformably overlies Anacacho limestone.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull. v. 53, no. 3, chart 9. Shown on correlation chart above Olmos formation in longitude of Eagle Pass and above Anacacho limestone in longitude of Anacacho Mountain and D'Hanis, and above Corsicana marl in latitude of Castroville. Navarro group.

Named for exposures on Escondido River below Eagle Pass, Maverick County.

†Escondido Series[1]

Miocene, middle: Southern California.

Original reference: O. H. Hershey, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, pl. 1, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 518, table 4. Succession of volcanic rocks and continental sediments, the former being mainly basaltic and andesitic lava flows with considerable associated agglomerate. Middle Miocene.

Type section: Tick Canyon, Los Angeles County.

Escondido Creek Leucogranodiorite

Cretaceous: Southern California.

E. S. Larsen, Jr., and N. B. Keevil, 1947, Geol. Soc. America Bull., v. 58, no. 6, p. 489. Named in report on study of batholith of southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 87–89, pl. 1. Fine-grained light-colored rock that ranges in composition from leucogranodiorite to leucotonalite and averages granodiorite. Along most of its contact, it intrudes Santiago Peak volcanics but in some places intrudes both Green Valley tonalite and San Marcos gabbro. Derivation of name given.

Named from its excellent and characteristic development in canyon of Escondido Creek, San Diego County. Largest exposed mass of this rock occupies area about 7 square miles mostly in drainage of Escondido Creek.

Escudo Sandstone

Miocene, middle (Relizian): Central California.

Martin Van Couvering and H. B. Allen, 1943, California Div. Mines Bull. 118, pt. 3, p. 496–500. Poorly sorted buff calcareous fossiliferous sandstone. Maximum thickness 150 feet. Underlies Alferitz formation (new); unconformably overlies Hannah formation (new).

Occurs in Devils Den oil field district, northwestern Kern County, adjacent to Kings County line, about 40 miles east of Paso Robles and about 60 miles northeast of Bakersfield.

Eshamy Granite[1]

Mesozoic(?): Southeastern Alaska.

Original reference: U.S. Grant and D. F. Higgins, 1910, U.S. Geol. Survey Bull. 443, p. 34–35, 46.

Practically surrounds Granite Bay and occupies nearly all of neck land between Granite and Eshamy Bays, Prince William Sound region.

Eshe Porphyry

Tertiary: Central Colorado.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 81–83, pl. 1. Comprises stocks, dikes, and sill-like sheets of quartz monzonite porphyry and quartz diorite porphyry. Quartz monzonite near Eshe Ranch is light cream to grayish brown. Rock has finely granular goundmass and phenocrysts of feldspar, biotite, hornblende, and quartz.

Prominent around Eshe Ranch, after which rocks are named, in sec. 33, T. 8 S., R. 76 W. Underlies series of ridges and hills in northern and northwestern parts of South Park, Park County.

†Eska Conglomerate[1]

Miocene(?): Central southern Alaska.

Original reference: G. C. Martin and F. J. Katz, 1912, U.S. Geol. Survey Bull. 500, p. 15, 52–54.

F. F. Barnes and T. G. Payne, 1956, U.S. Geol. Survey Bull. 1016, p. 1, 13. Eska conglomerate found to be divisible, at least in Wishbone Hill district, into two formations, Wishbone (new) below and Tsadaka (new) above.

Extends west from valley of Eska Creek, for which it is named, Cook Inlet region.

Eskota Beds[1]

Permian: Central northern Texas.

Original reference: J. W. Beede and W. P. Bentley, 1921, Texas Univ. Bull. 1850, p. 16, 22, 29, 51, 53.

Probably named for Eskota, Fisher County.

Eskota Dolomite[1] or Gypsum[1]

Eskota Dolomite (in Custer Formation)

Permian: Central northern Texas.

Original reference: A. M. Lloyd and W. C. Thompson, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 953, pl. 10.

Robert Roth, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 422. In Fisher, Nolan, and Coke Counties, Eskota dolomite occurs from a few feet to 20 feet above base of Custer formation.

Probably named for Eskota, Fisher County.

Eskridge Shale[1] (in Council Grove Group)

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: J. W. Beede, 1902, Kansas Univ. Sci. Bull., v. 1, p. 181.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 47. Shale and minor amount of limestone and locally thin coal beds; red and green shale predominant in most exposures; in central Kansas, a seemingly persistent limestone, as much as 2 feet thick, overlain locally by coaly material and underlain by green shale, occurs a few feet from base. Thickness 20 to 40 feet. Underlies Cottonwood limestone member of Beattie limestone; overlies Neva limestone member of Grenola limestone (redefined). Wolfcamp series.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 99–100. Formerly considered top unit of Wabaunsee group. Reclassification of section by Moore (1936, Kansas Geol. Survey Bull. 22) and others has since placed Eskridge in Council Grove group. Overlies Neva limestone; underlies Cottonwood limestone. Identification of Cottonwood in Pawnee County is uncertain and recognition of upper limit of Eskridge is accordingly doubtful. Thickness 80 to 90 feet, increasing southward.

M. R. Mudge and H. R. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 13 (table 2), 69–71, pls. Thickness 32½ to 38 feet in Wabaunsee County, Kans. Overlies Grenola limestone; underlies Beattie limestone. Note on type locality and probable type section.

Type locality: Vicinity of Eskridge, Wabaunsee County, Kans. Probable type section: About 1⅛ miles south of Eskridge in SW¼NW¼NW¼ sec. 17, T. 14 S., R. 12 E., where upper half of shale is exposed.

Esmeralda Formation[1]

Miocene, upper, and Pliocene, lower: Southwestern Nevada and central eastern California.

Original references: H. W. Turner, 1900, Am. Geologist, v. 25, p. 168–170; 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 197–208.

H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723, p. 43–50. In Manhattan district, subdivided into (ascending) Hedwig breccia, Round Rock, Diamond King, and Bald Mountain lake beds members.

D. I. Axelrod, 1940, Washington Acad. Sci. Jour., v. 30, no. 4, p. 163–170. Lower Pliocene.

H. G. Ferguson, S. W. Muller, and S. M. Cathcart, 1953, Geology of the Coaldale quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–23]. Roughly divisible into two lithologic units: upper, dominantly sedimentary but containing some volcanic material; lower, in which pyroclastic material grading from fine-grained tuff and pumice to coarse rhyolite breccia exceeds the bedded material. Sedimentary rocks include fanglomerate, conglomerate, and coarse sandstone at normal contact with older rocks grading outward into fine-grained sandstone, calcareous and sandy shales, marls, and impure hard limestones. Estimated thickness 1,000 feet in Stewart Valley, probably thicker to south, but estimate of 14,800 feet at type locality is probably excessive. Older than Oddie rhyolite. Upper Miocene and lower Pliocene.

Type locality: Big Smoky Valley, Silver Peak quadrangle, Nevada. Named for development in Esmeralda County, Nev. [before county was subdivided].

Esmond Granite

Mississippian(?) or older: Northeastern Rhode Island.

Alonzo Quinn, R. G. Ray, and W. L. Seymour *in* Alonzo Quinn and others, 1948, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 3, p 13, 15, geol. map (bedrock). Light-gray, pink, and fresh-colored medium- to coarse-grained slightly gneissic granite. Much of rock may be termed alaskite. Formerly included in Milford granite. Cuts Blackstone series discordantly.

Exposed in western part of Pawtucket quadrangle. Named for village of Esmond located just beyond southwest corner of quadrangle.

Esmont slate facies (of Candler Formation)

Lower Paleozoic(?): South-central Virginia.

W. R. Brown and H. C. Sunderman, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1356. Facies of Candler formation in James River synclinorium. Age not stated.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2). Age of Candler formation is shown on columnar section as Lower Paleozoic(?).

Type locality of Candler formation is Candler Mountain, 2 miles south of Lynchburg, Campbell County.

Esopus Grit, Shale, or Siltstone

Esopus Grit or Shale (in Oriskany Group)[1]

Esopus Shale (in Onondaga Group)

Esopus Shale Member (of Onondaga Formation)

Lower or Middle Devonian: Eastern New York, northern New Jersey, and northeastern Pennsylvania.

Original reference: L. Vanuxem, 1842, Geology of New York, pt. 3, p. 127–130.

Bradford Willard, 1938, Pennsylvania Geol. Survey, 4th ser. Bull. G–11, p. 5, 6 (fig. 3), 14–16. Included in Onondaga group in Pennsylvania. Esopus shale (Caudi-galli grit of early writers) consists of not less than 250 feet of gray brown-weathering sandy shale. Overlies Oriskany. Grades upward into Buttermilk Falls limestone (new).

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1758–1759, chart 4. In Onesquethaw stage (new). Lower or Middle Devonian.

Winifred Goldring and R. H. Flower, 1942, Am. Jour. Sci., v. 240, no. 10, p. 677–678, 679, 689–690, 694. Formation restricted, beds formerly classed as upper Esopus are separated into Sharon Springs formation (new).

Winifred Goldring and R. H. Flower, 1944, Am. Jour. Sci., v. 242, no. 6, p. 340. Name Carlisle Center formation proposed for preoccupied name Sharon Springs.

J. M. Berdan, 1950, New York State Water Power and Control Comm. Bull. GW–22, p. 10 (table 2), 17–18. In Schoharie County, Esopus consists of about 80 feet of brownish-gray siltstone. Underlies Carlisle Center formation; overlies Oriskany sandstone. Lower or Middle Devonian.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 731 (fig. 2), 732–734. At Highland Mills, N.Y., formation comprises (ascending) Highland Mills member (new), middle member, and Woodbury Creek member (new). Overlies Connelly conglomerate; underlies Kanouse sandstone. Thickness about 200 feet. Lower Devonian. Esopus stage recognized.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Onondaga formation as mapped includes Esopus shale in easternmost part of state.

Named from Esopus settlement and Esopus Creek, Ulster County, N.Y.

†Esopus Millstones[1]

Silurian: Eastern New York.

Original reference: W. W. Mather, 1840, New York Geol. Survey 4th Rept., p. 246–250.

Extends north from Shawangunk Mountain nearly to Kingston. Present village of Esopus is about 10 miles south of Kingston, Ulster County.

Esopus Slate[1]

Lower Devonian: Eastern New York, northern New Jersey, and northeastern Pennsylvania.

Original reference: N. H. Darton, 1894, New York State Geologist 13th Ann. Rept., p. 209–210, 244–245, 302.

Named for Esopus settlement and Esopus Creek, Ulster County, N.Y.

Esopus Stage

Lower Devonian: Eastern North America.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 737–739. Proposed for eastern North America. Has been customary to conclude that Esopus formation is either upper Deerpark (Oriskany) or lower Onesquethaw (Schoharie) age. Discovery of Highland Mills and Woodbury Creek member faunas makes it clear that Esopus time is of same order as either Deerpark or Onesquethaw. In eastern New York and Pennsylvania, stage will be represented by relatively unfossiliferous Esopus formation. Elsewhere in eastern United States, strata of this age are absent owing to disconformity between strata of Oriskany and Onondaga age.

Espada Formation

Upper Jurassic and Lower Cretaceous: Southern California.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 22–23, pls. 1, 2. A series of dark-greenish-brown thin-bedded silty shales and a lesser amount of thin interbeds of hard fine-grained sandstone; locally thin lenses of conglomerate with well-rounded chert pebbles. No complete section exposed at any one locality. At type locality where base is exposed, consists of 1 to 5 feet of dark-brown conglomeratic sandstone resting unconformably on highly sheared clay shale of Honda formation (new); conglomerate is overlain by about 4,000 feet of dark-greenish-brown shale and thin hard sandstone which is unconformably overlain by lower Miocene beds. In San Lucas and Wons Canyons, a maximum thickness of 6,800 feet is exposed; base is in fault or intrusive contact with serpentine; top is unconformably overlain by Eocene beds. Relationship of Espada to Upper Cretaceous Jalama formation (new) not definitely known; but these are believed to be in contact at head of Salsipuedes Canyon, where relationship appears to be an unconformity, and at Nojoqui Canyon, where shales of Espada are in conformable contact with sandstones and shales believed to be the Jalama.

Type locality: South side of Canada Honda about 3 miles east of Point Pedernales, Santa Barbara County. Other exposures: Salsipuedes and El Jaro Canyons, Nojoqui and Alisal Canyons, San Lucas and Wons Canyons.

Esperance Sand Member (of Vashon Drift)

Pleistocene: Northwestern **Washington.**

R. C. Newcomb, 1952, U.S. Geol. Survey Water-Supply Paper 1135, p. 19–25, pl. 1. Largely an advance outwash deposit consisting of sand and gravel up to 400 or 500 feet thick; discontinuous silt beds common. Overlies Admiralty clay (new).

Exposed in scattered areas in western part of Snohomish County.

Esperanza Trachyte[1]

Tertiary, middle or upper: Northwestern Arizona.

Original references: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743; Carl Lausen, 1931, Arizona Bur. Mines Bull. 131, Geol. Ser. 6, p. 30, map.

Named for Esperanza Canyon, Oatman district.

Espey Creek Limestone Member (of Chappel Formation)

Mississippian: Central Texas.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 22, 26, 28. Commonly made up of several layers of hard crystalline crinoidal limestone, each layer having a thickness of from 3 to 8 or 10 inches; in many areas where member is not more than 1 foot thick, it consists of a single layer containing crinoidal debris or coquina somewhat loosely cemented and sparsely fossiliferous. Thickness ranges from 6 inches to 4 feet. Most persistent member of formation and is present almost everywhere along Barnett-Ellenburger contact. Chappel comprises [ascending] King Creek marl (new), Ives conglomerate, Espey Creek limestone, and Whites Crossing coquina (new) members.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 810 (footnote). Plummer's Espey Creek limestone member of Chappel formation is same as Chappel limestone of Sellards (1933) and Cloud and Barnes (1948), excluding basal 15 inches referred by him to the Chappel at Espey Creek.

Name derived from exposures along Espey Creek southeast of Hallenbeck ranchhouse, Lampasas County.

Espina Breccia[1]

Miocene, upper(?): Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 69.

Forms Espina Hill, Goldfield district.

Espinal formation

[Upper Devonian] (Tombstonian): Southeastern Arizona.

[C. R.] Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 227, 228 (table).

Name applied to upper 150 feet of Martin limestone of Ransome (1904). Older than Vecol formation (new); overlies Patagonia limestone (new).

Name taken from great intermont plain which washes its outcrops; Bisbee region.

Espinal Grit (in Joserita Member of Lowell Formation)

Lower Cretaceous: Southeastern Ariznoa.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11–12. Coarse partly conglomeratic grit with imperfectly rounded and subangular pebbles of limestone, quartzite, chert, arkose, and sandstone. Large inclusions of underlying yellow dolomite. Southward grades into sandstone, arenaceous shale, and limestone. Thickness 4 feet. Underlies Corta sandstone (new); overlies unnamed dolomite.

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Espinaso Formation or Volcanics

Tertiary: Northwestern New Mexico.

C. E. Stearns, 1943, Jour. Geology, v. 41, no. 5, p. 304 (fig. 2), 309–310. Includes water-laid breccia, conglomerate, and tuff, with massive flows and explosive material in subordinate amounts. Thickness more than 1,000 feet. Overlies Galisteo formation with contact transitional; unconformably underlies Santa Fe formation. Name credited to Kirk Bryan and J. E. Upson (unpub. ms.).

C. E. Stearns, 1953, Am. Jour. Sci., v. 251, no. 6, p. 415–452. Comprises detrital beds deposited by mud flows and streams radiating from centers of contemporaneous eruption in Ortiz Mountains and Cerrillos Hills, with a few interbedded lava flows. Overlies Galisteo formation without stratigraphic break; hence, assigned to Duchesnean (latest Eocene). Thickness as much as 1,450 feet. Underlies Abiquiu(?) formation.

Older than Cieneguilla limburgite (new) and separated from it by time interval during which a small body of augite quartz latite was intruded, solidified, and exposed by subsequent erosion. Type locality stated.

A. E. Disbrow and W. C. Stoll, 1957, New Mexico Bur. Mines and Mineral Resources Bull. 48, p. 5 (table 1), 11–24, pl. 1. Described in detail in Cerrillos area in connection with four major periods of igneous activity that occurred during Espinaso time. Thickness more than 2,000 feet. Extrusion of Espinaso volcanics may span Oligocene and early Miocene time. Mapped as Oligocene(?).

Ming-Shan Sun and Brewster Baldwin, 1958, New Mexico Bur. Mines and Mineral Resources Bull. 54, p. 22. In this report [discussion of volcanic rocks of Cienega area], age of Espinaso volcanics is considered to be some or all of time between and including late Eocene and middle Miocene.

Type locality: Espinaso Ridge along Arroyo Pinovetito. Espinaso de Clotero Montoya (also known as Pinovetito Ridge) is hogback 5 miles long, 11 miles southeast of Cerrillos, Santa Fe County.

Espiritu Santo Formation

Devonian(?): Northern New Mexico.

E. H. Baltz and C. B. Read, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1752–1759, 1766 (fig. 12), 1770, 1771–1772. Name applied to sequence of sandstone, arenaceous limestone, calcarenite, and crystalline dolomitic limestone overlying crystalline rocks of Precambrian age near confluence of Holy Ghost Creek (formerly called Espiritu Santo Creek) and Pecos River at Tererro. Thickness at type locality more than 30 feet; consists of basal sandstone more than 11 feet thick, overlain by interbedded thin sandstone, calcarenite, and sandy limestone 5 feet thick; thin-bedded dolomitic limestone 11 feet thick; at top, sandy limestone, shale, and limestone pebble conglomerate 3½ feet thick. Unconformably underlies Tererro formation (new). Correlated with Devonian rocks on the basis of lithology and stratigraphy only; therefore classed as Devonian(?). Further studies must precede correlation, firm age assignments, and adjustments in terminology of Espiritu Santo, Tererro, and Arroyo Penasco formations.

Type locality: In quarry west of Pecos River about 75 yards north of Holy Ghost Creek at Tererro, San Miguel County.

Esplanade Sandstone Member (of Supai Formation)[1]

Permian: Northern Arizona.

Original reference: D. White, 1929, Carnegie Inst. Washington Pub. 405, p. 11.

Grand Canyon.

Espy Formation (in Washita Group)

Lower Cretaceous: Western Texas.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 1004–1007, pl. 1. Consists of three unnamed members: lowest, 679½ feet thick, is primarily light- to dark-gray and bluish limestone, slightly arenaceous, with small lentils and thin intercalated layers of shale and sandy shale; middle, 340½ feet thick, consists of platy white thin-bedded to laminated arenaceous to argillaceous limestone; upper, about

266½ feet thick, is principally buff and olive-brown sandstone. At type locality, where exposed thickness is 1,021 feet, it is chiefly thin beds of almost pure dense gray limestone, with buff marly limestone, brown sandstone, and a few interbedded shale layers. In northern Quitman Mountain area, base is not exposed, and consequently relationships to underlying formations of Fredericksburg group are not certainly known; in adjacent areas, relations appear conformable; in northern Quitman Mountain area, conformably underlies Etholen formation with sharp contact; in Devil Ridge area, conformably underlies group of shales designated as Eagle Ford.

Type locality: Low hills upheld by Washita strata east of Love Hogback and southeastern part of Devil Ridge, northern Quitman Mountains, Hudspeth County. Name derived from Espy Ranch about 10 miles east of Love Hogback.

Esquibel Member (of Los Pinos Formation)

Miocene(?) or Pliocene(?): Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 45–46. Arkosic sandstone, sandy conglomerate, some thin beds of tuff or tuffaceous siltstone, and felsitic tuff. Thickness 600 feet. Underlies Cordito member (new): overlies Biscara member (new). Name credited to Butler (unpub. dissert.). Biscara and Esquibel members as differentiated by Butler, mapped here as single unit, Biscara-Esquibel member (new).

Exposed westward from near divide on Tusas-Tres Piedras Road.

Essex Limestone[1] Member (of Edgewood Limestone)

Lower Silurian (Albion Series): Northeastern Illinois.

Original reference: T. E. Savage, 1912, Illinois Acad. Sci. Trans., v. 4, p. 100.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53; no. 4, chart 3. Member of Edgewood limestone. Albion series.

Named for Essex, Kankakee County.

Essex Series

Precambrian: Southern California.

J. C. Hazzard and E. F. Dosch, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 308–309. Composed of basal quartz-feldspar-biotite gneiss 1.500 feet thick, 500- to 600-foot marble, quartzite, and schist unit, designated Chubbock marble member, and upper unit of quartz-feldspar-biotite gneiss at least 5,000 feet thick. Overlain by Lower Cambrian(?) quartzite. Older than Fenner granite gneiss (new).

Well exposed in southern Piute Mountains, north of Barrel Spring, in northern Old Woman Mountains, and at Chubbuck on Santa Fe Railroad, San Bernardino County.

Establishment Member (of Mifflin Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 10, 15A, 16. Limestone, thick-bedded; dolomite, moderately argillaceous and shaly, thin-bedded. Thickness 2 to 7 feet. Shown on columnar section as underlying Hazelwood member (new) and overlying Boarman member (new).

In copy of guidebook used by compiler, a handwritten note states that Brickeys Member overlies Boarman Member. Thus, the sequence would be (descending) Hazelwood, Establishment, and Brickeys. Compiler had no way of determining what change, if any, had been made in other copies of the guidebook.

Occurs in Dixon-Oregon area.

Estelle Tonalite

Estelle Quartz Diorite[1]

Cretaceous: Southern California.

Original reference: P. H. Dudley, 1935, California Jour. Mines and Geology, v. 31, no. 4, p. 491, 502, map.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 70, 138, pl. 1. Described as Estelle tonalite, a light-gray rock with grains up to a few millimeters in length. Intrudes Temescal Wash quartz latite porphyry which surrounds it on all sides.

Occurs in first valley east of Estelle Mountain, Riverside County.

Ester Ash Bed

Pleistocene: East-central Alsaka.

T. L. Péwé, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 713. Gritty 6-inch-thick gray to white pure glass volcanic-ash layer near base of Ester "Island" section. Has sharp contacts with upland silt both above and below.

In "Island" section [sec. 8], T. 1 S., R. 2 W., about 8 miles west of Fairbanks. Named from adjacent Ester Creek.

Ester Lakes Graywackes, Slates, and Tuffs

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1611–1613. Name applied to thick series of graywackes, slates, and tuffs above Kekekabic [Lake] tuffs and agglomerates in Knife Lake synclinorium. Conglomerate lenses and agglomerates present. Slates are thin bedded; dark gray on fresh fracture. Graywackes grade into grit on one side and slate on the other; usually weather whitish to dirty brown. Thin bands of red jasper may be found between the tuffs and graywacke layers. They are the only red jasper beds observed in Knife Lake series. Estimated thickness of Ester Lake graywackes several thousand feet. In this report, Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Ester Lake graywackes as unit 14 occurring above feldspar porphyry intrusives and below Crooked Lake pebble conglomerate.

Report discusses a belt in western Vermilion district more or less parallel to international boundary.

Estes System[1]

Precambrian: Southwestern South Dakota.

Original reference: J. J. Runner, 1934, Am. Jour. Sci., 5th, v. 28, p. 354–372.

J. R. Berg, 1946, South Dakota Geol. Survey Rept. Inv. 52, p. 3–4, geol. map. There are three systems of Precambrian sedimentary rocks in Black Hills. According to Runner (1934), these are (ascending) Nemo, Estes, and Lead.

Well exposed along Estes Creek, Black Hills.

Estes Park Beds

Precambrian: Eastern Colorado.

M. F. Boos, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1372. Estes Park beds of Big Thompson series of metasedimentary formations and Longs Peak (Silver Plume) and Mount Olympus granitic rocks constitute bedrock of Estes Park Valley.

Estes Park Valley east of Rocky Mountain National Park, Larimer County.

Esther Granite[1]

Paleozoic(?): Southeastern Alaska.

Original reference: U. S. Grant and D. F. Higgins, 1910, U.S. Geol. Survey Bull. 443, p. 39–41, 46.

Occupies greater part of Esther Island, at southern end of Port Wells, Prince William Sound region.

Estill Clay[1]

Estill Member (of Crab Orchard Clay Shales)

Silurian (Niagaran): East-central Kentucky and southwestern Ohio.

Original references: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145; 1906, Kentucky Geol. Survey Bull. 7, p. 10, 59.

A. C. McFarlan and D. J. Jones, 1952, Kentucky Geol. Survey, ser. 9, Bull. 10, p. 10, 13, 14. In much of outcrop along eastern flank of Cincinnati arch, Ohio shale rests on Estill clay; elsewhere Boyle limestone intervenes.

R. N. Thomas, chm., 1955, Kentucky Geol. Soc. Field Trip, p. 31 (fig. 11). Shown on generalized section of Serpent Mound region, Adams and Highland Counties, Ohio, as Estill member of Crab Orchard clay shales. Thickness 70 feet. Underlies Ribolt member; overlies Dayton limestone.

Type exposure: Northeast of Estill Springs, Estill County, Ky.

Etchegoin facies (of San Ardo Group)

Pliocene: Western California.

T. A. Baldwin, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1986 (fig. 6), 1988. Ocher-brown dirty and pebbly fossiliferous sands; intermediate unit of three overlapping facies. Paso Robles gravels grade laterally to fossiliferous Etchegoin sands, which in turn finger out in diatomaceous Pancho Rico shale.

Exposed on slopes of Pancho Rico Canyon and nearby gulches which drain westward to Salinas River near San Ardo, Monterey County.

Etchegoin Formation[1]

Etchegoin Beds, Group, or Stage

Pliocene, middle: Southern California.

Original reference (Etchegoin beds, including Etchegoin sands and San Joaquin clays): F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 178–192.

W. F. Barbat and John Galloway, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 4, p. 477 (table 1), 482–483. Formation restricted to exclude San Joaquin clay. Highest member of Etchegoin sand has been described as "upper *Mulinia*" zone, and top of upper zone is chosen as base of San Joaquin clay as this zone marks important lithologic and faunal change. Etchegoin sand rests with marked unconformity on Reef Ridge shale on Reef Ridge, southwest of Kettleman Hills.

W. P. Woodring, Ralph Stewart, and R. W. Richards, 1940, U.S. Geol. Survey Prof. Paper 195, p. 26–27, 55–75, pl. 3. There is no general agreement in classification and nomenclature of Pliocene strata underlying Tulare formation. Anderson (1905) originally divided them into two units, San Joaquin clays and Etchegoin sands, but he also used name Etchegoin in group sense (Etchegoin beds) for both. Arnold and Anderson (1910, U.S. Geol. Survey Bull. 398) divided this part of section into two formations, Etchegoin formation and Jacalitos formation, the latter embracing original part of Coalinga beds of Anderson (1905). Mapping in Kettleman Hills has shown desirability of recognizing as a separate unit the upper part of Etchegoin formation of Arnold and Anderson (1910, U.S. Geol. Survey Bull. 398). Because this unit corresponds to F. M. Anderson's San Joaquin clay, that name has recently been revived (Barbat and Galloway, 1934). Nomland (1917, California Univ. Dept. Geology Bull., v. 10, no. 14), Gester and Galloway (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 10), and Barbat and Galloway (1934) extended name to embrace Jacalitos formation—that is, they adopted Anderson's (1908, California Acad. Sci. Proc., 4th ser., v. 3) revised nomenclature with the exception that Etchegoin was not used in group sense. Reed (1933, Geology of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists) raised Etchegoin to group rank and extended name Jacalitos to include Arnold and Anderson's Etchegoin minus the San Joaquin. In view of conflicting opinions and undesirable features of other schemes, a compromise involving restriction of name of Etchegoin to Arnold and Anderson's Etchegoin minus the San Joaquin is adopted in this report. This solution was reached independently by Goudkoff (1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 4). Exposed part of formation has thickness of about 700 feet in North dome and estimated exposed thickness of about 600 feet in Middle dome. With exception of freshwater beds near top of formation in North dome, formation consists of marine deposits, principally sandstone and conglomerate, and silt. Faunal zones mapped.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 225 (fig. 4), 240–246. Discussion of geology of San Benito quadrangle. Term Etchegoin is herein used as group as Nomland (1917) used it to include the Jacalitos, Etchegoin, and possibly San Joaquin formations of Coalinga district, which cannot be distinguished lithologically in field in this region. One cartographic division is separated, a series of red beds 400 to 600 feet thick on nonmarine origin at base, which is quite different character from rest of group. Group lies chiefly in narrow belt, 2 miles wide, between San Andreas and San Benito fault zones. Here it reaches maximum thickness of 3,500 feet. In Sulphur Creek area, the Etchegoin extends 2 miles farther east, overlapping sediments of Butts Ranch syncline, but with reduced thickness of only 750 feet. Main belt, along San Benito River, continues northwest of quadrangle beneath San Benito gravels and reappears in Lomerias Muertos, northwest of Hollister. To the southeast, belt extends through Priest Valley and Waltham Canyon (where it has thickness of 8,000 feet) into Coalinga district. Basal red beds of main Etchegoin belt rest disconformably upon Santa Margarita formation southwest of San Benito

River. Eastern belt rests with as much as 90° angular discordance upon upper Cretaceous, middle Eocene, and middle Miocene sediments of Butts Ranch syncline. In some areas, in fault contact with Franciscan.

Umberto Young, 1943, California Div. Mines Bull. 118, pt. 3, p. 523, 524, (fig. 224). Unconformably overlies Belridge diatomite in Midway-Sunset area.

J. W. Durham, R. H. Jahns, and D. E. Savage, 1954, California Div. Mines Bull. 170, chap. 3, p. 60 (fig. 2). Chart shows Etchegoin megafaunal "stage" equivalent to Venturian microfaunal stage.

Name derived from Etchegoin Ranch, about 20 miles northeast of Coalinga, where formation is characteristically developed.

†Etchegoin Formation (broad sense)[1]

Pliocene: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 178–192.

Occurs on summit and flanks of Anticline Ridge and on southeast end of Joaquin Ridge. Named for exposures in vicinity of Etchegoin Ranch, 20 miles northeast of Coalinga, in NW¼ sec. 1, T. 19 S., R. 15 E., Fresno County.

Etchegoin Sands[1]

Pliocene: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 178–192.

Named for exposures in vicinity of Etchegoin Ranch, 20 miles northeast of Coalinga, in NW¼ sec. 1, T. 19 S., R. 15 E., Fresno County.

Etholen Conglomerate[1]

Etholen Formation (in Washita Group)

Lower Cretaceous: Western Texas.

Original reference: J. A. Taff, 1891, Texas Geol. Survey 2d Ann. Rept., p. 723, 736.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 1007–1009, pl. 1. Described as Etholen formation in northern Quitman Mountains. Consists of gray to black limestone conglomerate, with thin lentils and beds of arenaceous shale, buff to olive-brown sandstone, gray limestone, and red nodular limestone. Greatest thickness, about 500 feet, occurs on Etholen Hill, away from which formation becomes thinner. Conformably overlies Espy formation (new), contact sharp; upper contact of formation not exposed.

R. M. Huffington, 1947, Harvard Univ. Summ. of Theses, 1943–45, p. 196–197. Overlies Lasca formation (new).

Type locality: Etholen Knobs, northwest of Etholen section house, and in nearby small hills south of railway, in Quitman Mountains, Hudspeth County. Formation appears to occupy large syncline upon which central dome of Etholen Hill has been superimposed.

Etna Quartz Monzonite Porphyry[1]

Post-Carboniferous: Central Colorado.

Original reference: R. D. Crawford, 1913, Colorado Geol. Survey Bull. 4, p. 80.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 30. Name changed to Mount Aetna quartz monzonite porphyry because name Etna had previously been used elsewhere in United States for a rock unit. Spelling of Etna changed to Aetna to conform to that used on topographic base map of Garfield quadrangle.

Exposed on Mount Aetna (Etna), Garfield quadrangle, Chaffee County.

Etna Sandstone[1]

Pennsylvanian: Central Tennessee and West Virginia.

Original reference: J. J. Stevenson, 1904, Geol. Soc. America Bull., v. 15, p. 125, 201.

Extends on west side of basin north to middle Tennessee and on east side to probably 50 miles north from New River in West Virginia.

†Euchee phase[1]

Miocene, upper(?): Northwestern Florida.

Original reference: L. C. Johnson, 1893, Science, v. 21, p. 90–91.

Named for development at Eucheeanna, Walton County.

Euclid Siltstone Member (of Bedford Shale)

Euclid Sandstone Lentil (in Bedford Shale)[1]

Mississippian: Northern Ohio.

Original reference: W. F. Morse and A. F. Foerste, 1909, Jour. Geology, v. 17, p. 166.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1356. Termed Euclid siltstone member; unit is of unknown areal extent and composed predominantly of massive light-bluish-gray coarse-grained siltstone and some very fine grained sandstones in beds from 3 to 18 inches thick. Maximum thickness about 20 feet. In lower part of the Bedford below Sagamore siltstone member; separated from underlying Cleveland member of Ohio shale by a few feet of dark-gray and black shale and some thin siltstones.

Named for Euclid Creek east of Cleveland, Cuyahoga County. Exposed from Independence Township Cuyahoga County, northeastward to Willoughby Township, Lake County.

Eudora Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: J. Bennett, 1896, Kansas Univ. Geol. Survey, v. 1. p. 113.

Eudora Shale[1] Member (of Stanton Limestone)

Pennsylvanian (Missouri Series): Northeastern Kansas, south-central Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, 2d ser., p. 12, 26, 27, 31, 34.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 118. Overlies Captain Creek limestone member; underlies Stoner limestone member (this is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947). Lower part consists of black fissile shale or in some places of dark clay shale containing thin carbonaceous layer: upper part is greenish to bluish gray and is soft and clayey. Thickness ranges from only 1 foot in some northern outcrops to 50 feet in part of Montgomery County, Kans.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32. In Nebraska, underlies Dyson Hollow limestone zone or member (new) of Stoner limestone. Persistent in Kansas, Missouri, southeastern Nebraska, and south-central Iowa. Type locality stated.

Type locality: West of north-south side road where it joins the east-west Highway about 2 miles east of Eudora, Douglas County, Kans.

†Eufaula sands[1]

Upper Cretaceous: Southwestern Alabama and northeastern Mississippi.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–1888 geographic map of Alabama.

Probably named for exposures at Eufaula, Barbour County, Ala.

Eugene Formation[1]

Oligocene, lower and middle: Northwestern Oregon.

Original reference: W. D. Smith, 1924, Econ. Geology, v. 19, no. 5, p. 462.

H. E. Vokes, P. D. Snavely, Jr., and D. A. Meyers, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–110. As interpreted here, name is extended to include all marine Oligocene sands exposed in hills along southern margin of Willamette Valley. Also a few exposures on hills projecting above alluvium of valley floor, a belt of exposures along western margin of Coburg Hills, and a long tongue extending from area east of Spencer Butte southeastward to vicinity of Dorena Dam. Beds exposed in these outcrops form well-defined unit consisting primarily of coarse- to fine-grained highly arkosic, micaceous sandstones weathering to a yellow to orange-brown color. Thickness about 8,000 feet in hills along southern border of Willamette Valley. Beds have prevailing north-northwest strike and a northeast dip that averages between 10° and 15°. At all exposures mapped Eugene rests on tuffs of Fisher formation; contact is marked by soft friable, arkosic and quartzose sandstone that contains fossil wood. Evidence indicates Eugene and Fisher formations are contemporaneous.

R. E. Corcoran and F. W. Libbey, 1956, Oregon Dept. Geology and Mineral Industries Bull. 46, p. 7, pl. 1. Geographically extended into Salem Hills area where exposed thickness is about 2,200 to 2,500 feet. Unconformably overlain by Salem lavas (new).

I. S. Allison and W. M. Felts, 1956, Geology of the Lebanon quadrangle, Oregon (1:62,500): Oregon Dept. Geology and Mineral Industries. Thickness 400 to at least 2,000 feet in Lebanon quadrangle. Cut out by basic intrusives and unconformably overlain by Stayton lavas in northwestern part of quadrangle. Overlies Mehama volcanics. Oligocene.

U.S. Geological Survey currently considers the Eugene Formation to be lower and middle Oligocene.

Typically exposed in city of Eugene, Lane County.

Euless Member (of Woodbine Formation)

Euless Formation (in Woodbine Group)

Upper Cretaceous (Gulf Series): Northeastern Texas.

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 475, 476, 477, 480. Defined as surface unit which intervenes between basal Pine Bluff member of the Lewisville and base of the Dexter sands. Upper part of formation is gray and dark fossiliferous shales and sandstones. In subsurface, unconformably overlies South Tyler formation. Designation of base of the Euless (base of Dexter sand member), both in surface and in subsurface, is a matter of opinion; in certain areas, base of the Dexter is considered base of the Gulf Cretaceous.

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 242, p. 10. Rank reduced to member status and restricted to a shale unit, in part carbonaceous, with interbedded sandstone lenses, that forms upper part of the Euless as originally defined. Estimated thickness 45 or 50 feet.

Type locality: Town of Euless, Tarrant County.

Eulie Shale (in Chattanooga Shale)

Lower Mississippian: Central Tennessee.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 885, pl. 1. Soft argillaceous shale in three gray, yellowish, or greenish layers, with top layer of nodules at Bransford; it is single layer of greenish shale with nodules at base at Westmoreland. Thickness 6 to 9 inches. Overlies Gassaway shale (new); underlies Westmoreland shale (new). The Eulie and Westmoreland are complementary in their stratigraphic relations; the absence of either would make determination of the status of the other way difficult.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 11. Eulie shale is gray to greenish-gray mudstone that contains phosphatic nodules. Campbell held that this shale was of early Mississippian age, but present writer [Hass] classifies this shale as very late Devonian. Name Eulie shale is not used in present report [Chattanooga shale and Maury formation]; beds so named by Campbell are placed in Maury formation and not named.

Identified only at Bransford, Westmoreland, and Eulie, Sumner County.

Eunice Formation

Pleistocene: Southwestern Louisiana.

J. A. Doering, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1831. Name used for formation covering Lake Charles-Ville Platte-Opelousas-Lafayette area. Younger than newly defined Oberlin formation. Unit has been referred to as upper Beaumont.

Town of Eunice, St. Landry Parish, lies approximately in the center of the area.

Euphemia Dolomite[1] (in Durbin Group)

Middle Silurian: Southwestern Ohio.

Original reference: A. F. Foerste, 1917, Ohio Jour. Sci., v. 17, p. 187, 201, 202.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as basal formation of group. Stratigraphically above Lilley formation.

R. J. Bernhagen, chm., 1960, Ohio Acad. Sci. Geology Sec. Guidebook 35th Ann. Field Conf., p. 13, 17–18, 21. Silurian section in Yellow Springs region shows Euphemia dolomite, 7 to 15 feet thick, above Massie shale and below Springfield dolomite. Niagaran.

Type locality: At quarry described as Lewisburg stone quarry, 1 mile northwest of Lewisburg, Preble County. Euphemia is one-half mile northwest of Lewisburg.

†Eureka Beds[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Probably named for Eureka, Greenwood County.

†Eureka Limestone[1]

Lower, Middle, and Upper Cambrian and Lower Ordovician: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 622.

Tintic district.

†Eureka Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 67, 73.

Named for Eureka, Greenwood County.

Eureka Quartzite[1]

Eureka Group

Middle to Upper(?) Ordovician: Northern Nevada, eastern California, and western Utah.

Original reference: A Hague, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 262.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 8 (table 1), 10–11. Underlies Hanson Creek formation (new) and overlies Pogonip limestone in Roberts Mountains region, Nevada.

G. S. Campbell, 1951, Utah Geol. Soc. Guidebook 6, p. 20, 21 (fig. 4). Underlies Fish Haven dolomite in Millard County, Utah. Thickness about 850 feet.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 29–32, pl. 2. Described in Eureka district where it is 300 to 350 feet thick, underlies Hanson Creek formation and overlies Pogonip group, but in some areas overlies Goodwin limestone and in others Antelope Valley limestone (new). Kirk (1933, Am Jour. Sci., 5th, v. 26) recognized inadequacy of outcrops in Eureka district proper and proposed that section along west base of Lone Mountain be chosen as new type locality. This redesignation has been accepted by U.S. Geological Survey and Lone Mountain section is commonly regarded as an appropriate standard section for comparative purposes.

R. L. Langenheim, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2086 (fig. 2), 2087 (fig. 3), 2092–2095. In Independence quadrangle, California, Eureka group includes Barrel Spring formation, about 150 feet thick, in lower part and an undifferentiated part, about 200 feet, above. Overlies Pogonip group; underlies Ely Springs formation. Mohawkian.

J. F. McAllister, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–95. In Ubehebe Peak quadrangle, California, overlies Pogonip limestone and underlies Ely Springs dolomite. Thickness, 2½ miles north of quadrangle, 400 feet.

G. W. Webb, 1956, Utah Geol. and Mineralog. Survey Bull. 57, p. 13–14; 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2340–2342, 2343–2359. In Lone Mountain area, Eureka quartzite is restricted to the higher 181 feet of Kirk's (1933) section; lowermost 40 feet of post-Pogonip beds are placed in Copenhagen formation. Restricted Eureka is divided into three members which differ from Kirk's subdivision. Lower 35 feet is designated lower discolored quartzite member; middle 95 feet, white quartzite member; upper, gray quartzite member. Normally overlain by dark dolomites generally considered to be Cincinnatian. Correlations discussed.

H. R. Pestana, 1960, Jour. Paleontology, v. 34, no. 5, p. 109–112. Group includes Johnson Spring formation (new) which is name proposed for undifferentiated upper part of Eureka group of Langenheim and others (1956). Middle Ordovician.

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 10 (fig. 3), 23–24, pl. 1. In White Pine district, overlies Pogonip formation of Mount Hamilton group (new); underlies Hanson Creek dolomite. Thickness 250 to 400 feet. Age of formation probably Middle Ordovician but may be Upper Ordovician in upper part.

U.S. Geological Survey currently considers the Eureka quartzite as Middle to Upper(?) Ordovician.

Standard section: Kirk's Lone Mountain section which is along west base of Lone Mountain, about 15 miles airline northwest of Eureka, Eureka County. Named for exposures at Eureka, Nev.

†Eureka Shale[1]

Devonian(?): Northern Arkansas.

Original reference: J. C. Branner and F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. xiii, 26–27.

Named for Eureka Springs, Carroll County.

Eureka Tuff (in Silverton Volcanic Group)

Eureka Rhyolite (in Silverton Volcanic Series)[1]

Tertiary, middle and upper: Southwestern Colorado.

Original reference: Whitman Cross and Ernest Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 120.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 14, 77–78. Mainly in flows or welded tuffs. Maximum observed thickness near Eureka Gulch of 2,000 feet, thins out to west, north, and east. Typical exposure and geographical extent cited.

U.S. Geological Survey currently classifies the Eureka Tuff as a formation in the Silverton Volcanic Group and designates the age as middle and late Tertiary on the basis of a study now in progress.

Greatest and most typical exposure in steep walls of Animas Valley at and above Eureka Gulch. Widely distributed in Silverton quadrangle and extends eastward down Henson Creek as far as Lake City and for a few miles into San Cristobal quadrangle.

Eutaw Formation[1]

Eutaw Formation (in Selma Group)

Upper Cretaceous: Alabama, western Georgia, eastern and northern Mississippi, and western Tennessee.

Original reference: E. W. Hilgard, 1860, Miss. Geol. and Agric. Rept., p. 3, 61–68.

L. W. Stephenson and W. H. Monroe, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1642 (fig. 2), 1648–1649. Formation includes Tombigbee sand member at top. Underlies (west to east) Coffee sand, Mooreville tongue of Selma chalk, and Blufftown formation. Blufftown formation, as defined here, includes additional beds below Blufftown marl (as originally defined) that were correlated with upper part of Eutaw by Veatch (1909, Georgia Geol. Survey Bull. 18) and with "typical beds of Eutaw" by Stephenson (1911).

C. W. Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 13–17. As herein described, formation in Georgia is restricted to beds that Stephenson (1911, Georgia Geol. Survey Bull. 26) thought lay below Tombigbee sand member but has since discovered that they are equivalent to it. Beds that Stephenson called Tombigbee sand member are herein called Blufftown formation. Eutaw is more than 100 feet thick. Base of formation is littoral deposit of coarse gray or iron-stained crossbedded sand; remainder consists chiefly of platy sandy clay and clayey sand. Unconformably overlies Tuscaloosa formation; uncomformably underlies Blufftown formation.

L. C. Conant and W. H. Monroe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 37. Restricted at base to exclude glauconitic crossbedded sand, gravelly sand, and laminated clay beds herein named McShan formation.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. As mapped in Mississippi, includes Tombigbee sand member; overlies Tuscaloosa formation, undifferentiated.

W. H. Monroe, L. C. Conant, and D. H. Eargle, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 188 (fig. 1), 207–210. Unconformably overlies McShan formation and apparently overlaps it toward north. Underlies Mooreville chalk. Includes Tombigbee sand member at top. Thickness about 175 feet.

D. H. Eargle, 1955, U.S. Geol. Survey Bull. 1014, p. 23–32. In Georgia, formation in Chattahoochee River valley consists of basal bed containing coarse grains of quartz sand and other detrital materials as well as borings of *Halymenites major*. Basal sand is overlain by dark-gray soft shale interbedded with fine white sand. Toward the east formation apparently becomes nonmarine and consists of pale-tinted sands containing a few thin beds of clay. Thickness about 125 feet in Chattahoochee Valley; thins toward the east, possibly owing in part to overlap, to about 77 feet in Marion County. East of Flint River, cannot be differentiated from overlying Blufftown formation. Overlies Tuscaloosa formation. Crops out along narrow belt from Chattahoochee River to Flint River; east of Flint River, forms base of sequence of rocks so similar lithologically that Eutaw and overlying rocks up to base of Ripley formation cannot be differentiated.

H. L. Reade, Jr., and J. C. Scott, [1948], Profile showing geology along U.S. Highway 331, Montgomery County, Alabama (1:16,000): Alabama Geol. Survey. Map legend shows Eutaw formation in Selma group.

W. S. Parks, 1960, Mississippi Geol. Survey Bull. 87, p. 22 (table 2), 30–40, pl. 3. Eutaw, in this report [Prentiss County], refers to strata between McShan formation below and Coffee formation above and includes two distinct units: the lower typical Eutaw beds, and Tombigbee sand member. Thickness 185 to 225 feet.

Named for Eutaw, Greene County, Ala.

Evacuation Creek Member (of Green River Formation)[1]

Eocene: Northeastern Utah and northwestern Colorado.

Original reference: W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168.

D. C. Duncan and Carl Belser, 1950, U.S. Geol. Survey Oil and Gas Inv. Map OM–119. Described in Piceance Creek basin, Colorado. Forms upper part of formation and contains alternating brown-weathering siltstone, sandstone, and gray marlstone near base but grades upward to predominantly sandstone and minor marlstone. In some reports, upper part of sequence in central part of basin has been tentatively assigned to Bridger formation. These upper beds are equivalent to upper part of Evacuation Creek member as identified near Parachute Creek. Because no convenient horizon was found to subdivide upper part of sequence penetrated by drilling, it is included in Evacuation Creek member. Thickness about 1,000 feet as recognized in well cuttings and surface sections. Overlies Parachute Creek member.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 413–416. Described in Duschesne, Uintah, and Wasatch Counties, Utah, where it is 600 to 865 feet thick and consists chiefly of bedded shale, mudstone, marlstone, siltstone, and sandstone. Includes Horse Bench sandstone bed. Overlies Parachute Creek member. Transitional and intertonguing relationships with overlying Uinta formation. Top of member rises toward central part of Uinta Basin as indicated by correlation of tuff beds. Contact selected arbitrarily and defined by reference to correlatable tuff beds here included in Evacuation Creek.

Named for exposures on Evacuation Creek, Utah.

Evans Granite[1]

Precambrian(?): Central northern Colorado.

Original references: J. Underhill, 1906, Colorado Univ. Studies, v. 3, no. 4, p. 272; 1906, Colorado Sci. Soc. Proc., v. 8, p. 103–122.

Probably named for Mount Evans, Clear Creek County.

Evans Creek coal series[1]

Eocene: Western central Washington.

Original reference: B. Willis, 1886, U.S. 10th Census, v. 15, pls. 81, 84.

Puget Sound region.

Evans Gulch Porphyry[1] (in Gray Porphyry Group)

Upper Cretaceous(?) or early Tertiary: Northern central Colorado.

Original reference: S. F. Emmons, J. D. Irving, and G. F. Loughlin, 1927, U.S. Geol. Survey Prof. Paper 148.

C. H. Behre, Jr., 1953, U.S. Geol. Survey Prof. Paper 235, p. 52–53, 57, pl. 1. Closely resembles Mount Zion porphyry. Probably no Mount Zion porphyry occurs in area here described [west slope of Mosquito Range], but possibly some highly altered rock on south slope of Prospect Mountain, here mapped as Evans Gulch porphyry, should be grouped with Emmons' Mount Zion porphyry. In igneous sequence, intrusion of quartz diorite porphyry was followed by intrusions of Evans Gulch and Sacramento porphyries and typical Lincoln porphyry; relative ages of these porphyries not determinable. Older than Iowa Gulch porphyry. Igneous rocks that are younger than Precambrian in area of this report are either wholly or mainly Tertiary and only possibly in part late Cretaceous or early Pleistocene in age.

Named for exposures in Evans Gluch, east of Leadville, Rake County.

Evans Landing facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 167–169.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 2. Mississippian facies nomenclature discussed. Correlation chart lists Evans Landing as facies of Carwood formation.

Type section: Along steep ravine and cascade, cut into Ohio Valley bluff, north of road, center SE¼ sec. 4, T. 6 S., R. 5 E., 1½ miles north of Evans Landing, Harrison County.

†Evanston coal series[1]

Upper Cretaceous or Eocene: Southwestern Wyoming.

Original reference: C. A. White, 1870, U.S. Geol. and Geog. Survey Terr. 11th Ann. Rept., p. 240–241.

Exposed north of Evanston, Uinta County.

Evanston Formation[1]

Upper Cretaceous and Paleocene: Southwestern Wyoming.

Original reference: L. Lesquereux, 1876, U.S. Geol. and Geog. Survey Terr. Bull. 5, 2d ser., p. 244–248.

H. E. Wood 2d, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 19, pl. 1. Tentatively called Paleocene (Puercan); underlies Almy formation.

J. I. Tracey, Jr., and S. S. Oriel, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 126–128. Veatch (1907 U.S. Geol. Survey Prof. Paper 56) showed formation limited to three small areas near Evanston. Present mapping shows fairly wide distribution of rocks lithologically and temporally equivalent to the Evanston within Fossil Basin. On east side of basin, unit may be traced for great distances where boulder beds dip 25° to 30° to west and form hogbacks. Along this belt, mapped as Almy formation by Veatch, the Evanston conformably overlies Adaville formation, but north of Kemmerer the boulder beds truncate large syncline in the Adaville. Thickness ranges widely due to lack of uniformity in deposition and to subsequent erosion; 1,200 feet near southern boundary of Kemmerer quadrangle, uppermost several hundred feet not present. Contact with overlying Wasatch formation poorly exposed; apparently gradational at type locality, but angular unconformity present at many places. Latest Cretaceous and Paleocene. Formation is significant because of its relation to structural framework of basin; it indicates that principal period of formation of basin extended from latest Cretaceous (Lance) through Paleocene; also dates at least part of orogeny in thrust belt as Late Cretaceous.

Well exposed north of Evanston, Uinta County.

†Evanstonian series[1]

Paleocene: Wyoming.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36. 65–66.

Evansville Sandstone Bed (in Wellington Formation)[1]

Permian: Central northern Oklahoma.

Original reference: J. M. Patterson, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 3, p. 243, 251.

Exposed three-fourths mile east of Evansville.

Everett Member (of Nachusa Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 15B. Shown on columnar section as uppermost member of Nachusa formation; overlies Elm member (new); underlies Hazel Green member (new) of Quimbys Mill formation. Thickness 2 to 6 feet.

Occurs in the Dixon-Oregon area.

†Everett Schist[1]

Ordovician: Southwestern Massachusetts and northwestern Connecticut.

Original reference: W. H. Hobbs, 1893, Jour. Geology, v. 1, p. 717–736, 780–802.

Named for fact it has its maximum thickness within area of Mount Everett, Mass.

†Everglades Limestone[1]

Pleistocene: Southeastern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 101, 154, 157, 325.

Probably named for the Everglades.

Evergreen Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Occurs in Evergreen mine, north of Evergreen Bluff, Ontonagon County.

Evergreen Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Occurs in Evergreen mine, north of Evergreen Bluff, Ontonagon County.

Everona Limestone[1]

Lower Ordovician: Northeastern Virginia.

Original reference: A. I. Jonas, 1927, Geol. Soc. America Bull., v. 38, p. 842.

Exposed from Mitchells Ford, on Rapidan River, to southwest of Rivanna River near Charlottesville, Albemarle County. Named for Everona, Orange County.

Eversole Chert[1] Member (of Columbus Formation)

Middle Devonian: Central Ohio.

Original reference: C. R. Stauffer, 1909, Ohio Geol. Survey Bull. 10, p. 72–74.

J. W. Wells, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 276 (fig. 1). Shown on generalized section as chert member of Columbus formation.

Wilber Stout and R. A. Schoenlaub, 1945, Ohio Geol. Survey, 4th ser., Bull. 46, p. 21. In Delaware County, underlies Klondike member; overlies Bellepoint member. Thickness 10 feet.

J. W. Wells, 1947, Ohio Jour. Sci., v. 47, no. 3, p. 121 (fig. 3). Shown on chart as underlying Delhi (Klondike) member and overying Bellepoint member.

Named for Eversole Run, Delaware County.

Everton Formation

Everton Formation (in Buffalo River Group)

Everton Limestone[1]

Middle Ordovician: Northern Arkansas and southern Missouri.

Original reference: A. H. Purdue, 1907, Geol. Soc. America Bull., v. 18, p. 251–256.

G. C. Branner, 1929, Arkansas Geol. Survey Geol. Map of Arkansas. Includes Calico Rock sandstone member (new).

H. S. McQueen, 1937, Missouri Geol. Survey and Water Resources 59th Bienn. Rept., app. I, p. 6, 9. Everton formation (sandstone and dolomite) included in Buffalo River Group.

J. A. Straczek and D. M. Kinney, 1950, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–1. Mapped in Batesville manganese district. Unconformably underlines St. Peter sandstone. Middle Ordovician.

E. B. Brewster and N. F. Williams, 1951, Guidebook to the Paleozoic rocks of northwest Arkansas: Arkansas Resources Devel. Comm., Div. Geology, p. 12, columnar section. Formation includes Kings River member in lower part and Newton sandstone member in upper part. Thickness about 400 feet. Overlies Powell dolomite; underlies Jasper limestone. Lower Ordovician.

E. E. Glick and S. E. Frezon, 1953, U.S. Geol. Survey Circ. 249, p. 4–6, measured sections. Formation described in Newton County, Ark., where it overlies Powell dolomite and underlies St. Peter sandstone. Thickness about 405 feet. Composed of four lithologic units (ascending): sequence of dolomite and sandstone, 245 feet exposed, base covered; Newton sandstone member, 8 feet thick; sequence of dolomite and sandstone, 80 feet thick; and Jasper member, 55 feet thick. Middle Ordovician.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 117. Basal formation in Buffalo River group. Underlies Jasper formation.

Named from Everton, Boone County, Ark.

Evington Group

Paleozoic(?): South-central Virginia.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1), 93. Includes (ascending) Candler formation (new), Joshua schist (new), Arch marble (new), Pelier schist (new), Mount Athos formation, and Slippery Creek greenstone (new). Overlies Precambrian. Paleozoic(?).

G. H. Espenshade, 1954, U.S. Geol. Survey Bull. 1008, p. 14, 15 (table 1), pl. 1. Comprises (ascending) Candler formation, Archer Creek formation (new), Mount Athos formation, and unnamed greenstone.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2), 28–30, pl. 1. Age shown on columnar section as Lower Paleozoic(?).

Type locality: In vicinity of Evington, 11 miles southwest of Lynchburg, Campbell County. Lynchburg quadrangle.

Ewing Limestone Member (of Conemaugh Formation)[1]

Ewing Limestone (in Conemaugh Group)

Ewing limestone member

Upper Pennsylvanian: Southeastern Ohio, western Pennsylvania, and northern West Virginia.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, p. 889, 890, 897, pls. facing p. 889, 900, 912.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 78, 95, 96, fig. 21. Ewing limestone in Conemaugh group. Overlies Pittsburgh red beds; separated from overlying Ames limestone by Harlem coal. Thickness in Fayette County, 5 to 10 feet.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 45–46, geol. map. In Morgan County, Ewing limestone member (Conemaugh series) is nonpersistent; stratigraphically overlies Cow Run sandstone and shale member; occurs from 6 to 11 feet below Barton coal and from 30 to 40 feet below Ames limestone. Thickness 6 inches to 4¾ feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 127–129. Member of Upper Bakerstown cyclothem in report on Athens County. Throughout outcrop area, the Ewing is represented by three lithologic varieties. First is single nodular layer 2 to 12 inches thick of light-gray to gray dense brecciated or sandy micaceous limestone. Second type includes layers but more commonly nodules and veins of limestone distributed in thicknesses of up to 15 feet of sandy shale and shaly sandstone. Third type comprises small nodules of limestone embedded in clay shale. Limestone in any of these types may be ferruginous. In Dover Township, a 6-inch layer of ironstone represents Ewing member. Overlies Cow Run sandstone member. Conemaugh series.

Named for Ewing Site, in Sunday Creek valley, Hocking or Perry County, Ohio.

Excello Formation (in Cabaniss Group)

Excello Formation (in Cherokee Group)

Excello Shale Member (of Senora Formation)

Pennsylvanian (Des Moines Series): Western and northern Missouri, southeastern Kansas, and northeastern Oklahoma.

W. V. Searight *in* W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. Shown on stratigraphic column as uppermost formation in Cabaniss group. Underlies Blackjack Creek limestone member of Fort Scott formation; overlies Lagonda formation. Exposed in Carroll and Livingston Counties.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as formation in Cabaniss group. Underlies Fort Scott formation of Marmaton group; overlies Mulky formation.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 3, 5, 14 (fig. 4). Geographically extended into Oklahoma where it is at top of Senora formation. Overlies Breezy Hill limestone. Cabaniss group.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 31 (fig. 20), 35. Formation composed largely of black fissile shale which contains abundant flattened, phosphatic concretions and large biscuit-shaped concretions which measure a few feet in diameter. Thickness at type section about 4 feet. Underlies Blackjack Creek limestone member of Fort Scott; overlies Mulky formation. Type section designated.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 88–89. Geographically extended into Kansas. Thickness 2 to 5 feet. Uppermost division of Cabaniss subgroup of Cherokee group.

Type section: NW¼ sec. 30, T. 56 N., R. 14 W., 2.6 miles west of U.S. Highway 63, west of Excello, Macon County, Mo., in highwall of coal strip pit.

Excelsior Formation[1]

Middle Triassic(?): Southwestern Nevada.

Original reference: S. W. Muller and H. G. Ferguson, 1936, Geol. Soc. America Bull., v. 47, p. 241–252.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1953, Geology of the Coaldale quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-23]. Described in Coaldale quadrangle. Dominantly volcanic. Estimated thickness 12,000 feet, but no complete section present. Nowhere in contact with Lower Triassic Candelaria formation, and it is presumed that two are present on different plates of major thrust. In hills near Readlich, greenstone breccia with pillow lavas unconformably overlies Diablo formation and appears to mark base of Excelsior. On southern flank and crest of Pilot Mountains, formation is unconformably overlain by Jurassic Dunlap formation and in adjacent Mina quadrangle is unconformably overlain by Upper Triassic Luning formation. Tentative assignment of formation to Middle Triassic is based on fossils from interbedded limestone lens in volcanic rocks of Gillis Range, about 50 miles northwest, but lack of contact with Candelaria and presence of volcanic rocks of probable Permian age in Toyabe Range, 60 miles northeast, make assignment to Middle Triassic uncertain.

D. I. Axelrod and W. S. Ting, 1960, California Univ. Pub. Geol. Sci., v. 39, no. 1, p. 3. In fault contact with upper Pliocene Wichman formation (new).

Named for Excelsior Mountains, where formation is well exposed in Gold Range mining district, about 6 miles southwest of Mina, Mineral County.

Exeter Diorite[1]

Upper Devonian(?): Southeastern New Hampshire.

Original reference: C. H. Hitchcock, 1870, 2d Ann. Rept. Geol. New Hampshire, map and p. 32.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Probably belongs to New Hampshire plutonic series of Upper Devonian(?) age.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. and Devel. Comm., p. 66, 187. Has average composition of granodiorite, though still termed diorite. Included in newly named Hillsboro plutonic series which is younger than Lower Devonian(?) and older than Mississippian(?).

Named for occurrence in Exeter Township, Rockingham County.

Exeter Sandstone[1]

Upper Jurassic: Western Oklahoma.

Original reference: W. T. Lee, 1902, Jour. Geology, v. 10, p. 45–46.

R. B. Johnson, 1959, U.S. Geol. Survey Bull. 1071–D, p. 94–95. Entrada sandstone can be traced from Huerfano Park area by surface exposures and subsurface data to type locality of Exeter sandstone in northwestern New Mexico. In view of wide usage of name Entrada sandstone, and general acceptance of correlation of Entrada sandstone with Ocate and Exeter sandstones, names Exeter and Ocate sandstones are herein abandoned for usage in southeastern Colorado and northeastern New Mexico and name Entrada sandstone used.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in Cimarron County, Okla. Jurassic.

Named for exposures near Exeter post office [now called Johnson], Union County, N. Mex.

Exline cyclothem (in McLeansboro Group)

Pennsylvanian: Illinois and Iowa.

J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, p. 145. Cyclothem in McLeansboro group. In sequence above Gimlet cyclothem and below Trivoli cyclothem.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 119–121. Cyclothem includes Exline limestone and shale. Strata here referred to Exline cyclothem were formerly included in upper part of Gimlet cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 54 (table 3). Term discontinued.

Named for Exline, Appanoose County, Iowa.

Exline Limestone (in Appanoose Group)

Exline Limestone (in Henrietta Group)

Exline Limestone (in Pleasanton Group)

Exline Limestone Member (of Modesto Formation)

Pennsylvanian (Missouri Series): Southern Iowa, northern and western Illinois, and northern Missouri.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 62, 65–66. Limestone at top of Henrietta group. Upper 3 inches laminated lower 1 foot massive; dark blue gray, earthy, medium grained; well jointed, weathers brown and slabby; fossiliferous with *Chonetes* and white crinoid stems which contrast strongly with weathered yellow-brown matrix. Separated from underlying Cooper Creek limestone (new) by underclay, coal, and shale. Traced into northern Missouri.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 31). Shown on chart at top of Appanoose group in Iowa.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. v. (fig. 1), 10. In Pleasanton group, Missouri series.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38, 49 (table 1). Member of Modesto formation (new). In northern western Illinois, overlies Lonsdale limestone member and underlies Trivoli sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: About 1½ miles south of southwest corner of Exline, Appanoose County, Iowa. Well exposed in west-flowing tributary ravine of North Shoal Creek, SE¼ sec. 6, T. 67 N., R. 17 W.

Extension Breccia (intrusive)[1]

Tertiary: Central Nevada.

Original reference: T. B. Nolan, 1930, Nevada Univ. Bull., v. 24, no. 4, p. 17.

Well exposed in Tonopah Extension mine, Tonopah district.

Eyer Formation (in Hatter Group)

Eyer Member (of Hatter Formation)

Middle Ordovician (Bolarian): South-central Pennsylvania.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 193. Lowermost member of formation. Dark impure limestone, partly calcarenite. Thickness 6 feet in type section. Underlies Grazier member (new); overlies Clover member of Loysburg formation.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 7–10. Relationship to Grazier member not definitely known. Unit is either truncated by the Grazier or represents an offlapping unit subsequently overlapped by that member. Thus, beds may be stratigraphically more closely related to Loysburg formation than to the Hatter, but are included in the Hatter because of strong lithologic similarity to Grazier member. Maximum thickness 37 feet. Derivation of name stated.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8 p. [1402], 1407. Rank raised to formation in Hatter group or Hatterian subseries (Bolarian series).

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 82, 102. Discussed as a member.

Type section: On two sides of Pennsylvania Railroad cut north of Union Furnace, Huntingdon County. Named for Eyer, north of Union Furnace.

Fabius Group

Devonian or Mississippian: Missouri, Illinois, Indiana, Iowa, and Kentucky.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 101, chart 5; J. M. Weller, 1948, (abs.) Am. Jour. Sci., v. 246, no. 3, p. 150. Proposed for those lower Kinderhookian strata which are variously referred to either Mississippian or Devonian system. In type area, in Mississippi Valley, group consists of (ascending) Grassy Creek shale, Saverton shale, and Louisiana limestone. Unconformably overlies strata ranging from Ordovician to Devonian age and, locally at least, is overlain unconformably by strata of Easley group (new).

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 14. Replaced by Champ Clark group (new).

M. G. Mehl, 1960, Denison Univ. Sci. Lab. Jour., v. 45, art. 5, p. 94. Weller and others (1948) proposed that the Kinderhook be considered a series and divided into two groups, the Easley and Fabius. The Easley was to include all Kinderhookian strata which are almost universally recognized to be of Mississippian age and the Fabius to include those Kinderhookian strata which are believed by some to be Mississippian but by others to be Devonian. Position of the committee in establishing two Kinderhook groups based on above distinction does not appear tenable. It is here recommended that terms Fabius and Easley groups be dropped from list of stratigraphic designations in Missouri.

Name derived from South Fabius River which flows from Knox through northern Marion County, Mo., where above formations are well exposed.

Fagasa Gabbro

Pliocene(?): Samoa Islands (Tutuila).

R. A. Daly, 1924, Carnegie Inst. Washington Pub. 340, p. 113–115. Elliptical body of gabbro with diameters of 100 to 200 meters. Cuts across older series of basalts.

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1296. Appears to be dike in Pago volcanic series (new), considered to be Pliocene or early Pleistocene(?).

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 162. Pliocene(?).

Occurs on divide about 300 meters south of Pago Pago-Fagasa trail.

Fagundas Conglomerate[1]

Pennsylvanian: Pensylvania.

Original reference: J. F. Carll, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 38–40.

Occurs in hill tops at Fagundas, Warren County.

Fairbank Formation or Tongue (of Fountain Formation)

Pennsylvanian: Eastern Wyoming and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 3, 32, 35, 44; R. L. Bates, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 10, p. 1990–1991. Consists of red sandstone or quartzite which is locally calcareous. Basal tongue of Fountain formation. Comprises Division VI of Hartville "formation" (Condra and Reed, 1935). Thickness 30 to 100 feet. Underlies Reclamation group (new); overlies Pahasapa limestone.

Type locality: North Platte River bluffs immediately north and northwest of site of abandoned village known as Fairbank, in sec. 27, T. 27 N., R. 66 W., Platte County, Wyo.

Fairbanks Loess

Quaternary: Central eastern Alaska.

T. L. Péwé, 1958, U.S. Geol. Survey Geol. Quad. Map. GQ–110. Massive, homogeneous, unconsolidated eolian silt. Buff to tan-gray when dry, brown when wet. Contains three white volcanic ash beds ½ inch to 6 inches thick. Thickness ranges from 3 feet on upper hill slopes to maximum of 200 feet on middle slopes and low hill tops.

Named from city of Fairbanks. Widespread on upper slopes and hilltops in northern one-half of Fairbanks (D-2) quadrangle. Excellent exposures in placer excavations in quadrangle, especially on Gold Hill, 8 miles west of Fairbanks, and in center sec. 8, T. 1 S., R. 2 W., 9 miles west of Fairbanks.

Fairbury Trachyte (in Garren Group)

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Includes varied sequences of extrusive members in vicinity of Fairbury Draw on Bell ranch. Consists of four members: basal breccia about 140 feet thick; plagioclase trachyte member which varies in thickness from 190 to 390 feet; anorthoclase trachyte member about 100 feet thick; and tuff member (thickness not given). Overlies Pantera trachyte (new); underlies Means trachyte (new).

Composite type section: East face of Garren Mountain for basal breccia; north face of Buck Mountain for plagioclase trachyte member; southeast bank near mouth of Fairbury Draw for anorthoclase trachyte member; east face of Blanquito Hill and west slope of hill east-northeast of Bell's ashpit for tuff member, Culberson County.

Fairfax[1] (coalbearing rocks)

Eocene: Western Washington.

Original reference: W. F. Jones, 1914, Geol. Soc. America Bull., v. 25, p. 122.

Probably named for town of Fairfax, Pierce County.

Fairfax Formation[1]

Pennsylvanian (Conemaugh): Northern West Virginia and western Maryland.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

Exposed around Fairfax, Grant County, W. Va.

Fairfax Limestone[1]

Pennsylvanian: Northern West Virginia.

Original reference: D. B. Reger, 1923, West Virginia Geol. Survey Rept. Tucker County, p. 130, 149, 156.

Visible near summit of Fairfax Knob, Grant County.

Fairfax Schist

Precambrian(?): Northern Vermont.

E. C. Jacobs, 1935, (abs.) Geol. Soc. America Proc. 1934, p. 85. Fine-grained schist. Outcrop belt several miles wide. At eastern margin is in undertermined contact with Mount Mansfield series of schist and gneisses.

Present in Green Mountain area.

†Fairfield coal group (in Mesaverde Group)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: E. T. Hancock and J. B. Eby, 1930, U.S. Geol. Survey Bull. 812C, p. 206, 208-230.

In Meeker, Axial, and Monument Butte quadrangles. Named for Fairfield mine, Meeker quadrangle.

Fairfield Member (of Canajoharie Formation)

Fairfield Slate[1]

Middle Ordovician (Mohawkian): East-central New York.

Original reference: Lardner Vanuxem, 1842, Geology New York, pt. 3, p. 56–60.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 270–271, pl. 4. Redefined as shale member at top of Canajoharie formation. Includes upper three graptolite zones of the formation; uppermost is Fort Plain zone. At type locality of the Canajoharie, member contains conspicuous set of five metabentonites in lower part. Higher up, beds become interbedded black shales and gray-weathering silty shales; include metabentonites. Composed of silty and sandy beds in Minaville section where upper limit is uncertain. Maximum thickness at least 450 feet. Overlies Minaville member (new) of Canajoharie formation; underlies Utica formation. Extends westward as gradationally overlapping tongue of the formation passing through the Dolgeville interbedded facies into upper Denmark member (new) of Sherman Fall formation. Derivation of name.

Named for Fairfield Township, Herkimer County.

Fairfield Member (of Cuyahoga Formation)[1]

Mississippian (Kinderhook): South-central Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 671.

F. T. Holden, 1942, Jour. Geology, v. 50, p. 45. Included in Hocking Valley conglomerate facies. Consists of thick coarse- and medium-grained sandstones alternating with shale layers commonly of equal thickness with the sandstones. Thickness of each sandstone may be as much as 65 feet. Overlies Lithopolis sandstone member; underlies Black Hand conglomerate member.

Named from development in Fairfield County.

Fairhaven Diatomaceous Earth Member (of Calvert Formation)

Fairhaven Member (of Calvert Formation)[1]

Miocene, middle: Eastern Maryland.

Original reference: G. B. Shattuck, 1904, Maryland Geol. Survey, Miocene Volume, p. lxxii.

Lincoln Dryden and R. M. Overbeck, 1948, Maryland Dept. Geology, Mines and Water Resources [Repts.] Charles County, p. 53–56. Described in Charles County where it is about 75 feet thick at Popes Creek. Of this total, only one bed, 17 feet thick, contains more than an insignificant proportion of diatoms; it is suggested that term Fairhaven member be used for lower part of Calvert formation and "diatomaceous earth" or "diatomite" be reserved for the one bed containing a high percentage of diatoms.

Named for Fairhaven, Anne Arundel County.

Fairlee Quartz Monzonite

Fairlee Granite Gneiss[1]

Ordovician: East-central Vermont and west-central New Hampshire.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table facing p. 288.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 499. Belongs to Highlandcroft magma series.

J. B. Hadley, 1950, Vermont Geol. Survey Bull. 1, p. 22. Described as coarse-grained greenish-gray quartz monzonite with local pink tinges. Generally appears more or less crushed and foliated; converted to phyllonite on margins of the body. Age designated probably Upper Ordovician. Extends into New Hampshire. Type locality given.

Type locality: Strikingly exposed on cliffs known as the Palisades in Fairlee, Orange County, Vt.. Forms several prominent hills in Mount Cube quadrangle in Bradford, Vt., and Piermont, N.H.

Fairmont Shale Member (of Hennessey Shale)[1]

Permian: Central northeastern Oklahoma.

Original reference: F. L. Aurin, H. G. Officer, and C. N. Gould, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, p. 786–799.

Named for exposures near Fairmont, Garfield County.

†Fairmount Gneiss[1]

Precambrian: Southeastern Pennsylvania.

Original reference: T. D. Rand, 1887, Pennsylvania 2d Geol. Survey Ann. Rept. 1886, p. 1601–1603.

Forms hill at Fairmount, in vicinity of Philadelphia.

Fairmount Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Central eastern Ilinois.

Original reference: E. F. Lines, 1912, Illinois Geol. Survey Bull. 17, p. 59, 75.

Crops out over area of less than 2 square miles near Fairmount, Vermilion County.

Fairmount Limestone Member (of Fairview Formation)[1]

Fairmount Formation (in Maysville Group)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and northern Kentucky.

Original reference: J. M. Nickles, 1902, Cincinnati Soc. Nat. History Jour., v. 20, p. 78.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Fairmount formation, in Maysville group, shown on generalized stratigraphic column of Ordovician and Silurian rocks exposed in Jefferson and Switzerland Counties. Limestone, blue, thick bedded at top; contains minor amounts of shale. Thickness 30 to 60 feet. Occurs above Mount Hope formation and below Bellevue formation. Cincinnatian.

Named for Fairmount, a part of Cincinnati, Ohio.

†Fairmount Slate[1]

Upper Cambrian: Northwestern Georgia.

Original reference: H. K. Shearer, 1918, Georgia Geol. Survey Bull. 34, map opposite p. 43.

Named for development about Fairmount, Gordon County.

Fairplay Glacial Substage

Pleistocene (Wisconsin): Central Colorado.

Q. D. Singewald, 1950, U.S. Geol. Survey Bull. 955–D, p. 103, 123, 125, 128, pl. 9 [1951]. The times of maximum ice advance and of the two principal ice stands during retreat are called Fairplay, Briscoe, and Alma substages, respectively of Wisconsin stage of glaciation.

In northwestern Park County.

Fairplay Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 33, fig. 3. Shown on columnar section as underlying Mortimer member (new) and overlying Eagle Point member (new).

Occurs in Dixon-Oregon area.

Fairport Chalky Shale Member (of Carlile Shale)[1]

Upper Cretaceous: Western Kansas and southeastern Colorado.

Original reference: W. W. Rubey and N. W. Bass, 1925, Kansas Geol. Survey Bull. 10, p. 16, 40.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 24. Thickness 85 feet in Russell County to 147 feet in Hamilton County. Underlies Blue Hills shale member; overlies Greenhorn limestone.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 121. In Baca County, Colo., consists of alternating beds of chalky limestone and tan platy to fissile chalky shale.

Named for exposures a few miles south and west of Fairport, Russell County, Kans.

Fairview Diorite[1]

Tertiary: Central southern Colorado.

Original reference: W. Cross, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 291.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 197. In Silver Cliff-Rosita region, the volcanics, in order of decreasing age, consist of Rosita fragmental andesite, Bunker massive andesite, Fairview diorite in dikes cutting earlier andesite, Bald Mountain dacite flows, rhyolite in dikes, eruptive channels and flows, Pringle andesite, trachyte flows, and Bassick agglomerate.

Named for Mount Fairview, Silver Cliff-Rosita Hills region.

Fairview Formation (in Maysville Group)[1]

Fairview Formation (in Covington Group)

Fairview Member (of Martinsburg Formation)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, north-central Kentucky, and Pennsylvania.

Original reference: R. S. Bassler, 1906, U.S. Natl. Mus. Proc., v. 30, p. 10.

R. S. Bassler, 1919, The Cambrian and Ordovician deposits of Maryland: Maryland Geol. Survey, p. 157, 173. Martinsburg shale in southern Pennsylvania and Maryland include a lower Maysville division (Fairview) consisting of fossiliferous gray sandstone with *Orthorhynchula linneyi* beds at top. Thickness 300 feet. Overlies Eden division; underlies upper Maysville division (Oswego sandstone).

Bradford Willard and A. B. Cleaves, 1939, Geol. Soc. America Bull., v. 50, no. 7, p 1175, 1176, 1177, 1183. Upper member of Martinsburg formation in Pennsylvania. Thickness 135 to 246 feet. Overlies beds of Eden and older in lower part of formation. Underlies Bald Eagle member of

Juniata formation, transitional. Massive sandstone at top of Martinsburg in Schuylkill Gap area is herein named Shochary sandstone member. Lithologically, stratigraphically, and faunally, it appears to be correlate of Bassler's Fairview sandstone in south-central section but it is not traceable through.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on generalized column of Ohio as overlying Latonia formation of Eden group. Thickness 115 feet. Includes (ascending) Mount Hope and Fairmount members.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1029–1030. Middle formation of Covington group. Overlies Eden formation; underlies McMillan formation. Fairview and McMillan formations constitute standard for median Cincinnatian Maysville stage.

R. R. Pulse and W. C. Sweet, 1960, Jour. Paleontology, v. 34, no. 2, p. 237–264. Fairview formation (Bassler, 1906) has been divided into two members (ascending) Mount Hope and Fairmount (Nickles, 1902). These units were originally distinguished by their contained bryozoan faunas, the Mount Hope being the "*Amplesopora septosa beds*" and the Fairmount the "*Dekayia aspera* beds." Formation consists of 100 to 120 feet of thin alternating beds of bluish-gray fossiliferous limestone and greenish-gray shale. Individual beds are both laterally and vertically gradational, and a number of different structural types of both limestone and shale occur within formation. In general, shale beds are thicker and limestone beds correspondingly thinner in lower 50 to 60 feet than in upper 60 to 70 feet. As a result, formation can be crudely subdivided into two members of about same thickness, which correspond roughly, at least in type section, to Nickles' (1902) Mount Hope and Fairmount divisions. In present study, more calcareous upper Fairview has been assigned to the Fairmount, and shalier lower Fairview has been regarded as Mount Hope. In sections where this interval is well exposed, the level of first appearance of *Strophomena planoconvexa* was considered to mark boundary between the two members. Overlies Eden formation; underlies McMillan formation. Conodonts described.

Named for Fairview Heights, Cincinnati, Ohio.

†Fairview Shale[1]

Lower Devonian: Colorado.

Original reference: J. M. Hill, 1909, U.S. Geol. Survey Bull. 380, p. 24, 35–36.

J. W. Gabelman, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 8, p. 1584. Term Fairview facies could be applied to lower part of Parting quartzite member of Chaffee formation in northern Sangre de Cristo Range. This part of Parting has been termed Elbert facies but name Fairview facies is more applicable as Lower Devonian Fairview shale is geographically nearer to region discussed.

Named for fact that shale forms hanging wall in Fairview mine located 7½ miles northwest of Pitkin, Gunnison County. Crops out in Quartz Creek district.

Fairview Valley Formation

Permian: Southern California.

O. E. Bowen, Jr., *in* L. A. Wright and others, 1953, California Jour. Mines and Geology, v. 49, pl. 2. Shown on columnar section as unconformably underlying Sidewinder volcanic series (new) and unconformably overlying Oro Grande series. Thickness about 6,075 feet.

O. E. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 16 (fig. 2), 36–42, pls. 1, 3, 7. Described as tightly folded series of clastic and limy sediments including dark-gray limestone conglomerate, gray-green hornfelsed, silty and sandy limestones, and dense black limestone in thin lenses. Intruded and overlapped by volcanic rocks of Triassic(?) Sidewinder volcanic series (new).

Type section: Fairview Valley, Barstow quadrangle, San Bernardino County. Crops out over area of approximately 3 square miles north and northwest of Southwestern Portland Cement Co.'s Reserve quarry and west of Sidewinder gold mine.

Fais Limestone

Pleistocene or Quaternary (early Holocene): Caroline Islands (Fais).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 347. (correlation chart) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 68, table 5 [English translation in library of U.S. Geol. Survey, p. 82–83]. Named on correlation chart. Elevated coral reef limestone. Younger than Caroline limestone. Principally coral limestone; lesser amount of *Halimeda* limestone. Pleistocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 31. Early Holocene.

Fais (Feys) Island. Constitutes second, third, and fourth terraces on island.

Fajardo Formation

Fajardo Shales[1]

Upper Cretaceous: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 61.

C. A. Kaye, 1959, U.S. Geol. Survey Paper 317–A, p. 7 (table 2), 10 (fig. 4), 27–29, pl. 2. Termed Fajardo formation in San Juan area because shale is not prevalent lithology. Consists of light-colored ashy siltstone, siliceous siltstone, and chert, interfingering graywacke, conglomerate, and impure limestone. A little south of Río Guaynabo section, massive to stratified purplish-gray tuff, interbedded in upper part of section, that may be equivalent of Meyerhoff's and Smith's San Diego formation, are included in the Fajardo because it seems that the typical ashy siltstone is only a facies and that formation consists of wide range of rock types forming an interfingering sequence. Maximum thickness, Trujillo Alto Road, estimated 3,000 feet; northwest of Guaynabo, 1,885 feet. Overlies Figuera volcanics; contact conformable in some places, but in others angularity exists. No fossils found. Believed to be Paleocene or Eocene.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover, 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 141–143. Fajardo formation of this report includes both Fajardo shales of Berkey and underlying volcanic sandstones that Meyerhoff (1931, New York Acad. Sci., v. 1, pt. 3) apparently called Luquillo formation of Cretaceous age. Formation crops out in northeastern corner of island across nose and along northwestern limb of dissected northeast-trending anticline underlying Luquillo Range and adjacent areas. Base is obscured by faulting, and contact relation with underlying volcanic complex not known. Rocks tentatively correlated with Fajardo formation crop out in central Puerto Rico in faulted blocks that lie across main axis of Puerto Rico anticlinorium. Basal contact with volcanic complex in central Puerto Rico appears to be unconformable. Between these two areas, rocks equivalent to Fajardo appear to have been removed by faulting and subsequent erosion. Thickness of formation and equivalent strata ranges from about 8,000 feet in eastern part of island and 6,500 feet in central Puerto Rico to only a few feet in southernmost outcrops in south-central part of island. Includes Aguas Buenas limestone member at base in central Puerto Rico. Upper Createaceous.

Named for outcrops in vicinity of Fajardo, in northeastern part of island.

Falcon Granite Gneiss

Precambrian: Central northern Colorado.

M. F. Boos, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1179. Invaded Idaho Springs and younger Precambrian formations, preceding Mt. Evans quartz monzonite.

Denver Mountain Park Area.

Falcon Limestone Member (of Lykins Formation)

Falcon Tongue (of Minnekahta Limestone in Lykins Formation)

Permian: North-central Colorado and southern Wyoming.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 31, 33. fig. 7. Impure limestone containing numerous thin, irregular, varvelike laminae of red silt ranging in thickness from paper thin to one-tenth inch. Locally several 2-inch seams of vuggy limestone contain black brittle bituminous material. Unit represented at Ralston Creek by unindurated irregularly interlaminated red and gray calcareous silt. Thickness ranges from 2 to 3½ feet. At type locality, unit lies 46 feet stratigraphically below base of Glennon limestone (new) and 58 feet above Lyons formation. Underlies Bergen shale member (new); overlies Harriman shale member (new).

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Designated tongue of Minnekahta limestone in Lykins formation. Underlies Glendo shale member of Lykins. Falcon tongue extends at least from Horse Creek, Wyo., southward to Red Creek Canyon, which is between Colorado Springs and Canyon City, Colo.

Type locality: In west fork of Glennon Canyon, Golden-Morrison area, Jefferson County, Colo. Named from Mount Falcon in southwest part of Morrison quadrangle, sec. 9, T. 5 S., R. 70 W., about 2½ miles southwest of town of Morrison.

Falcon Sandstone Member (of Cook Mountain Formation)

Eocene (Claiborne): Western Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 263. Proposed for upper 500 feet, approximately, of Cook Mountain formation. Characterized by massive crossbedded fossiliferous marine sandstone beds. Underlies La Perla shale member (new) of Yegua formation; overlies Veleno member (new) of Cook Mountain formation.

Named for town of Falcon, on American bank of Rio Grande, 2 miles north of Starr-Zapata County line.

Falkirk Dolomite[1] (in Bertie Group)

Falkirk Member (of Bertie Formation)

Upper Silurian: Western New York.

Original reference: G. H. Chadwick, 1917, Geol. Soc. America Bull., v. 28, p. 173–174.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Member of Bertie formation. Continues eastward into Fiddlers Green dolomite member.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Formation in Bertie group. Overlies Oatka shale; underlies Scajaquada shale. Field work has not demonstrated lateral continuity of Falkirk and Fiddlers Green as shown on present chart. Thick glacial deposits conceal these units in area where they may merge (north of Seneca Lake). Possibility of facies change should not be overlooked. At present time, distinct names are retained for western and central New York.

Derivation of name not stated. Falkirk is in Erie County.

Fall Creek Conglomerate Lentil (of Chemung Formation)[1]

Upper Devonian: Northeastern Pennsylvania and central southern New York.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 74–79, 82, 98, 100, 236.

Bradford Willard, 1939, Pennsylvania Geol. Survey Bull. G–19, p. 300. White (1881) thought that Cascade sandstone, which he recognized in lower Chemung in Susquehanna County, might be equal to Fall Creek conglomerate previously described by Sherwood (1878, Pennsylvania 2d Geol. Survey, v. G) from northern Bradford and Tioga Counties. Because Fall Creek is now considered to be at top of Chemung, this correlation seems unlikely, nor is either the Fall Creek or the Cascade to be correlated with Cuba sandstone, because the Cuba is still higher, at base of Conneaut group. White placed Fall Creek below New Milford formation by 200 to 325 feet, an obvious error if the Fall Creek of White was the same as that of Sherwood. Present study would place Fall Creek below the Luthers Mills by about 50 feet. Hence, it should be very near contact between beds of highest Chemung and lowest Canadaway.

Type locality: Falls Creek, Bradford County, Pa.

Falling Run Member (of Sanderson Formation)

Mississippian (Kinderhookian): Southeastern Indiana and northern Kentucky.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 835, 848–849, 857–858. Consists of phosphatic nodules and is final phase of Sanderson; represents near-shore facies resulting from retreat of sea around Cincinnati dome. Thickness commonly less than 1 foot. Stratigraphic position is beneath Underwood formation (new), but in most of southern Indiana the Underwood is absent, and Falling Run is overlain by Henryville formation (new). Overlain by New Providence shale in Kentucky.

Type section: On Falling Run Creek, at end of Market Street, New Albany, Floyd County, Ind. Traced from Ohio River north to Uniontown, Jackson County, Ind., and south and east through Kentucky to Irvine, Estill County.

Falling Springs Sandstone Member (of New Scotland Formation)

Lower Devonian: Central Pennsylvania.

F. M. Swartz, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1923; 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 57, 67, 83. Medium-bedded solid calcareous sandstone. Thickness 23 feet at type locality. Underlies Mandata shale and chert (new). Derivation of name given.

Named for Falling Springs, Perry County, where best exposed.

Fallis Sandstone Member (of Wellington Formation)[1]

Permian: Northeastern Oklahoma.

Original reference: J. M. Patterson, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 3, p. 243, 248.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1522 (fig. 2). Included in Minco division of Permian.

H. D. Miser and others, 1954, Geologic Map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Fallis sandstone member of Wellington formation.

Named for town of Fallis, sec. 29, T. 15 N., R. 2 E., Lincoln County.

Fall River Formation (in Inyan Kara Group)

Fall River Sandstone Member (of Colorado Shale)

Fall River Formation (in Dakota Group)

Fall River Sandstone (in Inyan Kara Group)[1]

Lower Cretaceous: Western South Dakota and northeastern Wyoming.

Original references: W. L. Russell, 1927, Am. Jour. Sci., 5th, v. 14, p. 402; 1928, Econ. Geology, v. 23, no. 2, p. 135–137.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7). Shown on columnar section as basal member of Omadi sandstone (new). Underlies Skull Creek member; overlies Fuson shale.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2170, 2173–2175, 2197 (fig. 2). Formations in Black Hills that are equivalent to Colorado shale are Fall River sandstone, Skull Creek shale, Newcastle sandstone, Mowry shale, Belle Fourche shale, Greenhorn formation, Carlile shale, and Niobrara formation. Fall River sandstone and equivalent rocks discussed in northern Black Hills, central and northwestern Montana.

K. M. Waagé, 1958, Wyoming Geol. Assoc. Gundebook 13th Ann. Field Conf., p. 71–76. Discussion of regional aspects of Inyan Kara stratigraphy. Fall River sandstone overlies Fuson-Lakota sequence and underlies Skull Creek sandstone.

R. E. Davis and G. A. Izett, 1958, Am. Assoc. Petroleum Geologists Bull. v. 42, no. 11, p. 2745–2756. Formation in northern Black Hills consists of about 120 to 140 feet of well-bedded siltstone, silty claystone, and very fine- to fine-grained sandstone. Subdivided into three and locally four units. Includes Keyhole sandstone member (new) in upper part.

Underlies Skull Creek shale; overlies sequence of lensing and interfingering continental deposits of claystone, siltstone, and sandstone that seem genetically related to underlying Morrison formation and which have been referred to variously as Lakota and Fuson formations undifferentiated, or Lakota formation. Separated from underlying rocks by nearly planar surface of transgressive disconformity.

K. M. Waagé, 1959, U.S. Geol. Survey Bull. 1081–B, p. 58–64, 79–81. Fall River formation (Dakota sandstone of Darton) is redefined so that its basal contact conforms to the transgressive disconformity [see Dakota group] and formation becomes upper part of twofold division of Inyan Kara group as herein redefined. In terms of Russell's (1928) definition of Fall River and Darton's interpretation of the Dakota in Fall River area, the redefinition consists of shift downward in basal contact. In terms of remainder of the Inyan Kara outcrop, redefined Fall River would include, locally, a variable thickness of shale and thin-bedded sandstone, which Darton included in the Fuson. Russell's (1928) definition included "the sandstone and interbedded shales of post-Fuson age lying below the base of the Graneros shales." Russell included Quarry sandstone (Ward, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2) in these beds. That is, he followed Darton's restriction of the latter's Dakota formation in Fall River Canyon inasmuch as base of Quarry sandstone marked Fuson contact in both classifications. Russell gave type locality "at Evan's Quarry." Actually there are two Evan's quarries both abandoned. The newer quarry shows only face of the massive sandstone and a few of beds above, whereas original Evan's quarry shows the massive sandstone and, in a gully leading from it, all beds beneath it to basal contact of Fall River formation. Good exposures of formation above Quarry sandstone are present a short distance downstream on northeast side of river below falls formed by Quarry sandstone. This general area in vicinity of the falls and the two quarries is here included as part of type locality. Thickness at type locality 158 feet where it overlies Lakota formation and underlies Skull Creek shale. Throughout Black Hills, formation maintains thickness of 110 to 160 feet. Basal contact sharply delimited by transgressive disconformity. Upper contact commonly an abrupt change from sandstone to gray sandy shale, which grades within 5 to 15 feet to black clay shale typical of Skull Creek. Contact, even where relatively sharp is conformable. In southern and eastern Black Hills, formation has threefold subdivision because of tongue of continental beds similar to Lakota formation.

W. A. Pettyjohn, 1960, (abs.) South Dakota Acad. Sci. Proc., v. 38, p. 34–38. Dakota controversy discussed. Suggested that term Dakota group be used to include Lakota, Fuson, Fall River, Skull Creek, and Newcastle formations.

U.S. Geological Survey currently classifies the Fall River as a member of the Colorado Shale in Montana on the basis of a study now in progress.

Type locality: Exposures in bluffs of Fall River in area of the falls and Evan's quarries which lie on opposite sides of river just above the falls. All exposures are in N½ sec. 33, T. 7 S., R. 6 E., Hot Springs quadrangle, Fall River County, S. Dak.

Fall River Sandstone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: Robert Hay, 1887, Kansas Acad. Sci. Trans., v. 10, p. 7, cross section.

Named for Fall River, Greenwood County.

Falls Formation[1]

Lower Ordovician: Central southern Oklahoma.

Original references: E. O. Ulrich, 1928, Manuscript chart exhibited at New York Meeting of Geol. Soc. America; 1930, U.S. Natl. Museum Proc., v. 76, art. 21, p. 73.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey.

Named for exposures on Falls Creek, sec. 33, T. 1 S., R. 2 E., Murray County.

Falls City Limestone (in Admire Group)

Falls City Limestone (in Admire Shale)[1]

Falls City Limestone Member (of Chicago Mound Formation)

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 9, 17, 30.

G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 5, 9. Rank raised to formation in Admire group. Includes (ascending) Miles limestone, Reserve shale, and Lehmer limestone member.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 37. Rank reduced to member status in Chicago Mound formation (new). Includes Miles limestone, Reserve shale, and Lehmer limestone as beds. Thickness about 9 feet.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 52. Underlies West Branch shale; overlies Hawxby shale.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1). Falls City limestone underlies West Branch shale member of Janesville shale (new); overlies Hawxby shale member of Onaga shale (new). Wolfcamp series.

Type locality: In Lehmer quarry, sec. 32, 2½ miles south and 1½ miles west of Falls City, Richardson County, Nebr.

Falls City Shale[1]

Eocene (Jackson): Southeastern Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1314.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2631. Replaced by Conquista clay member (new) of McElroy formation. Name Falls City preempted.

Type locality: West of Falls City, in bed of San Antonio River, forming falls of the river, Karnes County.

†Falls Creek Formation[1]

Lower Ordovician (Chazy): Central southern Oklahoma.

Original reference: C. E. Decker and C. A. Merritt, 1931, Oklahoma Geol. Survey Bull. 55, p. 12, 98.

Arbuckle and Wichita Mountains.

Falls Mills Limestone (in Hinton Formation)[1]

Mississippian: Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 295, 338.

Type locality: Along Bluestone River slightly northwest of Falls Mills, Tazewell County, Va. Also observed in Summers County, W. Va.

Falls Mills Sandstone (in Hinton Formation[1] or Group)

Falls Mills Sandstone (in Pennington Formation)

Mississippian (Chester): Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 295, 335.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5, pl. 2, columns 97–99. Shown on correlation chart as sandstone in Pennington formation in southwest Virginia; occurs below Princeton sandstone and above Avis limestone.

Type locality: In edge of Tazewell County, Va., just west of Falls Mills Station; makes falls across Bluestone River.

Falls Mills Shale (in Hinton Formation)[1]

Mississippian: Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 295, 336.

Type locality: Along Bluestone River slightly northwest of Falls Mills, Tazewell County, Va. Also observed in Mercer and Summers Counties, W. Va.

Falor Formation

Pliocene: Northwestern California.

G. A. Manning and B. A. Ogle, 1950, California Div. Mines Bull. 148, p. 7, 14 (fig. 2), 22–25, pls. 1, 2. Poorly consolidated marine sandstones, clays, silts, and conglomerates. Thickness 750 to 2,000 feet; upper 200 feet are red beds. In fault contact with Franciscan. Beds strike approximately N. 40° W., and dip homoclinally about 20° NE. Name replaces term Boulder formation as used by authors in unpublished theses.

Type locality: Along Maple Creek near Falor Ranch, Blue Lake quadrangle, Humboldt County.

Fan Mountain Glaciation

Recent: Northern Alaska.

R. L. Detterman, A. L. Bowsher, and J. T. Dutro, Jr., 1958, Arctic, v. 11, no. 1, p. 45, 57, 60 (table 1), figs. 3, 10. Six glacial advances recognized in northern Brooks Range and on Arctic Slope. Fan Mountain represents most recent glacial advance recorded in region. Preceded by Alapah Mountain glaciation (new). Moraines are fresh, bare of tundra, and generally restricted to cirque areas. Kettle lakes present behind a few of the moraines. Small glaciers confined to higher, larger, and mainly north-facing cirques characterized the glaciation.

Named for glacial deposits at thresholds of cirques in vicinity of Fan Mountain, 13 miles south of Shainin Lake. Moraines appear to be present in many cirques in higher parts of Brooks Range, generally above altitude of 4,600 feet in vicinity of Alapah Mountain.

Fannettsburg Member (of Shippensburg Formation)

Middle Ordovician (Bolarian): South-central Pennsylvania and western Maryland.

L. C. Craig, 1959, Geol. Soc. America Bull., v. 60, no. 4, p. 715 (fig. 1), 722–727. Name proposed for middle member of formation. Described at type locality as light- to dark-gray medium-grained to coarsely crystalline limestone in platy to massive beds. Shows two intertonguing facies; dark and fine grained in eastern belts of outcrop, and lighter medium to coarsely crystalline in western belts. Crude vertical zoning also present in western belts; lower part typically medium gray, rather thick-bedded coarse calcarenite with layers of *Solenopora* conglomerate, and upper part dark-gray cross-laminated fine calcarenite in platy beds. Contains four metabentonite beds in eastern outcrops. Maximum thickness 263 feet; 39 feet at type locality. Conformably overlies Pinesburg member (new); conformably underlies Doylesburg member (new) in type section and disconformably underlies Mercersburg formation in eastern belts.

Type section: Exposure on south side of U.S. Route 30, 1 mile southwest of St. Thomas, Franklin County, Pa. Named for the exposure east of Pennsylvania Route 75, 2.6 miles southwest of Fannettsburg in Path Valley.

Fanney Rhyolite[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for prominent outcrops in vicinity of Fanney mine, on Fanney Hill, Mogollon district.

Fant Meta-Andesite[1] or **Andesite**

Lower Jurassic: Northern California.

Original reference: J. S. Diller, 1908, U.S. Geol. Survey Bull. 353.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map. I–175, p. 5 (table 2). Fant andesite overlies Hardgrove sandstone; underlies Thompson limestone. Lower Jurassic.

Named for an unidentified locality near Taylorsville, Plumas County.

Fant Tuff Member (of Catahoula Tuff)[1]

Oligocene or Miocene, lower: Southwestern Texas.

Original reference: T. L. Bailey, 1926, Texas Univ. Bull. 2645, p. 46, 65, 66–80, 178–179.

H. H. Cooper, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 11, p. 1432. Principally volcanic tuff. Thickness 100 feet. Underlies Soledad member; overlies Frio formation.

Named for exposures near Fant City, northern Live Oak County.

Fantastic Lava Beds

Cenozoic: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, geol. map. Named on geologic map.

Mapped in Lassen County, northeastern part of Lassen Volcanic National Park.

Farallon Quartz Diorite

[Upper Cretaceous]: Western California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 9. Name applied to quartz diorite exposed on Farallon Islands. These outcrops have been regarded by geologists as the ancient core of a mountain range which once extended along coast of California and which supplied sediments for Franciscan formation and for many of Cretaceous formations. Age determination by potassium-argon method 89.5 million years.

Farallon Islands are off the coast of California near San Francisco Bay.

Faraway Ranch Formation

Faraway Ranch Series

Cenozoic: Southeastern Arizona.

H. E. Enlows, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 106 (fig. 1). Series comprises (ascending) buff pahoehoe biotite dacite—thickness 400 feet; basalt breccia—175 feet; lapilli tuff—200 feet; soft white rhyolite tuff—10 feet; and hard pink rhyolite tuff—10 feet in Rhyolite Canyon section, Chiricahua National Monument. Uncomformably underlies Rhyolite Canyon series (new).

H. E. Enlows, 1955, Geol. Soc. America Bull., v. 66, no. 10, p. 1217, 1221 (table 2). Formation overlies Bonita Park formation (new) in Hands Pass region just east of Chiricahua National Monument. Most of rhyolite deposits of Cenozoic age in Monument, heretofore termed flows, are more correctly classified as welded rhyolite tuff or ignimbrite, the result of many eruptions of nuées ardentes. Thickness at least 800 feet. Underlies Rhyolite Canyon formation. Probably correlative with Blacktail formation (new). Derivation of name given.

F. F. Sabins, 1957, Geol. Soc. America Bull., v. 68, no. 10, p. 1325–1327, pl. 1. In Cochise Head and Vanar quadrangles, all but minor part of formation consists of volcanic flows and agglomerate. Lenses of lacustrine deposits and stream-deposited tuff constitute minor part. Lacustrine deposits comprise a red clastic sequence and a light-colored sequence containing fresh-water limestone. In southeast part of the area, formation overlies Nipper formation (new), but to the north and west it unconformably overlies Bisbee group. Late Cretaceous to late Tertiary.

Named from outcrops near Faraway Ranch on lower Bonita Canyon, a short distance west of Chiricahua National Monument, Cochise County.

Farewell Glaciation

Pleistocene: Central southern Alaska.

A. T. Fernald *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 6–7, 13 (table 1); A. T. Fernald, 1960, U.S. Geol. Survey Bull. 1071–G, p. 222, 225–233. Two major glaciations of western part of Alaska Range recognized in Upper Kuskokwim region. The younger, Farewell, succeeded Selatna glaciation (new). Represented along South Fork of Kuskokwim River by prominent moraines; along Middle Fork by two moraines; and along West Fork by single V-shaped moraine which lies in broad open valley within mountainous area. Twofold division of Farewell glaciation, which is well displayed on piedmont slope along South and Middle Forks, may represent two distinct glaciations.

Along South Fork of Kuskokwim River near Farewell; also along Middle and West Forks. In Upper Kuskokwim region. Named after settlement of Farewell on Sheep Creek, just outside moraines of South Fork.

Fargo Limestone[1]

Pennsylvanian: Southeastern Nebraska and southwestern Iowa.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 15, 26, 27.

Type locality: Prominent cliff in valley side near Fargo, Richardson County, Nebr. Exposed between Weeping Water Valley and Walnut Creek, from 4 miles northwest of Fargo to near Rulo, and in spur south of Rulo, Richardson County, Nebr.

Fargo Canyon Diorite

Upper Jurassic: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 12, 44, 45, 59–60. Massive to moderately foliated. Cut by granite and pegmatitic granite dikes which are offshoots of White Tank and San Jacinto batholiths. Probably a correlative of Bradley granodiorite (new). In Little San Bernardino Mountains, the Fargo Canyon cuts Chuckwalla complex (new).

Named for exposures in Fargo Canyon, Little San Bernardino Mountains, northeast of Indio, Riverside County.

Farisita Conglomerate

Oligocene(?): Southeastern Colorado.

R. B. Johnson and G. H. Wood, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 709 (fig. 2), 718. Consists of buff conglomeratic sandstone and siltstone beds. Individually beds are lenticular and highly cross-laminated and show limonite stains on bedding surfaces. Conglomeratic fragments range in size from pebbles to 8-foot boulders and are subangular to rounded and very poorly sorted. Rocks generally poorly cemented. Ranges in thickness from thin edge to about 1,200 feet. Unconformably overlies Huerfano formation and older rocks of Cenozoic, Mesozoic, and Precambrian age. Unconformably underlies Devils Hole formation.

Robert Berner and L. I. Briggs, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1533. Detailed mapping demonstrated that accurately dated Huerfano formation interfingers with Farisita formation in central part of basin. This dates Farisita as late early Eocene (Wasatchian), middle Eocene (Bridgerian), and probably late Eocene. Uppermost beds of formation may be still younger.

Named from exposures along Turkey Creek north of town of Farisita. No more specific type section reported or described owing to nature of outcrops, which are very scarce and discontinuous. Occurs entirely within Huerfano Park.

Farland[1] (limestone)

Lower Cretaceous: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Farley Limestone Member (of Wyandotte Limestone)

Farley Limestone Bed (in Lansing? Formation)[1]

Farley Limestone Member (of Lane Shale)

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: H. Hinds and F. C. Greene, 1915, Missouri Bur. Geology and Mines, v. 13, 2d ser., p. 29, 155.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, pl. 5. Shown on chart as member of Lane shale. Thickness 2 to 10 feet. Underlies Bonner Springs shale member; overlies Island Creek shale member.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2033; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vi (fig. 2), 14. According to interstate agreement, Farley limestone is classified as uppermost member of Wyandotte limestone. Overlies Island Creek shale member; underlies Bonner Springs shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 25, fig. 5. Uppermost member of Wyandotte limestone. Comprises two or three gray argillaceous limestone beds separated by thin shales and varies considerably in thickness. Thickness about 2 feet in Madison County; more than 7 feet in Union County. Overlies Island Creek shale; underlies Bonner Spring shale.

Named for exposures near Farley, Platte County, Mo.

Farm Creek Intraglacial Substage

Pleistocene (Wisconsin): North-central United States.

M. M. Leighton, 1960, Jour. Geology, v. 68 no. 5, p. 549, 550. Name applied to Farmdale-Iowan intraglacial substage. Represented by black soil, wood, and peat that overlie Farmdale silt and underlie Iowan and Tazewell (Peorian) loess. This report also gives consideration to other classifications of the Wisconsin including one proposed by Frye and Willman (1960).

Named for Farm Creek, Tazewell County, Ill.

Farmdale Stade, Loess

Farmdale Drift, Till, Silt

Farmdale Substage, Subage, Glaciation

Farmdalian Substage

Pleistocene (Wisconsin): Mississippi Valley.

M. M. Leighton, 1947, *in* Itinerary State Geologists Conf. on loess deposits-Illinois portion, p. [8]. Names Farmdale(?) and Farmdale loess(?) listed on correlation chart.

M. M. Leighton and H. B. Willman 1950, Jour. Geology, v. 58, no. 6, p. 602–603. Silt deposit which lies on weathered zone and erosional slopes of Illinoian drift and which has very youthful profile of weathering beneath Peorian loess was described by Leighton (1926, Jour. Geology, v. 34) as late Sangamon loess. This is unit named Farmdale (Leighton, 1948, *in* H. L. Wascher, R. P. Humbert, and J. C. Cady, Soil Sci. Soc. America Proc., v. 12, p. 390). Farmdale substage and loess are pro-Wisconsin. Farmdale is older than Iowan. Loess has definite valley relationships to Illinois River valley (ancestral Mississippi), present Mississippi Valley below mouth of Illinois River and Wabash and lower Ohio Valleys. Such a relationship suggests a valley-train source. This, in turn, implies an extension of an ice sheet during Farmdale into drainage basin of ancestral Mississippi prior to Iowan substage but not yet recognized in series of drift sheets because it fell short of subsequent ice lobes.

J. C. Michelson, 1950, Iowa Acad. Sci. Proc., v. 57, p. 268–269. Loess, exposed in sec. 31, Magnolia Township, Harrison County, Iowa, believed to be equivalent to Farmdale loess of Illinois as defined by Leighton. Thickness 4 feet. Overlies Loveland loess; underlies Iowan loess. A section which shows similar succession of loesses is exposed near St. Charles, Mo. These loesses are called Loveland, Farmdale, and Peorian.

P. R. Shaffer, 1954, Science, v. 119, no. 3098, p. 693–694; 1956, Illinois Geol. Survey Rept. Inv. 198, p. 13–24. Part of glacial drift in northern Illinois formerly mapped as Illinoian is Farmdale in age, the earliest substage of Wisconsin stage. Drift sheet consists of till and widespread deposits of water-laid materials in form of kames, eskers, and kame terraces. So far as known, this is first reported occurrence of glacial drift of Farmdale age. This drift is uppermost drift in northern half of Boone County, in all but small areas in southeastern and northwestern Winnebago County, southeastern Stephenson County, northern Ogle County, and small areas in eastern Carroll and northern Whiteside Counties. The loess (Peorian) cover which varies from a few inches to about 5 feet is usually leached. Farmdale drift passes beneath Shelbyville drift.

G. E. Ekblaw and H. B. Willman, 1955, Illinois Acad. Sci. Trans., v. 47, p. 129–138. Farmdale drift described in vicinity of Danville.

R. V. Ruhe, Meyer Rubin, and W. H. Scholtes, 1957, Am. Jour. Sci., v. 255, no. 10, p. 671–689. New radiocarbon dates in Iowa permit grouping of age values and raise new problems in stratigraphic correlation of late Pleistocene deposits in Iowa and adjacent regions. Older group of ages greater than 29,000 years dates Iowan substage and pre-Iowan deposits. Old group of ages of 22,900 to 25,100 years dates the Farmdale substage. Intermediate group of ages ranges 14,000 to 17,000. A possible interpretation of radiocarbon dates from Iowa places Iowan substage in older position than Farmdale, rather than younger, as hitherto believed. Farmdale is dated in Iowa at 24,500 years B. P.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 174. Discussion of Wisconsin glaciation in Illinois River valley. Farmdale (sub-age, glaciation) is oldest of five advances. Pinkish-colored Farmdale loess was leached to depth of 7 feet before deposition of overlying Peorian loess in those few places where its thickness was that great. Farmdale subage was followed by Iowan subage.

L. R. Ray, 1957, Jour. Geology, v. 65, no. 5, p. 542–544. Farmdale loess recognized in section at Medora, Ky. Thickness about 5 feet. Overlies Loveland loess; underlies Tazewell loess.

J. C. Frye and H. B. Willman, 1960. Illinois Geol. Survey Circ. 285, p. 1, 2, 3, 6, 11–12. Presentation of revised time-stratigraphic classification of Wisconsinan stage of Lake Michigan lobe. Wisconsinan consists of (ascending) Altonian (new), Farmdalian, Woodfordian (new), Twocreekan, and Valderan substages. Farmdalian substage is based on Farmdale slit exposed in Farm Creek area, Tazewell County. Deposits in this stratigraphic position have been known since the last century and for many years were assigned to late Sangamon. Rock-stratigraphic unit, Farmdale silt, consists of massive silt, noncalcareous, light-brown to pale-purple, that commonly contains wood fragments and is locally replaced by peat. Although some Farmdale silt probably was initially deposited as loess during Farmdalian time, it is believed that much of it was derived by water transport and colluvial action from older Roxana loess (new). Radiocarbon dates from Farmdale silt and peat range from 26,150±600 (W–381) to 22,900±900 (W–68). On the basis of these dates, their positions within Farmdale deposits, and dates from both younger and older deposits, it is herein suggested that the range of radiocarbon years for Farmdalian substage is 28,000 to 22,000. Although till in several areas (Shaffer, 1956; Ekblaw and Willman, 1957 [1955]) has been referred to the Farmdale, present data indicate absence of till of Farmdalian age. It is here concluded that the Farmdalian is the major interval of glacial withdrawal within Wisconsinan as developed in Lake Michigan lobe rather than an episode of glacial advance.

W. D. Thornbury, 1958, Am. Jour. Sci., v. 256, no. 7, p. 457. Possibility exists that some of till that has been considered Tazewell in age in upper Wabash Valley may be Farmdale or Iowan.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529–540. Presentation of classification of Wisconsin glacial stage of north-central United States. Farmdale glacial substage, oldest in sequence, is separated from Iowan glacial substage by Farm Creek intraglacial substage (new). Author [Leighton] does not agree with classification presented by Frye and Willman (1960); among the reasons cited one (1) C–14 dates of large pulmate land snails in Roxana silts of Frye and Willman are in question; (2) C–14 dates of wood from black soil, peat, and muck, heretofore referred to as Farmdale substage, belong to boreal Farmdale-Iowan intraglacial substage, the overlying loess being Iowan; (3) no deposit of Wisconsin age intervenes between Farmdale materials Sangamon weathered zone; (4) only humus forest bed, peat, and related materials separate Farmdale loess and drift from deposits below from Iowan loess and Iowan drift above; and (5) Iowan substage is not datable by spurious fragments of wood found in its base but is shown by stratigraphic and other geologic evidence to be younger than Farmdale.

Name amended to Farmdale Stade to comply with Stratigraphic Code adopted 1961.

Named from exposure in Farm Creek section near Farmdale, Tazewell County, Ill.

Farmers Siltstone Member (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 125–126, 128, 129, 130. Even-bedded uniform-grained siltstones generally 25 to 35 feet thick. Included in Bluestone facies (new) of the formation. In type area, underlies 15-foot unnamed shale and siltstone unit and overlies Henley shale member of New Providence formation.

Well exposed at quarry of Rowan County Freestone Co. and adjacent hillside, at village of Farmers, about 6 miles southwest of Morehead, Rowan County. Named for village of Farmers.

Farmington Complex

See Farmington Canyon Complex.

Farmington Sandstone Member (of Kirtland Shale)[1]

Upper Cretaceous: Northwestern New Mexico and southwestern Colorado.

Original reference: C. M. Bauer, 1916, U.S. Geol. Survey Prof. Paper 98–K.

Harley Barnes, E. H. Baltz, Jr., and P. T. Hayes, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM-149. Described in Red Mesa area, La Plata and Montezuma Countries, Colo. Middle member of Kirtland; overlain and underlain by unnamed shale members. Consists of thin- to massive-bedded lenses of sandstone separated by shale and sandy silty shale. Thickness about 345 feet.

Well exposed near Farmington, San Juan County, N. Mex.

Farmington Shale Member (of Modesto Formation)

Farmington Shale (in McLeansboro Formation)[1]

Farmington Shale (in McLeansboro Group)

Pennsylvanian: Western and northern Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 309.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 116, 189, 190, 191, 193, 194, 195. Shale is gray to olive green; commonly contains gray ironstone concretions as much as 2 inches thick by 1 foot in maximum diameter. Maximum thickness 50 feet. Locally, in Glasford quadrangle, entirely cut out by Gimlet sandstone. Included in Sparland cyclothem. Overlies Sparland (No. 7) coal, which in turn overlies Copperas Creek sandstone. In McLeansboro group. Derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38, 49 (table 1), pl. 1. Reallocated to member status in Modesto formation (new). Underlies Gimlet sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois.

Type locality: Outcrops in Farmington Township, T. 8 N., R. 4 E., Fulton County.

Farmington Canyon Complex

Precambrian: North-central Utah.

A. J. Eardley, 1939, Geol. Soc. America Bull. v. 50, no. 8, p. 1282, pl. 1, Rocks of Farmington Canyon complex crop out in mouth of Little Cottonwood Canyon.

A. J. Eardley and R. A. Hatch, 1940, Jour. Geology, v. 48, no. 1, p. 59 (fig. 3), 61–72. Name given to large group of crystalline rocks in north-central Utah area. Rocks are distinctly stratified throughout region. Contains metamorphosed mafic rocks, injection gneisses, silicic igneous rocks, and metamorphosed sedimentary rocks. Type locality stated.

A. J. Eardley and R. A. Hatch, 1940, Geol. Soc. America Bull., v. 51, no. 6, p. 810 (fig. 3), 815. In Willard Canyon [between Ogden and Brigham City] underlies Tintic quartzite.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 823, 827. Thickness about 10,000 feet. Underlies an ancient sequence which is probably Upper Proterozoic and in part Lower Cambrian.

R. E. Cohenour, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 34–36, 37 (fig. 2). Precambrian rocks of western Uinta Mountains and central and northern Wasatch Mountains are divisible into two main groups. Older group is divisible into two sequences: older, Farmington Canyon complex, and younger, Little Willow series. Most of the description of Farmington Canyon is based on an unpublished thesis by Larsen (1957).

Type locality: Farmington Canyon and Bountiful Peak, Davis County.

Farm Ridge Drift

Pleistocene (Wisconsin): Northern Illinois.

H. B. Willman and others, 1942, Illinois Geol. Survey Bull. 66, p. 145 (fig. 85), 146 (fig. 86), 161–162. Largely till but includes sand and gravel as lenses in the till, in kames, in one large esker, in subglacial channels, and as outwash deposits in front of the moraine and overlying the ground moraine; till is medium to light gray, yellowish, or brownish, silty, clayey. Thickness in Farm Ridge moraine commonly 30 to 40 feet, although in some of higher hills as much as 60 feet; in ground moraine commonly 5 to 15 feet. Overlies Bloomington till. [Report lists six drifts in the Tazewell; for sequence see under Shelbyville.]

Named for Farm Ridge post office at one time located on prominent part of moraine about 5 miles west of Grand Ridge in Farm Ridge Township, Streater quadrangle, La Salle County.

Farragut Limestone

Middle Ordovician: Northeastern Tennessee.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1156–1157. Proposed for coarsely crystalline variegated limestone, or marble (of Knoxville and surrounding area) which overlies Lenoir limestone (restricted) and underlies Tellico sandstone. Thickness 115 feet. Zone has been referred to stratigraphically as "Holston" marble in this area and represents principal zone quarried for commercial "Tennessee marble"; just east of Knoxville along Holston River, Keith (1895) assigned name "Holston" to lentils of variegated marble occurring within Chickamauga limestone; since term was originally assigned to type of lithology occurring at different horizons, term "Holston" is of no significance as definite formational unit.

Type section: Appalachian Marble Co. quarry, 1.4 miles due east of Lowes Ferry. Named for site of Admiral Farragut homestead at Lowes Ferry on Tennessee River 9.5 miles southwest of Knoxville.

Farrer Formation

Farrer Member or facies (of Price River Formation)

Farrer Noncoal-Bearing Member (of Price River Formation)[1]

Upper Cretaceous: Central eastern Utah and central western Colorado.

Original reference: D. J. Fisher, 1936, U.S. Geol. Survey Bull. 852.

Teng-Chien Yen, 1954, U.S. Geol. Survey Prof. Paper 254–B, p. 59, 60, 62. Listed in fossil collection locality data both as formation and as member of Price formation.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 187, 191–192, figs. 2, 3, pl. 3. Beds of coarse to fine sandstone, shale, and sandy shale. Do not contain appreciable coal although a few thin beds found at various horizons. Lenslike sandstones constitute bulk of rocks and are somewhat darker than sandstones in Neslen facies. Shales mostly gray but in places olive green. Castlegate member included in base of Farrer facies west of Woodside and in top of Neslen facies eastward. Rocks thicken from about 1,200 feet in Price River Canyon, Utah, to about 1,500 feet near Palisade, Colo. Facies comprises whole of formation at Price River Canyon but only upper part of formation near Palisade. Upper boundary coincides with that of formation and underlies North Horn formation with transitional contact in Price River Canyon and disconformably underlies Tuscher formation east of Green River. Montana age.

Named for local mine in Coal Canyon, Utah. In Book Cliffs.

Farrington Sand Member (of Raritan Formation)

Upper Cretaceous: East-central New Jersey.

H. C. Barksdale and others, 1943, The ground-water supplies of Middlesex County, New Jersey: New Jersey State Water Policy Comm. [Spec. Rept. 8], p. 104–140. Medium- to fine-grained sand (No. 1 sand of previous reports) in lower part of Raritan between Woodbridge clay above and Raritan fire clay below. Separated from Sayreville sand member (new) by Woodbridge clay. Lower part, 10 to 20 feet thick, is coarse, arkosic, light-gray, or light-yellow sand commonly containing sprinkling of small pebbles. Arkosic material, as seen in outcrop, is partly kaolinized, the white kernels of the partly decomposed feldspar standing out in contrast to the gray and yellow sand and gravel; occasionally the gravelly beds contain numerous small chunks of red and white clay. Lenses of clay, commonly only a few feet thick, are present, and thin clay seams are fairly common within limits of member. Thickness 80 feet. Most of the discussion deals with relation of unit to ground-water supply. In this report, Woodbridge and Raritan clays are considered informal economic names.

Crops out in band nearly 1 mile wide along southeast edge of Farrington Lake, Middlesex County.

Far Rockaway Gravels[1]

Tertiary: Southeastern New York.

Original reference: J. B. Woodworth, 1901, New York State Mus. Bull. 48, pl. 1, map.

In Oyster Bay and Hempstead quadrangles, Long Island.

Fashing Clay Member (of Whitsett Formation)

Fashing Clays[1]

Eocene, upper: South-central Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1315.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626 (table 1), 2633–2634. Termed member of Whitsett. At designated type locality, thin fossiliferous sandstone, less than 1 foot thick and containing *Corbula*-type pelecypods, overlies olive-gray bentonitic clay containing coquinas of *Corbula*, *Ostrea*, and other pelecypods, and septarian calcareous concretions. This section, about 20 feet thick, is exposed on western valley wall of small branch on Hierholzer Ranch. Elsewhere banks of oyster shells are found. Overlies Calliham sandstone member; overlain by Olmos sand of Ellisor (1933).

Type locality: About 1.8 miles south of Fashing School, and one-quarter mile south of sharp curve on Farm Road 99 where highway from Fashing to Whitsett bends from a southerly to southwesterly direction. Named for exposures around town of Fashing, Atascosa County.

Faulconer Formation

Faulconer Limestone Member (of Perryville Formation)[1]

Middle Ordovician: Central Kentucky.

Original reference: A. F. Foerste. 1912, Denison Univ. Sci. Lab. Bull. 17, p. 23, 32, 131, 132.

A. C. McFarlan, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 992. Exposure in northern Jessamine County seems to indicate that the Faulconer and Salvisa are not entirely distinct stratigraphic units but are lithologic facies, in part contemporary.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1640. Term Perryville is synonym of Benson; name Devils Hollow division of upper Lexington is proposed for post-Woodburn "Perryville" of Frankfort-Versailles area. At its type section, the Devils Hollow includes 15 feet of "Faulconer" rock and 10 feet of the "Salvisa".

J. A. Stokley and F. H. Walker, 1953, Kentucky Geol. Survey, ser. 9, Rept. Inv. 8, p. 44, 45. At Harrodsburg, Mercer County, Faulconer formation is 18½ feet thick; underlies Salvisa formation.

Named for Faulconer, Boyle County.

Fauquier Formation

Precambrian: North-central Virginia.

A. S. Furcron, 1939, Virginia Geol. Survey Bull. 54, p. 1, 37–41, pl. 1. Series of marbles, graphitic slates and graphitic schists, mica schists, and biotite-garnet gneisses. In vicinity of Fauquier White Sulphur Springs and west of Piney Mountain, it is extensively intruded by dikes of greenstone, amphibolite, or metagabbro of Catoctin age. Oldest rocks of sedimentary origin in area [Warrenton quadrangle]. Underlies Precambrian Catoctin volcanic series and locally Warrenton agglomerate member (new) of Catoctin. Rocks of Fauquier were formerly classified with Loudoun formation of Cambrian age.

Named for exposures in vicinity of Fauquier White Sulphur Springs, Fauquier County. Formation enters quadrangle from north where it follows west side of Watery Mountain and extends southwestward through quadrangle.

Favret Formation

Middle Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]. Thin-bedded black bituminous limestone and interbedded black shale, generally underlain by massive dark-gray to brown dolomite. Thickness at type locality 800 feet; locally much thinner. Conformably underlies Augusta formation (new); overlies Dixie Valley formation (new), contact gradational.

Type locality: Favret Canyon, west slope of Augusta Mountain.

Faxon Limestone[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. M. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Dixon schist and below Swede Pond quartzite.

Type locality: Faxon Pond, Warren County.

Fayette Breccia[1]

Middle Devonian: Northeastern Iowa.

Original reference: W. J. McGee, 1884, 10th Census, v. 10, Rept. on Building stones, p. 262–263.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 69. It may be interpolated that term "Fayette breccia" as used by Calvin (1898 Iowa Geol. Survey, N. 8) included basal Cedar Valley beds and that, in all cases where "Fayette breccia" lies above Independence shale, it is basal Cedar Valley and not the lithographic Davenport ("Lower Davenport of Norton").

Occurs at Fayette, Fayette County, Quasqueton, Buchanan County, and elsewhere.

Fayette facies (of Flagstaff Formation)

Paleocene, upper: Central Utah.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., no. 8, p. 29, pl. 11. Consists of light-gray to buff extremely dense massive locally fossiliferous limestone. Thickness of nearly 500 feet on north side of Mellor Canyon. Unconformably overlies Price River formation. Exact correlation of Fayette facies with Flagstaff of other areas not known; believed to be roughly correlative with unit B of Valley Mountain facies (new).

Particularly well exposed on north side of Mellor Canyon about 2 miles north-northeast of village of Fayette, Gunnison quadrangle.

†Fayette Sandstone[1]

Pennsylvanian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487, 497.

Named for Fayette Station, Fayette County, W. Va.

†Fayette Sandstone[1] or Formation

Eocene (Jackson): Northwestern Louisiana and eastern and southern Texas.

Original reference: E. T. Dumble and R. A. F. Penrose, Jr., 1890, Texas Geol. Survey 1st Ann. Rept., pl. 3, p. xxxiii, 17, 47, 57, 58, 63.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 266–270. Fayette formation described in area between Laredo and Rio Grande City, Tex. Classification followed is that of Kane and Gierhart (1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 9) in which names Fayette and Jackson are used synonymously; it is understood that Fayette has been restricted so that some of beds of lower Jackson are not now included in Fayette. Thickness in Starr County about 1,500 feet. Contains three prominent marine sandstone tongues separated by shaly beds of marginal to nonmarine facies. Named units include (ascending) Salineno sandstone tongue, Resendez shale member (new), Roma sandstone tongue. Gorgora shale member (new), Sanchez sandstone tongue, Agua Verde shale member (new), and Villa Nueva sandstone member. Overlies Yegua formation; underlies units termed uppermost Jackson.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2625–2626. History of usage summarized. On the basis of recent fieldwork, it is believed that the Jackson of west Gulf Coastal Plain should be classified as a group and that name Fayette, of varied usage in the past, be abandoned.

Named for Fayette County, Tex. Section exposed at Lipan Hills, Atascosa County, as described by Dumble (1924) has been regarded as type section.

Fayetteville Shale[1]

Fayetteville Formation

Upper Mississippian: Northern Arkansas, southern Missouri, northeastern, central, and eastern Oklahoma.

Original reference: F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. 26, 42–49.

R. A. Brant, 1941, *in* Tulsa Geol. Soc. [Guidebook] Field Trip, Oct. 18. strat. sections. In Tulsa-Choteau-Grand River area, overlies Grand River limestone (new) and underlies Pitkin limestone or rocks of Morrow age.

W. H. Easton, 1942, Arkansas Geol. Survey Bull. 8, p. 17 (table), 19–20; K. C. Jackson, 1959, Fort Smith Geol. Soc. Guidebook 1st Field Conf., p. 56. In Arkansas, includes Mayes limestone member near base.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 267–268. Geographically extended into Missouri where it occurs in outliers of Boston Mountains, Reed Mountain, Lennox Mountain, and Oakleigh Mountain. Consists of black fissile carbonaceous shale and thin lenticular beds of dark-gray limestone; contains discus-shaped concretions of earthy limestone. Overlies Batesville sandstone; underlies Pennsylvanian Hale sandstone.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 66–71. Described on flanks of Ozark uplift in northeastern Oklahoma. Formation is typically developed on Bragg Mountain escarpment where it is 110 feet thick. Lower 95 feet is largely black fissile shale with thin interbeds of blue-black lithographic limestone; upper part consists of interbedded limestone and shale; grades upward into overlying Pitkin through 6½-foot zone of rubbly nodular-weathering black to gray lithographic limestone; in eastern Adair County 165 feet thick; lower 100 feet consists of black fissile shale with black lithographic septarian concretions; overlying Wedington sandstone member is as much as 25 feet thick. Unconformably overlies Hindsville limestone; where Hindsville is absent, the Fayetteville rests upon "Boone" chert knobs; where the Pitkin is missing Hale formation rests upon the Fayetteville; in northernmost exposures in Craig County, succeeded unconformably by sandstones and shales of Middle Pennsylvanian age.

K. C. Jackson, 1959, Fort Smith Geol. Soc. Guidebook 1st Field Conf., p.-55–56. Fayetteville, in area of this report [southwestern Washington County, Ark.], is divided into four units. Major part of formation is lower black shale member; near base of this unit is a locally developed limestone known as Mayes limestone member. Lower shale member is overlain by Wedington shale member. Upper member is light-colored silty shale. Thickness 100 to 247 feet. Underlies Pitkin formation. Chesterian.

Named for Fayetteville, in valley of West Fork of White River, Washington County, Ark.

Faywood Rhyolite

Tertiary: Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 37, pl. 1. Described as two domelike plugs of cream-colored fine-grained flow-layered rhyolite. Also minor flows. Both plugs intrude Rubio Peak flows and Sugarlump tuffs.

One plug forms Mimbres Mountain in secs. 17, 18, 19, 26, T. 20 S., R. 10 W.; other plug located near Faywood Hot Springs, in secs. 15, 16, 21, 22, T. 20 S., R. 11 W., Dwyer quadrangle.

Fearn Springs Sand Member (of Nanafalia Formation or Wilcox Formation)

Fearn Springs Formation

Eocene, lower: Mississippi and Alabama.

F. F. Mellen, 1939, Mississippi Geol. Survey Bull. 38, p. 33–37. In this report [Winston County] four divisions of Wilcox series are recognized: Fearn Springs (new), Ackerman, Holly Springs, and Hatchetigbee. In complete section, Fearn Springs formation lies disconformably on lignite of Betheden formation (new) and is disconformably overlain by grit-bearing arkosic(?) sand of Ackerman formation. Contains ball-type clays, stoneware clays, silty clays, silt, sand, lignite, and siderite. Thickness 0 to more than 50 feet. Fearn Springs is possibly equivalent to Ackerman formation as limited in Alabama by Cooke (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 2) or to Coal Bluff series of Langdon (1895). At time of Cooke's correlation, the Ackerman was defined as all the Wilcox below Holly Springs formation.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Mapped as sand member of Wilcox formation.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 47 (fig. 1). Correlation chart shows Fearn Springs (sand) member at base of Wilcox group (undifferentiated) in Mississippi.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 18–19. Redefined as member of Wilcox formation in Mississippi and member of Nanafalia formation in Alabama. Unit is more of a channel sand in Alabama than in Mississippi. Thickens and thins greatly along strike. Maximum thickness in Alabama 80 feet, in western Butler County. In area of type locality, in addition to fine-grained sands and clay originally assigned to unit by Mellen, it also includes coarse sand (originally considered to be colluvium) exposed farther downhill from type locality but actually forming main part of member. In Mississippi, member varies both in thickness and texture, but in general thickest sections carry coarsest material. Greatest thickness, about 100 feet, and very coarse throughout, is in northern Lauderdale and southern Kemper Countries. Fine-grained sands and clays which commonly mark top of member are lenticular; some lenses pinch out completely within single exposure. Member thins northward, becomes finer textured, and, in northern Mississippi, is indistinguishable from overlying Wilcox.

F. F. Mellen, 1950, Mississippi Geol. Survey Bull. 69, p. 7–20. Discussion of confusion existing in use of term Fearn Springs. Proposed that section of Fearn Springs clays at Flat Rock Church be regarded as alternate locality of formation. At this locality, basal Ackerman gritty sand which caps ridge overlies stoneware clays of Fearn Springs, at top of which is fossil leaf-bearing ironstone. About 300 yards to the west, Betheden kaolin is exposed in stream channel.

F. S. MacNeil, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 5, p. 1062–1073. Report is reply to Mellen's (1950) article. Evidence is presented to show that Mellen's interpretation of type locality was erroneous. From section compiled at Fearn Springs, based in part on auger hole, it is shown that upper part of Fearn Springs member (of Wilcox formation) consists of about 28 feet of laminated to slightly crossbedded fine sandy or silty micaceous clay. Above this lies coarse red sand that Mellen called basal Ackerman sand, Below silty clay is concealed interval of 19 feet, and below this is exposed 27½ feet of coarse crossbedded sand some fine gravel and clay balls. Much of the disagreement between Mellen and writer [MacNeil] hinges on this lower unit of coarse sand, found to have total thickness of 34½ feet. This same sand in nearby exposures can be seen to be the sand Mellen included in most other sections as his basal Ackerman sand. Probably this accounts for Mellen's failure to map the Fearn Springs and Ackerman separately in Winston County. This 34½-foot unit of coarse sand is in turn underlain by 12½-foot interval composed of tough silty clay, coarse sand, clay balls, and sand containing lignitized logs that probably represents Betheden formation as defined by Mellen. There are, therefore, two coarse sands: one below the silty clay phase of the Fearn Springs and another above it. Mellen believes that only one sand exists. This erroneous interpretation led to the following misapplication of names: (1) sand in lower part of type exposure of Fearn Springs, which Mellen believed to be colluvium, is in reality in place; in other exposures, Mellen has termed unit basal Ackrman sand: (2) name Fearn Springs was applied to part of Naheola formation at surface in Lauderdale and Kemper Counties, Miss., (Foster, 1940, Mississippi Geol. Survey Bull. 41) and to entire Naheola formation in subsurface in both Alabama and Mississippi (Mellen, 1950): and (3) Naheola, as used by Mellen (1950) in his subsurface diagrams, includes mainly Matthews Landing marl bed of Smith and Johnson (1887), a zone of fossiliferous greensand and clay that was once regarded as basal part of Naheola formation, but is now designated Matthews Landing marl member of Porters Creek clay. Also suggested that name Fearn Springs be made to include Betheden unit and name Betheden be abandoned.

J. S. Attaya, 1951, Mississippi Geol. Survey Bull. 71. p. 8–10. Fearn Springs formation overlies Porters Creek formation in Lafayette County. Most data from drill holes.

T. W. Luck, 1956, Mississippi Geol. Survey Bull. 80, p. 18–25. Formation described in Benton County where greatest exposed thickness is about 103 feet at Hickory Flat, lower contact not exposed. Underlies Ackerman formation; overlies Betheden formation.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 143–165. Described in Kemper County where it is treated as basal member of Nanafalia formation.

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 98. Sand beds included in Gravel Creek member (new) of Nanafalia have been called Fearn Springs sand member. However, name Fearn Springs is not used in this report for lower member of Nanafalia in Alabama because boundary positions at Fearn Springs type locality are in dispute and stratigraphic relationships with section in Alabama are uncertain.

Type locality: SE¼NE¼ sec. 3, T. 13 N., R. 14 E., one-fourth mile west of Fearn Springs, Winston County, Miss. Alternate locality: At Flat Rock Church (old Hurley School) near center sec. 9, T. 5 S., R. 2 E., Benton County, about one-half mile west of Tippah County line.

Federal Hill Beds (in Patapsco Formation)[1]

Lower Cretaceous: Northeastern Maryland.

Original reference: L. F. Ward, 1905, U.S. Geol. Survey Mon. 48, p. 566–569, 598.

At Federal Hill, in Baltimore.

Felch Formation (in Menominee Group)

Felch Schist[1]

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise and C. K. Leith, 1911, U.S. Geol. Survey Mon. 52, p. 303, 307.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Name Felch formation used in preference to lithologic term schist. In type locality, designated strata occur between Randville dolomite and Vulcan iron-formation; in Menominee district, term Felch formation is applied to distinctive sericitic slate-quartzite sequence which similarly lies above Randville dolomite and below the Vulcan iron-formation and which has been referred to as "Traders quartzite" and "Footwall slate." Forms basal unit of group.

Named for typical development at Felch Mountain, Dickinson County.

†Felch Mountain Iron-Bearing Series[1]

Precambrian (Huronian): Michigan.

Original references: C. R. Van Hise, 1892, U.S. Geol. Survey Bull. 86, p. 195; 1892, U.S. Geol. Survey Mon. 19, p. 473.

Felch Mountain district.

Feldt Ranch Beds (in Ash Hollow Formation)

Pliocene: Southwestern Nebraska.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 141. Name applied to 15 feet of beds of loose crossbedded sand and gravel, cemented grit, and porous limestone that occur in lower part of Ash Hollow formation in type section of the Ogallala.

Type locality: On north side of South Platte Valley, 2 to 2½ miles east and northeast of Ogallala, Keith County. (Also type locality of Ogallala.)

Feliz Granodiorite

Pre-Cretaceous(?): Southern California.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 7 (table 1), 12–14, pl. 1. Name applied to fine- to medium-grained granodiorite that occurs in Feliz pluton. Except for microbreccia in western end of Riverside fault block, Feliz granodiorite is confined to Mount Hollywood fault block where it is in intrusive-fault contact with older quartz diorite and with metamorphosed basic igneous rocks. Suggested sequence of intrusion in area is Vermont quartz diorite (new), Lar quartz diorite (new), and Feliz granodiorite.

Exposed in Griffith Park and for short distance south of Los Feliz Blvd., city of Los Angeles.

Fena Beds

Eocene: Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 51, table 4 [English translation in library of U.S.

Geol. Survey, p. 61, 62; S. Hanzawa in Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 31–32. Conglomerate with very little liparitic material; pebbles are chiefly andesite and greenish shale, and considered to have originated from underlying Santa Rosa beds. Unconformably underlies Asan limestone. Correlated with Densinyama formation of Saipan.

Type locality: Fena, Guam.

Fence Lake Gravel

Tertiary-Quaternary: Central western New Mexico.

R. J. Marr. 1960, (abs.) Arizona Geol. Soc. Digest, v. 3, p. 181. Incidental mention.

Present on Lynch Ranches, 23 miles east of St. Johns, Ariz. Town of Fence Lake is in Valencia County.

Fencepost limestone[1]

Fencepost limestone bed (in Pfeifer Shale Member of Greenhorn limestone)

Upper Cretaceous: North-central Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 50.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 111. Bed at top of Pfeifer shale member. Blue gray, weathers to light tan.

Extensively quarried for fence posts near Downs, Osborn County.

Fence River Formation (in Baraga Group)

Precambrian (Animikie Series): Northern Michigan.

J. E. Gair and K. L. Wier, 1956, U.S. Geol. Survey Bull. 1044, p. 14 (table 2), 57–58, pl. 1. Name applied to magnetic rock exposed at Sholdeis exploration where it consists of (ascending) (1) magnetite-specularite-quartz rock, (2) thinly banded rock rich in quartz, magnetite, hornblende, and epidote, and (3) massive garnet-grunerite schist. Estimated thickness probably as much as 250 feet. Conformably overlies eastward-dipping Hemlock formation; underlies biotite-quartz schist that resembles schists of Hemlock formation. If this schist were considered to be part of the Hemlock, the Fence River would be an upper member of the Hemlock; if the schist is considered a basal member of Michigamme slate, the Fence River is a distinct formation between the Hemlock and Michigamme; the latter view is adopted in this report.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 36. Assigned to newly defined Baraga group of Animikie series.

Only known exposure is in SE¼NE¼ sec. 21, T. 45 N., R. 31 W., Baraga County. Formation is represented by strong linear north-trending magnetic anomaly crossing northeastern part of area, on east flank of the Amasa oval, extending northward beyond Kiernan quadrangle to the exposure at Sholdeis exploration. Named for Fence River, which crosses magnetic belt 1,100 feet south of the exploration.

Fenner Granite Gneiss

Precambrian: Southern California.

J. C. Hazzard and E. F. Dosch, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 309. Granite gneiss, in part augen. Considered younger than Essex series (new) and older than Kilbeck granite gneiss (new).

Well exposed at Mountain Springs in Piute Mountains, in northern Old Woman Mountains and at Chubbuck, San Bernardino County.

Fentress Formation

Fentress shale division (of Lee Formation)[1]

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Div. Geology Bull. 33–B, p. 276, 384, 385.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 4. Glenn used name Fentress shale to include all strata of Pennsylvanian age beneath Rockcastle conglomerate in Fentress County and vicinity, where these beds are primarily shale and where Sewanee conglomerate is too thin to be mapped. Name is here changed to formation because of local occurrences of sandstone. Definition, however, remains the same. Formation includes beds equivalent to parts of two groups: the entire Gizzard group and all of Crab Orchard Mountains group (new) below Rockcastle conglomerate; hence, it is equivalent to Raccoon Mountain formation (new). Warren Point sandstone, Signal Point shale (new), Sewanee conglomerate, Whitwell shale, Newton sandstone, and Vandever formation. In localized areas, some of the constituent formations are recognizable. Name, Fentress formation, is used only where Sewanee conglomerate is not mappable.

Probably named for development in Fentress County.

Ferdig Shale Member (of Marias River Shale)

Upper Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2792 (fig. 3), 2794–2795; 1959 Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1). Inconspicuous disconformities divide member into three units (ascending) : dark-gray shale containing maroon-weathering layers of dark-gray syngenetic ferruginous dolostone and few thin beds of bentonite; micromicaceous silty bentonitic shale characterized by abundant surface litter of small thin flakes of rusty iron-stained shale, which contain gray and yellow-weathering concretionary limestone beds, secondary gypseous concretions, sandy shale, and thin persistent layers of sandstone; and dark-gray shale or sandy siltstone with thin layers of gray limestone concretions. Thin layer of pebbly sandstone present at top of middle unit and persists from type section southward for more than 100 miles. Total thickness of member at type section about 225 feet. Disconformably underlies Kevin shale member (new) ; overlies Cone calcareous member (new) :

Type section: Composite from exposures 3 to 5 miles northwest of Ferdig and from outcrops 8 miles southeast. Name derived from post office of Ferdig at SE cor. sec. 30, T. 35 N., R. 1 W., Sunburst quadrangle, Toole County, which is located over the subcrop of member on east flank of Kevin-Sunburst dome.

Ferdinand Limestone (in Mansfield Group)

Pennsylvanian (Pottsville) : Southwestern Indiana.

D. W. Franklin, 1944, Illinois Acad. Sci. Trans., v. 37, p. 87 (fig. 1), 88, 89. Consists of black shiny opaque chert with casts of productids and dark-blue gray argillaceous dull limestone. Thickness about 2 feet.

Lies about 20 feet below top of group; separated from underlying Fulda limestone (new) by about 15 feet of shale, underclay and coal.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2), 19. Included in Ti Valley series (new).

Well exposed northeast of Ferdinand in T. 3 S., R. 4 W., and west of Ferdinand State Forest, Dubois County.

Ferguson Gypsum Member (of Blaine Gypsum)[1]

Permian: Western Oklahoma.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 47.

Named for Ferguson, Blaine County.

Ferguson Mountain Formation

Permian (Wolfcampian-Leonardian): Eastern Nevada.

J. S. Berge, Apr. 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 5, p. 10 (fig. 2), 18–24, pl. 4, chart (strat. section). (Footnote on chart refers to Steele's article in Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., 1960, p. 91, 106–107. Road logs in guidebook dated Sept. 8–10.). Ferguson Mountain formation is named for thick carbonate sequence overlying Ely limestone at Ferguson Mountain. Steele (1959, unpub. thesis) termed part of this the Ferguson Spring[s] formation, but name and type locality he selected are ill chosen. Therefore Ferguson Spring[s] formation is herein redefined and name Ferguson Mountain formation proposed. This proposal is based on applicability of name to topographic sheet (Elko NK 11–12) of area. The area on topographic sheet is referred to as Ferguson Mountain. not Ferguson Springs Mountains. Type section is in secs. 21 and 22, T. 30 N., R. 69 E., Elko County. Measured section obtained on east side of Ferguson Mountain on spur directly north of principal east-trending canyon on this part of mountain. In adjacent areas surrounding spring area, southeastern side of Ferguson Mountains near U.S. Highway 50, no Ferguson Mountain formation is present. Geology there consists instead, of Guilmette limestone, Ely limestone, Tertiary volcanics, and Quaternary and Recent alluvium. Area is complexly folded, and is fractured by faulting. Seventeen hundred feet to the west in the southern part of the mountain, fault block of Ferguson Mountain formation is juxtaposed against various rock types but cannot be considered type section. Steele (1959) dates this section Upper Lower Missourian to Upper Upper Wolfcampian with total thickness of 3.085 feet, of which 1,111 feet is Pennsylvanian and remaining 1,974 feet is assigned to Lower Permian. He [Steele] also extends lower part of his formation to Mid-Pennsylvanian disconformity with upper limit in contact with Pequop formation of Leonardian age. Ferguson Mountain formation consists predominantly of dark-gray to light-gray limestones. Thickness 1,985½ feet, of which 1,717½ feet is assigned a Wolfcampian age and 268 feet lower Leonardian. Underlies Pequop formation; overlies Ely limestone. On chart (stratigraphic section) Ferguson Mountain is shown above Strathearn formation and below Pequop formation.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart), 1428 (fig. 3). Name appears on chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. Underlies Pequop formation; stratigraphically above Strathearn(?).

Type section: Secs. 21 and 22, T. 30 N., R. 69 E., Elko County. Measured section on east side of Ferguson Mountain.

Ferguson Springs Formation

Pennsylvanian-Permian: Northeastern Nevada and western Utah.

J. S. Berge, Apr. 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 5, p. 11 (fig. 3), 18. (Footnote on stratigraphic chart refers to Steele's article in Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf.) Steele (1959, unpub. thesis) named Ferguson Spring[s] formation. His name and type locality were ill chosen and Ferguson Spring[s] formation is herein redefined and renamed Ferguson Mountain formation. Correlation chart (in column credited to Steele) Ferguson Springs formation unconformably overlies Ely limestone and underlies Pequop formation. Pennsylvanian (Missouri-Virgil) and Permian (Wolfcamp).

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 93 (chart), 101, 104 (pl. 5, fig. 3). (Road logs dated Sept. 8–10). Name applied to those limestones occurring above the middle Pennsylvanian regional unconformity and stratigraphically below Pequop formation of Leonardian age. Light- to medium-gray, crypto- to fine-crystalline, bioclastic, silty, limestone sequence with thin interbeds of bituminous shale. Thickness 3,185 feet at type section. Lower 1,101 feet dated upper Pennsylvanian in age, with lower 592 feet assigned to Missourian, and remaining 519 feet to Virgilian. Upper 1,984 feet dated Wolfcampian. At nearly all known localities, including type area, formation rests disconformably on Ely limestone.

Type section: Sec. 16, T. 30 N., R. 69 E., Elko County, Nev. Named for Ferguson Springs, 1½ miles south of measured section.

†Fernandan system[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., pl. 3, p. lvi, 267–276.

Named for San Fernando Creek, Llano County.

Fernando Formation

Fernando Group[1]

Pliocene and Pleistocene: Southern California.

Original reference: G. H. Eldridge and R. Arnold, 1907, U.S. Geol. Survey Bull. 309.

D. L. Durham and R. F Yerkes, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–196. Group includes Repetto formation below and unnamed conglomeratic and siltstone sequence above. Overlies Sycamore Canyon member of Puente formation; underlies La Habra formation. Pliocene.

U.S. Geological Survey currently classifies the Fernando as a formation and designates its age as Pliocene and Pleistocene on the basis of a study now in progress.

Named for exposures in San Fernando Valley, Los Angeles County.

Fern Creek Formation (in Chocolay Group)

Precambrian (Animikie Series): Northern Michigan.

F. J. Pettijohn and F. A. Hildebrand, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1927. Named Fern Creek conglomerate; in unfaulted contact with reddish granite gneiss and pegmatite; contains large subrounded boulders derived from subjacent pre-Huronian and truncates, at an angle of 30° or more, the foliation of these basement rocks. Underlies Sturgeon quartzite.

F. J. Pettijohn, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1289. Formation includes at top a 100-foot thick tillite member, containing 2 to 5 percent of siltstones as much as 6 feet in diameter scattered in fine-grained nonbedded graywacke matrix; tillite is underlain by thinly laminated member characterized by scattered rafted cobbles; this bed grades down into pebbly arkoses and coarse granite-bearing conglomerates which lie unconformably on a granite gneiss basement. Tillite cannot be, by any correlation currently accepted, the correlative of Canadian Cobalt (Gowganda) tillite.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 35. Formation is basal unit in newly defined Chocolay group.

Occurs near Fern Creek, Dickinson County.

Ferndale Sandstone

Pliocene, upper: Northwestern California.

H. D. MacGinitie, 1943, California Div. Mines Bull. 118, pt. 3, p. 633. Fine-grained gray sandstone with thin interbed of clay shale. Thickness about 2,500 feet. Underlies Wildcat formation; overlies Pico formation.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 33. Name Ferndale sandstone abandoned. Unit redefined as Scotit Bluffs sandstone.

Occurs in central and southern Humboldt County.

Fern Glen Limestone

Fern Glen Limestone (in Osage Group)[1]

Fern Glen Member (of Chouteau Formation)

Lower Mississippian (Osage Series): Eastern Missouri and southwestern Illinois.

Original reference: S. Weller, 1906, St. Louis Acad. Trans., v. 16, p. 438.

J. M. Weller, 1939, *in* Stuart Weller and J. M. Weller, Illinois Geol. Survey Rept. Inv. 59, p. 8, pl. 1. Formation crops out only on Valmeyer anticline, and exposures occur from Dennis Hollow northward to SW¼ sec. 35, T. 2 S., R. 11 W. Consists chiefly of deep red more or less argillaceous limestone with interbedded shale. Thickness about 50 feet. Underlies Burlington-Keokuk limestone.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 198–199. Interpreted as member of Chouteau formation.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 20. In certain parts of Ozark border area in western St. Clair and Monroe Counties, and possibly in northwestern Jackson County, Fern Glen limestone, of early Osage age, directly overlies Moccasin Springs formation (new) of the Niagaran.

Charles Collinson and D. H. Swann, 1958, Geol. Soc. America Guidebook Field Trip St. Louis Mtg., p. 24 (fig. 3), 50 (fig. 9), 51. Chautauqua, Jersey County, Ill., is northernmost outcrop at which Fern Glen is both characteristically and well exposed. Here it has lost its distinctive red color. Shale grades upward into crinoidal limestone of Burlington; the contact is placed at point where chert nodules lose their greenish color; and the limestone becomes relatively pure. In some areas, consists of light-greenish-gray crinoidal limestone containing greenish-gray chert bands. In vicinity of Jerseyville, the Fern Glen cannot be differentiated from lower Burlington, thus indicating that it is actually a shaly facies of the Burlington. Overlies Sedalia dolomite. Valmeyer series [which includes Osage group]. Thickness about 20 feet.

Named for occurrence near Fern Glen Station, 20 miles west of St. Louis, St. Louis County, Mo.

Fernow Gneiss

Pre-Ordovician(?): North-central Washington.

E. A. Youngberg and T. L. Wilson, 1952, Econ. Geology, v. 47, no. 1, p. 2–4, 12. Name applied to series of quartz-amphibole gneisses, thickness of which is unknown because they extend outside mapped area. Age sequence not clear; it would appear that Fernow units is older than less metamorphosed Buckskin and Martin Ridge schists (both new); this would require that beds be overturned because Fernow gneisses lie stratigraphically above schists.

Named for occurrence in vicinity of Mount Fernow, near Holden, Chelan County.

Fernow Quartz Latite

Fernow Rhyolite[1]

Eocene, middle: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, pl. 74.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 30–32. Referred to as quartz latite.

U.S. Geological Survey currently considers the Fernow Quartz Latite to be middle Eocene in age.

Named for Fernow Canyon in southern part of Tintic district.

Fern Ridge Tuffs[1]

Miocene or Pliocene, lower and middle: Northwestern Oregon.

Original reference: T. P. Thayer, 1933, Pan-Am. Geologist, v. 59, no. 4, p. 317.

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 8, fig. 1. Consist of conglomerates, tuffs, and breccia; lower beds are mainly tuffs, sandstones, and fine pebble beds; upper part comprises coarse andesitic conglomerates which contain boulders as much as 18 inches in diameter in tuffaceous matrix. Maximum thickness about 1,500 feet, northeast of Mehama. Conformably overlies Stayton lavas and are probably part of same general sequence. Mehama volcanics (new), Stayton lavas, and Fern Ridge tuffs are traceable as distinct formations to crest of Mehama anticline. Miocene.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 15–16, pl. 2. Overlie Columbia River basalt and underlie lava of Pliocene or younger age. Tuffs can be traced northward into Molalla River drainage where they have been referred to correlative Molalla formation. Age shown on chart as lower and middle Pliocene.

Type locality: Fern Ridge, about 5 miles northeast of Stayton, Marion County.

Fernvale Limestone or **Formation** (in Richmond Group)[1]

Fernvale Formation (in Patterson Ranch Group)

Upper Ordovician: Western Tennessee, northwestern Alabama, northern Arkansas, southwestern Illinois, southeastern Missouri, and central eastern, and northeastern Oklahoma.

Original reference: C. W. Hayes and E. O. Ulrich, 1903, U.S. Geol. Survey Geol. Atlas, Folio 95, p. 2.

W. H. Shideler, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 367–368. The "Fernvale" extending from Glen Park, Mo., and Valmeyer, Ill., to south side of Arbuckles in Oklahoma, is a massive uniformly crystalline limestone with varied fauna of ostracods and trilobites; this differs from typical Fernvale. Name Ada is proposed for the crystalline limestone.

J. M. Weller, 1939, *in* Stuart Weller and J. M. Weller, Illinois Geol. Survey Rept. Inv. 59, p. 7. Exposed in limited area in Kimmswick quadrangle where Ordovician rocks are brought to surface in Mississippi River bluff at crest of Valmeyer anticline. Consists of brownish coarsely crystalline limestone with many fossils. Thickness 6 to 14 inches. Overlies Kimmswick limestone; underlies Maquoketa shale.

C. E. Decker, 1942, Oklahoma Acad. Sci. Proc., v. 22, p. 153, 154 (table 1). Formation included in Patterson Ranch group (new). Overlies Viola; underlies Sylvan.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 92–93. Chiefly limestone with considerable amount of impurities, in some places highly siliceous. Commonly light gray but ranges from nearly white to brown or reddish tints. Lies on various members of Kimmswick; unconformable below Maquoketa formation. Thickness about 4 feet. Lowest Upper Ordovician in Missouri; correlates with part of Arnheim of Kentucky; continuous with Fernvale of Arkansas and Illinois.

A. M. Gutstadt, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 3, pt. 1, p. 524. Templeton and Willman (1953, unpub. ms.) reported name Ada limestone preempted and proposed name Cape limestone for the Missouri "Fernvale".

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 26–27, pls. 3, 4. Limestone described on south and west flanks of Ozark uplift in northeastern Oklahoma. Massive coarsely crystalline fossiliferous crinoidal limestone. Light gray to pink and weathers lead gray. Maximum thickness 18 feet; average thickness 14 feet. Unconformably overlies Fite limestone and conformably underlies Sylvan shale south and east of Tahlequah; northeast of Tahlequah unconformably underlies Chattanooga black shale. Upper Ordovician, Richmondian.

G. B. Martin, 1960, Gulf Coast Assoc. Geol. Sci. Trans., v. 10, p. 201–205. In Alabama, Fernvale formation consists mainly of gray to blue crystalline thin-bedded fossiliferous limestone. Thickness 12 to 20 feet. Unconformably underlain by Leiper formation or by Hermitage formation. Recommended that in this area name Chickamauga be avoided in favor of more specific Leipers and Fernvale formations.

Named for Fernvale, Williamson County, Tenn.

†Ferriferous Limestone[1]

Ferriferous ironstone member

Pennsylvanian (Allegheny Series) : Pennsylvania, Ohio, and West Virginia.

Original reference: H. D. Rogers, 1858, Geology of Pennsylvania: Philadelhia, J. P. Lippincott & Co., v. 2, pt. 1, p. 491.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 45–46, table 1. Ferriferous ironstone member of Scrubgrass cyclothem in report on Perry County. Name Ferriferous was first applied to limestone which, in present usage, is known as Vanport. In this report, term Ferriferous is restricted to ironstone directly overlying Vanport member. Thickness 6 inches to 1 foot. Underlies Lower Kittanning clay of Lower Kittanning cyclothem. Allegheny series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 60. Term Ferriferous is one of few descriptive names still used as name for rock units in Pennsylvanian rocks. A useful bed for correlation in a series of beds lacking distinguishable members in Athens County [this report], and without its positive identification, recognition of any members of Scrubgrass cyclothem within county would have been uncertain or impossible.

Ferris Formation[1]

Upper Cretaceous and Paleocene: Central southern Wyoming.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Prof. Paper 108, p. 228, 230.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 81–82. Supposed unconformity between the Medicine Bow and Ferris is now regarded as nonexistent or as marked by a transitional zone indicating erosional irregularity. Basal 1,000 feet of Ferris is a coal-barren conglomeratic zone whose matrix and pebbles are similar to those of Medicine Bow. This zone yields remains of *Triceratops* and a Cretaceous flora not materially different from the lower Medicine Bow and Lance. Typical Paleocene flora has been found in lowest coal-bearing strata just above the latest dinosaur remains of the Ferris, indicating that the Cretaceous-Tertiary boundary is at or near that level. Concluded that Medicine Bow formation encompasses basal dinosaur-bearing part of the Ferris and that the remainder of the Ferris, about 5,500 feet, is Paleocene.

Well exposed on old Ferris Ranch, on North Platte River, Carbon County.

Ferron Sandstone Member (of Mancos Shale)[1]

Upper Cretaceous: Central and southeastern Utah.

Original reference: C. T. Lupton, 1914, U.S. Geol. Survey Bull. 541, p. 128.

E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, no. 3, p. 438, 440 (fig. 2). In Wasatch Plateau, Ferron sandstone member overlies unnamed lower shale member that is equivalent to "Tununk shale" of Gilbert's (1877) section in Henry Mountains and underlies unnamed shale member below Emery sandstone member (new).

C. B. Hunt and R. L. Miller, 1946, Utah Geol. Soc. Guidebook 1, p. 8 (table). Generalized section of exposed sedimentary rocks in Henry Mountains structural basin shows that Ferron sandstone member of Mancos overlies Tununk shale member and underlies Blue Gate shale member. Thickness 150 to 250 feet.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 36, 37 (table), 80–83, pl. 1. Underlies Blue Gate shale member; overlies Tununk shale member. Thickness about 800 feet in southern Castle Valley; thins to about 75 feet at northeast end of valley and thinned part becomes increasingly shaly eastward; at Green River represented only by very thin sandy beds. In Henry Mountain region, almost 300 feet thick but thins eastward to about 150 feet; probably did not extend far east of Henry Mountains. In most parts of the region, consists of three lithologic units each having about same thickness: at base is sequence of interbedded sandstone and shale; overlying is massive sandstone; and at top is lenticular carbonaceous and coal-bearing shale and sandstone. Data on type locality. Gilbert (1877) applied name Tununk sandstone to this member.

Type locality: In Castle Valley near town of Ferron, Emery County.

Ferron Point Formation[1] (in Traverse Group)

Middle Devonian: Northeastern Michigan.

Original reference: A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 524–526.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3), 581–582, 583. Described in Thunder Bay region where it underlies Genshaw formation (redefined) and overlies Rockport Quarry limestone. Thickness at type section about 18½ feet. Included in Traverse group.

Type section: West wall of Rockport quarry at Rockport, sec. 6, T. 32 N., R. 9 E., Alpena County.

Ferry Lake Anhydrite (in Trinity Group)

Lower Cretaceous (Comanche Series): Subsurface in Louisiana, Arkansas, Mississippi, and Texas.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 4, 35–36, cross sections. Consists of about 250 feet of white to gray finely crystalline anhydrite which contains minor amounts of interbedded gray to black shale, dense limestone, and dolomite. Lies conformably between Rodessa below and Mooringsport formation (new) above. Name replaces Glen Rose massive anhydrite. Type section will be described in paper by Shreveport Geological Society.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2354–2355. Redefined as formation which occupies stratigraphic interval between base of Rusk formation (new) and top of Rodessa formation as they are recognized in Caddo Lake (Ferry Lake) area of western Caddo Parish, La. Formation thins as anhydrite grades into shale and limestone northward into southern Arkansas where it is represented in outcrop by interval of gypsum within DeQueen limestone. Ferry Lake is regional wedge thickening basinward from southern Arkansas into northern Louisiana and reaching thickness of about 250 feet in type area; extends into Texas where it grades rather abruptly into porous fossiliferous and oolitic limestones; thins to featheredge in central Mississippi. Type well designated.

Type well: Gulf Refining Co.'s Caddo Levee Board "O" Gas Unit Well No. 1, Jeems Bayou field, sec. 10, T. 20 N., R. 16 W., Caddo Parish, La. Top of unit placed at 3,823 and base at 4,072 feet.

Fetzer Tongue (of Arline Formation)

Middle Ordovician (Mohawkian): Eastern Tennessee, northern Georgia, and southwestern Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 64, chart 1 (facing p. 130). In type section, consists of 6 to 8 feet of nodular crumbly limestone with thin granular interbeds. Has general lithology of Arline formation. Generally more argillaceous than underlying beds of Lenoir limestone; overlies Paperville formation (new). Virtually the same unit as Botetourt limestone member of Edinburg formation of Shenandoah Valley of Virginia. Page 83 mentions Fetzer formation. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: Along U.S. Route 64 about 3 miles southwest of Benton Station, Benton (TVA 126–NW) quadrangle, Polk County, Tenn. Named from Fetzer Creek not far from type section along Ocoee River. Recognized in southeastern belts of Southern Appalachian region from Wytheville, Va., to Georgia.

Fibron Limestone[1]

Fibron Limestone Member (of Hendricks Dolomite)

Middle Silurian (Niagaran): Northern Michigan.

Original reference: R. A. Smith, 1916, Michigan Geol. Survey Pub. 21, p. 153.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 15. Member occupies position near top of formation. Thickness at type section about 30 feet; maximum thickness about 50 feet; thickness in type section of Hendricks 18 feet. Member is thickest high calcium layer in formation.

Type section: Abandoned Fibron quarry, about 3 miles east and 3 miles north of Rexton, Mackinac County.

†Fickett Series[1]

Silurian(?), Devonian, and Mississippian: Northern central Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 242.

Named for river called Fickett River in early reports but now known as John River.

Fidalgo Formation[1]

Triassic(?): Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington Univ. Pub. Geol., 2, p. 142–146.

Occurs on Fidalgo Head and at several localities in southeastern part of Fidalgo Island. Composes Burrows, Young, Allan, Saddlebag, Dot, and Hat Islands, and Williamson Rocks, and major part of Cypress Island.

Fiddlers Green Dolomite (in Bertie Group)

Fiddlers Green Dolomite Member (of Bertie Formation)

†Fiddlers Green Limestone[1]

Upper Silurian: Central and western New York.

Original reference: T. C. Hopkins, 1914, New York State Mus. Bull. 171, p. 12.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 9, fig. 1. Rank reduced to member status at base of Bertie formation. Underlies unnamed middle member. Overlies Camillus. Grades into Brayman shale (redefined).

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7, 9. In central New York, dolomite is considered member at base of Bertie formation. Underlies Forge Hollow member (new). Thickness 25 to 30 feet. Not restricted to Syracuse region; may be traced east and west for considerable distances. Continues westward into Falkirk member of Bertie; therefore should not be referred to Camillus shale of Salina group. Upper Silurian.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Basal formation in Bertie group in central New York. Underlies Forge Hollow shale. Fieldwork has not demonstrated lateral continuity of the Falkirk and Fiddlers Green as indicated on present chart. Thick glacial deposits conceal these units in area where they may merge. Possibility of facies changes should not be overlooked. At present, distinct names are used in western and central New York.

First described in Syracuse quadrangle.

†Fido Sandstone[1]

Upper Mississippian: Southwestern Virginia.

Original reference: Charles Butts, 1927, Virginia Geol. Survey Bull. 27.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Abandoned on basis of this report. Equivalent to top beds of Greenbrier and basal beds of Bluefield.

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1911. Butts (1927) ignored Reger's 1926 terminology, used names "Cove Creek" limestone and "Fido" sandstone for certain stages of the Mauch Chunk, and assigned everything between the Gasper (Upper Union) and St. Louis ((Hillsdale) to the Ste. Genevieve. This assignment of certain lower rocks to the Ste. Genevieve was merely an avoidance of Pickaway, Taggard, Patton, and Sinks Grove. Continued use of Butts' illogical Ste. Genevieve column has led to confusion. [See Denmar formation.]

Named for exposures in vicinity of Fido, Scott County.

†Fierro Limestone[1]

Mississippian, Pennsylvanian, and Permian: Southwestern New Mexico.

Original reference: S. Paige, 1916, U.S. Geol. Survey Geol. Atlas, Folio 199.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 7. Formation names were assigned to Carboniferous rocks in Silver City, Santa Rita and Fierro mining districts without regard to their stratigraphic relations to previously named formations in other districts of State. Consequently, several synonymous formational names were proposed for Mississippian rocks of this area. Paige (1916) introduced name Fierro for limestone beds resting on Devonian Percha shale and unconformably overlain by Cretaceous Beartooth quartzite. Lower part of the Fierro has been correlated with Lake Valley formation.

Named for Fierro mine in northeastern part Silver City quadrangle.

Fifes Peak Formation

Fifes Peak Andesite

Oligocene or Miocene: South-central Washington.

W. C. Warren, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2035. Name applied to a unit consisting of basic andesite flows and pyroclastics forming upper part of Keechelus andesitic series in Mount Aix quadrangle. Unconformable on lower part of Keechelus series. Overlapped by marginal flows of Yakima basalt.

W. C. Warren, 1941, Jour. Geology, v. 49, no. 8, p. 800–802. Described as a group of flows, agglomerates, and tuffs. Proportion of flows to agglomerates and tuffs varies from place to place; on the whole, the pyroclastic materials have the greater volume. Flows are black on fresh exposures; they are dense to vitreous, porphyritic, with clear phenocrysts of plagioclase. On weathered surfaces, rock is brownish with chalky phenocrysts. Tuffs are yellow to buff. Agglomerates are variable in color with grays, reds, and purples predominating. Underlies Yakima basalt. Presumably not younger than middle Miocene.

Occurs in Mount Aix quadrangle in vicinity of Fifes Peak, Yakima County.

Figuera Volcanics

Figuera Formation[1]

Paleocene, upper, or Eocene, lower: Pureto Rico.

Original reference: H. A. Meyerhoff and I. F. Smith, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 284.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 60 (table 7), 71. Thickness 500 feet. Underlies Fajardo shale; overlies Trujillo Alto limestone. Upper Cretaceous.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 9 (fig. 3), 22–27, pl. 2. Figuera volcanics in San Juan area consist of pyroclastic rocks of variable thickness with lenticular calcareous beds and included blocks of older limestone (Trujillo Alto? limestone) in basal part. Characteristically hornblende andesite of mauve to greenish color. Greatest thickness, about 3,000 feet, south and east of Guaynabo; about 600 feet on Trujillo Alto Road. Meyerhoff and Smith placed the Figuera stratigraphically between Trujillo Alto limestone and Fajardo shales, but noted that no outcrop of Trujillo Alto was seen in vicinity of the Figuera. The absence of common contact with Trujillo Alto at type locality and uncertainty that Fajardo shales of Meyerhoff and Smith at Fajardo and those in San Juan area are stratigraphically identical raise an element of uncertainty as to identity of the two volcanic sequences. Near Pueblo Seco and La Muda, Figuera volcanics conformably overlie Trujillo Alto limestone; between Guaynabo and Rio Piedras, apparently separated from underlying rocks by angular unconformity because north of Guaynabo the Figuera overlies Monacillo limestone (new) whereas to the south it overlies Frailes formation (new). Underlies Fajardo formation. No diagnostic fossils found above Trujillo Alto, but it is proposed that Figuera volcanics correlate with late Paleocene or early Eocene deposits of Loiza, to east, and Corozal, to west.

Two parallel bands occur near Ceiba, one at east coast of Punta Figuera, from which formation has been named; the other extends from Puerto Medio Mundo into interior for undetermined distance.

Filer Sandstone Lentil (of Amherstburg Formation)

Middle Devonian: Michigan (subsurface).

K. K. Landes. 1951, U.S. Geol. Survey Circ. 133, p. 2 (fig. 2), 7, 9, 12. Lies within carbonate rock sequence above Sylvania sandstone member of Amherstburg formation and below Lucas formation. Thickness exceeds 50 feet in Bay and western Manistee Counties, and as much as 100 feet in western Michigan.

Type section: Ruggles and Rademacher well 24, sec. 12, T. 21 N., R. 17 W., Filer Township, Manistee County. Confined for most part to western flank of Michigan Basin.

Fillmore Limestone (in Pogonip Group)

Lower Ordovician (Canadian): West-central Utah and eastern Nevada.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 9 (fig. 2), 13–16, 29 (fig. 4), 37–38, 39–40, 41–43, 45–50. Characteristically a complex of thin-bedded interbeds of intraformational conglomerate, limy siltstone, muddy limestone, and limy shales, with occasional layers of calcilutite; individual beds thin and lens out, or grade into other beds, within short distances. Thickness, composite section, about 1,500 feet; entire thickness not exposed in any one section. Thins eastward from Ibex, Utah; westward in Nevada, thickness changes little, but lithology changes considerably—intraformational conglomerates become less prominent, and quartz detritus less conspicuous in limestone, chert becomes more prominent, and several thick-bedded resistant beds appear. Overlies House limestone (new); underlies Wahwah limestone (new). Pogonip group redefined in this report.

Type localities: Ibex sections D, G, and H, are designated as type localities of various portions as listed in section descriptions. These are, respectively, approximately 2 miles south-southeast of Government Well 108 which is located in sec. 1, T. 22 S., R. 14 W.; NW¼ sec. 8, T. 23 S., R. 14 W.; east slope of lava capped butte approximately at ¼ cor. sec. 5, sec. 6, T. 23 S., R. 14 W. Name derived from Fillmore, Millard County, Utah.

Final shales (in Chuaran series)

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 113. Brown more or less sandy shales. Some thin limestone layers included. Thickness 600 feet. Underlies Oveja formation (new) unconformably; overlies Marble limestone.

Exposed in Chuar Valley under Cape Final, a long tongue reaching down from Kaibab Plateau; Grand Canyon region.

Fina-sisu Formation

Oligocene, upper: Mariana Islands (Saipan).

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 60–62, chart 1, pls. 1, 2. Calcareous marine tuffs and interbedded andesite flow rocks, with distinctive planktonic smaller Foraminifera in some of tuffs. Flows commonly less than 20 feet thick but one is 80 to 100 feet. Maximum exposed thickness about 400 feet in type section; base of formation nowhere exposed. Overlapped by Tagpochau limestone.

Type section: Fina-sisu hills or ridge, south of As Lito village. Section extends eastward from fault at west side of Fina-sisu hills up ravine 300 to 400 feet south of structure section C–C' (pls. 1, 2), and south of As Lito village, to unconformably overlapping *Acropora*-rich facies of Mariana limestone.

Finger Bay Volcanics

Tertiary(?): Southwestern Alaska.

R. R. Coats, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 5, p. 75–76, pls. 6; pt. 7, p. 101, pl. 8. Sequence of volcanic rocks on Adak Island consisting of black, dark-gray, purplish-gray, greenish-gray and grayish yellow-green basaltic tuff, basalt flows, tuff-breccia, agglomerate, and dikes with a few small rhyolitic flows and dikes. Some rocks conspicuously porphyritic. In general, rocks are intensely altered and locally recrystallized. Thickness at least 2,000 feet and possibly as much as 15,000 feet. Intruded by Zeto Point basalt porphyry (new). Tentatively assigned to the Mesozoic.

F. S. Simons and D. E. Mathewson, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 4, p. 57, 60–61, pls. 4, 5. Oldest rocks exposed on Great Sitkin Island. Predominantly andesitic and basaltic greenstone, and include coarse- to fine-grained porphyritic flows, amygdaloidal flows, coarse flow-breccia, pillow lava, and dense fine-grained rocks that are probably flows, and also coarse- to fine-grained tuff. Unconformably underlies Sand Bay volcanics (new). Chain of islands between Great Sitkin and Adak seem to be composed largely if not entirely of Finger Bay volcanics. Source of volcanics not known.

F. S. Simons and D. E. Mathewson, 1955, U.S. Geol. Survey Bull. 1028–B, p. 27–28, pl. 5. Age not definitely known but believed to be late Paleozoic. Mapped as Pennsylvanian(?) or Permian(?).

R. R. Coats, 1956, U.S. Geol. Survey Bull. 1028–C, p. 48–49. Described on northern Adak Island. Leaf impressions, identified as *Annularia stellata* (Schlotheim) Wood, of Pennsylvanian or Permian age, have been collected from sandstone in northernmost outcrops, isolation of sequence in which fossil was found from type area about Finger Bay and Sweeper Cove introduces the possibility that rocks of more than one age are included in the mapped unit. At present, Finger Bay volcanics are regarded as Paleozoic(?).

G. D. Fraser and G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–M, p. 377–384. Coats (1956) included a body of fossiliferous yellow sandstone of volcanic composition, basaltic flows, and sills that crop out between Clam Lagoon and Andrew Lake in northern Adak Island in his Finger Bay volcanics as mapped. The rocks are Pennsylvanian or Permian as indicated by impressions of fossil leaves. Relations of these fossiliferous rocks to rocks of Finger Bay volcanics, which are continuous with those mapped as Finger Bay volcanics in southern Adak Island (and identical with those of Kagalaska Island) are uncertain. Volcanic sandstone beds of northern Adak Island are doubtless terrestrial beds, whereas Finger Bay volcanics of this report is interpreted as marine Tertiary(?) age believed more probable than Paleozoic(?) for Finger Bay volcanics.

Underlies southern part of northern Adak Island; well exposed in Finger Bay from which it takes its name. Also on chain of islands extending eastward to Great Sitkin Island and beyond; in central part of Aleutian Islands.

Finger Lakes Group

Finger Lakes Stages

Upper Devonian (Senecan): North America.

G. A. Cooper and others, 1942. Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1734, chart 4. Devonian is subdivided into 10 stages of which the Finger Lakes is seventh in sequence (ascending). [For complete sequence see Helderberg stage this reference.] Preceded by Taghanic stage (new). Includes strata from top of Geneseo shale to base of Chemung stage (Cayuta shale and sandstone and Grimes sandstone). Sequence includes Genesee and Naples groups.

A. T. Cross and J. H. Hoskins, 1951, Jour. Paleontology, v. 25, no. 6, p. 718 (fig. 3). Shown on composite stratigraphic column of western New York and northwestern Pennsylvania as Finger Lakes group. Includes Portage and Catskill formations. Overlies Taughannock group; underlies Chemung group.

Type section (stage): In Finger Lakes country of New York where these rocks are exposed on all the larger lakes.

Finis Formation (in Caddo Creek Group)

Finis Shale Member (of Graham Formation)[1]

Pennsylvanian (Canyon Series): Central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31; Texas Univ. Bull. 2132, p. 127–128.

B. F. Howell, Wagner Free Inst. Sci., v. 28, no. 1, p. 4. Referred to as Finis formation in Caddo Creek group, Canyon series.

Named for Finis, Jack County.

Finlay Limestone

Finlay Limestone (in Fredericksburg Group)[1]

Finlay Limestone (in Sixshooter Group)

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 47.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 1004. In vicinity of northern Quitman Mountains, overlies Cox sandstone; underlies Kiamichi formation. Thickness about 100 feet. Basal formation of Fredericksburg group.

R. M. Huffington, 1947, Harvard Univ. Summ. of Theses, 1943–1945, p. 196. In Quitman Mountains, overlies Cox formation; underlies Tarantula formation (new).

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 22–24, pls. 1, 10. Described in Eagle Mountains, Hudspeth County. Thickness 198½ feet. Overlies Cox sandstone; underlies Kiamichi formation. Map bracket shows the Finlay as basal formation in Fredericksburg group.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Described in Wylie Mountains and vicinity where it is basal formation of Sixshooter group (new). Underlies Boracho formation (new); overlies Cox sandstone. Thickness 110 to 170 feet.

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 374 (fig. 2), 378–379. Described in Kent quadrangle. Basal member of Sixshooter group. Underlies Levinson limestone member (new) of Boracho limestone. Unconformably overlies Cox sandstone. Thickness 40 feet.

Named for Finlay Mountains, El Paso County.

†Finley Limestone[1]

Lower Ordovician (Beekmantown): Southwestern Missouri.

Original reference: E. M. Shepard, 1904, Bradley Geol. Field Sta. Drury Coll. Bull. 1, pt. 1, p. 42.

Finley Creek, Christian County.

Finley Knob Shale Member (of Carwood Formation)[1]

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 100, 111, 116, 148, 151, 152, 154, 158, 162–163.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 75. Finley Knob shale member included in Bennettsville facies of Carwood.

Name derived from Finley Knob, on Knobstone Escarpment, NW¼ sec. 5, T. 2 N., R. 6 E., 6 miles west of Vienna, Scott County.

Finney Greenschist

Age not stated: Northern Washington.

R. W. Jones, 1959, Dissert, Abs., v. 20, no. 3, p. 994. Consists of actinolite-, tremolite-, glaucophane-, and crossite schists with interlayered quartz-albite schists. Forms core of synclinorium. Gold Mountain phyllite (new) forms adjacent anticlinorium.

Report discusses geology of Finney Peak area, northern Cascades.

Finnie Sandstone Member (of Abbott Formation)

Finnie Sandstone (in Tradewater Formation)[1]

Pennsylvanian: Western Kentucky, southern Illinois, and southern Indiana.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Bull. 17, p. 13, 14, 23, 24.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 34, 83. Massive sandstone in lower part of Tradewater formation between Ice House above and Bell coals; locally attains maximum thickness of 60 to 80 feet. Recognized in Indiana.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1), 62. Reallocated to member status in Abbott formation (new). Replaces name Delwood sandstone so that term Delwood may be retained for the coal. Overlies Willis coal member (new); underlies Delwood coal member (new). Thickness about 60 feet at type section of Abbott. Type locality stated. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Along road for less than 2 miles north of Mulfordtown [Milfordtown], near Caseyville, Union County, Ky. Named for Finnie Bluff, on road north of Milfordtown.

Fire Clay Hill Bentonitic Shale (in Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 19–22, pl. 2. Fluffy soil indicative of bentonite with gentle to steep scarps, characterizes weathered outcrop of these gray to purplish beds. Towards the base, calcareous concretions and geodes as much as 6 inches in diameter occur sporadically and in places are associated with concretions of iron-oxide and copper-bearing concretions. Agate beds banded with red, orange, green, yellow, and white occurs at base of shales, ranges in thickness from fraction of an inch to almost a foot, and is remarkably persistent total. Thickness changes a little from East Reef to West Reefs; average is 10–13 feet. Underlies Trail Hill sandstone (new); overlies Hartley shale and sandstone (new).

Best exposures of shales on East Reef 1,000 feet north of Duffin mine. Best exposures of agate bed at base of Fire Clay Hill south of old town of Silver Reef, Silver Reef (Harrisburg) Mining District, Washington County.

Fire Creek Underclay (in New River Group)

Pennsylvanian (Pottsville): Eastern West Virginia.

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 18. Medium gray clay, about 4 feet thick, in lower part of New River group; about 900 feet below base of Kanawha group. Commonly occurs immediately below Fire Creek coal, but locally is separated from it by a foot of carbonaceous shale.

Present in Webster County.

Firemoon Limestone Member (of Piper Formation)

Middle Jurassic: Central and eastern Montana (subsurface and surface) and western North Dakota (subsurface).

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 97, 101–102. Consists of 69 feet of buff to brown, dense to earthy limestone in type section, which is typical of member throughout much of northern and eastern Montana. Locally becomes sandy and oolitic. In some wells, member is dolomitic and cherty, especially on east flank of Sweetgrass arch. In south-central Montana, unit is thinly bedded with much varicolored claystone and locally some gypsum. Pebbly oolitic and coquinoid limestones common. Very uniform in thickness. In outcrop sections, member appears transitional with underlying Tampico shale member (new) and overlying Bowes member (new), but in subsurface of northern Montana stratigraphic boundaries generally sharp. West and south of Bearpaw Mountains, it overlaps Tampico member and unconformably rests on Madison limestone. Occasionally in contact with Amsden formation on Big Snowy platform. Unit is correlative to middle limestone member of Piper as described by Imlay and others (1948).

Type section: Interval from 4,618 to 4,687 feet in Murphy Corp. No. 1 Firemoon well, center SE¼SE¼ sec. 12, T. 30 N., R. 41 E., Valley County, Mont.

First Street terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941 (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703 (fig. 8), 1710, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name First Street proposed for terrace deposit that is younger than and lies about 18 feet below Beaumont (Sixth Street) terrace. Composed of dark weathering silt overlying limestone gravel.

Named for occurrence at corner of First and Chicon Streets, Austin, Travis County. Extends much of length of First Street east of Congress Avenue.

Fish Creek Argillite[1]

Paleozoic(?): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 80, map.

Occurs along Fish Creek, Stevens County.

†Fish Creek Beds[1]

Upper Cretaceous: Central southern Montana.

Original reference: E. Douglass, 1902, Am. Philos. Soc. Proc., v. 41, p. 207–221.

In area east of Crazy Mountains and south of Big Snowy Mountains, in basin of Musselshell River. Well exposed between Fish and Mud Creeks, a few miles from where the latter empties into Musselshell River Sweetgrass County.

Fish Creek Gypsum

Miocene: Southern California.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 22, pl. 2. Playa deposit of white bedded gypsum and anhydrite. Ranges in thickness from knife edge to about 100 feet. Rests on Split Mountain conglomerate and is overlain by Imperial formation in western Fish Creek Mountains.

Occurs in Fish Creek Mountains in southwestern Imperial Valley.

Fish Creek Sandstone Member (of Greene Formation)[1]

Permian: Southwestern Pennsylvania, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K, p. 42.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 17. Fish Creek sandstone listed in summary of stratigraphic sections of Dunkard group in Harrison County. Thickness about 30 feet. Occurs above Fish Creek coal and below unnamed shale below Hostetter coal and (or) fire clay.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Fish Creek sandstone listed in Greene series. Occurs above Fish Creek coal and below Hostetter coal.

Named for exposures on Fish Creek, southwestern Greene County, Pa.

Fish Creek Shale (in Greene Formation)[1]

Permian: Northern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 183.

Named for association with Fish Creek coal.

†Fish Creek shale (in Medinan Group)

Lower Silurian: Western New York, and southern Ontario, Canada.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1987–1988. Name proposed for medium-dark-gray argillaceous rock with minor amounts of angular quartz silt, secondary silicia, and secondary calcite. Thin beds of calcareous sandstone occur near base. Includes Rumsy Ridge sandstone member (new) 6 feet above base in Niagara Gorge. Maximum thickness 24 feet. Underlies Manitoulin dolomite; overlies Whirlpool sandstone with transitional contact. Unit corresponds to lower part of Power Glen formation of Ontario, and abandonment of latter name suggested.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Name preoccupied; replaced by Rumsy Ridge shale herein given formational status.

Type locality: In Niagara Gorge. Best sections include those near old tunnel for abandoned New York Central Railroad, 0.9 mile south of center of village of Lewiston and 0.2 mile south of American end of Lewiston suspension bridge, Niagara County, N.Y. Also well exposed where Fish Creek cascades down east wall of Niagara Gorge, 500 feet south of Lewiston Bridge.

Fisher Formation[1]

Eocene, upper, and Oligocene: Northwestern Oregon.

Original reference: H. G. Schenck, 1927, California Univ. Pub. Dept. Geol. Sci. Bull., v. 16, no. 12, p. 451, 459.

H. E. Vokes, P. D. Snavely, Jr., and D. A. Myers, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–110. Continental Fisher formation consists of approximately 7,000 feet of clastic material, largely andesitic lapilli tuffs and breccias, but includes also large amounts of basaltic and some rhyolitic fragmental debris; in lower part of formation are lenses of coarse water-laid conglomerate that may be as much as 50 feet thick and contain boulders predominantly of andesitic composition, as much as 4 feet in diameter. At all exposures mapped, Eugene formation rests on tuffs of the Fisher, the contact being marked by soft friable arkosic and quartzose sandstone that contains much fossil wood. Evidence indicates Fisher and Eugene formations are contemporaneous. Overlies Spencer formation (redefined). Upper Eocene and Oligocene.

Typically exposed in vicinity of Coyote Creek sec. 12, T. 18 S., R. 5 W., about 8 miles west of Eugene, and near Fisher Butte, one-quarter mile west of Oak Hill, Lane County.

Fisher Quartz Latite

Fisher Latite-Andesite[1]

Tertiary, middle or upper: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13, p. 20, 23–33.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13, 172–185, pl. 1. Termed Fisher quartz latite. Characteristically a chaotic aggregate of flows and breccias. Outcrops are mostly light gray to brownish and somewhat darker than those of rhyolites of Potosi volcanic series. Maximum thickness about 1,000 feet. Overlies different formations of Potosi volcanic series from Conejos quartz latite to Piedra rhyolite; also locally overlies older rocks and Creede formation. In most places, not overlain by younger formations but locally overlain by Hinsdale formation.

T. A. Steven and J. C. Ratté, 1960, U.S. Geol. Survey Prof. Paper 343, p. 13–28, pls. 1, 2. Fisher quartz latite, in Summitville district, differentiated into two members separated by an unconformity. Lower member consists of rhyo-dacite and quartz latitic flows, volcanic domes, and pyroclastic rocks (tuff and volcanic breccia) that were erupted onto irregular surface cut across earlier volcanic rocks of San Juan Mountains. Resulting pile of volcanic rocks was faulted, locally altered by hydrothermal activity, and deeply eroded before renewed eruptions poured out quartz latitic lava flows to form upper member of formation. Unconformable above Conejos formation. Middle or upper Tertiary.

Named for exposures in vicinity of Fisher Mountain, Creede quadrangle.

Fish Haven Dolomite[1]

Upper Ordovician: Southern Idaho and northeastern and western Utah.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 407, 409.

L. L. Sloss, 1954, Geol. Soc. America Bull., v. 65, no. 4, p. 365, 366, 367 (fig. 1). In Lemhi arch, Idaho, overlies Kinnikinic quartzite and underlies Laketown and(or) Jefferson dolomite. Thickness 41 to 700 feet.

R. W. Rush, 1956, Utah Geol. and Mineralog. Survey Bull. 53, p. 12 (fig. 3), 16 (fig. 4), 18–19, measured sections. In western Millard County, Utah, is predominantly dolomite with chert; subdivided into five unnamed members. Thickness 505 to 590 feet. Conformably underlies Roberts Mountain[s] formation; overlies Eureka quartzite.

P. D. Proctor and others, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–45. Mapped in Allens Ranch quadrangle where it is 280 feet thick. Overlies Opohonga limestone and underlies unit referred to as Bluebell and Fish Haven undifferentiated.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 10, 11 (fig. 3). In East Tintic Mountains, underlies Bluebell dolomite and overlies Opohonga limestone. Thickness 275 to 350 feet. As used in this area, includes lower third of Bluebell dolomite of Loughlin (1919); thus, it includes Eagle dolomite plus lower half or so of Beecher dolomite.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 28 (fig. 4), 31–33. In Stansbury Mountains is as much as 260 feet thick, underlies Laketown dolomite and overlies Kanosh shale. In northern areas, where Kanosh is missing, overlies Garden City formation.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 137–140. In Fivemile Pass-North Boulter Mountain area consists essentially of dark-gray and medium gray-blue aphanitic to coarse-crystalline dolomite in thin- to massive-bedded layers, with some gray chert. Thickens gradually through Boulter Mountains to about 70 feet in Rattlesnake spur area. Disconformably underlies Laketown dolomite; overlies Opohonga limestone.

M. H. Staatz and F. W. Osterwald, 1959, U.S. Geol. Survey Bull. 1069, p. 17–21, pl. 1. Described in Thomas Range, Juab County, Utah, where it is 280 to 303 feet thick; overlies Swan Peak formation and underlies Floride dolomite (new).

Named for exposures on Fish Haven Creek, Bear Lake County, Idaho.

†Fish House Beds[1]

Pleistocene: Southern New Jersey.

Original reference: L. Woolman, 1897, New Jersey Geol. Survey Ann. Rept. State Geologist 1896, p. 201.

At Fish House, on Delaware River, about 5 miles north of Camden, Camden County.

Fish House Clay[1]

Pleistocene: Southern New Jersey.

Original reference: R. D. Salisbury, 1895, New Jersey Geol. Survey Ann. Rept. State Geologist 1894.

At Fish House, on Delaware River, about 5 miles north of Camden, Camden County.

Fishkill Limestone[1]

Cambrian and Ordovician: Southeastern New York.

Original reference: J. M. Clarke, 1909, New York State Mus. Bull. 133, p. 12–18.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 329, 343. Name rejected. Stockbridge has priority.

Crops out in town of Fishkill, northwest of road from Fishkill Village to Matteawan, Dutchess County.

Fishpot cyclothem

Pennsylvanian (Monongahela Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 168 (map 21), 170–172. Embraces interval between Redstone cyclothem (new) below and Lower Sewickley cyclothem (new) above. Normal sequence includes six members (ascending): Pomeroy sandstone, Fishpot redbed, Fishpot limestone, Fishpot underclay, Fishpot coal, and Fishpot roof shale. Thickness varies from 15 to 50 feet; average 44 feet; variability is attributed to thickening and thinning of Pomeroy sandstone. In area of this report, Monongahela series is discussed on cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Present in Athens County.

Fishpot Limestone Member (of Monongahela Formation)[1]

Fishpot Limestone (in Monongahela Group)

Fishpot limestone and shale member

Upper Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K.

M. N. Shaffner, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 141. Shown on columnar section below Sewickley sandstone and above Redstone coal in Monongahela group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 71–72, geol. map. Fishpot limestone and shale member (Monongahela series) occupies interval between Pomeroy sandstone (below) and Fishpot clay members. In Morgan County, consists of an alternation of limestone and calcareous shale layers which vary rapidly in thickness and lateral extent. Thickness 15 to 33 feet. Basal contact is uncertain where the sandstone and shale development extends upward in thick section; summit boundary indefinite where Fishpot coal and clay members are absent and where overlying Lower Sewickley sandstone is shaly; locally the Fishpot extends to or near base of Meigs Creek (No. 9) coal. In three localities; Pomeroy sandstone occupies entire interval of Fishpot limestone.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 171. Member of Fishpot cyclothem in report on Athens County. Thickness as much as 34 feet. Monongahela series.

Probably named for occurrence at mouth of Fishpot Run in southern Washington County, Pa.

Fishpot roof shale member

See Fishpot cyclothem.

Fishpot Sandstone (in Monongahela Formation)[1]

Upper Pennsylvanian: Eastern Ohio.

Original reference: R. E. Lamborn, 1930, Ohio Geol. Survey, 4th ser., Bull. 35, p. 29, 32, 181, 234, 235–236.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 71. Term Fishpot sandstone, as defined by Lamborn (1930), was applied to a sandstone occurring between the Fishpot and Sewickley (Meigs Creek) coals. Probable correlation with Lower Sewickley sandstone of West Virginia was recognized by Lamborn; thus, the term Fishpot as applied by Lamborn is stratigraphically higher than the Pomeroy sandstone of Lovejoy. On "Generalized Section of Rocks of Ohio," published by Ohio Geological Survey (Stout, 1939 and 1947), the sandstone above the Redstone (Pomeroy) (No. 8–A) coal is designated as the Fishpot or Pomeroy sandstone. However, the Ohio Geological Survey no longer considers the Fishpot sandstone correlative with the Pomeroy sandstone, and term Fishpot is abandoned.

Type locality and derivation of name not stated.

Fishpot underclay member

See Fishpot cyclothem.

Fisk Formation (in Admiral Group)

Permian (Wolfcamp Series): North-central Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, p. 66 (fig. 1), 95–96. Proposed for the limestones and underlying shales and sandstones ("Indian Creek bed" of Drake, 1893 [Indian Creek shale member of Admiral formation]) that occur above the Hords Creek formation (redefined) and below the disconformity at the base of the newly defined Jim Ned shale.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip June 11–12, p. 15. Wildcat Creek shale and Overall limestone members of Admiral formation are names being introduced by R. C. Moore to replace "Indian Creek" shale and "Coleman" limestone of earlier reports. These two members are equivalent to the Fisk formation.

Name derived from village of Fisk about 12 miles southwest of Coleman, Coleman County. Fisk is located on upper part of the formation.

Fiske Creek Formation

Upper Jurassic[?] or Cretaceous[?]: Northern California.

Klaus Küpper, 1956, Cushman Foundation Foram Research Contr., v. 7, pt. 2, no. 152, p. 40–47. Description of Upper Cretaceous pelagic Foraminifera from "Antelope shale" of Taliaferro (1954). Kirby (1943, California Div. Mines Bull. 118) referred to these strata as Horsetown formation of Shasta group. J. Lawton (unpub. thesis) has proposed term Fiske Creeke formation for this unit. In present report, term "Antelope shale" is used as most suitable published name, although it is a junior homonym of "Antelope formation" (Miocene) subsurface, Kern County, Calif., described by Noble (1940, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3).

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Uppermost of six formations in area studied. Overlies Brophy Canyon formation (new). Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Fiss Fanglomerate (in Tropico Group)

Miocene(?): Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 137 (fig. 1), 138, 141. Composed of ill-sorted cobbles and boulders of pinkish-brown rhyolitic volcanic and granitic rocks; crudely bedded; nonfossiliferous. Thickness at type section about 500 feet; 1 mile northwest 900 feet; at Antelope Buttes about 1,700 feet. Overlies Gem Hill formation (new), in places unconformably; top is eroded, and, north of Rosamond, fanglomerate is unconformably overlain by gravel of probable Pleistocene age.

Type locality: Fiss Hill, in west-central part sec. 1, T. 9 N., R. 13 W., San Bernardino base and meridian, 1½ miles north-northeast of Tropico mine, 4½ miles northwest of Rosamond, Rosamond quadrangle, Kern County. Crops out discontinuously about 8 miles along southwestern margin of Rosamond Hills from the west end 6 miles northwest of Rosamond to Red Hill.

Fitch Formation[1]

Middle Silurian: West-central New Hampshire.

Original references: M. P. Billings and A. B. Cleaves, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 196; 1933, Am. Jour. Sci., 5th ser., v. 25, no. 146, p. 149.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 24–27. Formation is in chlorite metamorphic zone northwest of the Ammonoosuc River. Interbedded rocks in that area include bluish-gray limestone, white marble, buff dolomite slate, gray calcareous slate and gray slate; less common are white calcareous sandstone, gray arenaceous limestone, white arkose and light-gray quartz conglomerate. In other areas, formation is represented in staurolite metamorphic zone by white to buff marble, greenish-gray diopside-actinolite granulite, greenish-gray actinolite marble, purplish-brown actinolite-biotite schist, purplish-brown biotite-calcite schist, light-gray arenaceous marble, white quartzite, and light-gray mica schist. Also includes amphibolites in area west of Newport. Overlies Clough formation: underlies Littleton formation. Distribution discontinuous; hence, not everywhere present between Clough and Littleton formations.

Named for [G. E.] Fitch Farm, 2 miles northwest of Littleton, Grafton County.

Fitchburg Granite[1]

Upper Carboniferous or post-Carboniferous: Central Massachusetts and south-central New Hampshire.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 231–233, map.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 67. Represented mostly by granodiorite in the Fitchburg pluton in New Hampshire. Granodiorite was mapped with the granite by Emerson (1917).

Outcrop area extends through Fitchburg, Mass.

Fitch Hill Arkose[1]

Silurian (Niagaran): Northwestern New Hampshire.

Original reference: F. H. Lahee, 1913, Am. Jour. Sci., 4th, v. 36, p. 231–250.

Forms Fitch Hill, northwest of town of Lisbon, Grafton County.

Fitch Hill Granite Gneiss[1]

Silurian(?): Northwestern New Hampshire.

Original reference: F. H. Lahee, 1913, Am. Jour. Sci., 4th, v. 36, p. 231–250, map.

Probably named for proximity to Fitch Hill, northwest of town of Lisbon, Grafton County.

Fitchville Formation

Lower Mississippian: Central Utah.

M. D. Crittenden, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 63, 65, 69 (fig. 3). Basal beds in Provo area are characterized by yellowish-weathering unit ranging from 1 to 10 feet thick and varying in composition from limy siltstone to well-cemented quartzite; bulk of formation is dolomite, commonly with two distinct and roughly equal units—a lower one of light-gray medium-grained dolomite and an upper one of coarser grained dark-gray dolomite—separated by a few feet of yellowish limy siltstone much like that at base. Thickness 170 to 265 feet. In some places overlies limestone member of Ophir shale, and in others overlies about 200 feet of Maxfield limestone; underlies Gardison limestone (new). Unit formerly presumed to be Devonian and called Jefferson(?) dolomite (Calkins and Butler, 1943, U.S. Geol. Survey Prof. Paper 201). Name credited to Morris and Lovering.

Named for exposures on Fitchville Ridge, East Tintic Mountains.

Fite Limestone[1]

Ordovician: Central eastern Oklahoma.

Original reference: I. H. Cramm, 1930, Oklahoma Geol. Survey Bull. 40-QQ, p. 20–22.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 24–26, pls. 3, 4. Described on southwestern flank of Ozark uplift as a predominantly light-gray dense lithographic limestone characterized by specks and streaks of clear calcite; near base is a 3-foot bed of buff sandy dolomite underlain by 2 feet of gray lithographic limestone; upper beds are massive when fresh but weather into layers 4 to 20 inches thick. Thickness about 8 feet. Unconformably underlies Fernvale limestone; believed to conformably overlie Tyner formation; alternating ledges of Tyner and Fite lithologies in basal parts are thought to represent transition from dominantly dolomite facies of Tyner to lithographic limestone of Fite.

Named from exposures on estate of Dr. Fite in sec. 11, T. 17 N., R. 22 E., northeast of Tahlequah, Cherokee County.

Fittstown Member (of Bois d'Arc Formation)

Silurian and Devonian: South-central Oklahoma.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 45–47, fig. 4. Name proposed for upper member of formation. Described as fossiliferous calcarenite with relatively low silt-clay content; beds 6 or 8 inches thick; locally contains nodules and lenses of chert. Thickness difficult to determine due to gradational nature of lower boundary; maximum thickness 75 feet (on Haragan Creek); on Lawrence uplift, thickness ranges from 25 to 60 feet. Overlies Cravatt member; underlies Frisco formation.

Type locality: Along Chimneyhill Creek, SE¼ and NE¼ sec. 4, T. 2 N., R. 6 E., Pontotoc County. Named from town of Fittstown.

Fitzwilliam Granite[1]

Upper Carboniferous or post-Carboniferous: Southwestern New Hampshire and central northern Massachusetts.

Original reference: C. H. Hitchcock, 1873, Am. Assoc. Adv. Sci. Proc., v 21, p. 134–135.

Named from Fitzwilliam, Cheshire County, N.H.

Fivemile Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 295–296, 338–340.

Type locality: Fivemile Creek, along Princeton-Narrows Road, 4.5 miles southeast of Princeton, Mercer County, W. Va.

Five Oaks Limestone (in Cliffield Group)

Five Oaks Limestone (in Lurich Formation or Group)

Five Oaks Limestone Member (of Cliffield Formation)

Middle Ordovician: Northeastern Tennessee and southwestern Virginia.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 826, 863, 884 (fig. 3). In Tazewell County, the strata embraced by the Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into 29 zones (ascending). Name Five Oaks limestone member of Cliffield formation is applied to zone 4, described as the first calcilutite, the lowest of four zones of fine-grained high-calcium limestone. Thickness at type locality 50 feet; average thickness about 25 feet. Overlies Blackford member (new); underlies Ward Cove member (new). Five Oaks member is Butts' Mosheim in Burkes Garden, Thompson Valley, and in median and northwestern belts west of Tazewell but does not correspond to the Mosheim of the Yellow Branch section in Lee County.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 57–58. In area between Brushy and Walker Mountains, the Five Oaks is considered a formation in Cliffield group.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66, p. 17 (fig. 3), 44–46. Overlies Elway limestone (new).

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1148–1150. Widely distributed and represented in all belts in southwestern Virginia and northeastern Tennessee. In local absence of the Blackford, the Five Oaks rests directly on Beekmantown dolomites. Thickness at Rye Cove, Va., 90 feet.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 33–34, 41–43. Probably correlates with Rob Camp limestone of Jonesville district. Discussion of problems of correlation and summary of nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 69, 72. Included in Lurich formation or group (new).

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Quad. Map GQ–111. In Duffield quadrangle, the upper 15 feet of the Elway may be equivalent to the Five Oaks limestone as used by Cooper (1945) in Scott County.

Type locality: In lime quarry at Five Oaks village, about 4 miles northeast of Tazewell, Tazewell County, Va.

Five Point Limestone Member (of Janesville Shale)

Five Point Limestone (in Admire Shale)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: R. C. Moore and G. E. Condra, Oct. 1932, Revised classification chart of Pennsylvanian rocks of Kansas and Nebraska.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Reallocated to member status in Janesville shale (new). Underlies Hamlin shale member; overlies West Branch shale member. Wolfcamp series.

Type locality: Five Point Creek, near Five Point School, sec. 25, T. 1 N., R. 15 E., 2 miles south and 4½ miles west of Falls City, Richardson County, Nebr.

Fizzle Flat Lentil (in Terlingua Formation)

Cretaceous (Gulf Series): Western Texas.

C. G. Moon, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 151, 159 (fig. 2), 160, 164. Name applied to a 50-foot rock unit that occurs about the middle of the Bouquillas-Terlingua sequence and is considered as the base of the Boquillas-Terlingua unit. The lentil, termed a transition zone, is predominantly a creamy-yellow platy impure limestone.

Occurs in Agua Fria quadrangle, in southwestern part of Brewster County, in Big Bend region.

Flades Clay[1]

Silurian (Niagaran) : East-central Kentucky.

Original references: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145; 1906, Bull. 7, p. 10, 18, 60.

Named for Flades Creek, east of Crab Orchard, Lincoln County.

Flag Pond Granite Group

Precambrian: North Carolina and Tennessee.

Ebraham Shekarchi, 1959, Dissert. Abs., v. 20, no. 4, p. 1323. Crystalline complex is divided into two groups, Flag Pond granite and unakite granite. Both groups contain mylonite, pegmatite, diorite bodies, basic dikes, and various types of granite. Flag Pond granite group is a medium- to fine-grained granite with units of sheared biotite granite.

Report discusses geology of Flag Pond quadrangle, Tennessee-North Carolina.

Flag Rock Formation

Precambrian: Southwestern South Dakota.

T. A. Dodge, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 563. Graphitic, sandy, or pyritic schists: some quartzite. Thickness 5,000 feet. Unconformably overlies Northwestern formation; underlies Grizzly formation (new).

J. A. Noble and J. O. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 944, 949–952, pl. 1. Heterogeneous. Most abundant material is light-gray sericitic phyllite or schist. Special feature of formation is the Iron Dike that forms conspicuous outcrops on hilltop to east and northeast of Lead. This consists of dense siliceous jaspery material, for the most part without visible bedding. Thickness 5,000 feet, but there may be some duplication by faulting. Overlies Northwestern formation; underlies Grizzly formation.

In Lead district.

Flag Spring Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Ohio.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, p. 889–890.

Named for well-known locality in Walnut Township, Gallia County.

Flag Spring Trachyte[1]

Tertiary, middle or upper: Northwestern Arizona.

Original reference: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743.

Well exposed in cliffs along Cottonwood Canyon. Named for Flag Spring, in the canyon, Oatman district.

Flagstaff Limestone[1]

Flagstaff Formation

Paleocene, upper, and Eocene, lower(?) : Central eastern Utah.

Original reference: E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, p. 150–151, 488.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 135–136. Limestone, gray shale, gray sandstone, some oil shale. Thickness 300 to 1,500 feet. Overlies North Horn formation with local unconformity; underlies Colton formation. Age uncertain, more likely Paleocene than lower Eocene.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., No. 8, p. 25–33, pl. 2. Formation described in Gunnison quadrangle; term limestone considered inappropriate in area west of Sevier Valley where unit contains large amounts of sandstone and conglomerate. Four more or less distinct facies in area: Valley Mountain, yellow, gray, and red dense massive limestone with some shale; red limestone, arenaceous, in part, interbedded with considerable amounts of sandstone and conglomerate; Fayette facies, massive gray dense limestone; and Willow Creek, conglomerate and limestone. Throughout extent, lacustrine Flagstaff strata are gradational with fluviatile sediments of underlying North Horn formation and overlying Colton formation. Fauna indicates early Tertiary no younger than Eocene, and, in view of other date, late Paleocene age seems acceptable.

S. L. Schoff, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 622 (table 2), 631–632. Described in Cedar Hills area where it is 750 feet thick; overlies North Horn formation and underlies Colton formation. Upper Paleocene and lower Eocene.

Aurèle La Rocque, 1960, Geol. Soc. America Mem. 78, 100 p. Formation divided into three units: lowest, Paleocene; middle, Paleocene or Eocene; and upper, Eocene. This determination made on basis of study of molluscan faunas. Unconformably overlies North Horn formation; underlies and interfingers with Colton formation; where Colton is absent, underlies Green River formation. Type section noted.

U.S. Geological Survey currently designates the age of the Flagstaff Limestone as upper late Paleocene and lower Eocene(?) on basis of a study now in progress.

Type section: On slopes of Flagstaff Peak, T. 20 S., R. 5 E., San Pete County.

Flambeau Quartzite[1]

Precambrian (Huronian): Northwestern Wisconsin.

Original reference: W. O. Hotchkiss and others, 1915, Wisconsin Geol. Nat. History Survey Bull. 44, econ. ser. 19, p. 50.

Probably named for exposures at Flambeau or on Flambeau River, Rusk County.

†Flaming Gorge Group[1]

Upper Jurassic: Northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 51, 146, 151.

Named for Flaming Gorge, on south side of Green River, at mouth of Henrys Fork, Uintah County, Utah.

†Flanagan Limestone[1]

Middle Ordovician: Central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 2.

Term Flanagan Limestone abandoned. Woodburn and Brannon Limestones, formerly classified as members of the Flanagan are now classified as members of Cynthiana Formation.

Named for exposures at Flanagan Station, Clark County.

Flannigan Coal Member (of Bond Formation)

Pennsylvanian: Southeastern and eastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), pl. 1. Assigned member status in Bond formation (new). Occurs above Mount Carmel sandstone member and below Reel limestone member. Coal named by Newton and Weller (1937, Illinois Geol. Survey Rept. Inv. 45). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Flannigan Township, T. 6 S., R. 5 E., Hamilton County.

Flannigan cyclothem (in Bond Formation)

Flannigan cyclothem (in McLeansboro Group)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 10; J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). In sequence, occurs below Macoupin cyclothem and above Shoal Creek cyclothem. Thickness about 26 feet.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Bond Formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Named from exposures in Flannigan Township, Hamilton County.

Flat Creek Coal Member (of Bond Formation)

Pennsylvanian: Central and southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), 72, pl. 1. Name applied to coal member stratigraphically above Bunje limestone member (new) and below Witt coal member (new). Thickness about 1 foot. Name credited to J. A. Simon (unpub. ms.). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼SE¼ sec. 24, T. 6 N., R. 5 W., Bond County. Named for exposures along Flat Creek.

Flat Creek cyclothem (in Bond Formation)

Flat Creek cyclothem (in McLeansboro Group)

Pennsylvanian: South-central Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). Name appears in list of cyclothems in McLeansboro group. Occurs below an unnamed cyclothem below the Millersville cyclothem and above Bunje cyclothem (new).

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 6, 7, 11, pl. 1. Simon (1946, unpub. thesis) worked out sequence above Shoal Creek limestone in Bond County and proposed terms (ascending)

Sorento, Bunje, and Flat Creek for cyclothemic units in lower half of interval. A persistent cyclic succession intervenes between the Flat Creek and Millersville; term Reel limestone has been used for the limestone in this succession. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 43, 52 (table 2), pl. 1. In Bond formation (new). Below Witt cyclothem (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Center E½ sec. 24, T. 6 N., R. 5 W., Bond County.

Flat Gap Limestone Member (of Olive Hill Formation)[1]

Flat Gap Formation

Lower Devonian: Western and central Tennessee.

Original reference: C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 738.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 302–306, figs. 2, 88. Rank raised to formation. Overlies various units of Ross formation (new)—Ross limestone member, Bear Branch facies, Birdsong shale member; unconformably underlies Harriman formation which truncates it northward. Maximum thickness 55 feet at type exposure herein stated.

Type exposure: On Flat Gap Creek, northeast of Olivehill, Hardin County.

†Flathead Formation[1] or Shales[1]

Middle Cambrian: Montana and northwestern Wyoming.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110.

Named for exposures in Flathead Pass, in northeast corner of Threeforks quadrangle, Montana.

Flathead Quartzite[1] or Sandstone

Flathead Sandstone Member (of DePass Formation)

Middle Cambrian: Montana and northwestern Wyoming.

Original references: A. C. Peale (Flathead formation with Flathead quartzite, 125 feet at base, and Flathead shales, 290 feet above), 1893, U.S. Geol. Survey Bull. 110, p. 20–22, pl. 4; W. H. Weed, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 285–286.

Charles Deiss, 1936, Geol. Soc. America Bull., v. 47, no. 8, p. 1271–1272, 1288, 1289 (fig. 5), 1317 (fig. 9), 1326–1328. Presentation of revision of type Cambrian formations and sections of Montana and Yellowstone National Park. Publications dealing with problem of Cambrian nomenclature in area are discussed. Peale's original Flathead and Gallatin formations are not valid because latter included both Middle and Upper Cambrian rocks. Although Weed and others used Peale's names, the Flathead and Gallatin formations, meanings of these names were never redefined and given official status. Because of error by Walcott, formational name Gallatin was dropped, but name Flathead was retained to include only strata equivalent to Flathead quartzite member of Peale's Flathead formation. In present report, names given by Weed (1900) for Little Belt Mountains are retained to designate type Cambrian formations of central and southern Montana and Yellowstone National Park. These names, Flathead, Wolsey, Meagher, Park, Pilgrim, and Dry Creek, are chosen for types because they were correctly used by Weed (1900); they have been widely used by later writers, and they are taken from carefully measured and located sections. These formational names were correctly taken from geographic features. However, the location of these geographic features were not and are not the type localities or sections of either the original or emended formations. This fact must be clearly understood by future workers. Weed's (1900) definition of Flathead sandstone quoted. Flathead sandstone (herein emended) is basal formation of Cambrian system and everywhere in Montana and Yellowstone Park rests upon Precambrian rocks. Underlies Wolsey shale (emended). Within region, maximum thickness of Flathead is 276 feet in Beaver Creek area; least thickness, 93 feet on Crowfoot Ridge; 243 feet at emended type section; thins northward to average of 90 feet in northwestern Montana. Consists of crossbedded, thin- and thick-bedded sandstones, which have been indurated locally into quartzites. Most diagnostic characteristic is presence of tan and white pure quartz pebbles, which range from less than one-fourth inch to more than 3 inches in diameter, are well rounded, and are largely concentrated into thin lenses. Most exposures exhibit purple-maroon and buff banding, particularly in lower half of formation; upper half commonly thinner bedded, more sandy, and contains intercalated, micaceous, sandy, thin beds of shale. Oolitic hematite or hematitic sandstone, as much as 2 feet thick, commonly marks top of formation. Emended type section is on Belt Creek; formation is better exposed, more complete, and less metamorphosed on Crowfoot Ridge in Yellowstone National Park, Checkerboard Creek in Castle Mountains, and on Beaver Creek in northern part of Big Belt Mountains. Weed took name Flathead for his formation in Little Belt Mountains from Peale's (1893) Three Forks section. By using name Flathead, Weed created confusion in nomenclature, but not in the stratigraphy, because he neither stated nor implied that type section of Peale's Flathead quartzite member was type of Flathead sandstone (formation) in Little Belt Mountains. Weed gave his Belt Creek section as part of his definition of the formation and thereby indicated it as type of his Flathead sandstone. Comparison of the original and emended Belt Creek section shows a sill at top instead of near bottom of latter section and a thickness of 243 feet instead of 168 feet (sills excluded in both cases). In this section, Flathead sandstone is incompletely exposed, and contact with Wolsey shale is covered. It is however, the best known section of basal Cambrian formation in Little Belt Mountains. Because Weed indicated Belt Creek section as the type, the emended one is retained in that capacity for Flathead sandstone.

B. M. Miller, 1936, Jour. Geology, v. 44, no. 2, p. 118–119. Formation described in northwestern Wyoming where it averages about 175 feet in thickness and consists of quartz sandstones and quartzites which unconformably overlie Precambrian rocks and conformably underlie Gros Ventre formation.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1083, 1088–1089, 1098–1100, 1101 (fig. 3), 1103. Deiss (1933, Montana Bur. Mines and Geology Mem. 6) divided Cambrian rocks in northwestern Montana into 11 formations—Flathead quartzite at base overlain by Wolsey shale. Sequence is herein revised—Flathead sandstone is overlain by Gordon shale. In Wind River Canyon area, Wyoming, Flathead sandstone is considered member of DePass formation. Underlies Gros Ventre member; overlies pre-Beltian granite. Thickness in type section of Depass 280 feet.

Charles Deiss, 1939, Geol. Soc. America Spec. Paper 18, p. 34, 35–37. In Dearborn River-Monitor Mountain section, Lewis and Clark Range, Mont., Flathead sandstone is 102 feet thick and conformably overlies Miller Peak formation.

E. N. Goddard, 1940, U.S. Geol. Survey Bull. 922–G, p. 163, 165 (table). In Phillipsburg area, Montana, Flathead quartzite is 135 feet thick, underlies Silver Hill formation; overlies Spokane formation.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 213 (table 1), 219. In Saypo quadrangle, Montana, Flathead sandstone is 50 to 100 feet thick; underlies Gordon shale and unconformably overlies Precambrian Ahorn quartzite (new).

Adolph Knopf, 1950, Am. Mineralogist, v. 35, nos. 9–10, p. 839. On Greenhorn Mountain, overlies Greenhorn Mountain quartzite (new). In extant geologic maps, Greenhorn Mountain quartzite has been included with "undifferentiated Devonian and Cambrian" strata, with the result that the Flathead, which averages 100 feet in thickness with little deviation from this thickness over scores of miles, is implied to have thickness of several thousand feet on Greenhorn Mountain.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 20, 27, 29, 34. Unconformably overlies two major rock types. North of line connecting Melrose, Whitehall, Three Forks, and Livingston, overlies Belt series; south of this line, overlies Precambrian metamorphics including Cherry Creek series, Pony series, and other unnamed units.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. In Wind River basin, underlies Buck Spring formation (new).

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 44. In Johnson County, Wyo., Flathead sandstone unconformably overlies Precambrian granite and underlies Gallatin limestone and Gros Ventre formation, undivided. Consists of about 260 feet of tan to light-brown medium- to coarse-grained quartz sandstone.

M. M. Knechtel, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1994–1995. In Little Rocky Mountains, Mont., underlies Emerson formation (new).

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 7–8, pls. 1, 2, 3. Five lowest natural map units of Cambrian in southern Elkhorn Mountains, Mont., are lithologically similar to Flathead sandstone, Wolsey shale, Meagher limestone, Park shale, and Pilgrim dolomite of nearby areas, as redefined by Deiss (1936), and these formational names have been adopted. Flathead quartzite is 100 to 119 feet thick; overlies Belt series (Spokane shale) and underlies Wolsey shale.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 10, 11. Flathead sandstone is oldest sedimentary formation in Buffalo-Lake De Smet area. Together with overlying undifferentiated Gros Ventre and Gallatin formations, it crops out in narrow belt marked by valleys and saddles between Precambrian granite and metamorphic rocks to the west and high ridges of Bighorn dolomite to the east. Thickness 344 feet at Johnson Creek where it consists mainly of yellowish-gray fine- to coarse-grained crossbedded sandstone with some interbedded green micaceous siltstone and shale. Middle Cambrian.

Type section (emended): On Belt Creek, Little Belt Mountains, Cascade County. Incomplete section of Flathead measured from Archean contact, 40 to 50 feet above railroad track on spur one-half mile north of mouth of Hoover Creek and 5¼ miles S. 35° E. of Monarch, in Belt Creek valley in NE¼ sec. 14, SW¼ sec. 13, N½ sec. 24, and SE¼ sec. 25, T. 15 N., R. 7 E., near north edge of Little Belt Mountains. Weed gave locality of his Monarch (Belt Creek) section as "Section of beds exposed north of Belt Creek, 8 miles south of Monarch." Only Archean rocks, as indicated correctly on Weed's geological map, are present from 5½ to 8 miles south of Monarch along Belt Creek. Named for exposures in Flathead Pass, northeastern corner Three Forks quadrangle, Montana.

Flatiron Andesites[1]

Cenozoic: Northern California.

Original reference: H. Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 214–367, map.

Cenozoic: O. P. Jenkins, 1943, California Div. Mines Bull. 118, pt. 4, p. 676.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, p. 77 (table 2), 80 (table 4). Listed on tables and mentioned in text in report on uranium geochemistry of Lassen volcanic rocks.

Flatiron Ridge is in Shasta County in southern part of Lassen Volcanic National Park.

Flatiron Coquinite Member (of Riceville Formation)

Upper Devonian: Northwestern Pennsylvania.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 14 (footnote), 278 (footnote). Caster (1934) credited with renaming Roystone coquinite as Flatiron; Roystone here considered to be in good standing. Footnote (with initials of G. H. Ashley) states that "bed here named 'Flat-iron' (Roystone) coquinite is same as Marvin Creek limestone of Ashburner" (1880).

Occurs in McKean and western Potter Counties. Probably named for Flat Iron Station near Olean, Rock City, Cattaraugus County, N.Y.

Flat Lick Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: W. R. Jillson and J. M. Hodge, 1919, Kentucky Dept. Geology and Forestry, ser. 5, Bull. 3, p. 1, 2, 3, 9–10, 34.

Well exposed in cliffs along river near Artemus and forms base of Flat Lick Plateau. Named because it is well exposed by the doming at Flat Lick, Knox County.

Flat Ridge Formation (in Mount Rogers Volcanic Group)

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 48, 49–52, pls. 1, 60. Volcanic agglomerate and conglomerate, arkose, tuffaceous slate, and basalt. Cornett basalt member (new) generally at base of formation. Volcanic agglomerate, flow breccia, and thin basalt flows near base form Cinnamon Ridge member (new). In Mount Rogers volcanic series. Main part of formation composed of purplish-red feldspathic tuff, purplish-red shale, and purple arkose. In places, tuffaceous layers conglomeratic; at some localities, thin layers of tuff replaced by apple-green pinite; in others, tuff is buff sericitic slate. Purple-banded quartzite, with layers of red jasper and interbedded purplish-red shale in many places. Conglomerate of granite boulders as much as 10 inches in diameter and of smaller fragments in dark-colored arkosic matrix forms base of formation just west of Cinnamon Ridge. Estimated thickness on hill 1 mile north of Union Church 150 feet. On Comers Rock Branch, north of Comers Rock village, thickness estimated to be 250 feet. Overlies older Precambrian rocks in vicinity of Comers Rock village.

Named from village of Flat Ridge located in Grayson County 5 miles west of Gossan Lead district (as mapped). Mapped in the district.

Flat Rock Dolomite Member (of Lucas Formation)

Flat Rock Dolomite Member (of Detroit River Dolomite)[1]

Middle Devonian: Southeastern Michigan, and western Ontario, Canada.

Original reference: W. H. Sherzer and A. W. Grabau, 1909, Geol. Soc. America Bull., v. 19, p. 541.

G. M. Ehlers, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1455–1456. Detroit River group revised. Flat Rock dolomite of Sherzer and Grabau cannot be distinguished in outcrop or in well borings as distinct formation. There is little doubt that strata of this dolomite are part of Amherstburg dolomite. Name Flat Rock should be dropped from nomenclature.

K. K. Landes, 1951, U.S. Geol. Survey Circ. 133, p. 1. Term Flat Rock does not merit formation status. At type locality in town of Flat Rock, a bed of carbonate rock 2 or 3 feet thick is poorly exposed in channel of Huron River. This section has not been identified with certainty anywhere else. It is the opinion of the writer [Landes] that these strata actually belong in Lucas formation.

Named for exposures at Flat Rock, Wayne County.

Flat Rock Formation

Precambrian: Southwestern South Dakota.

T. A. Dodge, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 563. Name appears on list of Precambrian rocks of area. Consists of sandy or pyritic schists about 5,000 feet thick.

J. A. Noble and J. A. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 944 (fig. 1), 949–952. Examples of varied lithology: abundant light-gray sericitic phyllite or schist; soft sooty black phyllite or schists with pyrite; quartzites in bands that range in thickness from about 2 feet to about 20 feet; features known as Iron Dike, a dense siliceous jaspery material without visible bedding. Unconformable above Northwestern formation. Underlies Grizzly formation; unconformably overlies Northwestern formation.

Occurs at Homestake mine in vicinity of Lead, Lawrence County.

Flat Rock Creek Granite

Age not stated: Central southern Virginia.

J. P. Meador, 1949, (abs.) Virginia Acad. Sci. Proc. 1948–1949, p. 137. Varies in texture from medium grained to coarse grained and in structure from granulose to gneissose. Lies between Virgilina greenstone and the injected gneisses.

Area discussed is in eastern half of Lunenburg County. Granite covers approximately one-fourth of mapped area.

Flat Top Granite

Precambrian: Southwestern Oklahoma.

C. A. Merritt, 1958, Oklahoma Geol. Survey Bull. 76, p. 33–34. Named by Thomas Polk (1948, unpub. thesis). In present study, name Flat Top granite is not used because in many areas the Flat Top could not be distinguished from the Reformatory granite.

Named for occurrence on Flat Top Mountain, Altus Lake area.

Flat-top limestone[1]

Devonian or Mississippian(?): Western Colorado.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 281, 292.

Named for Flat-top Mountain, north of Glenwood Springs, Garfield County.

Flat-top Sandstone[1]

Pennsylvanian: Southeastern Oklahoma.

Original reference: H. M. Chance, 1890, Am. Inst. Min. Engrs. Trans., v. 18, p. 653–661.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey. Name preoccupied.

Flattop Schist[1]

Precambrian: Western North Carolina.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 4.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 30; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Occurs in association with Linville metadiabase, Montezuma schist, and metarhyolite.

Named for Flattop Mountain, Cranberry quadrangle, Watauga County.

Flat Top Mountain Sandstone (in Pottsville Group)[1]

Pennsylvanian: Northeastern Kentucky.

Original reference: J. B. Hoeing, 1913, Kentucky Geol. Survey, 4th ser., v. 1, pt. 1, p. 81.

Upper Big Sandy Valley and headwaters of North Fork of Kentucky River.

Flattop Mountain Sandstone Member (of Pocahontas Formation)

Flattop Mountain Sandstone (in Lee Formation)

Flattop Mountain Sandstone (in Pocahontas Group)

Flattop Mountain Sandstone (in Pottsville Group)[1]

Lower Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: I. C. White, 1908, West Virginia Geol. Survey, v. 2A, p. 13.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey, Greenbrier County, p. 242–243. At top of Pocahontas group in southern West Virginia. Generally hard, medium grained, micaceous, and bluish gray to brown. Thickness 10 to 40 feet. In vicinity of Duo, apparently coalesces with Pierpont sandstone, cutting out beds that normally occcur between the two sandstones.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 19). Shown on correlation chart as sandstone in Lee formation in Virginia.

U.S. Geological Survey currently classifies the Flattop Mountain Sandstone as a member of Pocahontas Formation on the basis of a study now in progress.

Named for Flattop Mountain, 2 miles northwest of Pocahontas, Va.

Flattop Mountain suite

Tertiary: Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 39, 43 (map 2). Complex of flows and small intrusive masses that represent a period of eruptive activity in a restricted center. Rocks range from highly siliceous rhyolite to rhyodacite. Colors range from white through bluish purple to almost black. Strong flow layering present in some units and is locally distorted. Thickness exceeds 1.000 feet. Name credited to H. R. Blank (unpub. thesis).

Occurs in vicinity of Flattop Mountain, Washington County.

†Flatwoods Clay[1]

Eocene, lower: Southwestern Alabama, northeastern Mississippi, and western Tennessee.

Original reference: E. W. Hilgard, 1860, Mississippi Geol. and Agr. Rept., p. 110–111, 275.

Named for low, flat land covering several counties in northeast Mississippi, resembling broad river and generally known as the "Flatwoods country."

†Flatwoods Group[1]

Eocene: Western Tennessee.

Original reference: J. B. Killebrew and J. M. Safford, 1874, Resources of Tennessee, p. 44.

Occurs on Porter's Creek.

†Flatwoods Shale[1]

Middle and Upper Cambrian: Eastern Alabama.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. on Cahaba coal fields, p. 148, map, and structure sec. opposite p. 162.

Named for level, badly drained lands in valley region of eastern Alabama, which are generally known as "Flatwoods."

Flaxman Formation[1]

Pleistocene (Wisconsin): Northern Alaska.

Original reference: E. D. Leffingwell, 1919, U.S. Geol. Survey Prof. Paper 109, p. 103, 142, map.

Well exposed on Flaxman Island, Canning River region.

Flaxville Formation

Flaxville Gravel[1]

Miocene, upper, or Pliocene: Northern Montana and western North Dakota, and Alberta and Saskatchewan, Canada.

Original reference: A. J. Collier, 1917, Washington Acad. Sci. Jour., v. 7, p. 194–195.

R. B. Colton, 1955, U.S. Geol. Survey Geol. Quad. Map [GQ–67]. Flaxville gravel described in Wolf Point quadrangle, Montana. Unconformably overlies Fort Union strata and is unconformably overlain by glacial deposits. In some areas, underlies preglacial Wiota gravels (new). Average thickness about 40 feet. Very late Miocene or early Pliocene.

E. G. Meldahl, 1956, North Dakota Geol. Survey Rept. Inv. 26. Mapped in Grassy Butte area, McKenzie County. Stratigraphically above Golden Valley formation.

I. J. Witkind, 1959, U.S. Geol. Survey Bull. 1073, p. 10 (table), 13, pl. 1. Discussion of Smoke Creek-Medicine Lake-Grenora area, Montana and North Dakota. Flaxville gravel above Fort Union formation, crops out along west edge of area. Thickness 10 to 20 feet. Miocene or Pliocene.

A. D. Howard, 1960, U.S. Geol. Survey Prof. Paper 326, p. 16 (table 2), 17, pl. 1. Average thickness 30 feet. In eastern Montana, stratigraphically above Rimroad gravel. One probable occurrence reported in North Dakota. Miocene or Pliocene.

Named for Flaxville, Daniels County, Mont.

Fleanor Formation

Middle Ordovician (Mohawkian): Northeastern Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 65, chart 1 (facing p. 130). Name proposed for about 200 feet of maroon and red shale, thin gray limestones, siltstone, and calcarenite. Underlies Rockdell formation; overlies Elway formation. Name attributed to B. N. Cooper and G. A. Cooper.

Named from exposures on a farm lane along Foster Branch near Fleanor Mill, 2 miles northeast of Heiskell, Powell Station (T.V.A. 137–SE) quadrangle.

Fleener facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 184–186.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Correlation chart lists Fleener facies of Carwood formation.

Named for exposures in vicinity of old village and post office of Fleener, NE¼SW¼ sec. 22, T. 10 N., R. 1 E., Monroe County.

†Fleming Clay[1] or Group[1]

Fleming Formation (in Grand Gulf Group)

Miocene: Eastern Texas and Western Louisiana.

Original reference: W. Kennedy, 1892, Texas Geol Survey 3d Ann. Rept., p. 45, 62.

H. N. Fisk, 1940, Louisiana Geol. Survey Bull. 18, p. 150–173. Formation, in surface exposures in Rapides Parish, divided into (ascending) Lena, Carnahan Bayou, Dough Hills, Williamson Creek, Castor Creek, and Blounts Creek members (all new). Overlies Catahoula formation; underlies Pleistocene. Grand Gulf group.

H. B. Stenzel, F. E. Turner, and C. J. Hesse. 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 7, p. 977–1011. In light of new age determinations, it is believed that term Fleming formation is applicable to clay beds near Burkeville, Tex., and that term Lagarto, formerly used, is not.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, p. 1721–1726. In this report, Fleming is considered a group name including both Oakville and Cuero (new) formations. Unconformably overlies Catahoula formation; unconformably underlies Goliad formation.

J. J. Quinn, 1952, Texas Univ. Bur. Econ. Geology Rept. Inv. 14, p. 5–6. New faunal evidence leads to conclusion that the Fleming is middle Miocene in age.

P. H. Jones, 1954, Louisiana Geol. Survey Bull. 30, p. 52 (table 2), 55–56. Formation in subsurface in southwestern Louisiana, underlies Foley formation (new).

Named for Fleming, Tyler County, Tex.

Fleming Formation (in Cabaniss Group)

Fleming Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas, southwestern Missouri, and northeastern Oklahoma.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 195. Cherokee group is divided into 15 cyclic formational units. The Fleming, 10th in the sequence (ascending), overlies the Mineral and underlies the Coalvale. Average thickness 24 feet. Contains coal bed ranging from 12 to 20 inches in thickness. [For complete sequence see Cherokee group.]

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Fleming formation in Cabaniss group. Underlies Croweburg formation; overlies Robinson Branch formation (new).

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as a coal cycle in Senora formation, Cabaniss group, in Oklahoma.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 25 (fig. 14). Fleming, as exposed in highwall of Ellis mine in SW¼SW¼ sec. 18, T. 34 N., R. 32 W., Vernon County, Mo., underlies Croweburg formation and overlies Mineral formation. Consists of (ascending) limestone, black shale, sandstone, underclay, and coal. Thickness more than 15 feet. Cabaniss group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 62–63, 66–68. Formation in Cabaniss subgroup of Cherokee group. Where complete succession is present, formation includes (ascending) calcareous shale and thin beds of limestone, dark shale, sandstone, underclay, and Fleming coal. Over most of outcrop in Kansas consists of Fleming coal and its underclay, lying on underclay or dark shale properly included in Robinson Branch formation.

Type locality and derivation of name not given.

Fletcher Anhydrite Member (of Salado Formation)

Permian (Ochoa): Southeastern New Mexico (subsurface).

W. B. Lang, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 1, p. 63, 69, 75–78. Massive dense fine crystalline to granular crystalline anhydrite of pale-maltese-gray, clear, or pale-bluish color. Contains minor amounts of gray dolomitic silt. Practically free from insoluble grit. Thickness ranges from 50 to 100 feet or more; 69 feet in Fletcher No. 1 well. Unconformably overlies Carlsbad limestone.

Name taken from Fletcher No. 1 well, in lot 4, sec. 1, T. 21 S., R. 28 E., Eddy County, in which this core test was made.

Fleury Member (of Day Point Formation)

Middle Ordovician (Chazyan): Northwestern Vermont and northeastern New York.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 824 (fig. 3), 825 (fig. 4), 826 (fig. 5), 827–829, geol. sections. [At type section] consists of 115 feet of light-gray fossiliferous calcarenite in medium to heavy cross-laminated beds. Biohermal masses, principally of *Lamottia heroensis* Raymond, are in a zone 44 to 51 feet from base, and similar structures of *Stromatocerium* and bryozoans are about 20 feet from top. Reef masses not present in northern Champlain Valley. On Valcour Island, thickness reaches 220 feet, the upper 65 feet being calcisiltite distinguished poorly from that of succeeding Crown Point limestone, and 35 feet is similarly transitional near South Hero. Overlies Wait member (new).

Type section: The Head, southern Isle La Motte, Vt. Name derived from Fleury Bay.

†Flint Creek Beds[1]

Miocene, upper: Central western Montana.

Original reference: E. Douglass, 1906, Carnegie Mus. Annals, v. 2, p. 153–154.

P. E. Vanzolini, 1952, Jour. Paleontology, v. 26, no. 3, p. 453. Beds assigned to upper Miocene.

Typically exposed in a line of bluffs, 100 to 150 or more feet, high on west side of valley of Flint Creek, beginning about 1 mile north of village of New Chicago and extending southward several miles; Philipsburg region.

Flint Hill Sandstone (in Little Osage Member of Fort Scott Formation)

Pennsylvanian (Des Moines Series): Central Missouri.

F. C. Greene, and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 6, fig. 1. Channel type sandstone and siltstone that occurs above Blackwater Creek shale in Little Osage member and below Higginsville limestone member. Name credited to A. G. Unklesbay.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources [Rept.] 2d ser., v. 33, p. 96, 97. At type section, consists of gray to yellowish-brown fine- to medium-grained massive resistant friable calcareous sandstone; locally contains brownish-red and purple streaks. Thickness 5⅔ feet.

Type section: W½SW¼ sec. 11, T. 50 N., R. 13 W., Boone County. Name derived from Flint Hill near Flint Hill School. [1949 reference states type section as NW¼SE¼ sec. 11.]

†Flint Hills division[1]

Permian: Central Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 6–9.

Named for Flint Hills, Cowley and Butler Counties.

Flint Ridge Clay (in Pottsville Formation)[1]

Pennsylvanian (Pottsville Series): Southern Ohio.

[Original reference]: Wilber Stout, 1927, Ohio Geol. Survey Bull. 31, p. 108–112.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 31, table 1. Included in Flint Ridge cyclothem. Dominantly gray and plastic, locally gray and very sandy; contains siderite nodules. Thickness 6 inches to 8 feet. Overlies Flint Ridge shale and (or) sandstone; underlies Flint Ridge coal.

Extends across State from Mahoning County to Scioto County. Underlies Flint Ridge coal which was named for occurrence on Flint Ridge in Licking County.

Flint Ridge cyclothem

Pennsylvanian (Pottsville Series): Southeastern Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 31–32, 137, table 1, geol. map. Includes (ascending) Flint Ridge shale and (or) sandstone, 13 feet; Flint Ridge clay, 4 to 8 feet; Flint Ridge coal. Occurs below Middle Mercer cyclothem and above Lower Mercer cyclothem. In area of this report, the Pottsville series is described on a cyclothemic basis; 10 cyclothems are named. [For sequence see Anthony cyclothem.]

Exposed in western and northern Perry County.

Flint Ridge Flint[1]

Flint Ridge Flint (in Breathitt Formation)

Pennsylvanian: Eastern Kentucky.

Original reference: W. C. Morse, 1931, Kentucky Geol. Survey, ser. 6, v. 36, p. 296, 305.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 22). Shown on correlation chart as occurring in upper part of Breathitt formation.

Exposed below top of Flint Ridge at head of Leatherwood Branch of South Quicksand Creek, Troublesome quadrangle, Breathitt County.

Flint Ridge Flint (in Allegheny Formation)[1]

Pennsylvanian: Central Ohio.

Original reference: E. B. Andrews, 1871, Ohio Geol. Survey Rept. Prog. 1870, pl. opposite p. 242.

Named for Flint Ridge, 2½ miles southeast of Newark, Licking County.

Flint Ridge Limestone (in Allegheny? Formation)[1]

Pennsylvanian: Central Ohio.

Original references: E. B. Andrews, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 86, 91–93; 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 89, 94–95.

Named for Flint Ridge, Licking County.

Flint Ridge Shale (in Pottsville Formation)[1]

Pennsylvanian (Pottsville Series): Central and southeastern Ohio.

Original reference: C. L. Herrick, 1887, Denison Univ. Sci. Lab., v. 2, pt. 1, p. 10–12.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 31, table 1. Flint Ridge shale and or sandstone included in Flint Ridge cyclothem in Perry County. Thickness about 13 feet thick; underlies Flint Ridge clay; overlies Boggs member of the Pottsville.

Named for Flint Ridge, Licking County.

Flint River Formation

Flint River Formation (in Vicksburg Group)[1]

Oligocene, upper: Southern Georgia, southeastern Alabama, northwestern Florida, and southwestern South Carolina.

Original reference: C. W. Cooke, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 8, p. 1170–1171.

C. W. Cooke and A. C. Munyan, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 792. Flint River formation, formerly supposed to be facies of Glendon limestone, has proved to be somewhat younger. Tentatively correlated with Chickasawhay member of Byram of Mississippi. Formation overlaps Eocene formations as far as the Clayton. East of Oconee River, it is overlapped by Hawthorn formation but reappears in Savannah drainage basin. Report is about the coast plain of Georgia.

F. S. MacNeil, 1944, Southeastern Geol. Soc. [Guidebook] 2d Field Trip, p. 35–37. Recent mapping in southwestern Alabama has shown that Flint River is not a single unit of deposition but a mixture of argillaceous and siliceous residuum of Oligocene limestones and disarranged beds of Miocene formations. It appears, therefore, that except at its northward extremity, where Tampa and Hawthorn beds have been eroded away or were never deposited, the Flint River contains materials of Oligocene, if the residuum of the Ocala is excluded from it, Miocene, and possibly of more recent age. If the formation is to be dated from time that it assumed its present form, it is probably largely Pleistocene or Recent.

F. S. MacNeil, 1946, Southeastern Geol. Soc. [Guidebook] 4th Field Trip, p. 64. Suggested that name Flint River be abandoned and that the heterogeneous beds to which name was applied be designated as residuum of Jackson, Oligocene, and Miocene, undifferentiated.

C. W. Cooke, 1959, U.S. Geol. Survey Prof. Paper 321, p. 2 (table 1). In discussion of Cenozoic echinoids, age of Flint River formation (Georgia) is given as late Oligocene.

Named from exposures on Flint River between Red Bluff, 7 miles above Bainbridge, to Hales Landing, 7 miles below Bainbridge, Decatur County, Ga.

Flood Member (of Blackleaf Formation)

Lower Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2787–2790, 2792 (fig. 3); 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 90. At type section, consists of three parts having combined thickness of 138 feet; lower part is light-brown ledge-making sandstone; middle is poorly exposed dark-gray fissile shale with thin interbeds of flaggy sandstone and concretions of dark-brown ironstone or iron-stained limestone; upper part is massive light-brown cliff-forming sandstone that contains large dark-brown-weathering concretions of calcareous sandstone. Basal member of formation; underlies Taft Hill glauconitic member (new).

Type section: On south side of Sun River valley 4½ miles west of city of Great Falls, in SW¼NW¼ and NE¼ sec. 7, T. 20 N., R. 3 E., Cascade County, about 5 miles northwest of Flood Siding. Named for exposures along bluffs on west side of Missouri River in vicinity of Flood Siding on Great Northern Railway in NW¼ sec. 34, T. 20 N., R. 3 E.

Florena Shale Member (of Beattie Limestone)

Florena Shale Member (of Garrison Shale)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: C. S. Prosser, 1902, Jour. Geology, v. 10, p. 712.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 47. Middle member of Beattie limestone. Underlies Morrill limestone member; overlies Cottonwood limestone member. Consists of highly fossiliferous gray shale containing thin limestone beds in southern Kansas. Thickness 3 to 18 feet. Wolfcamp series.

Named for exposures in quarries near Florena, Marshall County, Kans.

Florence Dolomite

Cambrian: West-central Vermont.

G. W. Bain, 1938, New England Intercollegiate Geol. Assoc. [Guidebook] 34th Ann. Field Mtg., p. 8. Described as mainly well-bedded buff-weathering sandy dolomite with some graywacke and micaceous slate. Characterized by ripple marks, corrasion channels, solifluction structures, and interformational breccias. Thickness 1,000 feet. Underlies Pittsford Valley dolomite (new); overlies Clarendon dolomite (new).

Occurrence: Central Vermont marble belt, Rutland County.

Florence Gravel[1]

Pleistocene: Northwestern Illinois.

Original reference: O. H. Hershey, 1895, Am. Geologist, v. 15, p. 7–12.

Typically exposed in banks of Yellow and Crane's Creeks, a few miles west and south of Freeport. Named for Florence Township, Stephenson County.

†Florence Limestone (in Chase Group)[1]

Permian: Central Kansas.

Original reference: C. S. Prosser. 1895, Jour. Geology, v. 3, p. 771–786, 798.

Named for Florence, Marion County.

Florence Limestone Member (of Barneston Formation)

Florence Flint (in Chase Group)[1]

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: C. S. Prosser, 1895, Jour. Geology, v. 3, p. 771–786, 798.

G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 41. Florence flint member of Barneston formation (new).

R. C. Moore, 1936, Kansas Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12. Florence limestone member of Barneston limestone.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 45. Limestone, an abundance of flint, and a minor amount of shale; limestone is commonly lighter in color than the included nodules and layers of gray flint; shale partings common locally. Thickness between 35 and 45 feet. Underlies Oketo shale member; overlies Blue Springs shale member of Matfield shale. Wolfcamp series.

Named for exposures near Florence, Marion County, Kans. Because of large amount of flint or chert it contains, the limestone has been known generally as the Florence flint.

Florencia Formation[1]

Pleistocene: Northwestern Illinois.

Original reference: O. H. Hershey, 1897, Am. Jour. Sci., 4th, v. 4, p. 90–98.

Name derived from Florence Township, Stephenson County.

Flores Limestone

Upper Cretaceous: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 63–67. Dark- to light-gray pure limestone occurring in beds 5 to 10 feet thick. Present as allochthonous blocks in Ildefonso formation (new) emplaced by faulting or possibly by sliding.

Type locality: Quarry about 0.25 kilometer to northeast of intersection of Routes 154 and 153, Coamo quadrangle. Named from village of Las Flores.

Florida Gravel[1]

Pleistocene: Southwestern Colorado and northwestern New Mexico.

Original reference: W. W. Atwood and K. F. Mather, 1932, U.S. Geol. Survey Prof. Paper 166.

V. C. Kelley, 1949, New Mexico Univ. Pubs. in Geology 2, chart facing p. 22. Shown on correlation chart of New Mexico formations as present in San Juan County.

Named for fact it caps Florida Mesa in southwestern Colorado.

Floride Dolomite

Upper Ordovician or Silurian: Northwestern Utah.

F. W. Osterwald, 1953, U.S. Geol. Survey Trace Elements Inv. Rept. TEI–330, p. 105; M. H. Staatz and F. W. Osterwald, 1959, U.S. Geol. Survey Bull. 1069, p. 19 (fig. 2), 21–22, pl. 1. Predominantly fine grained and light to medium gray. Thickness 100 to 135 feet. Overlies Fish Haven dolomite; underlies Bell Hill dolomite (new). Formation may be wholly Ordovician, wholly Silurian, or both.

Type section: Half a mile north of Floride mine in NE¼NE¼ sec. 3, T. 13 S., R. 12 W., Juab County. Named for occurrence at Floride mine. Crops out chiefly along east side of Spor Mountain in southern half of range.

†Floridian Group[1] or Series[1]

Pliocene, lower: Southwestern Florida.

Original reference: A. Heilprin, 1887, Wagner Free Inst. Sci. Trans., v. 1, p. 28–32, 64A–64B, May, 1887.

Named for development on west coast of Florida.

Florissant Lake Beds[1]

Oligocene: Central Colorado.

Original reference: W. Cross, 1894, U.S. Geol. Survey Geol. Atlas, Folio 7.

H. E. Woods 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 19–20. Oligocene, probably Orellan. Paleontological evidence as to age is both uncertain and conflicting. Only mammal, *Peratherium*, is known only from the Oligocene and the John Day. Paleobotanical evidence has usually been interpreted in favor of a much more recent age. Comprise determination as Oligocene and perhaps Orellan represents return to opinions of Cope, Lesquereux, and Scudder.

Named for Florissant, Teller County.

Flour Bluff Sand

Oligocene: Southern Texas (subsurface)

Alexander Deussen and K. D. Owen, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1630 (fig. 5), 1631 (fig. 6), 1632, 1634. Name suggested for the thick body of sand above an Oligocene marine shale wedge [Old Ocean sand] and below the Fleming, or zone of reworked Cretaceous foraminifera, now loosely designated as the *Discorbis*. Name Pierce Estate also suggested for this unit.

Named for well No. 38 (Hurlbutt and Still, Phillips No. 1), in west section of Nueces County.

Flour Sack Member (of Bright Angel Shale)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 82–83. Facies changes within member are striking. At Diamond Creek, Quartermaster Canyon, and Columbine Falls, consists almost entirely of thin fissile micaceous green and purple shale. West of these localities, at Rampart Cave and Diamond Bar Ranch, thin platy limestone replaces much of shale. Farther west, at mouth of Grand Canyon, shale forms only lower 30 feet of section. Thickness averages about 100 feet. Underlies Rampart Cave member (new) of Muav formation; overlies Meriwitica tongue (new).

Named from former rapids of that name 8 miles east of Grand Wash Cliffs, western Grand Canyon.

Floweree Member (of Marias River Shale)

Upper Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2792 (fig. 3), 2793–2794; 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 91. Chiefly dark-gray noncalcareous shale, medium-gray siltstone, and lentils of sandy siltstone and fine sandstone that locally contains scattered granules of dark-gray chert. Limestone concretions present on east side of Sweetgrass arch and on Kevin-Sunburst dome. A few marine fossils present. About 63 feet thick at type section; regionally shows seemingly unsystematic variation in thickness from 13 to 150 feet. Basal member of Marias River shale (new) underlies Cone calcareous member (new); overlies Bootlegger member (new) of Blackleaf formation.

Type section: Two miles northeast of Floweree on north side of Black Coulee in S½NE¼ sec. 17, and SW¼NW¼ sec. 16, T. 23 N., R. 6 E., Chouteau County. Named for station of Floweree on Great Northern Railway in E½SE¼ sec. 24, T. 23 N., R. 5 E, and contiguous part of sec. 19, T. 23 N., R. 6 E., Chouteau County.

Flowerpot Shale (in El Reno, Nippewalla, or Peace River Group)

Flower-pot Shale (in Cimarron Group)[1]

Permian: Central southern Kansas, western Oklahoma, and Texas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 24–27.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1782, 1791–1792. Included in Nippewalla group (new).

H. C. Fountain, 1939, *in* Am. Assoc. Petroleum Geologists Bull., v. 23, no. 5, p. 764; Robert Roth, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1412. Included in Pease River group (new).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on correlation chart as formation in El Reno (San Andres) group.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 158; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 39. Red soft gypsiferous shale. Average thickness 180 feet. In Nippewalla group below Blaine formation and above Cedar Hills sandstone. Leonardian.

Robert Roth, 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 902–904. At type locality of Pease River group, underlies Blaine formation and overlies San Angelo formation. Thickness 274 feet. Includes Chaney gypsum and anhydrite and Kiser gypsum and anhydrite.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 11 (fig. 2), 15–16 (fig. 3), pl. 1. Described in Carter area, Oklahoma, where it conformably overlies Duncan sandstone and conformably underlies Blaine formation. Includes Chaney gypsum and Kiser gypsum members. Thickness 165 feet. El Reno group, Guadalupe series.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on correlation chart in Nippewalla group. Guadalupian.

Named for Flowerpot [Flower-pot] Mound, Barber County, Kans.

Floyd Limestone[1]

Upper Devonian: Central northern Iowa.

Original reference: A. O. Thomas, 1912, Science, new ser., v. 36, p. 569–570.

In Floyd County.

Floyd Shale[1]

Upper Mississippian: Northwestern Georgia, northern central Alabama, and southern Tennessee.

Original reference: C. W. Hayes, 1891, Geol. Soc. America Bull., v. 2, p. 143.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 90). Age shown on correlation chart as Chesterian.

Charles Butts, 1948, Georgia Geol. Survey Bull. 54, p. 49–52. In northwestern Georgia, predominantly gray to black fissile shale but includes beds of limestone like those of the "Bangor" and, at one place, a thick bed of sandstone; some beds of limestone have been mapped as "Bangor," but in such places the amount of limestone falls far short of the real "Bangor," and these beds are regarded as part of the Floyd in this report. Estimated thickness at least 1,500 feet. Occurs above Pennington shale. Distribution noted.

Named for development in Floyd County, Ga. Occurs only east of White Oak Mountain and Taylor Ridge where it occupies several large and more or less detached areas.

Floyds Knob Formation (in Borden Group)[1]

Floyds Knob Member (of Edwardsville Formation)

Lower Mississippian: Southeastern Indiana and northern Kentucky.

Original reference: P. B. Stockdale. 1929, Ohio Jour. Sci., v. 29, no. 4, p. 170.

P. B. Stockdale, 1931, Indiana Div. Geology Pub. 98, p. 76, 193–200. Includes the following facies: Goss Mill limestone, Fordyce Knob sandstone, and Cisco Branch.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 192–200, 228. Geographically extended into northern Kentucky where it extends across the Kentucky outcrop belt to Ohio boundary. Thickness seldom over 5 feet; commonly only 1 or 2. Overlies Brodhead formation (new); underlies Muldraugh formation (new).

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 799. Rank reduced to member of Edwardsville formation.

Named for Floyds Knob three-fourths mile east of post office of same name, 3 miles northwest of New Albany, Clark County, Ind.

Fly Sandstone

Pennsylvanian (Monongahela Series): Eastern Ohio.

A. T. Cross, W. H. Smith, and Thomas Arkle, Jr., 1950, Field guide for the special conference on the stratigraphy, sedimentation, and nomenclature of the Upper Pennsylvanian and Lower Permian strata (Monongahela, Washington, and Greene series) in the northern portion of the Dunkard Basin of Ohio, West Virginia, and Pennsylvania: West Virginia Geol. and Econ. Survey, Sec. 26 (upper part). Fly sandstone shown on profile of strata from upper part of Benwood limestone to about the Washington coal horizon along Pennsylvania Highway 88. Description reads: upper Benwood sandstone (Fly sandstone of Ohio, Arnoldsburg of some reports).

Fly Creek Limestone[1]

Upper Cretaceous: Central southern Montana.

Original reference: J. F. Kemp and P. Billingsly, 1921, Geol. Soc. America Bull., v. 32, p. 474 (chart).

Flying W Formation

Precambrian: East-central Arizona.

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (table 1), 1500–1501. pl. 1. Volcanic members of formation are: green, amygdaloidal basaltic pillow lavas containing sparse iron ore; a 150-foot-thick black, porphyritic keratophyre which extends 3½ miles from Colcord to Houden Mesa; and a conglomerate composed of well-rounded gravel, cobbles, and boulders of volcanic rock. Thickness 375–3,200 feet. Unconformably underlies Houden formation (new); overlies Alder formation on south slope of Colcord Mesa with gradational contact, but elsewhere basal member of Flying W formation is either a conformable cobble conglomerate or a pillow lava.

Type section: On lowest tributary to Walnut Creek; base of section approximately 4,450 feet elevation 1 mile north-northwest of Flying W ranchhouse. Good exposures also occur west of Spring Creek three-quarters mile northwest of ranchhouse. Named from Flying W Ranch on Spring Creek, 12 miles west of Young, Ariz., Diamond Butte quadrangle.

Fodderstack Sandstone (in Redoak Mountain Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, 19, pls. 2, 3, 4. Thickness at least 12 feet in Cross Mountain section; about 5 feet in Petros section. Separated from underlying Caryville sandstone (new) by shale interval that ranges in thickness from 50 to 150 feet and contains the Sharp coal; separated from overlying Silvey Gap sandstone (new) by shale interval that ranges from 45 to 110 feet in thickness and contains the Red Ash and Walnut Mountain coal.

Named from Little Fodderstack Mountain, Petros quadrangle, where it forms a bench on which a trail encircles the mountain.

Foley Formation

Pliocene: Southwestern Louisiana (subsurface).

P. H. Jones *in* P. H. Jones, A. N. Turcan, Jr., and H. E. Skibitzke, 1954, Louisiana Dept. Conserv. Geol. Bull. 30, p. 56–61. Sequence of fine- to medium-grained sands interbedded with soft to moderately hard gray-green to brown laminated clays penetrated by a number of water wells in vicinity of Oakdale. Thickness at Oakdale about 1,500 feet; at Mamou, 18 miles down dip, thickness is about 2,500 feet. Includes Mamou member above and Steep Gully member (both new). Underlies Williana formation; overlies Fleming formation.

Named for town of Foley, central Allen Parish. Name Oakdale has been used for other deposits.

†Folley Limestone[1]

Lower Ordovician (Chazy): Central eastern Missouri.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59, 61.

Named for Foley, Lincoln County.

Folsom Vent Basalt

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 127, 155 (fig. 28). Name applied to basalt that issued from Folsom Vent. Folsolm Vent basalt rests on 5 feet of alluvial sands and gravels, which in turn rest directly on sediments of Cretaceous Niobrara group.

Folsom Vents, two cinder cones and associated basalt, cover less than one-half square mile near mouth of Hereford Park, 1 mile west of Union County line on New Mexico State Highway 72.

Fonda Limestone Member (of Tribes Hill Formation)

Lower Ordovician (lower Canadian): East-central New York.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76 (fig. 2), 89–90. Name proposed for youngest most fossiliferous member of formation in Mohawk Valley. Silty, sandy phosphatic calcarenites and dolomitic calcilutite predominate; rest of unit consists of pebble conglomerates, calcitic dolomite, steel-gray dolomisiltite and oolitic dolomitic limestone. Contains ripple marks, cross-laminations, and mud cracks filled with glauconite. Maximum thickness 22 feet; has variable thickness and spotty distribution. Overlies Wolf Hollow member (new); unconformably underlies Chuctanunda Creek dolomite (new).

Type locality: Abandoned quarry 0.5 mile east of Stone Ridge, Montgomery County.

Fond du Lac Beds

Fond du Lac Sandstone[1] (in Lake Superior Series or Keweenawan Group)

Precambrian: Northeastern Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. Nat. History Survey Final Rept., v. 4, p. 567.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 10, 12–15. Fond du Lac beds are lower formation in Lake Superior series. Occur below Hinckley sandstone. Contact with Hinckley not exposed in east-central part of southeastern Minnesota. Thickness 235 feet at Fond du Lac. Base not exposed.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1058–1061. Included in upper part of Keweenawan group. Thickness several hundred to more than 2,000 feet.

Named for exposures on both banks of St. Louis River from Fond du Lac, Carlton County, westward.

Fontana Shale[1] Member (of Cherryvale Formation)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 85, 91, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Member of Cherryvale formation; underlies Block limestone member; overlies Winterset limestone member of Dennis formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 38. Considered formation in Nebraska; overlies Dennis formation; underlies Sarpy formation (new). Thickness 15 feet at type locality; 5 feet at Kansas City, 2 to 7 feet in Missouri; 6½ feet in Sarpy County, Nebr., and near Wimberton, Iowa.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Lowermost member of Cherryvale. Consists of gray calcareous silty micaceous shale. Thickness 10 feet. Underlies Block limestone member; overlies Winterset member of Dennis limestone.

Type exposures: In roadcuts at NE cor. sec. 11, T. 18 S., R. 23 E., and at middle of west side of NW¼ sec. 36, T. 18 S., R. 23 E., near Fontana, Miami County, Kans.

Fontenelle Tongue (of Green River Formation)

Fontenelle Member (of Green River Formation)

Eocene: Southwestern Wyoming.

J. H. Donavan, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 60, 62, 63–64. Proposed to designate sequence of alternating buff-brown sandstones and green and gray mudstones, which conformably overlie Knight member of Wasatch; underlies marginal facies of Laney shale member of Green River. Thickness as much as 300 feet. East of Big Piney, interfingers laterally with New Fork tongue (new) of Wasatch. Middle Eocene.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1072. Rank reduced to tongue of Green River. This change is based on inference that unit merges with rest of Green River formation some distance downdip below outcrop belt. Eocene.

Type locality: Sec. 13, T. 24 N., R. 114[115] W., about one-half mile south of Fontenelle Creek, Lincoln County.

Fool Creek Conglomerate

Oligocene(?): West-central Utah.

F. W. Christiansen, 1951, Utah Geol. Soc. Guidebook 6, p. 9, (fig. 2), 10–11; 1952, Geol. Soc. America Bull., v. 63, no. 7, p. 727–728, pl. 1. Thickness 0 to 1,800 feet. Unconformably overlies North Horn(?) formation; unconformably underlies Bonneville and pre-Bonneville sediments.

Well exposed in Dry Fork of Fool Creek and in long spur projecting westward from Canyon Range in area immediately south of small farming community of Fool Creek.

Foraker Limestone (in Council Grove Group)

Foraker Limestone (in Wabaunsee Group)[1]

Foraker Limestone Member (of Sand Creek Formation)

Permian: Central northern and central Oklahoma, southern Kansas, northwestern Missouri, and southeastern Nebraska.

Original refence: K. C. Heald, 1916, U.S. Geol. Survey Bull. 641, p. 21, 25.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273. Overlies Janesville shale (new) of Admire group.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 78–85, pl. 1. Described in Pawnee County, Okla., where it is between 60 and 70 feet thick. Includes (ascending) Americus limestone, Hughes Creek shale, and Long Creek limestone members. Members are traceable southward from Nebraska across Kansas and into Lincoln County, Okla. Basal formation of Council Grove group; underlies Johnson shale; overlies Admire formation. Wolfcamp series.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 14 (table 2), 53–58. Described in Wabaunsee County, Kans., where it averages about 47 feet in thickness. Comprises (ascending) Americus limestone, Hughes Creek shale, and Long Creek limestone members. Underlies Johnson shale; overlies Hamlin shale member of Janesville shale.

Named for Foraker, Osage County, Okla.

Forbes Formation

Upper Cretaceous (Chico Series): Northern California.

Listed as uppermost formation in Chico series; overlies Guinda formation (new). J. M. Kirby, 1942, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 899.

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 282–283, 291, 293. Described as chiefly shale and siltstone with minor thin sandstones. Thickness 1,875 to 3,000 feet. Underlies upper Pliocene Tehama gravels; conformably overlies Guinda formation. Type locality designated.

Type locality: On crest and east flank of Rumsey Hills, Tps. 12 and 13 N., R. 3 W., Yolo County.

†Forbes limestone (in Shawnee Formation)[1]

Pennsylvanian: Northwestern Missouri, southwestern Iowa, and southeastern Nebraska.

Original reference: C. R. Keyes, June, 1898, Am. Geologist, v. 21, p. 349.

Exposed in top of bluffs of Missouri and Nodaway Rivers, near town of Forbes, Holt County, Mo.

Forbush Creek facies (of New Providence Formation)

Lower Mississippian: Southern Kentucky.

H. J. Klepser, 1937, Ohio State Univ. Abs. Doctors' Dissert. 24, p. 182–183. Name applied to unit that represents featheredge of New Providence formation.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77. Includes Beaver Creek member of New Providence formation.

Occurrences are in Clinton, Cumberland, Monroe, Pulaski, Russell, and Wayne Counties.

Ford Sandstone[1]

Pennsylvanian: Central southern Iowa.

Original reference: H. Hinds, 1909, Iowa Geol. Survey, v. 19, p. 99, 131, 178.

Probably named for Ford, Warren County.

Fordham Gneiss[1]

Fordham Gneiss (in New York City Group)

Precambrian: Southeastern New York and western Connecticut.

Original reference: F. J. H. Merrill, 1890, Am. Jour. Sci., 3d, v. 39, p. 388–389.

D. M. Scotford, 1956, Geol. Soc. America Bull., v. 67, no. 9, p. 1158, 1159 (table 1), 1170–1173, pl. 1. Assigned to New York City group (new).

J. J. Prucha, 1956, Am. Jour. Sci., v. 254, p. 672–684. Basal formation of New York City group. Conformable to overlying Inwood marble, and Manhattan formation. Traced almost continuously from New York City northeast and east to vicinity of Danbury, Conn. Cannot be considered equivalent of Precambrian gneiss of Hudson Highlands. Interlayering of Fordham, Inwood, and Manhattan type lithologies within formation belts reflects original alternation in type of sediments laid down. Such alternation in lithologic types is most pronounced near the contacts between principal formation belts. So-called Lowerre quartzite, formerly considered basal member of New York City group, is no valid formation but a highly sheared phase of Fordham gneiss. Nonexistence of "Lowerre quartzite" invalidates any correlation based upon presumed similarities in stratigraphic sequences between New York City group and Cambro-Ordovician series north of Hudson Highlands. New York City group may be lower Paleozoic.

T. W. Fluhr, 1957, Geol. Soc. America Eng. Geology Case Histories 1, p. 2, 6 (fig. 1). Fordham is a series of metamorphosed sediments and forms base of Fordham-Inwood-Manhattan group. There is disagreement as to age of formations; some geologists believe they are Precambrian; they are here considered to be early Paleozoic.

J. W. Clark, 1958, Connecticut Geol. and Nat. History Survey Quad. Rept. 7, p. 15–18, geol. map. Mapped in Danbury quadrangle. Stratigraphically below Inwood marble. In Bethel quadrangle to the south, the Inwood is absent and the Fordham lies against Manhattan formation.

Named for fact it forms anticlinal ridge of Fordham Heights, which borders eastern shore of Harlem River, N.Y.

Ford River Granite

Precambrian (Huronian) : Michigan.

R. M. Dickey, 1938, Jour. Geology, v. 46, no. 3, p. 321–335. Granite porphyry which comprises most of the southern complex of the Upper Peninsula of Michigan. It has been considered post-Huronian and named Republic granite by Lamey (1933, Jour. Geology, v. 41).

Type locality and derivation of name not given. Ford River is in Delta County.

Fordyce Knob sandstone facies[1] (of Floyds Knob Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 208–210.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Correlation chart lists Fordyce Knob sandstone as facies of Floyds Knob formation.

Name derived from Fordyce Knob, SE¼NE¼ sec. 9, T. 1 S., R. 5 E., 2 miles southwest of Borden, Clark County.

Forelle Limestone[1]

Forelle Limestone Member (of Goose Egg Formation)

Forelle Limestone (in Phosphoria Group)

Forelle Limestone Member (of Lykins Formation)

Permian: Southeastern Wyoming and northeastern Colorado.

Original reference: N. H. Darton, 1908, Geol. Soc. America Bull., v. 19, p. 430.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1950, Nebraska Geol. Survey Bull. 13–A, p. 2 (fig. 2), 6, 9. Formation in Phosphoria group. Overlies Glendo shale (new); underlies Freezeout shale.

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Reallocated to member status in Lykins formation. Underlies Livermore shale member (new); overlies Glendo shale member.

U.S. Geological Survey classifies the Forelle Limestone as a member of the Goose Egg Formation on the basis of study now in progress.

Named for railroad station a few miles south of Laramie, Wyo.

Foreman Argillite[1]

Upper Jurassic: Northern California.

Original references: C. H. Crickmay, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 81; no. 5, p. 895.

Occurs at Taylor's Diggins, in south fork of Forman [Foreman] Ravine, Mount Jura.

Foreman Formation[1]

Upper Jurassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–175, table 2. Shown on paleotectonic map as underlying Combe sandstone and overlying Hinchman sandstone.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California, Westwood sheet (1:250,000): California Div. Mines. Mapped with Triassic and (or) Jurassic metavolcanic rocks.

Named for exposures at Foreman and in Foreman's Ravine, northeast of Taylorsville, Plumas County.

Forest Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for occurrence in old Forest mine, Ontonagon County.

Forest Conglomerate[1] (in Bohemian Range Group)

Precambrian: Northern Michigan.

Original reference: S. H. Broughton, 1863, Remarks on mining interest and details of geology of Ontonagon County; pamph. of 24 pages and map, Philadelphia, 1863, map, p. 19.

Exposed 500 feet north of old Forest mine, Ontonagon County.

Forest Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Forest City Limestone (in Shawnee Formation)[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 55, 57.

Named for Forest City, Holt County.

Forest City sand rock (in Shawnee Formation)[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 55, 57.

Named for Forest City, Holt County.

Forestdale Marble[1]

Forestdale Member (of Mendon Formation)

Precambrian: West-central Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 362, 394.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 21 (table 1), 28, 30, 33, 35, geol. map. Rank reduced to middle member of Mendon formation. This is unit termed "pebbly, crystalline limestone" member of Mendon series (Whittle, 1894). Member is buff to rusty-weathering; white to gray dolomite marble. Thickness featheredge to 115 feet. Occurs about 600 feet above base of formation; absent in some areas. Lower Cambrian.

P. H. Osberg, 1959, New England Intercollegiate Geol. Assoc. Guidebook 51st Ann. Mtg., p. 45, 46. In Coxe Mountain area, Vermont, Forestdale dolomite overlies Pinnacle formation. Precambrian(?). Names Mendon and Nickwacket have been used for rocks included in Pinnacle of this report.

Excellent section at Forestdale, Rutland County.

Forest Grove Formation[1]

Mississippian (Chester): Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Upper shale of Green Hill member of Pride Mountain formation (both new) is equivalent to lower part of Morse's Forest Grove formation.

Named for school located on formation near old Mingo village and Southward Bridge, Tishomingo County.

Forest Hill Sand[1]

Forest Hill Formation (in Vicksburg Group)

Forest Hill Member (of Jackson Formation)

Oligocene, lower: Southern Mississippi and southwestern Alabama.

Original reference: C. W. Cooke, 1918, Washington Acad. Sci. Jour., v. 8, p. 187, 191–193.

F. E. Mellen, 1940, Mississippi Geol. Survey Bull. 39, p. 12 (table), 23. Reallocated to member status in Jackson formation. In Yazoo County, consists of argillaceous lignitic silt, thin argillaceous allocthonous lignite; lignitic leaf-bearing montmorillonitic clays; and fine-grained crossbedded sand. Thickness 60 to 80 feet. Overlies Yazoo member; underlies Mint Springs facies of Glendon member of Vicksburg formation. Eocene.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1314 (fig. 1), 1318–1324. Cooke originally regarded Forest Hill sand as contemporaneous with Red Bluff clay but later accepted view of group of Gulf Coast geologists that the Red Bluff comes in from the east as a wedge between Yazoo clay and Forest Hill sand. Concept derived from present study is that Forest Hill is deltaic equivalent of Red Bluff, as Cooke originally believed. Vicksburg group is restricted below to exclude Forest Hill sand and Red Bluff clay. Chart shows Forest Hill overlies Yazoo clay of Jackson group and underlies Mint Spring marl member of Marianna limestone. Oligocene.

H. A. Tourtelot, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 6. Forest Hill sand and Red Bluff clay mapped together in Choctaw County, Ala.

H. N. Fisk, 1944, [U.S.] Mississippi River Comm., p. 13 (table 2), 15. Table shows Forest Hill formation at base of Vicksburg group. Oligocene.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1838 (fig. 6), 1839 (footnote). Forest Hill sand overlies Shubuta (clay) member (new) of Yazoo formation.

W. J. Hendy, 1948, Mississippi Geol. Soc. [Guidebook] 6th Field Trip, p. 27–28. As used in this report, formation includes Red Bluff member.

W. H. Monroe, 1954, U.S. Geol. Survey Bull. 986, p. 62–74, pls. 2, 3. Forest Hill sand crops out in belt across Mississippi from Yazoo County on the west through Hinds, Rankin, Scott, and Smith Counties, in which area it is interposed between belts of outcrops of Yazoo clay and Mint Spring marl member of Marianna limestone; from eastern Smith County to Alabama line through Jasper, Clarke, and Wayne Counties, it is underlain by and may interfinger with Red Bluff clay. Thickness 68½ feet at type locality (herein stated); thickness generally 100 feet.

Type locality: On Jackson-Raymond Road, one-half mile northeast of Forest Hill School in NE¼ sec. 22, and NW¼ sec. 23, T. 5 N., R. 1 W., Hinds County, Miss.

Forestville Member (of Canadaway Formation)

Upper Devonian (Senecan): Southwestern New York.

I. H. Tesmer, 1954, Dissert. Abs., v. 14, no. 12, p. 2317, 2318. Name given to unit formerly known as Gowanda member of Canadaway formation. Underlies Laona member; overlies South Wales member. Different type locality designated.

[Probably named for Forestville, Chautauqua County.]

Forestville Shale[1]

Mississippian: Michigan.

Original reference: C. H. Gordon, 1900, Michigan Geol. Survey, v. 7, pt. 3, p. 23.

Probably named for exposures at Forestville, Sanilac County.

Forge Hollow Dolomite (in Bertie Group)

Forge Hollow Member (of Bertie Formation)

Upper Silurian: Central New York.

L. V. Rickard, 1955, New York Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7, 9 (strat. column). Gypsiferous shales, 25 to 40 feet thick. Overlies Fiddlers Green member; underlies Williamsville member.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Rank raised to formation in Bertie group. Overlies Fiddlers Green dolomite; underlies Oxbow dolomite (new). Fieldwork has not demonstrated lateral continuity of Forge Hollow and Scajaquada as indicated on present chart. Thick glacial deposits conceal these units in area where they may merge. Possibility of facies changes—for example, Falkirk to Forge Hollow—should not be overlooked. For the present, distinct names are retained for western and central New York.

Occurs in Clockville and Munnsville areas.

Forked Deer Limestone[1]

Lower Ordovician: Northeastern Tennessee.

Original reference: G. M. Hall and H. C. Amick, 1934, Tennessee Acad. Sci. Jour., v. 9, no. 2, p. 158–161.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 49. Kingsport limestone (new) replaces Jefferson City formation (Oder, 1934) and Forked Deer formation (Hall and Amick, 1934).

Named for Forked Deer Creek in valley in which U.S. Highway 25 is located, Morristown quadrangle, Hamblen County.

†Fork Mountain Slate[1]

Pennsylvanian: Southwestern Arkansas.

Original references: A. H. Purdue, 1909, Slates of Arkansas: Arkansas Geol. Survey, p. 30, 40; 1914, U.S. Geol. Survey Bull. 586.

Named for Fork Mountain, Polk County.

Fork Ridge Sandstone Member (of Mingo Formation)[1]

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 39, 40.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 82, 83, 89, 140. In Mingo formation about 40 feet below Mingo coal.

Named for Fork Ridge, Bell County, Ky.

Forlorn Hope Shale

Lower Cambrian: Southeastern Nevada.

J. F. Mason *in* A. W. Grabau, 1936, Paleozoic formations in the light of the pulsation theory, v. 1, Lower and Middle Cambrian pulsation: 2d ed., Peiping, China, University Press, Natl. Univ. Peking, p. 275–276. Green argillaceous shale with *Olcnopsis*. Thickness 115 feet. Overlies Pioche formation (restricted); underlies Comet shale (new). Pioche shale of Walcott (1908), and Westgate and Knopf (1927) includes Comet shale, Forlorn Hope shale, and Pioche shale as used here. Lower to Middle Cambrian boundary was placed at top of Forlorn Hope shale in order to cause *Olenopsis* to fall at summit of Lower Cambrian.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1149, 1159. Mason (1936) did not define term Forlorn Hope and did not indicate type locality. Term Forlorn Hope not used in this report [Highland Range area, Nevada].

Type locality and derivation of name not given.

†Forman Volcanics

Miocene, upper: Western Nevada.

V. P. Gianella, 1934, Mining and Metallurgy, v. 15, no. 331, p. 299. Interbedded with Sutro tuffs (new); older than Mount Kate volcanics (new).

V. P. Gianella, 1936, Nevada Univ. Bull., v. 30, no. 9, p. 53. Similar name is used for a formation in California; therefore, renamed Alta andesite series.

Forms hanging wall of the Comstock lode throughout most of its length and entirely encloses the Silver City system of veins, Silver City district.

Forrest Shale[1]

Lower Cretaceous: Southeastern Arizona.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 64, no. 2, p. 129, 138, 139.

Named for Forrest Ranch, a few miles east of Bisbee.

Forreston Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 15A, 15C. Shown on columnar section as underlying Eldena member (new) of Nachusa formation (new) and overlying Victory member (new) of Grand Detour formation (new). Thickness 4 to 17 feet.

Occurs in Dixon-Oregon area.

Fort Adams Member (of Pascagoula Formation)

Miocene: Southwestern Mississippi.

G. F. Brown and W. F. Guyton, 1943, Mississippi Geol. Survey Bull. 56, p. 22, 23 (table), 47–50, pl. 3. Calcareous green clay, indurated blue claystone, compact sand, and light coarse sand. Overlies Homochitto member (new). Thickness 135 to 235 feet (data based on test well). Derivation of name given.

This may or may not be unit referred to as Fort Adams or Ellisville phase of Grand Gulf Group.

Named for exposures along bluff above Fort Adams, southwestern Wilkinson County. Supposedly can be followed in northeasterly direction from Fort Adams across Wilkinson County into Franklin County.

†Fort Adams[1] or Ellisville phase[1]

Oligocene(?) or Miocene: Southern Mississippi and southern Louisiana.

Original reference: L. C. Johnson, 1893, Science, v. 21, p. 90–91.

Named for Fort Adams, Wilkinson County, Miss., and Ellisville, Jones County, Miss.

Fort Ancient division (in Richmond Group)[1]

Fort Ancient Member (of Waynesville Formation)

Upper Ordovician: Southwestern Ohio.

Original reference: A. F. Foerste, 1909, Denison Univ. Sci. Lab. Bull. 14, p. 292.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on generalized section of

Ohio as basal member of Waynesville formation. Underlies Clarksville member; overlies Oregonia member of Arnheim formation.

Named for Fort Ancient, Warren County.

Fort Ann Limestone (in Great Meadows Formation)

Fort Ann Limestone Member (of Tribes Hill Formation)

Lower Ordovician: East-central New York.

R. R. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939. Named as member of Tribes Hill formation.

R. R. Wheeler, 1942, Am. Jour. Sci., v. 240, no. 7, p. 518, 522. Limestone is middle member of Tribes Hill in Champlain and Hudson Valleys. Underlies Benson dolomite member; overlies Norton member. Represents division C 3 of Brainerd's and Seely's "Calciferous" (1890, Geol. Soc. America Bull., v. 1, p. 501–516).

John Rodgers, 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for Field Trips in New England, p. 35 (table 2). Described as persistent limestone layer at top of Great Meadows formation (new). Refers to R. H. Flower (unpub. ms.).

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 74. Subdivisions of Tribes Hill of Champlain Valley are poorly defined and can not be used in Mohawk Valley.

Probably named for occurrence at Fort Ann, Washington County.

Fort Apache Limestone Member (of Supai Formation)[1]

Permian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 533–536.

R. L. Jackson, 1951, Plateau, v. 24, no. 2, p. 86, 88, fig. 2. Underlies Corduroy member (new); overlies Big "A" sand facies.

Described in Fort Apache Indian Reservation.

Fort Atkinson Limestone Member (of Maquoketa Shale)

Fort Atkinson Limestone (in Maquoketa Group)[1]

Upper Ordovician: Northeastern Iowa and western Wisconsin.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 98.

W. H. Twenhofel, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 50). Shown on correlation chart as limestone member of Maquoketa formation. Underlies Brainard limestone member; overlies Clermont shale member.

Named for exposures in quarry west of old fort at town of Fort Atkinson, Winneshiek County, Iowa.

†Fort Benton Group[1]

Upper Cretaceous: Southeastern Montana, Colorado, Kansas, southern Minnesota, Nebraska, northern New Mexico, South Dakota, and eastern Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1862, Philadelphia Acad. Nat. Sci. Proc., v. 13, p. 419, 421.

Occurs along Missouri River from 10 miles above James River to Big Sioux River, along eastern slope of Rocky Mountains, and at Black Hills. Named for Fort Benton, on Missouri River, about 40 miles below Great Falls, Mont.

Fort Buchanan Formation (in Sonoita Group)

Upper Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 59. Consists of a basal conglomerate about 400 feet thick overlain by a series of alternating hard gray sandstones and soft maroon shales approximately 1,500 feet thick. The lower division of Sonoita group; underlies Fort Crittenden formation (new). Rests on andesitic flows.

In Casa Blanca Canyon, Patagonia Mountains. Name adopted from the nearby ruins of an old fort.

Fort Cassin Formation[1]

Lower Ordovician: Northwestern Vermont and eastern New York.

Original reference: R. P. Whitfield, 1890, Am. Mus. Nat. History Bull., v. 3, p. 25–28.

John Rodgers, 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for Field Trips in New England, Nov. 10–12, p. 35 (table 2). Described in Fort Ann 15-minute quadrangle, New York, as consisting of interbedded limestone and dolomite with a basal sandstone. Thickness 150 feet. Underlies Providence Island dolomite; overlies Smith Basin formation.

Named for Fort Cassin, Addison County, Vt.

Fort Covington Glaciation

Fort Covington Till

Pleistocene: Northwestern New York.

Paul MacClintock, 1958, Glacial geology of the St. Lawrence seaway and power project: New York State Mus. and Sci. Service, p. 6–25. Younger of two episodes of glaciation in area. Advance followed Malone glaciation (new) and came from the northwest. Till forms morainal ridges, mantles the northeast-southwest drift hills, and lies on varved sediments in St. Lawrence seaway excavations.

Named for Fort Covington, Franklin County, in vicinity of which till forms strong morainal ridges.

Fort Crittenden Formation (in Sonoita Group)

Upper Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 27 (table). Named on table. Soft red and yellow clay and sandstone. Early Tertiary.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 59. Consists of (ascending) alternating yellow thin-bedded shales and hard sandstones, 600 feet thick; yellow, red, and black shale alternating with hard yellow and pink sandstone, 200 feet thick; light-colored conglomerate, 350 feet thick; thin-bedded sandstone, 80 feet thick; soft light-colored shale and gray and buff sandstone and shale; conglomerate composed of large boulders, probably over 1,000 feet thick; and south of the Greaterville fault, terminates in a thick series of scarlet-red strata. Upper division of Sonoita group; overlies Fort Buchanan formation (new). Geographical area given. Late Cretaceous.

In Casa Blanca Canyon, Patagonia Mountains. Name adopted from the nearby ruins of an old fort.

Fort Denaud Member (of Caloosahatchee Marl)

Pleistocene: Southern Florida.

J. R. DuBar, 1957, Illinois Acad. Sci. Trans., v. 50, p. 192, (table 1). Table shows Fort Denaud as lowermost member of Caloosahatchee. Underlies Bee Branch limestone member (new); overlies Tamiami formation.

J. R. DuBar, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 136, (fig. 4), 139–143. Typically strata are light colored, with cream, white, and light gray predominating, although some units are mottled yellow brown. Composed of sandy and silty marls, soft and relatively unconsolidated; near Ortona Locks in Hendry County, a thin hard calcareous sandstone almost barren of fossils forms slight ledge at or below water level. Several units (faunizones) and numerous facies are recognized; includes (ascending) *Cyrtopleura costata* faunizone, basal oyster biostrome, and a brackish-water bed characterized by *Rangia nasuta*. Exposed thickness rarely exceeds 5 feet and commonly is less, although locally may be as much as 8 feet. Base of lower beds observed only where Caloosahatchee marl laps onto erosional remnants of Tamiami formation. Underlies Bee Branch member; where erosion has been intense, member is unconformable below Fort Thompson or Pamlico formation.

Named for exposures along stretch of Caloosahatchee River extending between point ½ mile and 3½ miles upstream from Fort Denaud in Hendry County.

Fort Dodge Gypsum[1]

Permian(?): Central northern Iowa.

Original reference: W. J. McGee, 1884, Rept. 10th Census, v. 10, Rept. on building stones, p. 257, 258.

Occurs in vicinity of Fort Dodge, Webster County.

Fort Ellis Beds[1]

Pliocene(?): Central southern Montana.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 287.

In vicinity of Fort Ellis, near Bozeman, Threeforks quadrangle.

†Fort Gaines[1]

Eocene, lower: Western Georgia and southern Alabama.

Original reference: E. A. Smith, 1888, Geographic map of Alabama: Alabama Geol. Survey Rept. Prog. 1884–1888.

Probably named for Fort Gaines, Clay County, Ga.

Fort Hall Formation (in Thaynes Group)[1]

Lower Triassic: Southeastern Idaho.

Original reference: G. R. Mansfield, 1915, Washington Acad. Sci. Jour., v. 5, p. 492.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 31, pl. 1. Mapped in Ammon and Paradise Valley quadrangles where thickness is about 1,000 feet.

Bernard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 172. Mansfield (1916, Washington Acad. Sci. Jour., v. 6) raised Thaynes to rank of group and subdivided it into (ascending) Ross Fork limestone (called Ross limestone in Mansfield's 1916 paper), Fort Hall formation, and Portneuf limestone. In area between Fort Hall Indian Reservation and Gray's Range, these three divisions of Thaynes are distinctive. Eastward toward Salt River Range and southward toward Bear Lake Valley, the Ross Fork and Fort Hall formations lose their identity. The Portneuf is a much more distinctive unit, and parts of it can be traced from Fort Hall, Idaho, to Cumberland, Wyo. Name Portneuf is retained, but in present paper names Ross Fork and Fort Hall are not used.

Named for old Fort Hall, the site of which is in valley of Lincoln Creek, which appears on some maps as Fort Hall Creek. Formation occupies a prominent ridge along north side of valley.

†Fort Hays division or Group[1]

Upper Cretaceous: Western Kansas.

Original reference: B. F. Mudge, 1876, U.S. Geol. and Geog. Survey Terr. Bull. 2, p. 218–221.

Named for old Fort Hays, Ellis County.

Fort Hays Limestone Member (of Niobrara Formation)[1]

Upper Cretaceous: Western Kansas, eastern Colorado, northeastern New Mexico, and southeastern South Dakota.

Original reference: S. W. Williston, 1893, Kansas Acad. Sci. Trans., v. 13, p. 108–109.

R. L. Griggs, 1948, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 1, p. 30–31. Described in Colfax County, N. Mex., where it underlies Smoky Hill marl member and overlies Carlile shale. Consists of seven or eight limestone beds that are separated by beds of calcareous shale. Thickness 15 to 20 feet. Believed to be equivalent to part of Timpas limestone of previous usage.

E. J. Bolin, 1952, South Dakota Acad. Sci. Proc., v. 31, p. 190. Geographically extended into southeastern South Dakota. It is difficult to distinguish Fort Hays and Smoky Hill members on lithologic basis, but, this investigation demonstrated that they could be distinguished on basis of microfossils. Thickness of Fort Hays varies from 50 to 80 feet.

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–146. Described in La Veta area, Huerfano County, Colo., where it crops out as prominent hogback on flanks of Greenhorn anticline. Consists of thick beds of light-gray chalky limestone alternating with thin interbeds of gray calcareous shale. Average thickness 60 feet. Underlies Smoky Hill marl member; overlies Codell sandstone member of Carlile shale.

M. A. Jenkens, Jr., 1957. Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Parks basin, Colorado, p. 53, pl. 1. Described in Red Dirt area, Grand County, Colo., where it is about 14 feet thick; underlies Smoky Hill member; overlies Codell sandstone here included in the Benton because Graneros, Greenhorn, and Carlile cannot be distinguished in this area. Believed that names Fort Hays and Smoky Hill have priority over terms Timpas and Apishapa; use of the former terms would help standardize Niobrara terminology in west-central Colorado.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as Fort Hays limestone member of Niobrara chalk. Underlies Smoky Hill chalk member; overlies Codell sandstone.

Named for old Fort Hays, well-known landmark in western Kansas.

Fort Hunter Sandstone Member (of Mahantango Formation)

Middle Devonian: Central Pennsylvania.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 138, 139, 164, 165 (fig. 38), 180–182. Thin, very hard dark-gray rusty-weathering sandstone. At type locality, unit is interbedded in more shaly lower part of Montebello sandstone facies of the Mahantango. Occurs near base of Skaneatels facies of Mahantango from Perry County east of the Schuylkill River. Thickness about 5 feet. Was called Rockville by Willard and Cleaves (1938), but that name is preoccupied.

Type locality: Southernmost quarry at Rockville, Dauphin County. Named for Fort Hunter, 4 miles north of Harrisburg.

Fort Johnson Member (of Tribes Hill Formation)

Lower Ordovician (Lower Canadian): East-central New York.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76 (fig. 2), 84–85. Name proposed for basal member of formation in Mohawk Valley. Breccia of dolomite cobbles or a sandstone stratum commonly forms base. Lower part is predominantly dolomite (dolomisiltite and dolomarenite). Above is a transition zone of calcite dolomite and dolomitic limestone. Upper part is primarily thick-bedded white-weathering blue-black dolomitic calcilutite in which irregular buff-weathering dolomite patches stand out in relief. Thickness 28 feet at type locality where base is concealed. Thickened extension of lower half of unit reaches 90 feet in northeastern part of Amsterdam quadrangle; this interval, when traced into Saratoga Springs area, is coextensive with Gailor dolomite. Underlies Palatine Bridge member (new) and is overlapped by it northward; contact gradational west of Cranesville and unconformable to the east. Overlies an unnamed dolomite, usually conformably.

Type locality: Abandoned quarry and West Shore Railroad cut 2 miles east of Fort Hunter, Montgomery County. Named for village of Fort Johnson on north side of Mohawk River northeast of Fort Hunter.

Fort Kent Shale

Lower Devonian: Northern Maine, and northwestern New Brunswick, Canada.

O. O. Nylander, 1940, Geological formations of the St. John River valley, northern Maine and New Brunswick; Caribou, Maine, privately printed, p. 3–4. Name proposed for distorted, folded beds of shale. Overlies unnamed sandstone.

Crops out in vicinity of hill in southern part of town of Fort Kent about 1¼ miles northwest of Daigle post office, Aroostook County, Maine. Well-exposed in village of Edmunston and along road to St. Basil, New Brunswick, Canada.

†Fort Knox Sandstone[1]

Pennsylvanian: Southwestern Indiana.

Original reference: J. Collett, 1874, Indiana Geol. Survey 5th Rept., p. 323.

Named for Fort Knox, Knox County.

Fort Littleton Formation (in Portage Group)[1]

Upper Devonian: Eastern and central Pennsylvania.

Original reference: Bradford Willard, 1935, Geol. Soc. America Bull., v. 46, no. 8, p. 1199, 1218.

Bradford Willard *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G 19, p. 210–218. Summary discussion. Underlies Chemung group or Catskill facies group; overlies Rush formation. Since there is a definite line of separation between Burket member of the Rush and Harrell member of the Fort Littleton, use of terms Fort Littleton and Rush in sense of formations is convenient.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Stratigraphically restricted; Parkhead sandstone is shown as distinct unit overlying Fort Littleton formation, not a member of the latter.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3. Fort Littleton contains Trimmers Rock sandstone, Brallier shale, and Harrell shale members.

Named for Fort Littleton, a village in northeastern part of Fulton County.

Fort Logan Beds[1]

Miocene, lower: Western central Montana.

Original reference: E. Douglas, 1903, Carnegie Mus. Annals, v. 2, p. 150–151.

W. T. Thom, Jr., 1957, Billings Geol. Soc. Guidebook, 8th Ann. Field Conf., p. 11 (table 1). Name appears on generalized stratigraphic section for Crazy Mountain Basin and nearby areas. Underlies Deep River beds, together the two units are dated as middle and upper Miocene.

Named for military post in Meagher County near which beds are best exposed.

Fort Mountain Gneiss

Precambrian: Northwestern Georgia.

A. S. Furcron, K. H. Teague, and J. L. Calver, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1195. Thrust faults supplementary to the mapped overthrust, which separates the eastern crystalline block from known Paleozoic sediments of the Great Valley, bring up a Precambrian biotite augen gneiss, Fort Mountain gneiss, intruded by granite, upon which Ocoee rocks are unconformable. Talc deposits and associated schists, Cohutta schist, occur in upthrust block of Fort Mountain gneiss but not in the Ocoee series.

A. S. Furcron and K. H. Teague, 1947, Georgia Geol. Survey Bull. 53, p. 9–11, pl. 1. Fort Mountain gneiss, as mapped, is a complex of igneous and metamorphic rocks which contains numerous bodies of Corbin granite and Cohutta schist. Intruded by Corbin granite. Derivation of name given.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 277–278. Fort Mountain (granite) gneiss forms narrow belt 4 to 5 miles long on west slope of Fort and Cohutta Mountains and lies south of Holly Creek embayment of Cartersville thrust block. Hayes (U.S. Geol, Survey Dalton folio, unpub.) states that the gneiss is overlain by basal arkosic conglomerate, black slate, graywacke, and conglomerate. Lower part of sedimentary series that overlies the granite gneiss should be Hurricane graywacke (new). Fort Mountain gneiss considered a hybrid rock and regarded as part of injection complex below Ocoee series.

Named from Fort Mountain, Murray County. Crops out in two distinct belts in the Fort and Cohutta Mountain district, east of Chatsworth.

Fort Niobrara Formation[1]

Pliocene: Nebraska, Colorado, and Wyoming.

Original reference: H. F. Osborn, 1909. U.S. Geol. Survey Bull. 361, p. 115.

F. W. Johnson, 1936, Am. Jour. Sci., 5th, v. 31, p. 469. Name Valentine has priority over Fort Niobrara formation.

F. W. Walker, 1938, Am. Jour. Sci., 5th, v. 36, no. 213, p. 215, 219. Proposed to consider terms Fort Niobrara and Niobrara River as obsolete and incompatible to good geologic nomenclature. Name Valentine beds should be retained and applied to lower 175 to 225 feet of unconsolidated sands of Ogallala formation in Valentine area.

Type locality: On Niobrara River, near Fort Niobrara, Cherry County, Nebr.

Fort Payne Chert[1] or **Formation**

Lower Mississippian: Northern and eastern Alabama, northwestern Georgia, Kentucky, northeastern Mississippi, and Tennessee.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept on Cahaba coal field, p. 155–156, sec. opposite p. 152, map.

H. J. Klepser, 1937, Ohio State Univ. Abs. Doctors' Dissert. 24, p. 182. Formation, in Eastern Highland Rim area, includes a northern facies, Greasy Creek, and a southern facies, Short Mountain (both new).

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 52–54. Referred to as formation. Term Fort Payne has been used in many ways since its original definition by Smith (1890). As presently used in Tennessee, restricted to the characteristically cherty strata between Chattanooga shale (or Maury or New Providence, if present) and the so-called Warsaw formation. Age of top and bottom of unit varies with locality; main mass of unit is primarily of Keokuk age. Maximum thickness in Tennessee about 275 feet. Includes Greasy Creek facies and Short Mountain facies.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 86–88, 90, 92–94). Shown on correlation chart as Osagean.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 106–108, pt. 1, pls. Grainger formation is recognized in belts southeast of Whiteoak Mountain and Wallen Valley faults, and Fort Payne chert in those northwest, except that belt along Cumberland escarpment northeast of Jacksboro fault is shown as grading from Fort Payne chert near La Follette to Grainger formation near Cumberland Gap. Thickness 100 to 200 feet.

A. T. Allen and J. G. Lester, 1953, Georgia Geol. Survey Bull. 60, p. 192, 193. Columnar section at Little Sand Mountain, Ga., shows Fort Payne chert, 390 feet thick, overlies Chattanooga shale and underlies St. Louis limestone.

G. T Malmberg and H. T. Downing, 1957, Alabama Geol. Survey County Rept. 3, p. 16 (table 3), 34–39. Chert crops out in northwestern Madison County over area of about 50 square miles. Thickness (determined from well logs) 95 to 160 feet. Unconformably overlies Chattanooga shale; conformably underlies Tuscumbia limestone. Osage.

Named for development at Fort Payne, De Kalb County, Ala.

Fort Pena Formation[1]

Middle Ordovician: Southwestern Texas.

Original reference: P. B. King, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 9, p. 1066, 1070.

T. S. Jones, 1953, Stratigraphy of the Permian basin of West Texas: West Texas Geol. Soc., p. 7–8. Age given as Middle Ordovician.

W. B. N. Berry, 1960, Texas Univ. Bur. Econ. Geology Pub. 6005, p. 20–23. In the Solitario and old Jones Ranch areas, Alsate shale is not present between characteristic limestones of Marathon limestone and Fort Pena formation; in its place is white to buff quartzose sandstone 20 to 50 feet thick herein named Rodriquez Tank sandstone. Underlies Woods Hollow shale. Graptolite fauna discussed.

Type locality: On ridge directly north of old Fort Pena Colorada, Brewster County.

Fort Plain[1]

Fort Plain Shale Member (of Canajoharie Shale)

Fort Plain zone (of Fairfield Member of Canajoharie Formation)

Middle Ordovician: Eastern New York.

Original reference: Rudolf Ruedemann and G. H. Chadwick, 1935, Science, new ser., v. 81, no. 2104, p. 400.

Rudolf Ruedemann, 1947, Geol. Soc. America Mem. 19, p. 119. Referred to as Fort Plain shale member of Canajoharie. Underlies Chuctenunda shale member.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 57–58. Uppermost zone of Fairfield member. Composed of silty shale at Canajoharie, but of black shale along West Canada Creek. Underlies Utica shale; overlies rocks of Dolgeville facies in Little Falls and southeastern Utica quadrangles. Thin metabentonite occurs just above contact with Dolgeville in stream south of County Home, Utica quadrangle; thickness of zone here at least 50 feet.

Type locality and derivation of name not given but may have been named for Fort Plain, Montgomery County.

Fortress Mountain Formation

Lower Cretaceous: Northern Alaska.

W. W. Patton, Jr., 1956, *in* George Gryc and others, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 219–221, figs. 2, 5. Consists of shale and large percentage of coarse graywacke sandstone and conglomerate. Conglomerate and sandstone typically green to gray and composed chiefly of chert, feldspar, and mafic igneous fragments in mudstone matrix. Beds of coarse clastics several feet to more than 1,000 feet thick, and intercalated with dark gray soft clay and silt shale and gray to green siltstone. Thickness at type section, the thickest known section, approximately 10,000 feet; over most of foothills, less than 5,000 feet and generally less than 3,000 feet. Locally overlies Okpikruak formation and older rocks with angular discordance; overlies Tiglukpuk formation at type locality. Succeeded stratigraphically possibly by part of Torok formation and by Nanushuk group.

R. M. Chapman and E. G. Sable, 1960, U.S. Geol. Survey Prof. Paper 303–C, p. 69–73, pls. 8, 9, 18. Described in Utukok-Corwin region where it is more than 4,400 feet thick and consists mostly of marine shale, siltstone, graywacke-type sandstone, and some conglomerate. No distinct contact with overlying Torok formation exposed in mapped area. Early Cretaceous.

Type section: A composite of several partial sections exposed along Kiruktagiak River and on Castle Mountain. Named from exposures on Fortress Mountain (lat 68°34'30'' N., long 152°58' W.), where typically exposed. Mapped over wide area in southern half of Arctic Foothills province from Sagavanirktok River west beyond Kukpowruk River.

Fort Ridgely Granite (in Minnesota Valley Granite Series)

Precambrian: Southwestern Minnesota.

E. H. Lund, 1956, Geol. Soc. America Bull., v. 67, no. 11, p. 1482, 1483. Pinkish-gray porphyritic granite with aligned phenocrysts 2 inches or more in length that stand out prominently on slightly weathered surfaces. Dark inclusions locally abundant, and where these are present the rock resembles Morton gneiss but lacks typical contorted structure of the Morton. May be a less contaminated and more massive facies of the Morton.

Exposed in vicinity of Fort Ridgely State Park, Nicollet County.

Fort Riley Limestone (in Chase Group)[1]

Fort Riley Limestone Member (of Barneston Limestone)

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 14.

G. E. Condra and J. E. Upp. 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 41. Uppermost member of Barneston formation (new).

R. C. Moore, 1936, Kansas Geol. Soc. Guidebook 10th Ann. Field Conf., p. 12 (fig. 4), 69 (fig. 45). Overlies Oketo shale member (new).

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44–45. Limestone, light-gray and tan, massive and thin-bedded, with minor amount of gray shale. Basal part contains thin, more or less shaly beds that are overlain by massive "rim rock," which contains fossil algae; thin shaly beds and locally clay shale deposits occur in middle part; upper strata rather massive but less so than the "rim rock." Thickness 30 to 45 feet. Underlies Holmesville shale member of Doyle shale. Wolfcamp series.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Fort Riley limestone in Chase group.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 80, p. 111–114. Currently considered to be top member of Barneston formation. Underlain in turn by Oketo shale member and Florence limestone (Florence flint) member. These subdivisions of Barneston have been traced across Kay County, Okla. Between Kay and Pawnee Counties, Florence limestone member disappears and only a noncherty limestone, here considered to be Fort Riley member, extends southward as far as Pawnee County. In Kay County, consists of about 31 feet of soft light-gray to buff limestone with massive algal bed more than 10 feet thick occurring locally in lower part. Overlies Matfield shale; underlies Doyle shale.

Named for Fort Riley, Geary County, Kans.

†Fort Scott coal series[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 25–26.

Probably named for exposures at Fort Scott, Bourbon County.

Fort Scott Limestone[1] (in Marmaton Group)

Fort Scott Limestone (in Henrietta Group)

Fort Scott Limestone Member (of Henrietta Formation)[1]

Pennsylvanian (Des Moines Series): Eastern Kansas, western Missouri, southwestern Iowa, and northeastern Oklahoma.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 25.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 25–26 (fig. 2), 36–37, measured sections. Basal formation in Henrietta group. From Missouri River northward, formation includes parts of three cyclothems. At type section, southeastern Kansas, formation is predominantly limestone, but, northeastward in Missouri, shale becomes increasingly prominent, and, in latitude of Missouri River, shale is predominating rock type; if formation has been correctly traced, there are three limestone members which persist into Iowa. In ascending order, these limestones are called by Missouri Survey the lower Fort Scott ("Mulky cap rock"), the "Rhomboidal," and upper Fort Scott "Lexington bottom-rock"). These limestones are herein named (ascending) Blackjack Creek, Houx, and Higginsville. Underlies Labette shale; overlies Cherokee shale (group).

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 302–309. Cline (1941) named lower member the Blackjack Creek, the upper, the Higginsville, and a thin limestone that occurs between them, the Houx. Name Little Osage shale is here proposed for beds between Blackjack Creek and Higginsville limestones, and Houx limestone is considered bed in Little Osage shale. Bennett (1896, Kansas Univ. Geol. Survey, v. 1) probably regarded exposure in cut a short distance east of Missouri Pacific Railway station in Fort Scott as type exposure; a better type exposure is herein designated. Thickness at this exposure 27¾ feet. Overlies Cherokee shale; underlies Labette shale.

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 28, p. 93–96, measured sections, pl. 7. Fort Scott, in east-central Missouri, consists of alternating beds of shale and limestone below which there is section of shale, base of which is marked by a sandstone, the Squirrel. Although the Squirrel is usually placed in upper part of Cherokee, it is believed that more detailed work will show that it belongs at base of Henrietta group. Unconformably overlies Lagonda shale of Cherokee group. Thickness in Callaway County about 54 feet.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Columnar section, Jackson and Cass Counties, shows formation includes (ascending) Blackjack Creek limestone, Houx limestone, Backwater [Blackwater] Creek shale (new), and Higginsville limestone members. Overlies Lagonda sands and shales; underlies Labette shale. Henrietta group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. v (fig. 1), 5–6 Name Henrietta group suppressed. Fort Scott reallocated to Marmaton group Missouri. Includes (ascending) Blackjack Creek limestone, Little Osage, and Higginsville limestone members. Little Osage member includes (ascending) Houx limestone, Blackwater Creek shale, and Flint Hill sandstone (new). Underlies Labette formation.

W. B. Howe, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2093. Breezy Hill limestone member of Cherokee formation seems rather consistently to have been identified as lower Fort Scott in northern Oklahoma, whereas the true lower Fort Scott limestone (Blackjack Creek) of type area is actually the next limestone unit above the Breezy Hill. Lithologically, the Breezy Hill in northern Oklahoma is very much like lower Fort Scott limestone of type region, and the true lower Fort Scott (Blackjack Creek) has developed a somewhat different lithology.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 20–25, pl. 1. Described in Tulsa County. According to present usage, term Fort Scott is applied to two limestones and an intervening shale at type locality where aggregate thickness is about 30 feet. Formation maintains its tripartite character southward into Oklahoma, but upper limestone member does not extend south of T. 25 N., R. 16 E., southeastern Nowata County. Lower limestone member extends southward beyond Tulsa County and is overlain, at least locally by middle shale member. These two members are not more than 10 feet thick in most exposures south of Arkansas River. Conformably overlies Senora formation; conformably underlies Labette shale.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Fort Scott formation, Marmaton group, shown on northern midcontinent composite stratigraphic section above Excello formation, Cabaniss group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 33, fig. 5. Fort Scott has not been completely differentiated in Iowa, but the following members have been identified (ascending): Blackjack Creek limestone, Summit coal, Houx limestone, and Higginsville limestone. Shale section underlies Higginsville; this interval is about 15 feet thick in Appanoose County and about 7 feet in Madison County. Underlies Labette shale; overlies Cherokee shale. Marmaton group. Classification of Marmaton group used in this report is that agreed upon by State Geological Surveys in northern midcontinent region (Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11). Although Iowa Survey is not entirely in agreement on this classification, it is used here for convenience of those who may be familiar with grouping as used in other states of region.

Type exposure: Cement plant quarry NE¼ sec. 19, T. 25 S., R. 25 E., northeast of Fort Scott, Bourbon County, Kans.

†Fort Scott Marble (in Cherokee Shale)[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim, Rept., p. 26.

Probably named for exposures at Fort Scott, Bourbon County.

†Fort Scott marble series (in Cherokee Shale)[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 26.

Probably named for exposures at Fort Scott, Bourbon County.

Fort Shafter (Schafter) Gravel[1]

Pleistocene(?): Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 62, 64, 65–71.

G. A. Macdonald and D. A. Davis, 1956, *in* Jacques Avias and others, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 82–83. Fort Schafter gravel included by Stearns (1935, Hawaii Div. Hydrog. Bull. 1) in older alluvium. Underlies lowest tuff of Honolulu volcanic series in area northeast of Pearl Harbor. Pleistocene(?). Type locality.

Type locality: Bluff on edge of Fort Shafter Terrace overlooking Moanalau Gardens and lower gorge of Moanalau Stream. South side of Koolau Range about 17 miles west of Makapuu Head.

Fort Sill Limestone } (in Arbuckle Group)
Fort Sill Formation[1] }

Upper Cambrian: Southern Oklahoma.

Original reference: E. O. Ulrich, 1932, Geol. Soc. America Bull. v. 43, no. 3, p. 742–747.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 20–21, measured sections. Basal formation of Arbuckle group. Consists chiefly of thin beds of limestone; thick beds occur at intervals. Thicknesses: 120 to 283 feet in Arbuckle Mountains; 224 to 369 feet in Wichita Mountains. At type section, underlain by 44 feet of Honey Creek limestone and overlain by conglomerates of Signal Mountain formation. In Wichita Mountains, Fort Sill and Signal Mountain formations are separated by about 200 feet of Royer dolomite; in Arbuckle Mountains, separated by 675 to 771 feet of Royer.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Fort Sill limestone.

Type section: On west end of McKenzie Hill, in secs. 7 and 8, T. 2 N., R. 12 W., Comanche County. Named for Fort Sill military post where part of formation is exposed in quarry near south edge of post.

†Fort Sill Series[1]

Tertiary(?): Southwestern Oklahoma.

Original reference: T. B. Comstock, 1890, Texas Geol. Survey 1st Ann. Rept., p. 322, 324, 328.

Named for Fort Sill, Comanche County.

†Fort Smith Formation[1]

Pennsylvanian (Allegheny): Western Arkansas.

Original reference: A. J. Collier, 1907, U.S. Geol. Survey Bull. 326, p. 12, 18–20, map.

Named for Fort Smith, Sebastian County.

Fort Stanton Shale[1]

Upper Cretaceous: Southern central New Mexico.

Original reference: G. H. Hansen, 1931, George Washington Univ. Bull., Summ. Theses 1925–1928, p. 84.

Near Fort Stanton Reservation, Sierra Blanca region.

Fort Thompson Formation[1]

Pleistocene: Southern Florida.

Original reference: E. H. Sellards, 1919, Florida Geol. Survey 12th Ann. Rept., p. 71–72, 75, 76, 118.

J. R. DuBar, 1957, Illinois Acad. Sci., Trans., v. 50, p. 192 (table 1); 1958, Gulf Coast Assoc., Geol. Soc. Trans., v. 8, p. 133, 135, 144–147. Includes Coffee Mill Hammock marl member above and Okaldakoochee marl member (new). Overlies Caloosahatchee marl and where that unit is absent rests on Tamiami formation. Underlies Pamlico formation or Lake Flirt marl.

J. R. DuBar, 1958, Florida Geol. Survey Bull. 40, p. 38, 64–71, 82–83, 85, 122–136, 142–144. Represented along Caloosahatchee River by thin succession of alternating fresh-water and marine marls that bear unconformable relationship to underlying Caloosahatchee. Downstream from Fort Denaud where Caloosahatchee is absent, Fort Thompson beds rests on Tamiami formation. Overlying beds are unconformable and belong either to Pamlico formation or Lake Flirt marl. Maximum thickness about 8 feet. Marine sediments are subdivided into *Chalmys* bed and Coffee Mill Hammock marl. Fresh-water deposits are interbedded with marine sediments. Wisconsinan.

Typically exposed at Fort Thompson, just below Goodno's Landing.

ortune Formation

Devonian: Southwestern Missouri.

J. G. Grohskopf, E. L. Clark, and S. P. Ellison, Jr., 1943, Missouri Geol. Survey and Water Resources 62d Bienn. Rept., app. 4, p. 9–15. Name applied to the sequence of sandstone, chert, and limestone which intervenes between Cotter dolomite below and Sylamore sandstone above. Thickness at type section 6 feet. Locally, the Compton or Chattanooga may lie on the Fortune.

Type section: NE¼SW¼SW¼ sec. 4, T. 23 N., R. 26 W., Barry County. Name derived from Fortune Branch. Formation restricted in its outcrops to eastern one-fourth of Cassville quadrangle and western one-fourth of Shell Knob quadrangle, an area of approximately 100 square miles.

Fortune Lakes Slate (in Paint River Group)

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 39. Uppermost formation in group. Consists mostly of slate and minor graywacke, with characteristic thin beds (10 feet or less) of course massive graywacke about 300 feet above the base; sideritic slate is present in some areas between Crystal Falls and Alpha; one exposure near Fortune Lakes contains oxidized chert-sideritic rock (iron formation). Aggregate thickness probably at least 4,000 feet. Overlies Stambaugh formation (new).

Main areas of exposure are between Crystal Falls and Fortune Lakes, and in the area between Alpha and Brule, Iron County. Name derived from Fortune Lakes.

Fort Union Formation[1]

Fort Union Group or Series

Upper Cretaceous and Paleocene: North Dakota, northwestern Colorado, Montana, South Dakota, and Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1862, Philadelphia Acad. Nat. Sci. Proc., v. 13, p. 433.

W. G. Pierce, 1936, U.S. Geol. Survey Bull. 847–B, p. 57–64. Formation, in Rosebud coal field, Montana, comprises Lebo shale member below and Tongue River member above. Overlies Lance formation. Eocene.

G. G. Simpson, 1937, U.S. Natl. Mus. Bull. 169, 287 p. Fort Union group in Crazy Mountain field, Montana, comprises Lebo formation below and Melville formation (new) above. Thickness about 6,350 feet. Overlies Bear formation (new). Paleocene. Mammalian faunas described.

A. J. Collier and M. M. Knechtel, 1939, U.S. Geol. Survey Bull. 905, p. 11–12, pls. 1, 3. Formation is about 1,000 feet thick in McCone County, Mont. Comprises Lebo shale member below and Tongue River member above. Overlies Lance formation. Eocene.

G. L. Jepsen, 1940, Am. Philos. Soc. Proc., v. 83, no. 2, p. 231–238. Term Polecat Bench formation proposed to replace term "Fort Union" in vicinity of Polecat Bench, Park County, Wyo.

Erling Dorf., 1940, Geol. Soc. America Bull., v. 51, no. 2, p. 213–236. Discussion of relationship between floras of type Lance and Fort Union formations. Paleobotanical evidence supports known vertebrate evidence in placing boundary between true Lance and the "Fort Union" at base of nondinosaur-bearing Tullock, Ludlow, or Bear formations or their equivalents; that is, at top of *Triceratops*-bearing Hell Creek or Lance formations as originally defined. Table of proposed revision shows Fort Union group comprises Tullock formation (equivalent to Ludlow formation and Cannonball marine member) in lower part, and several formations (not discussed) in upper part. Overlies Lance formation (equivalent to Hell Creek formation). Paleocene.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 20, pl. 1. Referred to as Fort Union series or group. Paleocene.

W. M. Laird and R. H. Mitchell, 1942, North Dakota Geol. Survey Bull. 14, p. 16–23, measured sections. Group, in southern Morton County, comprises Ludlow, Cannonball, and Tongue River formations. Overlies Hell Creek formation. Paleocene.

W. E. Benson and W. W. Laird, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1166–1167. Formation in North Dakota; underlies Golden Valley formation (new).

R. W. Brown, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 7, p. 1265–1274. Recent paleontologic and stratigraphic evidence points toward retention of Sentinel Butte shale within Fort Union formation of Paleocene series. Unit has been considered by some geologists to be of Wasatch (Eocene) age.

W. D. Johnson, Jr., and R. P. Kunkel, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–148. Formation in Oliver and Mercer Counties, N. Dak., is about 500 feet thick, underlies Golden Valley formation and overlies Cannonball formation.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Formation, as mapped, includes Tongue River, Lebo shale, and Tullock members.

P. R. May, 1954, U.S. Geol. Survey Bull. 995–G, p. 267–268. Described in Wibaux area, Montana and North Dakota, where it comprises Ludlow, Tongue River, and Sentinel Butte members. Conformably overlies Upper Cretaceous Hell Creek formation.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 60–62, pls. Formation, in Buffalo-Lake De Smet area, Wyoming, consists of nonmarine sandstone, shale, and conglomerate which overlies Lance formation and underlies Kingsbury conglomerate member of Wasatch formation. In west-central part of area, formation is divided into two members by an angular unconformity, beneath which as much as 2,600 feet of strata in middle and lower parts of formation may locally have been removed by erosion. Thickness about 3,900 feet south of Buffalo.

Named for exposures at old Fort Union, near mouth of Yellowstone River, later called Fort Buford and now town of Buford, McKenzie County, N. Dak.

Fort Wallace Ash Bed (in Ash Hollow Member of Ogallala Formation)

Pliocene: Northwestern Kansas.

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 253–254. Name applied to volcanic ash bed. At type locality 1½ feet thick. Occurs 29 feet above Ogallala-Pierre shale contact and 65½ feet below top of the "algal limestone." Lies stratigraphically above Rawlins ash bed (new) and below Fort Wallace ash bed (new).

Named for exposures south of old Fort Wallace in tributary canyons along south side of Smoky Hill River valley in west line of SW¼ sec. 7, T. 14 S., R. 38 W., Wallace County.

Fort Washington[1]

Eocene: Southern Maryland.

Original reference: T. A. Conrad, 1830, Acad. Nat. Sci. Philadelphia Jour., v. 6, p. 205–217.

Fort Washington and vicinity, Prince Georges County.

Fort Washington Gneiss[1]

Precambrian: New York.

Original reference: R. P. Stevens, 1867, New York Lyc., Nat. History Annals, v. 8, p. 116–120.

Occurs in and around Fort Washington Park.

Fort Worth Limestone[1] } (in Washita Group)
Fort Worth Formation }

Fort Worth Limestone Member (of Georgetown Limestone)

Lower Cretaceous (Comanche Series): Central and eastern Texas, southwestern Arkansas, and central southern and southeastern Oklahoma.

Original reference: R. T. Hill, 1889, Texas Geol. Survey Bull. 4, p. xiv, xxi, xxii.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Correlation chart shows Fort Worth limestone above Duck Creek formation and below Denton clay member of Denison formation.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Correlation chart shows Fort Worth limestone above Duck Creek limestone and below Denton clay. [Denison formation abandoned and members raised to formation rank.] Washita group, Comanche series, Lower Cretaceous.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 26–27, table 4. Foraminifera of formation described.

W. J. Fox and O. N. Hopkins, Jr., 1960, Baylor Geol. Soc. Guidebook 5th Field Conf., p. 88, 91. In central Texas, considered member of Georgetown limestone. Overlies Duck Creek limestone member and underlies Denton shale member.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 27–29, pl. 2. Limestone described in Tarrant County, Tex., where it is about 32 feet thick and consists of regularly alternating dense gray limestone beds, 6 to 12 inches thick, and gray marls, 2 feet or less in thickness. Apparently conformable with underlying Duck Creek formation and overlying Denton marl member of Denison formation. Washita group.

Named for exposures at Fort Worth, Tarrant County, Tex.

Fortymile Granite[1]

[Precambrian]: Eastern Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 135, 137.

Fortymile district.

†Fortymile Group[1]

†Fortymile Series[1]

Precambrian and Paleozoic: Central eastern Alaska.

Original reference: J. C. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 145–155.

Named for exposures along canyonlike valley of Fortymile Creek.

Fossil Creek Volcanics[1]

Middle Ordovician: Northeastern Alaska.

Original reference: J. B. Mertie, Jr., 1936, U.S. Geol. Survey Bull. 872.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Typically exposed in White Mountains, about 50 miles north of Fairbanks, where they crop out just north of Fossil Creek, in belt about 40 miles long, Yukon-Tanana region.

Fossil Lake Formation[1]

Pleistocene: Central southern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Type locality: Fossil Lake, northern part of Lake County.

Fountain Formation[1]

Pennsylvanian and Permian: Eastern Colorado and southeastern Wyoming.

Original reference: W. Cross, 1894, U.S. Geol. Survey Geol. Atlas, Folio 7.

A. K. Miller and H. D. Thomas, 1936, Jour. Paleontology, v. 10, no. 8, p. 723–724. Results of this study indicate that Fountain sandstone of Colorado thins northward by continental overlap and that the Fountain of Laramie Basin, which near Laramie interfingers with marine beds of the Casper, represents only upper part of type Fountain in Colorado. The arkosic beds disappear north of Laramie and are replaced by marine beds of different lithology.

R. H. Beckwith, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1451–1453. Formation in Elk Mountain district, Carbon County, Wyo., is 150 feet thick; consists of red sandstone, shaly sandstones, white limestones, and pink arkosic grits; partly marine. Overlies Madison limestone; underlies Tensleep sandstone. Unit here called Fountain lies between Madison and Tensleep in same position as beds of comparable lithology and thickness called Amsden in Rollins uplift (Dobbin and others, 1928, U.S. Geol. Survey Bull. 796). Pennsylvanian.

G. E. Condra, E. E. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 35, 44. Includes Fairbank tongue.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 14 (fig. 3), 15 (table 1), 16–24. Described in Golden-Morrison area, where it is 760 to 1,130 feet thick and consists typically of red, arkosic sandstones, conglomerates, and minor beds of red, arenaceous mudstones. Rests nonconformably on Precambrian gneisses and schists; underlies Lyons formation. Upper Pennsylvanian.

K. P. McLaughlin, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1937–1968. Described in Colorado Springs quadrangle where it consists of thick series of red irregularly bedded coarse-grained arkosic sandstones and conglomerates sparsely interbedded with thin shales and locally fossiliferous. Greatest known thickness is at type locality where nearly 4,400 feet of red sandstones and conglomerates are exposed in valley of Fountain Creek between Manitou and West Colorado Springs. Paleozoic exposures are cut out for distance of about 10 miles along mountain front by overthrusting along Cheyenne Mountain thrust. As result, Fountain exposures in Manitou embayment are separated from those in southwestern part of quadrangle. In latter area, thickest surface exposures are of order of 1,500 feet. Rests on Glen Eyrie formation in most of Manitou embayment. In southwestern part of quadrangle, Fountain overlies older Paleozoic formations with angular unconformity or rests directly on eroded Precambrian rocks. Along Little Bear Creek is in contact with Ordovician Manitou dolomite and Harding sandstone and Mississippian Madison limestone; south of Little Bear Creek rests on Pikes Peak granite. Underlies Lyons sandstone.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 33–34. Lower part of Pennsylvanian along eastern side of Front Range is Fountain formation. Maximum thickness about 4,500 feet near Colorado Springs where it includes Glen Eyrie shale member at base. In northern part of Colorado, underlies Ingleside formation; underlies Lyons sandstone south of Loveland.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 39. In Pueblo County, Colo., overlies Beulah limestone.

S. L. Pederson, 1953, Wyoming Geol. Assoc. Guidebook 8th Ann. Field Conf., p. 18–21, 23. Boundary between Permian and Pennsylvanian systems has been determined on paleontological evidence in Gilmore Canyon section, Albany County, Wyo., (Thomas and Thompson, 1953, Wyoming Geol. Survey Bull. 46) and if projected into the other section it seems possible that upper part of Fountain formation may be Permian in age.

Typically developed on Fountain Creek below Manitou Springs in Colorado Springs quadrangle, and at head of same stream in northeastern corner of Pikes Peak quadrangle.

Fountain Peak Rhyolite

Miocene(?): Southern California.

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, p. 33, pl. 2. Includes at least two intrusive facies and an unknown amount of pyroclastic material having general composition of rhyolite vitric tuff.

Occurs in northern Providence Mountains, San Bernardino County. Forms main intrusive mass around Fountain Peak, as well as dike system that extends therefrom.

Fourmile Limestone (in Wreford Limestone)[1]

Permian: Southeastern Nebraska, eastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 31.

Type locality: Head of a branch of Fourmile Creek, near Kansas-Nebraska line, about 10½ mile south and one-half mile east of Humboldt, Nebr. Named for Fourmile Creek, in southwestern part of Richardson County, Nebr.

†Fourmile Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Bull. 686–D, p. 17–20.

U.S. Geological Survey has abandoned both the Nelagoney Formation and the Fourmile Sandstone. The Fourmile is equal to Cochahee Sandstone member of Vamoosa Formation.

Named for exposures on the point south of Fourmile Creek in SW¼ sec. 30, T. 24 N., R. 10 E., Osage County.

Four Mile Dam Formation (in Traverse Group)

Middle Devonian: Northeastern Michigan.

G. A. Cooper and A. S. Warthin, 1941, Washington Acad. Sci. Jour., v. 31, no. 6, p. 260. Fossiliferous limestone, which at its type section is a part of a reef of uncertain thickness overlain unconformably by Norway Point formation.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3), 587–589. Overlies Alpena limestone. Includes Dock Street clay member at base. Thickness at type section 8 feet; thickness where Dock Street clay member is present about 16 feet. Included in Traverse group.

Type section: At Four Mile Dam on Thunder Bay River, Alpena County.

Fowkes Formation

Fowkes Formation (in Wasatch Group)[1]

Eocene, upper: Southwestern Wyoming and eastern Utah.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 20, pl. 1. Tentatively assigned to late Paleocene (Tiffanian and Clarkforkian).

J. L. Tracey, Jr., and Steven S. Oriel, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 128 (table 1), 129, 130. Formation, as defined by Veatch, and its lithologic equivalents to the north in Fossil Basin are of late Eocene age and are youngest of early Tertiary rocks yet found in basin. Formation appears to be valid formation despite Veatch's misconception regarding its stratigraphic position (between Almy and Knight formations) and its erroneous inclusion in Wasatch group. His lithologies are accurate, and unit is distinctive, recognizable, and mappable. Unit is cut by faults limited in distribution. Formation is here removed from Wasatch group. Separated from underlying Green River formation by unnamed unit consisting of pink and green to red mudstone, sandstone, conglomerate, and interbedded limestone.

A. J. Eardley, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 167. Fowkes formation was presumed by Veatch to lie between Almy and Knight formations. He pointed out hills on west side of Bear River valley northwest of Evanston as locality where this relation could best be seen and recognized that in other places the Fowkes is absent. Norwood tuff of early Oligocene age (Eardley, 1944) had been traced from area east of Coalville anticline nearly to Evanston, Wyo., into tuffaceous outcrops labeled Fowkes by Veatch. Reexamination of geologic map of Evanston area showed Fowkes outcrops to be compatible with a post-Knight age, except those on west side of Bear River. This area was revisited, and the conclusion was reached that the contact is due to normal faulting. These relations are deceptive because a red unit exists in tuffs adjacent to fault, a gray unit exists on other side of fault in the red Knight, and it appears from most ground positions that the Fowkes extends under the Knight. Concluded that the Fowkes is Norwood and of early Oligocene age. Name Fowkes has priority and is applied to all Norwood outcrops.

Named for exposures at Fowkes Ranch, about 9 miles from Evanston, Uinta County, Wyo.

Fowler Limestone[1]

Upper Ordovician: Southern Kentucky.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 434.

Named for Fowlers Landing, Cumberland County.

Fox Member (of Santa Rosa Island Formation)

Pleistocene, upper: Santa Rosa Island, California.

P. C. Orr, 1950, Geol. Soc. America Bull., v. 71, no. 7, p. 1113, 1115–1116. Consists of basal marine facies and overlying of calcareous clays, sand, and eolianite. Sands have been dated at more than 33,000 years B. P. Thickness about 10 feet. Overlies Garanon member (new); underlies Tecolote member (new). Fox platform cuts both Garanon terrestrial alluvium and Rincon shale.

Deposits occur in Garanon Canyon, Gasoline Alley (present head of Fox Gulch), Skull Gulch, Tecolokito Canyon, Tecolote Canyon, and Deer Gulch.

Fox Canyon Member (of San Pedro Formation)

Pleistocene, lower: Southern California.

California State Water Resources Board, 1953 (revised 1956), California State Water Resources Board Bull. 12, v. 2, p. B–80, B–103, pls. B–1C, B–2. Basal member of formation. Consists of sand and gravel with some clay and silt lenses; generally white or gray; irregularly bedded. Thickness 100 to 400 feet. Overlies Grimes Canyon member (new) of Santa Barbara formation.

T. L. Bailey, 1954, *in* Pacific Petroleum Geologist, v. 8, no. 9, p. 1. Mostly gravel and coarse sand, the lower 200 to 500 feet of the formation.

R. G. Thomas and others, 1954, California Div. Mines Bull. 170, chap. 6, p. 20, pls. 2, 6, 7. About 300 feet thick. Lies at or near base of formation.

Named from exposures in Fox Canyon, about 1 mile west of Bradley Road, Ventura County.

Foxen Mudstone

Foxen Formation[1]

Pliocene, middle(?) and upper: Southern California.

C. F. Tolman, 1927, Econ. Geology, v. 22, no. 5, p. 459. Named on stratigraphic column. Described as fine sandstone and diatomite 750 feet thick. Underlies the lower Fernando; overlies Harris formation. Pliocene.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1336 (fig. 1), 1340 (table 1), 1353–1355. Consists chiefly of mudstone and siltstone but includes fine-grained silty sandstone and fine-grained volcanic ash. Maximum exposed thickness 800 feet (at type locality). In complete sections, such as type region, gradationally overlies diatomaceous strata of Sisquoc and grades upward into Cebada fine-grained member of Careaga sandstone. Type region designated.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. 222, p. 10 (table), 36–42. History of name given. Term mudstone used as a more appropriate lithologic designation. As defined here, formation is not represented along Foxen Canyon, which furnished the name and was presumably intended by proposers as the type region. Diatomaceous strata along and near Foxen Canyon are now referred to the Monterey shale and the upper part of Sisquoc. In most sections where the Foxen is thick, typical diatomaceous strata of the Sisquoc formation are separated from typical Foxen strata by a transition zone as much as 100 feet thick. Middle(?) and late Pliocene.

Type region. North slope of western Purisima Hills, Santa Maria district, Santa Barbara County.

Fox Ford Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 378.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 76. Sandstone about 500 feet thick. Underlies Horse Creek clays and shales; overlies bed No. 8. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Fox Hills Sandstone (in Montana Group)[1]

Fox Hills Formation

Upper Cretaceous: South Dakota, eastern Colorado, Montana, North Dakota, and Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1862, Philadelphia Acad. Nat. Sci. Proc., v. 13, p. 419, 427.

J. Henderson, 1920, Colorado Geol. Survey Bull. 19. Fox Hills sandstone, in northeastern Colorado, includes Milliken sandstone member.

W. T. Thom, Jr., and C. E. Dobbin, 1924, Geol. Soc. America Bull., v. 35, no. 3, p. 484–495. Includes Colgate member.

W. V. Searight, 1934, South Dakota Geol. Survey Rept., Inv. 22, p. 4–15. In South Dakota, Fox Hills sandstone includes all beds between uppermost transition beds of the Pierre and gumbo clays and gumbo sands of lower Hell Creek member of Lance. In Stoneville coal area, Meade County, formation is divided into four members, which consist of basal member of alternating beds of shale and sandstone, sandstone member with thin beds of shale, Stoneville member (new), and sandstone member composed of thin interbedded shale. Thickness 435 to 465 feet.

C. H. Dane and W. G. Pierce, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 10, p. 1312–1313. Fox Hills sandstone described in Denver basin, Colorado, where it is 200 to 300 feet thick; overlies Pierre shale and underlies Laramie formation. Consists, in lower part, of buff or brown sandstone and sandy shale containing large gray to brown hard sandy concretions and, in upper part, chiefly of soft, poorly consolidated white sandstone.

Erling Dorf, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 275; 1942, Carnegie Inst. Washington Pub. 508, p. 1–78, pls. [preprint 1938]. Medicine Bow formation of southern Wyoming and the so-called "Laramie" formation of northwestern Colorado occupy similar stratigraphic positions above a marine sandstone which carries a distinctive Fox Hills fauna, including the diagnostic *Sphenodiscus lenticularis*. This marine sandstone, hitherto included in Medicine Bow or underlying Lewis shale, is separated as distinct unit and referred to Fox Hills formation. Thickness of Fox Hills 375 to 400 feet in Hanna basin, Wyoming; about 475 feet in northwestern Colorado.

R. E. Morgan and B. C. Petsch, 1945, South Dakota Geol. Survey Rept. Inv. 49. p. 11–18. fig. 4. Described as formation in Dewey and Corson Counties. Contains two identifiable units of almost pure sandstone but two others that, over considerable part of area, are much less sandy in character. Sandstone members are herein named Trail City (below) and Timber Lake. Thickness 120 to 250 feet. Overlies Pierre formation; underlies Hell Creek formation.

S. P. Fisher, 1952, North Dakota Geol. Survey Bull. 26, p. 10–16. Most extensive of formations outcropping in Emmons County. Trail City and

Timber Lake members recognized. These members pinch out eastward and disappear between southwestern corner and center of county. Upper 160 to 230 feet of formation is series of gray to brown sands with thin gray shales. It lies above *Halymenites* bench of Timber Lake member and is capped by sandstone bed. Overlies Pierre formation; underlies Hell Creek formation.

R. E. Stevenson, 1957, Areal geology of McIntosh quadrangle (1:62,500): South Dakota Geol. Survey. Formation includes (ascending) Trail City member, 65 feet thick; Timber Lake member, 20 to 25 feet; Bullhead member (new), and Colgate member, 15 feet. Underlies Hell Creek formation.

Named for exposures in Fox Ridge, northwestern Armstrong and southwestern Dewey County, S. Dak.

Foys Limestone (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: J. P. Lesley, 1879, Pennsylvania 2d Geol. Survey Rept. Q_2, p. xxii, 320.

Foy's Knob, Wayne Township, Lawrence County.

Fra Cristobal Formation (in Mud Springs Group)

Pennsylvanian (Derry Series): Central New Mexico.

M. L. Thompson, 1948, Kansas Univ. Paleont. Contr. 4, Protozoa, art. 1, p. 73. Name proposed to replace Hot Springs formation proposed by Thompson (1942). Term Hot Springs preoccupied. Overlies Apodaca formation; underlies Cuchillo Negro formation.

Type locality: West end of Whiskey Canyon, just west of westernmost box canyon, near north end of Mud Springs Mountains, Sierra County. Name derived from Fra Cristobal Range on east side of the Rio Grande.

Fraction Breccia[1] (of Esmeralda Formation)

Miocene, upper: Central Nevada.

Original reference: J. E. Spurr, 1905, U.S. Geol. Survey Prof. Paper 42, p. 39, map.

Named for occurrences around Fraction No. 1 and No. 2 mine, Tonopah district.

Frailes Formation

Upper Cretaceous: Puerto Rico.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (chart), 9 (fig. 3), 10 (fig. 4), 16–19, pl. 2. Marine accumulation of shale, siltstone, and graywacke, with lenticular limestone in lower part, La Muda limestone member, massive lapilli tuff in middle, and well-bedded tuffaceous limestones, Leprocomio limestone member (new), in upper part. Thickness 2,300 feet. Underlies Monacillo formation (new); overlies Tortugas andesite (new) and locally Hato Puerco tuff; in some areas, La Muda member rests on what seems to be Guaynabo formation; in at least one locality, overlies an unnamed andesite porphyry sill. Variable nature of lower contact is taken in part to result from lenticular nature of La Muda member and in part from discordant and overlapping nature of Frailes onto eroded surface of older rocks. Faunal evidence, particularly the ammonites, shows formation to be Late Cretaceous.

Named after Barrio Frailes, east of Guaynabo, in which formation is well developed. Typical section (described in detail) is exposed in roadcuts on Highway 175 along left bank of Río Grande de Loíza west and north of Trujillo Alto.

Fraileys Shale

Mississippian (Chester Series): Southeastern Illinois, southwestern Indiana, and northeastern Kentucky.

A. C. McFarlan and others, 1955, Kentucky Geol. Survey, ser. 9, Bull. 16, p. 18, 19–20. New name is needed for the "Golconda" as recognized east of Todd County, Ky., and north into Indiana. Fraileys shale is proposed for the middle "Golconda," that is, the interval between Haney limestone (new) and Beech Creek limestones wherever sandstone [Big Clifty] is insignificant or lacking. Consists largely of shale with minor amounts of limestone and mudstone. Typically 70 to 90 feet thick in Illinois with extremes of about 45 to 140 feet; at type locality 94 feet.

Type locality: Easternmost exposure of the Golconda in Illinois, on the south slope of hill along west edge of NE¼SE¼ sec. 9, T. 12 S., R. 10 E., Cave in Rock quadrangle, Hardin County, Ill. Named for an abandoned village 1 mile to northeast, known variously as Fraileys, Fraileys Landing, or Fraileys Store.

Frame Shale Member[1] (of Mahantango Formation)

Middle Devonian: South-central Pennsylvania.

Original references: Bradford Willard, 1935, Geol. Soc. America Proc. 1934, p. 361; 1935, Geol. Soc. America Bull., v. 46, no. 8, p. 1279, 1283.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart at top of Mahantango formation, above Chaneysville sandstone member.

Named for Frame School about 6 miles north of Chaneysville, Bedford County.

Francis Formation[1]

Pennsylvanian (Missouri Series): Central and central southern Oklahoma.

Original reference: G. D. Morgan, 1924 [Oklahoma] Bur. Geology Bull. 2, p. 113–119.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as extending northward from Pontotoc County across Seminole County; north of Seminole County, name Francis is dropped and other terminology (Coffeyville, Nellie Bly) is used.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 62, pl. 1. In this report [Seminole County], northern names are carried south to Canadian River; interval designated by Morgan as "Francis" is herein described under headings "Coffeyville" and "Nellie Bly." Type locality stated.

Type locality: Town of Francis, northeastern Pontotoc County, and "all that portion of the outcrop which extends for distance of 3 miles north, and for a similar distance south of Canadian River" (Morgan, 1924).

Franciscan Formation[1]

Franciscan Group

Jurassic and Cretaceous: Western California.

Original references: A. C. Lawson, 1895, Am. Geologist, v. 15, p. 347; 1895, U.S. Geol. Survey 15th Ann. Rept., p. 415.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, p. 123–125 [preprint 1941]. In Oregon, the Franciscan overlies the Galice unconformably, and the Galice, both faunally and lithologically, is equivalent to the Mariposa, the age of which has been well established as Kimmeridgian and slightly older (Portlandian). In northern California, the Galice has been converted into slate, whereas the Franciscan is unmetamorphosed. In northern California, unmetamorphosed Franciscan occurs in proximity to Mariposa-Galice slates. Franciscan is therefore younger than Kimmeridgian. It is believed that the Franciscan does not extend below Portlandian or, at the lowest, the upper Kimmeridgian. Field evidence does not support theory of unconformity between Franciscan and "Knoxville."

N. L. Taliaferro, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 2, p. 109–219. Franciscan-Knoxville problem discussed. The unconformity between Franciscan and Knoxville, reported by many writers, is unsupported by field evidence. The Knoxville is herein regarded as upper phase of Franciscan. Since these names have become fixed in the literature, it is here suggested that name Franciscan-Knoxville group be used for entire sequence.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 195–198, 225 (fig. 4), 226 (fig. 5). In San Benito quadrangle, Franciscan group is in fault contact with Santa Lucia granite, believed to be pre-Franciscan. Thickness difficult to determine because of strong folding and lack of exposures of base and top. Thickness of 10,000 feet measured across section on north limb of syncline exposed along Las Aguilas Creek. Most of the contacts with younger rocks are faults, except for many of those with San Benito gravels which are depositional.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 15–23, pls. 1, 2, 3. Franciscan formation and related intrusive rocks comprise most of southern half of Tesla quadrangle and extend into adjacent quadrangles. Base of formation not exposed, and top cannot be distinguished. Thickness of sediments as obtained graphically from cross-sections E-E' and H-H' about 12,000 feet. Tolman (1915) reported section of 15,000 feet in this area and divided section into three members: Corral Hollow shales, dense bluish-gray arkosic sandstone, as lower part; folded and crumpled cherts as middle member; and Oak Ridge [Oakridge] sandstone as upper member. Because Oak Ridge is a divide in northwest corner of Mount Hamilton quadrangle, Tolman probably extended his section into this area adjoining on the south. In Tesla area, sandstone is predominant rock type throughout Franciscan section; likewise shales and cherts occur throughout section as interbeds in the sandstone; hence, Tolman's divisions are not recognized in this report, and section of Franciscan rocks is left undivided. In fault contact with Lower Cretaceous Horsetown formation; Plio-Pleistocene Livermore gravels is only younger formation which is in depositional contact with Franciscan.

J. A. Cushman and Ruth Todd, 1948, Cushman Lab. Foram. Research Contr., v. 24, pt. 4, no. 322, p. 90–98. Paper records foraminiferal fauna from New Almaden quicksilver district, Santa Clara County, in rocks ascribed to Franciscan group. Limestone in which the foraminifera occur has been traced to that mapped as Calera limestone member in Santa Cruz quadrangle to west. Foraminifera seem to indicate that beds are younger than Jurassic.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 22. Honda formation (new) may be equivalent to type Knoxville, but its highly sheared condition and unconformable relationship with Espada formation (new) suggests that it may be shale member of Franciscan.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 15–26. Formation crops out or is present beneath alluvium in almost two-thirds of San Jose-Mount Hamilton area. Comprises sandstone and shale, conglomerate, chert, and contemporaneous volcanics, and schists. Thickest continuous section is just east of Calaveras fault, where at least 6,000 feet of beds are exposed. In fault contact with Knoxville.

C. C. Church, 1952, Cushman Foundation Foram. Research Contr., v. 3, pt. 2, p. 68–70. Discussion of Cretaceous foraminifera from Calera limestone member of Cahil sandstone of the Franciscan. Evidence indicates that the Calera is somewhere near middle Cretaceous or basal Upper Cretaceous. It now seems to be general conclusion that Franciscan-type rocks cover wide range in age from Upper Jurassic to middle or even basal Upper Cretaceous. More detailed work is necessary to narrow the age limits of various members.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 12–16, pl. 1. In Eel River valley area, Humboldt County, Franciscan formation is about 10,000 feet thick. In fault contact with Yager formation (new); unconformably overlain by Wildcat group (undifferentiated).

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 11–20, pls. 1, 3. In Ortigalita Park quadrangle, the Franciscan (group, formation) is exposed in eastern limb of asymmetrical anticline, overturned adjacent to Ortigalita thrust. Total thickness difficult to estimate because faults are difficult to trace in homogeneous graywacke sediments, but erratic attitudes and some development of phyllonites indicate a zone of dislocation southwest of Sugarloaf. The layered sequence above this zone is 8,000 to 10,000 feet in thickness, and if repetition is absent or minor, the thickness (measured on section E-E' through Ortigalita Peak) is at least 20,000 feet. Neither top nor bottom of group is represented. In fault contact with Lower Cretaceous Wisenor formation (new). Map bracket shows age Jurassic(?).

Julius Schlocker, M. G. Bonilla, and R. W. Imlay, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 11, p. 2372–2381. *Douvilleiceras* sp., an ammonite of Early Cretaceous age, has been found in graywacke-type sandstone that is part of narrow band of exposures in cliffs along southern shore of inlet to San Francisco Bay—an area regarded as in type locality of Franciscan group. Thus, age of part of group is Early Cretaceous, Albian. Because Franciscan rocks in other localities are overlain by beds containing Upper Jurassic fossils, it is proposed that Franciscan group be assigned to both the Cretaceous and Jurassic(?) periods pending subdivision and more precise age designations within the group.

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–88. Group, in Hayward quadrangle, comprises greenstone volcanic rocks, mainly lava with thin pyroclastic and sedimentary interbeds; chert with shale partings; sandstone; and muscovite-rich graywacke with interbedded arenaceous shale, conglomerate, chert, and greenstone. Relative ages of these units not known. Aggregate exposed thickness 2,000 to 3,000 feet. Unconformably overlain by Upper Jurassic Knoxville. Unconformity may be local and does not necessarily conflict with generalization (Taliaferro, 1941) that Franciscan and Knoxville are regionally conformable and gradational, nor is it incompatible with his conclusion that Franciscan was deposited in a brief part of Late Jurassic time. However, fossils found in recent years in western part of Franciscan make it difficult to accept so limited an age for entire formation. Presence of these fossils has been explained by appealing to elaborate faulting mechanism, but it is here suggested that Franciscan eugeosynclinal sedimentation continued in peninsular area long after it gave way to miogeosynclinal sedimentation of Shasta series type farther east. In Hayward quadrangle, Franciscan rocks seem to be no younger than Late Jurassic.

W. P. Irwin, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2284–2297. Franciscan group is assemblage of detrital and chemical sedimentary and volcanic rocks that crop out discontinuously in a structurally complex, northwesterly trending belt along Coast Ranges. On the east, along west side of Sacramento Valley, a thick section of detrital sedimentary rocks has been subdivided into Knoxville, Paskenta, and Horsetown formations, of Late Jurassic and Early Cretaceous age, and several units of Late Cretaceous age. Franciscan group is widely held to be restricted to Late Jurassic age, the Knoxville formation to be a shaly phase of Franciscan group, and the two overlain unconformably by detrital strata of Cretaceous age. Paleontologic evidence indicates this view to be incorrect. The Franciscan group seems to have been deposited contemporaneously with the Knoxville, Paskenta, Horsetown, and lower Upper Cretaceous strata, because fossils ranging from Late Jurassic to early Late Cretaceous in age have been found in the group. The Franciscan group and strata of Sacramento Valley section may represent two facies of same stratigraphic section.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 3–6, fig. 2, geol. map. Discussion of geology of Pleasanton area, Alameda and Contra Costa Counties. Questionable Jurassic rocks mentioned in this paper have been referred to as Franciscan group; this does not imply that any of the formations mapped by Lawson are included or mapped in Pleasanton area. In adjoining areas, Crittenden (1951) and Huey (1948) called questionable Jurassic rocks Franciscan "formation." This term is considered inappropriate for a complex group of various lithologic types which here includes, metamorphic rocks, sandstone and interbedded shale, basalt, chert, and serpentine. Thickness of about 6,000 feet estimated from Indian Creek northeast to large chert outcrop shown near eastern edge of geologic map; top and base not recognized in area. In Arroyo del Valle region, Franciscan rocks are in fault contact with Upper Cretaceous Del Valle formation (new) and are unconformably overlain by Pliocene Livermore gravels. In Indian Creek area, group is unconformably overlain by Ciebo sandstone. Briones serpentine-arenite overlies Franciscan basalt unconformably near south fork of Apperson Creek; in southern part of La Costa Valley quadrangle, Franciscan rocks are in fault contact with Tertiary rocks or locally unconformably overlain by Oursan sandstone.

C. G. Higgins, 1960, California Univ. Pubs. Geol. Sci., v. 36, no. 3, p. 203–205, geol. map. In northwestern Sonoma County, formation unconformably underlies Ohlson Ranch formation (new).

Named for exposures at San Francisco, San Francisco County.

Francis Creek Shale (in Carbondale Group)

Francis Creek Shale and Limestone (in Carbondale Formation)[1]

Francis Creek Shale Member (of Carbondale Formation)

Pennsylvanian: Western and central Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 309.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 88–89, 203. In Carbondale, group thickness 40 to 45 feet near Lewistown and near type locality; 55 feet near Colchester. Shale is wholly or partially truncated in areas of Pleasantview sandstone channels; replaced by Jake Creek sandstone (new) in southern part of Vermont quadrangle. Included in Liverpool cyclothem where it occurs below the Jake Creek sandstone and above Colchester (No. 2) coal. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 46 (table 1), pl. 1. Termed Francis Creek shale member of Carbondale formation (redefined). Occurs about Colchester (No. 2) coal member and below Jake Creek sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata of Illinois.

Type locality: Roadcut on west side of Francis Creek, NE¼SW¼ sec. 22, T. 5 N., R. 1 E., Vermont quadrangle, Fulton County.

Francoisian series[1]

Precambrian: Missouri.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 253.

Derivation of name not stated.

Franconia Breccia[1]

Upper Devonian or Upper Carboniferous: West-central New Hampshire.

Original reference: New Hampshire Geol. Survey 4th Ann. Rept. 1872, as interpreted by J. D. Whitney and M. E. Wadsworth *in* Harvard Coll. Mus. Comp. Zoology Bull., v. 7, (geol. ser. I), opposite p. 396.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Formed by injection of numerous binary granite dikes into the Kinsman quartz monzonite. Mapped as part of the latter.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 63–64. Abandoned as a formation name in New Hampshire although it has priority over the Franconia of the upper Mississippi Valley.

Occurs in Franconia and Lincoln [Townships], Grafton County.

†Franconia Gravel[1]

Pleistocene: Eastern Virginia.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 326–330, 339.

Well exposed at gravel pits of Alexandria & Fredericksburg Railroad at Franconia Station, 6 miles southwest of Alexandria.

Franconia Sandstone[1]

Franconia Formation

Upper Cambrian: Southeastern Minnesota, northern Illinois, and southwestern Wisconsin.

Original reference: C. P. Berkey, 1897, Am. Geologist, v. 20, p. 345–383.

A. C. Trowbridge and others, 1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf., p. 81, 92, 134, 140, 159, 431, 446, 449, 455. Comprises (ascending) Ironton sandstone, Goodenough (new), Hudson (new), and Bad Axe (new) members.

C. R. Stauffer, G. M. Schwartz, and G. H. Thiel, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1902. In suggested classification of Minnesota Upper Cambrian, the Franconia includes (ascending) Ironton member, Taylors Falls (new) or Goodenough member, Minnesika (new) or Hudson member, and Bad Axe member. Underlies Judson member (new) of St. Lawrence formation.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1228 (table 1), 1236–1239. Minnesota classification shows Franconia formation subdivided into (ascending) Ironton, Taylors Falls, Hudson, and Bad Axe members. Underlies Nicollet Creek member (new) of St. Lawrence formation. Overlies Galesville member of Dresbach formation. St. Croixian series.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9, 35–41, measured sections. Formation described in detail in southeastern Minnesota where it comprises (ascending) Ironton, Taylors Falls, Hudson, and Bad Axe members. Overlies Dresbach formation; underlies St. Lawrence formation, St. Croixian series.

R. R. Berg, 1951, Minnesota Geologist, v. 8, no. 4, p. 1–3. Twenhofel, Raasch, and Thwaites (1935) proposed faunal zonation of the Franconia and applied geographic member names to the zones. Present study has resulted in discrimination of units of uniform lithic character, properly called member. Previously proposed names are rejected. Formation consists of (ascending) Woodhill, Birkmose, Tomah, and Reno members. Mazomanie sandstone member represents a nonglauconitic facies that interfingers with and replaces glauconitic sandstones to north and east. Distribution of faunal zones of Franconia stage is largely independent of lithic units of Franconia formation.

H. B. Willman and J. S. Templeton, 1951, Illinois Acad. Sci. Trans., v. 44, p. 109–113. Oldest formation exposed in northern Illinois. About 30 feet exposed in quarry in or near Oregon, Ogle County. Underlies Trempealeau formation.

G. O. Raasch, 1951, Illinois Acad. Sci. Trans., v. 44, p. 147. Bad Axe member of Franconia underlies Arcadia member (new) of Trempealeau formation.

R. R. Berg, 1954, Geol., Soc. America Bull., v. 65, no. 9, p. 857–882. Redefined Franconia formation described in detail. Redefinition of formation based on rock types results in different interpretation of lower and upper contacts and adds as much as 30 feet to its total thickness. Formation consists of quartzose sandstones that range from 150 to 210 feet thick within outcrop area. Member names—Ironton, Goodenough, Hudson, and Bad Axe which were in reality faunal zones—are rejected, and names Woodhill, Birkmose, Tomah, and Reno are applied to members. Mazomanie member interfingers with and replaces Reno member. Overlies Galesville member of Dresbach; underlies St. Lawrence formation.

Named for exposures in vicinity of Franconia, Chisago County, Minn.

Franconian Stage

Upper Cambrian: North America.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Upper Cambrian comprises three stages (ascending): Dresbachian, Franconian, and Trempealeauan. The Franconian consists of six faunal zones: *Elvinia*, *Ptychopleurites*, *Conaspis*, *Prosaukia-Ptychaspis*, *Briscola*, and *Dikelocephalus postrectus*.

R. R. Berg, 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 857–882. Limits of Franconian stage were defined to coincide with Franconia formation, and this has resulted in artificial faunal boundaries. Greatest faunal change takes place between *Ptychaspis* and *Prosaukia* subzones. Saukinid trilobites first appear in *Prosaukia* subzone, and together with species of *Dikelocephalus* they form dominant group in overlying Trempealeauan stage. Redefinition of stage boundaries would place the contact at the faunal change within the Reno and Mazomanie members.

W. C. Bell, R. R. Berg, and C. A. Nelson, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 425–436. Franconian stage originated with Correlation Chart (Howell and others, 1944) and was defined by faunal criteria as a time-stratigraphic unit conincident with Franconia formation. When lithostratigraphic nomenclature is separated from biostratigraphic nomenclature, upper boundary of Franconia formation cannot be made to coincide with a biostratigraphic, and therefore stage, boundary. Recommended that boundary between Franconian and Trempealeauan stages be placed at top of *Ptychaspis-Prosaukia* zone. This produces nomenclatorial paradox; the upper part of Franconia formation in places belongs in Trempealeauan rather than Franconian stage. It is not likely that geologists in upper Mississippi Valley will abandon use of Franconia formation, though there are reasons for doing so. Type section of formation included only lower Mazomanie member, and nowhere in St. Croix Valley is exposed above river level a complete section of the formation as it is now defined. Might be more satisfactory to propose a new stage name.

Name derived from Franconia, Chisago County, Minn.

Frankford Gneiss[1]

Precambrian: Southeastern Pennsylvania.

Original reference: T. D. Rand, 1900, Philadelphia Acad. Nat. Sci. Proc., pt. 1, p. 279.

Exposed at Frankford, Philadelphia County.

Frankfort Shale[1]

Upper Ordovician: Central and east-central New York.

Original reference: L. Vanuxem, 1840, New York Geol. Survey 4th Rept., p. 372–373.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 601 (fig. 3). Stratigraphic diagram shows Harter shale member (new) of Frankfort formation.

G. M. Kay, 1953, New York State Mus. Bull. 347, p. 59 (fig. 42), 64–67. Formation described in Utica quadrangle where it comprises (ascending) Harter shale, Hasenclever sandstone (new), and Moyer (new) members. Thickness about 540 feet. Overlies Utica shale; underlies Silurian Oneida conglomerate. Eden group, Cincinnatian series.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 13, fig. 1. At Sharon Springs, unconformably underlies Brayman shale (redefined).

Typical exposure: Along Moyer Creek, southwest of Frankfort, Herkimer County.

Franklin Formation } (in Puget Group)
Franklin Series[1]

Eocene: Western Washington.

Original reference: G. W. Evans, 1912, Washington Geol. Survey Bull. 3, p. 42–49.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 26 (table), 55–62. Described in Green River area as Franklin formation in Puget group. Consists of a series of interbedded sandy and argillaceous and carbonaceous shales together with thick beds of massive brown sandstone; basal part of formation includes a 210-foot basal sandstone, the Franklin. Thickness about 3,600 feet. Underlies Kummer formation; overlies Bayne formation.

Probably named for town in King County.

Franklin Limestone[1]

Franklin Formation

Precambrian: Western New Jersey, Delaware, and eastern Pennsylvania.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 431–456.

D. M. Fraser *in* B. L. Miller, D. M. Fraser, and R. L. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–48, p. 162–170, 172, pl. 1. In Northampton County, associated graphitic quartz schist has been included with limestone to comprise Franklin formation. May also include clastic sediments of somewhat more argillaceous type; most extensive member is the coarse-grained graphite-bearing limestone. There is little evidence to indicate relative age of Franklin and Moravian Heights (new) formations and Pochuck gneiss, but this is the assumed sequence. In Chestnut Hill area, Franklin limestone occurs adjacent to Moravian Heights formation; no contact is observable; both formations have been injected and altered by invasions of Byram granitic material.

W. S. Bayley, 1941, U.S. Geol. Survey Bull. 920, p. 1–12, 19–46, pl. 5. Described in Delaware Water Gap and Easton quadrangles, Pennsylvania, where it is dominant formation. Associated with it are sedimentary schists, slaty rocks, and gneisses (here mapped as Pickering gneiss) and generally believed to be older. Relationship to Hardyston quartzite not observable in area of report.

Named for occurrence at Franklin Furnace, Sussex County, N.J.

Franklin Limestone (in Washington Formation)[1]

Permian: Southwestern Pennsylvania.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 97, 102.

Franklin and Amwell Townships, Greene County.

Franklin Sandstone[1]

Eocene: Western Washington.

Original reference: G. W. Evans, 1912, Washington Geol. Survey Bull. 3, p. 42–49.

Probably named for town in King County.

Franklindale Limestone Lentil (of Chemung Formation)[1]

Upper Devonian: Central northern Pennsylvania.

Original reference: H. S. Williams and E. M. Kindle, 1905, U.S. Geol. Survey Bull. 244.

Exposed in Gulf Brook section, west of Franklindale, Bradford County.

†Franks Conglomerate[1]

Pennsylvanian (Desmoinesian and Missourian): Central southern Oklahoma.

Original reference: J. A. Taff, 1903, U.S. Geol. Survey Geol. Atlas, Folio 98.

W. E. Ham, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2040–2044. The four principal conglomerates in the Arbuckle Mountains region are divisible into two general groups, an older consisting of "Franks" and Deese, and a younger consisting of Collings Ranch (new) and Vanoss. All but the Vanoss (youngest) are preserved in synclinal grabens and are moderately to strongly folded and faulted. The "Franks," which contains rocks chiefly from Hunton through Arbuckle, has maximum thickness of 1,500 feet and consists of conglomerate interbedded with and grading into fossiliferous shales, limestone, and sandstones. The "Franks" is considered an orogenic product of the first great period of uplift in the Arbuckle Mountains, which began as broad domal folding of the Hunton anticline in early Desmoinesian time; the conglomerates were closely folded, locally overturned, and faulted in late Pennsylvanian (middle Missourian) time.

Named from exposures in vicinity of Franks, Pontotoc County.

Franson Member or **Tongue** (of Park City Formation)

Permian: Eastern Utah, northwestern Colorado, eastern Idaho, southwestern Montana, and western Wyoming.

T. M. Cheney *in* V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologist Bull., v. 40, no. 12, p. 2842–2843; 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 15–19, 31, 37, pls. 2, 3. Proposed for light-gray and grayish-brown carbonate rock, cherty or sandy carbonate rock, and calcareous sandstone that overlie Meade Peak tongue (new) of Phosphoria formation and underlie Woodside formation. In Montana, Wyoming, and Idaho, has been considered upper part of Rex chert member or the C member of Phosphoria formation (Klepper, 1951, U.S. Geol. Survey Bull. 969–C). At type locality, about 235 feet thick and consists of a lower unit, about 65 feet thick, of dominantly light-gray and grayish-brown carbonate rock; middle unit, about 85 feet thick, dominantly light-gray and brownish-gray carbonatic sandstone containing chert as beds and nodules; and upper unit, about 85 feet thick, dominantly white and light-gray carbonate rock; some beds of the upper unit, are reddish brown and are probably laterally continuous with Mackentire tongue of Woodside formation. Lower contact gradational but placed at top of gray and greenish-gray cherty phosphatic carbonate rock of upper part of Meade Peak tongue. Thickness 830 feet in southern Wasatch Mountains, but over most of its extent ranges from 50 to 200 feet in thickness. In most of Utah, western Wyoming, and parts of Montana, underlain by tongue of Phosphoria, either Meade Peak or Rex; in eastern Utah and northwestern Colorado, underlain by

Weber sandstone; in parts of Montana and Wyoming where Meade Peak and Rex are absent, Franson is difficult to separate from lower (unnamed) member of Park City; in northernmost Utah, eastern Idaho, western Wyoming, and southwestern Montana, interfingers basinward with the Rex, Tosi, and Meade Peak members of Phosphoria, and in Utah intertongues shoreward with red and greenish gray shales of Woodside formation; in western Wyoming, Montana, and northeastern Idaho, Franson tongue is overlain by Retort phosphatic shale member (new) of Phosphoria.

Named from exposures on north side of Franson Canyon near the mouth in S½SE¼ sec. 15, and N½NE¼ sec. 22, T. 1 S., R. 6 E., Summit County, Utah.

Frazier Well Gravel

Pre-Pleistocene: Northwestern Arizona.

Donaldson Koons, 1948, Science, v. 107, no. 2784, p. 475. Consists of well-rounded pebbles and boulders of vein quartz, granite, gneiss, schist, red and white quartzite, and sandstone. Deposits vary in thickness from thin veneer to more than 200 feet. Found at elevations ranging from 5,660 feet, 12 miles southwest of Frazier Well, to 7,150 feet, 5 miles northwest of the Well.

Best exposed near Frazier Well, Hualpai Reservation, after which the gravels are named.

Freda Sandstone (in Oronto Group)[1]

Precambrian: Northern Michigan and northern Wisconsin.

Original reference: A. C. Lane and A. E. Seaman, 1907, Jour. Geology, v. 15, p. 680, 692.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1474–1479. Oronto group revised to exclude Eileen sandstone and Amnicon formation. Thickness of Amnicon given by Thwaites (1912) —5,000 feet—is included in his estimate of the Freda, and the 2,000 feet assigned to the Eileen is included in the Orienta (in Bayfield group). Thickness of Freda 12,000 feet. Overlies Nonesuch shale; underlies Orienta sandstone.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27 In Ahmeek quadrangle, Michigan, Freda consists of red fine- to medium-grained sandstone with prominent white streaks and blotches; contains minor amounts of red shale and conglomerate. Lowermost 700 feet of formation exposed here consists of light-gray fine- to medium-grained sandstone with purple streaks. Total thickness of formation where more fully exposed about 5,000 feet. Contact with underlying Nonesuch shale transitional.

Named for exposures at new stamp mills at Freda, Houghton County, Mich., and along adjacent shore.

Frederick Limestone[1]

Upper Cambrian: Central northern Maryland.

Original reference: C. R. Keyes, 1890, Johns Hopkins Univ. Circ. 84, v. 10, p. 32.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept.] Carroll and Frederick Counties, p. 43–47. Thickness in Frederick Valley 480 feet. Underlies Ordovician Grove limestone in center of Frederick Valley syncline and in several narrow areas northwest of Frederick. In eastern part of valley, unconformably overlaps Lower Cambrian Antietam quartzite; here Lower Cambrian Tomstown dolomite, which overlies the Antietam in normal sequence in foothills west of Triassic border, is not present.

Probably named for occurrence in vicinity of Frederick.

Fredericksburg Gneiss[1]

Precambrian: Northeastern Virginia.

Original reference: J. T. Lonsdale, 1927, Virginia Geol. Survey Bull. 30.

Well exposed in quarries northwest of Fredericksburg, Spotsylvania County.

Fredericksburg Granite[1]

Precambrian: Northeastern Virginia.

Original reference: J. T. Lonsdale, 1927, Virginia Geol. Survey Bull. 30.

Well exposed along Rappahannock River in Stafford and Spotsylvania Counties.

Fredericksburg Group[1]

Lower Cretaceous (Comanche Series): Texas and southern Oklahoma.

Original reference: R. T. Hill, 1887, Am. Jour. Sci., 3d, v. 33, p. 296–299.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, pl. 1. As mapped in Eagle Mountains, Hudspeth County, Tex., comprises Finlay limestone and Kiamichi formation. Overlies Cox sandstone of Trinity group; underlies Georgetown limestone of Washita group.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, includes Goodland limestone and Walnut clay. Kiamichi mapped with Washita group.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 20–22. As used in this report [Cretaceous Foraminifera of Texas] group includes (ascending) Walnut clay, Goodland limestone, Edwards limestone, and Kiamichi formation. Overlies Paluxy formation of Trinity group; underlies Duck Creek formation of Washita group.

P. E. Lozo, 1959, Texas Univ. Bur. Econ. Geology Pub. 5905, p. 3 (fig. 2), 28 (fig. 13), measured sections. In this report [Symposium on Edwards limestone], Fredericksburg group comprises (ascending) Paluxy sand, Walnut formation, Comanche Peak limestone, Edwards limestone, and Kiamichi formation. Overlies Glen Rose limestone of Trinity group; underlies Georgetown limestone of Washita group or Kiamichi shale where Kiamichi is considered part of Washita group. A southern complex of the Edwards, Comanche Peak, and Walnut formations is indicated to pass northward into a complex composed of the Goodland, Walnut, and Paluxy formations. Classification of included stratigraphic intervals as Fredericksburg division follows Hill's early nomenclature and concept of an integrated subseries representing a major and distinct cycle of sedimentation.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 11–21, pls. 1, 2. In Fort Worth area, group comprises (ascending) Walnut marl and Goodland formation. Overlies Paluxy sandstone of Trinity group; underlies Kiamichi formation of Washita group.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 16 (table 5), 31–34. In McCurtain County, only Goodland limestone is included in Fredericksburg group. No mappable stratigraphic boundary present between Kiamichi formation and Goodland limestone, and Kiamichi is mapped with Washita group. Unconformably overlies Paluxy sand of Trinity groups.

Named for Fredericksburg, Gillespie County, Tex.

†Fredericksburg Sandstone[1]

Lower Cretaceous: Virginia.

Original reference: W. B. Rogers, 1842, Philadelphia Acad. Nat. Sci. Proc., v. 1, p. 142.

Fredericksburg, Spotsylvania County.

†Fredericktown dolomite[1]

Upper Cambrian: Southeastern Missouri.

Original reference: C. R. Keyes, 1895, Missouri Geol. Survey Sheet Rept. 4, v. 9, p. 18, 19, 48.

Named for exposures at Fredericktown, Madison County.

Fredonia Limestone or **Oolite Member** (of Ste. Genevieve Formation)[1]

Fredonia Member (of Ste. Genevieve Limestone)

Upper Mississippian: Western Kentucky, southern Illinois, southern Indiana, southeastern Missouri, and western Tennessee.

Original reference: E. O. Ulrich and W. S. T. Smith, 1905, U.S. Geol. Survey Prof. Paper 36, p. 24, 40.

F. E. Tippee, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 11, p. 1655–1656. Fredonia member is divisible into three units: upper limestone, middle sandstone, and lower limestone. Name Spar Mountain sandstone is here proposed for the middle sandstone member, heretofore known as a "sub-Rosiclare sandstone."

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 19–20, pl. 1. Termed Fredonia member by Indiana Geological Survey. Unit does not contain a higher proportion of oolite than do other members of formation. Thickness 30 to 115 feet. Base of member is 10 to 20 feet below Lost River chert (Elrod, 1899). Lowest member of formation; underlies Rosiclare member.

Named for exposures at Fredonia, Caldwell County, Ky.

Freedhem Tonalite

Precambrian (late Algoman): Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1002, 1009, 1010, pl. 1. Metatonalite to granodiorite, tonalite most common; black to light gray, fine to medium granitoid, weak primary foliation. One of five major intrusives in late Algoman; these cannot be shown to be members of a single magma series; age relations of the named intrusives, St. Cloud gray granodiorite, Hillman tonalite, Freedhem tonalite, and Warman quartz monzonite are indeterminate because no contacts are exposed.

Name applied because most of its outcrops are around town of Freedhem, Morrison County.

Freedom Dolomite[1]

Precambrian: Central southern Wisconsin.

Original reference: S. Weidman, 1904, Wisconsin Geol. Nat. History Survey Bull. 13, p. 51.

Named for occurrence southwest of North Freedom, Sauk County.

Freeman-Jewett Shale

Miocene: Southern California.

T. W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 12 (fig. 2), 38, pls. 1, 2, 3. Light-grayish-brown thin-bedded, somewhat punky semisiliceous or diatomaceous shale; commonly contains thin laminae of fine silty sand. Thickness about 500 feet. Conformably underlies Bena gravels; conformably overlies Walker formation. Equivalent of lower Miocene Freeman-Jewett silt of the east side of San Joaquin Valley oil fields.

Crops out in Cottonwood Canyon, Kern County.

Freeport Clay[1]

See Upper Freeport Clay and Lower Freeport Clay.

Freeport coal group (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original references: H. D. Rogers, 1858, Geology of Pennsylvania, v. 2, pt. 1, p. 474–492; J. P. Lesley, 1877, Pennsylvania 2d Geol. Survey Rept. H_3, p. xxiii.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 78. Rogers (1858) used Freeport as a group name for strata between Lower Freeport and Lower Mahoning sandstones. Strata in above interval are now recognized as including three cyclothems (ascending) Lower Freeport, Bolivar, and Upper Freeport.

Name taken from town of Freeport, Armstrong County, Pa.

Freeport Formation[1] (in Allegheny Group)

Pennsylvanian: Pennsylvania.

G. H. Ashley, 1923, Eng. and Mining Jour.-Press, v. 115, no. 25, p. 1108; 1926, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 65, p. 28, pl. 4. Allegheny group, of Pittsburgh series, subdivided into (ascending) Clarion, Kittanning, and Freeport formations. Freeport comprises (ascending) Freeport sandstone, Freeport lower limestone, Freeport lower clay, Freeport lower or D coal, Butler sandstone, Bolivar flint clay, Freeport upper limestone, Freeport upper clay, Freeport Upper or E coal. Underlies Mahoning formation.

M. N. Shaffner, 1946, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 55, p. 51–65. Allegheny group subdivided into (ascending) Clarion, Kittanning, and Freeport formations. The Freeport includes all rocks between top of Upper Freeport coal and top of Upper Kittanning coal. Comprises (ascending) Freeport and Kittanning sandstones, Lower Freeport clay and limestone, Lower Freeport coal, Butler sandstone, Bolivar fire clay, Upper Freeport limestone, and Upper Freeport coal and clay.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Field Trip Pittsburgh Mtg., p. 70 (fig. 5), 71. Allegheny group subdivided into three formations (ascending): Clarion, Kittanning, and Freeport.

E. G. Williams, 1960, Jour. Paleontology, v. 34, no. 5, p. 910 (fig. 2). Formation includes (ascending) Lower Freeport sandstone, Lower Freeport coal, Butler sandstone, and Upper Freeport coal. Overlies Kittanning formation which contains Upper Kittanning coal at top. Allegheny group.

Name taken from town of Freeport, Armstrong County, Pa.

Freeport Gravel[1]

Pleistocene: Northwestern Illinois.

Original reference: O. H. Hershey, 1897, Am. Geologist, v. 19, p. 207–209.

Occurs 2 miles east of Freeport, Stephenson County.

†Freeport Limestone Member (of Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania, Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 492.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 27. Discussion of limestones of eastern Ohio. From 3 to 12 feet below base of Upper Freeport coal, there is an irregular bed of limestone which Rogers (1858) called Freeport limestone in northwestern Pennsylvania and which Newberry (1878, Ohio Geol. Survey, v. 3) apparently described as the White limestone in Mahoning County. In his report on Lawrence County, Pa., White (1879, Pennsylvania 2d Geol. Survey Rept. Q_2), at the suggestion of Lesley, renamed Butler limestone, which underlies Lower Freeport coal and which was not recognized by Rogers, the Lower Freeport and called the Freeport limestone of Rogers, the Upper Freeport. This terminology has been accepted in reports dealing with geology of coal measures in Pennsylvania, West Virginia, and Ohio.

Name taken from town of Freeport, Armstrong County, Pa.

Freeport Sandstone Member (of Allegheny Formation)[1]

Freeport Sandstone (in Allegheny Group)

Freeport Sandstone (in Freeport Formation)

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 474–477.

G. H. Ashley, 1926, Pennsylvania Topog. and Geol. Atlas 65, p. 28, pl. 4. Freeport sandstone included in Freeport formation.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C26, p. 60, 74–75. Formation in Allegheny group. Lies below Lower Freeport coal and fire clay and above Upper Kittanning coal. Consists of thin- to medium-bedded brown medium-grained micaceous sandstone, locally crossbedded. Thickness as much as 15 feet exposed in roadcut 1 mile southwest of Indian Head. Two miles southwest of Markleysburg along State line, a massive sandstone bed crops out which appears to be about 80 to 100 feet below Upper Freeport coal. Area of report, Fayette County.

Name taken from town of Freeport, Armstrong County, Pa.

†Freezeout Limestone[1]

Triassic(?): Central Wyoming.

Original reference: F. B. Peck, 1904, Wyoming Hist. and Geol. Soc. Proc. and Coll., v. 8, p. 28–41.

Freezeout Mountains.

Freezeout Shale (in Phosphoria Group)

Freezeout Tongue (of Chugwater Formation)[1]

Permian: Southeastern Wyoming.

Original reference: H. D. Thomas, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1664, 1670.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2; 1950, Nebraska Geol. Survey Bull. 13–A, p. 2 (fig. 2), 3. Chugwater, as used in Wyoming, is synonymous with Spearfish redefined. Freezeout tongue of Chugwater is here designated as a member or a formation. Chart shows Freezeout shale in Phosphoria group.

N. C. Privrasky, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 50, 52. Term Freezeout shale should be abandoned in Powder River Basin and unit referred to as unnamed shale member of Goose Egg formation.

Present in Freezeout Hills.

Fremont Limestone[1] or Dolomite

Fremont Formation

Middle and Upper Ordovician: Eastern and central Colorado.

Original reference: C. D. Walcott, 1892, Geol. Soc. America Bull., v. 3, p. 154–167.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 39. Described along Front Range where it consists of limestone as much as 50 feet thick. Overlies Harding sandstone; underlies Williams Canyon limestone.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 32. At type section, limestone is 190 feet thick; maximum thickness 290 feet a few miles north of Priest Canyon.

J. W. Gabelman, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 8, p. 1582 (fig. 3), 1583. In Sangre de Cristo Mountains, Fremont consists of fairly uniform dark-gray to black crystalline dolomite. Overlies Harding quartzite; underlies Parting member of Chaffee formation. Thickness as much as 400 feet.

W. C. Sweet, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 2, p. 294–300. Referred to as formation. Thickness 283½ feet. Lower 208 feet is massive dolomite; upper 75 feet is shale and dolomite and is here named Priest Canyon member. Overlies Harding formation; underlies Williams Canyon formation.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 13. In Garfield quadrangle, Fremont is dolomite. Thickness 15 to 135 feet. Uncomformably overlies Harding quartzite; uncomformably underlies Parting member of Chaffee formation.

Type section: Harding Quarry at Canon City. Named for exposures in Fremont County.

French Slate[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 622, 645, 649.

J. J. Runner, 1928, Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included at top of Snowy Range series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consist of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

Named for French Creek in Medicine Bow Mountains.

Frenchburg Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 180, 182, 183–184, pl. 17. Included in Morehead facies (new), Brodhead formation. Occurs in massive beds up to 6 feet thick. Thickness of member 10 to 17 feet. Underlies Haldeman siltstone member (new); overlies Christy Creek siltstone member (new).

Type section: Quarry one-half mile west of Frenchburg, Menifee County.

French Creek limestone member[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 135–136.

Type section: Ravine at "Glendale" Cemetery, in Meadville City, Crawford County.

French Creek Shale Member (of Root Shale)

French Creek Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: R. C. Moore, May 1935, Kansas Geol. Survey Bull. 20, table opposite p. 14.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Root shale (new). Overlies Jim Creek limestone member; underlies Nebraska City limestone member of Wood Siding formation (redefined).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 11, fig. 5. Geographically extended into southwestern Iowa where it is uppermost unit in Wabaunsee group. Overlies Jim Creek limestone.

Type locality: French Creek, northeastern part of Pottawatomie County, Kans.

French Flat Sandstone

Pliocene, middle: Southern California.

D. I. Axelrod, 1950, Carnegie Inst. Washington Pub. 590, pl. 1. Shown on plate 1 as stratigraphically below Piru Gorge sandstone (new). [Text refers to a thick sand unit near French Flat. French Flat sandstone may be basal formation of Ridge Basin group.]

Occurs in Ridge Basin area along U.S. Highway 99 between Los Angeles and Bakersfield, in the region from 5 miles north of Castaic to the vicinity of Gorman.

French Lick Coal Member (of Mansfield Formation)

Pennsylvanian: South-central Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 26, 27, pl. 1. Important stratigraphic marker or key bed about 50 feet below top of lower unit of Mansfield. Average thickness about 1 foot. Coal named by D. W. Franklin (1939, unpub. thesis). Franklin's type section for coal, in SW¼NW¼ sec. 4, T. 2 N., (sic) R. 2 W., not located. Another locality noted which may be one to which Franklin referred.

Type locality: Quarry and mine in NE¼NE¼ sec. 5, T. 1 N., R. 2 W., approximately 1 mile west of town of French Lick, Orange County.

French Lick Stone (in Chester Group)[1]

Mississippian: Southwestern Indiana.

Original reference: E. T. Cox, 1871, Indiana Geol. Survey 2d Ann. Rept., p. 81.

Named for French Lick Springs, Orange County.

Frenchmans Bay Series

Silurian: Southeastern Maine.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1797. Named to include Bar Harbor detrital facies and Cranberry Island volcanic facies. Replaces four series of Shaler (1889), Schooner Head, Suttons Island, Cranberry Island, and Bar Harbor. Presumably Silurian.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 172–173, 176–177. Includes all sedimentary rocks overlying Bartletts Island schist; these form a seemingly indivisible succession exhibiting two contrasting and interfingering facies, Bar Harbor and Cranberry Island facies.

Occurs on Mount Desert Island, Hancock County, which is bordered on the east by Frenchman Bay.

French Pond Granite[1] (in New Hampshire Plutonic Series)

Upper Devonian(?): West-central New Hampshire.

Original reference: M. P. Billings, 1935, Geology of Littleton and Moosilauke quadrangles, New Hampshire, Moosilauke map, p. 28, 36.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Included in New Hampshire plutonic series of Upper Devonian(?) age.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, p. 61. Heterogeneous rock composed of five phases. In New Hampshire plutonic series.

Confined to circular stock 3 miles in diameter 3 miles southeast of Woodsville. Named from French Pond, 4½ miles southeast of Woodsville, Moosilauke quadrangle.

Frenchtown Diorite[1]

Age(?): Northeastern Maryland.

Original reference: G. P. Grimsley, 1894, Cincinnati Soc. Nat. History Jour., v. 17.

Near Frenchtown, Cecil County.

Frenck Shale[1]

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 94, 96.

Derivation of name not given.

Frensley Limestone (in Dornick Hills Group)

Frensley Limestone Member (of Lake Murray Formation)

Pennsylvanian: Eastern Oklahoma.

Jerome Westheimer, 1936, Correlation of the Pennsylvanian formations of the Ardmore basin and the Franks graben, Oklahoma: Ardmore Geol. Soc., last 3 pages of mimeographed program of a conference on correlation of the Pennsylvanian System of the Ardmore basin, held May 5, 1936. At base of the Pumpkin Creek south of Ardmore, nodular white dense limestone varying in thickness from 1 to 10 feet or more. Limestone contains an undescribed species of Fusulina which also occurs 50 feet below top of the Atoka in the so-called Red Oak member. Name Frensley is here proposed for this limestone and the shale overlying it and beneath the overlying prominent sandstone. Frensley marks top of the Atoka or Red Oak of eastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1). Shown on correlation chart of area south of Arbuckles. Pennsylvanian (Des Moines).

R. M. Jeffords, 1942, Kansas Geol. Survey Bull. 41, pt. 5, p. 250. Corals collected from Frensley limestone, Lampasas age, southeast of Ardmore, Okla.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Shown on chart as Frensley limestone, in Dornick Hills group; Lampasas series.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 139, 140 (fig. 3). Rank reduced to member status in Lake Murray formation (new). Overlies Griffin sandstone (equivalent to Lester) member; underlies Big Branch formation. Atoka series.

Well exposed on Frensley Farm in SE¼ sec. 30, T. 3 S., R. 2 E., Carter County.

Fresnal Group

Pennsylvanian (Virgil Series): Central and southwestern New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 73–79. Term proposed for all sedimentary rocks that are definitely referable to the Virgil series between top of the Keller group (new) and base of the Permian Wolfcamp (above). Thickness at type locality 530 feet; in San Andres Mountains apparently more than 1,000 feet thick. At type locality, composed of argillaceous to essentially pure limestone, arkosic sandstone, conglomerates, and gray to red shale; more than 50 percent of rocks are clastics, but most of them are of marine origin. In central part of State, group is composed largely of red shale, with interbedded thin nodular to irregularly bedded fossiliferous limestone and arkosic sandstone. Many faunal as well as lithologic units recognized in type section of group, but formational names not applied at this time; includes Bruton formation (new) in lower part in area of Oscura Mountains. In Fresnal Canyon in north end of Sacramento Mountains, upper Virgil strata of Fresnal group are overlain unconformably by 250 feet of strata of undetermined age. These strata are composed largely of clastic red shale, gray shale, sandstone, and conglomerates. In some areas, the Abo formation rests directly on the Bruton.

Carel Otte, Jr., 1959, New Mexico Bur. Mines Mineral Resources Bull. 50, p. 18, 19. Holder formation includes the Fresnal and Keller groups in classification of Thompson (1942). Thompson's detailed section of Fresnal group forms upper 530 feet of Pray's (1952, unpub. thesis) Holder formation and is overlain by Laborcita formation (new).

Type locality: Fresnal Canyon along State Highway 83, east of La Luz, in north end of the Sacramento Mountains. Section is mainly in NW¼ sec. 30, T. 15 S., R. 11 E., Otero County.

†Fresnian Stage

Eocene, late: California.

V. S. Mallory, 1953, (abs.) Jour. Paleontology, v. 27, no. 6, p. 903; 1954, Pacific Petroleum Geologist, v. 8, no. 11, p. 1. One of six stages, based on foraminiferal assemblages, in lower Tertiary of California. Includes interval between Oligocene Refugian stage above and Narizian stage. Also spelled Fresnoian.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 18. Term discontinued. Fresnian incorporated in redefined Narizian stage.

Fresnoian Stage

See Fresnian Stage.

Friant Formation

Miocene or Pleistocene(?): Southern California.

G. H. Jones, 1940, Am. Geophys. Union Trans., v. 21, pt. 1, p. 62 (fig. 2), 66. Composed of cemented sandy, tuffaceous lake-laid sediments; overlies granite.

G. A. Macdonald, 1941, California Univ. Pub., Dept. Geol. Sci. Bull., v. 26, no. 2, p. 262–265, map 1. Thickness varies; along northwestern side of Table Mountain about 250 feet; thickens to southwest; near lower end of Little Dry Creek, minimum exposed thickness 320 feet; entire series dips southwestward from 2° to 4°. Unconformably overlaps Ione formation near Little Table Mountain; on eastern side of San Joaquin Valley, lies on granitic rocks and crystalline schists; in some areas, capped by basaltic lava flows.

F. D. Trauger, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1531. Probably Pleistocene.

Typically exposed both east and west of San Joaquin River in vicinity of Friant, Fresno County.

Friedrich Shale Member (of Root Shale)

Friedrich Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: R. C. Moore, 1935, Kansas Geol. Survey Bull. 20, table opposite p. 14.

G. E. Condra and E. C. Reed, 1938, Nebraska Geol. Survey Paper 12, p. 9. In Nebraska, formation includes (ascending) Minersville shale, Palmyra limestone, and Otoe shale members (all new).

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in

Root shale (new). Underlies Jim Creek limestone member; overlies Grandhaven limestone member of Stotler limestone (new).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 11, fig. 5. Geographically extended into southwestern Iowa. Bluish gray to light gray, micaceous, and silty in upper part. Thickness 10 feet. Underlies Jim Creek limestone. Overlies Grandhaven limestone. Wabaunsee group. Interval from lower part of Friedrich shale through Grandhaven limestone is exposed along bluffs of Missouri River and major tributaries in Fremont County extending from NW¼ sec. 1 to NW¼ sec. 13, T. 69 N., R. 43 W. Condra and Reed suggest that their Otoe shale, Palmyra limestone, and Minersville shale may occupy horizon of Friedrich shale.

Type locality: Friedrich Creek, sec. 6, T. 22 S., R. 11 E., Greenwood County, Kans.

Friendsville Black Shale (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 574.

Probably named for occurrence at Friendsville, Garrett County.

Friendsville Coal Member (of Mattoon Formation)

Pennsylvanian: Central and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 51 (table 1), pl. 1. Assigned member status in Mattoon formation (new). Occurs at base of formation about 50 feet below McClearys Bluff coal member. Coal named by Fuller and Clapp (1904, U.S. Geol. Survey Geol. Atlas, Folio 105). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Secs. 13 and 24, T. 1 N., R. 13 W., Wabash County.

Friendsville Formation[1]

Pennsylvanian: Southwestern Indiana.

Original reference: Marshall Harrell, 1935, Indiana Div. Geology Pub. 133, p. 73 (chart).

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 84. Division of post-Alleghenian in western Indiana between McClearys Bluff above and St. Wendells formations, which is supposed to include Friendsville coal, Wabash County, Ill.; correlations between Friendsville and southwestern Indiana may have been erroneous, and Friendsville coal may be higher than its supposed equivalent in Indiana.

Type locality and derivation of name not given.

†Frijole Limestone Member (of Delaware Mountain Formation)[1]

Permian: Western Texas.

Original reference: W. G. Blanchard, Jr., and M. J. Davis, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 973, 987.

Named for exposures at Frijole post office, Culberson County.

Frijole Shale[1]

Permian: Western Texas.

Original reference: J. E. Adams, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 6. p. 785.

Occurs in wells at top of Delaware Mountain section Loving County.

Frio Clay[1]

Oligocene(?): Eastern Texas.

Original reference: E. T. Dumble, 1894, Jour. Geology, v. 2, p. 554.

M. C. Israelsky, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 2, p. 376–382. Annotated bibliography of pertinent papers dealing with term Frio; also shows various uses of term as interpreted by the reviewer.

A. C. Ellisor, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1344–1375. Anahuac formation (new) lies between basal sands of Fleming above and subsurface Frio below.

A. D. Warren, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 221–227. Plummer (1932, Texas Univ. Bull. 3232) and Ellisor (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11) used Frio as term for subsurface strata thought to be equivalent to surface beds of same name as restricted and defined by Plummer. However, it has been determined that surface Frio of Texas is outcrop equivalent of subsurface Vicksburg. Suggested that term Frio could be suppressed in case of the surface Vicksburgian equivalent in Texas and another name applied to that unit.

D. H. Eargle and J. L. Snider, 1957, Texas Univ. Bur. Econ. Geology Rept. Inv. 30, p. 11 (fig. 2), 14. Frio clay discussed in report on uranium-bearing rocks, Karnes County area. Believed to be present in subsurface beneath Catahoula tuff in central and southern Karnes County. Formation consists of light-greenish-gray clay that is bentonitic and slightly calcareous and which weathers to a characteristic brown silty or clayey soil. Although its strike is apparently same as that of underlying beds, the Frio is believed to rest unconformably on sands of Jackson formation. Downdip from outcrop, lower part of Frio of subsurface contains fauna characteristic of Vicksburg of east Gulf Coastal Plain and formation is therefore classed as Oligocene(?) in age. Thickness about 200 feet (well data in Karnes County).

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2634. Discussion of Jackson group of south-central Texas. Southwest from point in northern Live Oak County, near community of Esseville, Frio clay, of Oligocene(?) age, extends to the Rio Grande. This usage of Frio is in the sense that Bailey (1926, Texas Univ. Bull. 2645) described the formation, restricting it to clays that lie conformably on the Jackson and that are overlain unconformably by Catahoula tuff (the Gueydan formation of Bailey).

Named for exposures at and near mouth of Frio River, Live Oak County.

Frio Formation

Frio Stage

Oligocene: Subsurface in Louisiana and Texas.

Alexander Deussen and K. D. Owen, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1616–1620, 1634. Inaccurate correlation of so-called subsurface Frio with surface Frio formation noted. Name Van Vleck sands suggested to replace "Frio" in subsurface.

M. C. Israelsky, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 2, p. 376–382. An annotated bibliography of pertinent papers dealing with term Frio; also shows various uses of term as interpreted by reviewer.

A. D. Warren, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 221–227. History of usage of term Frio in subsurface and proposal of formal type section for Frio Formation and Stage. Plummer (1932, Texas Univ. Bull. 3232) and Ellisor (1933, Am. Assoc. Petroleum Geologists Bull. 17, no. 11) used Frio as term for subsurface strata thought to be equivalent to surface beds of same name as restricted and defined by Plummer. It has been determined, however, that surface Frio of Texas is outcrop equivalent of subsurface Vicksburg. Between 1933 and 1940, workers, unaware of equivalency of subsurface Vicksburg to surface Frio, adopted term Frio for subsurface strata between middle Oligocene (Anahuac) and Vicksburg. This usage is firmly entrenched in the literature. Suggested that term Frio could be suppressed in case of the surface Vicksburgian equivalent in Texas and another name applied to that unit. Frio Stage is that part of subsurface stratigraphic section between base of Anahuac sediments and top of Vicksburg Stage. In type well, Frio Formation is present from 7,663 feet to 9,725 feet, whereas the stage continues down to 9,961 feet. Formation consists of dark to very dark, varicolored shales and silty shales and massive to thin-bedded strata of sand and silty sand. Top of formation is top of first sand below *Marginulina* zone of the Anahuacian, and base of lowest sand above Vicksburg Stage is considered base of Frio Formation. Stage in subsurface of Louisiana extends across southern half of State from Sabine River to Pearl River and is situated between base of Anahuacian *Marginulina* zone and top of Vicksburgian. Threefold division of Frio into upper, middle, and lower units is facilitated on basis of lithology and paleontology.

Type locality and well (formation and stage): China gas-distillate field in northeast Jefferson Davis Parish, La.; field is 6 miles southwest of Elton, La. Type well: Continental Oil-Union Sulphur, H. J. Shoesmith No. 1. Well is located 330 feet south and 330 feet east of NW cor. sec. 1, T. 8 S., R. 4 W.

Frisbie Limestone[1] Member (of Wyandotte Limestone)

Frisbie Limestone Member (of Iola Limestone)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 92, 97.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Shown on columnar section of Jackson and Cass Counties, Mo., as limestone member of Iola formation; underlies Quindaro shale member; overlies Liberty Memorial shale member (new) of Chanute shale.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2032, 2033; 1949, Kansas Geol. Survey Bull. 83, p. 103. Settlement of the "Iola problem" has led to a number of changes in the Missouri Survey's classification of middle and upper Kansas City beds so as to bring interstate agreement in nomenclature. Frisbie limestone, Quindaro shale, and Argentine limestone, which were indicated as members of Iola limestone in western Missouri, are classified with overlying Island Creek shale and Farley limestone as members of the Wyandotte.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 35. Thickness 1 to 3 feet in Kansas, ⅔ foot in Cass County, Nebr., and a few inches on Middle River, southwest of Winterset, Iowa.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 25, fig. 5. In Madison County, the Frisbie is a blue dense, locally fossiliferous limestone. Thickness one-half foot. Basal member of Wyandotte; underlies Quindaro shale member; overlies Lane shale.

Named for Frisbie, Johnson County, Kans. Well exposed at middle of north side of sec. 17, T. 12 S., R. 23 E.

Frisco Limestone[1] (in Hunton Group)

Lower Devonian: Northeastern and south-central Oklahoma.

Original reference: C. A. Reeds, 1926, Am. Mus. Nat. History Jour., v. 26, p. 470–473.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 7, 47–49. In south-central Oklahoma, formation is a fossiliferous calcarenite with almost no argillaceous calcilutite. Maximum thickness about 41½ feet. Overlies Fittstown member (new) of Bois d'Arc limestone. Underlies Woodford formation. Reeds did not designate type section but mentioned that best exposures were along Bois d'Arc Creek; these exposures can be used as type section.

G. G. Huffman, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 33–35, pl. 4. Described on flanks of Ozark uplift, northeastern Oklahoma. Light- to dark-gray, fine- to medium-crystalline, thick bedded, coquinoid fossiliferous limestone. Locally, sandy, cherty, and dolomitic beds may be present. Thickness 0 to 7 feet. Unconformably overlies St. Clair limestone; separated from overlying Sallisaw or Sylamore by unconformity, and locally, small cavities in Frisco are filled with Sylamore sandstone. Early Devonian.

Type section: Along Bois d'Arc Creek and near Coal Creek, NE¼ sec. 11, T. 2 N., R. 6 E., 7 miles south of Frisco, Pontotoc County.

Frog Mountain Sandstone[1]

Lower or Middle Devonian: Northern and central Alabama and northwestern Georgia.

Original reference: C. W. Hayes, 1894, Geol. Soc. America Bull., v. 5, p. 470.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Lower or Middle Devonian.

H. E. Rothrock, 1949, Alabama Geol. Survey Bull. 61, pt. 1, p. 11–12, fig. 2. Described in Coosa coal field, St. Clair County, Ala., where it is 80 feet thick and unconformably underlies Chattanooga(?) shale. Lower or Middle Devonian.

W. H. Robinson, J. B. Ivey, and G. A. Billingsley, 1953, U.S. Geol. Survey Circ. 254, p. 50. In Birmingham area, crops out along Red Mountain above Red Mountain formation.

Type locality: Frog Mountain, Cherokee County, Ala.

Frondosa limestone[1]

Ordovician: Southern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 7.

Derivation of name not stated.

Frontier Formation (in Colorado Group)[1]

Frontier Sandstone Member (of Mancos Shale)

Frontier Formation (in Mancos Group)

Upper Cretaceous: Western Wyoming, Colorado, Idaho, southern Montana, and Utah.

Original reference: W. C. Knight, 1902, Eng. Mining Jour., v. 73, p. 721, in a paper on Uinta County, Wyo.

C. T. Lupton, 1916, U.S. Geol, Survey Bull. 621, p. 167, 169, 171. In Basin oil field, includes (ascending) Peay and Torchlight sandstone members. Thickness about 565 feet. Overlies Mowry shale; underlies Cody shale.

J. D. Sears, 1926, U.S. Geol. Survey Bull. 781–B, p. 16 (table), 18, 19. In Rock Springs uplift, Sweetwater County, Wyo., Frontier formation is 70 to 160 feet thick; overlies Aspen shale and underlies Baxter shale.

W. T. Thom, Jr., 1935, U.S. Geol. Survey Bull. 856, p. 49. Thickness of formation about 410 feet in Soap Creek field. Consists chiefly of dark shale and beds of bentonite lithologically similar to lower part of overlying Carlile shale. Division between the two formations arbitrarily placed at top of thick bentonite bed exposed east of Soap Creek dome, which lies a short distance above several thin layers of coarse sandstone containing small chert pebbles and shark teeth. These layers are confined to top 100 feet of formation at Soap Creek but apparently become thicker toward northwest. Overlies Mowry shale. Colorado group.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 101, 102, 103. Member of Mancos shale in Uinta basin, Utah. Thickness 156 feet at Red Creek; 157 feet at Rim Rock; 163 feet at Colorado border. Overlies Middle shale member; underlies Upper shale member. Stratigraphically above Aspen shale member.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1), 839–840. In north-central Wasatch Mountains, underlies Henefer formation (new) and overlies Aspen formation. Consists of coal-bearing series of hogback-making gray sandstones separated by dark shales and friable sandstones; coarse conglomerate in middle of section. Thickness about 10,000 feet.

D. M. Kinney and J. F. Rominger, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim, Map 82; D. M. Kinney, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–123. Member of Mancos shale in Whiterocks River-Ashley Creek area, Uintah County, Utah, where it is 80 to 90 feet thick; overlies Mowry member and underlies unnamed member. Member, in Duchesne and Uintah Counties, Utah, is 210 to 250 feet thick; overlies Mowry member and underlies unnamed member.

H. L. Foster, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1538 (table), 1577–1584. Frontier formation in this area [Teton County, Wyo.] is characterized by tan sandstones with some interbedded sandstones, a few thin nodular limestones, many fossiliferous beds. Thickness about 2,750 feet. Overlies Mowry shale; contact placed at base of typical Frontier-type sandstone, above which no bentonite or porcellanite beds were observed. Conformably underlies Cody shale.

J. D. Love, 1948, Wyoming Geol. Assoc. Guidebook 3d Ann. Field Conf., p. 108–109. Frontier, as defined in central Wyoming, consists of sandstone and shale sequence overlying Mowry and underlying Cody shale. Frontier, as defined in type area and other parts of western Wyoming, comprises quite different set of beds. Correlation from southwest corner of Wind River basin southwestward through Bison basin, Rock Springs uplift, and Church Buttes to type area indicates that Cody shale and probably at least part of Mesaverde formation of central Wyoming are age equivalent of type Frontier and that part of Frontier formation of central Wyoming is age equivalent of Aspen shale of western Wyoming. Name Frontier is applied in this report [Wind River basin] to the sandstone and shale above the Mowry shale and below the Cody shale, in conformity with long-accepted usage, but not with the implication that formation is the same age as at type area. Thickness 650 to 1,030 feet.

G. E. Untermann and B. R. Untermann, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 5, p 688–689 (table 1) Shown on generalized columnar section as formation in Mancos group in Green River and Yampa River Canyons. Thickness 200 feet. Overlies Mowry formation; underlies an upper Mancos shale.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–111, sheet 2. In Hardin area, Montana and Wyoming, includes Soap Creek bentonite bed (new).

Keith Young, 1951, Jour, Paleontology, v. 25, no. 1, p. 35–68. Formation in southern Montana is divided into seven stratigraphic units (unnamed). Faunas obtained from units of formation of southern Montana are compared with faunas from Frontier formation and Carlile shale of other areas. Suggested that term Carlile shale be discontinued as rock name in southern Montana and that Frontier be redefined to include all rocks between top of Mowry shale and base of Niobrara formation. Frontier section (Thom and others, 1935) east of Soap Creek oil field was used as section of reference.

T. H. Kiilsgaard, 1951, Idaho Bur. Mines and Geology Pamph. 92, p. 14–17. Extent and thickness of Frontier formation in Horseshoe area has long been subject of conjecture. Schultz (1918, U.S. Geol. Survey Bull. 543) mentioned its occurrence and noted that it contained producing coals in Lincoln County. Kirkham (1922, Idaho Bur. Mines Bull. 4) and Stalder (1928, unpub. rept., Teton County) mentioned that formation covers large parts of the district. In present report [Horseshoe Creek], term Frontier is restricted to those Upper Cretaceous sediments, essentially gray to buff sandstones, shales, and beds of coal, which overlie basal conglomerate separating Aspen and Frontier formations. Thickness 3,905 feet. Formation occupies most of Horseshoe Creek basin. It is bounded on west by Jackson fault and is underlain to south and east by Aspen formation. Northward, it passes beneath Tertiary volcanics.

A. E. Granger and others, 1952, Utah Geol. Soc. Guidebook 8, p. 15, pl. 2. In Wasatch Mountains, east of Salt Lake City, overlies Kelvin formation and underlies Cretaceous(?) conglomerate. Thickness at least 8,000 feet. Tuffaceous beds similar to porcellanites of Aspen formation crop out near base.

W. A. Cobban and J. B. Reeside, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 10, p. 1913–1961. Formation in its type area, consists of about 2,000 feet of sandstone, coal, bentonite, and porcellanite. At Cumberland Gap. Wyo., 15 miles south of Frontier, lower half of formation consists of nonmarine sandstone, siltstone, mudstone, and water-laid volcanic rocks with some coal, carbonaceous shale, and limestone. Upper half consists of sandstone, mudstone, and some coal. Underlain by marine Aspen shale of Early Cretaceous age; overlain by 6,000 feet of marine Hilliard shale of middle Late Cretaceous age, which in turn is overlain by 4,000 feet of largely nonmarine Adaville formation. Nonmarine lower half cannot be precisely dated, but is probably Cenomanian. Marine beds in upper half are dated as of late Greenhorn (Turonian), early Carlile (Turonian), and early Niobrara (Coniacian) ages. Nonmarine unit near top believed to be of late Carlile age (Turonian). Northward from type area, formation does not appear to change greatly as far as Fontenelle basin, but upper half of overlying Hilliard shale changes to sandstone and shales of Adaville aspect. Farther north in Snider basin, a thin equivalent of typical Frontier can be identified, but it is overlain by great thickness of sandstone and shale that is not greatly different from the Frontier. Surface measurements suggest as much as 13,000 feet, but there may be duplication of beds not readily seen on surface. Uppermost part has not yielded fossils, but main part of these beds contains Niobrara fossils, and the entire sequence above the Aspen has been called Frontier by some authors. Formation passes eastward into dominantly marine rocks with fewer and thinner beds of resistant sandstone. Inasmuch as the sandstone beds that locally form top of Frontier pass eastward into shale, the upper limit of formation changes in age. Ordinarily one of three large units of sandstone forms top of formation. Youngest sandstone unit, of early Niobrara age, is tongue shaped, extending from southwest and northwest corners of Wyoming into central part of State. Sandstone beds of about middle Carlile age form top of formation for some distance eastward in Wyoming, northeastern Utah, and northwestern Colorado, beyond the eastern limits of the sandstone beds of early Niobrara age. In much smaller area in north-central Wyoming and south-central Montana, sandstone beds of pre-Carlile age form top of the Frontier. In Cumberland Gap section, formation contains Oyster Ridge sandstone member. Detailed discussion of specific areas. Correlation chart.

C. C. O'Boyle, 1955, Intermountain Assoc. Petroleum Geologists Guidebook 6th Ann. Field Conf., p. 33 (columnar section), 34. In northwestern Colorado (western part), overlies the Mowry and underlies Mancos formation; in eastern part, occurs above Dakota formation and below Niobrara equivalent.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 15. Nomenclature revised in Hardin district, Montana and Wyoming. Names Frontier and Eagle, which appear on maps published by Thom and others (1935), Richards and Rogers (1951), and Knechtel and Patterson (1952, U.S. Geol. Survey Circ. 150; 1955, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-36), have been eliminated from nomenclature in present report. Strata that were designated Frontier formation are assigned to Belle Fourche member of Cody shale.

J. D. Haun, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 84–89. In Powder River Basin, top of Frontier is placed at top of Wall Creek sandstone member. Base of Frontier placed at base of Clay Spur bentonite. Overlies Mowry shale; underlies Carlile shale except in Buffalo-Crazy Woman Creek area where it underlies Cody shale. Thickness varies from almost 1,000 feet in southwest part of basin to 600 feet in subsurface northeast of Kaycee and to 800 feet in southeastern part of basin. Use of name Frontier, with Wall Creek sandstone member at top, can be extended to east and northeast to region where Greenhorn limestone becomes distinct. If Greenhorn limestone is distinctly present, Black Hills nomenclature should be used.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 43–46, pls. 1, 3. In Buffalo-Lake De Smet area, formation is 500 feet thick and consists of interbedded light-gray sandstone and dark-gray shale with a few beds of bentonite and conglomerate. Overlies Mowry shale; underlies Cody shale.

H. R. Ritzma, 1959, Utah Geol. and Mineralog. Survey Bull. 66, p. 34, 36–37. Frontier sandstone member of Mancos overlies Mowry shale member and underlies main body of Mancos in Daggett County. Average thickness about 200 feet.

N. C. Williams and J. H. Madsen, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 122–123. In Coalville area, Utah, beds previously assigned to Frontier formation contain a heretofore unnoted major tectonic interruption; hence, the Frontier formation should be divided in recognition of this unconformity. Name Frontier is retained for beds below the angular unconformity, and name Wanship is applied to immediately overlying beds. Thickness of restricted Frontier 2,132 feet.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136–146. Formation revised is Coalville area. Comprises (ascending) Longwell sandstone, Spring Canyon, Chalk Creek, Coalville, Allan Hollow, Oyster Ridge, Dry Hollow, Grass Creek, Judd shale, and Upton sandstone members. All member names except Oyster Ridge are new. Overlies rocks tentatively assigned to Aspen shale; underlies Henefer formation. Intraformational unconformity recognized, but formation is not divided on basis of this hiatus; hence, Williams and Madsen's (1959) Wanship not used in present report. On correlation chart, column credited to Trexler (1955, unpub. thesis) shows Frontier formation comprises (ascending), Aspen zone, Skunk Point sandstone, Chalk Creek, Grass Valley shale, Oyster Ridge, Coalville conglomerate, Dry Hollow sandstone, Meadow Creek sandstone, Judd shale, and Upton shale members. Between Skunk Point sandstone and Chalk Creek member are about 2,800 feet of sandstone, shale, and conglomeratic sandstone not recognized as Frontier. Most of this interval is Chalk Creek member of present report.

Type area: Southwestern Wyoming. Named for exposures near Frontier, 2 miles north of Kemmerer, Lincoln County, Wyo. Characteristically exposed at Cumberland Gap, 15 miles south of Frontier.

Front Range Granite Group[1]

Precambrian: Colorado.

Original reference: T. S. Lovering and others, 1935, Geologic map of Colorado.

Includes following named units: Cripple Creek Granite, Curecanti Quartz Monzonite, Eolus Granite, Mount Rosa Granite, Pikes Peak Granite, Powderhorn Granite, Sherman Granite, Silver Plume Granite, Tenmile Granite, Trimble Granite, Twilight Granite, Vernal Mesa Quartz Monzonite, and Whitehead Granite.

Named for development in Front Range.

†Frostburg Formation[1]

Permian: Western Maryland.

Original reference: P. T. Tyson, 1837, Maryland Acad. Sci. Trans., v. 1, p. 92–98.

Named for Frostburg, Allegany County.

Frozen Head Sandstone (in Vowell Mountain Group)

Frozenhead Grit (in Anderson Sandstone)[1]

Pennsylvanian (Pottsville Series): Eastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33–B, p. 324–328.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, 19, pls. 2, 4. Reallocated to Vowell Mountain group (new) and referred to as Frozen Head sandstone. In type locality 35 feet thick; in Cross Mountain section 60 feet thick; maximum thickness 100 feet. Occurs near top of group; overlies an unnamed shale unit; underlies shale interval below Low Gap sandstone (new) of Cross Mountain group (new).

Exposed on Frozen Head Mountain, Petros quadrangle, Morgan County. [Board on Geographic Names gives Frozen Head as correct spelling.]

Fruitland Formation[1]

Upper Cretaceous: Northwestern New Mexico and southwestern Colorado.

Original reference: C. M. Bauer, 1916, U.S. Geol. Survey Prof. Paper 98–P.

Harley Barnes, E. H. Baltz, Jr., and P. T. Hayes, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–149. Described in Red Mesa area, La Plata and Montezuma Counties, Colo., where it is 510 to 520 feet thick and consists of a sequence of sandstone, shale, and coal beds. Underlies Kirtland shale; overlies Pictured Cliffs sandstone.

P. T. Hayes and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144. Discussed in Baker-Dome-Fruitland area, New Mexico, where it underlies Kirtland shale and intertongues with underlying Pictured Cliffs sandstone.

Named for small settlement on San Juan River, San Juan County, N. Mex.

Frye Mesa Beds (in Gila Conglomerate)

Pleistocene: Southeastern Arizona.

P. A. Wood, 1959, Arizona Geol. Soc. Guidebook 2, p. 60. Consist of conglomerate containing large boulders set in brown silty matrix. Maximum thickness adjoining Graham Mountains about 700 feet. Unit thins rapidly toward center of Safford Valley. Conformably overlie Solomonsville beds. Name credited to W. L. Van Horn and L. A. Heindl (unpub. theses).

In Stafford Valley, [Graham County].

Fulda Limestone (in Mansfield Group)

Pennsylvanian (Pottsville): Southwestern Indiana.

D. W. Franklin, 1944, Illinois Acad. Sci. Trans., v. 37, p. 87 (fig. 1), 88–89. Dark-blue-gray dense pure brittle, sparsely fossiliferous limestone. Thickness 2½ feet. Occurs near top of group about 15 feet below Ferdinand limestone (new).

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2), 19. Included in Ti Valley series (new).

Named for exposures along road between Fulda and New Boston, eastern Spencer County. Well exposed in S½SW¼ sec. 33, T. 4 S., R. 4 W.

Fulda Sandstone[1]

Permian: Central northern Texas.

Original reference: E. C. Case, 1907, Am. Mus. Nat. History Bull. 23, p. 660-662.

Named for prominent development near station of Fulda, Baylor County.

Fullerton Formation[1]

Fullerton Member (of Blanco Formation)

Fullerton Member (of Chase Channel Formation)

Pleistocene (Aftonian): Southern, central, and northern Nebraska and western Kansas.

Original reference: A. L. Lugn and G. E. Condra, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 190.

O. S. Fent, 1950, Kansas Geol. Survey Bull. 85, p. 64–65. Top member of Chase Channel formation (new), a subsurface unit in western Kansas. Maximum thickness 30 feet. Gray silty clay containing much sand. Gradationally overlies Holdrege member; underlies Meade formation.

G. E. Condra and E. C. Reed, 1950, Nebraska Geol. Survey Bull. 15–A, p. 12 (fig. 6), 16. Formation is composed of silt and calcareous clay grading locally into fine sand. Occurs between Holdrege and Grand Island formations in Loess Plains area. Thickness varies between a few feet and 50 feet or more; average 20 to 30 feet. Grades westward into "Aftonian formation" which was developed generally on the Holdrege sand and gravel plain where subdrainage was not active.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 52 (fig. 2), 59–60, 61, 64. Considered upper member of Blanco formation in Kansas. Where exposed in Sedgwick County, consists of 8 feet of gray to greenish-gray silt and sand and overlies Permian shale; underlies red sandy silts and silty sands tentatively classed as Crete-Loveland.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Chart of revised classification of Kansas Pleistocene shows Fullerton as member of unnamed formation in Meade group. Overlies Holdrege member; and occurs below Afton soil.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown as formation in Kansas. Nebraskan-Aftonian.

Named for exposures in vicinity of Fullerton, Nance County, Nebr.

Fullington Shale[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 361, 379.

Named for Fullington Ranch, at Belvidere, Kiowa County.

Fulton Shale (in Eden Group)[1]

Fulton Beds (in Economy Member of Latonia or Eden Formation)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

Original reference: A. F. Foerste, 1905, Science, new ser., v. 22, p. 150.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Chart shows Fulton formation in

Utica group. Occurs below Latonia formation of Eden group and above Point Pleasant formation of Trenton group.

L. H. Lattman, 1954, Am. Jour. Sci., v. 252, no. 5, p. 257–276. Report is based on reexamination of stratigraphy of sub-Eden beds of Ordovician age along Ohio River at its crossing of Cincinnati arch. Review of the literature reveals several sources of confusion in nomenclature and correlation. Study of detailed section at West Covington and Carntown, Ky., and Point Pleasant, Ohio. Rogers Gap [member of Cynthiana] formation, uppermost member of the Mohawkian, and overlying Fulton shale, lowermost member of the Cincinnatian, are faunally indistinguishable in this area. They appear to be lithologic facies of same time-rock unit. Faunal and lithologic evidence indicates advisability of extending the Cincinnatian series downward to embrace the Cynthiana formation, rather than including this formation in the Mohawkian.

K. E. Caster, E. A. Dalve, and J. K. Pope, 1955, Elementary guide to the fossils and strata of the Ordovician in the vicinity of Cincinnati, Ohio: Cincinnati Mus. Nat. History, p. 12 (fig. 3). Chart shows Fulton beds at base of Economy member of Latonia formation.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030–1031. In this report [Eden conodonts from Cincinnati region], Eden formation is classified as lowermost formation in Covington group and divided into (ascending) Economy (including basal Fulton beds), Southgate, and McMicken member. Economy member is also referred to as "Fulton-Economy" member.

Named for Fulton, formerly a suburb of Cincinnati, Ohio.

Fulton Shale Member (of Monongahela Formation)[1]

Fulton shale and sandstone member

Upper Pennsylvanian: West Virginia, eastern Ohio, and western Pennsylvania.

Original reference: G. P. Grimsley, 1907, West Virginia Geol. Survey Rept. Ohio, Brooke, and Hancock Counties, p. 92.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 36, 37. Thin shale member which in eastern Ohio occurs about midway between the Sewickley and Uniontown coals. In Jefferson County, Ohio, and northwestern West Virginia, underlies Arnoldsburg limestone.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 178, 180. Shale and sandstone member of Arnoldsburg cyclothem in report on Athens County. In Athens County, olive-green shaly sandstone that occurs above Benwood coal bed has been identified as the Fulton "green" shale. Here, the Fulton shale is separated from Benwood coal by bedded sequence of silty shale or fine-grained sandstone that averages nearly 10 feet in thickness. Fulton shale, itself, is an olive-green massive calcareous and micaceous unit that contains shaly partings and averages 4½ feet in thickness. Monongahela series.

Exposed at Fulton, Ohio County, W. Va.

Fults Member (of Salem Limestone)

Mississippian (Valmeyer Series): Southwestern Illinois.

J. W. Baxter, 1959, Dissert. Abs., v. 19, no. 11, p. 2910. Salem limestone is subdivided into four members [sequence not indicated] to which the names Kidd, Fults, Chalfin, and Rocher are assigned. Fults member consists of alternating beds of fine-grained dolomitic limestone and beds which contain admixtures of skeletal debris and microcrystalline non-skeletal grains.

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 2–3, 7, 22–24, pl. 1. Three general rock types predominate; very fine grained argillaceous silty earthy, mostly dolomitic limestone; mostly fine-grained dolomitic limestone with less detrital clay and silt; and medium-grained bioclastic limestone. Maximum thickness 34 feet. Conformably overlies Kidd member; contact with Chalfin member is at base of semilithographic bed.

Type section: In SE¼NE¼ sec. 20, T. 4 S., R. 10 W., near village of Fults, southern Monroe County.

Funeral conglomerate[1]

Tertiary: Southeastern California and southwestern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 78.

Well developed on flanks of Funeral Range, northeast of Death Valley in southeastern California.

Funeral Formation

Funeral Fanglomerate

Pliocene and Pleistocene(?): Southeastern California and southwestern Nevada.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 956–957. In addition to fanglomerate and other arid-basin deposits, unit contains interbedded flows of basalt. Lies unconformably on all other formations; in Amargosa Valley, unconformably overlain by a series of flat-lying beds that contain Pleistocene fossils. Thickness 3,000 feet. Deposited later than Amargosa thrusting. Name credited to T. P. Thayer.

Typically exposed between base of Funeral Range and Ryan, in Death Valley, southeastern California.

Funks Formation

Upper Cretaceous (Chico Series): Northern California.

J. M. Kirby, 1942, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 899. Listed as underlying Guinda formation and overlying Sites Formation (both new).

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 282, 284, 291, 293. Described as consisting mainly of greenish-gray clay shale and siltstone. Thickness 620 to 2,500 feet. Typical exposures noted.

Typical exposures in vicinity of Stone Corral Creek in W½ sec. 27, T. 17 N., R. 4 W., and along Funks Creek in W½ sec. 10, T. 17 N., R. 4 W., Colusa County.

Funk Valley Formation (in Indianola Group)

Upper Cretaceous: Central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 128, 133 (fig. 17). Thick unit of marine sandstone and shale of Niobrara age overlying Allen Valley shale (new). At type locality, formation consists of three clearly separable members: (1) basal series of sandstones with interbedded shale, about 900 feet thick; (2) middle unit of gray marine shale, 650 feet thick; and (3) upper sandstone 700 feet thick. Underlies Sixmile Canyon formation (new).

Type locality: Ridges bordering Funk Valley in secs. 34 and 35, T. 18 S., R. 2 E., Salt Lake Meridian, 3 to 4 miles southwest of Manti. Formation also forms marginal foothills of Wasatch Plateau for more than 4 miles south of Crystal Spring. In Salina Canyon, basal 600 feet of formation is exposed.

Funston Limestone (in Council Grove Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 23.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 64–65. Condra (1935) employed term Bigelow limestone to comprise three units (ascending): Sabetha limestone (Crouse limestone), Blue Rapids shale, and Funston limestone, It is here proposed that Bigelow be dropped as stratigraphic term and that Crouse limestone, Blue Rapids shale, and Funston limestone be recognized as formations.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 13 (table 2), 84–86, pls. Described in Wabaunsee County, Kans., where it commonly consists of three thin beds of moderately hard massive limestone separated by gray beds of shale. Contains biostrome that extends into parts of four counties in east-central Kansas. Thickness 8 to about 26 feet. Overlies Blue Rapids shale; underlies Speiser shale. Council Grove group.

Type locality: In bluffs of Kansas River valley south of Funston, Kans. Named for Camp Funston, Riley County.

Furnace Limestone[1]

Furnace Formation

Paleozoic: Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 352–365, map.

R. B. Guillou, 1953, California Div. Mines Spec. Rept. 31, p. 5, 10–12, pl. 1. Consists of three members, gray, white, and black. Stratigraphic position of only basal gray member is known. It crops out beneath Chicopee formation (new) in overturned and faulted limb of anticline southwest of Cactus Flat. White and black members are separated from the gray by granitic intrusions and faults, and their relative age is not known with certainty. Thickness about 6,000 feet. Intruded by Cactus quartz monzonite. Considered Mississippian-Pennsylvanian(?).

J. F. Richmond, 1960, California Div. Mines Spec. Rept. 65, p. 15–25, pl. 1. About one-third of total area of formation mapped by Vaughan is exposed in area of this report [south of type area]. Consists chiefly of calcite and dolomitic marbles which may be as much as 5,000 feet thick. Conformably overlies Chicopee Canyon formation which name replaces preoccupied Chicopee formation of Guillou (1953). Probably at least 1,000 feet of Furnace formation is Mississippian and remainder may be in part Pennsylvanian.

U.S. Geological Survey currently designates the age of the Furnace Limestone as Paleozoic on the basis of a study now in progress.

Named for Furnace Canyon, San Bernardino Mountains, San Bernardino County.

Furnacean series[1]

Miocene: California.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 78. Crops out in Furnace Canyon, east of Death Valley, Inyo County.

Furnace Creek Formation

Miocene or Pliocene: Southern California.

H. D. Curry *in* D. I. Axelrod, 1940, Jour. Geology, v. 48, no. 5, p. 527, 528, 531. Consists of several thousand feet of lavas, pyroclastics and terrestrial sediments. Lower part of formation primarily highly colored volcanics and pyroclastics with some fanglomerates, all presumably in unconformable contact with earlier Tertiary rocks. Pyroclastics grade laterally and vertically into tuffaceous lake and playa sediments. Unconformably underlies Ryan formation (new). Beds strongly folded into an asymmetrical syncline striking northwest.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 955–966. Unconformably underlies Greenwater volcanics (new); unconformably overlies Artist Drive formation (new). Thickness 2,500 feet.

Exposed in area drained by Furnace Creek Wash in central Death Valley region.

Furnace Creek Quartz Diorite Gneiss

Precambrian: Southeastern Pennsylvania.

T. V. Buckwalter, 1953, Pennsylvania Acad. Sci. Proc., v. 27, p. 115, 118. Name proposed for dark-greenish-gray medium-grained, usually homogeneous rock. Considered a recrystallized migmatic resulting from assimilation of hornblende gneiss and gabbro by Byram gneiss. Does not have obvious gneissic structure. Contains diffuse bands and clots of hornblende. Everywhere grades into Byram gneiss, Pochuck gneiss, or more common mechanically assimilated migmatites of these units.

Type locality: In South Mountain near headwaters of Furnace Creek and very near the Blainsport-Newmanstown Road. Area is near the point where Berks, Lancaster, and Lebanon Counties meet.

Furnace Ridge Conglomerate (in Gettysburg Sandstone lithofacies)

Triassic: Southeastern Pennsylvania.

D. B. McLaughlin and R. C. Gerhard, 1953, Pennsylvania Acad. Sci. Proc., v. 27, p. 136, 137. Coarse quartz-pebble conglomerate with interbedded red quartzose sandstone; occurs in lower part of lithofacies. Thickness 3,000 feet. Disappears rapidly westward near Mount Hope, Lancaster County, by interfingering with sandstones. Remains prominent to east beyond northeastern Lancaster County.

Maximum development along Hammer Creek, Lancaster County. May be named for Furnace Ridge in Lancaster quadrangle.

Furnaceville iron ore[1]

Silurian: Central and western New York.

Original reference: J. M. Clarke, 1906, New York State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12.

Tracy Gillette, 1947, New York State Mus. Bull. 351, p. 38–46. In Genessee Gorge, the Furnaceville is underlain by 3 feet of rather typical basal Reynales and overlain by the *Pentamerus* part of the same formation.

This condition holds for only a short distance to the east where the hematitic limestone appears to gradually fade into a true limestone. A few miles farther east, the Furnaceville is present again but occupies a position at base of the Reynales. Furnaceville constitutes a lithologic unit easily recognized and mappable; it can be traced for a long distance and with more assurance than most Clinton formations. Hence, it seems preferable to use it as a formational name to designate the lowermost hematitic limestone of Clinton group. Genesee Gorge lentil is considered a part of Furnaceville iron ore.

H. L. Alling, 1947, Geol. Soc. America Bull., v. 58, no. 11, p. 996, 998 (fig. 2), 1000. Furnaceville is herein defined as the ore that occurs at or near the base of the Reynales limestone.

Typically developed in vicinity of Furnaceville, Wayne County.

Furnaceville Shale[1]

Silurian: Central and western New York, and Ontario, Canada.

Original reference: M. Y. Williams, 1919, Canada Geol. Survey Mem. 11, p. 47.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 35. Now included in Neahga shale.

Fuson Member (of Lakota Formation)

Fuson Shale (in Dakota Group)

Fuson Shale (in Inyan Kara Group)[1]

Lower Cretaceous: Western South Dakota, northwestern Nebraska, and eastern Wyoming.

Original reference: N. H. Darton, 1901, U. S. Geol. Survey 21st Ann. Rept., pt. 4, p. 530.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7). Middle formation in Dakota group. Overlies Lakota formation; underlies Omadi sandstone (new).

K. M. Waagé, 1959, U. S. Geol. Survey Bull. 1081–B, p. 33, 84. History of stratigraphic nomenclature in Black Hills area and revision of nomenclature of Inyan Kara group. Darton's Fuson is key to difficulties that have arisen in attempts to map his threefold subdivision (Lakota, Fuson, and Dakota) in different parts of Black Hills. In southeastern corner of Black Hills where Minnewaste limestone is present and lower part of the Fall River is generally a massive sandstone affording a clearcut base, upper and lower contacts of Darton's Fuson are sharp and unmistakable. Minnewaste limestone is limited to small fraction of total outcrop of Inyan Kara group and basal part of Fall River formation is commonly shaly outside of limited area in southern Black Hills where they were first used. In subsequent work outside of southeastern Black Hills, Darton's interpretation of Fuson varied from one exposure to next [examples cited]. Consequently, both Darton's contact of Fuson and Dakota (Fall River) formations and his contact of the Lakota and Fuson formations wander up and down in the section with lateral changes in ratio of sand to clay-rock in beds above and below the persistent transgressive disconformity [see Dakota group]. Darton's measurement of type Fuson (Darton, 1901) and a revision (Darton and Paige, 1925, U.S. Geol. Survey Geol. Atlas, Folio 219) corresponds closely to section 10 (of present report), and his base of the Dakota (Fall River) is precisely at the transgressive disconformity. Fuson shale is reduced to member status in redefined Lakota formation. Name Fuson has been widely misapplied outside of Black Hills to beds equivalent to Skull Creek shale, as a result of Darton's miscorrelation with the Dakota equivalents of Colorado Front Range. Use of name Fuson as member of Lakota in limited area of southern Black Hills, where Minnewaste is present, may be helpful but should not be used beyond limits of Minnewaste. If this procedure is followed, Fuson member should be given new type locality. At Darton's type section, herein stated, is 92 feet thick; consists of siltstone, claystone, and sandstone; separated from overlying Fall River formation by transgressive disconformity.

W. A. Pettyjohn, 1960, (abs.) South Dakota Acad. Sci. Proc., v. 38, p. 34–38. Dakota controversy discussed. Suggested that term Dakota group be used to include Lakota, Fuson, Fall River, Skull Creek, and Newcastle formations.

Type section: At apex of sharp north bend in Dry Creek, Fuson Canyon, SW¼SE¼NE¼SW¼ sec. 36, T. 5 S., R. 6 E., Custer County, S. Dak.

Fusselman Dolomite

Fusselman Limestone[1]

Middle Silurian: Western Texas and southern New Mexico.

Original reference: G. B. Richardson, 1908, Am. Jour. Sci., 4th, v. 25, p. 476, 479–480.

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 164, 170. In Franklin Mountains, Tex., underlies Canutillo formation (new).

L. P. Entwistle, 1944, New Mexico Bur. Mines Mineral Resources Bull. 19, p. 13, (table 2), 19–20, pl. 2. Referred to as dolomite. In Silver City, N. Mex., area, disconformably overlies Raven member (new) of Montoya dolomite; unconformably underlies Percha shale. Thickness 75 feet.

F. R. Stevenson, 1945, Jour. Geology, v. 53, no. 4, p. 220 (fig. 2), 223 (fig. 3), 225 (fig. 5), 226 (fig. 6). In Sacramento and San Andres Mountains, N. Mex., underlies Onate formation (new). Onate replaces term Canutillo in this area.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pub. in Geology 4, p. 62, 66–68. In Caballo Mountains, thin sequence of light-gray-weathering, generally unfossiliferous claystone, limestone, calcitic dolomite, and dolomite referred to by Darton (1917, U.S. Geol. Survey Prof. Paper 108–C) as Fusselman(?) is here named Cutter formation and assigned to Montoya group. Fusselman dolomite poorly exposed in area of this report.

L. C. Pray and A. L. Bowsher, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1342. In Sacramento Mountains and other ranges farther west in south-central New Mexico, Darton identified the Upper Ordovician Montoya limestone, as well as two members of Fusselman limestone for which a Middle Silurian (Niagaran) age has been generally accepted. Recent study indicates that major erosional break within Montoya-Fusselman sequence occurs between the two members of Fusselman limestone in Sacramento Mountains. Fossils from lower member appear to be Upper Ordovician, and those of upper member appear to be Lower Silurian. Lower member of Fusselman is lithologically distinctive, widespread, and easily mappable in south-central New Mexico. In Sacramento

Mountains, it consists of 150 to 225 feet of medium to very light gray sublithographic dolomite that contains little chert; upper contact interpreted as disconformity. Upper member consists of resistant gray to brown cherty dolomite as much as 100 feet thick.

L. C. Pray, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1906–1917. Overlying cherty upper member of Montoya formation in Sacramento Mountains, and in many other ranges of south-central New Mexico, is lithologically distinctive unit that was termed lower member of Fusselman limestone by Darton (1917, U.S. Geol. Survey Prof. Paper 108–C). This lower member of Fusselman is herein designated as independent formation and named Valmont dolomite. The Valmont underlies unit termed "upper member of Fusselman limestone" by Darton (1928, U.S. Geol. Survey Bull. 794). Rock unit in Sacramento Mountains termed upper member of Fusselman limestone by Darton (1917; 1928) may be correlative with part of Fusselman limestone at type section designated by Richardson (1908) near El Paso. Correlation is open to question, and unit is herein referred to as Fusselman (?) formation.

L. C. Pray, 1958, West Texas Geol. Soc. Guidebook Franklin and Hueco Mountains, Tex., p. 30–43. Formation in Franklin Mountains is 608 feet thick, and consists largely of dolomite; divided into three lithologic units designated as lower, middle, and upper. Overlies Cutter dolomite of Montoya group. Type section suggested.

Type section (Pray): Northern Franklin Mountains, 6 miles north of Fusselman Canyon. Named for exposures in Fusselman Canyon, north of El Paso, Tex.

Fusselmannian series

Middle Siluric: Arizona and New Mexico.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 2, p. 107; no. 4, p. 253. Appears only on charts of geologic formations.

Fuyk Sandstone Member (of Rondout Waterlime)

Upper Silurian: Southeastern New York.

G. H. Chadwick, 1940, New York State Geol. Assoc. 16th Ann. Mtg. Field Guide Leaflets, p. 2. Sandstone included in Rondout waterlime.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 45, 46, 51, 55, 146 [1946]. Member of Rondout waterlime. Lower beds locally shaly and consist of reworked Normanskill arkose. Maximum thickness 20 feet. Underlies Manlius limestone. Has been called "Binnewater;" younger than that unit and not connected with it. Type locality designated.

Type locality: Ledge on west ridge of the Fuyk, west of Catskill.
