## LEXICON—PART 3, P-Z

**Paakea Basalt** (in Hana Volcanic Series)

Pleistocene(?) : Maui Island, Hawaii.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 230 (table), 251–252, pl. 1. Single aa flow; locally interflow clinker may indicate two flow units. Platy jointing rare; columnar jointing well developed. Sparsely vesicular with scattered phenocrysts of olivine in microcrystalline groundmass. Exposed thickness at mouth of Paakea Gulch approximately 150 feet; 1½ to 5 feet where tongues cross highway at Kapaula Gulch; 41 feet in test hole 12. Fills shallow valley cut in Kapaula lava (new). Each member of series is underlain by local erosional unconformity.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 102. Pleistocene(?).

Named for occurrence along Paakea Gulch. Flow entered area from southwest and divided into two branches which advanced to coast along valleys of Kapaula and Paakea, east Maui.

**Pablo Formation**

Permian(?) : South-central Nevada.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–40. Consists largely of greenstone and chert but contains small proportion of sedimentary rocks, chiefly slate and conglomerate. Contains also flows of felsitic lavas similar to intrusive Darrough felsite (new). Thickness probably exceeds 5,000 feet. Overlies Diablo formation; intrusive contact with Darrough felsite.

N. J. Silbering, 1959, U.S. Geol. Survey Prof. Paper 322, p. 6–10, pls. 10–11. Pablo formation is base of sequence in Union district, Shoshone Mountains, Nev. Three local members recognized. Lowest is coarse- and fine-grained sedimentary rocks interstratified with andesitic volcanic rocks; relatively thin limestone member; thick greenstone member composed of altered andesitic flows and volcanic breccia. Thickness about 2,450 to 3,450 feet. Base not exposed. Underlies Grantsville formation, little if any angular discordance.

Type locality: Pablo Creek, Toyabe [Toiyabe] Range.

Pabst Member (of Tyler Slate)[1]

Precambrian : Northwestern Michigan and northwestern Wisconsin.

Original reference: W. O. Hotchkiss, 1919, Eng. and Min. Jour., v. 108, p. 501–506.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 104 (table 10), 106 (table 11), 107 (fig. 6). Described from drill holes at Pence, Wis., as conglomerate and chert-carbonate rock. Thicknesses 16 feet and 30 feet.

Named for Pabst mine, east of Ironwood, Gogebic County, Mich.

Pacheco Group

Upper Cretaceous: West-central California.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 130–132, pl. 2 [preprint 1941]. Upper Cretaceous of central Coast Ranges divided into Pacheco group, below, and Asuncion, above. The groups are separated by Santa Lucian orogeny. In Pacheco Pass quadrangle, group consists of 7,000 to 8,000 feet of gray sandy shales, sandstones, and conglomerates which are either vertical or dip eastward at high angles; beds extend both north and south of quadrangle as continuous belt and also occur west of belt on El Puerto Creek in western Stanislaus County. Less widely distributed in central Coast Ranges than Asuncion group, but reverse may be case in northern Coast Ranges. Overlies Shasta group; in southern part of Diablo Range, Pacheco beds rest on Franciscan; to the north, they rest on Paskenta; to the east of Priest Valley and Waltham Creek, Pacheco conglomerates, grading upward into sandstones and shales, rest unconformably on Paskenta, Knoxville, and Franciscan in turn.

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 475–484. Name Jack Creek formation proposed as formational name for representative of Pacheco group in Santa Lucia Range.

F. M. Anderson, 1958, Geol. Soc. America Mem. 71, p. 15–30. Discussion of subdivisions of Pacific Coast Upper Cretaceous. Taliaferro's terms Pacheco and Asuncion groups used. Age of Pacheco ranges from latest Albian to close of Turonian time.

Named for development of beds in Pacheco Pass quadrangle especially on Quinto and Garzas Creeks.

Pacheta Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12, 14–15, pl. 27. Consists of following units (ascending): Lancha limestone (new), yellow dolomite, streaked and crossbedded sandstone with fragments of silicified trees, Tusonimo limestone (new), Cienda limestone (new), Black Knob dolomite (new), and Black Knob quartzite (new). Thickness 97 feet. Underlies Joserita member (new); overlies Morita formation.

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

**Pachuta Marl Member** (of Yazoo Clay)

Eocene, upper: Eastern Mississippi and western Alabama.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1830 (fig. 6), 1839 (footnote). Pachuta (marl) member of Yazoo clay (or formation) proposed for 6 to 25 feet of buff, gray, or white, partly indurated generally glauconitic fossiliferous marl, overlain by Shubuta (clay) member (new) and underlain by Cocoa sand member or North Creek clay member (new).

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 122, 126, pl. 3. In Choctaw County, Ala., consists of yellow sandy hard limestone with prints of fossils and light-gray almost white chalky marlstone irregularly indurated and containing white lime nodules; thins gradually from about 10 feet at Mississippi-Alabama line to about 5 feet in south-central part of county.

Type locality: Exposures on south side of Pachuta Creek, 1¼ miles south and southeast of Pachuta in SW¼ sec. 8, T. 2 N., R. 14 E., Clarke County, Miss.

Pacific muck

Pleistocene and Recent: Panamá.

[T. F. Thompson], 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 23–24. Series of low wave-cut benches and raised-beach or shallow-water bay deposits occurs at certain localities on Pacific side of Isthmus, above elevations attained by present tides. Locally similar to Atlantic Pleistocene deposits. Near city of Panamá, soft silt and clay-muck blanket covers underlying older agglomerates and tuffs. This layer deposited in late Pleistocene embayment and contains well-preserved fossils.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 341. Pleistocene. Informal name.

**Pacific Quartz Latite**[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for outcrops near Pacific mine, in western part of Mogollon district.

†Pacific Sandstone[1]

Lower Ordovician: Central eastern Missouri.

Original reference: S. H. Ball and A. F. Smith, 1903, Missouri Bur. Geology and Mines, v. 1, 2d ser., p. 79.

Named for Pacific, Franklin County.

**Packard Quartz Latite**

Packard Rhyolite[1] or Rhyolite Series

Eocene, middle: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, map.

P. D. Proctor and others, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–45. Referred to as Packard quartz latite. Flows, tuffs, and breccias as much as 400 feet thick.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 30–32, pl. 1. Packard quartz latite subdivided into four units: basal tuff, a few inches to as much as 100 feet thick, locally absent; lower vitrophyre, a few feet to more than 700 feet thick, locally absent; massive quartz latite a few feet to more than 2,300 feet thick; and upper vitrophyre. Packard and Fernow quartz latites are apparently parts of same volcanic series which have been separated geographically by overlying latite volcanic rocks.

D. R. Cook, 1957, Utah Geol. Soc. Guidebook 12, p. 65 (fig. 6). As shown on chart, Packard rhyolite series underlies Laguna latite series (new) and overlies Humbug formation.

J. M. Foster, 1959, Brigham Young Univ. Research Studies, Geology Ser., v. 6, no. 4, p. 35–36, pl. 4. Packard rhyolite series was followed by Laguna latite sequence.

Named for exposures on Packard Peak, Tintic district.

Packard Ranch Member (of Supai Formation)

Pennsylvanian: East-central Arizona.

R. L. Jackson, 1951, Plateau, v. 24, no. 2, p. 88, 89, figs. 2, 3. Arenaceous at type locality, becomes more calcareous eastward. Packard Ranch member of Oak Creek and Fossil Creek appears to intertongue with Naco formation to southeast. Underlies Oak Creek member (new) and overlies Naco formation.

Has optimum expression and development at Sycamore Canyon, and is recognizable both at Oak Creek Canyon and at Fossil Creek.

Pack Creek Substage

Pleistocene (Wisconsin) : Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Section [Guidebook] 2d Ann. Field Trip, correlation chart. Substage of Pinedale stage. Occupies Cary-Mankato interval between Cary sub-age and Mankato sub-age.

Twin Lakes area.

†Packer Clay[1]

Pleistocene (late Illinoian) : Southeastern Pennsylvania.

Original reference: E. H. Williams, Jr., 1894, Geol. Soc. America Bull., v. 5, p. 281–288.

Occurs between Easton and Topton divide and below level of 500 feet with exception of part of Saucon Valley west and south of Hellertown, Northampton County. Name derived from glacial lake named Packer.

**Packsaddle Schist[1]**

Precambrian (Llano Series) : Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lvii, lviii, 276–281, pl. 3.

V. E. Barnes, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. [1945] Intruded by Big Branch gneiss.

Virgil Barnes, Frederick Romberg, and W. A. Anderson, 1954, Internat. Geol. Cong., 19th, Algiers 1952, Comptes rendus, sec. 9, pt. 9, p. 152–153. Oldest Precambrian rocks in Llano uplift are most light colored, highly feldspathic metasediments, named Valley Spring gneiss, followed by dark-colored metasediments; including amphibolite, mica schist, graphite schist, and some marble, all of which are included in Packsaddle schist. These rocks are highly folded, and during folding it is believed the igneous rocks were intruded which were metamorphosed into Red Mountain gneiss and dioritic Big Branch gneiss. Date of intrusion of perioditic rocks, now serpentized into Coal Creek serpentine, in relation to Big Branch gneiss not satisfactorily determined. Town Mountain granite invaded the already deformed metasediments and was followed by Oatman Creek granite, Sixmile granite, and Llanite, the latter being the youngest.

Named for Packsaddle Mountain, Llano County.

**Packsaddle Mountain Granodiorite[1]**

Probably Jurassic or Cretaceous: Northern Idaho.

Original reference: J. L. Gillson, 1927, Jour. Geology, v. 35, no. 1.

Named for fact it composes Packsaddle Mountain, Bonner County.

Packwood Gravels

Pliocene to Pleistocene: Central California.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 22 (fig. 4), 42–43, pl. 1. Consists of poorly consolidated gravel, pebbly sandstone, silt, and clay. Estimated minimum thickness 500 feet. Reconnaissance indicates homoclinal dip to east of 10° to 30°, yielding a thickness of at least 3,000 feet with neither base nor top exposed. Underlies Santa Clara formation; overlies Orinda formation. Name credited to C. F. Tolman (unpub. rept.).

Sediments crop out in lower part of Packwood Creek, Morgan Hill quadrangle, where they occur in a block which has been dropped down between the Silver Creek and Calaveras fault zones. Area of study is in central Coast Ranges, about 50 miles southeast of San Francisco.

Pacoima Formation

Pleistocene, middle: Southern California.

G. B. Oakeshott, 1952, Petroleum World, v. 49, no. 1, p. 21 (map), 22. About 1,000 feet of poorly sorted gravels and fanglomerate. Unconformably overlies Saugus formation; unconformably underlies oldest terrace deposits. Fanglomerate [formation] has been distinctly folded along Little Tujunga syncline, and crystalline rocks have been thrust over it along Hospital fault.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 22 (fig. 2), 23 (fig. 3), 85–87, pl. 1. Formal proposal of name. Thickness 500 to 1,000 feet, south of San Gabriel fault; 200 feet, north of fault. In both areas, overlies Saugus formation and underlies terrace deposits; both contacts angular unconformities. Overlaps Elsmere member of Repetto near Olive View. Probably deposited in middle to early upper Pleistocene.

Type locality: At mouth of Pacoima Canyon one-half mile below Pacoima Dam, near eastern end of Sylmar 6-minute quadrangle, San Fernando quadrangle, Los Angeles County.

**Paddock Shale Member** (of Nolans Limestone)

Paddock Shale (in Sumner Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 61.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41. Member of Nolans limestone. Underlies Herington limestone member; overlies Krider limestone member. Thickness 7 to 10 feet in northern part of Kansas and about 30 feet in southern part. Leonard series.

Type locality: Roadcut one-fourth mile south of Krider, Gage County, Nebr. Named for Paddock Township, southern Gage County.

Paducah Formation[1]

Pleistocene: Western Kentucky.

Original reference: F. J. Fohs, 1907, Kentucky Geol. Survey Bull. 9, p. 67.

Probably named for Paducah, McCracken County.

Pagan Limestone

Pleistocene(?) or Recent: Mariana Islands (Pagan).

Risaburo Tayama, 1952, Coral reefs in the South Seas; Japan Hydrog. Office Bull., v. 11, table 4 [English translation in library of U.S. Geol.

Survey, p. 56]. Composed chiefly of reef-building corals; situated 1 to 2 meters above the reef flat and roughly 0.5 meter above the high-water mark. Covered with agglomerate. Recent.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 51–52. Pleistocene(?).

Forms outer caldera wall of island.

Page Ranch Formation

Tertiary: Southwestern Utah.

E. F. Cook, 1957, Utah Geol. Mineralog. Survey Bull. 58, p. 18, 20, 21, 61–63. Consists of two units: a lower gray to gray-brown poorly bedded rough-textured tuff-breccia which contains occasional subangular boulders to 6 feet in diameter in a matrix of smaller lithic fragments and broken mineral crystals; and an upper crystal biotite dacite ignimbrite, moderately welded, gray brown to purplish brown, containing sparse lithic fragments. Only in mountain northwest of Page ranch are two units together, where they appear to be conformable; elsewhere either one or the other missing. Maximum thickness at least 600 feet. Overlies Rencher formation (new).

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 92 (fig 2), 97–98. Subdivided into (ascending) Irontown and Kane Point tuff members. Kane Point has zircon age of 19 million years. This suggests that Rencher-Page Ranch period of extrusive-intrusive igneous activity is late Oligocene or early Miocene.

Mapped in northern half of Pine Valley Mountains, Washington and Iron Counties. Named for exposures capping mountain northwest of Page Ranch.

Pageton Sandstone[1]

Mississippian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 243.

Quarried at Pageton, McDowell County.

**Pago Volcanic Series**

Pliocene and Pleistocene(?) : Samoa Islands (Tutuila).

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285 (table 1), 1290–1299, pl. 1; G. A Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 187–188. Includes extra-caldera lavas, dikes, plugs, cinder cones, vitric tuffs, lithic tuffs, and breccias; and intra-caldera lavas, dikes, plugs, cones, tuffs, and breccias. Intra-caldera volcanics, about 2,141 feet, include massive aphanitic and porphyritic basaltic and andesitic lava flows, and cinder cones, associated with three trachyte plugs; and interbedded lithic-vitric tuff member is 50 to 500 feet thick. Extra-caldera unit, about 1,609 feet thick, consists of lower member of thin-bedded primitive olivine basalts, associated thin dikes, and thin beds of vitric and lithic tuff having aggregate thickness of more than 1,000 feet; upper member consists of basalts, basaltic andesites, andesitic basalts, and andesites, associated with five plugs. Flows are massive and have maximum thickness of 500 feet.

Forms entire central part of island. Type locality of intra-caldera tuff and breccia member is head of Pago Pago Valley on north side of trail to Fagasa.

**Pagoda Limestone**

Pagoda Oolite[1]

Middle Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 37.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1075, 1085, 1090 (fig. 2). Termed Pagoda limestone. Underlies Pentagon shale; overlies Dearborn limestone. Thickness type section 364 feet. Middle Cambrian.

Charles Deiss, 1939, Geol. Soc. America Spec. Paper 18, p. 40–41, measured sections. Underlies Steamboat limestone in central and southern sections. Detailed measured sections.

Type locality: On east side of peak lying N. 20° E. of top of Pagoda Mountain in SW¼ sec. 3, T. 22 N., R. 13 W. Named for Pagoda Peak, but not present on peak that forms very top of mountain.

**Pahala Ash** (in Kahuku Volcanic Series)

Pahala Basalt[1]

Pleistocene: Hawaii Island, Hawaii.

Original reference: W. O. Clark, L. F. Noble, and H. S. Washington, 1923, Am. Jour. Sci., 5th, v. 6, p. 119.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 62 (table), 64 (table), 67 (table), 68, 69, 71–76. Pahala basalt replaced by Kahuku volcanic series (new). Name Pahala here restricted to top ash member; as thus restricted it is the persistent ash formation, derived from several sources, which caps Hilina volcanic series on Kilauea, Kahuku volcanic series on Mauna Loa, and Hamakua volcanic series on Mauna Kea. Also overlies Hilina, Hawi, and part of Hualalai volcanic series; underlies Kau, Puna, and Laupahoehoe volcanic series. Includes Waiau tuff described by Wentworth. Thickness as much as 50 feet.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 122–123. Pahala ash, as used by Stone (1926, Bernice P. Bishop Mus. Bull. 33), included ash deposits on Mauna Loa and Kileau, but did not definitely include those on Mauna Kea. Wentworth (1938, Hawaiian Volcano Observatory, 3d Spec. Rept.) used term Pahala tuff in same general sense. Stearns and Clark (1930, U.S. Geol. Survey Water-Supply Paper 616) included the ash as upper member of Pahala basalt. Present usage follows that of Stearns and Macdonald (1946).

Named for town of Pahala on south slope of Mauna Loa. Crops out about 450 square miles, chiefly on Mauna Kea and Mauna Loa.

**Pahasapa Limestone[1]**

Lower Mississippian: Western South Dakota and northeastern Wyoming.

Original reference: N. H. Darton, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 4, p. 509.

E. P. Rothrock, 1955, North Dakota Geol. Soc. Guidebook Black Hills Field Conf., p. 76. Mississippian system represented in South Dakota by formations of Madison group, called Englewood and Pahasapa, where they outcrop, and Bakken, Lodgepole, Mission Canyon, and Charles where encountered in wells.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Mapped in northeastern Wyoming.

Name is Dakota [Sioux] Indian name for Black Hills

Pahranagat limestone[1]

Ordovician: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53, 80.

Named for Pahranagat Mountains, north of Las Vegas, Clark County.

**Pahrump Series**

Pahrump Group

Precambrian: Southern California.

D. F. Hewett, 1940, Washington Acad. Sci. Jour., v. 30, no. 6, p. 239–240; 1956, U.S. Geol. Survey Prof. Paper 275, p. 25–28, pl. 1. Comprises about 6,500 feet of sandstone, conglomerate, quartzite, shale, and dolomite. Unconformably overlies Precambrian granite gneiss; unconformably underlies sedimentary rocks that probably represent basal formation of Paleozoic rocks. Lower Cambrian in age. Divided into (descending) Kingston Peak formation, Beck Spring dolomite, and Crystal Spring formation.

D. F. Hewett, 1948, California Div. Mines Bull. 129, p. 197. In Kingston Range, San Bernardino County, underlies Noonday dolomite.

L. A. Wright, 1952, California Div. Mines Spec. Rept. 20, p. 7, 8 (fig. 4). In Superior Talc area, Death Valley region, all three formations of Pahrump series exposed in a relatively undeformed section; this is only known locality west of Kingston Range where all units occur in virtually complete thicknesses. Series more than 5,500 feet thick, composes a north-trending structural block forming Saratoga Hills; block is about 2 miles long and dips eastward at moderate to steep angles.

D. H. Kupfer, 1954, California Div. Mines Bull. 170, map sheet 19. Referred to as Pahrump group.

D. H. Kupfer, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 188–194, pls. 1, 2. Name changed to group. In Silurian Hills [this report], exposed part is more than 11,000 feet thick and can be subdivided into 35 mappable members. Because of rapid facies changes in group, these members may not be recognized in other areas, and hence, are not given formal names but numbered (ascending) 1 to 35. Correlation of these members with Hewett's formations are uncertain. The 35 members may all be part of Crystal Spring formation, or they may represent all of Hewett's formations and a younger, previously unrecognized formation. Coarse clastic sediments dominate group; sandstone, generally orthoquartzite, is most common rock type; beds of carbonate rock, mainly dolomite, occur throughout section. Nonconformable on older metamorphic rocks; in measured section, top not exposed. Intruded by granitic rocks of two or more ages. Thrust faulting and chaos structure of area discussed.

Occurs in Kingston Range, Ivanpah quadrangle. Name derived from valley that borders Kingston Range on the north. Silurian Hills in San Bernardino County are 15 miles southeast of Death Valley.

Paicines Formation[1]

Pliocene: Southern California.

Original reference: P. F. Kerr and H. G. Schenck, 1925, Geol. Soc. America Bull., v. 36, p. 470, 476, map.

Probably named for extensive development west of Paicines, San Benito County.

**Paine Shale Member** (of Lodgepole Limestone)

Paine Shale Member (of Madison Limestone)[1]

Lower Mississippian: Central northern, central southern, and southwestern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

L. L. Sloss and R. H. Hamblin, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 3, p. 315, 317–318, 319, 320, 321, 322, 323, 324. Reallocated to member status in Lodgepole limestone. At type locality and throughout southwestern part of state, characterized by thin-bedded dense limestones in units averaging 5 inches thick separated by almost equal amounts of calcareous shale and shaly limestone; chert lenticules common. In Big Snowy Mountains, member is highly massive. Eastward from Bridger and Gallatin Ranges, thins progressively and is missing in Pryor and Big Horn Mountains. Thickness 56 to 331 feet. Underlies Woodhurst member; overlies Three Forks limestone.

L. R. Laudon and J. L. Severson, 1953, Jour. Paleontology, v. 27, no. 4, p. 509 (fig. 2a). Columnar section Fairy Lake area, Bridger Mountains, shows Paine member overlying Sappington formation.

First mapped at and around Paine Gulch, southwestern corner Fort Benton quadrangle, Little Belt Mountains.

Paint Slate[1]

Precambrian: Northwestern Michigan.

Original reference: R. C. Allen, 1910, Michigan Geol. and Biol. Survey Pub. 3, geol. ser. 2, p. 100–101.

R. H. Nanz, Jr., 1953, Jour. Geology, v. 61, no. 1, p. 53, 55. Incidental mention in discussion of chemical composition of Precambrian slates.

Named for Paint River, Iron County.

**Paint Creek Formation**[1] **or Shale**

Paint Creek Formation (in New Design Group)

Upper Mississippian (Chester Series): Southern Illinois, southern Indiana, western Kentucky, and southeastern Missouri.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 125.

R. E. Stouder, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 3, p. 268 (fig. 1), 269, 270 (fig. 2), 275–277. Paint Creek used here to include group of formations above Sample sandstone and below Cypress sandstone between Ohio River and southern end of Hardin and Breckinridge Counties, Ky. Includes three distinct formations: basal limestone 30 feet thick, central sandstone and shale 20 to 40 feet thick, and upper limestone member about 8 feet thick. Aggregate average thickness 62 feet near Lodiburg. These formations have been lumped together as upper Gasper; this name inadequate because it was originally used to describe a local phase in a restricted territory. The three formations of Paint Creek are correlatives of the Indiana formations (ascending), Reelsville limestone, Elwren sandstone and shale, and Beech Creek limestone. Names Reelsville and Elwren here proposed for the two lower members of the Kentucky formation; descriptive term *Productus inflatus* zone, first used by C. Butts, is here used in same manner.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 827–828. Assigned to New Design group (new). In standard Mississippian section, overlies Bethel sandstone and underlies Cypress sandstone. In Monroe and Randolph Counties, Ill., and northern Perry County, Mo., uniformly consists of calcareous shale and interbedded limestone with a conspicuous dark-red nonlaminated clay 12 to 15 feet thick about 10 feet above base; in lower part, shale predominates and limestone beds are argillaceous and separated by numerous bluish shaly partings; in upper part, limestone layers are more massive, purer, and crystalline, and at top is limestone bed about 10 feet thick. In areas where Bethel sandstone is absent, Renault and Paint Creek formations cannot be separated. In Meade, Breckinridge, Ohio, and parts of Hardin and Grayson Counties, Ky., Paint Creek consists of five variable members; three of these, the lowermost, middle, and uppermost, are largely shale, and the two intermediate are somewhat massive limestone. From Todd County to Grayson County, Ky., where Bethel sandstone is absent, Renault and Paint Creek formations together form limestone unit that cannot be easily subdivided; these beds are now known as Girkin limestone. In Indiana, formation comprises three members (ascending): Reelsville limestone, Elwren sandstone and shale, and Beech Creek limestone.

O. E. Wagner, Jr., *in* L. W. Currier, 1944, U.S. Geol. Survey Bull. 942, p. 17–18. Referred to as Paint Creek shale in Fluorspar area of Hardin County, Ill.

Elwood Atherton and D. H. Swann, 1948, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 32, no. 2, p. 300. Lower Chester formations are correlated in western Illinois, subsurface of southeastern Illinois basin, Hardin County, Ill., and Indiana. Paint Creek of southern and western Illinois is divided into three members: upper limestone and shale zone, named Ridenhower member and correlated with "Paint Creek" of southeastern Illinois; middle sandstone and shale zone, correlated with Bethel sandstone of southeastern Illinois; and a lower "pink crinoidal limestone" correlated with upper part of "Renault" formation and called Downeys Bluff member in southeastern Illinois. Correlations credited to F. E. Tippie (unpub. ms.).

A. H. Sutton and W. A. Oesterling, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1786. Paint Creek was named by Weller (1913) from exposures in southwestern Illinois. Name Ridenhower was applied by Butts (1917) to same part of Chester section, the shale between the Bethel and Cypress sandstones in the Fluorspar district.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7. Paint Creek formation of standard Chester column has triple expression in southern Indiana (ascending): Reelsville limestone, Elwren sandstone, and Beech Creek limestone. Each of these is a distinct stratigraphic unit in parity with other formations of the Chester and deserves name in its own right.

Named for Paint Creek, Monroe County, Ill. Typically developed in tributary of Paint Creek about 5½ miles northeast of Prairie du Rocher.

†Painted Desert Formation[1]

Jurassic and older(?): Northern Arizona, northwestern New Mexico, and southwestern Utah.

Original reference: L. F. Ward, 1901, Am. Jour. Sci., 4th, v. 12, p. 401–413.

Named for Painted Desert, Coconino County, Ariz.

Painted Hill Formation

Pliocene, lower or middle: Southern California.

C. R. Allen, 1954, California Div. Mines Bull. 170, map sheet 20. Typically unconsolidated gray conglomerate, locally contains white sandstone, fresh-water limestone, and interlayered flows of olivine basalt. Thickness about 3,400 feet. Underlies Quaternary gravels; overlies Imperial formation with essential conformity although Imperial beds pinch out to north.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 324 (fig. 2), 325 (table 1), 328–329, pls. 2, 3. Name Painted Hill formation herein applied to continental beds that conformably overlie Imperial formation east of Painted Hills. Bramkamp (1934, Ph.D. thesis, Univ. California, Berkeley, p. 15) termed the unit Indio because its stratigraphic position is similar to that of Indio formation in the Indio Hills. North of point where Imperial formation pinches out, Painted Hill lies directly on Coachella fanglomerate with marked angular unconformity. Probably early or middle Pliocene.

Named for Painted Hill, San Gorgonio Pass area, Riverside County.

Painted Rock Formation

Painted Rock Sandstone Member (of Vaqueros Formation)

Miocene, lower: Southern California.

T. W. Dibblee, Jr., 1952, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Econ. Geologists guidebook, Joint Ann. Mtg., Los Angeles, p. 82, 86. Marine sandstone and siltstone, 5,500 feet thick. Underlies Monterey marine shale and associated lava flows and sills; overlies Soda Lake formation (new). Outcrops noted on road log.

I. T. Schwade, 1954, California Div. Mines Bull. 170, map sheet 1. Noted as occurring in hanging-wall block of Morales fault, Cuyama Valley. Here consists of about 50 percent sandstone.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2978 (fig. 3), 2986–2987, 2988 (fig. 7). Rank reduced to member status in Vaqueros formation. At designated type locality, consists of a sequence of sandstones and siltstones with minor amounts of shale; thickness about 5,430 feet; in vicinity of Painted Rock, about 6,000 feet. Overlies Soda Lake shale member; underlies Monterey clay shale; both contacts gradational. Eaton and others (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2) included upper 900 feet of section as part of their Temblor and called the rest, from which they report occurrence of *Turritella inezana*, "Vaqueros"; this separation was based on faunal content and not on lithology; because this predominantly sandstone section is lithologically inseparable throughout its areal extent, term Painted Rock sandstone member is applied. Top of sandstone at Caliente Mountain is stratigraphically about 800 feet lower than it is in northwestern Caliente Range. In southeastern Caliente Range, Painted Rock thins, and upper part grades laterally eastward into basal beds of nonmarine Caliente formation.

Type locality: Caliente Mountain and Midway Peak Southwest quadrangles. Name derived from Painted Rock, a sandstone knob on which Indian pictographs are preserved, sec. 17, T. 32 S., R. 20 E., Caliente Range. Range is an anticlinal uplift developed in thick series of Tertiary sediments and is partially overturned and thrustfaulted southwestward toward Cuyama Valley.

†Painterhood Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: F. C. Schrader and E. Haworth, 1905, U.S. Geol. Survey Bull. 260, p. 447.

Named for Painterhood Creek, Elk County.

Paint Lick Limestone (in Eden Group)[1]

Upper Ordovician: East-central Kentucky and southwestern Ohio.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 10, 19, 212, 215.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 24. In central Kentucky, divisions of Eden include Fulton, Million, and Paint Lick. Paint Lick constitutes lower and massive part of Garrard sandstone of Campbell (1898).

Probably named for Paint Lick Creek, Madison and Garrard Counties, Ky.

Paint Pot Crater Flow

Recent: Northern California.

C. A. Anderson, 1941, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 7, p. 371. Name applied to a basalt flow from Paint Pot Crater. Considered older than Burnt Lava flow.

Occurs on western flank of Medicine Lake Highland near Little Glass Mountain, Modoc Lava Bed quadrangle.

Paint River Greenstones (in Quinnesec Schist)

Precambrian (Huronian): Northern Michigan.

H. M. Martin, 1936, The centennial geological map of the northern peninsula of Michigan (1:500,000): Michigan Dept. Conserv., Geol. Survey Div. Pub. 39, Geol. Ser. 33. Shown on map legend. Occurs in Crystal Falls and Iron River districts.

**Paint River Group**

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 37. Uppermost of four groups in the series; younger than Baraga group. Comprises (ascending) newly defined Dunn Creek slate, Riverton iron-formation, Hiawatha graywacke, Stambaugh formation, and Fortune Lakes slate. In previous reports, these strata were considered part of the Michigamme slate. Iron River-Crystal Falls district is a deep tightly folded major synclinal structure incompletely bounded by Badwater greenstone; east of Crystal Falls, greenstone is absent and strata of the district proper rest directly on Michigamme slate. Recognition of stratigraphic position of Badwater greenstone formed basis for definition of Paint River group.

Named for Paint River which drains northern and eastern part of district, Iron and Dickinson Counties.

Paint Rock Bed (in Wichita Group)[1]

Paint Rock Limestone (in Lueders Group)

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 428.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in the Lueders here given group status. Underlies Maybelle limestone; overlies Talpa formation.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Type "Paint Rock" in Concho County has been traced into type exposure of Talpa limestone; "Paint Rock" is a synonym for Talpa limestone and preference in nomenclature is given latter term.

Named for Paint Rock, Concho County.

Pajarito Lavas

Mesozoic(?): Southern Arizona.

B. P. Webb and K. C. Coryell, 1954, U.S. Atomic Energy Comm. RME–2009, p. 8, pl. 1. Consists principally of massive coarse-grained rhyolite, with abundant pink feldspar phenocrysts. Underlies Oro Blanco conglomerate.

Well developed in Pajarito Mountains in southeast section of Ruby quadrangle, Santa Cruz County.

**Pajarito Shale**

Pajarito Shale Member (of Purgatoire Formation)

Lower Cretaceous: Northeastern New Mexico.

Ernest Dobrovolny and C. H. Summerson, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 62. Member consists of soft brown sandstone alternating with gray shale that contains *Ostrea quadriplicata;* on basis of this fossil, believed to be Washita in age. Overlies Mesa Rica sandstone member (new) or, where Mesa Rica is absent, Tucumcari shale member.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2005 (fig. 2), 2007. Rank raised to formation; term Purgatoire abandoned in Tucumcari-Sabinoso area. Thickness 50 to 60 feet.

Type locality and derivation of name not stated. First described in northwestern Quay County.

Pakoon Limestone

Permian (Wolfcampian): Northwestern Arizona.

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 515 (fig. 2), 524–525. Dolomitic limestones. Thickness 688 feet at type section; 305 feet in Grand Wash Cliffs. Overlies Callville limestone; underlies Queantoweap sandstone (new). Wedges out some distance west of termination of upper Callville member.

Grant Steele, 1960, Dissert. Abs., v. 20, no. 12, p. 4635. Overlies Ferguson Springs formation (new).

Type section: On west face and crest of Pakoon Ridge, northwest of Pakoon Spring, Mohave County, approximately T. 35 N., R. 16 W.

**Pala Conglomerate**[1]

Pleistocene: Southern California.

Original reference: A. J. Ellis, 1919, U.S. Geol. Survey Water-Supply Paper 446.

Occurs in valley of San Luis Rey, in vicinity of Pala, San Diego County.

Palafox Sandstone Member (of Mount Selman Formation)[1]

Eocene, middle: Southern Texas, and Tamaulipas, Mexico.

Original reference: W. G. Kane and G. B. Gierhart, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 9, p. 1370, 1371, 1377, 1381, 1385.

Forms a high cliff down the east bank of Rio Grande from mouth of Espada Creek to bluffs east of Palafox, Webb County, Tex. Can be traced from Rio Grande to Rio San Juan, Tamaulipas, Mex.

Palao Limestone

*See* Palau Limestone.

Palatine Bridge Limestone Member (of Tribes Hill Formation)

Lower Ordovician (lower Canadian): East-central New York.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76 (fig. 2), 85–87. Name proposed for thin-bedded fucoidal arenaceous dolomilutite with many intercalations of shaly calcilutite. Described as fine- to medium-grained light-blue-gray rock with "glassy" appearance on fresh fracture. Pebble calcarenite layers common near top; pyrite abundant in uppermost few feet. Maximum thickness 56 feet; much variation. Conformably underlies Wolf Hollow member (new); overlies Fort Johnson member (new) with gradational contact in exposures west of Cranesville and unconformably in those to the east. Represents part of original "Calciferous" which was termed "Fucoidal Layers."

Type locality: Quarry 0.5 mile west of Palatine Bridge, Montgomery County.

Palau Limestone

Miocene to Pleistocene: Caroline Islands (Babelthuap)

Risaburo Tayama, 1935, Tohoku Univ. Inst. Geology and Paleontology Contr. in Japanese Language, no. 18, p. 13, 14–15, 37–39 [English translation in library of U.S. Geol. Survey, p. 16–17, 43–44, 45–46]. Consists of basal tuffaceous sand and gravel which contains andesite blocks and coral masses; an *Acropora* bed, about 10 meters thick; massive coral limestone which carries Nullipore and Foraminifera. Overlies Babelthuap agglomerate. Resembles Mariana limestone and may be contemporaneous with it.

U.S. Army Corps of Engineers, 1956, Military geology of Palau Islands, Caroline Islands:

U.S. Army Corps of Engineers, Far East, p. 39 (table 5), 55–59, pls. 4, 8, 9, 10, 11. Maximum thickness probably 750 feet or more. Age ranges from Miocene to Pleistocene; Miocene age indicated only at two localities.

Chart and plates show Palau older than Peleliu limestone and younger than Ngeremlengui formation.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 52. Pleistocene.

Well developed along southern shore of Babelthuap; widely distributed in islands south of Babelthuap.

**Palestine Sandstone**[1]

Palestine Sandstone (in Elvira Group)

Upper Mississippian (Chester Series): Southern Illinois, southern Indiana, and western Kentucky.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 128.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 136, 137; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 838. Assigned to Elvira group (new). In standard Mississippian section, underlies Clore limestone and overlies Menard limestone. Generally thin bedded and flaggy and contains much sandy shale. More massive beds occur locally as in Pope County, Ill., and northern Christian County, Ky. Within short distance beyond latter locality, formation becomes shaly and loses its identity in Leitchfield shale. In southwestern Indiana, probably represented by thin Bristow sandstone.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 6. Name Palestine sandstone extended into southern Indiana where it replaces term Bristow sandstone. Local Indiana names of upper Chester dropped, and formations given names of standard Chester column.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, pl. 1. Palestine sandstone shown on stratigraphic column of upper Chester in Indiana as gray to brown flaggy sandstone and green-gray shale. Thickness 5 to 40 feet. Term Elvira group not used in Indiana.

Named for Palestine Township, Randolph County, Ill., where formation is well developed along some tributaries of Tindall Creek.

**Pali Volcanics**[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T.. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 123–124. Lithic tuff, cinder, agglomerate, vent breccia, and a lava flow and dike of nepheline basanite containing dunite inclusions. Maximum thickness of cinders about 40 feet; lava flow more than 20 feet. Uncomformably overlie Koolau volcanic series; also overlie Kaneohe, Nuuanu, and Aliamanu volcanics; underlie Salt Lake tuff. Pali cinders interbedded with alluvium in terraces-probably graded to the plus 95-foot (Kaena) stand of sea.

Crops out along road down the Nuuanu Pali, for which it is named. Exposed over about 0.2 square mile on face of Nuuani Pali (cliff) on northeast side of Koolau Range about 10 miles northwest of Makapuu Head.

**Palikea Formation** (in Koloa Volcanic Series)

Pleistocene: Kauai Island, Hawaii.

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1954, Volcano Letter 526, p. 3; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 124; G. A. Macdonald, D. A. Davis, and D. C. Cox, 1960, Hawaii Div. Hydrography Bull. 13, p. 20, 75–84, pl. 1. Sedimentary breccias and conglomerates intercalated with volcanic rocks of Koloa series and lying between Koloa lavas and eroded rocks of Waimea Canyon series. Thickness at type locality 700 feet; elsewhere not over 200 feet.

Type locality: Palikea Ridge, 3.2 miles southeast of Kawaikini Peak, on eastern side of central mountain massif of Kauai. Crops out as narrow bands along edge of central massif of Kauai and intercalated with Koloa lavas over eastern two-third of island.

†Palisade Andesite (in Potosi Volcanic Series)[1]

Miocene: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13.

**Palisade Diabase**[1]

Upper Triassic: Northern New Jersey and eastern New York.

Original reference: N. H. Darton, 1889, Am. Jour. Sci., 3d, v. 38, p. 134–139.

N. M. Perlmutter and Theodore Arnow, 1953, New York State Water Power and Control Comm. Bull. GW–32, p. 9 (table 2). Predominantly a medium- to coarse-grained dark-gray rock of intrusive origin consisting chiefly of plagioclase, augite, and hypersthene. Occurs as intrusive bodies in Newark group.

Forms the Palisades of the Hudson.

†Palisade Porphyry[1]

Precambrian (Keweenawan): Northeastern Minnesota.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 262–268.

Forms the Great Palisades of Minnesota coast of Lake Superior.

Palisade Canyon Rhyolite

Miocene, upper, or Pliocene, lower: Northeastern Nevada.

Jerome Regnier, 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1191, 1198. Consists of several flows, some of which are more than 200 feet thick. Rock is brownish red and weathers dark brown. Maximum thickness 500 feet. Flows thin out and disappear toward the east. Unconformably overlies Raine Ranch formation (new); underlies Carlin formation (new).

Forms cliff 500 feet high in Palisade Canyon, vicinity of Carlin. Separates Carlin basin from Pine Valley. Folded into open syncline in which Humboldt River flows and into an anticline that determines a ridge 1,000 feet high west of the river.

Palisades Conglomerate[1]

Pleistocene(?): Southwestern Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3.

A. J. Eardley, 1938, Geol. Soc. America Bull., v. 49, no. 2, p. 323, 338. Pleistocene(?).

On left bank of Yukon, about 35 miles below mouth of Tanana, at base of cliffs, 150 feet high, that have been named the Palisades, Yukon gold district.

Palisades Flow, Andesite

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 32, 62, 134. Thick andesitic flow forming Palisade Point. Rests on glacial moraines. Top is irregular, having monolithic crags and deep steep-sided fissures. Lies to west of Roundtop flow (new). In sections northwest of the Wineglass, white lump pumice and tuffaceous dacite [Wineglass welded tuff] cover Palisades flow. Was part of main andesitic cone of former Mount Mazama.

The Palisades are on northeast rim of Crater Lake.

†Palm Beach Limestone[1]

Pleistocene: Southern Florida.

Original reference: S. Sanford, 1909, Florida Geol. Survey 2d Ann. Rept., p. 209–211, table opposite p. 50.

Typically exposed in T. 45, R. 41, 12 miles west of Lantana, Palm Beach County.

Palm Canyon Complex

Paleozoic and (or) Mesozoic: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 12, 21–25, 36, 37, 38, pl. 1. A metasedimentary-igneous complex consisting largely of crystalline limestone, quartzites, and mica schists of phyllites, cut and locally injected by dioritic, granitic, pegmatitic, and silexitic material; highly deformed. Intruded by Bradley granodiorite (new), usually in form of sills.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 530. Paleozoic and (or) Mesozoic; wholly or partly correlative with Diamond Valley complex (new).

Named for typical exposures on the east side of lower Palm Canyon [south of Palm Springs], Riverside County. Exposed for 12 or 14 miles southeast of Palm Springs.

Palmer Gneiss[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 514.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1436 (table 1), 1455 (table 4), 1461. Palmer gneiss, previously considered pre-Huronian, consists of metamorphic Mesnard quartzite, Kona dolomite, Wewe slate, and Ajibik quartzite. Table 1 shows lower Huronian sequence in Marguette area (ascending) Mesnard, Kona, Wewe. Palmer gneiss not listed on this table.

Typical exposures west of Palmer Lake, Marquette district.

Palmer Volcanics[1]

Tertiary(?): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 103, map.

Occurs west of Palmer, Stevens County.

Palmerton Sandstone (in Onondaga Group)

Palmerton Sandstone Member (of Onondaga Formation)

Middle Devonian: Southeastern Pennsylvania.

F. M. Swartz, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 16, 52 (fig. 17), 108, 153. In area east of Schuylkill River to Carbon County, Oriskany sandstone is overlain by Bowmanstown chert and Palmerton sandstone; latter has for many years been mistaken for the Oriskany. Thickness 120 to 145 feet. Overlies Bowmanstown chert; underlies Esopus. Onondaga group. In eastern Monroe County and northwestern New Jersey, Esopus is believed to be contemporaneous with Bowmanstown chert and Palmerton sandstone.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1148, 1150, 1153, 1156, 1177. Description of a number of measured sections. Derivation of name given. Middle Devonian.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Lower or Middle Devonian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Onondaga formation, as mapped, includes Palmerton sandstone in Lehigh Gap area.

Named from exposures on ridges and in quarries north of Palmerton, Carbon County.

**Palmetto Formation**[1]

Lower and Middle(?) Ordovician: Southwestern Nevada.

Original reference: H. W. Turner, 1902, Am. Geologist, v. 29, p. 261–272.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–40. Mapped in Round Mountain quadrangle. Includes beds equivalent to Mayflower schist, Zanzibar limestone, and Toquima formation of Manhattan district. Slates carry graptolites of Chazy and Normanskill age, the former only from one locality in Toyabe Range. Estimated thickness 5,000 feet in Toquima Range and 2,500 feet or more in Toyabe Range. Map bracket shows Ordovician.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–45. Thickness in Mina quadrangle about 4,000 feet, base concealed. Tertiary volcanic rocks cover contact between Cambrian Miller Mountain formation (new) and Palmetto. Underlies Diablo formation.

B. M. Page, 1959, Nevada Bur. Mines Bull. 56, p. 15–18, 19 (fig. 7), pl. 7. Oldest rocks exposed in Candelaria mining district. Isoclinally folded and cut by numerous faults. Thickness 87 to 167 feet, although total thickness unknown; neither top nor base exposed. Upper part eroded prior to deposition of Diablo formation; in some areas, in fault contact with Candelaria formation.

Type locality: Palmetto Mountains, Silver Peak quadrangle, Esmeralda County.

Palmetto (type) granite

Paleozoic (epi-Paleozoic): Northeastern Georgia.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 40, 44. Porphyritic biotite granite that closely resembles Stone Mountain type except that it includes many phenocrysts of feldspar, generally microcline. In Greene and Elbert Counties, gradational into Stone Mountain type, and one appears to be but a phase of the other. In Greene County porphyritic type predominates, and in Elbert County equi-granular type is most common.

Named for exposures south of Palmetto, Fulton County.

Palm Park Formation

Oligocene: Southwestern New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 114 (fig. 14), 120–121. In southern part of Caballo Mountains, a sequence of clastic rocks which is probably older than McRae formation (new) and which underlies Santa Fe beds of Miocene-Pliocene age. Sequence has generally high content of volcanic debris as well as a few flows, all of which range from rhyolitic to basaltic in composition. Sequence divisible into lower dark-colored unit termed Palm Park formation and upper light-colored unit termed Thurmond formation. Generally has reddish-brown hue in outcrop. In some places, consists in large part of coarse bouldery conglomerate. At Palm Park where upper part is exposed, formation contains much reddish, grayish, and purplish-brown latitic to andesitic breccia and tuff. Reddish-brown tuffaceous clay and silt commonly intercalated with the tuff and breccia. Thickness probably at least 1,000 feet. Complete section nowhere exposed. At type locality, lower part of formation dropped below surface along Palm fault. Elsewhere, lower or upper boundaries may be covered by younger pediment-capping sediments. Base exposed along Apache Canyon where it stands steeply but in near conformity with underlying Magdalena beds. In this locality, upper beds are faulted beneath Thurmond formation.

Named for valley widely known as Palm Park located along southeastern edge of Caballo area, Sierra County.

Palms Granite

Precambrian: Southern California.

W. J. Miller, 1938, Geol. Soc. America Bull., v. 49, no. 3, p. 419 (fig. 1), 421–423. Typically a true granite, varying locally to a quartz monzonite, mostly medium grained, light gray, medium gray, and pinkish gray. Structure ranges from massive to highly foliated. Considered younger than Gold Park gabbro-diorite (new). Cut by White Tank monzonite (new).

Named from its typical and extensive development in Forty-nine Palms Mountain, Riverside County.

**Palms Quartzite**[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: C. R. Van Hise, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 338.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 85 (table 1). Included in Animikie series. Underlies Ironwood iron-formation; unconformably overlies Bad River dolomite.

Named for exposures just south of Palms mine, on Palms property, near Bessemer, Mich.

**Palm Spring Formation**[1]

Miocene, middle or upper: Southern California.

Original reference: W. P. Woodring, 1931, Carnegie Inst. Washington Pub. 418, p. 10.

L. A. Tarbet and W. H. Holman, 1944, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1782. Noted as overlying Imperial formation and underlying Borrego formation (new).

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 22, 23, 25, pl. 2. Described in Imperial Valley as a series of land-laid arkosic sandstones and red clays of Pliocene age. Thickness at type locality 4,800 feet; attains maximum thickness of 7,100 feet in Borrego Badlands; thins eastward to 6,800 feet on north flank of San Felipe Hills anticlinorium and to 3,600 feet or less on east-plunging nose and south flank of structural feature. In southwestern Imperial Valley, grades downward into marine Imperial formation and westward into Canebrake conglomerate (new); in Borrego Valley, grades upward into Borrego lacustrine beds; on Mecca anticline, unconformably overlies Mecca formation (new).

Named for spring on lower part of Vallecito Creek, a southwestward-flowing tributary entering Carrizo Creek about 1 mile above old stage station. Dibblee (1954) refers to type locality as south side of Carrizo Valley [Imperial and San Diego Counties].

Palmyra Limestone Member (of Friedrich Formation)

Pennsylvanian (Virgil Series): Northeastern Kansas and southeastern Nebraska.

G. E. Condra and E. C. Reed, 1938, Nebraska Geol. Survey Paper 12, p. 9. Defined as middle member of formation. Underlies Otoe shale member (new); overlies Minersville shale member (new).

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 14. Consists of one or two light-gray limestones containing *Triticites*. Thickness 1 to 3 feet.

Type locality: In cut-bank of Little Nemaha River, southeast of railroad station at Palmyra, Otoe County, Nebr.

†Palo Dur Beds[1]

Pliocene: Western Texas.

Original reference: W. B. Scott, 1894, Geol. Soc. America Bull., v. 5, p. 594–595.

Named for Palo Duro Canyon, western part of Panhandle of Texas.

Palolo Valley Mud Flow

*See* Kaau Mud Flow.

**Palomas Gravel**[1]

Pleistocene: Southwestern New Mexico.

Original references: C. H. Gordon, 1907, Science, new ser., v. 25, p. 824–825; 1907, Jour. Geology, v. 15, p. 91–92.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 114 (fig. 14), 123. Shown on correlation chart of formations in Caballo Mountains and adjoining areas. Occurs above Santa Fe formation, and appears to be both Pliocene and Pleistocene.

Named for exposures on Palomas River, Sierra County.

Palomasan series[1]

Quaternary: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 2, 10.

**Palo Pinto Limestone** (in Canyon Group)[1]

Palo Pinto Limestone (in Whitt Group)

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Reallocated to Whitt group (new). Expanded above to top of Wiles limestone and below to base of subjacent sandstone above Keechi Creek formation (redefined). Canyon series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 63. Recommended that name Palo Pinto be abandoned in Colorado River valley, and that beds called Palo Pinto with question by Nickell (1938, Texas Univ. Bur. Econ. Geology Pub. 3801) and shale unit between the beds and Capps limestone member be included in Brownwood shale member of Graford formation, in accordance with general current usage in Texas.

Named for Palo Pinto, Palo Pinto County.

**Palos Verdes Sand**[1]

Pleistocene, upper: Southern California.

Original reference: A. J. Tieje, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, no. 5, p. 502–512.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 53 (fig. 1), 56–59, pl. 1 Restricted to the marine deposits in Arnold's upper San Pedro series, that is, to deposits on the lowest (youngest) of 12 terraces. Consists of a thin veneer on terrace platform which bevels formations ranging in age from lower Pleistocene to Miocene. Composed of coarse-grained sand and gravel with silty sand and silt; limestone cobbles common in gravel. Thickness ranges from a few inches to 15 feet; average less than 10 feet. Type region designated as original type locality no longer exists.

Type region: Water front and adjoining region in San Pedro, Los Angeles County.

**Palouse Formation**[1]

Palouse soil

Pleistocene: Southeastern Washington, Idaho, and Oregon.

Original reference: R. C. Treasher, 1925, Science, new ser., v. 61, p. 469.

V. E. Scheid, 1940, Northwest Sci., v. 14, no. 3, p. 56–57. Discovery of fossil horse tooth from formation at Moscow, Idaho, raises question of age of formation.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 12. Formation appears to be correlative with Ringold formation and, if so, is of late Pliocene or Pleistocene age.

H. H. Waldron and L. M. Gard, Jr., 1954, U.S. Geol. Survey Geol. Quad. Map GQ–48; 1955, U.S. Geol. Survey Geol. Quad. Map GQ–56. Formation described in Hay and Penawawa quadrangles, Washington, where it mantles most of plateau upland surface and is a few inches to more than 200 feet thick.

Named for occurrence in Palouse Hills, southeastern Washington.

**Paluxy Sand**[1] or **Formation** (in Trinity Group)

Lower Cretaceous (Comanche Series): Eastern Texas, southwestern Arkansas, and southeastern Oklahoma.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 2, 42 (table 6), 43 (table 7). Overlies Mooringsport formation (new). Crops out in Little River and Hempstead Counties, Ark.

F. E. Lozo, 1949, Shreveport Geol. Soc. Guidebook 17th Ann. Field Trip, p. 85–92. Paluxy sand, heretofore generally considered as uppermost formation of Trinity group is indicated to be lateral equivalent of Walnut formation, in part, of central Texas. Paluxy sand, from type locality southward into central Texas, is more properly placed in Fredericksburg group on basis of sedimentary history.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 102, 109. Described in Llano region where it is uppermost formation in Trinity group. Extends in narrow band around east and northeast border of region and across central Burnet and north-central Lampasas Counties; occurs at base of Cretaceous outliers north of region. Commonly less than 10 feet thick. Overlies Glen Rose limestone; underlies Walnut clay of Fredericksburg group.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2334, 2335. Paluxy not included in Trinity group as defined in this report. Term Paluxy formation is restricted to those sandstones and shales which are time-stratigraphic equivalent of, and are laterally continuous with, part of the Walnut which is lowest formation of Fredericksburg group. Rusk formation occupies stratigraphic interval formerly termed Upper Glen Rose formation and Paluxy formation. Sandstones and red shales of upper part of Trinity group are time-stratigraphic equivalents of upper part of Glen Rose formation and are referred to in this report as "Paluxy-like" lithology.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 26–31. Paluxy sand described in McCurtain County where it is exposed as an east-trending belt about 8 to 10 miles wide which covers most of T. 6 S., Rs. 21 to 27 E. Thickness 0 to 880 feet. Conformably overlies De Queen limestone; unconformably underlies Goodland limestone.

Named for town and creek in Somervell County, Tex.

Palzo Sandstone Member (of Spoon Formation)

Palzo Sandstone (in Carbondale Group)

Pennsylvanian: Southern Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, Illinois Geol. Survey Bull. 67, p. 10, 15 (fig. 2) [1943]. Sandstone at base of Carbondale group; overlies DeKoven coal.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 46 (table 1), 63, pl. 1. Rank reduced to member status in Spoon formation (new). Occurs at top of formation above DeKoven coal member. Maximum thickness 40 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: SE¼ sec. 16, T. 10 S., R. 4 E., Williamson County. Named for exposures at Palzo, 10 miles north of Marion.

**Pamelia Limestone**[1] (in Black River Group)

Middle Ordovician : Northern New York.

Original reference: H. P. Cushing, 1908, Geol. Soc. America Bull., v. 19, p. 155.

F. P. Young, Jr., 1943, Am. Jour. Sci., v. 241, no. 3, p. 144–155. Basal formation of Black River group. Underlies Lowville. Consists essentially of dolomitic and shaly limestones with maximum thickness of 150 feet in Watertown region. Southeastward along Black River valley, it thins and disappears; westward, in Ontario, it retains its characteristic lithology but thins to 30 feet at Marmora, Hastings County.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 22–23. Greatest thickness, 150 feet, is in Jefferson County. Consists of lower division of about 70 feet composed of basal conglomerate and arkosic sandstones, dark-gray fossiliferous rock, and sublithographic limestone interbedded with gray dolomitic limestone. Upper division, about 80 feet thick, is light-gray or whitish earthy limestone interbedded with gray magnesian and sublithographic limestone. In both divisions, the dolomitic and earthy limestones weather to buff or yellowish-brown hue and are easily distinguished from overlying Lowville. Formation thins to east and west of its area of greatest thickness. Thins to disappearance in Oneida County to the east. Age and affinities of the Pamelia have been subject of debate, but it is generally conceded now that it has strongest ties with the Lowville rather than Chazy group.

J. H. Johnsen and G. D. Toung, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 1898. Exposure of formation reported east of Frontenac axis in New York. Thickness 3⅔ feet in quarry southeast of village of Chazy, Clinton County. Overlies Valcour formation; underlies Lowville limestone. Black River group (Lower Mohawkian).

Named for exposures at Pamelia, Jefferson County.

Pamelian (stage)

Ordovician (Black Riveran) : New York.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 94 (table 3). Name used in list of stage names for lowest division of Black Riveran series. Older than newly named Lowvillian [stage].

Name probably derived from Pamelia, Jefferson County, for which Pamelia limestone is named.

**Pamlico Formation**[1] or **Sand** (in Columbia Group)

Pleistocene : Atlantic Coastal Plain from Delaware to Mississippi.

Original reference: W. B. Clark, 1910, Geol. Soc. America Bull., v. 20, p. 651.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 74–75. Geographically extended into Florida where it includes all marine Pleistocene deposits younger than Anastasia formation. Consists chiefly of sand. Thickness ranges from featheredge to about 50 feet. Generally lies at altitudes of less than 25 feet above sea level on east, south, and west coasts.

G. F. Brown and others, 1944, Mississippi Geol. Survey Bull. 60, p. 60–61. Pamlico sand underlies Pamlico plain along north shore of Mississippi Sound. Much of outer edge of sand is capped by Recent beach and dune deposits from which it cannot readily be separated. Thickness on southeast bank of Wolf River 15 feet.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 50–51. In Prince Georges County, Md., and in District of Columbia, is entirely fluvial and estuarine. Thickness does not exceed 30 feet. Lies on valley floors cut in crystalline rocks and in sedimentary deposits ranging in age from Cretaceous Potomac group to Miocene Chesapeake group; may locally lie unconformably on Pleistocene Wicomico formation. Where it does not form the surface, overlain unconformably by Recent sediments. Formation accumulated during third cycle of downcutting and subsequent drowning of Potomac River; presumably this epoch is in later Pleistocene; it began during third glacial stage (Illinoian) and continued and was completed during third interglacial stage (Sangamon).

J. R. Dubar, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 133 (table 1), 135, 136 (fig. 4), 146, 147, 149 (fig. 13), 150, 154. In southwestern Florida, forms an almost continuous blanket of sand at elevations less than 25 feet above sea level. Generally rests with apparent unconformity on a member of the Fort Thompson, Caloosahatchee, or Tamiami formations. Between La Belle and Ortona Locks, commonly overlies Coffee Mill Hammock marl and may be overlain by Lake Flirt marl or lie exposed at surface; downstream from La Belle as far as Fort Denaud, rests, in many places, directly on Caloosahatchee formation, sometimes on upper shale bed and sometimes unconformably on Bee Branch member (new).

Named for Pamlico Sound, eastern North Carolina.

Pampa Schist

Jurassic or older: Southern California.

T. W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 12 (fig. 2), 18–22, pls. 1, 2, 3. Dark-gray mica schists; chiastolite-mica schists; chlorite greenstone schists. About 8,000 feet thick. Crops out within granitic rocks as linear inclusions with vertical or near-vertical attitudes. May be a phase of Kernville series, but its relationship to Kernville is obscured by granitic invasions.

Prominently exposed in Cottonwood Canyon drainage area west of Pampa Peak, Breckenridge Mountain quadrangle, Kern County.

**Pamunkey Group**[1]

Eocene, lower and middle: Eastern Virginia and eastern Maryland.

Original reference: N. H. Darton, 1891, Geol. Soc. America Bull., v. 2, p. 431–450, map.

N. H. Darton, 1951, Geol. Soc. America Bull., v. 62, no. 7, p. 752–759. Group includes Aquia and Nanjemoy formations.

R. R. Bennett and G. G. Collins, 1952, Washington Acad. Sci. Jour., v. 42, no. 4, p. 114–116. In Prince Georges County, Md., Aquia greensand, lower unit of group, overlies Paleocene Brightseat formation (new).

D. J. Cederstrom, 1957, U.S. Geol. Survey Water-Supply Paper 1361. Aquia formation is early Eocene; Nanjemoy formation is early and middle Eocene.

Named for exposures on Pamunkey River, Va.

**Panaca Formation**[1]

Pliocene: Eastern Nevada.

Original references: C. Stock, 1921, Geol. Soc. America Bull., v. 32, p. 146–147; 1921, Am. Jour. Sci., 5th, v. 2, p. 252–257.

D. A. Phoenix, 1948, Nevada State Engineer Resources Bull. 7, p. 34–38, 45–46, pl. 2. Described in Meadow Valley Wash drainage area; where best exposed, composed of terra-cotta to light-brown silts and fine sands and locally some diatomite and volcanic ash. Beds dip gently from both sides of Meadow Valley and are cut by faults of small displacement. Full thickness not known; where best exposed and most deeply dissected, estimated thickness at least 1,400 feet. Covered by Quaternary alluvium. Overlies Miocene(?) volcanic rocks. Pliocene.

Named for exposures near village of Panaca, Lincoln County.

**Panama Conglomerate Lentil** (in Cattaraugus Formation)

Panama Conglomerate[1]

Panama Conglomerate Member (of Venango Formation)

Panama Member (of Cattaraugus Formation)

Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: J. F. Carll, 1880, Pennsylvania 2d Geol. Survey Rept. $I_3$, p. 58, 60, 70, 124.

I. H. Tesmer, 1954, Dissert. Abs., v. 14, no. 12, p. 2317, 2318. Reallocated to member status in Venango formation. Underlies Cherry Creek member (new). Upper Devonian. Area of report, Cherry Creek quadrangle, New York.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 33. Basal member of Cattaraugus formation. Underlies Amity member; overlies Chadakoin formation of Arkwright group (new). Thickness 30 feet in Chautauqua County.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 19. Panama and Wolf Creek conglomerates and sandstones are contiguous. Panama has priority; name Wolf Creek abandoned.

Named for exposures at Panama, Chautauqua County, N.Y.

**Panamá Formation**[1]

Panamá Tuff

Miocene, lower: Panamá.

Original reference: R. T. Hill, 1898, Harvard Coll. Mus. Comp. Zoology Bull. 28, no. 5, p. 200–202.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (chart); W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 242, 246 (fig. 2); W. S. Cole, 1952, U.S. Geol. Survey Prof. Paper 244, p. 2 (fig. 1). Referred to as Panamá tuff.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 12, 39–42, 51 (fig. 4), pl. 1. Formation proper includes tuff, tuffaceous sandstone, tuffaceous siltstone and agglomerate. They evidently represent nonmarine, essentially fine grained tuff and tuffaceous strata that interfinger with and overlie La Boca marine member and Pedro Miguel agglomerate member. Estimated thickness at least 300 meters. Geologic map suggests that formation proper overlaps part of Caimito formation, but that relation needs confirmation. La Boca marine member apparently overlaps

Cucaracha and Culebra formations. La Boca member and presumably entire Panamá formation is not much younger than the Culebra formation and like the Culebra is considered early Miocene. Entire succession above Los Cascadas agglomerate (Culebra, Cucaracha, and Panamá formations) is believed to represent early half of early Miocene time; that is, the disputed Oligocene or Miocene.

Type area: Exposures along water front in city of Panamá, Panamá Province.

Panamint Metamorphic Complex[1]

Precambrian: Southeastern California.

Original reference: F. M. Murphy, 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

R. H. Hopper, 1947, Geol. Soc. America Bull., v. 58, no. 5, p. 403. This investigation has supported suggestion made by earlier workers that Murphy's Panamint metamorphic complex is Archean.

Occurs in southern part of Panamint Range, Inyo County.

Panamintan series[1]

Lower Cambrian: Eastern California, western Nevada, and Utah.

Original reference; C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 51, 53, 80.

Named for Panamint Mountains, eastern California.

Pancho Rico facies (of San Ardo Group)

Pliocene: Western California.

T. A. Baldwin, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1986 (fig. 6), 1988. Diatomaceous and silty mudstones which bear a fauna similar to Reed Ridge, Sisquoc, and Purisima formations. Pancho Rico is lowermost of three overlapping facies in group. Underlies and interfingers with sands of Etchegoin facies. Overlies Santa Margarita sand.

Exposed on slopes of Pancho Rico Canyon and the nearby gulches which drain westward to the Salinas River near San Ardo, Monterey County.

Pandermitan series[1]

Lower Cambrian: Nevada and Utah.

Original reference: C. R. Keyes, 1927, Pan-Am. Geologist, v. 48, p. 68.

Derivation of name not stated.

**Pando Porphyry**

Tertiary, lower: Central Colorado.

Ogden Tweto, 1951, Geol. Soc. America Bull., v. 62, no. 5, p. 510. Quartz latite porphyry composed of scattered quartz and plagioclase phenocrysts and grains of altered biotite in light-gray or buff dense groundmass. Weak linear orientation detected in most chilled Pando porphyry, but planar orientation is indiscernible. Forms persistent sill or zone of sills in Pennsylvanian shale just above Leadville limestone; also in small sills in pre-Pennsylvanian quartzites and dolomites and in few dikes. Cut by Elk Mountain and by Eagle River porphyries.

Main sill persistent for several miles along upper Eagle River, from East Fork northward beyond Gilman, and crops out boldly on slope just east of Pando. In southern part of Gore Range, Eagle and Summit Counties.

†Panhandle Beds[1]

Panhandle Formation

Pliocene: Northwestern Texas.

Original reference: J. W. Gidley, 1903, Am. Mus. Nat. History Bull., v. 19, p. 634–635.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 27. Formation, proposed by Gidley, for pre-Clarendon beds of Texas Panhandle but usually treated as Texas equivalent of Ogallala, not in regular current use in either sense. If unambiguous term in latter sense is desired, Llano Estacado formation is available.

G. L. Evans, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 617, Cummins (1890, Texas Geol. Survey 1st Ann Rept.) did not attempt to subdivide Cenozoic of Texas, and his Blanco beds are practically a synonym for what is now known as Panhandle formation, which includes all of plains Cenozoic in Texas except Recent surface sands.

G. L. Evans, 1949, West Texas Geol. Soc. Guidebook Field Trip 2, Nov. 6–9, p. 5–6. Names Couch and Bridwell formations proposed for Pliocene units exposed along eastern side of plains in Lubbock, Crosby, and Floyd Counties. Terms Ogallala and Panhandle have been applied to most of High Plains Cenozoic beds.

May be named for the Panhandle of Texas or for town in Carson County where beds are exposed.

**Paniau Volcanic Series**

Pliocene(?): Niihau Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 90–91; H. T. Stearns and G. A. Macdonald, 1947, Hawaii Div. Hydrography Bull. 12, p. 17 (table), 18–19, 42–45; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 125. Thin-bedded vesicular olivine basalts, both aa and pahoehoe, and correlative dikes and plugs. Total exposed thickness 1,281 feet. Separated from overlying Kiekie volcanic series (new) by erosional unconformity.

Type locality: East side Paniau Hill. Comprises central highland part of island.

**Panoche Formation**[1]

Panoche Group

Upper Cretaceous: Southern California.

Original reference: R. Anderson and R. W. Pack, 1915, U.S. Geol. Survey Bull. 603.

F. M. Anderson, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1612. Upper Cretaceous Chico series subdivided into Gaines group (new), western Shasta County; Panoche group, Diablo Range; and Moreno group, Diablo Range. Panoche group, including Chico Creek and Los Gatos beds, has characteristic faunas in its upper one-third, but lower and major part is barren.

F. M. Anderson, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1863. Chico series subdivided into three major groups: Pioneer (new), Panoche, and Orestimba (new). Panoche group is best exposed on west border of San Joaquin Valley, where it has average thickness of 14,200 feet on flanks of Diablo Range.

M. B. Payne, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1954–1955; 1951, California Div. Mines Spec. Rept. 9, p. 6 (fig. 2), 7, 8 (fig. 4), 12 (fig. 6). Formation underlies Dosados sand and shale member (new) of Moreno formation in type area of Moreno.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 130–134 [preprint 1941]; 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 472. In 1915 term Panoche was introduced for Cretaceous along west side of San Joaquin Valley north of Coalinga. Later work has shown that Panoche, as mapped at that time, includes Knoxville, Paskenta, and Horsetown and extends across several disconformities. Recently term Chico series has been used to include all Upper Cretaceous and Panoche as upper group of series. This usage is unfortunate because it makes the Chico include beds separated by a disconformity which locally becomes pronounced unconformity. Two group names proposed: Pacheco below and Asuncion above, the two separated by Santa Lucian orogeny. As originally defined and mapped, Panoche formation includes not only a part of present Asuncion group and all of Pacheco group but also Shasta and Knoxville. Use of Panoche as group name would cause confusion. Panoche formation should be used for sediments, chiefly sandstones above the Pacheco and below the Moreno.

F. M. Anderson, 1943, California Div. Mines Bull. 118, p. 185–186 [preprint 1941]. Panoche group, Chico series, subdivided into (ascending) Yolo, Butte, Joaquin, and Los Gatos faunal stages.

I. F. Wilson, 1943, California Jour. Geology and Mines, v. 39, no. 2, p. 199–204, 226 (fig. 5). Group, in San Benito quadrangle, exposed on both limbs of Butts Ranch syncline for distance of about 9 miles. The two belts continue to southeast beyond limits of quadrangle and are overlapped to northwest by San Benito gravels. To the southwest, belt is 7,000 to 9,000 feet thick; northeast, belt is 5,000 to 6,000 feet. A separate mass of Panoche beds, with exposed thickness of more than 4,000 feet, occurs in northwest part of quadrangle, in Browns Valley region, where it is in fault contact with the Franciscan to north and Eocene Los Muertos Creek formation (new) to south. On northeast side of Butts Ranch syncline, divided into (ascending) Paynes shale and sandstone, Call sandstone, and Butts Ranch shale members (all new); on southwest limb, divided into (ascending) Paynes shale and sandstone, Call sandstone, and Big Oak Flat shale and sandstone (new) members. On northeast flank of Butts Ranch syncline, group is in contact with Franciscan; this contact is a fault as far east as Chemise Ridge, but east of that point appears to be depositional; on southwest side of syncline, group rests on Knoxville and Paskenta formations. Underlies Moreno shale.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2). Correlation chart shows that Panoche group, Coalinga-Ortigalito area, comprises (ascending) Curry Mountain shale, Long Canyon sandstone, lower Waltham shale, Juniper Ridge sandstone, upper Waltham shale, Los Gatos sandstone, Alcade shale, Joaquin Ridge sandstone, Ragged Valley shale, and Brown Mountain sandstone.

Ralph Stewart, 1946, U.S. Geol. Survey Prof. Paper 205–C, p. 85–88, pl. 9. Formation. in Reef Ridge area, Coalinga district, is 7,000 feet thick; unconformably overlies Franciscan formation and unconformably underlies Avenal sandstone.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 16 (fig. 2), 24–31. Formation was first mapped across northern part of Tesla quadrangle by

Anderson and Pack. They recognized that formation, as they mapped it locally, included strata of Lower Cretaceous age (Horsetown of this report), which by more detailed mapping could be differentiated from Panoche proper. In recent years, there has been tendency to divide Panoche into different formations or establish new limits for it. Except for differentiation of Horsetown beds, the sense in which Panoche was orignally mapped in this area is retained in this report. Maximum thickness about 10,000 feet. Formation is in fault contact with Franciscan and Horsetown formations; overlain gradationally by Moreno Grande formation (new); overlain unconformably by Oursan(?), Cierbo, and Neroly formations and by Livermore gravels.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 12 (fig. 2), 24–32, pls. 1, 2, 3. Formation described in Ortigalita Peak quadrangle where it is most widespread formation unit of map area and underlies about 100 square miles of area mapped. Maximum thickness measured 30,000 feet. East of Ortigalita Peak, overlies Wisenor formation (new) with angular discordance. Elsewhere, Upper Cretaceous sediments are in fault contact with Franciscan formation or contact is obscured by Quaternary deposits. Contact with overlying Moreno formation is gradational. Taliaferro and Anderson proposed divisions of Panoche group wherein Anderson's Pioneer group is approximately the equivalent of Taliaferro's Pacheco group and Anderson's Panoche and Moreno groups are inclusive of Taliaferro's Asuncion group. In present report, both the Pacheco and Asuncion groups of Taliaferro or Pioneer and Panoche groups of Anderson are represented though they have not been satisfactorily separated.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec., Guidebook Spring Field Trip, Apr. 15–16, p. 4, 5 (fig. 3), 6 (fig. 4), 6 (fig. 5), 13 (fig. 6). Panoche group, in type area, subdivided into (ascending) Redil shale, Benito sandstone, Ciervo shale, Marlife shale, Television sandstone, and Uhalde sandstone and shale members (all new). In fault contact with underlying Franciscan; underlies Moreno shale.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull., v. 71, no. 10, chart 10e (column 15). Includes Center Peak conglomerate member (new) at base.

Named for development in Panoche Hills, Fresno County.

## Panola Formation[1]

Silurian and Devonian: Central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 2.

Named for Panola, Madison County.

## Panola Granite

Age not given: Northwestern Georgia.

L. A. Herrmann, 1954, Georgia Geol. Survey Bull. 61, p. 85. Shows no visible structure but has pronounced porphyritic texture formed by small phenocrysts of microcline. Unlike Stone Mountain granite or Lithonia gneiss in structure, texture and composition.

Located near southeastern part corner of DeKalb County where it forms a small prominence known as Hog Mountain south of Panola. Of limited areal extent.

**Pansy Lee Conglomerate**

Upper Cretaceous or Tertiary, lower: Northwestern Nevada.

Ronald Willden, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2381 (table 1), 2391–2394. Basal unit, poorly sorted pebble to boulder conglomerate with about one-half to two-thirds of clastics being exotic chert and quartzite, and remaining one-half to one-third locally derived. Conglomerate becomes better sorted upward and amount of locally derived material decreases. Coarse-grained sandstone interbedded with pebble conglomerate through most of section. Chert clasts light to dark gray, green, and a few red or reddish brown. Quartzite clasts dark gray to almost white, well sorted, fine to medium grained, and clean. Thickness 200 to 500 feet. Underlies assorted unnamed volcanic and sedimentary rocks; unconformably overlies King Lear formation (new).

Type locality: In sec. 1, T. 36 N., R. 36 E., and sec. 6, T. 36 N., R. 37 E., just north of Pansy Lee mine on north side of low hills between Blue Mountain and Winnemucca Mountain about 10 miles northwest of Winnemucca. Also exposed in Jackson Mountains on northeast flank of King Lear Peak and on east side of south end of Trout Creek Spur.

Pantano Formation

Miocene, lower: Central southern Arizona.

R. E. King, 1939, Geol. Soc. America Bull., v. 50, no. 11, p. 1692. Incidental mention as a conglomerate, the Pantano, near Tuscon. Age not stated. Name credited to C. F. Tolman (unpub. ms.).

D. J. Brennan, 1957, Dissert. Abs., v. 17, no. 7, p. 1533. Consists of 13,762 feet of conglomerate, sandstone, and mudstone, with three andesite flows intercalated with the sediments. Underlies younger sediments and thrust block of older rocks. Probably lower Miocene.

P. A. Wood, 1959, Arizona Geol. Soc. Guidebook 2, p. 59. Probably equivalent to Mineta beds which are in part lower Miocene.

At Cienega Gap, Pima County.

Pantera Trachyte (in Garren Group)

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Hard brownish-gray nonvesiculary andesine trachyte porphyry. No complete section exposed. Thickness about 350 feet in vicinity of type section. Overlies Hogeye tuff; disconformably underlies Moon trachyte.

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Quad. Map 23. Traced from type section in Wylie Mountains through the Van Horns and into northern Sierra Vieja; crops out west of Green River along eastern flank of Indio Mountains. Pinches out in center of Colquitt syncline. About 40 feet of Pantera intercalated with Chambers tuff in northern Sierra Vieja. Underlies Hogeye tuff.

Type section: South face of Pantera Peak, Wylie Mountains area, Culberson County.

Panther Conglomerate or Sandstone (in Pottsville Group)[1]

Panther Sandstone (in New River Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 185.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 97. Massive conglomeratic sandstone included in the New River group.

Exposed at Panther, McDowell County.

**Panther Tongue** (of Star Point Sandstone)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: F. R. Clark, 1928, U.S. Geol. Survey Bull. 793.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 180 (fig. 2). Underlies Storrs tongue of Star Point sandstone and separated from it by tongue of Mancos shale; overlies Masuk tongue of Mancos shale. A conspicuous cliff former at Helper. Can be traced from front of Wasatch Plateau, where it is 125 feet thick, to short distance east of Soldier Canyon, where it disappears in Mancos shale.

Exposed in Panther Canyon, southeast of Castlegate, Carbon County.

**Panther Canyon Formation**

Middle Triassic: North-central Nevada.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]; 1951, Geology of the Mount Moses quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–12]. Red shale, sandstone, conglomerate, and impure pink dolomite, weathering rusty brown. Total thickness about 700 feet in Mount Moses quadrangle. Thickness at type locality 300 feet; elsewhere, thins to 100 feet. Underlies Augusta Mountain formation; overlies China Mountain formation (new).

Type locality: Head of Panther Canyon, between Grass and Pumpernickel Valleys, Winnemucca quadrangle.

†Panther Creek Limestone Member (of Ochelata Formation)[1]

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: P. V. Roundy, K. C. Heald, and G. B. Richardson, 1922, U.S. Geol. Survey Bull. 686–Z, p. 397, pl. 55.

M. C. Oakes, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 728; 1940, Oklahoma Acad. Sci. Proc., v. 20, p. 105. Abandoned; identical with Birch Creek limestone.

Named for Panther Creek in southwest part of T. 26 N., R. 12 E., Osage County, where it is well exposed along valley rim to east and west.

Panther Mountain Shale and Sandstone[1]

Middle Devonian: Eastern New York.

Original reference: G. A. Cooper, 1933, Am. Jour. Sci., 5th, v. 26, p. 544, 550.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Panther Mountain sandstone shown on correlation chart below Portland Point limestone and extending downward to Solsville sandstone in some areas and to base of Otsego shale and sandstone in other areas. Middle Devonian.

Type section: In face of Panther Mountain, Hamilton County, along towpath about ½ mile south of Fultonham and up Panther Creek to its head, where the Portland Point is exposed on property of T. Wayman, 3½ miles east of Summit.

Panther Seep Formation

Pennsylvanian (Virgilian) : South-central New Mexico.

F. M. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 7 (table 2), 9 (fig. 3), 42–47, pl. 1. Silty brown shales, dark carbonaceous shales, dark argillaceous limestones, massive biostromal limestones, silty calcarenites, and silty calcareous sandstones; near Ash Canyon, two gypsum beds in upper part; near Rhodes and Hembrillo Canyon, numerous biohermal reefs. Thicknesses: 800 feet, Mocking Bird Gap; 1,458 feet, Rhodes Canyon; 1,825 feet, Hembrillo Canyon; and 2,390 feet, Ash Canyon. Underlies Bursum formation and locally Hueco formation; overlies unnamed sediments of Missourian age. Correlative to most of Holder formation of Sacramento Mountains, to upper part of Bar B formation of Caballo Mountains, and to Keller and Fresnal groups as measured by Thompson (1942) in Oscura, Mud Springs, and Robledo Mountains.

Type section: In or near Rhodes Canyon. Also well exposed in Bearden Canyon. Panther Seep is in Bearden Canyon, 4.1 miles from mouth of canyon where latter joins Rhodes Canyon, San Andres Mountains. Can be mapped from Mockingbird Gap to southern end of San Andres Mountains; upper part exposed in Franklin Mountains.

**Paola Limestone Member** (of Iola Limestone)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., Guidebook, p. 92, 97.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 68–69. Member, in Oklahoma, is 3 to 5 feet of massive calcareous sandstone and comprises three lenticular phases, which grade into each other, both laterally and vertically. Basal member of Iola; underlies Muncie Creek shale member; overlies Chanute formation.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 12, 13. Basal member of Iola formation as redefined for Missouri. Missouri Geological Survey had included Paola in Chanute formation.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Basal member of Iola. A light-gray sublithographic massive limestone with shale partings; fossiliferous. Thickness about 1 foot. Underlies Muncie Creek shale member; overlies Chanute shale.

Named for Paola, Miami County, Kans.

**Paoli Limestone**[1]

Paoli Limestone (in Blue River Group)

Paoli Member (of Renault Formation)

Upper Mississippian: Southern Indiana and central northern Kentucky.

Original reference: M. N. Elrod, 1899, Indiana Acad. Sci. Proc. 1898, p. 258–267.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 825; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 76). Considered member of Renault formation in Indiana.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Michigan, The Edwards Letter Shop, p. 7, 12. Renault formation of standard Chester column has triple expression in southern Indiana (ascending): Paoli limestone, Mooretown sandstone, and Beaver Bend limestone. Each of these is a distinct stratigraphic unit in parity with other formations of the Chester and deserves a name in its own right. Paoli limestone rests on Aux Vases sandstone or directly on Bryantsville breccia at top of Ste. Genevieve; underlies Mooretown shale or sandstone. Present from Ohio River to about 5 miles northwest of Greencastle, Putnam County, where it is cut off and overlapped by Pennsylvanian Mansfield sandstone.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 23, pl. 1. Thickness of Paoli limestone in Indiana 2¼ to 39 feet. Commonly light-gray, gray, tan, or light-brown dense finely granular semioolitic limestone with some crystalline beds; gray or greenish-gray calcareous shale occurs in middle of formation. Overlies Aux Vases formation; underlies Mooretown sandstone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 49–50, pl. 1. Uppermost formation in Blue River group (new). Redefined to include unit formerly known as Aux Vases formation in Indiana, and term Aux Vases is rejected in Indiana. Thickness (as redefined) 29 to 38 feet. Overlies Ste. Genevieve limestone; underlies Bethel formation of West Baden group (redefined).

Named for Paoli, Orange County, Ind.

Paoli Limestone[1]

Pennsylvanian: Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

*See* **Paola Limestone Member** (of Iola Limestone) correct spelling.

**Paonia Shale Member** (of Mesaverde Formation)[1]

Upper Cretaceous: Central western Colorado.

Original reference: W. T. Lee, 1909, U.S. Geol. Survey Bull. 341, p. 320 (table), 323.

E. C. Dapples, 1939, Econ. Geology, v. 34, no. 4, p. 371. In Anthracite-Crested Butte quadrangle, sequence of Mesaverde formation is (ascending) Baldwin sandstone (new), Rollins shale, Paonia shale, and Upper Mesaverde members.

Named for Paonia, Delta County.

Papanatas Conglomerate Member (of Redil Formation)

Upper Cretaceous: Central California.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec., Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Red boulder conglomerate 0 to 950 feet thick at base of Redil formation (new). In fault contact with Franciscan. Name credited to D. W. Sutton (unpub. thesis).

Type locality: Papanatas Canyon, secs. 23 and 24, T. 14 S., R. 10 E., Fresno County. Name derived from Papanatas Canyon.

Papatele Trachyte

Pleistocene(?): Samoa Islands (Tutuila).

R. A. Daly, 1924, Carnegie Inst. Washington Pub. 340, p. 106–108, 129–130. Small body of trachyte, probably volcanic neck, perhaps communicating with pipe through which Pioa trachyte welled up to fill main crater. Pioa rhyolite, Matafafao, Papatele, Afono, and Vatia trachytes were erupted contemporaneously or nearly so.

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285–1286 (table 1), 1302. Papatele trachyte plug is associated with Pago volcanics (new). Pliocene and early Pleistocene(?).

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 189. Pleistocene(?).

Crops out in Papatele summit, about 0.05 mile southeast of Pioa Peak, east of Pago Pago Bay. Covers about 0.02 square mile at Papatele Peak.

Papel Blanco Shale (in Puente Formation)

Miocene, upper: Southern California.

M. L. Krueger, 1943, California Div. Mines Bull. 118, p. 363. Shown on structure section as underlying Blanco sandstone (new) and overlying middle Puente(?).

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 521. Platy siliceous shale with some chert. Thickness about 330 feet. Upper part of Puente. Measured section noted.

Exposed in Slaughter Canyon, in southeastern Puente Hills between Chino and the Santa Ana River, San Bernardino County.

Paperville Formation

Middle Ordovician (Mohawkian): Northeastern Tennessee, northern Georgia, and western Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 82–83, chart 1 (facing p. 130). Thick succession of gray siltstones, black graptolitic shales and interbedded black limestones, and brown-weathering calcareous sandstones which were mapped as Athens in southeastern belts of Appalachian Valley in Tennessee. Beds form lower division of a buff-weathering shale-siltstone-sandstone succession totaling several thousand feet in thickness and overlying thin Fetzer formation [Fetzer tongue]. Underlies sandstones of "Tellico" formation. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: Along Steele Creek, near Paperville, for which it is named, near Bristol, Bristol (T.V.A. 206–SW) quadrangle, Tennessee.

Papoose Volcanics

Tertiary: Northwestern Wyoming.

R. D. Krushensky, 1960, Dissert. Abs., v. 21, no. 4, p. 849. Consist chiefly of water-laid volcanic sandstones and conglomerates and some volcanic breccias. Oldest of five layered volcanic units in area. Underlie Squaw flows (new).

Hurricane Mesa area, Park County.

†Parachucla Marl[1] or Shale[1]

Miocene, lower: Southern Georgia and southwestern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 15–16, 18; 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 435, 464, 466.

Named for exposures along Savannah River in vicinity of Parachucla, a locality in southeastern Georgia.

**Parachute Creek Member** (of Green River Formation)[1]

Eocene: Northwestern Colorado and northeastern Utah.

Original reference: W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168.

D. C. Duncan and N. M. Denson, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 94. Described in Garfield County, Colo., where it is essentially black-brown and gray marlstone including oil shale units; some beds of altered tuff, analcite, and chert; tongues of sandstone near base. Thickness 700 to 1,230 feet. Underlies Evacuation Creek member; overlies Garden Gulch member. Parachute Creek, Garden Gulch, and Douglas Creek members interfinger with a unit referred to as lower sandy member of Green River. Eocene.

M. D. Williams, 1950, Utah Geol. Soc. Guidebook 5, p. 102, 108. Member typical only of Piceance Creek basin of western Colorado and extreme eastern part of Uinta Basin. Age of Green River given as Middle Eocene.

J. R. Donnell, 1953, Rocky Mountain Assoc. Geologists Guidebook Field Conf. May 14, 15, and 16, chart (facing p. 16). Overlies Anvil Points member (new) and underlies Evacuation Creek member in area between Rifle and De Beque Canyon, Colo. Thickness about 1,125 feet.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 407–413. Described in Duchesne, Uintah, and Wasatch Counties, Utah. Most widespread, distinctive, and continuous phase of Green River formation of Colorado and Utah. Phase extends uninterruptedly from vicinity of summit of Wasatch Range in central Utah eastward across the Green River to Evacuation Creek area near Utah-Colorado State line. As herein extended, characteristically contains thin extensive beds of oil shale and ranges in thickness from 435 to 500 feet. Underlies Evacuation Creek member.

W. B. Cashion and J. H. Brown, Jr., 1956, U.S. Geol. Survey Oil and Gas Inv. Map OM–153. In Bonanza-Dragon oil-shale area, Uintah County, Utah, and Rio Blanco County, Colo., the Parachute Creek member overlies Douglas Creek member in part of the area and Garden Gulch member elsewhere. Thickness 360 to 735 feet.

Named for exposures in vicinity of Parachute Creek, Garfield County, Colo.

Paradise Conglomerate[1]

Carboniferous: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 295–298.

Forms east side of Eastons Point terminating northward at Sachuest Beach near Newport, Newport County, and farther north forms Paradise Rocks.

Paradise Formation[1]

Upper Mississippian: Southeastern Arizona and southwestern New Mexico.

Original reference: A. A. Stoyanow, 1926, Am. Jour. Sci., 5th, v. 12, p. 316–320.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 29–30, pl. 1. Mapped in Peloncillo Mountains of southwestern New Mexico. In Big Hatchet Mountains and in Chiricahua Mountains, upper part of formation consists of continental deposits, but in Peloncillo Mountains no evidence of continental beds observed.

Originally described from occurrence on east face of Chiricahua Mountains, not far from Paradise, an abandoned mining camp 45 miles northeast of Bisbee, Ariz., and 10 miles west of New Mexico line.

†Paradise Limestone[1]

Silurian (Niagaran) : Northeastern Utah.

Original reference: E. Blackwelder, 1910, Geol. Soc. America Bull., v. 21, p. 517–542.

Northern Wasatch Mountains.

Paradise Spring Complex

Upper Paleozoic(?) : Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 504, 531–532. Mentioned in discussion of age of Hinckley Valley complex. Paradise Spring contains crinoidal segments of presumably Late Paleozoic age.

Type locality and derivation of name not given. Area discussed is Barstow quadrangle.

**Paradox Formation**[1]

**Paradox Member** (of Hermosa Formation)

Paradox Formation (in Hermosa Group)

Middle Pennsylvanian: Western Colorado and southeastern Utah.

Original reference: A. A. Baker, 1933, U.S. Geol. Survey Bull. 841.

N. W. Bass, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 7, accompanied by paper on Paleozoic stratigraphy as revealed by deep wells in parts of southwestern Colorado, northwestern New Mexico, northeastern Arizona, and southeastern Utah. Rank reduced to member of Hermosa formation. Overlies and underlies unnamed parts of formation. On basis of fusulinids, believed to be Lampasas and Des Moines in age.

S. A. Wengerd and J. W. Strickland, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2169–2173. In this report [stratigraphy of Paradox Salt basin], the Paradox is termed a formation. Comprises three unnamed members: lower member, 0 to 200 feet, is predominantly anhydrite, gypsum, black shale, and minor dolomite; middle member, chiefly Paradox salt; and upper member, 200 to 500 feet, black silty calcareous shale, grayish-brown finely crystalline argillaceous dolomite, white anhydrite, gray to white finely crystalline gypsum, and brown argillaceous fine-grained limestone. Maximum depositional thickness probably not over 5,000 feet; present thickness in anticlines ruptured by salt flowage may exceed 12,000 feet. Overlies Pinkerton Trail limestone (new) ; underlies Hermosa formation. Results of study prove Paradox to be entirely of Cherokee age.

George Herman and C. A. Barkell, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 5, p. 867–872. Member, as used in this paper [stratigraphy and productive zones in Paradox Salt basin], includes not only the complex evaporitic sequences with minor carbonate and black shale interbeds but also overlying, underlying, and adjacent carbonates deposited in a restricted marine environment. Lies entirely within Hermosa formation and its equivalents, horizontally interfingering with and vertically grading into open marine sediments. Member is evaporite megacyclothem composed of discrete sedimentary sequences which are complete or partial cyclothems. Contact with lower (unnamed) Hermosa member gradational, the separation being made where open marine carbonates are overlain by either evaporites or carbonates deposited in a penesaline environment; underlies an upper Hermosa member.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2055 (fig. 3), 2056, 2065–2075. Formation in Hermosa group. Divisible into three mappable members. Lower member is penesaline complex of buff arkosic granulite, greenish-gray sandy siltstone overlain by gypsum along edge of San Luis uplift; interbedded black shale, dark-gray siltstone, gypsum, and dolomite in central part and along southwest shelves of Paradox basin; and dark-gray shales, gray porous dolomite, and gray cherty limestone higher on southwest Paradox sedimentational shelf. Middle member, or "salt member," grades shelfward into penesaline gypsum, anhydrite, and dolomite, and biohermal-biostromal dolomitic limestones. Upper member, similar to lower member, grades from penesaline strata shelfward into biostromal-biohermal dolomitic limestone, gray shale, and silty dolomite. Depositional thickness more than 4,000 feet along axis of Paradox basin. Underlies Honaker Trail formation, name introduced to replace previously used phrase upper Hermosa. Results of this study establish existence of important datum (the "P" datum), which is top of Paradox formation and, over great part of Four Corners region, is a disconformity which marks end of Paradox penesaline deposition and is mappable surface critical in evaluation of sedimentational and structural history of Paradox geosyncline.

N. W. Bass, 1958, Rocky Mountain Assoc. Petroleum Geologists Symposium on Pennsylvanian rocks of Colorado and adjacent areas, p. 92, 93. In southern half of White River uplift, Colorado, name Paradox formation is applied to sequence 1,500 to 1,900(?) feet thick, that is dominated by thick beds of gypsum and interbedded black shale and underlies redbeds of Maroon formation. Overlies Belden formation.

E. M. Shoemaker and W. L. Newman, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1843, 1845. Tenderfoot member (new) of Moenkopi overlies Cutler formation and, locally, Paradox member of Hermosa formation with angular unconformity. In Sinbad Valley and Fisher Valley, Ali Baba member (new) of Moenkopi overlies the Paradox.

Type locality: Paradox Valley, Montrose County, Colo.

Parashant Tongue (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 98–99. Consists chiefly of fine- and uniform-grained dolomite which appears steely gray on fresh surfaces and weathers rusty brown. Usually contains much glauconitic and ferruginous material both as disseminated grains and in lenses. Strongly cross-laminated at Toroweap. Average thickness about 10 feet. Older than Boucher tongue (new); younger than Lava Falls tongue (new).

Thin but persistent and conspicuous unit in Cambrian sequence of Grand Canyon, extending from vicinity of Granite Park eastward at least as far as Toroweap.

Parguera Limestone (in Mayagüez Group)

Upper Cretaceous: Southwestern Puerto Rico.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 199; 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 329–331, 333–335, pl. 1. Buff to gray medium-bedded calcilutite and medium-bedded to massive fragmental limestone (microcoquina) with less than 15 percent tuff and a slightly smaller amount of calcarenite. Słodowski (1956, unpub. thesis) described the Parguera as part of Ensenada formation. Mitchell (1922) described exposures at Ensenada as Ensenada shale, his term for medium-bedded calcareous material. Unit redefined because Ensenada formation of Slodowski includes limestones and volcanic rocks here placed in San Germán formation. In southern structures the Parguera lies probably conformably on Río Loco formation, or where that is absent, unconformably on Bermeja complex (new). Where top is exposed, probably disconformably overlain by Melones limestone (new).

Type area: Range of hills north of fishing village of La Parguera, Mayagüez area.

**Pariott Member** (of Moenkopi Formation)

Middle(?) Triassic: Southwestern Colorado and southwestern Utah.

E. M. Shoemaker and W. L. Newman, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1838–1839, 1842, 1847–1848. Consists of red-brown to purplish-brown sandstone and chocolate-brown, orange, and red mudstone, siltstone, and shale. Thickness at type section 134 feet; 252 feet in Sinbad Valley, Colo.; thickens abruptly toward the west and is several hundred feet thick where it dips beneath the surface beyond northwest end of Castle Valley, Utah, where it is overlain by a lens of gray silty conglomeratic sandstone assigned by Baker (1933, U.S. Geol. Survey Bull. 841) to Shinarump conglomerate and by Dane (1935, U.S. Geol. Survey Bull. 863) to Chinle formation. Overlies Sewemup member (new); unconformably underlies Chinle formation and in some areas truncated by it.

Type section: South side of Pariott Mesa, sec. 5, T. 25 N., R. 23 E., Grand County, Utah.

Paris Formation[1]

Middle Ordovician: Central Kentucky.

Original reference: J. M. Nickles, 1905, Kentucky Geol. Survey Bull. 5, p. 15.

Named for Paris, Bourbon County.

†Paris Shale[1]

Pennsylvanian (Allegheny): Western Arkansas.

Original reference: A. J. Collier, 1907, U.S. Geol. Survey Bull. 326, p. 12, 20–21, map.

Named for Paris, Logan County.

Parita Formation[1]

Recent(?): Panamá.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 263.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat. v. 5, Amérique Latine, fasc. 2a, p. 342. Poorly defined name for surficial deposits. Recent age implied. Note on derivation of name.

Present in Coclé Province. Hershey mentioned head of Bay of Parita. There is also town of Parita, 10 kilometers northwest of Chitré.

Park Granite[1]

Tertiary: Central northern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

Occurs on northern spurs of Park Mountain, British Columbia or Washington.

Park sandstone[1]

Carboniferous: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 37.

Derivation of name not stated.

**Park Shale[1] or Argillite**

Park Shale (in Gros Ventre Group)

Park Shale Member (of Gros Ventre Formation)

Middle Cambrian: Western Montana and northwestern Wyoming.

Original references: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55; Folio 56; 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 286.

Charles Deiss, 1936, Geol. Soc. America Bull., v. 47, no. 8, p. 1281, 1332–1333. Park shale, as herein emended, lies between Meagher limestone below and Pilgrim limestone above (both emended). Thickness at emended type section, 212 feet, base not exposed; maximum thickness (estimated) 330 feet on Keegan Butte, Little Belt Mountains. Dominantly green-gray, extremely fissile, nearly unfossiliferous, slightly micaceous shale. Weed did not designate type section. [See Flathead Quartzite].

Erling Dorf and Christina Lochman, 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 548. In southern Montana, underlies Maurice formation (new).

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2143–2144. Shaly beds resting conformably and transitionally on Meagher limestone in southwestern Montana are assigned to Park shale named by Weed from Little Belt Mountains and emended by Deiss (1936). Thickness 125 feet on north flank of Arrowhead Mountain, Centennial Range. Underlies Hasmark formation.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. Considered uppermost formation in Gros Ventre group. Overlies Death Canyon limestone; underlies Du Noir limestone of Gallatin group.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 12 (table 1), 13. Park shale considered member of Gros Ventre formation. Overlies Death Canyon limestone member; underlies Boysen limestone. Thicknesses: 121 feet, Gros Ventre Range; 108 feet, Teton Range; 158½ feet, Snake River Range.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 10, pls. 1, 2, 3. Five lowest natural Cambrian map units in southern Elkhorn Mountains, Mont., are lithologically similar to Flathead sandstone, Wolsey shale, Meagher limestone, Park shale, and Pilgrim dolomite of nearby areas, as redefined by Deiss (1936). These formational names have been adopted. Thickness 215 feet, exclusive of andesite sills. Underlies Pilgrim dolomite; overlies Meagher limestone.

Type section (emended): On north side of Dry Wolf Creek, on eastern side of Little Belt Mountains. Emended section measured on spur east of eastern small unnamed creek which heads on Big Baldy Mountain and north of Dry Wolf Creek; locality lies in sec. 14, T. 14 N., R. 9 E. Name Big Park, referred to by Weed, is unknown to present inhabitants of Dry Creek valley, Montana.

**Park City Formation[1] or Group**

Permian: Northeastern Utah, northwestern Colorado, eastern Idaho, southwestern Montana, and central and eastern Wyoming.

Original reference: J. M. Boutwell, 1907, Jour. Geology, v. 15, p. 439–458.

A. A. Baker and J. S. Williams, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 623 (fig. 4), 624–625. In Diamond Fork area, Utah, overlies Diamond Creek formation (new); underlies Woodside shale.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 477. Unconformably underlies Red Wash formation (new).

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2840–2844. At type locality, formation consists of upper member (Franson, new), and lower members, composed mainly of carbonate rock, separated by Meade Peak phosphatic shale tongue of Phosphoria. Tongues of formation extend into eastern Idaho, southwestern Montana, central and eastern Wyoming, and northwestern Colorado. Lower member defined as the interbedded carbonate rock, cherty carbonate rock, carbonatic sandstone, and carbonatic siltstone that overlie Weber quartzite in Utah, Wells formation (as restricted in this report) in Idaho, Tensleep sandstone in Wyoming, and Quadrant quartzite in Montana and that underlies Meade Peak tongue of Phosphoria. Beds that Thomas (1934) called Phosphoria in Wind River Mountains are herein designated as Park City, and Ervay tongue is considered member of Park City. Intertongues with Shedhorn sandstone (new).

T. M. Cheney and others *in* V. E. McKelvey and others, 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 12–15. Unit referred to as "lower member" is here named Grandeur member; not well exposed in type section of Park City.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2178. Rank raised to group in Confusion Range. Includes (ascending) Kaibab limestone, Plympton formation (new), and Gerster limestone. Overlies Arcturus formation; underlies Thaynes formation. Group considered correlative with Park City formation in other areas.

Named for Park City district, Utah.

Park City Volcanics

Oligocene, lower: North-central Utah.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 846; 1955, Utah Geol. Soc. Guidebook 10, p. 38, fig. 9. Chiefly andesitic. Norwood tuff (new) is fluviatile and lacustrine facies.

Present in Morgan Valley.

Park Creek Limestone Member (of Lykins Formation)

Permo-Triassic: Northern Colorado and eastern Wyoming.

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Underlies Red Hill shale member (new) ; overlies Stonewall Creek shale member (new).

Extends northward beyond Horse Creek, Wyo., and as far south as Lykins Gulch, Colo.

Parker Formation[1]

Parker Limestone (in McLeansboro Group)

Parker Limestone (in Wabash Formation)

Pennsylvanian : Southeastern Illinois and southwestern Indiana.

Original reference: M. M. Fidlar, 1933, Indiana Acad. Sci. Proc., v. 42, p. 137, 139.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 25). Shown on correlation chart as limestone near base of Wabash formation.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2). Shown on correlation chart as limestone in McLeansboro group.

May or may not be same unit referred to as Parkers Formation by Malott 1947.

First described in Knox County, Ind.

Parker Quartz Diorite[1]

Upper Jurassic(?) : Southern California.

Original reference: W. J. Miller, 1934, Univ. California at Los Angeles, Pub. in Math. and Phys. Sci., v. 1, no. 1, p 37–65, 83, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p 517, table 4 Listed under late Mesozoic intrusives.

Typical occurrence in Parker Mountain, west of Acton, San Gabriel Mountains.

**Parker Slate**[1]

Parker Shale

Lower Cambrian : Northwestern Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 371.

C. E. Resser and B. F. Howell, 1938, Geol. Soc. America Bull., v. 49, no. 2, p. 202–203. Unit termed a shale.

A. B. Shaw, 1954, Geol. Soc. America Bull., v. 65, no. 11, p. 1038–1044, 1045. Lower and Middle Cambrian.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1136, 1151. In Oak Hill sequence, northwestern Vermont, the Parker slate, 25 to 100 feet thick, overlies Dunham dolomite and underlies Rugg Brook formation. Lower Cambrian. Unit herein designated Parker slate is the Oak Hill slate of Clark (1934, Geol. Soc. America Bull., v. 45, no. 1).

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 528–531, pl. 1. Parker slate described in St. Albans area. Thickness about 250 feet in southwestern part of area where it is poorly exposed; thickens to maximum of 1,000 to 1,200 feet north of Fonda quarry. Overlies Dunham dolomite with erosional unconformity; underlies Rugg Brook dolomite. Lower and Middle Cambrian. Unit might properly be called Georgia slates, for Walcott's (1886, U.S. Geol. Survey Bull. 30) original Georgia shales began at Parker's ledge, the type locality of Parker slate, but older name has not been retained because of its confused history.

Named for exposures on old Parker farm and around sides of Parker Cobble, 2 miles northwest of Georgia Center, Milton quadrangle, Franklin County.

Parker Hill Sandstone Member (of Stanley Shale)

Pennsylvanian: Southwestern Arkansas.

N. H. Stearn *in* J. M. Hansell and J. C. Reed, 1935, Am. Inst. Mining and Metall. Engineers Trans., v. 115, p. 245. Name applied to a sandy zone about 175 feet thick, that occurs about 700 feet stratigraphically below the Gap Ridge member (new).

N. H. Stearn, 1936, Econ. Geology, v. 31, no. 1, p. 4 (fig. 2), 15–16. Thickness about 200 feet. Beds vertical. Pennsylvanian.

Named from Parker Hill mine, an important mining development in that horizon. Mine is in SE¼SW¼ sec. 1, T. 7 S., R. 26 W., Pike County.

Parker Hill Schist[1]

Pre-Devonian(?): Northwestern New Hampshire.

Original reference: F. H. Lahee, 1916, Jour. Geology, v. 24, p. 366–381.

Probably named for the Parker Hill in northwest corner of Moosilauke quadrangle.

Parkers Formation

Upper Pennsylvanian: Southwestern Indiana.

C. A. Malott, 1947, Indiana Acad. Sci. Proc., v. 57, p. 131–132, 133 (fig. 2), 138. Consists chiefly of shales with thin sandy beds near base, two thin coals with one near the top capped by a black sheety shale; this upper coal is the Parkers coal. Contains Rabens Branch bed (new) about 20 feet below Parkers coal and black sheety shale. Thickness 25 to 30 feet. Overlies Dicksburg Hills sandstone; underlies St. Wendells sandstone. Name is a variation of the name Parker, used for the coal, black sheety shale, and limestone of upper part of the formation by Fuller and Clapp (1904) in Patoka folio of the U.S. Geological Survey.

Name derived from Parkers Settlement in eastern Posey County, about 8 miles northwest of Evansville on State Road 66.

**Parkhead Sandstone Member** (of Jennings Formation)[1]

Parkhead Sandstone (in Portage Group)

Upper Devonian: Western Maryland, central Pennsylvania, and northeastern West Virginia.

Original reference: G. W. Stose and C. K. Swartz, 1912, U.S. Geol. Survey Geol. Atlas, Folio 179.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 16. Geographically extended into south-central Pennsylvania where it is referred to as Parkhead sandstone at top of Portage group. Occurs above Trimmers Rock sandstone.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 91. In Washington County, Md., consists of shale interbedded with massive conglomeratic sandstone; commonly three conglomerate horizons in east—at base, in middle, and near top; lower sandstone is highly fossiliferous, and upper one very massive near Parkhead; toward the west, sandstones grade laterally into shales that can scarcely be distinguished from overlying Woodmont shale; underlies Chemung sandstone.

Named from exposures at Parkhead Station, Washington County, Md.

**Parkman Sandstone** (in Montana Group)

**Parkman Sandstone Member** (of Claggett Formation)

**Parkman Sandstone Member** (of Judith River Formation)

**Parkman Sandstone Member**[1] (of Mesaverde Formation)

Upper Cretaceous: Northern Wyoming and southern Montana.

Original reference: N. H. Darton, 1906, U.S. Geol. Survey Prof. Paper 51, p. 13, 58.

C. H. Wegemann, 1918, U.S. Geol. Survey Bull. 670, p. 21–22. Lowermost member of Mesaverde formation. Consists of basal sandstone, 170 feet thick, a capping sandstone, 110 feet thick, and an intervening series of shale, carbonaceous shale, and coal beds, 190 feet thick. Separated from overlying Teapot sandstone member by unnamed shale interval 325 feet thick. Overlies Steele shale.

W. T. Thom, Jr., and others, 1935, U.S. Geol. Survey Bull. 856, p. 53–58, 128. At type locality, Parkman consists of conspicuous cliff-forming basal sandstone 70 feet thick, overlain in order named, by 120 feet of shale, 10 feet of white fine-grained sandstone, 75 feet of shale, and 5 feet of white sandstone. Aggregate thickness 280 feet. North of Parkman, top of sandstone is overlain by coal bed. Formation thickens northward and westward to maximum of 350 feet in northwestern part of Big Horn County, Mont. [this report], where it contains thick beds of shale. South of Crow Indian Reservation, sandstones of Parkman can be traced definitely, though not in continuous outcrop, from Parkman to Salt Creek and other localities in central Wyoming. Overlies Claggett shale; underlies Bearpaw shale. Montana group.

G. R. Downs, 1947, Wyoming Geol. Assoc. Guidebook 2d Ann. Field Conf., p. 139. Referred to as sandstone member of Claggett formation.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 63. Described in Hardin area, Montana-Wyoming, where it consists of about 250 feet of sandy shale and sandstone. Overlies Claggett shale member of Cody shale; underlies Bearpaw shale. Montana group.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 64, pl. 6. Parkman sandstone described in Johnson County, Wyo., where it is dominantly yellowish-gray sandstone, lower half of which contains large moderate-brown ellipsoidal concretions. Thickness as much as 720 feet. Overlies Cody shale; underlies Bearpaw shale. Parkman sandstone of mapped area referred to as Mesaverde formation 15 miles south of mapped area. There Mesaverde is divided into three units: Parkman sandstone member at base, unnamed member just above the middle, and Teapot sandstone member at top. The white to very light gray 8-foot sandstone at top of the Parkman in area of present report is probably equivalent to the Teapot sandstone member of Mesaverde, but lower members of Mesaverde cannot be recognized as distinct units in mapped area.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 12 (fig. 3), 14, pl. 1. Mapped in Hardin district, Montana and Wyoming, as lower member of Judith River formation. Underlies unnamed member; overlies Claggett shale member of Cody shale. Thickness about 350 feet.

J. M. Parker, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 90–102. Type Parkman was originally described as a 300- to 500-foot sandstone containing harder, darker concretions. Later work in Crow Indian Reservation (Thom and others, 1935) defined Parkman formation to include sandy unit between Bearpaw shale and Claggett shale. Type Teapot sand was also named in the basin [Powder River]. Present subsurface and outcrop control makes it possible to show that type Teapot is part of original Parkman, as first described near town of Parkman and as later defined on Crow Indian Reservation. Thus, to conform to usage in the north and west-central parts of basin and to remain with original definition, the Parkman should be treated as formation with Teapot sandstone as uppermost member and the so-called Parkman of southwest Powder River basin should be designated as lower Parkman member. Hose (1955), in surface mapping in Johnson County, Wyo., considered Teapot sandstone to be upper member of his "Parkman" formation. By using formation names Bearpaw, Parkman, Claggett, Eagle, Telegraph Creek, and Niobrara, it is possible to do away with terms Lewis, Cody, Steele, and Mesaverde in this area.

E. I. Rich, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2427–2428. Parkman sandstone member of Mesaverde formation, as used in this report, includes basal near-shore marine sandstone of the Mesaverde overlying Cody shale and underlying unnamed middle member of Mesaverde. A massive sandstone containing discontinuous shale lenses near base and top. Thickness 500 feet in southwestern part of Powder River basin; about 50 feet in southeastern part of Wind River basin.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 57–59, pls. Parkman sandstone described in Buffalo-Lake DeSmet area, Johnson and Sheridan Counties, Wyo., where it is about 720 feet thick. Grades into underlying Cody shale through transition zone as much as 150 feet thick. Underlies Bearpaw shale. Passes northward into nonmarine Judith River formation of central Montana.

Named for exposures near Parkman, Sheridan County, Wyo.

Parks Formation (in Kickapoo Creek Group)

Parks Formation (in Smithwick Group)

Parks Group

Pennsylvanian (Lampasas): North-central Texas (subsurface).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 84 (fig. 3), 86–87. Named as uppermost formation of Smithwick group. Includes limestones and sandstones that lie at depths of 3,626 to 3,820 feet in type well. Overlies Caddo Pool formation (new); underlies unnamed subsurface formations of Millsap Lake group.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 163. Rank raised to group. Typically consists of a variable sequence of dark shales, limestones, and sandstones between the black shales, gray, black and siliceous limestones of Smithwick group and an unconformity at the base of the conglomerates, sandstones, blue shales, and limestones of the Strawn series; in Brazos River outcrop section, this unconformity is placed at base of chert conglomerate overlying Dennis Bridge limestone at Dennis, Parker County. Near here, drilling indicates a thickness of about 1,600 feet for Parks group.

M. G. Cheney, 1947, Jour. Geology, v. 55, no. 3, p. 209. Kickapoo Creek group used in preference to Parks group. Parks retained as formation in Kickapoo Creek group.

Type well: Anza Oil Corp. Graham No. 1, central Young County. Named for town of Parks on Parks lease, central Stephens County.

Parks Creek Limestone (in Pottsville Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 72–73. Seville limestone was originally designated Parks Creek limestone by Savage (1927), apparently a typographical error for Barker Creek near Seville.

Derivation of name not stated but probably a creek in Fulton County.

**Parks Mountain Sandstone Member** (of Thrifty Formation)[1]

Parks Mountain Sandstone Member (of Chaffin Formation)

Upper Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 410.

Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 126–127. The member called "Parks Mountain bed" by Drake is an unconformable deposit whose base on east side of Parks Mountain south of Whon cuts out Thrifty beds to a horizon within 10 feet of *Bellerophon* limestone (Drake, 1893) and whose top on account of poor outcrops is not exactly determinable, though it is at or near top of Lohn shale as defined by Drake. Interval from top of Lohn shale to lowest observed beds of Parks Mountain deposits is 99 feet, but there is reason to believe that top of Parks Mountain member lies a short distance below top of Lohn as defined by Drake. Parks Mountain may prove to lie within limits set by Drake for Lohn shale and may be represented in Brazos River area by one of the sandstone lentils below the Blach Ranch limestone. Speck Mountain limestone is cut out by Parks Mountain sandstone at south end of Parks Mountain, and 2½ miles south of Whon almost entire Thrifty formation is missing. Underlies Chaffin limestone member.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in Chaffin formation. Thrifty group. Cisco series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 74, pl. 27. Member of Thrifty formation. Underlies Chaffin limestone member; overlies Breckenridge limestone member. Parks Mountain was termed Avis sandstone by Bullard and Cuyler (1935) because that name had been applied to the first conglomeratic sandstone bed above the Wayland shale of Plummer and Moore (1921 [1922]) in Brazos River valley and because this conglomerate holds same relation to the Wayland along the Colorado River. The Avis of Plummer and Moore has been shown by Wallace Lee and others (1938) to have originated before the Ivan limestone member [of Graham formation] was deposited, and therefore name Avis of Bullard and Cuyler cannot be correctly applied to the stratigraphically higher Parks Mountain sandstone.

Named for Parks Mountain, Waldrip quadrangle, Coleman County.

†Parkville Limestone (in Kansas City Formation)[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 51.

Named for exposures at Parkville, Platte County.

†Parkville shale[1]

Pennsylvanian: Northwestern Missouri and southwestern Iowa.

Original reference: C. R. Keyes, 1898, Am. Geologist, v. 21, p. 349.

Named for exposures at Parkville, Platte County, Mo.

**Parkwood Formation**[1]

Upper Mississippian: Northern Alabama.

Original references: C. Butts, 1910, U.S. Geol. Survey Bull. 400, p. 15, 20; 1910, U.S. Geol. Survey Geol. Atlas, Folio 175, p. 8.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 166, chart 5 (column 90). Formation, recognized only in small area in east-central Alabama, at various places overlies Pennington shale, Bangor limestone, or Floyd shale. Relations of these formations not clear; Pennington shale may grade laterally into either or both the Floyd and Parkwood; Floyd and Parkwood may also be gradational.

H. E. Rothrock, 1949, Alabama Geol. Survey Bull. 61, pt. 1, p. 18–19, fig. 2. Traced from outcrop in vicinity of Birmingham to southeast side of Shoal Creek valley. In this area, conformably overlies Floyd shale and underlies Shades sandstone member of Pottsville formation. Gray or olive-brown claystone and siltstone with fine-grained sandstone at base and tough black claystone at top. Thickness 460 feet. Mississippian.

R. B. Morton, 1949, Mississippi Geol. Soc. Guidebook 7th Field Trip, p. 37, 38, 40. Includes Little Shades sandstone (new) in basal part.

W. H. Robinson, J. B. Ivey, and G. A. Billingsley, 1953, U.S. Geol. Survey Circ. 254, p. 51. In Birmingham area, consists of about 2,000 feet of sandstone and shale, shale generally predominating.

Named for exposures at Parkwood, Jefferson County.

**Parma Sandstone**[1]

Pennsylvanian: Southern Michigan.

Original reference: A. Winchell, 1861, Michigan Geol. Survey 1st Bienn. Rept. Prog., p. 112, 138.

G. V. Cohee, Carol Macha, and Margery Holk, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–41, sheet 5. Basal formation of Pennsylvanian of Michigan. Thickness commonly less than 100 feet; attains maximum thickness of 150 feet in northeastern Clare County. Underlies Saginaw formation; overlies Bayport limestone.

Named for exposures at Parma, Jackson County.

Parmachenee Formation

Silurian (?): Central western Maine.

A. R. Cariani, 1959, Dissert. Abs., v. 19, no. 10, p. 2577. Thinly bedded gray phyllites, impure biotite quartzites, and black limestone. Contains notable amounts of pyrite and pyrrhotite. Older than Madrin formation (new); younger than Perry Mountain formation (new).

R. J. Willard, 1959, Dissert. Abs., v. 19, no. 11, p. 2918. Carbonaceous argillaceous quartz silts in Kennabago Lake quadrangle. Thickness about 2,000 feet. Silurian (?).

In Anson and Kennebago quadrangles.

**Parrish Limestone Bed** (in Cashaqua Shale Member of Sonyea Formation)

Parrish Limestone Lentil (in Cashaqua Shale[1] Member of Sonyea Formation)

Upper Devonian: West-central New York.

Original reference: J. M. Clarke and D. D. Luther, 1904, New York State Mus. Bull. 63, p. 31–32.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 12, 13. Lentil overlies Rock Stream flagstone member (new) of Cashaqua shale. Underlies Rhinestreet shale.

R. G. Sutton, 1960, New York State Mus. Bull. 380, p. 17–18, 53, 55, figs. 2, 5. Rye Point member (new) of Cashaqua formation includes red and green nodular limestone bed known as Parrish limestone lentil (Clarke and Luther, 1904).

U.S. Geological Survey currently classifies the Parrish as a bed in Cashaqua Shale Member of Sonyea Formation.

Well exposed in Parrish Gully at Parrish, Ontario County.

†Parsons Formation (in Pleasanton group)[1]

Pennsylvanian: Southeastern Kansas.

Original reference: G. I. Adams, 1903, U.S. Geol. Survey Bull. 211, p. 33.

U.S. Geological Survey has abandoned the term Parsons Formation because the following members are now treated as separate formations: Lenapah, Nowata, and Altamont.

Named for Parsons, Labette County.

**Parsonsburg Sand**

Pleistocene (late Wisconsin): Southeastern Maryland (subsurface and surface).

W. C. Rasmussen and T. H. Slaughter, 1955, Maryland Dept. Geology, Mines and Water Resources Bull. 16, p. 114 (table 17), 118–119. Composed predominantly of medium-grained sand but is poorly sorted. Materials range from size of small boulders (rare), through cobbles, gravel, very coarse to very fine sand, silt, and clay. In color, it is buff, tan, orange, or brown. Thickness in reference locality 25 feet; elsewhere ranges from a fraction of a foot to as much as 33 feet. In different places, rests unconformably on each of the earlier Pleistocene deposits. In reference locality, overlies the Walston silt (new). Overlain only by soils, alluvium, and peat of Recent series.

Reference locality is test hole Wi–Bg 11 at Melson, at north end of Parsonsburg Ridge. Named for Parsonsburg, a village 6 miles east of Salisbury.

**Parting Member** (of Chaffee Formation)

**Parting Quartzite Member** (of Chaffee Formation)[1]

Upper Devonian: Central Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1883, U.S. Geol. Survey Leadville Atlas; 1886, U.S. Geol. Survey Mon. 12.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 170–174. Described in Pando area where it is 45 to 57 feet thick, underlies Dyer dolomite member, and unconformably overlies Harding quartzite.

I. H. Mackay, 1953, Colorado School Mines Quart., v. 48, no. 4, p. 22, 27, 28. Described in Eagle and Pitkin Counties where it is 104 to 114 feet thick, underlies Dyer dolomite member, and disconformably overlies Manitou dolomite.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 907. In White River Plateau region, Parting member of Chaffee formation overlies Tie Gulch dolomite member (new) of Manitou formation (redefined). Top section in this area.

Named for exposures on Parting Spur, the spur that extends northwest from Dyer Mountain toward West Dyer Mountain, Lake County, east of Leadville.

Parting Shale

Parting Shale Member (of Oswaldo Formation)

Lower Pennsylvanian: Southwestern New Mexico.

Harrison Schmitt, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 780 (table), 781. Rests disconformably on Hanover limestone, the contact marked locally by thin conglomerate which is in places mainly white chert derived from underlying Hanover limestone. Where unmetamorphosed, the shale contains abundant plant remains. Some layers should be classified as fine-grained sandstone which, near main intrusive in area, is metamorphosed to quartzite. Thickness 18 feet. In lower Magdalena; underlies middle blue limestone.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 283 (fig. 5), 284. Basal member of Oswaldo formation. Thickness 18 to 20 feet.

Central Mining district, in vicinity of Hanover, Grant County.

**Partridge Formation**

Partridge Slate[1]

Upper Ordovician (?): Central and southern New Hampshire.

Original reference: M. P. Billings, 1934, Science, v. 79, no. 2038, p. 55–56

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Formation described. Chiefly dark-gray slate in chlorite metamorphic zone; includes thin-bedded light-gray quartzite and buff soda-rhyolite tuff at base. Is a gray mica schist in staurolite and sillimanite metamorphic zones. Age shown as Upper Ordovician (?).

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 19–21, 98. Maximum thickness 2,000 feet. Discussion of age; may be Middle Ordovician.

Named for Partridge Lake, Littleton Township, Grafton County.

†Partridge Point Formation[1]

Middle Devonian: Northeastern Michigan.

Original reference: A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 524–526.

A. S. Warthin, Jr., and G A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 593. Name Partridge Point should be abandoned in favor of Thunder Bay limestone.

Type locality: East shore of Partridge Point, 3 miles south of Alpena, Alpena County.

**Parunuweap Formation**

Pliocene(?): Southwestern Utah.

H. E. Gregory, 1945, Jour. Geology, v. 53, no. 2, p. 110–115. Includes conglomerates and alluvial or lacustrine silts. In Virgin and Parunuweap Valleys, conglomeratic phase consists chiefly of angular slabs of gray sandstone 1 to 4 feet in length, partly worn pebbles of limestone, elongated iron concretions 1 to 12 inches in diameter, and rounded pebbles of quartz, quartzite, and chert. In Kanab Valley, conglomerate includes angular blocks of basalt and many mud balls. In Coal Valley, chief components are slabs of pink and red limestone, gray sandstone, and rhyolite 1 to 3 feet in diameter, angular and rounded pebbles of quartzite, and chips of chalcedony. Along branches of Paria River, coarse gravels have consolidated into caliche mass that forms caps of mesas 50 to 70 feet above stream bed. Thickness 30 to 80 feet. Overlies Triassic, Jurassic, and Cretaceous formations; unconformably underlies sheets of basalt, talus, stratified sand, and gravel of very recent age.

Named for typical exposures in Parunuweap Valley—Kane, Washington, and Iron Counties.

Par Value Member (of Montoya Dolomite)

Upper Ordovician: Southwestern New Mexico.

L. P. Entwistle, 1944, New Mexico Bur. Mines Mineral Resources Bull. 19, p. 17. Composed of alternating bands of red chert and gray dolomite. Proportions are about one-third chert and two-thirds dolomite. Thickness at type locality 65 feet. Underlies Raven member (new); overlies Second Value member (new).

Typically developed on Par Value claim, Boston Hill mining district, Grant County.

Pasadena Formation[1]

Miocene: Southern California.

Original reference: R. Arnold and A. M. Strong, 1905, Geol. Soc. America Bull., v. 16, p. 188.

Flanks San Rafael Hills on south and underlies southern part of city of Pasadena, Los Angeles County.

Pasamonte Flow

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 138 (table 5), 139, 145. Oldest flow on east side of Don Carlos Hills.

Don Carlos Hills are in southwestern Union County.

Pasayten Andesite[1]

Lower Cretaceous: Central northern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map. 4.

Pasayten River, British Columbia and Washington, crosses this mass.

**Pasayten Formation**[1]

Pasayten Group

Lower Cretaceous: Central northern Washington, and southern British Columbia, Canada.

Original reference: G. O. Smith and F. C. Calkins, 1904, U.S. Geol. Survey Bull. 235.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull., v. 71, no. 10, p. 1533–1534, chart 10e (column 60). Shown as Lower and Upper Cretaceous on correlation chart. Includes red beds at top. Stratigraphically above Dewdney Creek formation. Age limits uncertain.

Term Pasayten group is used in Canadian publications.

Named for occurrences in Pasayten River valley.

Pasayten Volcanic Formation[1]

Lower Cretaceous: Central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 14.

Occurs in only one part of boundary belt, on densely thicketed slopes of Pasayten River valley.

**Pascagoula Clay**[1] or **Formation**

Miocene, upper: Mississippi, southwestern Alabama, and Louisiana.

Original reference: W. J. McGee, 1891, U.S. Geol. Survey 12th Ann. Rept., pt. 1, p. 409.

G. F. Brown and W. F. Guyton, 1943, Mississippi Geol. Survey Bull. 56, p. 30–50. In area of Camp Van Dorn, formation includes Homochitto member below and Fort Adams member above (both new). Overlies Hattiesburg formation; underlies Citronelle formation and younger terrace deposits. Report deals mostly with ground-water supply.

Named for exposures along Pascagoula River, in Jackson County, Miss.

**Paskenta Formation**[1]

Paskenta Group

Paskenta Stage

Lower Cretaceous (Shasta Series): Northern California and southern Oregon.

Original reference: F. M. Anderson, 1902, California Acad. Sci. Proc., 3d ser., Geology, v. 2, no. 1, p. 43–47.

F. M. Anderson, 1938, Geol. Soc. America Spec. Paper 16, p. 38 (table 1), 41–61. Name Paskenta was suggested by writer (Anderson, 1902) for lower part of Shasta series, as since defined, in belief then prevalent that it formed representative part of Knoxville series. Later investigation has shown that Knoxville is distinctly Jurassic, whereas Paskenta group has chronological range strictly within the Cretaceous-Berriasian-Valanginian and is distinct from Knoxville. Paskenta forms lower part of Shasta series and underlies Horsetown group. In its type district (Elder Creek to Thomas Creek and southward), group begins at south with massive lenses of conglomerate, above which it is prevailingly sandy with alternating beds of sandstone and sandy shales. Group has been identified stratigraphically and faunally on both sides of delta area—that is, in its type area and in Cottonwood district. Thickness 11,000 feet in axial area of delta; 8,000 feet on Middle Fork of Cottonwood; about 4,000 feet on Roaring River; and 5,300 feet in type district. In most sections, line of division between Paskenta and Horsetown has been determined faunally although in some places separation is aided by lithological changes. Includes several faunal zones.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 184 (fig. 68) [preprint 1941]; 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 916. Overlies Newville group (new) of Knoxville series.

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 458–459. Discussion of Cretaceous of Santa Lucia Range. In northern California, the Lower Cretaceous has been divided into two groups, Paskenta and Horsetown. It is believed that names Paskenta and Horsetown should be used as approximate faunal stages rather than group terms. Name Marmolejo formation is proposed for Lower Cretaceous of Santa Lucia Range.

F. G. Wells, 1955, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–38. Paskenta formation of Anderson (1902) mapped in southern Oregon.

M. A. Murphy, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2101 (fig. 2), 2103. Term Paskenta is used as stage name for lower part of Shasta series; occurs below Horsetown which is redefined as stage and discussed in detail. Rocks included in Anderson's "Horsetown group" and uppermost strata of his "Paskenta group" in vicinity of Ono have been subdivided into Ono and Rector formations (both new), the boundaries of which are not coincident with Anderson's group.

W. P. Irwin, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2284–2297. Franciscan group is widely held to be restricted to Late Jurassic age, the Knoxville to be an upper shaly phase of Franciscan group, and the two to be overlain unconformably by detrital strata of Cretaceous age. Paleontologic evidence indicates this view to be incorrect. Franciscan group seems mainly to have been deposited contemporaneously with the Knoxville, Paskenta, Horsetown, and lower Upper Cretaceous.

W. D. Wilkinson and others, 1959, Oregon Dept. Geology and Mineral Industries Bull. 50, p. 16. Paskenta formation listed in catalog of pre-Tertiary formations of Oregon. The 4,000 feet of dark or yellowish Cretaceous clay shales forming upper part of Knoxville of previous reports. Contains typical subtropical fauna with abundant *Aucella*.

Type district (Anderson, 1938): Immediately above village of Paskenta in western Tehama County, Calif., extending northward beyond Elder Creek, and southward toward Newville.

Paso Robles facies (of San Ardo Group)

Pliocene: Western California.

T. A. Baldwin, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1986 (fig. 6), 1988. Marine and nonmarine pebble beds, silica-cemented sands, and fresh-water clays, in part equivalent to original Paso Robles formation. Paso Robles is uppermost of three overlapping facies in group. Overlies and grades laterally into Etchegoin facies.

Exposed on slopes of Pancho Rico Canyon and nearby gulches which drain westward to Salinas River near San Ardo, Monterey County.

**Paso Robles Formation**[1]

Pliocene and Pleistocene (?) : Western California.

Original reference: H. W. Fairbanks, 1898, Jour. Geology, v. 6, p. 565–566.

R. G. Frame, 1938, California Oil Fields, v. 24, no. 2, p. 27–47. Described in Santa Maria oil district as interbedded unconsolidated fine- to coarse, bluish- to buff-colored sands and gravels, and beds of bluish-colored clay. Unconformably underlies surface alluvium and gravels; overlies Foxen formation. Thickness 250 to 500 feet (determined from well records).

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1336 (fig. 1), 1340 (table 1), 1358–1359. Conformably overlies Careaga sandstone; unconformably underlies Orcutt sand. Maximum exposed thickness about 2,000 feet. Upper Pliocene to lower Pleistocene (?).

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 39 (fig. 3), 47–50, pls. 1–5. Described in southwestern Santa Barbara County as a series of terrestrial gravels, sands, and clays of probable uppermost Pliocene and lower Pleistocene age conformably overlying Careaga sand. Extensively exposed in San Rafael foothills where it attains a maximum thickness of 4,500 feet; thins to southwest to about 2,000 feet in vicinity of Los Alamos Valley and to about 700 feet under Santa Rita Valley. Underlies Orcutt sand; discordance.

W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 49–51. Maximum exposed thickness 2,000 feet in Santa Maria district. Underlies Orcutt sand; overlies Careaga sandstone. Late Pliocene and early Pleistocene (?). Type region designated.

W. E. Ver Plank, 1952, California Div. Mines Bull. 163, p. 40. Discussed in connection with gypsum deposits in San Benito County. Contains lenses of gypsum 3 to 6 feet thick and up to 300 yards in diameter.

Type region: Salinas Valley in Coast Ranges northwest of Santa Maria district.

**Paspotansa Greensand Marl Member** (of Aquia Formation)[1]

Eocene, lower: Eastern Virginia and eastern Maryland.

Original reference: W. B. Clark and G. C. Martin, 1901, Maryland Geol. Survey, Eocene Volume, p. 58, 62–64.

R. A. Schmidt, 1948, Jour. Paleontology, v. 22, no. 4, p. 390, 392 (table 1), 393. Paspotansa greensand marl member (above) and Piscataway indurated marl member (below) are present at type locality of Aquia formation. They cannot be distinguished on basis of their ostracods. Lower Eocene.

Named for Paspotansa Creek, which enters Potomac River from Virginia bank, a mile below Potomac Creek.

Passaconaway Syenite

Carboniferous (?) : East-central New Hampshire.

A. P. Smith and others, 1938, Geologic map and structure sections of the Mount Chocorua quadrangle, New Hampshire (1:62,500) : New Hampshire Highway Dept. Passaconway [Passaconaway] syenite described as coarse- to medium-grained green syenite. Belongs to White Mountain magma series.

A. P. Smith, Louise Kingsley, and Alonzo Quinn, 1939, Geology of Mount Chocorua quadrangle, New Hampshire: Concord, New Hampshire State Plan. Devel. Comm., p. 8, 18. Referred to as Passaconaway syenite.

Crops out in area bounded roughly by Mount Passaconaway, Mount Whiteface and Hibbard Mountain in northern part of Mount Chocorua quadrangle.

Pass Creek Sandstone

Pennsylvanian and (or) Permian: South-central Colorado.

D. W. Bolyard, 1956, Rocky Mountain Assoc. Geologists Guidebook to geology of the Raton Basin, Colorado, p. 52, 55–56; 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1903 (fig. 5), 1904 (fig. 4), 1918–1919. Nonfossiliferous, greenish-gray to grayish-green medium- to light-gray, and pink sandstones, with a few interbeds of dark gray to black shale, siltstone, and limestone; lamination, cross-lamination, and crossbedding common. Thickness about 1,000 feet. Overlies Madera formation; underlies Sangre de Cristo formation. Contact with Sangre de Cristo obscured by faulting. Brill (1952) included these beds in Sangre de Cristo.

Named from exposure about 1½ miles south of Pass Creek Pass on U.S. Highway 160, Sangre de Cristo Mountains, between La Veta Pass and Westcliffe.

Pass Peak Conglomerate

Eocene, middle: Northwestern Wyoming.

A. J. Eardley and others, 1944, Hoback-Gros Ventre-Teton Field Conf. [geologic map]. Privately printed. Coarse red and gray conglomerates that grade into sandstone and shale toward basin. Thickness 1,000 to 5,000 feet. Unconformable below Camp Davis conglomerate (new); unconformable above Hoback formation (new).

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 74–75. Locally rests with angular unconformity on Hoback formation along eastern border of Hoback Range and near head of Little Granite Creek; in upper Horse Creek and Cache Creek drainages rests on Frontier formation. Derivation of name given.

J. A. Dorr, Jr., 1958, Geol. Soc. America Bull., v. 69, no. 10, p. 1218 (fig. 1). Early(?) Eocene.

Named from Pass Peak, a high point on Hoback basin-Green River divide about 4 miles north of point where U.S. Route 287 crosses divide.

Pasto Andesite

Eocene, pre-middle(?): Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 109–112, geol. map. Light- to medium-gray hornblende andesite that contains abundant phenocrysts of hornblende and common xenoliths of amphibole or hornblendite. Intrudes Ildefonso formation (new) and Robles formation, does not intrude Eocene Jacaguas group (new).

Typically exposed at Pasto in southwestern part of Barranquitas quadrangle. Crops out largely in Coamo, Barranquitas, and Río Descalabrado quadrangles.

Pastoria Sand Member (of White Bluff Formation)

Eocene (Jacksonian): Southeastern Arkansas.

L. J. Wilbert, Jr., 1953, Arkansas Div. Geology Bull. 19, p. 39, 40–56. Name applies to one of three marine facies of formation. Includes the more clastic elements of the formation. Typically argillaceous sand containing glauconite and molluscan remains. At type locality, estimated thickness is about 65 feet, base not exposed; thins northward to about 20 to 25 feet at South Red Bluff. Stratigraphically equivalent with Caney Point marl member; underlies Rison clay member and, in some areas, the Redfield formation; contact with underlying Claiborne gradational.

Type locality: White Bluff on Arkansas River, 3½ miles east of Redfield, Jefferson County. Name is derived from Pastoria quadrangle.

Patagonia Group

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 297 (table). Named on table. Contains Molly Gibson formation (new). Older than Santa Cruz group (new); younger than Bisbee group.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 30–31, 53. Sequence composed mainly of dark shales sporadically interbedded with arenaceous strata and volcanics and, in the upper third, with bedded arenaceous limestones (Molly Gibson formation). Geographic area given. Total thickness about 5,850 feet.

In Patagonia Mountains.

Patagonia limestone

[Upper Devonian] (Tombstonian): Southeastern Arizona.

[C. R.] Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 227, 228 (table). Name applied to the great median sector of the Martin limestone of Ransome (1904). Thickness 250 feet. Underlies Espinal formation (new); overlies Escacado limestone (new).

Name derived from well known mining camp in Santa Rita Mountains north [west-northwest] of Bisbee.

**Patapsco Formation** (in Potomac Group)[1]

Upper Cretaceous: Delaware, eastern Maryland, and eastern Virginia.

Original reference: W. B. Clark, 1897, Maryland Geol. Survey, v. 1, p. 156, 191.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 7–8. Patapsco is of Upper Cretaceous age because it lies between Arundel clay, which contains reptiles having Upper Cretaceous affinities, and Monmouth formation, which carries large marine fauna of late Upper Cretaceous. Presumably occupies position well down in series because it seems more closely related to Arundel than to Monmouth, from which it is separated by a gap representing several marine and nonmarine formations (Matawan, Magothy, and Raritan). Estimated thickness 200 or 300 feet.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2169 (fig. 1), 2173–2177. Lower Cretaceous. Assignment is made on basis of both floral and faunal evidence. Detailed discussion of problem.

Named for occurrence in valley of Patapsco River, Md.

Patillas Quartz Monzonite[1]

Age (?): Puerto Rico.

Original reference: C. R. Fettke, 1924, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 2, p. 161.

**Pato Red Member** (of Vaqueros Formation)[1]

Miocene, lower: Southern California.

Original reference: W. A. English, 1916, U.S. Geol. Survey Bull. 621, p. 191–215.

W. E. Ver Planck, 1952, California Div. Mines Bull. 163, p. 41. Mentioned in discussion of gypsum deposits in Ventura County. Gypsiferous zone occurs in the middle Miocene Caliente red beds which English designated the Pato member of the Vaqueros formation.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2995. These beds are here considered a part of Caliente formation.

Named for exposures in Pato Canyon, Cuyama Valley.

Patrick Greenstone[1]

Cretaceous (?) : Northwestern California.

Original reference: J. H. Maxson, 1933, California Jour. Mines and Geology, v. 29, no. 1–2, p. 134, map.

J. C. O'Brien, 1952, California Jour. Mines and Geology, v. 48, no. 4, p. 265. Mentioned in report on mineral resources of Del Norte County.

Occurs in Del Norte County. Map shows Patrick Creek cutting across the greenstone.

Patriot Limestone (in Conemaugh Formation)[1]

Pennsylvanian : Eastern Ohio.

Original reference : D. D. Condit, 1909, Ohio Nat., v. 9, p. 484.

Probably named for Patriot, Gallia County.

**Patterson Limestone Member** (of Shady Dolomite)[1]

Lower Cambrian : Southwestern Virginia.

Original reference: Charles Butts, 1933, Virginia Geol. Survey Bull. 42, p. 3, map legend.

G. W. Stose and A. I. Jonas, 1939, Virginia Geol. Survey Bull. 51–A, p. 14–15, pl. 1. Name Patterson, given by Butts (1933) to lower ribboned blue dolomite and limestone of Shady, is appropriate for these beds in main part of Great Valley north of Gleaves Knob overthrust because Patterson, the type locality, is located on these rocks. Name Patterson will be used in this sense in this report (Wythe and Carroll Counties) with understanding that it is not appropriate for the lower part of the Lower Cambrian rocks south of Gleaves fault, where sequence is different. Thickness about 620 feet. Underlies an unnamed massive white saccharoidal dolomite, 200 feet thick in upper part of the Shady; overlies Erwin quartzite.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 41–42. In Wythe and Pulaski Counties, Patterson underlies Austinville dolomite member (new).

Type locality: Patterson, Wythe County, where more than 100 feet is exposed in bluff on west side of Little Reed Island Creek.

**Patterson Point Formation**

Quaternary : Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 180–181, pl. 23. Dacitic ash and pumice and dacitic and andesitic pyroclastic debris. Upper unit 10 to 15 feet thick consists of light-grayish-white to bluish-gray, firmly consolidated ash and pumiceous lapilli. Lower unit as much as 25 feet thick consists of salmon-pink to grayish-white, very firmly consolidated or welded dacitic glass and pumice. Deposit several hundred feet thick. Generally massive. Overlies Double Point dacite (new).

Type section: In stream cut north of the 1,980 foot mountain at lat 51°57′40″ N., long. 178°30′50″ E., Little Sitkin Island, in Rat Islands group of Aleutian Islands. Extends 2 miles northwestward from Little Sitkin volcano toward Patterson Point.

Patterson Ranch Group

Ordovician: South-central Oklahoma.

C. E. Decker, 1942, Oklahoma Acad. Sci. Proc., v. 22, p. 153–155. Name proposed for limestone-shale series of formations—Viola, Fernvale, and Sylvan. Overlies Simpson group; underlies Silurian formations.

Name taken from Patterson Ranch on south edge of Arbuckle Mountains on east side of U.S. Highway 77. Formations are characteristically exposed on ranch and extend from highway eastward across it.

Pattiway Formation

Eocene (?): Southern California.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2977–2981. At type locality, formation unconformably underlies Simmler formation, but base is unexposed. Total exposed thickness 3,680 feet. Upper 3,300 feet composed predominantly of light-gray to buff, hard medium-grained arkosic sandstones with minor interbeds of dark-gray carbonaceous siltstone; upper part of this sandstone unit contains several lentils up to 30 feet thick of brown conglomerate made up of rounded cobbles of quartzite and granitic and dark porphyritic rocks; sandstone series grades downward into dark-gray micaceous silty shale containing carbonaceous materials; approximately 380 feet of this shale crops out and forms lowest exposed part of Pattiway. Overlies unnamed Upper Cretaceous sandstones and conglomerates. Age of formation not known definitely because it is generally unfossiliferous; lower shale of Caliente Range section has yielded a foraminiferal fauna suggesting an Eocene or Cretaceous age; lithologically unlike Cretaceous strata of region, and field relations indicate an Eocene age as most probable.

Type locality: Extreme southeastern end of Caliente Range, T. 10 N., R. 25 E., east of Cuyama Ranch and Ballinger Canyon quadrangles. Name derived from former settlement of Pattiway, a few miles east.

Patton Limestone (in Greenbrier Limestone[1] or Series)

Middle Mississippian (Meramecian): Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 450, 480.

Dana Wells, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 5, p. 903. Denmar formation (new) includes Sinks Grove and Patton limestones of Reger (1926). Age of Denmar Middle Mississippian (Meramecian series).

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1910–1912. The Patton and Sinks Grove do not represent a single stratigraphic unit; in Monroe County, where they were named, they are separated by 10 to 20 feet of plant bearing shale [Patton shale]. Use of term Denmar for these two units is without merit. Middle Mississippian.

Type locality: On south side of Second Creek just south of Patton, Monroe County, W. Va.

Patton Shale (in Greenbrier Limestone)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 450, 483.

Type locality: Northeast of Union, Monroe County, along Pickaway-Hillsdale road 0.8 mile southeast of Pickaway. Named for association with Patton limestone.

**Patton Shale Member** (of Pocono Formation)[1]

Patton Formation or Shale

Mississippian: Western Pennsylvania.

Original reference: M. R. Campbell, 1904, U.S. Geol. Survey Geol. Atlas, Folio 110.

P. A. Dickey, R. E. Sherrill, and L. S. Matteson, 1943, Pennsylvania Geol. Survey, 4th ser., Bull. M–25, p. 14–15. Mississippian strata of Oil City quadrangle are classified (ascending) Cussewago group, Berea group (including Corry sandstone), Cuyahoga group, Shenango formation, and Patton formation. The Patton consists of light-bluish-gray clay shale with included layers or lenses of poorly bedded soft red and green shale and fine- to medium-grained greenish-gray argillaceous sandstone. Thickness 60 to 70 feet.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227, p. 13. Member of Pocono formation. In Hollidaysburg-Huntingdon area underlies Burgoon sandstone member. Thickness about 40 feet.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 160, chart 5 (columns, 82, 106). Column 82, northwestern Pennsylvania, shows Patton shale above Shenango formation; in Osagean series. Column 106, subsurface southwestern Pennsylvania, shows Patton shale above Second gas sand and below Squaw sand; Kinderhookian series. According to text explanation of column 82, beds termed Patton consist largely of shale and include red beds. There is little or no evidence that these beds are of equivalent age at different places, and the Patton of northwestern Pennsylvania might as readily be correlated with part of the Maccrady of West Virginia or even part of Mauch Chunk of eastern Pennsylvania.

B. N. Cooper, 1948, Jour. Geology, v. 56, no. 4, p. 259 (footnote). Name Patton shale, which appears on Mississippian correlation chart (Weller and others, 1948) is invalid by reason of prior use of Patton for an older shale of Pocono age in western Pennsylvania.

R. C. Bolger and C. E. Prouty, 1953, Pennsylvania Acad. Sci., v. 27, p. 125. In Cameron County, Patton formation, about 60 feet thick, directly underlies Burgoon sandstone.

Named for outcrops on Redbank Creek, at Patton, near west line of Jefferson County.

**Patuxent Formation** (in Potomac Group)[1]

Lower Cretaceous: Eastern Maryland, Delaware, and eastern Virginia.

Original reference: W. B. Clark, 1897, Maryland Geol. Survey, v. 1, p. 156, 190.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Water Resources Bull. 10, p. 2–4, 5. Oldest formation of Coastal Plain in region of Prince Georges County and lies directly on crystalline rocks. Formation contains many unconformities, and there is presumably one at top separating it from overlying Patapsco formation. Locally, in District of Columbia, underlies red gravel thought to be the Bryn Mawr (Pliocene?). Unconformably underlies Arundel formation here considered Upper Cretaceous.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2173–2177. Reanalysis of Potomac group floras substantiates views expressed by earlier workers (especially Berry and Seward) that Patuxent and Arundel floras are essentially similar associations comparable in age and composition with Wealden flora of England, which at present is considered of Neocomian age. Detailed discussion of problem.

Named for development in upper valleys of Little and Big Patuxent Rivers, Md.

Pauba Formation

Pleistocene, upper: Southern California.

J. F. Mann, Jr., 1955, California Div. Mines Spec. Rept. 43, p. 3, 9, 13–14, pl. 1. Series of coarse fanglomerates and interbedded sands and silts about 500 feet thick. Unconformably underlies Dripping Springs formation (new); overlies Temecula arkose (new) with angular unconformity.

Occurs in Elsinore fault zone in western Riverside and northern San Diego Counties. Named from Pauba Rancho, east of Temecula, Riverside County.

**Paularino Member** (of Topanga Formation)

Miocene, middle: Southern California.

J. G. Vedder, R. F. Yerkes, and J. E. Schoellhamer, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–193. Consists primarily of a poorly exposed sequence of interbedded sandstone, siltstone, and breccia. Estimated maximum thickness 1,275 feet. Unconformably underlies Capistrano formation of late Miocene to early Pliocene age and unnamed sandstone of Pliocene and early Pleistocene(?) age. Overlies Los Trancos member (new) with probable disconformity.

Type area: North of Bonita Reservoir on Bonita Creek at northwest edge of San Joaquin Hills, Orange County. Name taken from Paularino Avenue near northwest margin of map.

Paulian glaciation

Paulian till[1]

Pleistocene (Wisconsin): Central Minnesota.

Original references: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203, 217; 1933, v. 60, p. 55.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 69, no. 2, p. 108 (fig. 2), 129. Referred to as glaciation.

Paulina Peak Rhyolites

Pleistocene: Central Oregon.

Howel Williams, 1935, Geol. Soc. America Bull., v. 46, no. 2, p. 261, 265–266, 281. Discussion of history of Newberry volcano. Paulina Peak rhyolites consist of as many as 12 flows with total thickness of at least 1,000 feet. Earliest rhyolites are pale gray, porphyritic and platy lavas, some are so vesicular as to be almost pumiceous. Platy rhyolites are succeeded by dense flows in which banding is less pronounced, and these by black pitchstones overlain by finely laminated flows. Near summit are many varieties of obsidian.

The rhyolite flows form girdle of cliffs that rise to Paulina Peak and the high shoulder running toward southwest.

Paupack Sandstone (in Catskill Formation)[1]

Paupack parvafacies (in Shohola facies group)

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $G_5$, p. 59, 68, 169, 170, 199, 200.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7). Shown as a parvafacies in Shohola facies group.

Named for Paupack Falls on Wallenpaupack Creek, Palmyra Township, Pike County.

Paupack Shales (in Catskill Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $G_5$, p. 68.

Name derived from Paupack Falls, Pike County.

**Pauwalu Basalt** (in Hana Volcanic Series)

Pleistocene(?) : Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 94, 95 (table). Oldest Hana lava in Keanae Valley. Dense fine-grained olivine aa basalt, jointed in columns 6 inches to 2 feet in diameter, with layer of clinker at top. Exposed thickness in sea cliff 130 feet; at Piinaau Falls, about 175 feet exposed, separated into two distinct layers by bed of clinker.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 125. Pleistocene(?).

Named after Pauwalu Point, where it is exposed in sea cliff, filling valley cut into older alluvium. Valley is about 2,000 feet wide at coast and extends to unknown depth below sea level.

**Pavant Flow**

Pliocene, upper, or Pleistocene, lower: Central Utah.

G. B. Maxey, 1946, Am. Jour. Sci., v. 244, no. 5, p. 328, pl. 1. Oldest flow in area. Lava beds are horizontal, underlie Pleistocene lake beds and Recent deposits, and were extruded probably in late Pliocene or early Pleistocene. Underlies Tabernacle flow (new).

P. E. Dennis, G. B. Maxey, and H. E. Thomas, 1946, Utah State Engineer Tech. Pub. 3, p. 28, pl. 1. Thickness about 1,800 feet. Base not exposed.

Extends from southern end of Pavant Valley to Pavant Butte at northern extremity of valley, Millard County. More than 5 miles wide.

Pavlof Volcanics

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, pl. 2. Agglomerate and interbedded lava flows. Name appears only on geologic map legend.

Mapped on summit and flanks of Pavlof Volcano, Alaska Peninsula.

Pavlof Sister Volcanics

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, pl. 2. Agglomerate and interbedded lava flows. Name appears only on geologic map legend.

Mapped on flanks of Pavlof Sister Volcano, Alaska Peninsula.

**Pawhuska Limestone[1] or Formation[1]**

Pennsylvanian (Virgil Series): Northeastern and central northern Oklahoma.

Original reference: J. P. Smith, 1894, Jour. Geology, v. 2, p. 199.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 98–99. Pawhuska formation does not crop out in Seminole County. Mentioned here because it has been mapped or traced across much of county by many geologists. Beds so mapped are ledges 9, 11, and 12 in upper part of Vamoosa formation. Pawhuska is truncated in or near sec. 20, T. 11 N., R. 7 E., in western Okfuskee County by overlying Ada formation.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 48–51, pl. 1. Formation is about 150 feet thick in northern Osage County and comprises (ascending) Lecompton, Plummer, Deer Creek, Little Hominy, Pearsonia (new), and Turkey Run members. Of these six members, only the Lecompton at the base and Turkey Run at top continue across Pawnee County and into Creek County. Formation thins southward to 56 feet in southern Pawnee County. In Creek County, formation is 60 to 75 feet thick from north line to south part of T. 16 N., but is 20 feet thick at one locality near middle of T. 15 N. Farther south, Turkey Run limestone member could not be found; Lecompton limestone member at base, 5 to 10 feet thick, and about 30 feet of shale and sandstone belonging to formation could be mapped in sec. 6, T. 14 N., R. 7 E. Lecompton member continues to south line of Creek County and is only part of Pawhuska that Ries (1954, Oklahoma Geol. Survey Bull. 71) could map in Okfuskee County. Conformable with Vamoosa formation below and conformable with younger rocks above as far south as middle of T. 15 N. It seems that Turkey Run member was not deposited farther south. The Lecompton has been mapped southward across Okfuskee County to surficial deposits associated with North Canadian River, but no representative of Pawhuska has been recognized farther south, where Pawhuska was probably completely removed by post-Vamoosa, pre-Ada erosion. Ada formation rests on rocks older than Vamoosa on north flank of Arbuckle Mountains, truncates Vamoosa, and probably truncates the Lecompton beneath surficial deposits associated with North Canadian River. Intergrades laterally with Vanoss formation. Name credited to Herbert C. Hoover (unpub. ms.).

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 37–44, pl. 1. Formation described in Pawnee County where it is included in Douglas-Shawnee group. Recent usage has placed bottom and top of formation at base of Lecompton limestone and top of Turkey Run limestone, respectively. Pawhuska can presumably be traced from Kansas-Oklahoma line southward into Creek County where one or both of bounding limestones pinches out. However, extent, correlation, and even status of the Pawhuska is open to question. In Kansas and northern Osage County, Okla., interval occupied by Pawhuska formation contains as many as 12 limestones separated by shale and a few thin coals and limestones. The limestones and coals thin and pinch out southward, and percentage of sandstone in section increases. Only Turkey Run and Lecompton limestones, which delimit formation, extend as far south as Pawnee County. No question has arisen on correlation of lower limit, but recent work has cast doubt on validity of upper correlation. According to Shannon (1954, unpub. thesis) and Carter (1954, unpub. thesis), Turkey Run limestone in Osage County is poorly developed and cannot be mapped; therefore, Moore's (1949, Kansas Geol. Survey Bull. 83) correlation of Turkey Run with Coal Creek limestone may be erroneous. South of Pawnee County, Lecompton member is thought to be equivalent to "Pawhuska" formation of Okfuskee County (Ries, 1954) which grades into basal part of Ada formation. An alternate theory by Tanner (1956, Oklahoma Geol. Survey Bull. 74) postulates that the "Pawhuska" is overlapped southward by Ada formation of Okfuskee County. Recent work has cast doubt on all these correlations. Some workers are of the opinion that the "Pawhuska" of Okfuskee County is southward extension of Bird Creek limestone of Wabaunsee group. Base of "Pawhuska" defines top of Vamoosa formation (Ries, 1954). If Pawhuska formation of Okfuskee County is in reality Bird Creek, Vamoosa formation extends upward into Wabaunsee group to base of Bird Creek and contains Pawhuska formation of Pawnee County. If such is the case, a difficult problem of subdivision and classification is posed. In Pawnee County, the Pawhuska rests conformably on Kanwaka shale of Vamoosa formation and is overlain conformably by Severy shale of Wabaunsee group.

Type locality: About 3 miles northwest of Pawhuska, formerly spelled Pawhuski, Osage County. Formation crops out in band 1 to 3 miles wide from Kansas-Oklahoma line, T. 29 N., Rs. 8 and 9 E., across Osage County and eastern Pawnee County; across west side of Creek County to middle of T. 15 N., R. 7 E., and representatives continue along west side of Creek County and west side of Okfuskee County to North Canadian River in T. 11 N., R. 7 E.

Pawling Gneiss[1]

Precambrian: Southeastern New York.

Original reference: T. N. Dale and L. M. Prindle, 1904, New York State Mus. 23d Ann. Rept., map; text by F. J. H. Merrill.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 329. Listed with names rejected by virtue of synonymy and (or) lack of usage.

Occurs in part of Pawling Township, Dutchess County.

Pawnee Limestone[1]

Pennsylvanian(?): Central northern Oklahoma.

Original reference: N. F. Drake, 1897, Am. Philos. Soc. Proc., v. 36, p. 326–387.

Named for Pawnee, Pawnee County.

**Pawnee Limestone**[1] (in Marmaton Group)

**Pawnee Limestone Member** (of Oologah Limestone)

Pawnee Limestone (in Henrietta Group)

Pawnee Limestone Member (of Henrietta Formation)[1]

Pennsylvanian (Des Moines Series): Eastern Kansas, southwestern Iowa, western Missouri, and northeastern Oklahoma.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 24–25.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, no. 11, p. 312–321. Subdivided into (ascending) Anna shale (new), Myrick Station limestone, Mine Creek shale (new), and Laberdie limestone (new) members. Thickness at type exposure, herein designated, 30 feet. Overlies Labette shale; underlies Bandera shale. Included in Marmaton group.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 37. Subdivided into two members. Lower member named Myrick Station; upper member to be named with type locality in Kansas. Included in Henrietta group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 6–7; L. M. Cline and F. C. Greene, 1950, Missouri Geol. Survey and Water Resources Rept. Inv. 12, p. 7–15, columnar sections and measured sections. Formation, as recognized in Missouri, includes beds from base of Anna shale to top of Coal City limestone member. Term Coal City has priority over Laberdie, and Laberdie is suppressed in favor of Coal City. Marmaton group.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 29. Term Oologah is extended to Kansas-Oklahoma line to include (ascending) Pawnee limestone, Bandera shale, and Altamont members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 31–32, fig. 5. In southwestern Iowa, comprises (ascending) Anna shale, Myrick Station limestone, Mine Creek shale, and Coal City limestone members. Marmaton group.

Type exposure: Near center N½S½ sec. 7, T. 27 S., R. 24 E., Bourbon County, Kans. Named for exposures on Pawnee Creek, near village of Pawnee (now Anna), Bourbon County.

†Pawnee limestone series[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 24–25.

Probably named for Pawnee Creek, near village of Pawnee, Bourbon County.

†Pawnee Creek Beds[1]

Pawnee Creek Formation

Miocene, middle, to Pliocene, lower: Northeastern Colorado.

Original reference: W. D. Matthew, 1900, Am. Mus. Nat. History Bull., v. 12, p. 24–25.

E. C. Galbreath, 1953, Kansas Univ. Paleont. Contr. 13, Vertebrata, art. 4, p. 14 (fig. 4), 15 (fig. 5), 18–19, 20–21, 22, 23, 24, 25, 26, 27 (fig. 8). Matthew did not designate type section for Pawnee Creek beds. [See this report for discussion of problem.] Pawnee Creek formation used in this paper as a mapping unit for known Miocene beds in Logan and Weld Counties. As used here, term includes Matthew's Pawnee Creek beds and Pawnee Creek fauna and upper part of his Martin Canyon beds with its fauna. This is an expedient to avoid further confusion in use of term Martin Canyon and to avoid introduction of new term prior to solving stratigraphic and correlation problems in area. It is difficult to determine whether or not Matthew's Pawnee Creek beds included upper Martin

Canyon beds in other localities, but possibly they did at all points except in Martin Canyon area. Formation is represented in northeastern Colorado by series of valley fills. Oldest deposits are in bottoms of canyons cut into Oligocene surface and consist of massive silt or fine consolidated sand in thin layers; capping the silts is widespread coarse rubble bed; overlying channel rubble are beds of massive, sandy silts containing layers of nodular concretions, gravel lenses, and thin channel sandstone; locally rubble is overlain by olive-gray silt followed by massive silts, and in still other localities rubble seems to be replaced by olive-gray silt in the depositional sequence. Thickness at type section herein designated 144 feet. Underlies Ogallala formation; overlies Cedar Creek member or Vista member (new) of White River formation.

Type locality: At Eubanks ranchhouse, Pawnee Buttes, NE¼ sec. 1, T. 10 N., R. 59 W., Weld County. Named for Pawnee Creek, Logan and Weld Counties.

**Pawpaw Formation** (in Washita Group)

Pawpaw Sandy Member (of Denison Formation)[1]

Pawpaw Shale Member (of Denison Formation)

Pawpaw Shale Member (of Georgetown Limestone)

Lower Cretaceous (Comanche Series): Northeastern and central Texas and central southern Oklahoma.

Original reference: R. T. Hill, 1894, Geol. Soc. America Bull., v. 5, p. 302, 303, 328–335.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Chart shows Pawpaw formation in Washita group. Occurs above Weno limestone and below Main Street limestone. [Term Denison formation abandoned.] Lower Cretaceous.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 28–29, table 4. Foraminifera of Pawpaw formation described.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 32–34. In Tarrant County, Tex., name Pawpaw is applied to shale sequence between Weno marly limestone member and Main Street limestone member of Denison formation. Consists chiefly of gray and bronze calcareous shale with few thin sandstone partings and several ironstone layers. Thickness 12 to 30 feet.

W. J. Fox and O. N. Hopkins, Jr., 1960, Baylor Geol. Soc. Guidebook 5th Field Conf., p. 88, 92. In central Texas, termed shale member of Georgetown limestone. Overlies Weno limestone member; underlies Main Street limestone member. In north Texas, composed predominantly of sandstone, which changes to marl near Waco. Marl is relatively soft, thinly bedded, with shale partings. Recognized as a 7-foot receding zone consisting of two shale beds separated by a 4-foot limestone.

Named for Pawpaw Creek, in southern and eastern part of Denison, Grayson County, Tex.

Pawtuckaway Complex (in White Mountain Magma Series)

Mississippian(?): Southeastern New Hampshire.

C. J. Roy and Jacob Freedman, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 908–914. Includes a variety of rocks ranging from gabbro to syenite, principal constituents being diorite and monzonite. Rocks become progressively less mafic from earlier gabbroic intrusion to latest monzonite and syenite. Structural character is best accounted for by cauldron subsidence mechanism of emplacement.

Named for occurrence in Pawtuckaway Mountains in Deerfield and Nottingham Townships, Rockingham County.

†Pawtucket Formation[1]

Pennsylvanian: Eastern Rhode Island.

Original reference: C. H. Warren and S. Powers, 1914, Geol. Soc. America Bull., v. 25, p. 439–475.

Named for Pawtucket, R.I.

Pawtucket Shale[1]

Pennsylvanian: Eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 159–164.

Well exposed in banks of Blackstone River on Division Street, Pawtucket, and at Valley Falls, Providence County.

**Paxton Quartz Schist[1]**

Carboniferous: Central Massachusetts, northern Connecticut, and south-central New Hampshire.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 73, 74, pl. 1. Discussed together with Hebron schist under heading of Hebron, or Paxton quartz schist. Probably early Paleozoic.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Refers to Woodstock (Paxton) quartz schist phase of Hebron gneiss of pre-Triassic age.

Named for development at Paxton, northwest of Worcester, Mass.

Paxton Creek Conglomerate (in Martinsburg Shale)

Ordovician: South-central Pennsylvania.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, ser. 4, Bull. G–8, p. 5, 6. Name proposed for a pebbly unit in the Martinsburg shale in the Harrisburg area. Consists of ill-sorted, poorly rounded white quartz pebbles and shale chips in a muddy matrix. Very hard rock; in places, true conglomerite.

Named for outcrop near Paxton Creek in Harrisburg, Dauphin County.

**Payette Formation[1]**

Miocene and Pliocene(?): Southwestern Idaho, northeastern Nevada, southeastern Oregon, and northwestern Utah.

Original reference: Waldemar Lindgren, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 632–634.

D. W. Scharf, 1935, Carnegie Inst. Washington Pub. 453, p. 99. Future geologic mapping may show that Sucker Creek beds (new) are an integral part of Payette formation.

B. N. Moore, 1937, U.S. Geol. Survey Bull. 875, p. 67–71, 97–100, pls. 8, 11. Subdivided into six unnamed members in Harper district, Malheur County, Oreg.: lower agglomerate and tuff member, 100 to 200 feet; lower diatomite member, 450 feet; gray ash member, 60 to 150 feet; upper diatomite member, 0 to 175 feet; rhyolite porphyry member, 0 to 10 feet; and yellow tuff member, 100 to 500 feet. Overlies flows of olivine basalt and hypersthene andesites correlated with Columbia River lava; capped by basalts. Only four members recognized in Otis Basin to the west. On basis of vertebrate fossils, upper member considered lower Pliocene; remainder of formation generally assigned to Miocene.

J. C. Bayless, 1950, Michigan Acad. Sci., Arts, and Letters, Papers, v. 34, p. 214–215. Term Camp Davis formation used in Snake River Plains, Idaho, in preference to term Payette formation, although term Payette has priority. Conglomerates are lithologically similar to those of Camp Davis formation of western Wyoming, and on that basis name Camp Davis is retained.

H. E. Corcoran, 1954, The Ore-Bin, v. 16, no. 12, p. 79–84. Lindgren did not designate type section; name apparently was suggested by exposures along Payette River in western Idaho. Because fossil leaves used by Knowlton (1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3; 1902, U.S. Geol. Survey Bull. 204) for original dating were found in vicinity of Marsh post office, it is proposed here that this locality be used as type section. Kirkham (1931, Jour. Geology, v. 39, no. 3) found that Payette and Idaho formations in Idaho, as well as in adjacent areas of Oregon, are separated by great thicknesses of rhyolite and basaltic lavas. He measured a maximum thickness of Payette of about 1,200 feet in vicinity of Lindgren's leaf locality near Marsh post office and a thickness of Idaho formation on south side of downwarp along Little Squaw Creek of 7,275 feet and on north side along Little Willow Creek of 18,633 feet. He reported fossil leaves of Miocene from Payette and flora and fauna of Pliocene or later age from Idaho. Recent study in Vale-Buchanan area, Oregon, shows that lake beds in area dip gently northeast into Snake River downwarp and that these sediments are separated from another underlying unit of terrestrial lake beds, which crop out farther to west, by series of lavas at least 5,000 feet thick. Upper lake beds assigned to Idaho formation and lower to Payette formation. Payette formation dated as middle to upper Miocene.

F. B. Van Houten, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2811. In Goose Creek area of northwesternmost Utah, and adjacent Idaho and Nevada, a 2,000-foot sequence characterized by carbonaceous and brittle bituminous shale and petroliferous limestone has been assigned to upper Miocene Payette formation. These deposits are well exposed on east flank of Goose Creek Range (T. 13 N., R. 18 W.) 8 to 10 miles north-northeast of village of Grouse Creek, Utah, as well as in scattered outcrops on west flank of Grouse Creek Range (S½, T. 12 N., R. 17 W.), several miles east of Grouse Creek.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 16–17. Rocks shown on Idaho State map (Ross and Forrester, 1947) as Payette and related strata include beds that, although having many resemblances, have considerable range in age. Rocks so grouped have affinities to Payette formation (commonly regarded as Miocene), Latah formation (middle or upper Miocene), and Idaho formation (Pliocene). Payette formation and related strata exposed principally along border of western part of Snake River Plain but continue at intervals and in relatively smaller masses into northern Idaho. Lack of adequate information led to somewhat arbitrary separation in which the unit that includes Payette formation is mostly west of 114° West longitude, and unit that includes Salt Lake formation is east of that meridian. This corresponds practically to current usage but some components of the two assemblages are nearly equivalent to each other. Early concept that Payette and Idaho formations represent two successive stages of large lake, with division between them at some horizon not definitely fixed, within sedimentary succession above Columbia River basalt (Lindgren, 1898) is so much at variance with facts now known that it must be abandoned. Kirkham (1931, Jour. Geology, v. 39, no. 3) desired to restrict the Payette to sedimentary rock that generally occurs interbedded with Columbia River basalt, commonly about 600 feet below top of the basalt unit—a suggestion that has much to commend it in areas in which he worked. He mapped the Payette on this basis in area in southwestern Idaho comprising T. 1 S., to T. 13 N., R. 5 W. to R. 1 E., inclusive, and the area within bend of Snake River northwest of Weiser. Evidence now available suggests that there is much local variation in stratigraphic positions of sedimentary rocks associated with Columbia River basalt and that in places it is still difficult to distinguish these from similar but younger rocks nearby. Uncertainty remains as to precise stratigraphic relation between strata of Payette age and those in northern Idaho that contain Latah flora. In general way, term Idaho formation is applied to those Cenozoic rocks in and near western part of Snake River Plain that have broad lithologic and genetic resemblances to Payette formation but are younger.

W. J. Mapel and W. J. Hail, Jr., 1959, U.S. Geol. Survey Bull. 1055–H, p. 221 (chart 1), 224–229. In Goose Creek district, rocks similar in many respects to Payette formation are herein designated Payette(?) formation. Thickness of Payette(?) in Cassia County, Idaho, 855 feet. Underlies Salt Lake formation.

Type section (Corcoran): Vicinity of Marsh post office, Boise County, Idaho. Named for exposures along Payette River in western Idaho.

Payne Sandstone[1]

Permian: Central Oklahoma.

Original reference: C. T. Kirk, 1904, Oklahoma Dept. Geology and Nat. History 3d Bienn. Rept., p. 9–11.

Named for Payne County.

Payne Branch Sandstone (in Hinton Formation[1] or Group)

Mississippian (Chesterian): Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey [Rept.] Mercer, Monroe, and Summers Counties, p. 296, 352.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 98). Shown on correlation chart as Payne Branch sandstone in Hinton group, Mauch Chunk series. Underlies Avis limestone; stratigraphically above Stony Gap sandstone.

Type locality: On north side of Payne Branch of Fivemile Creek, 0.8 mile southwest of Caperton School and 2.2 miles north of Hatcher, Mercer County.

Payne Branch Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 353.

Type locality: On north side of Payne Branch of Fivemile Creek, 0.8 mile southwest of Caperton School and 2.2 miles north of Hatcher, Mercer County.

Paynes Shale and Sandstone Member (of Panoche Group)

Upper Cretaceous: Northern California.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 201–202, 226 (fig. 5), pl. 3. Consists largely of interbedded dark-colored clay-shales, greenish sandstones, and limestones. In Browns Valley area, a conglomeratic layer about 150 feet thick occurs in middle of section. Thickness at type locality 2,100 feet; 5,200 to 8,500 feet thick on southwest limb of Butts Ranch syncline. Basal member of group; underlies Call sandstone member (new); overlies Paskenta and Knoxville formation, undifferentiated.

Type locality: Along Paynes Creek, on northeast side of syncline, 2½ miles north of Butts Ranch, San Benito County.

Paynes Creek Basalt[1]

Pleistocene, late, or Recent: Northern California.

Original reference: H. Hamlin, 1921, Dept. Int., U.S. Reclamation Service in cooperation with State of California and Iron Canyon Project Association, App. 1, p. 47, 50, 58, pl. 2.

Probably named for Paynes Creek, Chico quadrangle.

**Paynes Hammock Sand**

Miocene: Alabama and Mississippi.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1346–1354. Name applied to unit termed Upper Chickasawhay member (Blanpied and others, 1934). At type locality, consists of about 13 feet of greenish sand containing one indurated limestone ledge; sand is faulted against Marianna limestone in small side fault to main Jackson fault. Overlies Chickasawhay limestone (Lower Chickasawhay member of Blanpied and others). Intertongues at west with nonfossiliferous beds referred to Catahoula sandstone. Basal Miocene.

Type locality: Along branch entering Tombigbee River at Paynes Hammock, Ala., in SW¼ sec. 16, T. 5 N., R. 2 E. Recognized as far west as Keys Mill, Smith County, Miss.

Payson Drift

Payson Substage

Pleistocene (Illinoian): Illinois.

M. M. Leighton and H. B. Willman, 1949, *in* Itinerary State Geologists Field Conf. on late Cenozoic Geology of Mississippi Valley, p. 9 (table 1); 1950, Jour. Geology, v. 58, no. 6, p. 602 (fig. 2). Illinoian stage is divided into (ascending) Loveland, Payson, Jacksonville, and Buffalo Hart substages.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 125 (fig. 50), 136–137, geol. sections 46, 58, 59, 64, 66, 68. Till plain in area outside Jacksonville and Buffalo Hart moraines is referred to as Payson drift. It is surface drift of northwestern and west-central parts of Beardstown quadrangle and approximately western one-fourth of Vermont quadrangle. Generally less than 20 feet thick over Pleasanton Ridge; at least 140 feet thick in vicinity of Bader where it obliterates pre-Illinoian Valley of Sugar Creek; 110 feet thick in sec. 34, T. 6 N., R. 1 W., Vermont quadrangle where it obliterates a pre-Illinoian Valley. Derivation of name given.

Named for Payson, Pike County, which is on outermost Illinoian moraine.

Payton Ranch Limestone Member (of Gazelle Formation)

Upper Silurian: Northern California.

Michael Churkin, Jr., and R. L. Langenheim, Jr., 1960, Am. Jour. Sci., v. 258, no. 4, p. 259 (fig. 1), 260–266. Fairly continuous limestone layer, dissected by erosion and repeated by faulting; present in upper part of formation. Base of member thin-bedded and with thin interbeds of shale. Above basal part, limestone is poorly stratified, very thick bedded, fairly pure calcium carbonate; excepting local intraformational conglomerate and brecciated recrystallized areas along faults, limestone is finely crystalline or microcrystalline. Sparsely fossiliferous. Thickness at type locality 188 feet; other measured sections 85 to 134 feet. Over 600 feet of shales, sandstone, bedded chert, conglomerate, and scattered lenses of similar limestone occur below member; upper contact is everywhere either an erosional surface or a fault contact.

Type locality: On east side of high peak (elev. 4,320 feet) in NE¼SW¼ sec. 6, T. 42 N., R. 6 W., Yreka quadrangle, Siskiyou County.

**Peabody Granite**[1]

Late Paleozoic(?): Northeastern Massachusetts.

Original reference: C. H. Clapp, 1910, Igneous rocks of Essex County, Massachusetts.

U.S. Geological Survey has revived the term Peabody Granite on basis of a study now in progress.

In Peabody Township, Essex County.

†Peaceable Sand[1]

Pleistocene(?): Central Oklahoma.

Original reference: J. A. Taff, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 439.

C. C. Branson, Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey. The name Gerty sand is contemporaneous and is the established name.

Named for exposures along Peaceable Creek, Pittsburg County.

†Peace Creek Beds[1]

Pliocene, lower: Southern Florida.

Original reference: W. H. Dall, 1891, Philadelphia Acad. Nat. Sci. Proc. 1891, p. 120.

Named for exposures on Peace Creek, De Soto County.

Peace Valley Beds

Pliocene, middle: Southern California.

J. C. Crowell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 8, p. 1625 (fig. 4), 1629 (fig. 5), 1631–1632. Name applied to about 4,000 feet of soft gray-green sand, siltstone, and shale intercalated with thin-bedded buff and white sandstone. Underlies Hungry Valley formation (new). Base of section not exposed. In northeastern part of area, Peace Valley beds abut against the quartz monzonite basement.

Occurs in Hungry Valley area which is in Transverse Ranges about 55 miles northwest of Los Angeles.

**Peach Bottom Slate**[1]

Ordovician(?): Southeastern Pennsylvania and western Maryland.

Original reference: J. P. Lesley and P. Frazer, Jr., 1880, Pennsylvania 2d Geol. Survey Rept. $C_3$, map of Lancaster County.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 96–103, 106. Removed from Glenarm series. Ordovician(?).

S. L. Agron, 1950, Geol. Soc. America Bull., v. 61, no. 11, p. 1265–1306. Detailed discussion of structure and petrology of Peach Bottom slate which lies in center of Peach Bottom syncline. Underlain by Cardiff conglomerate and Peters Creek schist.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Probably Lower Paleozoic.

Named for exposures at Peach Bottom, York County, Pa.

Peach Lake Diorite[1]

Age(?): Eastern New York.

Original reference: R. Balk, 1936, Geol. Soc. America Bull., v. 47, no. 5, pl. 1.

Dutchess County.

Peach Orchard Sandstone (in Pottsville Formation)[1]

Peach Orchard Sandstone (in Breathitt Formation)

Pennsylvanian: Northeastern Kentucky.

Original reference: L. C. Robinson, 1927, Kentucky Geol. Survey, ser. 6, v. 26, p. 239.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 93, 97, 106. Three sandstones in Breathitt formation: Lower Peach Orchard, Upper Peach Orchard, and Peach Orchard (sometimes called Upper Peach Orchard). All occur in Lawrence and Martin Counties.

First described in Morgan County. Type locality not stated. Peach Orchard is in Lawrence County.

Peach Springs Member (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 99–101. In area of type locality, consists of thin-bedded gray limestone, some of which is aphanitic and some fine grained. Much mottled with brown siltstone. This locality apparently relatively near margin of limestone facies because in sections to north and west the rock is more aphanitic, medium to dark gray, much less mottled with brown siltstone, and thicker bedded. Thicknesss uniform in central Grand Canyon between Fossil Rapids and Toroweap; westward is slightly thicker; ranges from 42 to 90 feet. Older than Kanab Canyon member (new); younger than Spencer Canyon member (new).

Type locality: Approximately 8 miles south-southwest of mouth of Diamond Creek in Peach Springs Wash. Unit extends from vicinity of Fossil Rapids westward through the Grand Canyon.

†Peacock Formation (in Double Mountain Group)[1]

Permian: Central northern Texas.

Original reference: L. T. Patton, 1930, Texas Univ. Bull. 3027, p. 45.

U.S. Geological Survey has abandoned both the Peacock Formation and Double Mountain Group.

Named for exposures at town of Peacock, Stonewall County.

**Peale Formation**[1]

Mississippian : Northern California.

Original reference : J. S. Diller, 1908, U.S. Geol. Survey Bull. 353.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic Map of California Westwood sheet (1:250,000) : California Div. Mines. Mapped with Mississippian marine-sedimentary and metasedimentary rocks and Paleozoic metavolcanic rocks. May include some Pennsylvanian rocks.

Well exposed on trail from Wards Creek to Peale diggings, Taylorsville region.

Peanut Peak Member (of Chadron Formation)

Oligocene, lower : Southwestern South Dakota.

John Clark, 1954, Carnegie Mus. Annals, v. 33, art 11, p. 197. Designated as upper member of formation. Overlies the Crazy Johnson member (new). Author previously described unit as "Upper Member" of Chadron.

Type locality : At standard section of Chadron formation in Big Badlands on south fork of Indian Creek, Pennington County, sec. 34, T. 3 S., R. 12 E. Named from prominent butte in southern part of sec. 10, T. 4 S., R. 12 E.

**Pearce Volcanics**

Miocene or Pliocene : Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 9, 116–118, pl. 5. At west end of hill in north center sec. 1, T. 18 S., R. 25 E., hornblende andesite forms basal member and rests unconformably on Bisbee formation. Within a few hundred feet toward the east, however, andesite is overlapped by rhyolite which rests on Bisbee formation. In most other exposures of formation, rhyolites either overlie the andesites or are in fault contact with them. Andesitic parts of volcanics mostly normal flows, with subordinate flow breccias and a few thin water-laid andesitic tuffs. Flows are light pinkish gray to dark gray and weather to rather dark brown. Rhyolites include thick, massive flows, flow breccias, agglomerates, and tuffs, with fragmental rocks probably predominant. Flows range from light pinkish gray through pink to purplish and weather dark brown commonly glassy, with spherulites and lithophysae as much as 8 centimeters in diameter present in some of them. A few flows are lithic, and some are porphyritic black obsidian. In Sulphur Hills, 3,000 feet is probably minimum thickness for formation. Base exposed only in hills east and northeast of Township Butte. Upper limit of formation throughout map area is simply overlap of alluvium, and because the volcanic rocks have been highly deformed, it is impossible to estimate maximum orginal thickness.

Form a group of conspicuous isolated hills rising above alluvium of Sulphur Springs Valley in neighborhood of Pearce, from which name is derived. Six Mile, Pearce, and the Sulphur Hills, Township and Three Sisters Buttes, and Turkey Creek Ridge are all composed of these rocks. Central Cochise County.

Pearisburg Limestone[1]

Lower and Middle(?) Ordovician : Southwestern Virginia.

Original reference : R. S. Bassler, 1907, Mineral resources of Virginia by T. L. Watson, 137–138.

At Pearisburg, Giles County.

Pearl Shale (in Sumner Group)[1]

Pearl Shale Member (of Wellington Formation)

Permian : Eastern Kansas and southeastern Nebraska.

Original reference: J. W. Beede, 1909, Kansas Acad. Sci. Trans. v. 21, pt. 2, p. 255.

W. A. VerWiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 5. Included in Willington formation. Thickness 43 feet.

Named for exposures at Pearl, Dickinson County, Kans.

Pear Lake Quartz Monzonite

Jurassic-Cretaceous : Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 13, pl. 1. Light-colored coarse-grained rock that contains prominent pink potash feldspar, as well as white calcic oligoclase, gray quartz, and minor amount of biotite. In some respects resembles Lodgepole granite (new). Relation to other named plutonic rocks of area not determined.

Well exposed around Pear Lake in eastern part of area, Sequoia National Park.

**Pearlette Ash Member** (of Sappa Formation)

Pearlette Ash[1] Member (of Crooked Creek Formation and Meade Formation)

Pleistocene: Southwestern Kansas, Nebraska, Oklahoma, southeastern South Dakota to northwestern Texas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 53, 54.

J. C. Frye and C. W. Hibbard, 1941, Kansas Geol. Survey Bull. 38, pt. 13, p. 411. Cragin's Pearlette ash included in Meade formation (redefined).

C. W. Hibbard, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 742. Referred to as member of Meade formation.

G. E. Condra, E. C. Reed, and E. D. Gordon, 1947, Nebraska Geol. Survey Bull. 15, p. 22, 23, Pearlette ash has wide occurrence in Nebraska, Kansas, South Dakota, Iowa, and is perhaps best horizon marker in the Pleistocene. In Kansas, occurs between Upland and Crete (new) formations. Iowa places the volcanic ash exposed northeast of Little Sioux, Harrison County, in Loveland formation.

J. C. Frye, Ada Swineford, and A. B. Leonard, 1948, Jour. Geology, v. 56, no. 6, p. 501–523. Ash lentils, collectively called Pearlette, can be differentiated petrographically from other late Cenozoic ash deposits of Plains region and have been studed at localities extending from southeastern South Dakota to northwestern Texas. Associated molluscan fauna possesses a great degree of uniformity and stratigraphic significance. Pearlette ash and faunal zone occurs above Kansas till and below Loveland loess and Iowa till in Missouri Valley region and is judged to be early Yarmouthian in age.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no. 4, p. 69 (fig. 1), 71. Reallocated to member status in Crooked Creek formation (new). Thickness about 7 feet.

G. E. Condra, E. C. Reed, and E. D. Gordon, 1950, Nebraska Geol. Survey Bull. 15–A, p. 22–24. Pearlette ash, thickness 15 feet, occurs in Sappa formation.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 14–15. Bed in Sappa member of Meade formation.

J. C. Frye and A. B. Leonard, 1957, Texas Univ. Bur. Econ. Geology Rept. Inv. 32, p. 8 (fig. 2), 22. Included in Tule formation in western Texas.

C. W. Hibbard, 1958, Am. Jour. Sci, v. 256, no. 1, p. 55 (fig. 1), 58. Lentil in Atwater member (new) of Crooked Creek formation.

Named for old post office of Pearlette, Meade County, Kans.

Pearl Harbor Series[1]

*See* Pearl River Series.

Pearl River Series[1]

Pleistocene and Recent: Oahu Island, Hawaii.

Original reference: C. H. Hitchcock, 1900, Geol. Soc. America Bull., v. 11, p. 31–34.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p 125–126. Series of stratified rocks, about 1,000 feet thick, consisting of interbedded coral limestone, lagoon marl, poorly sorted terrigenous clays, silts, sands, and conglomerates, and beds of tuff. Locally interbedded with flows of Honolulu volcanic series. Overlies lavas of Koolau and Waianae volcanic series. Same as Pearl Harbor series (Hitchcock, 1912). Neither name (Pearl River series or Pearl Harbor series) now used.

Named after Pearl River, which drains into Pearl Harbor on south side of island.

**Pearsall Formation** (in Trinity Group)

Lower Cretaceous (Comanche Series): Southern Texas (subsurface).

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 10, p. 1441–1449. Defined for a sequence of dominantly shaly beds lying above the Sligo formation and below the Glen Rose limestone and representing the subsurface equivalents of the Travis Peak formation of the outcrop area. Type section extends from depths of about 8,835 to 9,360 feet, is 525 feet thick, and divisible into three members (ascending): Pine Island shale, 100 feet thick; Cow Creek limestone, 85 feet thick; and Hensell shale, 340 feet thick.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2340–2350. In this study, defined as a sequence of dominantly shaly beds stratigraphically above the Sligo formation and below the base of either the Glen Rose limestone or the Rodessa formation. Divisible into three members (ascending): Pine Island, Cow Creek or James limestone, Bexar shale. Undifferentiated where neither the James nor the Cow Creek member is recognized.

Type well: Amerada Petroleum Corp.'s Halff and Oppenheimer No. 8, in Pearsall field about 10 miles southwest of Pearsall, Frio County.

Pearson Glauconite Member (of Sabinetown Formation)

Eocene, lower (Wilcox): Western Louisiana and northeastern Texas.

Richard Wasem and L. J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 182 (footnote). Term Pierson glauconite was first used in field notes of Justin Rukas as a name for glauconite sands (first marine sand of

Sabinetown faunal unit) cropping out near railway station of Pierson, north of Natchitoches, La. Name is applied in this paper to westward extension of bed into Sabine County, Tex.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 63. Rank raised to member status in Sabinetown formation (restricted). Typically a fine-grained greensand or glauconitic sand which commonly contains considerable concretionary ironstone; fossiliferous. Thickness 32 feet. Reaches maximum development in Sabinetown area, thinning both northeastward and northwestward along strike. Underlies an upper unnamed member of the Sabinetown; overlies High Bluff member of Pendleton formation; in most exposures both upper and lower contacts are conformable and gradational.

First described from occurrence in Natchitoches Parish, La.

Pearsonia Limestone Member (of Pawhuska Formation)

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 49. Name applied to member of Pawhusk. Overlies Little Hominy member; underlies Turkey Run member. Name credited to J. A. Carter (unpub. thesis) who applied name to "red" limestone of Heald (1918, U.S. Geol. Survey Bull. 691–C).

Type locality and derivation of name not stated. Map shows town of Pearsonia in northern Osage County. The limestone extends only to sec. 28, T. 26 N., R. 8 E., Osage County.

**Pease River Group**

Permian (Leonard Series): Western Texas.

H. C. Fountain, 1939, *in* Am. Assoc. Petroleum Geologists Bull., v. 23, no. 5, p. 764. Name applied to the series of stratigraphic units from base of San Angelo up to base of Custer group. In tracing group northward to Mangum, Okla., it was demonstrated that it contained a part if not all of the Duncan sandstone, all of the Flowerport shale, Blaine, and Dog Creek shale up to base of Marlow or Custer group in Oklahoma and Kansas. Type exposure given.

Robert Roth, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1412, 1413. Rocks of Leonard age that overlie the Clear Fork group have been designated varyingly as San Andres group, El Reno group, Pease River group, and "Blaine of Texas". Pease River is adopted here because its upper and lower limits are easily recognized over much of east side of Permian basin. Includes beds from base of San Angelo sandstone up to base of Custer group which is 10 to 30 feet below base of Childress limestone. Average thickness 870 feet. Disconformable at base and regional unconformity at top.

Robert Roth, 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 893–907. Includes San Angelo, Flowerpot, Blaine, and Dog Creek formations as exposed in Texas. Correlation with Cherry Canyon formation (Guadalupe series) suggested. Thickness 874 feet at type locality which is herein stated.

Type exposure (Fountain): Along Pease River in Hardeman and Cottle Counties.

Type locality: South Fork of Wichita River and Little Croton Creek in King and Knox Counties, about 40 miles south of Pease River.

**Peasley Member** (of Highland Peak Formation)

Peasley Limestone

Middle Cambrian: Southeastern Nevada and western Utah.

H. E. Wheeler, 1940, Nevada Univ. Bull., Geology and Mining Ser., no. 34, p. 12 (fig. 2), 14, 17–27. Chiefly dark-gray (carbonaceous) medium-grained thickly bedded to massive limestone commonly with numerous calcite veinlets in areas of appreciable deformation; topmost strata variable in character in consequence of differential erosion during post-Peasley hiatus. Thickness at type section about 120 feet; in Ely Range 150 feet. Unconformably overlies Chisholm shale; unconformably underlies Burrows dolomite (new). This is unit "A" of Highland Peak limestone as described by Wheeler and Lemmon (1939); Burrows dolomite is unit "B" and Highland Peak is herein restricted to exclude these units.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 33–35, fig. 5. Recognized from Groom, Nev., to Wah Wah Range, western Utah. Chisholm shale thins out and disappears between Wah Wah and House Ranges, thus bringing similar Lyndon and Peasley limestone into contact. In House Range, their combined counterpart is herein named Millard limestone.

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 508. Thickness of Peasley given as 791 feet in section measured in Virgin Mountain, Clark County, Nev.; overlies Chisholm shale; underlies unnamed dolomitic limestone (Middle and Upper? Cambrian).

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 339, 340. Name Jangle limestone (new) substituted for Peasley limestone of Wheeler (1940) in Pioche and Groom districts.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 50 (fig. 4). Chisholm formation, as redefined in Wah Wah Range, includes Peasley limestone as used in that area by Wheeler (1948).

U.S. Geological Survey currently classifies the Peasley as a member of Highland Peak Limestone on basis of a study now in progress.

Type locality: On northwest spur of Comet Peak, on west side of Highland Range, Pioche district, Nevada. Spur forms secondary divide immediately south of Peasley Canyon.

**Peavy Pond Complex**

Peavy Complex

Precambrian: Northwestern Michigan.

R. W. Bayley, 1956, Dissert. Abs., v. 16, no. 8, p. 1427. Composed of gabbro with minor ultrabasic parts and fringed with intermediate and acid differentiates and hybrids. Intruded Hemlock and Michigamme formations during late middle Precambrian orogeny and metamorphism.

R. W. Bayley, 1959, U.S. Geol. Survey Bull. 1077, p. 10, 75–80, 82–92, pl. 1. Peavy Pond complex as designated here includes all intrusive rocks exposed on shores and islands of Peavy Pond. Cuts Hemlock and Michigamme formations in south part of Lake Mary quadrangle.

On shores and islands of Peavy Pond in secs. 14–17, 19–22, and 27–30, T. 42 N., R. 31 W., Iron County.

**Peay Sandstone Member** (of Frontier Formation)[1]

Upper Cretaceous: Southern Montana and northern Wyoming.

Original reference: F. F. Hintze, Jr., 1915, Wyoming Geol. Survey Bull. 10, p. 21.

J. H. Heathman, 1939, Wyoming Geol. Survey Bull. 28, p. 7 (table 2), 13. On south and east sides of Bighorn Basin, consists of concretionary sandstone about 87½ feet thick in lower part of formation.

Named for Peay Hills, Big Horn County, Wyo.

**Pecan Gap Chalk Member** (of Taylor Marl)[1]

Pecan Gap Chalk (in Taylor Group)

Upper Cretaceous: Northeastern Texas.

Original reference: L. W. Stephenson, 1918, U.S. Geol. Survey Prof. Paper 120–H, p. 156.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 38, 39 (fig. 4), 42–43 [1939]. Rank raised to formation in Taylor group. Bluish-white hard massive; partly sandy chalk and bluish-gray soft pliable sandy and chalky marl. Average thickness in Leon County wells 150 feet. Lies above Wolfe City sand and below unit referred to as upper Taylor marl.

J. T. Rouse, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 525–527. Detailed surface mapping in belt of outcrop from Collin County eastward into Red River County, shows that Pecan Gap chalk thins and disappears north and east and that Wolfe City sand, which underlies Pecan Gap, is to be correlated with Annona chalk (previously correlated with Pecan Gap).

H. R. Blank, N. L. Stoltenberg, and H. H. Emmerich, 1952, Texas Univ. Bur. Econ. Geology Rept. Inv. 12, p. 5, 10 (table 1), 12–15. Member described in Blacklands experimental watershed, near Waco. Consists of lower chalk, 8 to 25 feet; lower highly calcareous marl, 90 to 100 feet; upper chalk, about 13 feet; and upper highly calcareous marl (not known how much of this should be included in member). Overlies Wolfe City member with unconformity; underlies upland gravel (Ulvade formation).

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 45–46, table 4. Pecan Gap chalk (Taylor group) has been considered tongue of Annona chalk, with lower marl and Wolfe City sand being lateral equivalents of lower part of Annona chalk (the interpretation accepted here). Alternative hypothesis has been presented: that the chalk is transgressive formation, younger than the marl and sand units. Foraminifera described.

Typically exposed in cut of Gulf, Colorado, and Santa Fe Railway, one-half mile east of Pecan Gap, Delta County, Tex.

**Pecatonica Dolomite Member**[1] (of Platteville Formation)

Pecatonica Formation (in Platteville Group)

Middle Ordovician: Southern Wisconsin, northwestern Illinois, northeastern Iowa, and southeastern Minnesota.

Orginal reference: O. H. Hersey, 1894, Am. Geologist, v. 14, p. 175.

C. A. Bays, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 269. Underlies Miffin limestone member (new) of Platteville formation.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, 11 (fig. 3). In Dixon-Oregon area, Illinois, considered a formation in Platteville group. Consists of about 30 feet of dolomite and limestone, relatively pure, locally cherty, finely crystalline, and thick bedded; slightly argillaceous and has weak shale films in middle. Subdivided into (ascending) Hennepin, Chana, Dane, New Glarus, Medusa, and Oglesby members (all new). Underlies Mifflin formation; overlies Harmony Hill formation (new) in Ancell group (new).

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 275, 277–279. At designated type outcrop, Pecatonica dolomite member is 20 feet thick. Overlies Glenwood shale member; underlies McGregor limestone member.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1030–1031. Pecatonica member ranges in thickness from about 7 feet east of Mabel, Minn. to featheredge about 20 miles northwest; thickens as it continues into Iowa, Wisconsin, and Illinois; about 1 foot thick at Minneapolis.

Type locality: Bluff along Pecatonica River at Lattice Bridges, NW¼NW¼ sec. 21, T. 1 N., R. 6 E., Green County, Wis.

Pecatonica glaciation

Pecatonica till[1]

Pleistocene (pre-Wisconsin): Illinois.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203, 217.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 69, no. 2, p. 129. Referred to as glaciation.

Peckham Formation

Pleistocene, upper: Central California.

C. J. Leith, 1949, California Div. Mines. Bull. 147, p. 12 (fig. 2), 26–27, pls. 1, 2. Name proposed for nonmarine silts, sands, gravels, and limestone occurring near center of Quien Sabe quadrangle. Maximum thickness 300 feet. Formation flat lying and rests with as much as 90° angular discordance upon the Franciscan and as much as 25° upon Miocene [Quien Sabe] volcanics.

Name derived from Peckham Ridge, an eastward trending spur of Diablo Range which marks northern limit of exposures, Quien Sabe quadrangle, about 90 miles southeast of San Francisco.

Pecksport Member[1] of Marcellus Formation)

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 134, 219.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart above Solsville member and below Mottville member.

Type section: Livermore Gully, 1 mile east of railroad switch at Pecksport, Madison County.

†Pecos Formation[1]

Permian: Southeastern New Mexico.

Original reference: A. G. Fiedler and S. S. Nye, 1933, U.S. Geol. Survey Water-Supply Paper 639.

Named for exposures east of Pecos River, Roswell artesian basin.

Pecos shale[1]

Permian (?) : New Mexico.

Original reference: C. R. Keyes, 1909, Iowa Acad. Sci. Proc., v. 16, p. 159–163.

Rio Grande Valley.

Pecosan series[1]

Pecosian series[1]

Tertiary, upper : Eastern New Mexico and western Texas.

Original reference: C. R. Keyes, 1907, Iowa Acad. Sci. Proc., v. 14, p. 223–228.

Llano Estacado region.

Pecos Canyon Sandstone[1]

Permian : Northeastern New Mexico.

Original reference: J. K. Knox, 1920, Am. Assoc. Petroleum Geologists Bull., v. 4, p. 99–101.

In Santa Rosa-Tucumcari region.

†Pecos Valley Red Beds[1]

Permian and Triassic : Southeastern New Mexico.

Original reference : J. W. Beede, 1910, Am. Jour. Sci., 4th, v. 30, p. 131.

Crop out along foot of eastern flank of Sacramento Mountains and underlie alluvium in lower Pecos Valley. Well developed in walls of Rocky Arroyo, 20 miles west of Carlsbad, Eddy County.

Peculiar Shale (in Puente Formation)

Miocene, upper : Southern California.

M. L. Krueger, 1943, California Div. Mines Bull. 118, p. 363. Shown on structure section as underlying Mahala sandstone and conglomerate (new) and overlying Hunter sandstone and conglomerate (new).

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 521. Micaceous sandy shale with poor stratification. Thickness 657 feet. Upper part of Puente. Measured section noted.

Exposed in Slaughter Canyon in southeastern Puente Hills, between Chino and Santa Ana River, San Bernardino County.

Pecursian series[1]

Picursian series[1]

Precambrian : New Mexico.

Original reference : C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico : Des Moines, Robert Henderson, State Printer, p. 4, 10.

**Pedee Group**[1]

Peedee Group[1]

Pennsylvanian (Missouri Series) : Northwestern Missouri and eastern Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., Guidebook, p. 93, 97.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, v. 25, 2d ser., p. 28. Pedee recognized in northwestern Missouri where it includes Weston shale and Iatan limestone members.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 295. Term Pedee dropped from Iowa nomenclature. Weston shale and Iatan limestone included in Lansing group. Later work may warrant reestablishment of Pedee as independent group.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 78. Pedee is topmost division of Missourian rocks; includes Weston shale below and Iatan limestone above and possibly a few feet of sandy and clayey shale above the Iatan. Occurs between Stanton limestone of Lansing group and disconformity that defines top of Missourian series. Average thickness 90 feet.

Named from stream near Weston, Platte County, Mo., opposite Leavenworth, Kans., on Missouri River.

Pedernal Chert Member (of Abiquiu Tuff)

Miocene(?): North-central New Mexico.

F. S. Church and J. T. Hack, 1939, Jour. Geology, v. 47, no. 6, p. 618, 620, 622. Thin veneer of remarkably pure chert that overlies the broad plateaulike surface which forms summit of San Pedro Mountain in many places. It passes laterally, without losing continuity, into poorly consolidated conglomerate, sandstone, shale, and tuff, which, in Cerro Pedernal, are obviously part of Abiquiu tuff.

Mapped on San Pedro Mountain, and its horizon followed eastward into the high mesas of northern part of Jemez Mountains. Named after Cerro Pedernal, a mountain whose Spanish mame means "flint" It [the mountain] presumably was so named from outcrops of chert long quarried by the Indians.

†Pedernales Dolomite Member (of Wilberns Formation)

Upper Cambrian: Central Texas.

Frederick Romberg and V. E. Barnes, 1944, Geophysics, v. 9, no. 1, p. 88, fig. 7. Gray to pinkish gray dolomite. Overlies San Saba member; underlies unnamed dolomite at base of Ellenburger formation. Name credited to Josiah Bridge and V. E. Barnes.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 148, 150, 155–156, pl. 4 [1945]. Uppermost member of formation; lies between San Saba limestone member below and Tanyard formation of Ellenburger group above. Grades downward and laterally into San Saba, an essentially equivalent facies if considered in regional sense. In type area, lower 86 feet is fine grained and evenly bedded, contrasting sharply with overlying massive coarse-grained part; coarse-grained dolomites are predominantly light gray and silvery gray with occasional intervals of yellowish gray or nutria; fine-grained dolomite is yellowish gray to beige; entire section speckled to mottled with dull dark reddish purple in varying degrees; glauconite, common elsewhere, is present only in basal few feet of member; some chert present, mostly near top of fine-grained part. Thickness in type area 187 feet; in Cherokee area 70 to 150 feet. Dolomites here named Pedernales were formerly included in Ellenburger limestone. Type section designated.

Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 121–123, pls. 1, 2. Dolomite facies of upper part of Wilberns developed mostly in eastern part of Llano uplift. Commonly replaces and is equivalent to variable part of San Saba limestone member, which is characteristic of upper Wilberns in western part of uplift. In western Blanco County, replaces entire San Saba and includes beds equivalent to most of Point Peak shale member as well. Base extends lower in section in type area than at other places in uplift, but thicker sections have been measured elsewhere; this variation in thickness probably due to pre-Ordovician truncation of upper beds of Pedernales in vicinity of type section. Thickness on Backbone Ridge, Burnet County, 224 feet; at the Tanyard, Burnet County, 277 feet. Pedernales is that part of former Ellenburger limestone which Dake and Bridge (1932, Geol. Soc. America Bull., v. 43) called the Potosi and Eminence equivalents, and its removal from revised Ellenburger group and inclusion in Wilberns formation necessitated redefinition of Ordovician and Cambrian beds above and below systemic boundary (Cloud, Barnes, and Bridge, 1946 [1945]).

V. E. Barnes and W. C. Bell, 1954, San Angelo Geol. Soc. [Guidebook] March 19–20, p. 35, 36. Name Pedernales dolomite dropped.

Type section: Along Pedernales River from 1½ to 3 miles up stream from bridge on Johnson City-Marble Falls Highway 1 mile north of Johnson City, Blanco County.

Pedlar Formation (in Virginia Blue Ridge Complex)

Precambrian: Central Virginia.

R. O. Bloomer and H. J. Werner, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 582, pl. 1. Assemblage of granitic, granodioritic, syenitic, quartz dioritic, anorthositic, and unakitic rocks undifferentiable in the field. A green, white, or red coarse-grained granulose rock. Unconformably overlapped by sequence of Late Precambrian and Early Cambrian formations.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2), 9–11, pl. 1. Included in Virginia Blue Ridge complex (new). Prevailing facies in Lynchburg area is gray to gray-green massive medium- to coarse-grained hypersthene or hornblende quartz monzonite. Typical exposures cited.

Typical exposures found along upper reaches of Pedlar River of northwestern Amherst County. Named from the river. Forms most of the basement complex of the Blue Ridge northeast of Roanoke and many masses surrounded by the Marshall and Lovingston formations in the Piedmont.

Pedregosa Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 8–9, 17–18, pl. 27. Consists of (ascending) buff sandstone, white platy sandstone, gray and buff limestone, calcareous sandstone, white and yellow shale, greenish sandstone, and thin layers of argillaceous limestone, sandstone, and shale. Thickness 182 feet. Overlies Perilla member (new); underlies Mural limestone.

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated at Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

**Pedro Bentonite Bed** (in Gammon Ferruginous Member of Pierre Shale)[1]

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

C. S. Robinson, W. J. Mapel, and W. A Cobban, 1959, Am Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 106. Present at base of member in vicinity of Osage, Weston County, Wyo. Thickness 30 feet in Weston County. Thins laterally and a few miles north is less than 1 foot thick or is absent.

Named for exposures near Pedro, sec. 5, T. 45 N., R. 63 W., Weston County, Wyo.

Pedroian[1]

Pleistocene, lower: California.

Original reference: J. E. Eaton, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, p. 138.

**Pedro Miguel Agglomerate**

Pedro Miguel Agglomerate Member (of Panama Formation)

Miocene, lower: Panama.

[T. F. Thompson], 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 17–18. Pedro Miguel agglomerate proposed for extensive occurrence of this rock type in vicinity of Pedro Miguel Lock and its approach channels. In this area, associated with Cucaracha formation; in La Boca region, occurs near base of La Boca sediments (new) which are considered to be slightly younger than the Cucaracha.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 242, 246 (fig. 2). Lens of pyroclastics formerly referred to Las Cascadas agglomerate. In type region, pyroclastics overlie Cucaracha formation, but lower part apparently equivalent to upper part of Cucaracha sections. Farther south, pyroclastics occur as tongue in basal part of La Boca formation. Thickness varies; maximum averages about 300 feet.

W. P. Woodring, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–1; 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 40–41. Rank reduced to member status in Panama formation.

Type region: Pedro Miguel area. Recognized along and near Panama Canal from Pedro Miguel area to Pacific terminus.

Peebles Dolomite[1]

Silurian (Niagaran): Southwestern Ohio.

Original reference: A. F. Foerste, 1929, Ohio Jour. Sci., v. 29, no. 4, p. 168–169.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart below Greenfield dolomite and above Cedarville dolomite of Durbin group.

Type section: Between Peebles, Adams County, and base of Greenfield dolomite, several miles east.

Peebles granite facies (of Ogishke Conglomerate)

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1034–1035. One of three facies in Ogishke conglomerate. Contains a wide assortment of pebbles in which 36 rock types have been recognized. Thickness 2,100 feet. Underlies West Gull facies; unconformably above Dike Lake slate.

Described in Kekequabic-Ogishkemuncie area.

**Peedee Formation**[1]

Upper Cretaceous: Eastern South Carolina and eastern North Carolina.

Original reference: E. Ruffin, 1843, Agric. Survey South Carolina, 1st Rept., p. 6–7, 24–27.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 44; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Mapped in North Carolina where it crops out in a belt extending from Tar River at Greenville, Pitt County, southwest to South Carolina line. Near Greenville, only 3 or 4 miles wide, but to the southwest reaches maximum width of more than 25 miles. Variable gray to green argillaceous sands and impure limestones; locally, massive marine clays and interbedded sands. [Spelled Pee Dee.]

Named for exposures on Great Peedee River, S.C., the exposure at Burches Ferry, on west side of Peedee River in Florence County, being a typical one.

†Peedee Marl[1]

Miocene, upper: Northeastern South Carolina.

Original reference: E. Ruffin, 1843, Agric. Surv. South Carolina 1st Rept., p. 28.

Named for exposures in Peedee River region from Darlington to Allisons Ferry, Darlington and Florence Counties.

†Peedee River Marls[1]

Upper Cretaceous: Eastern South Carolina.

Original reference: F. S. Holmes, 1870, Phosphate rocks of South Carolina, p. 12, 13.

Peekskill Diorite Gneiss[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey and Marion Rice, 1921, New York State Mus. Bull. 225–226, p. 28.

Type locality: Along Peekskill Creek, Westchester County.

Peekskill Granite[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey, 1907, New York State Mus. Bull. 107, p. 377.

D. T. O'Connell, 1937, Geological excursions in New York City and vicinity Trip II: New York City Coll. Dept. Geology, p. 23. Considered to be acid differentiate of Cortlandt series.

Type locality: About 3 miles east-northeast of Peekskill, Westchester County.

Peekskill Norite[1]

Age(?): Eastern New York.

Original reference: R. Balk, 1936, Geol. Soc. America Bull., v. 47, no. 5, pl. 1.

Dutchess County.

Peekskill Phyllite[1]

Ordovician: Southeastern New York.

Original reference: C. R. Fettke, 1914, New York Acad. Sci. Annals, v. 23, p. 245–257.

Well exposed on northwest side of Peekskill Creek valley, Peekskill region.

Peekskill Creek Limestone[1]

Lower Cambrian to Middle Ordovician: New York.

Original reference: C. R. Fettke, 1914, New York Acad. Sci. Annals, v. 23, p. 201.

Peekskill Creek region.

Pe Ell Volcanics member (of Cowlitz Formation)

Eocene, upper: Southwestern Washington.

D. A. Henriksen, 1954, Dissert. Abs., v. 14, no. 12, p. 2316. Named as member of Cowlitz. Overlies Stillwater Creek member and underlies Olequa Creek member (both new).

D. A. Henriksen, 1956, Washington Div. Mines and Geology Bull. 43, p. 38, 46–48, pl. 1. Series of lapilli tuffs, agglomerates, breccia, and thin interbedded tuffaceous siltstones intercalated with lower part of Stillwater Creek member. Attains maximum thickness of 1,200 to 1,500 feet at type locality; thins eastward wedging out at surface about 4 miles southeast of Pe Ell.

Type locality: In banks of Chehalis River in sec. 4, T. 12 N., R. 5 W., and secs. 33 and 34, T. 13 N., R. 5 W., W. M., Lewis County.

**Peerless Formation**

Peerless Shale Member (of Sawatch Formation)[1]

Upper Cambrian: Central Colorado.

Original reference: C. H. Behre, Jr., 1932, Colorado Sci. Soc. Proc., v. 13, no. 3, p. 58.

Q. D. Singewald, 1947, Preliminary geologic map and section of the upper Blue River area, Summit County, Colorado (1:31,250): U.S. Geol. Survey; 1951, U.S. Geol. Survey Bull. 970, p. 9 (table). Rank raised to formation. In Summit County, consists of two parts. Lower, equivalent to "Transition shale" at Leadville; basal quartzite is purple to nearly black, faintly crossbedded, and 2 to 10 feet thick; middle part, 10 to 12 feet thick, is brownish weathering dolomite in beds 3 inches to 3 feet thick; upper 10 to 20 feet is green platy shale with intercalated thin dolomites, highest of which contain red casts. Upper part equivalent to basal "White limestone" at Leadville; thin-bedded drab-weathering to brownish-weathering dolomite; uppermost beds slightly shaly and locally contain partings of thin layers of green shale. Thickness about 60 feet on North Star Mountain (composite section); 85 feet south side Spruce Creek. Underlies Manitou limestone, upper boundary indefinite; overlies Sawatch quartzite, hiatus.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 161–165. Formation described in Pando area where it is 35 to 112 feet thick and consists of thin-bedded, buff, green, purple, and pink sandy dolomite and dolomitic sandstone. Conformably overlies Sawatch quartzite; unconformably underlies Harding quartzite.

I. H. Mackay, 1953, Colorado School Mines Quart., v. 48, no. 4, p. 8, 13–14, 15, 16, pls. Peerless member described in Thomasville-Woods area, Eagle and Pitkin Counties. Term "shale" is misnomer because unit here consists chiefly of thin-bedded gray to buff fine- to coarse-crystalline dolomites with numerous partings and stringers of arenaceous material, sandstones, and some shale. Thickness 50 to 102 feet. Basal part of formation. Upper part of formation; underlies Manitou dolomite.

R. R. Berg and R. J. Ross, Jr., 1959, Jour. Paleontology, v. 33, no. 1, p. 106–108. On basis of lithology and stratigraphic position, unit termed Ute Pass dolomite (Maher, 1950) in Missouri Gulch area is correlated with Peerless formation, and term Ute Pass is abandoned.

Typical occurrence on northwestern slope of Peerless Mountain, 6 miles east-southeast of Leadville.

Peerless Sandstones (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1914, West Virginia Geol. Survey Rept. Kanawha County, p. 281, 282.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 98. Considers the Kanawha a group.

Named for its association with the Peerless coal which was named for a mining village (now abandoned) on south side of Kanawha River just east of Lewiston, Kanawha County.

**Peers Spring Formation[1]**

Peers Spring Formation (in White Pine Group)

Peers Spring Formation (in White Pine Shale)

Lower Mississippian: Eastern Nevada.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171, p. 7, 20, map.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 25). Shown in Osagean series on correlation chart.

R. L. Langenheim, Jr., and J. H. Peck, Jr., 1957, (abs.) Geol. Soc. America Bull., v. 68, no. 12, pt. 2, p. 1833; 1959, Cahiers Géol., no. 56, p. 537–548. At Dutch John Mountain, formation consists of basal calcareous siltstone unit (about 140 feet thick), middle black fissile shale unit (about 420 feet thick) which includes ledge-forming limestone, and an upper poorly exposed silty shale unit (about 460 feet thick). These units, except the limestone, are present at Peers Spring, but faulting prevents satisfactory mesurement. Middle unit of the Peers Spring resembles the bulk of Chainman shale at Ely, Nev., but all three units together are lithologically similar to White Pine shale at Hamilton, Nev. Single specimen of *Cravenoceras hesperium* and single specimen of *Rayonnoceras* were collected from lower Peers Spring unit at Dutch John Mountain. *C. hesperium* fauna, including *Brachycycloceras*, present in rocks of presumed similar stratigraphic position at Peers Spring. Westgate's report of Lower Mississippian fossils in Peers Spring apparently based on collections from fault block of Bristol Pass limestone at Peers Spring. Available paleontologic evidence suggests Upper Mississippian age for Peers Spring and biostratigraphic correlation with White Pine, Chainman, and Perdido formations. Underlies Scotty Wash quartzite at Dutch John Mountain.

R. L. Langenheim, Jr., and Herbert Tischler, 1960, California Univ. Pubs., Geol. Sci., v. 38, no. 2, p. 108 (fig. 5), 110. Discussion of Quartz Spring area, Inyo County, Calif. Formations, Tin Mountain limestone, Perdido formation, and Rest Spring shale as defined by McAllister (1952) are utilized in discussion and description of rocks in area. On the other hand, Joana limestone, Peers Spring formation, and Chainman shale, with somewhat different limits, are formations to which these same rocks would be assigned in regional discussion of Mississippian stratigraphy in Great Basin. For purposes of expressing regional stratigraphic relationships, many already proposed names are redundant. Figure 5 presents a condensed set of already proposed names as restricted and applied to units of regional significance. Names Peers Spring formation and Chainman shale are retained for formational units within a White Pine group, although these three names have frequently been employed in a synonymous sense.

R. L. Langenheim, Jr., and others, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 151. Rank reduced to member status in White Pine shale. Constitutes lower 50 feet of formation; underlies Chainman member. Age of White Pine shale, Upper Mississippian. Report is on geology of Ely No. 3 quadrangle.

Named for occurrence in hills east and north of Peers Spring, 3 miles northwest of Bristol Pass, Pioche district, Lincoln County.

Peery Limestone (in Cliffield Group)

Peery Limestone Member (of Cliffield Formation)

Middle Ordovician: Southwestern Virginia.

B. N. Cooper and C. F. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 830–832, 863–864, 884 (fig. 3). In Tazewell County, strata embraced by the Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into 29 zones (ascending). Name Peery limestone member of Cliffield formation is applied to zones 8 and 9. The lower zone is dark-bluish-gray to black fine-grained argillaceous limestone containing *Lophospira;* upper zone is a succession of thick-bedded taupe- and dove-gray, rather pure calcilutites. Thickness about 50 feet; locally, as at Maxwell, Cliffield, and Gratton, the calcilutite alone exceeds 100 feet. Overlies Ward Cove member (new); underlies Shannondale limestone member of Benbolt limestone (both new).

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 68–69, pl. 8. In area between Brushy and Walker Mountains, the Peery is considered a formation in Cliffield group. In this area, the Peery overlies Athens formation. Thickness 10 to 18 feet.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 83. On southeast side of Clinch Mountain, overlies Rich Valley limestone (new) and underlies Benbolt shale.

Type locality: At south end of Peery Lime Co.'s quarry near State Highway 61, about three-fourths mile east of railroad station at North Tazewell, Tazewell County, Va.

**Pegram Limestone**[1]

Pegram Formation

Middle Devonian: Western Tennessee.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 400, 425.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as part Lower or Middle Devonian and part Middle Devonian.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 312–315. Pegram formation varies in thickness from featheredge to maximum of 30 feet in Cheatham County. Unit referred to as sandstone, limestone, shale, and so on, depending upon phase of occurrence of lithologic type. Unconformably overlain by Chattanooga shale. Major overlapping unit in central Tennessee; at the Whirl of Buffalo River and at Standing Rock Creek, rests on Camden limestone, on Mill creek, it is on Beech River; in Davidson and Cheatham Counties, rests on the Lego, Dixon, Bob, Beech River, and Bledsoe(?) formations; in Trousdale and Sumner Counties, overlies the Laurel.

Named for exposures at Pegram, Cheatham County.

**Pejepscott Gneiss**

Pejepscot Formation

Cambrian(?): Southwestern Maine.

L. W. Fisher, 1938, (abs.), Geol. Soc. America Proc. 1937, p. 81. Incidental use of term Danville-Pejepscot series of gneisses. Middle Silurian.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 113–115, pl. 1, table 1 (facing p. 112). Formation described. Consists of three phases: coarse-grained quartz-feldspar-biotite gneiss, fine-grained quartz-biotite schist, and amphibolite. Maximum thickness approximately 10,000 feet. Underlies Taylor Brook formation. Cambrian(?). Type locality given.

V. E. Shainin, 1948, Maine Geol. Survey Bull. 5, p. 10–11. Referred to as gneiss.

Type locality: Roadcut one-half mile west of village of Pejepscot, Sagadahoc County.

**Pekin Formation** (in Newark Group)[1]

Upper Triassic: Central North Carolina.

Original reference: M. R. Campbell and K. K. Kimball, 1923, North Carolina Geol. and Econ. Survey Bull. 33, p. 20–25.

J. A. Reinemund, 1955, U.S. Geol. Survey Prof. Paper 246, p. 28–31, pl. 1. Lowest of the three Triassic formations in Deep River basin; lies unconformably on pre-Triassic metamorphic and igneous rocks at bottom of the Triassic sedimentary wedge and crops out in a belt along northwest side of basin; underlies Cumnock formation. Rocks vary greatly from place to place but in general consist of gray conglomerate, red or brown coarse-grained sandstone, red or brown siltstone and claystone in lenticular beds, gray coarse-grained sandstone, and gray siltstone. Thickness 1,750 to 1,800 feet in northern part of Sanford basin; 3,000 to 4,000 feet in western part of basin.

Named for exposures at Pekin, Montgomery County. Outcrop ranges in width from 3/5 of a mile to 3½ miles in Sanford basin and attains width of 4½ miles in Colon cross structure and southern part of Durham basin.

Peleliu (Pelilieu) Limestone

Pleistocene to Recent: Caroline Islands (Peleliu, Ngemelis, and Angaur).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation table) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 67, table 4 [English translation in library of U.S. Geol. Survey, p. 80]. Raised coral reef limestone. Consists primarily of *Halimeda* limestone and secondarily of coral limestone. Older than Ngarekeukl limestone. Pleistocene.

U.S. Army Corps of Engineers, 1956, Military geology of Palau, Caroline Islands: U.S. Army Corp of Engineers, Far East, p. 59–60, pls. 4, 10, 11. Estimated thickness 100 feet; upper surface commonly at an altitude of 30 feet or less. In many areas overlie Palau limestone. Pleistocene to Recent. Has been called Angaur limestone on Angaur.

Crops out on Peleliu, Ngemelis, and Angaur in southern part of Palau Islands.

†Pelham Granite[1]

Upper Carboniferous or post-Carboniferous: Central Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 48.

Robert Balk, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–92. Name abandoned for rocks of the Pelham dome gneissic complex. These now subdivided and termed Dry Hill granite gneiss and Poplar Mountain gneiss.

Crops out in Pelham Township, Hampshire County.

†Pelham Limestone[1]

Ordovician: Alabama.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. on Cahaba coal field, p. 152, section opposite p. 162, map.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 83. Broad name that is nearly equivalent to Chickamauga limestone as it embraces interval from top of Knox to Clinton. Name long neglected while Chickamauga was becoming entrenched in the literature. Neither name now has any value because Chickamauga sequence of Georgia and Pelham of Alabama can be divided into several formations ranging in age from Marmor to Trenton or higher.

Named for Pelham, Shelby County.

†Pelham Quartzite[1]

Upper Carboniferous or post-Carboniferous: Western central Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18, pl. 34, map.

Crosses Pelham Township, Hampshire County.

†Pelham Saxonite[1]

Late Carboniferous or post-Carboniferous: Western central Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 47–55, pl. 34, map.

In Shutesbury Township, Franklin County and Pelham Township, Hampshire County.

Pelier Schist (in Evington Group)

Lower Paleozoic(?): South-central Virginia.

W. R. Brown, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1547. Incidental mention.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, 91 (fig. 1). Tan sericite-quartz schist. Contains thin quartzites. Biotite porphyroblasts characteristic. Cloritoid facies common. Thickness 400 feet. Underlies Mount Athos formation and overlies Arch Marble (new), all in Evington group (new) of Paleozoic(?) age. Type locality designated.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 29, 34–35, pl. 1. Proposed that schist phase of Mount Athos formation be separated and named Pelier schist. Age shown on columnar section as Lower Paleozoic(?).

Type locality: Railroad cuts at Six Mile Bridge ½ mile northwest of Mt. Pelier Church, 4½ miles east of Lynchburg, Campbell County. Lynchburg quadrangle.

Pella Beds[1]

Mississippian: Central southern and southeastern Iowa.

Original reference: H. F. Bain, 1895, Am. Geologist, v. 15, p. 318.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 815. Beds consist of a thin basal sandstone, overlain by 5 feet of shale and 25 feet of compact thin-bedded limestone which grades into shale to the northwest. Unconformably overlie Verdi member of St. Louis formation.

Named for exposures near Pella, Marion County.

Pellisier Granite[1]

Middle or Late Mesozoic: Central eastern California.

Original reference: G. H. Anderson, 1935, Pan-Am.Geologist, v. 64, no. 1, p. 66.

G. H. Anderson, 1937, Geol. Soc. America Bull., v. 48, no. 1, p. 8–11. The granites [Pellisier and Boundary Peak] are probably equivalent in age to the Sierra batholith—middle or upper Mesozoic. Derivation of name given.

Typically exposed on a surface of low relief, designated as Pellisier Flats, which occupies large area along the crest of Inyo Range.

Pelly Gneiss[1]

Precambrian: Central eastern Alaska, and Yukon Territory, Canada.

Original reference: A. J. Collier, 1903, U.S. Geol. Survey Bull. 218, p. 16.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Mapped as Lower Precambrian in Tanana region.

Named for exposures on Pelly River.

**Pelona Schist**[1]

Precambrian(?): Southern California.

Original reference: O. H. Hershey, 1902, California Univ. Pub. Dept. Geol. Bull., v. 3, pl. 1, map.

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Mapped in Valyermo quadrangle where it is overthrust by Pleasant View complex (new). Age relations of the two units unknown.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 49–50, pl. 1. In San Fernando quadrangle, Pelona schist is present only north of San Gabriel fault. Thickness about 7,500 feet. Many workers have suggested a probable Precambrian age for the Pelona, and others have considered age to be more likely Mesozoic than Precambrian. Age of schist must be considered in doubt because none of evidence presented to date has been entirely satisfactory. Map bracket shows pre-Cretaceous.

Named for Sierra Pelona, Los Angeles County.

†Pelton Basalt Member (of Deschutes Formation)[1]

Miocene, Pliocene, or Pleistocene, lower: Central northern Oregon.

Original reference: H. T. Stearns, 1931, U.S. Geol. Survey Water-Supply Paper 637, p. 139.

Exposed in Deschutes Canyon from line between Tps. 12 and 13 S., R. 12 E., to northern boundary of area; forms bench nearly one-quarter mile wide on both side of Deschutes River in northern part of T. 11 S., R. 12 E., and extends north and underlies former railroad station of Pelton.

**Pembroke Formation**[1]

Silurian: Southeastern Maine.

Original references: E. S. Bastin and H. S. Williams, 1913. Maine Water Storage Comm. 3d Ann. Rept., p. 168; 1913, Geol. Soc. America Bull., v. 24, p. 378, 379.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Assigned to Cayugan series [Upper Silurian].

Named for exposures near Pembroke, Washington County.

Pemigewasset Series[1]

Devonian or Carboniferous: Northwestern New Hampshire.

Original reference: C. H. Hitchcock, 1877, Geology New Hampshire, pt. 2, p. 142–148, 257–261.

Exposed over large areas along Pemigewasset River.

Pena Blanca Marls[1]

Oligocene: Panamá.

Original reference: E. Howe, 1907, Isthmian Canal Comm. Ann. Rept. 1907, App. E, pl. 147.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 343. In original reference, name appeared only on map explanation. That it was not intended as formal name is indicated by expression "marls of Pena Blanca" in text (p. 113). Strata at Pena Blanca are presumed to represent part of Caimito formation. Notes on locality.

Pena Blanca was village on Rio Chagres at site off northwest end of present Barro Colorado Island. Site is now submerged by waters of Gatun Lake, C. Z.

Pen Argyl Beds (in Martinsburg Shale)[1]

Upper Ordovician: Southeastern Pennsylvania.

Original references: C. H. Behre, Jr., 1926, Jour. Geology, v. 34, p. 485–487; 1927, Pennsylvania Geol. Survey, 4th ser., Bull. M9, p. 33, 104–107, maps.

Exposed at Pen Argyl, Northampton County.

Penasco quartzite[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 10.

Exposed near Pecuris, north of Santa Fe, Santa Fe County. Derivation of name not stated.

**Pence Ferruginous Slate Member** (of Ironwood Iron-Formation)[1]

Precambrian (Animikie Series): Northwestern Wisconsin and northwestern Michigan.

Original reference: W. O. Hotchkiss, 1919, Eng. Mining Jour., v. 108, p. 501, 505.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 104 (table 10), 106 (table 11), 107 (fig. 6). Underlies Anvil member; overlies Norrie member. Thicknesses (taken from drill holes) 102 and 122 feet.

Named for Pence mine, west of Hurley, Iron County, Wis.

Pendejo Tongue (of Hueco Formation)

Permian (Wolfcampian): Southeastern New Mexico.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93. Appears only on columnar section. Shown as tongue of thin bedded limestone and gray shale between unnamed tongues of arkose, and red mudstone of the Abo formation.

In southern part of Sacramento Mountains, Otero County.

Pendleton Formation (in Wilcox Group)

Eocene, lower: Eastern Texas and western Louisiana.

Richard Wasem and Louis J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 182–195. Proposed for lower Eocene sediments cropping out around southern margin of Sabine uplift in Louisiana and Texas which have been referred to previously as Pendleton faunal unit. Sediments are mainly nonmarine with a few interbedded shallow-water marine fossiliferous sands. Thickness 275 to 300 feet. Typically developed along Sabine River. Best exposed over wide area drained by two Louisiana tributaries Bayou Lenann and Slaughter Creek; in this region, subdivided into (ascending) Bayou Lenann, Slaughter Creek, and High Bluff members. Overlies Marthaville formation and underlies the Pearson (Pierson) glauconitic sand of the Sabinetown faunal unit. Pendleton faunal unit of earlier reports.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 50 (fig. 4), 56 (footnote), 61–63. Underlies Sabinetown formation (restricted). Term Pendleton is preoccupied. If in future it is considered advisable to abandon Tertiary name Pendleton, term Pendleton Ferry is suggested since the type locality is the old Pendleton Ferry Landing.

H. V. Andersen, 1960, Louisiana Dept. Conserv., Geol. Bull. 34, p. 71–81. Recent subsurface studies indicate that Wasem and Wilbert's 275- to 300-foot thickness for Pendleton is grossly underestimated and that their mappable lithologic sequences, or members, as these sequences were designated, cannot be recognized in subsurface. There are 17 glauconite units ranging from 1 to 18 feet thick in the 975 feet of Pendleton sediment Wilcox core (obtained by Carter Oil Co.) which could alter their biostratigraphic zones appreciably.

Type locality: At old Pendleton Ferry, Sabine County, Tex. Formation has been traced westward across Sabine County, Tex., and eastward to Red River in Natchitoches Parish, La.

**Pendleton Sandstone**[1]

Pendleton Formation

Middle Devonian: Eastern Indiana.

Original reference: E. T. Cox, 1879, Indiana Geol. Survey 8th, 9th, and 10th Ann. Repts., p. 62.

G. A. Cooper and others, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Lower or Middle Devonian.

A. H. Sutton, 1944, Illinois Geol. Survey Bull. 68, p. 166–167. All beds at Pendleton considered as a unit, the Pendleton formation; regarded as essentially equivalent to lower Geneva and Jeffersonville, a third lithologic facies of same stratigraphic unit. Conclusion based on similarity of fossils and on paleographic considerations which seem to make correlation with Schoharie untenable.

Exposed at Pendleton, southern Madison County.

Pendleton Ferry Formation

Eocene (Midway): Northeastern Texas and northwestern Louisiana.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 56 (footnote). Term Pendleton is preoccupied by Pendleton sandstone of middle Devonian of Indiana. If, in future, it is considered advisable to abandon the Tertiary name Pendleton, the name Pendleton Ferry is suggested since the type locality of Pendleton is the old Pendleton Ferry Landing.

Old Pendleton Ferry Landing is in Sabine County, Tex.

Pendola Shale

Upper Cretaceous: Southern California.

B. M. Page, J. G. Marks, and G. W. Walker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1729 (fig. 2), 1733 (fig. 3), 1734 (fig. 4), 1743–1744. Consists chiefly of dark-gray to greenish-gray silty thin-bedded shale with irregularly interbedded layers of dark-gray limestone or fine calcareous sandstone. Thickness 440 feet at type locality; 1,000 feet 1 mile north of type locality; sections are incomplete, top having been eroded. Unconformably overlain by Juncal formation (new), which overlaps it on south; overlies Debris Dam formation (new) with contact possibly unconformable.

Type locality: On nose of Agua Caliente anticline 1.8 miles northeast of Pendola Guard Station in small canyon tributary to Agua Caliente Canyon, Santa Barbara County. Base of section is 9,100 feet N. 50° E. of guard station and eroded top of section is 10,200 feet N. 55° E. of guard station.

Pend Oreille Andesite

Pend Oreille Valley Andesite

Miocene(?): Northeastern Washington.

M. C. Schroeder, 1949, (abs.) Northwest Sci., v. 23, no. 1, p. 39–40. Pend Oreille Valley andesite proposed for volcanics consisting of valley flows of dark-gray trachytic andesite.

M. C. Schroeder, 1952, Washington Div. Mines and Geology Bull. 40, p. 7 (chart), 24–25. Described as Pend Oreille andesite. Occurs as flows in an old valley that has been cut into the metamorphics of Newport group (new). Thickness about 1,100 feet. North of Skookum Creek unconformably underlies Tiger formation.

Crops out 1½ miles north of Furport along eastern edge of Pend Oreille River valley and forms valley wall for distance of 7 miles to Skookum Creek valley, Pend Oreille County.

Pend Oreille Group[1]

Carboniferous(?) and older(?): Southern British Columbia, Canada, and northeastern Washington.

Original reference: O. E. Le Roy, 1912, Canada Geol. Survey Summ. Rept. 1911, p. 142.

Pend d'Oreille River empties into Columbia River just north of Washington-British Columbia boundary.

**Penholoway Formation** (in Columbia Group)[1]

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

Original reference: (Penholoway terrace): C. W. Cooke, 1925, Georgia Geol. Survey Bull. 42, p. 24–26.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 75–77, pls. 2, 3. In southern Florida, Talbot, Penholoway, and Wicomico formations comprise conformable sequence of deposits whose differentiation is based mainly on location of their respective shore lines, namely 42, 70, and 100 feet above present sea level. Presumably Penholoway everywhere merges downward into deposits of Wicomico age, and Talbot into Penholoway and Wicomico successively. Sequence unconformably overlies Caloosahatchee marl and is likewise separated by a stratigraphic break from the Pamlico formation, which fringes around it.

Name derived from Penholoway Creek, Wayne County, Ga. Well exposed in Florida along Highway 18, the Childs-Okeechobee Road and west of Lake Okeechobee.

†Peninsular Limestone[1]

Eocene, upper: Northern Florida.

Original reference: W. H. Dall, 1903, Wagner Inst. Sci. Trans., v. 3, pt. 6, p. 1554.

Named for development in peninsular Florida.

Peñitas Formation

Pliocene(?): Panamá.

H. N. Coryell and R. W. Mossman, 1942, Jour. Paleontology, v. 16, no. 2, p. 233. Believed to correlate with Charco Azul formation.

In Burica Peninsula, Chiriquí Province.

Penman Formation

Pliocene, lower(?): Northeastern California.

Cordell Durrell, 1957, Pacific Petroleum Geologist, v. 11, no. 3, p. 3. Hornblende andesite mudflow breccia and volcanic conglomerate. Thickness 1,350 feet. Unconformable below Warner basalt; rests unconformably on Bonta formation (new) and all older rocks; unconformities marked by faulting.

Cordell Durrell, 1959, California Univ. Pubs. Geol. Sci., v. 34, no. 3, p. 165 (fig. 1), 174–177. Consists of three members. Lower, hypersthene andesite tuff with biotite dacite obsidian, pumice, and flow-banded lithic rocks, 150 feet thick. Middle, white-weathering hornblende andesite breccia, 250 feet thick. Upper, hornblende andesite mudflow breccia, volcanic conglomerate and fanglomerate, some volcanic sand and tuff, 950 feet thick. Rests directly on Calaveras formation in southwest corner of Blairsden quadrangle; in eastern part of quadrangle, rests across faults between older units, so that in different fault blocks it lies on granitic rocks, the Ingalls, Delleker, and Bonta formations; elsewhere rests on the Lovejoy; unconformably underlies Warner basalt. Lower Pliocene.

Named for Penman Peak in south-central part of Blairsden quadrangle.

†Pennell sandstone[1]

Upper Cretaceous: Eastern Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 64, 65.

Named from Mount Pennell.

**Pennington Shale,[1] Formation,[1] or Group**

Upper Mississippian: Southwestern Virginia, northern Alabama, northwestern Georgia, eastern Kentucky, and eastern Tennessee.

Original reference: M. R. Campbell, 1893, U.S. Geol. Survey Bull. 111, p. 28, 37.

Paul Averitt, 1941, Virginia Geol. Survey Bull. 56, p. 11–14, pls. 1, 2. Greater part of formation in Scott and Washington Counties, Va., is nonfossiliferous shale and sandstone. Full thickness not known because top is concealed by Saltville overthrust block, but about 2,250 feet is exposed. Overlies Cove Creek limestone.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 172–180. Formation described in Burkes Garden quadrangle. Comprises (ascending) Stony Gap sandstone, Avis limestone, and Falls Mills sandstone members. Thickness 1,000 to 1,700 feet. Overlies Bluefield shale and underlies Bluestone formation, both contacts conformable. Reger (1926, West Virginia Geol. Survey [Rept.] Mercer, Monroe, and Summers Counties) subdivided the Pennington [Hinton] into 45 units of which only three can be recognized with certainty in area of present report.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 166 chart 5 (column 90). Chart shows Pennington formation overlies Floyd shale and underlies Parkwood formation in east-central Alabama. Text states that relations of these formations are not clear and Pennington may grade laterally into either or both the Floyd and the Parkwood.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1, pls.; pt. 2, p. 110–112. Formation mapped and described in eastern Tennessee where it is heterogeneous and varicolored, including red, purple, and green clay shale, pink, red, green, and brown (normally calcareous) sandstone, and yellow shaly or silty fossiliferous limestone. Limestone is everywhere minor in amount; proportions of shale and sandstone vary widely. Overlies Newman limestone. Upper contact in northwestern belts not clearly defined except northeast of Jacksboro fault, where base of Pennsylvanian system is drawn at base of thick layer of pebbly white sandstone, which may be disconformable on Mississippian rocks. Elsewhere contact is drawn in transitional zone between red clay shale with scattered fossiliferous limestone beds and gray or brown sandy and silty shale with scattered coal beds. Contact thus records change from marine to nonmarine deposition, but it may not be drawn at same level everywhere, and possibly some beds included in Pennington northeast of Jacksboro fault are equivalent to some included in Pennsylvanian farther southwest.

Hence, thickness is not consistent; 200 feet or less near Chattanooga; 450 feet near Dayton; 150 feet at Cumberland Gap.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey County Rept. 3, p. 64–67. Formation, in Madison County, composed of about 80 to 100 feet of red, green, and purple earthy shales interbedded with thin layers of limestone; a massive bed of hard fossiliferous light-gray crystalline limestone about 20 feet thick occurs near top of formation. Overlies Bangor limestone and underlies Pottsville formation. In Alabama, name Pennington has not been used widely in older publications; rock units now designated as Pennington formation have been included in Bangor limestone.

K. J. Englund, 1957, U.S. Geol. Survey Coal Inv. Map C–39. Formation, in Pioneer quadrangle, Scott and Campbell Counties, Tenn., consists of fine-grained gray to buff sandstone interbedded with grayish-green and grayish-red shale. Thickness about 650 feet. Overlies Newman limestone; underlies Lee formation.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Because term Pennington has been extensively used and is still accepted in Tennessee and Kentucky, it is proposed to raise Pennington to rank of group to include Hinton, Princeton, and Bluestone formations. Overlies Bluefield formation. Wilpolt and Marden's work (1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38) indicates that the Pennington in Big Stone Gap area contains lithologic equivalents of Hinton formation, Princeton sandstone, and Bluestone formation of West Virginia. Wilpolt and Marden used these West Virginia names at both type locality and type section of the Pennington shale of Campbell, thus abrogating use of Pennington as formation name.

K. J. Englund and H. L. Smith, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 2015. Upper part of Pennington formation and lower part of Lee formation intertongue in their type area of outcrop, Lee County, Va., and in adjacent areas of Kentucky and Tennessee. The contact between these formations, which has been interpreted as an unconformity between Mississippian and Pennsylvanian systems, is transitional as result of intertonguing and lateral gradation between marine and nonmarine facies. Pennington-Lee contact, as determined lithologically in field, rises stratigraphically northward in this intertonguing sequence. According to literature, marine invertebrate fossils indicate Late Mississippian age of Pennington; plant fossils have been reported to show that Lee formation is of Early Pennsylvanian age. Intertonguing of Pennington and Lee formations suggests that these formations are partly contemporaneous.

Named for Pennington Gap, Lee County, Va., about 40 miles northeast along strike from Cumberland Gap.

**Penn Yan Shale Member** (of Genesee Formation)

Penn Yan Tongue (of West River Shale)

Upper Devonian: West-central New York.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 64–65. Name Penn Yan tongue proposed for lower shales of West River shale. Lower part consists of interbedded black and blue-black shales, blue-gray shales and thin limy argillaceous beds; unfossiliferous flags interbedded in dark shales. In upper part, shales generally lighter colored and more fossiliferous. Concretions plentiful; marcasite nodules present. Thickness about

140 feet in type area; thins eastward. In type region, contact with underlying Geneseo shale is difficult to determine but is placed at base of sequence of dark limy shales and interbedded shaly limestone layers. Top is placed arbitrarily at base of Crosby lentil of Starkey tongue (new), although Starkey-type flags being lower.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2814 (fig. 3), 2815, 2817 (fig. 4), 2818. In vicinity of Canandaigua Lake, a 50- to 60-foot sequence of dark-gray shale and mudrock containing thin beds of black shale, many layers of nodular limestone and calcareous nodules, and a few very thin beds of siltstone overlies Geneseo shale member of Genesee and underlies *Styliolina*-bearing Genundewa limestone member of Genesee. Traced eastward to Keuka Lake, this sequence of dark shaly rocks is Grossman's Penn Yan tongue of West River shale. Unit is here redesignated Penn Yan shale member of Genesee formation, because it is not a tongue of the West River. In its type area, the Penn Yan underlies Crosby sandstone of Torrey and others (1932), which can be traced westward into Genundewa limestone member. In type area, overlies Geneseo member and underlies Ithaca member. About 170 feet thick near Penn Yan; thins westward to Lake Erie where it is 9 inches thick. In Cayuga Lake area, underlies Sherburne flagstone member. Thickness about 105 feet near Ithaca.

Named from outcrops in streams along south side of Keuka Lake outlet near town of Penn Yan, Yates County. Well exposed in middle gully of three draining north into outlet at Seneca Mills.

**Penobscot Formation**[1]

Cambrian(?): South-central Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 3.

H. W. Allen, 1951, Maine State Geologist Rept. 1949–1950, p. 79. Sequence of metamorphosed sedimentary rocks in area of Rockland quadrangle, Knox County, is (ascending) Islesboro formation containing Coombs limestone member at top; Battio quartzite; Penobscot formation; and Rockland formation consisting of Weskeag quartzite member at base, a siliceous limestone member above the quartzite, and Rockport limestone member at top.

R. S. Houston, 1956, Maine Geol. Survey Bull. [7], p. 59. Upper Cambrian.

L. A. Wing, 1957, Maine Geol. Survey GP. and G. Survey 1, sheet 1. In Hancock and Penobscot Counties, appears to be overlain by Bucksport formation (new).

Named for exposures along western shore of Penobscot Bay, especially between Belfast Bay and Sandy Point, Waldo County.

Penobscot Bay Granite[1]

Upper Silurian or Lower Devonian: Maine.

Original reference: F. W. Toppan, 1932, Geology Maine, Dept. Geol. Union Coll., Schenectady, p. 44.

†Penokee Series[1]

Precambrian (upper Huronian): Northwestern Wisconsin and northwestern Michigan.

Original reference: E. T. Sweet, 1876, Wisconsin Acad. Sci., Arts, and Letters Trans., v. 3, p. 40–45.

Penokee region, Wis.

**Penon Blanco Volcanics** (in Amador Group)

Upper Jurassic: East-central California.

Original reference [Penyon Blanco agglomerate]: N. L. Taliaferro, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 149.

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 283, 284. Assigned to Amador group. In Merced River section, Penon Blanco volcanics underlie Agua Fria formation and overlie Hunter Valley cherts. Thickness about 9,000 feet. Age of Amador group believed to be upper Middle to lower Upper Jurassic.

Present in southern type section of Amador group along Merced River.

**Pensauken Formation** (in Columbia Group)[1]

Pleistocene: New Jersey and northern Delaware.

Original reference: R. D. Salisbury, 1894, New Jersey Geol. Survey Ann. Rept. State Geologist 1893, p. 57–60, 67–72.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Correlation chart shows Cape May (part) and Pensauken (part) as Sangamon and Pensauken (part) and Bridgeton (part) as Yarmouth.

H. G. Richards, 1945, Geol. Soc. America Bull., v. 56, no. 4, p. 401–402. Correlation chart discussed. Writer does not agree with the combining of Cape May (part) and Pensauken (part) in the Sangamon interglacial nor with the combining of the Pensauken (part) with the Bridgeton (part) in the Yarmouth interglacial. Evidence indicates that Cape May is of late Pleistocene age, whereas Pensauken is mid-Pleistocene or older. There is no unconformity within the Pensauken nor any field evidence of a hiatus within the Cape May. Lithologically, the Pensauken and Bridgeton are practically inseparable although the latter has been more eroded and occurs at higher elevations; they are regarded as Pensauken-Bridgeton complex of early Pleistocene, probably Nebraskan to Yarmouth.

W. C. Rasmussen and others, 1957, Delaware Geol. Survey Bull. 6, pl. 3. Mapped in northern Delaware. Sand and clay on margin of Piedmont, forming terrace deposits at altitudes of less than 180 feet.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped in eastern Pennsylvania. Illinoian stage.

Named for exposure at mouth of Pensauken Creek, at Hylton's pits [Burlington County], New Jersey.

**Pentagon Shale**[1]

Middle Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 38.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, 1074–1075, 1089, 1090 (fig. 2); 1939, Geol. Soc. America Spec. Paper 20, p. 42–45. As here defined, overlies Pagoda limestone and underlies Steamboat limestone. Thickness at type locality 290 feet. Middle Cambrian.

Type locality: On Continental Divide, in NE¼ sec. 24, T. 25 N., R. 12 W., Lewis and Clark Range. Named for Pentagon Mountain which lies approximately 2 miles northwest of type locality.

**Penters Chert**[1]

Lower or Middle Devonian: Central northern Arkansas.

Original reference: H. D. Miser, 1920, U.S. Geol. Survey Bull. 715–G.

D. M. Kinney, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 611–612. Discovery of fossils in a thin gray argillaceous limestone in Penters chert confirms the earlier suggested Lower or Middle Devonian age for the Penters. The Penters is unfossiliferous at its type locality.

Named for exposures at Penters Bluff Station, Izard County.

Pentoga Greenstones (in Quinnesec Schist)

Precambrian (Huronian): Northern Michigan.

H. M. Martin, 1936, The centennial geological map of the northern peninsula of Michigan (1:500,000): Michigan Dept. Conserv., Div. Pub. 39, Geol. Ser. 33. Shown on map legend. Occurs in Iron River district.

Peñuelas Shale[1]

Upper Cretaceous: Puerto Rico.

Original reference: G. J. Mitchell, 1922, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 3, p. 251.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 60 (table 7). Thickness 2,000 feet. Underlies Coamo tuff limestone; overlies San Germán limestone.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 55. Mitchell (1922) used name Peñuelas shale for rocks correlated with Rio Yauco formation of this report.

Typically exposed along military road from Ponce to Peñuelas at kilometer 67+ (10+ by old numbers), Ponce district.

Penutian Stage

Eocene, lower: Western and southern California.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 18 (fig. 3), 34–40, 76, 93, fig. 7. Replaces stage name Juniperan. Change made to avoid confusion with Junipero sandstone in Reliz Canyon area. In sequence, the Penutian includes interval between the younger Ulatisian and the older Bulitian stages. Type includes the 20 feet of olive to greenish-gray siltstone and shale whose lower part constituted the type of the Bulitian stage and the 25-foot sandstone "reef" containing orbitoidal foraminifera and megascopic fossils, in the NE¼ sec. 21, T. 28 S., R. 19 E., in vicinity of Media Agua Creek, Kern County. Comprises two zones, *Plectofrondicularia kerni* below and *Alabama wilcoxensis* above.

Represented on Santa Barbara coast, in Simi Valley, along west side of San Joaquin Valley, vicinity of and north of San Francisco Bay area. Name refers to a linguistic stock of northern California Indians. The Yokut Indians, who occupied territory around Media Agua Creek, were of this linguistic stock.

Penyon Blanco Agglomerate[1]

*See* **Penon Blanco Volcanics.**

**Peorian Loess**[1]

Peoria (n) Formation

Peoria Formation (in Sanborn Group)

Peoria Silt Member (of Sanborn Formation)

Pleistocene: Illinois, Iowa, Kansas, and Nebraska.

Original reference: Frank Leverett, 1898, Jour. Geology, v. 6, p. 244–249.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 6. Shown in stratigraphic section as Peorian formation (loess). Overlies Loveland formation; underlies Recent. Thickness 5 to 80 feet. Some dune sand of Peorian age.

G. B. Schultz and T. M. Stout, 1945, Am. Jour. Sci., v. 256, p. 55 (fig. 1). Peorian loess underlies Bignell formation (new).

G. E. Condra, E. C. Reed, and E. D. Gordon, 1947, Nebraska Geol. Survey Bull. 15, p. 25, 31–33; 1950, Nebraska Geol. Survey Bull. 15–A, p. 25, 32–33. Peorian formation, as exposed at type locality of Crete formation, consists of light-brownish-gray to buff loess in upper part, medium-light-gray in middle part, and light-gray to brownish, partly iron-stained in lower part. Thickness, including soil at top, 11 feet. Overlies Loveland formation. Peorian loess of middle to late Wisconsin age deposited to variable thickness widely on Loveland loess in Nebraska and other areas and on exposed areas of Todd Valley sand, and older formations. However, term Peorian, as now used, represents time interval between the Iowan and Mankato substages in Iowa and should not be applied formationally where this interval includes both till and loess substages, as in Illinois and parts of South Dakota. Contact with Bignell loess indicated by buried soils.

J. C. Frye and O. S. Fent, 1947, Kansas Geol. Survey Bull. 70, p. 45–50. Peorian loess has been described in western Illinois and Iowa and is exposed unconformably above Loveland loess in Missouri Valley area of Iowa and Nebraska. Unit has been traced westward from Missouri Valley across Nebraska and southward as far as central Kansas. Since term Peorian is now generally used in time sense, adjectival ending dropped for stratigraphic unit here called Peoria silt member of Sanborn formation. Member in upland areas may be a complex of loesses of slightly different ages, at a few places separated by feebly developed soils. Its lithologic continuity in Kansas and Nebraska warrants inclusion of the complex of loesses, associated colluvial silts on some slopes, and fluvial-eolian silts on lower levels within a single member. Buried soil on Peoria silt member has been named Brady. Peoria silt occurs extensively in northern tier of Kansas counties in upland areas and on slopes, overlain by deposits of Bignell silt above Brady soil. Thickness more than 100 feet at type locality of Sanborn. Overlies Loveland silt member.

R. L. Schreurs, 1956, U.S. Geol. Survey Water-Supply Paper 1358, p. 14 (table), 23. Peorian loess, in Buffalo County and adjacent areas, Nebraska, consists of wind deposits of grayish-yellow silty clay (loess), locally grading into dune sand; contains several buried soils. Thickness 0 to 75 feet. Overlies Todd Valley formation; underlies post-Iowan terrace deposits.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, p. 55 (fig. 1). Rank raised to formation in Sanborn group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Peoria formation shown on correlation chart in Bradyan stage [Kansas does not use Sanborn group.]

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 7, 10, 12, 13. Beyond limit of Shelbyville till the Peoria loess serves as a supplementary type for Woodfordian substage (new). Peoria loess has been called Peorian, but it is here used as rock-stratigraphic rather than time-stratigraphic unit and adjectival ending is dropped. Stratigraphically overlies Farmdale silt; overlies Roxana silt (new) of Altonian substage (new). Thickness 15 to 25 feet.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 536. Frye and Willman's (1960) type section of "Roxana silt" reinterpreted. "Roxana silt" is Peorian loess (basal part Iowan). Thickness 43 feet. Occurs above Farmdale loess. Unit termed Peoria loess by Frye and Willman is possibly Bignell loess.

Named for exposures in vicinity of Peoria, Tazewell County, Ill.

†Peorian Stage[1] (of deglaciation)

Pleistocene: Midcontinent.

Original reference: Frank Leverett, 1898, Jour. Geology, v. 6, p. 244–249.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1714. Under previous usage by U.S. Geological Survey, the Iowan drift was regarded as representing a distinct stage of glaciation separated from the Wisconsin by Peorian stage of deglaciation. Geological Survey now classifies the Iowan drift as representing an early substage of the Wisconsin stage, and name Peorian is not used either for a distinct stage or substage.

Named for exposures near Peoria, Tazewell County, Ill.

Pepino Formation[1]

Miocene: Puerto Rico

Original reference: R. T. Hill, 1899, Natl. Geog. Mag., v. 10, p. 109.

J. D. Weaver, 1956, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latrine, fasc. 2b, p. 336. Term no longer used.

Forms Pepino Hills in northern Puerto Rico.

**Pepper Shale Member** (of Woodbine Formation)

Pepper Formation[1]

Upper Cretaceous (Gulf Series): Eastern Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 270, 417–422.

L. W. Stephenson, 1953, U.S. Geol. Survey Prof. Paper 242–E, p. 57–66. Rank reduced to member of Woodbine formation. Thickness 23½ feet. Unconformably underlies Eagle Ford shale; unconformably overlies Grayson marl (formerly Del Rio clay). Mollusks described. Fossil evidence confirms conclusion that Pepper shale is southward extension of the Woodbine and probably an extension of Lewisville member.

Type locality: Exposure on small branch of Pepper Creek south of Belton-Temple Highway, Bell County, and 1.6 miles east of easternmost of two passes of highway under Santa Fe Railway.

Peppersauce Sandstone[1]

Peppersauce Canyon Sandstone[1]

Upper Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 476–477, 480, 481, 482.

D. L. Bryant, 1952, Arizona Geol. Soc. Guidebook for Field Trip Excursions in Southern Arizona, p. 37. Thickness of 20 feet in Peppersauce Canyon.

In Peppersauce Canyon, Santa Catalina Mountains.

†Pequanac Shale[1]

Middle Devonian: Northern New Jersey.

Original reference: H. B. Kummel, 1908, U.S. Geol. Survey Geol. Atlas, Folio 161.

Well developed along upper Pequanac River.

Pequawket Breccia[1]

Devonian(?): Northern New Hampshire.

Original reference: C. H. Hitchcock, 1877, Geology New Hampshire, pt. 2, p. 235, 239, 262, 675, pl. 11.

On southern slope of Mount Pequawket, now North Moat Mountain, North Conway quadrangle, White Mountain.

Pequop Formation (in Carbon Ridge Group)

Permian (lower Leonard to lower Guadalupe): Northeastern Nevada and northwestern Utah.

Grant Steele, 1959, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1105. Purplish-gray irregularly bedded platy silty limestones with interbedded fusuline coquinas. Thickness 1,525 feet at type section. Lower contact placed at red silt member, which overlies massive Wolfcampian limestones (unnamed formation), and upper contact placed at base of unnamed massive dolomite sequence, which is overlain by Phosphoria formation.

J. S. Berge, Apr. 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 5, p. 10 (fig. 2), 11 (fig. 3), 27–29, pl. 4, chart (strat. section). (Footnote on chart refers to Steele's article in Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf.) Formation, in Ferguson Mountain area. Elko County, consists of interbedded calcareous quartzite and silty limestones. Thickness 681½ feet. Overlies Ferguson Mountain formation (new): underlies Kaibab limestone of Park City group. Correlation chart, in column credited to Steele (1959, unpub. thesis) shows Pequop formation overlies Ferguson Springs formation (new): in column credited to Bissell (1960), the Pequop overlies Carbon Ridge formation and underlies Moorman Ranch formation. Leonardian.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). Name appears on correlation chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. In Utah, underlies the Kaibab and overlies Arcturus; in Moorman Ranch area, Nevada, underlies Moorman Ranch formation and overlies Murry [formation] (new); in Ferguson Mountain area, overlies Ferguson Mountain formation and underlies Plympton.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann Field Conf., v. 93 (chart 1), 106. (Road logs dated Sept. 8–10). Formal proposal of name. Overlies Ferguson Springs formation and in some areas Riepetown sandstone (new); underlies Loray formation. Includes Moorman Ranch member and Summit Springs evaporite member (new). Included in the Carbon Ridge herein raised to group status.

Type section: Sec. 3, T. 33 N., R. 65 E., Elko County, Nev. Section measured 1½ miles north of Jasper Railroad Tunnel in central part of Pequop Mountains.

**Percha Shale**[1]

Percha Formation

Upper Devonian: Southern New Mexico, southeastern Arizona, and southwestern Texas.

Original references: C. H. Gordon, 1907, Am. Jour. Sci., 4th, v. 24, p. 58–64; Science, new ser., v. 25, p. 824–825; Jour. Geology, v. 15, p. 91–92.

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 163 (fig. 3). Overlies progressively, Fusselman limestone and Canutillo shale from Silver City, N. Mex., to El Paso, Tex.

L. R. Laudon and A. L. Bowsher, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 12, p. 2122, figs. 21, 22. Formation unconformably underlies Caballero formation (new) in Sacramento Mountains, N. Mex.

F. V. Stevenson, 1944, Dallas Digest (Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Joint Ann. Mtg.), p. 95. Shale subdivided into lower Ready Pay member and upper Box member. Box member confined to Mimbres Mountain regions, whereas Ready Pay member believed to occur throughout southern New Mexico.

F. V. Stevenson, 1945, Jour. Geology, v. 53, no. 4, p. 241–244. Neotype section designated. Shale overlies Sly Gap formation in San Andres Canyon, N. Mex.

M. A. Stainbrook, 1947, Jour. Paleonotology, v. 21, no. 4, p. 297–302. Two members recognized in Percha by Keyes (1908). Basal black shale termed Silver and upper lighter colored shales termed Bella. There is little doubt that these names were proposed for identical divisions of Percha named Ready Pay and Box by Stevenson (1944), and there is little reason to replace earlier names. Early Mississippian. Shale recognized near top of Mount Martin, at Bisbee, Ariz.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pub. Geology 4, p. 72–78. fig. 8. In Caballo Mountains, N. Mex., Percha has several lithologies not all of which occur in every outcrop. Predominantly gray-weathering calcareous claystone, olive-drab-weathering shale, and rusty-weathering sandstone and siltstone. Thin limestone lentils and beds irregularly distributed. Thickness ranges from thin edge to 105 feet. Although dominantly a shale unit at type locality, it includes more than shale elsewhere and would be more usefully termed Percha formation. Proposed units such as Onate and Sly Gap are not distinguishable lithologically, and hence are not mappable in New Mexico. These are no more than faunal zones at best, and the prior and well-established term Percha formation should be retained and applied widely to this lithologically and topographically distinct unit as it crops out in New Mexico. Does not rest everywhere on same formation. In most places, as along main scarp of Timber Mountain, it rests on the Fusselman, in other places rests on dolomite of Montoya group. Commonly overlain by beds of Magdalena group, but in southern end of mountains, Lake Valley rocks intervene. Includes beds of Devonian (Middle and Upper) and Mississippian (Kinderhook) age.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines and Mineral Resources Mem. 1, p. 31. Beds of Percha aspect overlie a thin "Three Forks" zone in Rhodes Canyon and are probably the beds above the Contadero in Hembrillo Canyon. In Rhodes Canyon, the Percha formation is pale- to dark-olive-gray calcareous silty micaceous shale, with a few lenses and nodules of medium-gray or olive-gray calcareous micaceous siltstone. Beds referred to Percha are 75 feet thick in Rhodes Canyon including a basal 18 inches of possible Three Forks equivalent. Thickness 67 feet in Hembrillo Canyon. Formation thins north of Rhodes Canyon and is absent at Sly Gap.

Neotype section: In SW¼SW¼SE¼ sec. 14, T. 16 S., R. 7 W., 2½ miles southeast of Hillsboro, Sierra County, N. Mex. This exposure approximately one-half mile south of narrow canyon called "The Box," through which Percha Creek flows eastward into Rio Grande.

Perchan series[1]

Devonian: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines. Robert Henderson, State Printer.

**Perdido Formation**

Mississippian: Southern California.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 3, 14 (fig. 6), 22–25, pls. 1, 2, 3. Consists of siltstone, shale, limestone, chert, and conglomerate; pale red to dark gray weathering reddish brown, brown, or gray; siltstone predominant in upper part, limestone predominant in lower part, characterized also by bedded chert. Lithology is greatly diversified within one section and also from place to place so that heterogeneity is an outstanding characteristic. Thickness about 610 feet at type locality; 220 feet in canyon below Ubehebe mine, west of Quartz Spring area. Underlies Pennsylvanian(?) Rest Spring shale (new); overlies Tin Mountain limestone (new).

R. L. Langenheim, Jr., and Herbert Tischler, 1960, California Univ. Pub. Geol. Sci., v. 38, no. 2, p. 97–99, 137–140. In Quartz Spring area, consists of a lower limestone member and an upper siltstone member. Thickness about 424 feet (section incomplete). Overlies Tin Mountain formation. Late Mississippian.

Type locality: Extending south from Perdido Canyon, Inyo County. In the canyon, a fault between Perdido and Rest Springs formations cuts out uppermost part of Perdido, but this segment is well exposed south of Rest Spring. Type locality is supplemented by a second locality, about 3,000 feet south of Rest Spring. Named for Perdido Canyon, where formation is exposed from foot of southern wall, about 9,000 feet southeast of Quartz Spring, over hill to underlying Tin Mountain limestone.

Pereira Shale Member (of Alhambra Formation)

Eocene, upper: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 55–56, pl. 4A. Lowermost part consists of interbedded silty shale and silty sandstone which grades up from Roop sandstone (new) with no sharp break near middle of lower third of exposed section brownish-gray silty shales are replaced by thinly stratified light-gray to white shale with occasional thin layers of interbedded silty gray sandstone. Exposed basal part is 290 feet thick; approximately 200 feet of higher beds are concealed.

Type section: West limb of Pacheco syncline, in Santa Fe cuts and ditches east of Muir Tunnel, near Martinez, Contra Costa County.

Perilla Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 9, 17, pl. 27. Consists of (ascending) friable light-yellow shale, brown crystalline limestone, light-yellow shale and argillaceous limestone, and brown crystalline limestone. Thickness 251 feet. Underlies Pedregosa member (new): overlies Quajote member (new).

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Perini Hill Flows (in Clear Lake Volcanic Series)

Quaternary: Northern Califonrnia.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), 36, 41, pls. 1. 7. Andesitic flows bearing xenocrysts of quartz and xenoliths of aluminous rocks. Thickness 100 to 500 feet. Shown on columnar section above olivine basalt and below Boggs Mountain flows (new), but age relations of individual units of series are imperfectly know because some units are isolated and contacts of contiguous flows are commonly obscured by sliding.

Located on Perini Hill, about 3 miles southwest of Lower Lake. Lower Lake quadrangle, in Coast Ranges, about 70 miles north of San Francisco.

**Perkasie Member** (of Brunswick Formation)

Perkasie Shale (in Newark Group)[1]

Upper Triassic: Southeastern Pennsylvania and northwestern New Jersey.

Original references: B. S. Lyman, 1893, Geological and topographical map of Bucks and Montgomery Counties: Pennsylvania Geol. Survey; 1895, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 3, pt. 2, p. 2589–2638.

M. E. Johnson and D. B. McLaughlin *in* Erling Dorf, ed., 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 46, 50. Rank reduced to member status in Brunswick formation. Geographically extended to New Jersey where it consists of about 145 feet of red and dark-gray shale. Probably extends almost to western Montgomery County, Pa., but for part of extent is merged with thick hornfels aureole beneath large diabase sills and is indistinguishable.

Occurs near Perkasie Tunnel, Montgomery County, Pa.

Perkins Canyon Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). Named on cross section and structure section in report on Paleozoic continental margin in central Nevada. Underlies Gatecliff formation (new).

Toquima Range, Nye County.

**Perkinsville Formation**

Pliocene(?) to Pleistocene(?): Central Arizona.

R. E. Lehner, 1958, U.S. Geol. Survey Bull. 1021–N, p. 563–566, pls. 45, 47. Sedimentary rocks and intercalated lava flows. Sedimentary rocks primarily of coarse to fine gravel, but sand, silt, and some limestone also present. Gravel is increasingly coarse toward source areas north and south of Verde River. Bedding less evident to north and south, away from river. Lava is normal olivine basalts—except for one flow which is andesite. Basalt flows generally holocrystalline and porphyritic. Lava flows spread over part of Clarkdale quadrangle with uniform thickness of about 50 feet. Thickness of formation about 300 to 500 feet. Unconformably overlies all older formations in quadrangle; underlies Quaternary terrace gravel beds along Verde River at Perkinsville. Tentatively correlated with Verde formation.

Named from exposures on north side of Verde River near Perkinsville, Clarkdale quadrangle, Yavapai County.

Permenters Farm Beds (in Choctawhatchee Formation)

Miocene, middle: Western Forida.

H. R. Smith, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 269–274. Proposed to designate beds that lie above the *Arca* zone beds in Walton County. Lie below *Ecphora* zone and had been included in *Ecphora* by earlier workers. At type locality, consists of about 25 feet of fossiliferous marl. About 80 feet thick in well at Niceville.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 31. Choctawhatchee redefined as stage to include all Miocene sediments of post-Alum Bluff age in Florida panhandle and their equivalents in Central and Western Gulf States. In Florida panhandle, four biofacies, *Yoldia*, *Arca*, *Ecphora*, and *Cancellaria*, are recognized. Beds referred to as Permenters Farm beds are included in *Arca* facies. Recommended that term Permenters Farm beds be dropped.

Type locality: Roadcut on east bank of Alaqua Creek in sec. 17, T. 1 N., R. 19 W., Walton County.

**Perote Member** (of Providence Sand)

Upper Cretaceous: Eastern Alabama and western Georgia.

D. H. Eargle, 1948, Southeastern Geol. Soc. [Guidebook] 6th Field Trip, p. 44, 51–53; 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 105; 1955, U.S. Geol. Survey Bull. 1014, p. 70, 71 (fig. 11), 72. Consists chiefly of fine sand and silt which is carbonaceous and highly micaceous. Conformable with a coarser unnamed upper member. At type locality, approximately 150 feet thick and constitutes about half of entire Providence section. Overlies Ripley formation. Merges westward into Prairie Bluff chalk. Thins eastward, and at type locality of Providence (in Georgia) member is about 40 feet thick.

Type locality: Along U.S. Highway 29 in vicinity of village of Perote, southern Bullock County, Ala.

**Perris Quartz Diorite**[1]

Late Mesozoic(?): Southern California.

Original reference: P. H. Dudley, 1935, California Jour. Mines and Geology, v. 31, no. 4, p. 491, 501, map.

E. F. Osborn, 1939. Geol. Soc. America Bull.; v. 50, no. 6, p. 926. Noted as being the same as Val Verde tonalite (Wilson, 1937).

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 481, table 4. Described as massive to moderately gneissoid with some irregularly distributed basic inclusions or schlieren arranged roughly parallel to the foliation. Listed in plutonic series, Perris and Estell quartz diorite (Val Verde tonalite) are older than Lakeview quartz monzonite and younger than Virginia quartz norite. Cuts Box Springs complex (new). Late Mesozoic.

Richard Merriam, 1948, California Div. Mines Bull. 177, p. 14. Considered equivalent to Bonsall tonalite.

U.S. Geological Survey considers the Perris Quartz Diorite as Late Mesozoic(?).

Occurs in Perris fault block, in parts of Elsinore and Corona quadrangles, Riverside County.

Perry Formation[1]

Middle Devonian: Central Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Final Rept., v. 2, p. 1236–1237.

In Perry County.

**Perry Formation**[1]

Upper Devonian: Southeastern Maine, and southwestern New Brunswick, Canada.

Original reference: C. H. Hitchcock, 1861, Maine Board Agr. 6th Ann. Rept., p. 247–256.

D. H. Amos, 1958, Dissert. Abs., v. 19, no. 5, p. 1053. Discussion of geology of Calais and Robbinston quadrangles, Maine. Youngest stratified unit is Upper Devonian Perry formation. Consists of thick sequence of coarse clastic sediments containing interbedded basalt flows. All diorites and granites in area were emplaced in post-Silurian-pre-Upper Devonian interval because they exhibit intrusive contacts toward rocks of Upper Silurian age and have contributed detritus to Perry formation.

Named for development at Perry, Washington County, Maine, and elsewhere in Perry Basin.

†Perry limestone[1]

Silurian and Devonian: Eastern Missouri.

Original reference: C. R. Keyes, 1896, Missouri Geol. Survey, v. 11, p. 41.

Named for Perry County.

Perry Branch Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 179, 188, pl. 16. Uppermost member of Brodhead formation, Morehead facies (new). Thickness 25 to 40 feet. At type section underlies Floyds Knob formation and overlies Haldeman siltstone member (new) of Brodhead formation.

Type section: Along U.S. Highway 60 at spring 1½ miles west-northwest of Olive Hill; at hill along west side of Perry Branch, Carter County.

Perry Farm Shale Member (of Lenapah Limestone)

Pennsylvanian (Des Moines Series): Eastern Kansas, western Missouri, and northeastern Oklahoma.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 337, 338, 339, 340, pl. 1. Includes calcareous fossiliferous shale above Norfleet limestones member (new) and below Idenbro limestone member (new). Maximum thickness in Kansas about 10 feet; at type locality of Lenapah (Oklahoma) about 15 feet.

J. M. Jewett, 1955, Kansas Geol. Survey Bull. 58, p. 69. Discussed as a cyclothem in Lenapah megacyclothem.

Type locality: NW¼NE¼ sec. 7, T. 34 S., R. 18 E., Labette County, Kans.

Perry Mountain Formation

Silurian(?): Central western Maine.

A. R. Cariani, 1959, Dissert. Abs., v. 19. no. 10, p. 2577. Well-bedded quartzites intercalated with sandy biotite-muscovite schists and staurolite schists. Oldest formation in Anson quadrangle—underlies Parmachenee formation (new).

R. J. Willard, 1959, Dissert. Abs., v. 19, no. 11, p. 2918. Composed of basal conglomerates grading into cyclical argillaceous quartz siltstones in Kennebago Lake quadrangle. Thickness about 5,000 feet. Overlies Johns Pond formation (new). Lower part(?) of formation dated as Middle Silurian (Clinton).

In northwest corner of Anson quadrangle and in Kennebago Lake quadrangle.

**Perrysburg Formation**

Upper Devonian: Western and west-central New York.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Proposed for sequence between top of Hanover shale and base of Laona sandstone of Hall (1841). Clarke (1903) and Luther (1903) divided sequence into Dunkirk below and Portland above. Chadwick (1919) renamed upper part Gowanda beds as name Portland was preoccupied. Although Dunkirk and Gowanda can be traced from place to place in general way, they intergrade vertically to such an extent they cannot be mapped separately; hence, new name is proposed. In western New York, rocks of Perrysburg comprise wedge of Upper Devonian deltaic sediments that thickens to south and east; in this wedge, lithology varies from interbedded black and gray shales containing siltstones in area bordering Lake Erie to massive siltstones and sandstones containing some gray shale in vicinity of Pennsylvania-New York State line. Thickness at type locality 416 feet; in Chautauqua County 330 feet. Comprises seven members (described from northwest to southeast—the direction of increasing grain size and clastic content): Dunkirk shale. South Wales (new), Canaseraga sandstone, Gowanda, Hume shale (new), Caneadea, and Canisteo shale (new). Contact at base sharply defined wherever exposed; top of formation recognized with certainty only as far east as Laona sandstone of Hall can be identified. From Franklin Gulf eastward overlies Wiscoy sandstone.

Wallace de Witt, Jr., and G. W. Colton, 1953. U.S. Geol. Survey Geol. Quad. Map GQ-30. In Silver Creek quadrangle, includes Dunkirk shale, South Wales, and Gowanda members. Thickness about 400 feet.

L. V. Rickard, 1957, New York Geol. Assoc. 29th Ann. Mtg. Guidebook, p. 15 (footnote). In western New York, all recognized rock units present in interval between base of Dunkirk shale and base of Laona sandstone have been considered members of one encompassing unit, Perrysburg formation. Inasmuch as Laona or its correlate has not been traced eastward into Wellsville region, term Perrysburg cannot be applied to rocks of this interval in latter area.

Wallace de Witt, Jr., 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1935 (fig. 2). Overlies Hanover shale member of Java formation (new).

Type locality: On Big Indian Creek in Perrysburg Township, Cattaraugus County.

**Perryville Limestone**

Perryville facies (of Benson Formation)

Perryville Formation[1]

Middle Ordovician: Central Kentucky.

Original reference: J. M. Nickles, 1905, Kentucky Geol. Survey Bull. 5, p. 15.

A. C. McFarlan, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 989–996, pl. 1. Formation unconformably overlies the Lexington; unconformably underlies Cynthiana.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1635. Referred to as facies of Benson limestone.

D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 41 (fig. 2), 42. Perryville limestone in Lexington area consists of gray crystalline limestone ranging in thickness from 15 feet to knife edge, being thinnest or absent along crest of Cincinnati arch in Fayette County. Underlies Cynthiana formation; overlies Woodburn limestone.

Named for Perryville, Boyle County. Best developed on western and southern flanks of Jessamine dome.

**Perseverance Slate**[1]

Triassic or older: Southeastern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 93–94.

Named for Perseverance Camp, just east of Juneau.

Persimmon Gap Shale

Upper Ordovician: Southwestern Texas.

J. L. Wilson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 12, p. 2458 (fig. 2), 2462, 2470. Greenish and drab, light-brown and pink-weathering siliceous and gypsiferous shale. Thickness at type locality 28 feet; in sections in the Solitario 40 feet. In all sections of older Paleozoic southeast of Marathon region and in the Solitario, overlies Maravillas chert and underlies Caballos novaculite.

W. B. N. Berry and H. M. Nielsen, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2254–2259. Van der Gracht published table of formations in the Solitario (furnished by Baker) in which name Solitario formation was applied to 15 to 20 feet of bright-green siliceous and argillaceous shale between Maravillas and Caballos formations. Sellards (1932) described a green shale, 25 or 50 feet thick, overlying Maravillas chert in the Solitario. King (1937) mentioned a few feet of dark-green shale between the Maravillas and Caballos in the Rough Creek exposure. Wilson (1954) proposed name Persimmon Gap shale for shale between Caballos and Maravillas formations. Thus, Solitario formation of Baker and Sellards and Persimmon Gap shale of Wilson are same rock unit. Caballos novaculite is herein restricted to the two lower members as described by King (1937), and term Santiago revived and applied to upper three members of King's Caballos novaculite; hence, there is no need for names Persimmon Gap shale and Solitario formation.

Well exposed three-fourths of a mile up gulch east of road and ranger station at Persimmon Gap entrance to Big Bend National Park, Brewster County.

Perth Limestone Member (of Brazil Formation)

Middle Pennsylvanian: Southwestern Indiana.

H. C. Hutchinson, 1960, Indiana Geol. Survey Bull. 16, p. 19–21, pl. 16. Name proposed for marine unit that closely overlies Minshall coal. Numerous references have been made to this limestone and Wanless (1939) referred to it as Minshall limestone. Name Minshall herein abandoned. At type locality, limestone is gray, hard, argillaceous, and fossiliferous; weathers brown. Thickness 6.3 feet. Member lies 0.2 foot to 15 feet above Minshall coal and 3 to 15 feet below Coal II, which lies near top of Brazil formation.

Type locality: Abandoned strip mine of G. & F. Corp. in SW¼NE¼ sec. 3, T. 13 N., R. 7 W., Clay County, one-half mile northwest of town of Perth.

Peru Beds[1]

Pleistocene: Northeastern Illinois.

Original reference: C. O. Sauer, 1916, Illinois Geol. Survey Bull. 27.

Occurs along sides of valley, west of Peru, near western line of La Salle County.

Peru Limestone[1]

Middle Devonian: Central Pennsylvania.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. F, p. xix.

Occurs for several miles east and west of Peru, Juniata County, in Tuscarora Valley.

Peru Sandstone[1]

Lower or Middle Devonian: Central Pennsylvania.

Original reference: J. P. Lesley, 1878, Pennsylvania 2d Geol. Survey Rept. F, p. xix.

Occurs at Peru, Juniata County.

†Pescadero Series[1]

Upper Cretaceous, Eocene and Miocene: Western California.

Original reference: G. H. Ashley, 1895, Jour. Geology, v. 3, p. 435–439.

Named for exposures at Pescadero Point and near Pescadero, San Mateo County.

**Pescado Tongue** (of Mancos Shale)

Upper Cretaceous: Northwestern New Mexico.

W. S. Pike, Jr., 1947, Geol. America Mem. 24, p. 9, 34–35, fig. 2. Consists mostly of gray marine shale; underlain by a regular massive cliff-forming sandstone 35 feet thick. Splits Gallup member of Mesaverde into upper and lower parts. Tongue is 50 feet thick in area of typical exposure, and its lower contact occurs 209 feet above top of main mass of Mancos shale.

Named from typical exposures on north side of valley of Pescado Creek, below Pescado village, in sec. 32, T. 11 N., R. 17 W., and sec. 5, T. 10 N., R. 17 W., McKinley County.

**Peshastin Formation**[1]

Pre-Tertiary: Central Washington.

Original reference: G. O. Smith. 1903. U.S. Geol. Survey Prof. Paper 19.

C. E. Weaver, 1937. Washington [State] Univ. Pubs. in Geology, v. 4, p. 19. Peshastin formation consisting of black slate and lenses of limestone and bands of chert has been mapped in both Mount Stuart and Snoqualmie quadrangles and was considered by Smith (1903) as of probable Jurassic age. Later investigations by W. S. Smith (1916, Jour. Geology, v. 24, no. 6) indicate that, on basis of fossil evidence, Peshastin rocks exposed in mountains at headwaters of south fork of Skyhomish River are of Ordovician age.

R. M. Pratt, 1959, Dissert, Abs., v. 19, no. 12, p. 3278. Oldest rocks in Mount Stuart area are Chiwaukum schist and Peshastin slate. Peshastin slate and Hawkins formation form an apparently conformable sequence.

Named for canyon of Peshastin Creek, near mouth of Negro Creek, Mount Stuart quadrangle.

Peshastin Glacial Stage

Pleistocene: Central Washington.

B. M. Page, 1939, Jour. Geology, v. 47, no. 8, p. 785, 787–795. Oldest of three successive stages of valley glaciation in Leavenworth area. Characterized by deposition of Peshastin till and Peshastin outwash. Followed by Leavenworth glacial stage (new).

Petaca Schist

Petaca schist phase (of Ortega Quartzite)

Precambrian (Proterozoic): Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 43, pl. 3. Minor quartz-muscovite schist phase of Ortega quartzite. Locally contains quartzite members, some places conglomeratic, and in other places quite feldspathic. Along strike grades into typical Ortega quartzite.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 34–36, pl. 1. Typical Petaca schist is light-gray schistose slabby to massive slightly muscovite quartzite. Represents altered parts of the Ortega quartzite, part of the lower Kiawa Mountain formation, and many layers of Burned Mountain metarhyolite. Mapped separately from Ortega quartzite.

Nearly restricted to Mesa la Jarita, Las Tablas quadrangle, Rio Arriba County.

**Petaluma Formation**[1]

Pliocene, lower: Northern California.

Original reference: R. E. Dickerson, 1922, California Acad. Sci. Proc., 4th ser., v. 11, no. 19, map.

F. A. Johnson, 1943, California Div. Mines Bull. 118, p. 623 (fig. 276), 624 (fig. 277), 625. In Petaluma region, consists chiefly of clays with some interbedded sandstone and rare bodies of thin beds and lenses of clayey limestone. Thickness about 4,000 feet. Unconformable beneath Sonoma volcanics and Merced formation. Middle Pliocene.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 16 (table 3), 85–91, pls. 6, 10, 11. Described in area immediately north of San Francisco Bay where it is exposed in four areas. Largest exposure trends S. 40° E. from vicinity of Penn Grove into Tolay Creek valley where it abuts against sandstone of Franciscan group or is covered by sand and gravels of Merced formation; exposed thickness here about 4,000 feet. Northeast limits of formation (north of Petaluma Valley) lie along an irregular contact with the Sonoma volcanics; folded and beveled Petaluma beds are unconformable beneath Sonoma volcanics. Base not exposed at any locality investigated.

R. A. Stirton, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 10, p. 2011–2025. Discussion of vertebrate remains in Petaluma. Fossil equine specimens indicate an age transitional between middle Pliocene (Hemphillian) and late Pliocene (Blancan).

G. T. Cardwell, 1958, U.S. Geol. Survey Water-Supply Paper 1427, p. 26 (table 6), 32–35, pl. 1. Described in Santa Rosa and Petaluma Valleys where it is composed of strongly folded continental and brackish-water clay, shale, sand, and sandstone and contains some conglomerate and nodular limestone. Exposed thickness probably exceeds 3,000 feet. May be in depositional contact with Franciscan group, but only fault contacts are mapped. Unconformably overlain by Sonoma volcanics, Merced formation, and alluvium. Table 6 shows age middle or early Pliocene; map bracket shows Pliocene. Includes Orinda formation of Johnson (1934, unpub. thesis). Exposures largely confined to belt 1 to 2 miles wide along southwestern flank of Sonoma Mountains, extending from north of Penn Grove to near mouth of Tolay Creek.

Apparently named for exposures in vicinity of Petaluma, Sonoma County.

Petan Trachyte or Basalt (in Vieja Group)

Tertiary: Southwestern Texas.

D. L. Amsbury, 1957, Dissert. Abs., v. 17, no. 9, p. 1981. Named in a stratigraphic sequence as younger than Moonstone rhyolite (new) and older than Chinati Mountain (emended).

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 28. Uppermost formation Vieja group redefined. Consists of trachyandesite porphyry, dark greenish-gray to brownish-gray on fresh exposures. Maximum thickness about 300 feet. Appears as erosion remnants in form of small hills on Brite ignimbrite (new); discordantly underlies post-volcanic gravel.

D. L. Amsbury, 1958, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 22. Described in Pinto Canyon area where it overlies Brite rhyolite and underlies rocks of Chinati Mountain group. Type locality designated.

Type locality: Steep hill on which is Cleveland triangulation station. Named from Petan Ranch which occupies Capote Rim and Capote Draw from south fence of Brite Ranch to head of Pinto Canyon, Rim Rock country, Presidio County.

Pete terrane[1]

Cretaceous: Kansas.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 255.

Derivation of name not stated.

**Petersburg Formation[1]**

Middle Pennsylvanian: Southwestern Indiana.

Original reference: M. L. Fuller and G. H. Ashley, 1902, U.S. Geol. Survey Geol. Atlas, Folio 84, p. 2.

C. E. Wier, 1950, U.S. Geol. Survey Coal Inv. Map C–1. Described in Clay, Greene, and Sullivan Counties. Petersburg formation, as used by Cumings (1922, Indiana Geol. Survey Spec. Pub. 21), included rocks between unconformity at top of Coal IV and unconformity at top of Coal VII. Formation here restricted to rocks in interval between unconformity above Coal IV and unconformity above Alum Cave limestone member which is above Coal V. Restricted Petersburg includes Coals IVa and V and averages 115 feet thick. Consists of 95 to 125 feet of sandstone, shale, limestone, and coal. Interval from unconformity above Coal IV and base of Coal IVa is composed of 30 to 50 feet of sandstone and shale which grade into each other laterally and vertically. Overlies Linton formation (new); underlies Dugger formation.

Named for Petersburg, Pike County.

†Petersburg Granite[1]

Late Paleozoic: Eastern Virginia.

Original reference: A. I. Jonas, 1928, Virginia Geol. Survey prelim. ed. of geol. map of Virginia.

R. O. Bloomer, 1939, Virginia Geol. Survey Bull. 51, p. 141–145. In Richmond area, Petersburg granite consists of three facies: most common is gray to pink, medium-grained granite; a blue, relatively fine-grained facies (just west of Richmond); and a porphyritic facies occurs in a belt which extends north and south along eastern margin of Triassic basin. Intrudes Wissahickon gneiss; contact forms a zone of apophyses approximately 1 mile wide. Underlies Triassic sediments. Late Paleozoic.

First described from occurrences near Petersburg, Dinwiddie County, Va. Petersburg granite is a batholithic intrusion that extends from Hanover County, Va., southward into North Carolina.

Peters Creek Breccia

Middle Mississippian: West-central Indiana.

C. L. Bieber, 1959, Indiana Acad. Sci. Proc., v. 68, p. 265–267. Intraformational limestone breccia in Middle Mississippian limestone. As exposed at waterfall in small branch valley of Peters Creek, bed is nearly 6 feet thick. Bedding is indistinct, but associated limestones above and below are well bedded and nearly horizontal except for local rolls and arches. Over 90 percent of blocks (phenoclasts) in matrix are limestone. Base of breccia is in sharp contact with a wavy laminated layer of limestone 4 inches thick. Based mainly on lithology and sequence, age of breccia is believed to be early St. Louis.

Well exposed in SW¼NW¼ sec. 36, T. 16 N., R. 5 W., southwest of Fincastle, Putnam County.

**Peters Creek Quartzite**

Peters Creek Schist[1] or Formation

Lower Paleozoic(?) (Glenarm Series): Southeastern Pennsylvania, northern Maryland, and northeastern Virginia.

Original reference: A. I. Jonas and E. B. Knopf, 1921, Washington Acad. Sci. Jour., v. 11, p. 447.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 90–91. Peters Creek quartzite described in York County, where it underlies a belt 6 miles wide that covers most of southeastern corner of area. Divided into two parts by narrow area underlain by Cardiff conglomerate and Peach Bottom slate. At its northwestern boundary, in contact with Wissahickon formation. No estimate of thickness made. Major structure of the Peters Creek is synclinal. Intruded by Sykesville granite. Precambrian(?).

G. W. Stose and A. J. Stose, 1948, Am. Jour. Sci., v. 246, no. 7, p. 405, 408. Quartzose mica schist beneath Arvonia slate should be called Peters Creek formation. If Peters Creek formation belongs in Taconic sequence, it is part of a series that ranges in age up to Lower Trenton.

S. L. Agron, 1950, Geol. Soc. America Bull., v. 61, no. 11, p. 1267–1268. Peters Creek is series of interbedded chlorite-sericite and quartz-albite schists which underlies and encloses Peach Bottom syncline. Peters Creek lies above the Wissahickon schist and underlies Cardiff conglomerate.

P. W. Choquette, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1029 (table 1). Formation included in Glenarm series which is considered pre-Silurian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Probably Lower Paleozoic.

Named for exposures along Peters Creek which enters Susquehanna River at Peach Bottom, Lancaster County, Pa.

Peters Mountain Sandstone (in Pocono Formation)[1]

Mississippian: Central Pennsylvania.

Original reference: B. Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 573.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 18. Platy gray sandstone with some pebble beds. Overlies Second Mountain member and underlies Cove Mountain member (both new).

Named for Peters Mountain, Dauphin County.

**Peterson Limestone** (in Gannett Group)[1]

Lower Cretaceous: Southeastern Idaho and western Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 76, 82.

R. E. Peck, 1941, Jour. Paleontology, v. 15, no. 3, p. 285–286. Considered Lower Cretaceous on basis of faunal studies.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 42–43, pl. 1. Described in Ammon quadrangle, Idaho, where it is chiefly massive dark dense limestone, underlies Bechler conglomerate and overlies Ephraim conglomerate. Locally in juxtaposition with Twin Creek limestone. Involved in folds and faults. Thickness appears to be about 200 feet. Lower Cretaceous.

C. A. Moritz, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 65 (table 1), 66–67. In Gannett Hills region, Wyoming, consists of about 125 feet of gray compact sublithographic limestone with a few conglomeratic and brecciated zones. Overlies Ephraim conglomerate; underlies Bechler formation.

W. L. Stokes, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 80, 81 (fig. 1). Thickness along Idaho-Wyoming boundary about 200 feet; wedges out eastward.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 56, pl. 21. Described in Jackson Hole area as limestone member of Gannett group. Light- to medium-blue-gray and sublithographic. Thickness about 135 feet on Fall Creek; 113 feet in Snake River Bluff near mouth of Dog Creek. Overlies Ephraim conglomerate member; underlies Bechler "conglomerate" member.

Named for exposures east of Peterson's Ranch, along Tygee Creek, sec. 34, T. 7 S., R. 46 E., Boise meridian, Freedom quadrangle, Bannock County, Idaho.

Petersville Shale[1]

Mississippian: Northeastern Kentucky.

Original reference: W. C. Morse and A. F. Foerste, 1912, Kentucky Geol. Survey Bull. 16, p. 24.

Named for Petersville, Lewis County.

Petes Summit Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3). Discussion of Paleozoic continental margin in central Nevada. Clipper Canyon sequence comprises (ascending) Charcoal Canyon, Petes Summit, Sams Spring, and Joes Canyon formations (all new). Clipper Canyon sequence is isolated by surrounding Tertiary volcanic rocks.

Clipper Canyon, Toquima Range, Nye and Lander Counties.

Petoskey Limestone[1] (in Traverse Group)

Middle Devonian: Northern Michigan.

Original reference: A. W. Grabau, 1902, Michigan Geol. Survey Rept. 1901, p. 201, 210.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1776, chart 4. Contains several faunas of different age; at base is an assemblage suggestive of the Norway Point of Alpena County; above is a fauna resembling the Potter Farm formation; this is followed by an assemblage containing an element of the Thunder Bay fauna.

Probably named for exposures at Petoskey.

**Petrified Forest Member** (of Chinle Formation)

Upper Triassic: Northern Arizona, southeastern Nevada, west-central New Mexico, and southern Utah.

G. B. Maxey, 1946, Am. Jour. Sci., v. 244, no. 5, p. 337. Incidental mention in discussion of geology of Pavant Range, Millard County, Utah. Name credited to H. E. Gregory.

H. E. Gregory, 1947, Geol. Soc. America Bull., v. 58, no. 3, p. 223 (table 1), 228. Upper part light-red and brown, irregularly bedded sandstones and sandy, argillaceous, carbonaceous, and calcareous shales widely variable in composition; lower part brilliantly variegated friable shales of various composition and degrees of hardness, which weather into badland forms; contains fossil wood. Thickness 300 to 400 feet. Underlies Springdale sandstone member (new); overlies unnamed sandstone in basal part of formation.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 52 (table), 66, 67–68, strat. sections. Described in Zion National Park region where it is 650 to 800 feet thick. Derivation of name stated.

G. A. Kiersch, 1955, Mineral resources Navajo-Hopi Indian Reservations Arizona-Utah: Tucson, Univ. Arizona Press, v. 2, p. 4 (fig. 1), 5. In Navajo country, underlies Owl Rock member (new) and overlies Monitor Butte member (new). Locally overlies Shinarump conglomerate. Predominantly claystone but contains sandstone (Sonsela beds) in eastern part.

J. H. Stewart, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 457–458. Described in southeastern Utah where it conformably underlies Owl Rock member and in most areas conformably overlies Monitor Butte member; conformably overlies Moss Back member in part of White Canyon and Elk Ridge areas. Thickness in Monument Valley area 500 to 700 feet; 100 feet in White Canyon area and southern part of Elk Ridge area; north of these areas 70 feet or less. Near junction of Green and Colorado Rivers, loses identity probably by intertonguing and intergrading with Owl Rock member. Corresponds to "C" division of Chinle formation described by Gregory (1917, U.S. Geol. Survey Prof. Paper 93) in northeastern Arizona. Geographically extended into Nevada and New Mexico.

R. F. Wilson, 1959, Dissert. Abs., v. 19, no. 11, p. 2918. As result of this study, the Chinle is redefined to include only lower part of Petrified Forest member.

Named for fact that it contains band of fossil wood closely resembling dominant rock in Petrified Forest of Arizona. Present in all of northern Arizona and southern Utah, extends into southeastern Nevada and west-central New Mexico. In most of these areas, forms thickest and most characteristic part of formation.

Petros Sandstone (in Slatestone Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Two sandstones separated by a shale break that includes Petros coal. Thickness 50 to 60 feet in type area; 45 feet in Cross Mountain section. Underlies a shale interval 40 to 170 feet thick that includes Blue Gem coal and in turn underlies Sand Gap sandstone (new); overlies a shale interval 40 to 190 feet thick that contains Coal Creek coal and in turn overlies the Stephens sandstone (new).

Named from town of Petros, Morgan County.

**Pewabic Amygdaloid**[1] (in Ashbed Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. Pumpelly, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 21–25, 28.

T. M. Broderick, C. D. Hohl, and H. N. Eidemiller, 1946, Econ. Geology, v. 41, no. 7, p. 678 (fig. 1). Name appears on geologic section of Michigan copper district.

Named for occurrence in Pewabic mine, Houghton County.

**Pewabic Flow**[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (Chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Pewabic Quartzite[1]

Precambrian (Huronian) : Northeastern Minnesota.

Original reference: N. H. Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept., p. 79, 86.

Occurs in region of Gunflint Lake to Ogishke Muncie Lake. Named for Chippewa word meaning iron.

**Pewabic West Conglomerate**[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan) : Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 82, chart.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

Probably named for occurrence in old Pewabic West mine, Houghton County.

**Pfeifer Shale Member** (of Greenhorn Limestone)[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: N. W. Bass, 1926, Kansas Geol. Survey Bull. 11, p. 32.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Chalky shale and chalky limestone in alternating layers, "Fencepost limestone bed" at top; blue gray, weathers to light tan. In Hamilton County, Pfeifer shale member and the underlying Jetmore chalk member are thicker than farther east; they cannot be distinguished and have been together designated the Bridge Creek limestone member. Thickness of Pfeifer shale typically 19 to 21 feet in Ellis and Russell Counties. Includes Fencepost limestone bed. Underlies Fairport chalky shale member of Carlile formation.

Named for exposures 2½ miles northwest of Pfeifer, Ellis County.

Phalen Lake Volcanics[1]

Tertiary(?) : Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 101, map.

Forms steep escarpment overlooking west side of Phalen Lake, Stevens County.

Phantom Flows, Lavas

Pleistocene: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 30, pl. 6. Oldest of visible lavas of former Mount Mazama seems to have issued from vent close to the Phantom Ship, on south wall of caldera. How high

Phantom cone rose is impossible to tell; after activity ceased, summit was eroded and buried by flows and other ejecta from central vents of Mount Mazama. Unconformity separates Phantom flows from those of Mazama proper.

Phantom Ship, probably remnant of Phantom Cone, is on south wall of caldera of Crater Lake.

Phantom Migmatite

Precambrian: Northern Arizona.

Ian Campbell and J. H. Maxson, 1937, 17th Internat. Geol. Cong. Abs. of Papers, p. 65 (1939, Rept., v. 2, p. 260); 1938, Carnegie Inst. Washington Year Book 37, p. 363. Mentioned in discussion of Archean rocks of Grand Canyon.

Type locality: Phantom Creek, Grand Canyon area.

Phantom Canyon Quartzite

Precambrian (Algonkian): South-central Colorado.

J. D. Martinez, 1959, Dissert. Abs., v. 20, no. 3, p. 995. Incidental mention only.

In vicinity of Canyon City.

Phelan Limestone

Carboniferous(?): Northwestern Utah.

V. E. Peterson, 1942, Econ. Geology, v. 37, no. 6, p. 471 (table 1). Consists of coarse to finely crystalline, light blue-gray, massive-bedded limestone, locally cherty. Thickness 1,000 to 1,500 feet. Overlies newly named Wardlaw shale.

In Ashbrook mining district on west side of Goose Creek Range.

Phelps Sandstone[1]

Lower Mississippian: Southwestern Missouri.

Original reference: E. M. Shepard, 1898, Missouri Geol. Survey, v. 12, pt. 1, p. 49, 77–82.

E. B. Branson and M. G. Mehl, 1939, (abs.) Missouri Acad. Sci. Proc., v. 4, no. 6, p. 167. Bushberg is equivalent to the Phelps and should be called Phelps. The Phelps is basal Mississippian.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 71–72. Phelps sandstone as defined by Shepard has not proven useful unit in stratigraphic studies except, perhaps, as a subsurface catchall. In light of uncertainty of stratigraphic connotation of Phelps, it is here recommended that term be dropped from list of names in Missouri columnar section.

Named for Phelps mines, Greene County.

**Phi Kappa Formation**[1]

Lower Ordovician and later(?): Central Idaho.

Original reference: L. G. Westgate and C. P. Ross, 1930, U.S. Geol. Survey Bull. 814, p. 10, 18.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 8. Phi Kappa formation, largely argillaceous quartzite, and the unnamed argillite beneath it are together probably broadly equivalent to Ramshorn slate, Kinnikinic quartzite, and Saturday Mountain formation.

Named for exposures along Phi Kappa Creek, Hailey quadrangle.

Philadelphia Brick Clay[1]

Pleistocene: Southwestern New Jersey and southeastern Pennsylvania.

Original reference: H. C. Lewis, 1881, Philadelphia Acad. Nat. History Sci. Proc., v. 32, p. 258–272, 296–309.

Philadelphia is in part built on this clay.

†Philadelphia Mica Schist and Gneisses[1]

Precambrian (Glenarm Series) : Southeastern Pennsylvania.

Original reference: C. E. Hall, 1881, Pennsylvania 2d Geol. Survey Rept. $C_6$, p. 28–31, map.

Extends from Delaware River at Trenton westward across Schuylkill River into Delaware County.

Philadelphia Red Gravel[1]

Pleistocene: Southeastern Pennsylvania.

Original reference: H. C. Lewis, 1881, Philadelphia Acad. Nat. Sci. Proc., v. 32, p. 258–272, 296–309.

Well exposed near University of Pennsylvania in Philadelphia.

†Philipsburg Formation[1]

Lower Ordovician: Eastern New York and northwestern Vermont.

Original reference: R. P. Whitfield, 1890, Am. Mus. Nat. History Bull., v. 3, p. 25–28.

Philipsburg Series[1]

Lower Ordovician and older(?) : Southern Quebec, Canada, and northwestern Vermont.

Original reference: W. E. Logan, 1863, Canada Geol. Survey, p. 273–280, 844–854.

Named for village of Philipsburg, Quebec, where lower formations of series are well exposed.

Philson Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: F. and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$, p. 286, 292.

Probably named for exposures at or near Philson, Somerset County.

Phipsburg Limestone[1]

Age(?) : Maine.

Original reference: C. T. Jackson, 1838, Rept. on geology of Maine, v. 2, p. 61–62.

Phipsburg Basin.

Phoenix Beds[1]

Cretaceous: Oregon.

Original reference: F. M. Anderson, 1902, California Acad. Sci. Proc., 3d ser., v. 2, p. 1–62.

Southern part of Oregon Basin.

**Phoenix Limestone Lentil** (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 44, map, sections.

Crops out at mouth of Phoenix mine, Bingham district.

Phoenix Volcanic Group[1]

Mesozoic(?) and older(?): Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps.

The town of Phoenix is in midst of this large though interrupted area of basic volcanics.

Phoenix or Schroeppel Shale[1]

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

D. W. Fisher, 1959, New York State Mus. Sci. Service Map and Chart Ser. No. 1. Gillette (1947) in his detailed study of Clinton group ignored Chadwick's (1918) Phoenix and Schroeppel shales, probably because they were so loosely defined. Instead he introduced name Willowvale for the green fossiliferous shale beneath the Herkimer and above the Kirkland. Gillette's view is followed in present report.

Type locality: At Phoenix, Schroeppel Township, on Oswego River, Oswego County.

†Phoenix Mine Group[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 175–178. Exposed in Phoenix mine in Keweenaw County.

**Phoenix Park Quartz Latite**[1] (in Alboroto Group)

Tertiary, middle or late: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull. 718.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 93 (table 18). Alboroto rhyolite described in San Juan district. Upper part is biotite-hornblende latitic rhyolite; includes Equity and Phoenix Park quartz latites [both part of Alboroto group] of Creede district.

Named for development about Phoenix Park, Creede district.

†Phoenixville Shale (in Newark Group)[1]

Upper Triassic: Southeastern Pennsylvania.

Original reference: B. S. Lyman, 1894, Am. Philos. Soc. Proc., v. 33, p. 197–215.

At Gwynedd and Phoenixville tunnels, Bucks and Montgomery Counties.

**Phosphoria Formation**[1]

Phosphoria Group

Permian: Idaho, western Montana, northeastern Utah, and western Wyoming.

Original reference: R. W. Richards and G. R. Mansfield, 1912, Jour. Geology, v. 20, p. 683–689.

H. D. Thomas, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1655–1697. Marine limestone and sandstone tongues extend southeastward from the Phosphoria and Dinwoody formations of Wind River Mountains and Owl Creek Mountains, interfingering with red shales in base of Chugwater formation in central and southeastern Wyoming. Intercalated marine beds and red shales constitute the red-bed "Embar" of central Wyoming. Phosphoria includes Sybille tongue (new), Forelle tongue, and Ervay tongue (new).

G. E. Condra E C. Reed, and O. J. Scherer, 1940, Nebraska Geol Survey Bull. 13, p. 2, 6, 9; 1950, Nebraska Geol. Survey Bull. 13–A, p. 2, 3, 6, 9. Group comprises (ascending) Opeche shale, Minnekahta limestone, Glendo shale (new), Forelle limestone, and Freezeout shale. Overlies Cassa group (new); underlies Dinwoody formation or Spearfish formation (redefined). Permian.

N. D. Newell, 1948, Geol. Soc. America Bull., v. 59, no. 10, p. 1056 (fig. 2), 1057. In Confusion Range, Utah, Phosphoria formation, 4,555 feet thick, overlies the Kaibab and underlies Woodside.

W. R. Lowell and M. R. Klepper, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 241. Beaverhead formation (new) unconformably overlies Cretaceous Kootenai, Triassic Dinwoody, and Permian Phosphoria.

J. J. McCue, 1955, (abs.) Wyoming Univ. Pubs., v. 19, no. 2, p. 82. In southeastern part of Big Horn Basin includes Nowood member (new).

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2844–2852; 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 20–31. Phosphoria formation consists of chert, carbonaceous mudstone and phosphorite in its typical area in southeastern Idaho. These rocks intertongue with, and pass laterally into, sandstone in south-central Montana and northwestern Wyoming, carbonate rock in west-central Wyoming, and carbonate rock and subordinate sandstone in northeastern Utah; thin tongues of phosphatic and cherty rocks persist over all of these areas. Carbonate rocks in turn intertongue with, and pass laterally into, greenish-gray and red beds in eastern Wyoming, southeastern Montana, eastern Utah, and northwestern Colorado. Plan of nomenclature developed to describe these rocks has following elements: (1) retains name Phosphoria formation for chert-mudstone-phosphorite facies and identifies as tongues of the Phosphoria rocks of these lithologic types that interfinger with sandstone and carbonate rock along fringe of phosphate field; (2) retains name Park City formation for sequence of carbonate rock and sandstone in Utah, restores this name for similar carbonate rock in west-central Wyoming, and identifies as tongues of the Park City formation beds of carbonate rock that interfinger with other formations in Idaho, western Wyoming, and Montana; (3) introduces name Shedhorn sandstone, for sandstones of Phosphoria age in northwestern Wyoming and southwestern Montana. Three members recognized at type locality—Meade Peak phosphatic shale, Rex chert, and cherty shale. Three other members—the lower cherty member (laterally continuous with lower beds of Meade Peak), Retort phosphatic shale member, new, (laterally continuous with the cherty shale member), and Tosi chert member, new, (laterally continuous with upper part of the Retort and cherty shale member)—are not present in broader area of typical development of the Phosphoria. Eastward, parts of Phosphoria grade laterally into sandstone of Shedhorn and carbonate rock of Park City formations, but other parts extend as tongues over most of field. Thickness at type locality 250 to 450 feet; thickens to about 1,300 feet in south-central Idaho. Underlying formations: Quadrant quartzite, Montana; Tensleep sandstone, Wyoming; Wells formation, Idaho; Weber quartzite or sandstone, Utah and Colorado.

Named for typical exposures in Phosphoria Gulch, which joins Georgetown Canyon, 2½ miles northwest of Meade Park, Idaho.

Piasa Limestone Member (of Modesto Formation)

Piasa Limestone (in McLeansboro Formation)[1]

Piasa Limestone (in McLeansboro Group)

Pennsylvanian: Southeastern and southwestern Illinois.

Original reference: H. E. Culver, 1925, Illinois Geol. Survey Coop. Min. Ser. Bull. 29, p. 20.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 21 (table), 30–31. Included in Sparland cyclothem, McLeansboro group. Overlies Danville (No. 7) coal; underlies unnamed shales.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 48 (table 1), pl. 1. Rank reduced to member status in Modesto formation (new). In southeastern area, occurs below De Graff coal member (new); in southwestern area occurs below Rock Branch coal member (new), Piasa limestone, De Graff coal, Pond Creek coal, and Lake Creek coal members may be included in complex West Franklin limestone member in eastern part of area. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: E½ sec. 25, T. 8 N., R. 10 W., Jersey County. Named for Piasa Creek.

†Picacho Limestone[1]

Permian: Southeastern New Mexico.

Original reference: A. G. Fiedler and S. S. Nye, 1933, U.S. Geol. Survey Water-Supply Paper 639.

Named for Picacho, Lincoln County, in vicinity of which lower part is well exposed.

Picacho de Calera Formation[1]

Upper Devonian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 485, 488.

W. D. Pye, 1959, Arizona Geol. Soc. Guidebook 2, p. 277. Age given as Upper Devonian in catalog of formation names in southern Arizona and northern Sonora.

In Picacho de Calera Hills, 25 miles northwest of Tucson.

Picard Shale Member (of Nesson Formation)

Jurassic: Subsurface in Montana and North Dakota, and Manitoba, Canada.

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 104, 105, fig. 2. Shale unit that conformably overlies Poe evaporite member (new) and underlies Kline member (new). In type section, consists of 40 feet of dark-red shale which is slightly silty in part and contains masses or thin interbeds of white earthy gypsum in lower half of unit. Thins laterally toward margins of Williston basin.

Type section: Interval 6,610 to 6,650 feet in Deep Rock Oil Corp. No. 1 Picard well, center NW NE sec. 6, T. 29 N., R. 52 E., Roosevelt County, Mont.

**Picayune Formation** (in Silverton Volcanic Group)

Picayune Quartz Latite (in Silverton Volcanic Series)

Picayune Volcanic Group (in Silverton Volcanic Series)[1]

Tertiary, middle and upper: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 120.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 14, 76–77, pl. 1. Picayune quartz latite made up of interlayered flows, tuffs, breccias, and agglomerates of a quartz latite of intermediate silica content, in San Juan region. Rocks chiefly dark-purple or greenish quartz latites grading into rhyolites on one hand and into darker quartz latites on the other. Thickness 1,800 feet.

Pickens Sandstone[1]

U.S. Geological Survey currently classifies the Picayune as a formation in Silverton Volcanic Group and designates the age as middle and late Tertiary on basis of a study now in progress.

Small exposures in Animas Valley and in its minor tributary, Picayune Gulch, from which unit takes its name.

Pickaway Limestone (in Greenbrier Limestone)[1]

Mississippian (Meramecian): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 450–473.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 272–277; J. M. Weller and others, 1948. Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 98, 99). Limestone in Greenbrier series. Underlies Union limestone; overlies Taggard formation [shale]. Meramecian series.

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1910–1912. Discussion of paper by Wells (1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 5). Butts (1927, Oil and gas possibilities at Early Grove, Scott County, Virginia) ignored writer's [Reger] previous terminology. He used names Cove Creek limestone and Fido sandstone for certain stages of Mauch Chunk and assigned everything between the Gasper (Upper Union) and St. Louis (Hillsdale) to the Ste. Genevieve. Use of Cove Creek and Fido was violation of custom because writer's names were already in print. Butts' classification of rocks to the Ste. Genevieve was merely an avoidance of Pickaway, Taggard, Patton, and Sinks Grove.

Type locality: Along State road between Pickaway and Union, Monroe County, W. Va.

Pickens Sandstone[1]

Pennsylvanian: Northern West Virginia.

Original reference: J. A. Taff and A. H. Brooks, 1896, U.S. Geol. Survey Geol. Atlas, Folio 34.

Named for Pickens, Randolph County.

**Pickering Gneiss**[1]

Precambrian: Eastern Pennsylvania and New Jersey.

Original references: B. L. Miller, 1912, Econ. Geology, v. 7, p. 767; 1925, Pennsylvania Geol. Survey, 4th ser., Bull. $M_7$, p. 61–66; F. Bascom, 1932, U.S. Geol. Survey Geol. Atlas, Folio 223.

W. S. Bayley, 1941, U.S. Geol. Survey Bull. 920, p. 12–45, pl. 5. Area of report is Delaware Water Gap and Easton quadrangles, New Jersey and Pennsylvania. There is in the Highlands a series of schists and gneisses which are different from predominating gneisses of district and which at many places are evidently closely associated with Franklin limestone and at some places apparently grade into the limestone. They are regarded as sedimentary. Their relations to Pochuck, Byram, and Losee gneisses are not clear, but, because the Pochuck, Byram, and Losee are believed to be intrusive in the limestone, it is inferred that they are also intrusive in sedimentary gneisses and schists associated with the limestone. The sedimentary schists, slaty rocks, and gneisses are here included under name Pickering gneiss; and the Pochuck gneiss of which they have heretofore been treated as a part is restricted to the black gneisses of igneous origin which are intrusive in the Franklin limestone and the sedimentary gneisses and schists.

Named for fact that Pickering Creek, Chester County, Pa., lies almost wholly within this gneiss area.

Pickhandle Formation

Miocene, middle: Southern California.

O. E. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 138. Mentioned in discussion of silver-barite veins at Waterman mine, Calico district. Principal vein roughly follows bedding of a sequence of dacitic tuffs, lakebed clays and siltstones, and granitic fanglomerate probably belonging to Pickhandle formation; jasper appears bedded and may have been an original member of Pickhandle. Name credited to Thane McCulloh (unpub. rept.).

Waterman mine is in NE¼ sec. 13, T. 10 N., R. 2 W., 4 miles north of Barstow, via Camp Irwin Road, Barstow quadrangle, San Bernardino County.

**Pico Formation**

Pico Formation (in Fernando Group)[1]

Pliocene: Southern California.

Original reference: B. L. Clark, 1921, Jour. Geology, v. 29, p. 608–609, chart facing p. 586.

G. B. Oakeshott, 1950, California Jour. Mines and Geology, v. 46, no. 1, p. 50 (table 1), 54 (fig. 2), 56–61, pls. 14, 16. Described in Placerita oil field. Consists of three members: lower Pico marine, middle Pliocene; upper Pico marine, upper Pliocene; and continental upper Pliocene Sunshine Ranch member. Marine members not recognized north of San Gabriel fault. Thickness about 3,000 feet. Unconformably underlies Saugus formation; overlies Elsmere member of Repetto siltstone, gradually overlaps it, and lies directly on crystalline rocks at Whitney Canyon and north.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 23 (fig. 2), 24 (fig. 3), 74–75, 81–83, pls. 1–3. Term Pico is here applied to members of middle and upper Pliocene age. Three members recognized: marine middle Pliocene Lower Pico, marine upper Pliocene Upper Pico, and continental upper Pliocene Sunshine Ranch member. Underlies Saugus formation; overlies Repetto formation. Present both north and south of San Gabriel fault in San Fernando quadrangle.

E. L. Winterer and D. L. Durham, 1958, U.S. Geol. Survey Oil and Gas Inv. Map OM–196. In Ventura Basin, Pico formation consists of light-olive-gray and bluish-gray siltstone and fine-grained sandstone, light-brown and gray sandstone and conglomerate. Upper part interfingers with Saugus formation; lower part interfingers with Towsley formation. Thickness about 5,000 feet in western part of area; only a few hundred feet to the east, near Placerita oil field. Many beds that are here referred to Pico formation were included in the Saugus by Kew (1924, U.S. Geol. Survey Bull. 753).

D. L. Durham and R. F. Yerkes, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–195. Term Pico in Los Angeles Basin should be replaced by a new formational name. Strata not named in present report.

Named for exposures in Pico Canyon, Los Angeles County.

Pico Peak Series

Cambrian(?): Central Vermont.

H. E. Hawkes, Jr., 1941, Geol. Soc. America Bull., v. 52, no. 5, p. 653, 654, 657. Local unit consisting of quartz schists, quartzites, quartzose gneisses and dolomitic marble. Replaces Mount Holly series in this area. Underlies Plymouth Union series (new). Age difficult to determine without fossil evidence.

Type locality: East side of Green Mountain Range in Plymouth and Bridgewater Townships, Windsor County. Distinctive marble bed best exposed in valley east of Blue Ridge Mountain.

Picton Granite[1]

Precambrian: Northern New York.

Original reference: J. M. Clarke, 1909, New York State Mus. Bull. 133, p. 9–10.

Crops out on Grindstone and Wellesley Islands. Named for Picton Island (also called Robbins Island) in St. Lawrence River.

Pictonian Stage

*See* Trenton Stage.

**Pictured Cliffs Sandstone**[1]

Upper Cretaceous: Northwestern New Mexico and southwestern Colorado.

Original reference: W. H. Holmes, 1877, U.S. Geol. and Geog. Survey Terr. 9th Ann. Rept. for 1875, p. 248, 250, 251, pl. 35.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2159. Discussion of revised nomenclature of Mesaverde group in San Juan basin and its bearing on problem of nomenclature of Pictured Cliffs and Cliff House sandstones. As result of southward thinning and termination of Lewis shale, Pictured Cliffs and Cliff House sandstones are in direct contact and for several miles southeast of Newcomb form an inseparable unit. It seems advisable, however, to maintain name Pictured Cliffs and its identity as a distinct formation for the following reasons: its long-standing and well-understood usage; it represents closing stages of marine Cretaceous deposition in San Juan basin, and there is some suggestion that part of it may have had a northern source differing from that of underlying Mesaverde; everywhere separated from Mesaverde in subsurface; known intertonguing relations with both Lewis shale and overlying Fruitland formation suggest that there may develop a need for named tongues of Pictured Cliffs.

Named for Pictured Cliffs on San Juan River, in northwestern New Mexico.

Picuris Basalts

Precambrian (Proterozoic) : Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 23–24, 44. Series of basalt and andesite flows that occur principally interspersed with the sedimentary schists of the Hopewell series in Picuris and Petaca areas. The basalts could be grouped definitely as part of the Hopewell series, except that they persist up into Ortega quartzite, especially in Petaca area; therefore, the basalt intrusives have been given a distinctive name. Although basalts are schistose, their igneous nature is definitely established by presence of lath-shaped phenocrysts of plagioclase. Half a mile thick in Picuris Canyon.

Most readily recognizable exposure observed in Picuris area is near mouth of Picuris Canyon. Also recognized in Petaca area, Rio Arriba and Taos Counties.

Picuris Tuff

Miocene (?) : Northern New Mexico.

E. C. Cabot, 1938, Jour. Geology, v. 46, no. 1, p. 91. In Badito locality, consists of (ascending) about 680 feet of buff water-laid tuff interbedded with cemented gravel; 190 feet of salmon-pink sandy clay with layers of cemented gravel; 10 feet of giant conglomerate characterized by rounded boulders having maximum size of about 4 feet; 100 feet of gravel similar to unit below but with smaller pebbles and cobbles; 40 feet of basaltic lava; and some gravels above basalt. Total thickness about 1,000 feet. About 2 miles east of Badito section, red and green silts and clays and a giant conglomerate, totaling 200 feet in thickness, lie below the tuff so that total thickness of Picuris in this area seems to be in excess of 1,200 feet. Overlies Magdalena formation unconformably. Tertiary (pre-Santa Fe).

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 52, pl. 1. Probable Miocene. Maximum thickness estimated to be from 1,250 to 1,750 feet. Exposed on northeast, southeast, and across central parts of Picuris Range.

Brewster Baldwin, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 118. Although Cabot (1938) extended Picuris tuff southward to include exposures just north of Santa Fe, Kottlowski is proposing name Bishops Lodge member of Tesuque formation.

Beds crop out typically in the Picuris reentrant near towns of Badito and Placita, Taos County.

†Piedmont Group[1]

Precambrian and Cambrian : Western North Carolina.

Original reference: W. C. Kerr, 1869, North Carolina Geol. Survey Rept. 2, p. 13–35.

Named for development in Piedmont Plateau of North Carolina.

Piedmont Sandstone

Permian: Western Oklahoma.

Henry Schweer *in* O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1553 (fig. 9). Shown on cross section at top of Cedar Hills member of Hennessey formation. Underlies Flowerpot shale.

Type locality and derivation of name not stated.

†Piedmont Sandstone (in Pottsville Formation)[1]

Pennsylvanian: Northern West Virginia, Maryland, and western Pennsylvania.

Original reference: C. A. Ashburner, 1877, Am. Philos. Soc. Proc., v. 16, p. 519–560.

Probably named for Piedmont, Mineral County, W. Va.

†Piedra Formation[1]

Upper Cretaceous: Southwestern Colorado.

Original reference: W. Cross and A. C. Spencer, 1899, U.S. Geol. Survey Geol. Atlas, Folio 60.

**Piedra Rhyolite** (in Potosi Volcanic Group)

Piedra Rhyolite or Group (in Potosi Volcanic Series)[1]

Tertiary, middle or upper: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13, p. 20, 36.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 144–156. Piedra rhyolite included in Potosi volcanic series. Thickness 2,000 to 3,000 feet. Made up of four distinct members: lower rhyolite, tridymite rhyolitic latite, tuff, rhyolitic latite.

E. S. Larsen, Jr., and others, 1958, U.S. Geol. Survey Bull. 1070–B, table 2. Lead-alpha dating of Piedra rhyolite shows age to be about 16 million years.

U.S. Geological Survey tentatively assigns a middle or late Tertiary age to the Piedra.

Named for exposures in Piedra Peak, San Cristobal quadrangle.

Piedras Altas Formation (in Asuncion Group)

Upper Cretaceous: West-central California.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 132 [preprint 1941]. Lower formation of Asuncion group (new) in southern Santa Lucia Range. Underlies Godfrey shale (new).

Santa Lucia Range is mountainous area, between Salinas Valley and the coast, which extends from Monterey Bay to central part of San Luis Obispo County.

**Piegan Group**

Precambrian (Belt Series): Western Montana.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1890–1892. Limestones, dolomites, and dominantly argillaceous clastics which lie between Missoula and Ravalli groups. Despite variations, they form the sole dominantly calcareo-magnesian group in the Meagher facies and the second in the Glacier Park. Characterized by great development of calcareous algae. Contains Siyeh, Spokane, and Sheppard formations in ascending order at type locality.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 112–113. Restricted at top to exclude Shepard formation which is included in Missoula group. Where Helena limestone is recognizable, it is regarded as upper formation of group. Greyson, Spokane, and Empire shales (named in ascending order), which overlie the Newland and underlie the Helena in vicinity of Helena, may be local units or may correspond to argillaceous rocks of other regions. Principal component of group has been variously called Siyeh, Newland, and Wallace limestone or formation, and these names are retained locally. In Glacier Park, Piegan group, as herein defined, consists largely of massive dolomite and dolomitic limestone with interbedded argillite, quartzite, oolite, and mud breccia. Maximum reported thickness 5,400 feet. Overlies Ravalli group.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. As mapped, includes Wallace formation, Newland limestone, Siyeh limestone, Greyson shale, Spokane shale, Empire shale, and Helena limestone.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 33–43, pls. 1, 2. Restricted to include only Siyeh limestone. As far as Glacier National Park and neighboring areas are concerned, name "Piegan group" as restricted might well be dropped. At present, name is retained because of its usefulness in correlation throughout Montana and because of Siyeh limestone is expected to be divided into several units of formational rank when more detailed mapping is done. At that time, Siyeh limestone may be restricted in its application or abandond.

Type locality: Piegan Mountain, Glacier National Park. Well exposed on Mounts Gould, Wilbur, Cleveland, Lineham, and other high peaks of Glacier-Waterton region.

Pie Knob Andesite[1]

Pleistocene: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pub., Dept. Geol. Bull., v. 2, p. 403–404, map.

Forms large part of Pie Knob, north of University Campus, Berkeley, Alameda County.

**Pierce Limestone** (in Stones River Group)[1]

Middle Ordovician: Central Tennessee.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 258–267.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 32–34. Gray and blue to light-blue and dove-colored thinly bedded limestone separating the more massively bedded overlying Ridley limestone and underlying Murfreesboro limestone. Thickness 23 to 28 feet. Type section was at Pierce's Mill which has now been replaced by a power plant located on north bank of East Fork of Stones River one-half mile south of Walterhill on Murfreesboro-Lebanon Highway. Formation is nearly completely exposed, base and lower part being exposed on west side of power plant, and the top few feet and contact with overlying Ridley occurring east of power plant.

Type section: Pierce's Mill, point at which Murfreesboro and Lebanon Turnpike crosses Stones River, Rutherford County.

Pierce shales[1] (in Tusayan series)

Pennsylvanian (?) : Northwestern Arizona.

Original reference: C. [R.] Keyes, 1922, Pan-Am. Geologist, v. 38, no. 3, p. 251, 337.

Charles Keyes, 1936, Pan.-Am. Geologist, v. 66, no. 3, p. 215 (table). Underlies Seligman limestones; unconformably overlies Elden limestones. In Tusayan series (new) of Carbonic age.

Exposed in section at mouth of Grand Canyon near Pierce's ferry.

†Pierce Canyon Redbeds[1] (in Dockum Group)

Permian or Triassic: Southeastern New Mexico and western Texas.

Original reference: W. B. Lang, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 2, p. 262–270.

A. M. Morgan, 1942, Am. Geophys. Union Trans., v. 23, pt. 1, p. 33 (figs. 5, 6). Cross sections show Pierce Canyon redbeds in Dockum group below Santa Rosa sandstone and above Rustler formation.

U.S. Geological Survey has abandoned Pierce Canyon Redbeds in favor of Dewey Lake Redbeds.

Named for exposures in vicinity of Pierce Canyon, southeast of Loving, Eddy County, N. Mex.

Pierce Estate Sands

Oligocene: Southern Texas (subsurface).

Alexander Deussen and K. D. Owen, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1630 (fig. 5), 1631 (fig. 6), 1632, 1634. Name suggested for the thick body of sand above an Oligocene marine shale wedge [Old Ocean sand] and below the Fleming, or zone of reworked Cretaceous foraminifera, now loosely designated as *Discorbis*. Name Flour Bluff also suggested for this unit.

Named for well No. 20 in east section Wharton County (Pierce Estate Fee No. 2).

Piercefield Gneiss[1]

Precambrian: New York.

Original reference: H. P. Cushing, 1907, New York State Mus. 60th Ann. Rept., pt. 2, p. 463, 469–470.

Named for exposures about Piercefield, St. Lawrence County.

Piermont Group

Precambrian: Eastern Nevada.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 158–159, 160. Sequence of clastic rocks. Thickness approximately 10,000 feet. Four mappable units (ascending): A, B, C, and D recognized. Base not exposed. Underlies Prospect Mountain quartzite. Cambrian-Precambrian boundary arbitrarily placed at top of ledge-forming shaly interval about 100 feet thick at top of unit D.

Named for Piermont Creek on eastern side of Schell Creek Range, Ely quadrangle. Well exposed on second ridge north of creek.

**Piermont Member** (of Albee Formation)

Ordovician: West-central New Hampshire.

J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle (1:62,500):

New Hampshire Highway Dept. Consists of dark-gray quartz-mica schist, mica schist, staurolite schist and local beds of fine conglomerate, of volcanic origin in part, interbedded with the schists and quartzites of the Albee formation. Upper Ordovician(?).

J. B. Hadley, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 117, 119 (fig. 2), 126–127. Maximum thickness estimated 1,000 feet. Occurs about 1,000 feet above base of Albee formation. Type locality cited.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Ordovician(?).

Type locality: Mount Cube area. Occurs in and near village of Piermont, Grafton County.

Pierpont Sandstone (in Pocahontas Group)

Pierpont Sandstone (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 218.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 98; P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 217, 244. Included in Pocahontas group, Pottsville series.

Exposed at Pierpont Station on Slab Fork of Guyandot River, Wyoming County.

**Pierre Shale** (in Montana Group)[1]

Upper Cretaceous: South Dakota, eastern Colorado, western Minnesota, Montana, Nebraska, New Mexico, North Dakota, and eastern Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1862, Philadelphia Acad. Nat. Sci. Proc., v. 13, p. 419, 424.

K. F. Mather, James Gilluly, and R. G. Lusk, 1928, U.S. Geol. Survey Bull. 796–B, p. 77, 86–92. Pierre shale, in northeastern Colorado, includes (ascending) Hygiene sandstone, Terry sandstone, Rocky Ridge sandstone, Larimer sandstone, and Richard sandstone members and unnamed higher beds. Thickness 4,500 to 10,000 feet. Overlies Niobrara formation; underlies Fox Hills sandstone.

W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A, p. 3–4. Pierre shale, in Black Hills area, includes (ascending) Gammon ferruginous member with Groat sandstone bed, Mitten black shale member, unnamed mudstone and shale, Monument Hill bentonitic member, and unnamed dark-gray fissile shale and mudstone. Overlies Niobrara formation; underlies Fox Hills sandstone.

M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7. Pierre shale, in northwestern Kansas, includes (ascending) Sharon Springs, Weskan, Lake Creek, Salt Grass, and Beecher Island members. Overlies Niobrara chalk.

C. S. Lavington, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 4, p. 399. Pierre shale, in eastern Colorado, contains Apache sandstone in basal part.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 5–63. Pierre formation, in region along Missouri River, divided into (ascending) Gregory, Sully, Virgin Creek, Mobridge, and Elk Butte members (all new). Thickness 361 to 1,204 feet. Overlies Niobrara formation; underlies Fox Hills formation.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2337–2346. Pierre shale, as herein revised for central South Dakota, comprises (ascending) Sharon Springs, Gregory, Crow Creek, DeGrey (new), Verendrye, Virgin Creek, Mobridge, and Elk Butte.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 22–23. Pierre shale, northwestern Kansas, is 1,000 to 1,400 feet thick. Includes the following members (ascending): Sharon Springs shale, 155 feet; Weskan shale, 170 feet; Lake Creek shale; Salt Grass shale; unnamed shale; and Beecher Island shale. Overlies Niobrara formation.

S. P. Fisher, 1952, North Dakota Geol. Survey Bull. 26, p. 8–10. Oldest formation exposed in Emmons County. Most of unit belongs to Elk Butte member although some Mobridge may be present. Thickness 135 feet. Underlies Fox Hills formation.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 109. Underlies Sanborn formation at type section of Sanborn.

G. C. Prescott, Jr., 1953, Kansas Geol. Survey Bull. 100, p. 53–54. In Cheyenne County where it is poorly exposed and is oldest outcropping in formation, the Pierre underlies Ogallala formation.

G. H. Wood, Jr., S. A. Northrop, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–141. Described in eastern Colfax County, N. Mex., where it is 1,600 to 1,700 feet thick. Overlies Smoky Hill marl member of Niobrara formation. Interfingers with overlying Trinidad sandstone.

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–146. In La Veta area, Huerfano County, Colo., the Pierre shale is about 2,000 feet thick. A 10-foot bed of sandstone that forms ledge about 500 feet above base of Pierre is exposed on western flank of Greenhorn anticline. This sandstone may be Apache sandstone of Prommel (Lavington, 1933). Overlies Smoky Hill marl member of Niobrara formation; underlies Trinidad sandstone.

C. S. Robinson, W. J. Mapel, and W. A. Cobban, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 101–123. Marine Pierre shale, on northern and western flanks of Black Hills, consists of dark-gray shale with some sandy shale and sandstone, and many beds of bentonite. Thickness 2,000 to 2,700 feet. In this area, divided into several members on basis of lithologic differences in the shale and presence of sandy and bentonitic units. These are (ascending) Gammon ferruginous member (including Groat sandstone bed), Mitten black shale member, an unnamed upper part that consists of half or more of formation, and near top Monument Hill and Kara bentonitic (new) members. Overlies Niobrara formation; underlies Fox Hills sandstone.

Named for exposures at old Fort Pierre, in either Stanley or Hughes County, S. Dak.

Pierson Glauconite

*See* Pearson Glauconite Member (of Sabinetown Formation).

Pierson Limestone[1] (in St. Joe Group)

Pierson Limestone Member (of Chouteau Formation)

Mississippian (Osage): Southwestern Missouri.

Original reference: S. Weller, 1901, Jour. Geology, v. 9, p. 140, 144.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 193. Rank reduced to member of Chouteau formation. Overlies Northview member;

underlies Reeds Spring member. Maximum thickness about 30 feet. Cannot be distinguished from rest of Chouteau north of Greene County; continues at least as far as Barry County. Lower Mississippian.

C. P. Kaiser, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2157–2160. Recommended that term Pierson be dropped as a synonym of St. Joe; both St. Joe and Pierson occupy same stratigraphic position; fauna of both formations are identical.

T. R. Beveridge and E. L. Clark, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 71, 72 (fig. 1), 75, 76. Uppermost formation in St. Joe group. Overlies Northview formation. Kinderhookian-Osagean line is defined as contact between Northview and Pierson. Pierson is extended northward to include silty dolomitic limestone unit which lies between Northview and Burlington in west-central Missouri. This unit was included in Sedalia by Moore (1928) and Kaiser (1950). In Greene County, Northview is included in Chouteau group. Note on type area.

Type area: North side of county road D in NE¼SW¼SW¼ sec. 29, T. 29 N., R. 20 W., near Turner Station, Greene County. Named from exposures on Pierson Creek.

Pierson Point Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 80.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 42. "Pierson Point" shale, as defined by Condra (1927), includes at its type locality the section between Dover and Tarkio limestones and not from Maple Hill limestone as was originally supposed. This makes it part of "Table Creek shale;" however, Maple Hill limestone is missing at "Pierson Point" type locality leaving the latter without an upper boundary marker, but the Maple Hill is well developed at other places. Name "Pierson Point" is dropped, and name Wamego (new) applied to shale between Maple Hill and Tarkio limestones.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 15. Reference made to Pierson Point shale by Condra and Reed (1943) is in error and name is retained because recent excavation at type locality exposes full thickness of the member, about 9 feet. Thickness in Missouri 3 to 4 feet.

H. G. O'Connor, 1953, Kansas Geol. Survey [Repts.], v. 12, pt. 1, p. 18–19, pl. 1. In eastern Kansas, name Stormont limestone member (new) is applied to lowest of three limestones occurring near middle of Pierson Point. The Stormont at its type locality occurs about 12 feet below Maple Hill limestone and 13½ feet above Tarkio limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12. In N½SE¼SW¼ sec. 36, T. 70 N., R. 43 W., Fremont County, beds are exposed which are here tentatively correlated with part of Table Creek-Willard shale interval. At top of section, 3½ feet of blocky green shale is identified as basal part of Pierson Point shale. Overlies Tarkio limestone.

Type locality: Pierson's Point, a spur of upland about 2 miles southeast of Falls City, Richardson County, Nebr. Well exposed on east flank of Pony Creek near Pony Creek Bridge, 1½ miles south of Falls City.

Cotype locality: Upland 4 miles west of Wamego, Kans.

**Pigeon Slate**[1] **or Siltstone** (in Snowbird Group)

Precambrian (Ocoee Series): Eastern Tennessee and western North Carolina.

Original reference: A. Keith, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 2.

P. B. King, 1949, Am. Jour. Sci., v. 247, no. 8, p. 639–640. Term Pigeon siltstone used in this report (base of the Cambrian in southern Appalachian). Name derived from same type locality as Pigeon slate of Keith's early work.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 956–957. Pigeon siltstone included in Snowbird group (herein rank raised). Thickness at designated type locality 10,000 to 15,000 feet. Consists of uniform body of gray to greenish-gray thin- to thick-bedded siltstone, composed of recrystallized quartz and feldspar silt in a matrix altered to sericite and chlorite. Siltstone is well exposed along Pigeon River northwest of Waterville; it is not represented in Snowbird group farther south, where it disappears by intertonguing with Roaring Fork sandstone (new). Contact with Roaring Fork is placed at top of highest persistent sandstone bed at any locality, but sandstones finger out westward so that the base of the Pigeon as thus defined descends in this direction. At east end of mountains, the Pigeon is overlain conformably by Rich Butt sandstone (new) and other unclassified formations.

Type section (siltstone): Along Little Pigeon River between Richardson Cove and Pittman Center, Sevier County, Tenn. Pigeon slate was named for exposures near West Fork of Little Pigeon River, Sevier County.

**Pigeon Point Formation**

Upper Cretaceous: Northern California.

C. A. Hall, Jr., D. L. Jones, and S. A. Brooks, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2855–2859. Dominantly brown and greenish-gray sandstone interbedded with siltstone, mudstone, and conglomerate; convoluted bedding and sole markings common. Estimated thickness more than 8,500 feet; base not exposed. Formation is both faulted against and unconformably overlain by Vaqueros(?) and Purisima formations of Tertiary age. Sedimentary rocks of Cretaceous age exposed along Pacific Coast south of Pesadero Point were originally assigned to the Chico formation by Branner, Arnold, and Newsom (1909, U.S. Geol. Survey Geol. Atlas Folio 163). However, application of this term to beds lithologically different, located nearly 200 miles from type locality of Chico, is unwarranted in absence of established continuity between the two sections; hence, new name is proposed.

Type section: All rocks exposed in sea cliffs from Pescadero Point to midway between Franklin Point and Ano Nuevo Point, or between lat 37°07′45″ N. and long 122°20′ and 122°25′ W. Named from prominent headland on Pacific Coast, approximately 5 miles south of town of Pescadero, San Mateo County. Rocks crop out in a belt a little less than 2 miles wide.

**Piinaau Basalt** (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 95 (table), 96. Dense dark-gray nonporphyritic basalt.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 126. Pleistocene(?)

Named for exposures along banks of Piinaau Stream. Flow followed gulch cut into older alluvium along foot of west wall of Keanae Valley, and at sea spread out to form terrace on each side of gulch.

**Pike Gravel** (in Trinity Group)

Pike Gravel Member (of Trinity Formation)[1]

Lower Cretaceous (Comanche Series) : Southwestern Arkansas.

Original reference: H. D. Miser and A. H. Purdue, 1918, U.S. Geol. Survey Bull. 690–B.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Pike gravel, basal formation in Trinity group in Arkansas. Underlies Delight sand (new). Subsurface equivalents discussed.

Named for Pike, Pike County.

**Pike Creek Volcanic Series**[1]

Pliocene, lower : Southeastern Oregon.

Original reference: R. E. Fuller, 1931, Washington [State] Univ. Pub. in Geology, v. 3, no. 1, p. 7–130.

Howel Williams and R. R. Compton, 1953, U.S. Geol. Survey Bull. 995–B, p. 24 (table), 25–27, pls. 8, 9. Rhyolitic and dacitic flows and tuffs. Thickness more than 1,500 feet. Overlies Alvord Creek formation; unconformably underlies basalts and lavas and Steens Mountain volcanic series. Early Pliocene. In addition to exposures at type locality, unit here considered to include siliceous volcanic rocks that crop out west of Alvord Lake, on Red Hill, along Cottonwood Creek, and at Tumtum Point.

Type locality : West of Alvord Desert, Harney County.

Pike River Granite[1]

Precambrian : Wisconsin.

Original reference: C. C. Wang, 1932, Geol. Soc. China Bull., v. 11, no. 4, p. 426–428.

**Pikes Peak Granite**[1]

Pikes Peak Group

Precambrian : Eastern Colorado.

Original reference : W. Cross, 1894, U.S. Geol. Survey Geol. Atlas, Folio 7.

J. M. Bray, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 769–770. In this report, Pikes Peak group (Algonkian) includes (ascending) Boulder Creek granite and Overland Mountain granite (new).

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 7–8. Granite described in Garfield quadrangle where it is cut by a granite referred to as Silver Plume(?).

Forms main mass of Pikes Peak.

Piketon Gravel[1]

Tertiary : Southeastern Missouri.

Original reference: C. F. Marbut, 1902, Missouri Univ. Studies, v. 1, no. 3, p. 18, 27, 32.

Named for exposures at Piketon, Stoddard County.

Pikian series[1]

Precambrian : Colorado.

Original reference : C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 281, 284.

Pilar Phyllite Member (of Ortega Formation)

Precambrian : Central northern New Mexico.

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 8 (fig. 2), 19–21, pl. 1. Name proposed to replace Hondo slate because the latter name had been applied to other rocks prior to Just's usage. The rock is dense, homogeneous, and hard, and is gray-black to black in color, with a gray sheen on cleavage surfaces. Has irregular slaty cleavage. Minimum thickness appears to be 2,300 feet in Picuris Range. Overlies Rinconada schist member and underlies Vadito formation.

Name derived from village of Pilar, situated at north-central border of Picuris Range at a point several miles east and north of prominent outcrops of the phyllite. Occurs in two main east-west belts of half a mile width that extend from upper Hondo Canyon to Piedra Lumbre Canyon, and thence offset to the south to continue as a single, westward tapering belt; Picuris Range, Taos County.

Pilarcitos Sandstone (in Franciscan Group)[1]

Jurassic(?) : Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416 (table).

Along Pilarcitos Creek and Pilarcitos Lake, in San Mateo County.

**Pilcher Quartzite** (in Missoula Group)

Precambrian (Belt Series) : Western Montana.

W. H. Nelson and J. P. Dobell, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–296. Reddish quartzite with strongly accentuated crossbedding. Overlies Garnet Range quartzite.

Mapped in Bonner quadrangle. Type locality and derivation of name not given.

**Pilchuck Clay Member** (of Vashon Drift)

Pleistocene : Northwestern Washington.

R. C. Newcomb, 1952, U.S. Geol. Survey Water-Supply Paper 1135, p. 18–19, pl. 1. Largely an advance outwash deposit, characteristically fine-grained; some sediments are dirty sands and gravels with thick clay beds and peat streaks; some clays are massive and yellow and nearly white in color. In some areas, overlies Admiralty clay (new).

Exposed in scattered areas in western part of Snohomish County.

**Pilgrim Limestone**[1] or **Dolomite**

Upper Cambrian : Montana.

Original references: W. H. Weed, 1899, U.S. Geol. Atlas, Folio 55; Folio 56; 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 284–287.

Charles Deiss, 1936, Geol. Soc. America Bull., v. 47, no. 8, p. 1280–1281, 1333–1335. Weed's definition emended. Pilgrim is basal formation of Upper Cambrian in Montana and Yellowstone Park. Overlies Park shale (emended); underlies Dry Creek shale (emended). At emended type locality herein designated, consists of thick- and thin-bedded light- and dark-gray crystalline to fine-grained irregularly bedded limestones; variable amounts of tan and buff clay irregularly disseminated; interbedded limestones are 2- to 20-inch beds of hard gray crystalline intraformational conglomerates whose flat pebbles consist of gray-green, tan, and maroon, argillaceous lithographic limestone. Lower part of formation in north-central Montana contains more shale than upper and middle parts; in western and southern part of State, lower-middle and upper parts of formation consists of massive thick-bedded hard finely crystalline dark-gray limestone, which is oolitic and mottled drab tan or buff. Thicknesses: 315 feet, type locality; 661 feet, Big Snowy Mountains; 175 feet, Big Belt Mountains; 172 feet, Crowfoot Ridge, Yellowstone Park. Lower part of Pilgrim in north-central Montana contains more shale than upper and middle parts and also more than in western and southern parts of State and in Yellowstone Park. In latter areas, the lower-middle and upper parts of Pilgrim consist of massive thick-bedded hard finely crystalline dark-gray limestone, which is oolitic and mottled drab tan or buff. These are the beds Peale (1893, U.S. Geol. Survey Bull. 110) called "Mottled limestones" in Gallatin formation in his Three Forks section. [See Flathead quartzite.]

Erling Dorf and Christina Lochman, 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 551. Unit termed Pilgrim by Deiss (1936) in Crowfoot Ridge section is the Maurice formation (new).

Christina Lochman and Donald Duncan, 1944, Geol. Soc. America Spec. Paper 54, p. 2–3, 4 (fig. 1), 6–9. Dry Creek-Pilgrim boundary discussed. Dry Creek shale partly emended by restricting all limestone pebble conglomerates and gray-green shales to the Pilgrim formation. This restriction gives lithologic unity to both Dry Creek and Pilgrim in all sections and restricts the fossil horizons to the Pilgrim. Park-Pilgrim contact is boundary between Middle and Upper Cambrian.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 16–17. As used in this report, the Pilgrim is a carbonate unit, essentially Dresbachian in age, underlain by Park shale and overlain by Red Lion or Snowy Range formation. Locally, where post-Cambrian erosion has removed Red Lion, the Pilgrim may be directly overlain by Maywood formation. Consists of four rock types: limestone conglomerate; crystalline limestone; oolitic limestone, some of which has distinctive mottling; and dolomite. Lochman and Duncan draw Park-Pilgrim boundary to coincide with Middle-Upper Cambrian time boundary; in present report, the boundary is drawn to conform with lithologic change from shale to limestone; the boundary thus drawn differs from late Middle Cambrian to early Upper Cambrian. Term Maurice has been used for Pilgrim equivalent, but distinction between the two is presence of mottled oolitic limestone in the Maurice. Name Maurice considered unnecessary.

P. W. Richards, 1957, U.S. Geol. Survey Bull. 1021–L, p. 397, 398–399. Described in area east and southeast of Livingston, Mont., where it is 175 feet thick and crops out as first cliff-forming unit above Precambrian rocks. Underlies Snowy Range formation. Name used in preference to Maurice in this area.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 10–12, pls. 1, 2, 3. Five lowest Cambrian natural map units in southern Elkhorn Mountains are lithologically similar to Flathead sandstone, Wolsey shale, Meagher limestone, Park shale, and Pilgrim dolomite of nearby areas as redefined by Deiss (1936) and these formational names have been adopted. Pilgrim dolomite is 380 to 510 feet thick. Threefold subdivision recognized. Lower unit, typically about 50 feet, is principally mottled light-gray and dark-gray crystalline dolomite. Middle unit, typically about 175 feet, is light-gray and medium-gray crystalline limestone with irregular ribbons of yellowish-gray silty dolomite. Upper unit, 150 to 225 feet thick, is light-gray medium-crystalline to sugary dolomite that weathers to rough cuspate surface; beds typically between 6 inches and 4 feet but rather indistinct. Underlies Maywood or Red Lion formation. Upper Cambrian.

Type locality (emended section): North side Dry Wolf Creek, Little Belt Mountains. Section measured on spur east of eastern small unnamed creek, which heads on Big Baldy Mountain, and on Dry Wolf Creek. Locality lies in sec. 14, T. 14 N., R. 9 E. Section begins at point 350 feet up the small stream from its mouth at Dry Wolf Creek, 2 miles west of mouth of Lion Gulch. Section was not measured opposite Lion Gulch where Weed said he measured his section because at that place Cambrian rocks are largely covered with glacial drift and lower beds of emended section are beneath floor of that part of Dry Wolf Creek valley. Named for exposures in valley of Pilgrim Creek, southwestern corner Fort Benton quadrangle.

Piliguilla Conglomerate

Pliocene(?): Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no. 29, p. 134 (correlation chart), pl. 10 (map). Name appears on correlation table. Overlies Chucunaque formation. Pliocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 343. Undefined name. Pliocene(?).

In Darién area.

**Pillar Bluff Limestone**

Lower Devonian: Central Texas.

V. E. Barnes, P. E. Cloud, Jr., and L. E. Warren, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 166–169 [1945]. Proposed for calcitic rocks carrying a fauna of Helderberg age. Predominantly of two types: One a fine- to coarse-grained yellowish-gray to ivory-colored fairly pure highly fossiliferous limestone; the second type of limestone is fine to very fine grained, gray, dull yellow, or olive drab, ranging to gold and light bronze with roan splotches; slightly dolomitic, few or no fossils. Finer grained limestone occurs below the more coarsely granular coquinalike limestone. Because of manner in which Pillar Bluff is preserved, no estimation of thickness is practical.

Type locality: Ancient joint or cave filling at Pillar Bluff on Pillar Bluff Creek, 5 miles southwest of Lampasas and just south of Lampasas County line in northern Burnet County. This pocket of Lower Devonian rocks, replete with fossils, is surrounded by limestone and dolomite of Ellenburger group (Lower Ordovician) of the *Ceratopea* "*keithi*" zone. Lies 30 feet vertically below lower margin of covering debris which conceals overlap of Carboniferous strata on the Ellenburger.

†Pillar Falls Mud Flow[1]

Miocene, upper(?): Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 32, 38–39, pl. 5. Thickness about 40 feet. Rests on eroded surface of Shoshone Falls andesite.

H. T. Stearns, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 463. Suggested that the Pillar Falls mud flow represents the typical block lava top of the underlying Shoshone Falls andesite.

Type section: At Pillar Falls on Snake River, in Jerome and Twin Falls Counties.

**Pillsbury Shale** (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Northeastern Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275–2276. Defined to include strata between Stotler limestone (new) above and Zeandale limestone (new) below. Replaces Langdon shale of Condra and Reed (1943). Thickness ranges from about 1 foot to 50 feet; average thickness 25 feet.

Type exposure: In roadcut in SE¼NE¼NE¼ sec. 28, T. 10 S., R. 9 E., Riley County. Name derived from Pillsbury Crossing, a ford across Deep Creek in NE¼NW¼ sec. 5, T. 11 S., R. 9 E., Riley County. Sections typical of facies changes of formation, designated as paratype sections, are exposed in stream bank in center of SW¼NE¼ sec. 32, T. 10 S., R. 9 E., Riley County, and in NE¼NE¼ sec. 19, T. 11 S., R. 13 E., Wabaunsee County.

Piloncillo Formation

Tertiary: Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 10–11, 17 (table 1), pl. 1. Sediments occur as small alluvial fans, windblown tuffaceous dune sands, tuffs, and stream-channel sandstones and conglomerates. At type locality, tuffaceous and fluvial sediments reach maximum thickness of 400 feet in a buried valley. Elsewhere formation is either absent or much thinner. All clastic sediments of similar age and lithology in Dwyer quadrangle have been mapped as Piloncillo, even where their outcrops are not continuous with the type locality.

Type locality: Given in text as Piloncillo Hill, after which the sediments were named, in sec. 18, T. 18 S., R. 10 W., Dwyer quadrangle. Shown on plate 1 as sec. 18, T. 19 S., R. 10 W.

Pilot Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 195. Cherokee group is divided into 15 cyclic formational units. The Pilot, seventh in the sequence (ascending), occurs below the Scammon and above the Weir. Includes Pilot coal. [For complete sequence see Cherokee group.]

Type locality and derivation of name not given. Cherokee outcrop in Kansas covers an area of about 1,000 square miles and includes parts of Labette, Bourbon, Crawford, and Cherokee Counties.

**Pilot Shale**[1]

Pilot Shale Member (of White Pine Shale)

Upper Devonian and Lower Mississippian: Eastern Nevada and Utah.

Original reference: A. C. Spencer, 1917, U.S. Geol. Survey Prof. Paper 96, p. 24, 26, map.

G. S. Campbell, 1951, Utah Geol. Soc. Guidebook 6, p. 22. Geographically extended into Confusion Range, Millard County, Utah, where it is from 900 to 1,200 feet thick and consists of buff papery shales interbedded with thin black platy limestone. Overlies Guilmette formation; underlies Joana (Joanna) limestone. Upper Devonian.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2), 149. Rank reduced to member status in White Pine shale. Basal member of formation; underlies Joana member.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 52–53. Described east of Eureka where there are four narrow bands of outcrop. Where exposures are good, two units can be distinguished. Lower one, which makes up one-third or more of formation, is more calcareous, and some of the beds are thin-bedded shaly limestones rather than platy calcareous shales; commonly pinkish or reddish; sandy limestone contains conodont fauna. Upper unit is lithologically more uniform; it is yellowish-brown- or dark-gray-weathering black platy shale, which in most places is calcareous. Thickness ranges from about 315 feet in Packer Basin to 425 feet in Water Canyon; poorly exposed section in Pancake Range is approximately 1,000 feet; it is probable that formation has localized fault movement within it that may account for variations in thickness. Overlies Devils Gate limestone; underlies Joana limestone; both contacts sharp. Faunal evidence indicates Late Devonian age; stratigraphic relations suggest that beds of early Mississippian age are also present in upper part of formation. Pilot shale is basal part of White Pine shale as defined by Hague (1892, U.S. Geol. Survey Mon. 20) at Eureka.

R. L. Langenheim, Jr., 1960, Illinois Acad. Sci. Trans., v. 53, nos. 3, 4, p. 122–131. Discussion of Pilot shale, West Range limestone, and Devonian-Mississippian boundary in eastern Nevada. At reference section, herein designated, Pilot shale consists of upper unit of 190 feet of nonfossiliferous black fissile shale and a lower unit, 193.1 feet thick, of black calcareous siltstone with interbedded silty limestone and minor amounts of fine-grained gray limestone. Overlies Guilmette limestone, contact sharp; underlies Joana limestone, contact sharp. The 383.1 feet of Pilot shale at reference section are comparable to the 350 feet of covered rock assigned to Pilot shale just north of Pilot Knob. It is assumed that the members present at Willow are also present at Pilot Knob and underlie the bench between Joana limestone and Guilmette on west side of Ward Mountain as mapped by Langenheim and others (1959). At type locality of West Range limestone, 32 feet of lower Pilot shale overlies the West Range. At this locality, the lower Pilot is disconformably overlain by Bristol Pass (Joana) limestone.

Reference section: Exposure south-southwest of triangulation station "Willow," sec. 6, T. 13 N., R. 63 E., on west flank of Egan Range about 2 miles north of south boundary of Ely No. 3 quadrangle. Named for Pilot Knob in western part of Ely quadrangle, Nevada.

Pilot Creek Basalt Member (of Cove Mountain Formation)

Tertiary : Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1). Thickness 0 to 400 feet. Underlies Cedar Spring member (new) ; overlies Racer Canyon tuff member (new).

Occurs in Washington County.

Pilot Knob conglomerate[1]

Upper Cambrian : Southeastern Missouri.

Original reference : C. R. Keyes, 1894, Missouri Geol. Survey, v. 4, p. 30, 31.

Occurs on Pilot Knob, Iron County.

Pilot Knob facies (of Brodhead Formation)

Lower Mississippian : Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 146–148. Consists mainly of shale and siltstone. Average thickness approximately 200 feet. Comprises, in lower part, Culver Springs shale below and Lebanon Junction siltstone members (both new) of Brodhead formation. Merges with Holtsclaw Hill facies (new) on west and Athertonville facies (new) on east. Underlies Floyds Knob formation; overlies New Providence formation, Keith Knob facies (new).

Named for Pilot Knob, 4½ miles northeast of Lebanon Junction, southern Bullitt County. Pilot Knob is one of many "knobs" characteristic of region.

Pilot Knob Formation[1]

Precambrian : Southeastern Missouri.

Original references : E. R. Buckley, 1908, Am. Min. Cong. Rept. Proc. 10th Ann. Sess., p. 286; 1909, Missouri Bur. Geology and Mines, 2d ser., v. 9, pt. 1, p. 15–17.

Pilot Knob Iron Formation[1]

Precambrian : Southeastern Missouri.

Original reference : G. W. Crane, 1912, Missouri Bur. Geology and Mines, v. 10, 2d ser.

Pilot Knob Sandstone[1] Member (of Anderson Formation)

Pennsylvanian : Northern Tennessee.

Original reference : L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33–B, p. 23, 33, 319.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, pl. 4. Renamed Pilot Mountain sandstone because name Pilot Knob is preoccupied.

Occurs in Tennessee coal field in Briceville region.

Pilot Knob Tuff (in Dessau Formation)

Upper Cretaceous : South-central Texas.

C. O. Durham, Jr., 1955, Corpus Christi Geol. Soc. [Guidebook] Ann. Field Trip, Mar. 11–12, p. [58, 59], pl. 16. Tuff mentioned in discussion of Upper Cretaceous volcanics in Travis County. Stratigraphic section shows Pilot Knob ash in Dessau formation below St. Edwards tuff (new) in Burditt formation. Page [59] refers to Pilot Knob mudflows. [Durham refers to article published by him (1949, Shreveport Geol. Soc. Guidebook 17th Ann. Field Conf.) entitled "Stratigraphic relationships of the Pilot Knob volcanics." However, in copy of guidebook used by compiler title reads "Pilot Knob pyroclastics"].

Pilot Knob is 6 to 8 miles south-southwest of State Capitol, Austin, Travis County.

Pilot Mountain Andesite

Age not stated: Northern California.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, p. 77 (table 2). Listed on table accompanying report on uranium geochemistry of Lassen volcanic rocks.

Pilot Mountain is in southeastern part of Lassen Volcanic National Park.

Pilot Mountain Sandstone (in Vowell Mountain Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, 19, pls. 2, 3, 4. New name for Pilot Knob sandstone (Glenn, 1925). Name Pilot Knob preoccupied. Thickness at designated type locality 60 feet; in Cross Mountain section 35 feet. Overlies a shale interval about 100 feet thick at base of group and underlies shale interval 35 to 90 feet thick which in turn underlies Frozen Head sandstone.

Type locality: Pilot Mountain in Duncan Flats quadrangle. Also well developed in Petros, Windrock, Fork Mountain, Lake City, Norma, and Block quadrangles.

Pima Sandstone[1] or Formation

Middle Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 466, 482.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1 (column 41). Listed as formation.

Traced from Whetstone Mountains, Cochise County to Picacho de Calera Hills, Pima County.

Pimoe Flow

Recent: Maui Island, Hawaii.

Grote Reber, 1959, Geol. Soc. America Bull., v. 70, no. 9, p. 1246, 1247, pl. 1 (fig. 4). May have been extruded during earthquake in 1938. Radiocarbon dating gives $<$ 100 years.

On southwest side of Haleakala.

Pimple Hill Conglomerate[1] (in Cherry Ridge Red Beds)

Upper Devonian: Northeastern Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 571, 578.

Bradford Willard *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 279 (table 30), 284. Upper Devonian.

Named for Pimple Hill, a knob in Monroe County.

**Pinal Schist**[1]

Precambrian : Southeastern Arizona.

Original reference : F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. Mapped in Globe quadrangle. Early Precambrian.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8–9 (table), 10–11, pl. 5. Described in central Cochise County where it is oldest formation exposed. Contains several small intrusive masses of albite granite, quartz diorite, gneissic granite, and sausuritic quartz monzonite which are also referred to the Precambrian. Base on which the Pinal was deposited not exposed in area; hence, no reliable estimate of thickness possible. Underlies Bolsa quartzite. In areas of intense metamorphism, distinguished with difficulty from metamorphosed Bisbee formation.

F. F. Sabins, Jr., 1957, Geol. Soc. America Bull., v. 68, no. 10, p. 1320–1322, table 1, pl. 1, Several rock types included in Pinal schist in Cochise Head and Vanar quadrangles. Unnamed quartzite member, of light-pink to light-gray medium- to coarse-grained quartzite, is most conspicuous unit for it forms rugged precipice of Bowie Mountain and ridge southwest of Helens Dome. Underlies Bolsa quartzite.

D. W. Peterson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–128. Mapped in Haunted Canyon quadrangle. Probably intruded by Ruin granite but contacts not exposed in quadrangle.

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 113. In fault contact with Samaniego granite (new).

Rocks well exposed in Pinal Mountains, whence their name.

Pina Vititos sandstone[1]

Upper Cretaceous : New Mexico.

Original reference. C. R. Keyes, Conspectus of geologic formations of New Mexico : Des Moines, Robert Henderson, State Printer, p. 2, 10.

Around southern end of the Rocky Mountains. Derivation of name not stated.

**Pinckneyville Granite**[1]

Pinckneyville Quartz Diorite Complex

Post-Carboniferous : Eastern Alabama.

Original references : W. F. Purdy, 1922, Elisha Mitchell Sci. Soc. Jour., v. 38, p. 16; 1922, Alabama Geol. Survey map of Clay County; 1923, Alabama Geol. Survey County Rept. 1, p. 51–62.

H. R. Gault, 1945, Geol. Soc. America Bull., v. 56, no. 2, p. 181–246. Quartz diorite complex, originally described as granite, is one of largest intrusions in Alabama. Underlies area extending from Coosa River in northwest Elmore County northeast through Coosa and Tallapoosa Counties into Clay County. Dark-gray coarse-grained quartz diorite gneiss constitutes major part of complex; smaller amounts of granodiorite and granite gneiss. Intrudes Ashland mica schist and Wedowee formation. Age uncertain.

Named for occurrence in vicinity of Pinckneyville, Clay County.

Pine Sand

Pleistocene, upper: Eastern North Carolina.

W. B. Wells, 1944, Elisha Mitchell Sci. Soc. Jour., v. 60, no. 2, p. 131–132, pls. 63, 64. Vertical cliff exposes four layers (or horizons) which show progressively decreasing consolidation upward; each lies unconformably on the preceding. Maximum thickness of exposure a little more than 9 feet. Pine sand is a poorly consolidated stratum of highly variable thickness; thin superficial peaty medium-sand deposits in upper zone. Underlies Galveston sand (new); overlies Castalia sand (new).

Exposed between Kure's Beach fishing pier and Ethyl Dow Bromine Plant on lower Cape Fear Peninsula.

**Pine Sandstone Member** (of Pottsville Formation)[1]

Lower Pennsylvanian: Central Alabama.

Original reference: Charles Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175, p. 10.

H. E. Rothrock, 1949, Alabama Geol. Survey Bull. 61, pt. 1, p. 22, fig. 2. Shown on columnar section (St. Clair County) as light-gray to light-brown friable conglomeratic sandstone 210 to 250 feet thick; in lower part of formation, stratigraphically above Shades sandstone member and separated from it by 200 to 230 feet of claystone, siltstone, and sandstone; underlies about 2,800 feet of sandstone, siltstone, and carbonaceous claystone with thin coaly beds.

Named for Pine Ridge, Jefferson County.

Pinean series[1]

Devonian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 55, 80.

Eureka district.

†Pine Barren beds[1]

Name applied in some early Alabama reports to the basal Eocene beds now known as Clayton formation, which are "best seen in eastern Wilcox County, on Pine Barren Creek and in adjoining part of Butler County in Little Texas region."

Statement above appeared in the Wilmarth lexicon. The compiler of present report searched several early Alabama publications but failed to find any reference that used the expression "Pine Barren beds." There were references to a "Pine Barren section" and "section on Pine Barren Creek." Therefore, it is believed that MacNeil's (1946) Pine Barren Member (see below) is the first formal usage of the term Pine Barren.

**Pine Barren Member** (of Clayton Formation)

Paleocene: Southwestern Alabama.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 8–9. Proposed for lower member of Clayton. Hard crystalline fossiliferous coarse sandy limestone ["*Turritella* rock"] about 8 feet thick forms upper part of member; below this is sequence of limestone, sandy clay shale, and loose to moderately porous to tight fine-grained calcareous sand; beds of crystalline *Turritella*-bearing limestone occur at several levels in these lower beds; coarse-grained sandy channel limestone or calcareous sand occurs sporadically at base. Maximum thickness about 175 feet. Underlies McBryde limestone member (new).

Type locality: In roadcuts and ditches on south side of Pine Barren Creek, along State Highway 100, from southern junction with State Highway 11 to bed of creek at McConnicos Mill in SE¼ sec. 21, T. 12 N., R. 10 E., Wilcox County.

Pine Bluff Member (of Lewisville Formation)

Pine Bluff volcanic zone (in Eagleford Formation)

Cretaceous: Northeastern Texas.

R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 138, 139–143. Lower most of three volcanic zones in the Medill-Woodland area. At Pine Bluff locality, zone is represented by 37 feet of tuffaceous sand which is characterized by the development of large concretionary masses, spherical to flattened ellipsoidal in shape; this persistent concretionary zone referred to as "Cannon Ball" zone. Westward from Pine Bluff, a clay shale-tuffaceous sand wedge breaks "Cannon Ball" zone into an upper and a lower "Cannon Ball" zone. Separated from overlying Kanawha volcanic zone by a shale interval that varies from 158 to 212 feet in thickness; overlies a shale and tuffaceous sand above the base of the Eagleford.

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945, Reference Rept., v. 2, p. 475, 476, 477. Reallocated to basal member of Lewisville formation. Unconformably overlies Euless formation.

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 242, p. 4. Locally abandoned; as used in this report, the so-called Pine Bluff member is a part of the Lewisville member of the Woodbine formation.

First described in Medill-Woodland area where it is well exposed at Pine Bluff, Red River County.

†Pine Canyon Limestone[1]

Mississippian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 18. Term Pine Canyon abandoned in favor of Deseret limestone, the more widely accepted stratigraphic name. Loughlin (1919) locally included within boundaries of Pine Canyon the upper cherty member of Gardner dolomite which is upper unit of upper member of Madison limestone of this report [East Tintic Mountains].

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 38 (fig. 5), 40, 43–45. In Stansbury Mountains, subdivided into three units: lower and upper cherty limestone and a medial sandstone, siltstone, and argillaceous limestone unit. Lower cherty unit was placed in Madison group by Morris (1957). Thickness 170 to 950 feet. Unconformably overlies Gardner dolomite; underlies Humbug formation. Name Pine Canyon is used in preference to Deseret limestone as latter did not include the cherty beds.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 43–49, 158–161. Described in southern Oquirrh Mountains where it consists of a lower member, chiefly limestone, 258 feet thick, and an upper member, chiefly limestone with shale, 378 feet thick. Some of upper strata of what Gilluly (1932, U.S. Geol. Survey Prof. Paper 173) mapped as Madison limestone are included in lower member of Pine Canyon limestone of this report. A prominent phosphatic shale is used as key bed in marking base of upper member. Gilluly (1932) placed this bed as basal unit of his Deseret limestone; Deseret is herein restricted. Overlies Gardner dolomite (used in this area in preference to Madison). In Fivemile Pass quadrangle and northern Boulter Mountains, Pine Canyon is 1,289 feet thick and includes both lower and upper members; uppermost beds of upper member may represent southerly extension of Deseret limestone. Underlies Humbug formation; overlies Gardner formation.

Named for exposures in Pine Canyon, between Godiva Mountain and Sioux Peak, Tintic district.

Pinecate Formation[1] (in San Lorenzo Group)

Oligocene: Southern California.

Original reference: P. F. Kerr and H. G. Schenck, 1925, Geol. Soc. America Bull., v. 36, p. 470, 472, map.

J. E. Allen, 1946, California Div. Mines Bull. 133, p. 18 (fig. 2), 27, pls. 1, 2, 3. Described in San Juan Bautista quadrangle. Upper formation of San Lorenzo group. Thickness about 1,000 feet. Underlies Vaqueros sandstone; overlies San Juan Bautista formation.

Typically exposed at Pinecate Peak, 4 miles northwest of San Juan, and also near San Juan Cement Works, San Benito County.

Pinecone Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 98 (fig. 4). Named on structure section in report on Paleozoic continental margin in central Nevada. Underlies Wildcat Peak formation (new).

Toquima Range, Nye County.

Pine Creek Conglomerate[1]

Cretaceous(?): Southeastern Iowa.

Original reference: J. A. Udden, 1899, Iowa Acad. Sci. Proc., v. 6, p. 54–56.

Leland Horberg, 1950, Illinois Acad. Sci. Trans., v. 43, p. 173. Incidental mention in report on correlation of preglacial gravels of Henry County, Ill., with gravels in other parts of Mississippi Valley region.

Named for Pine Creek, Muscatine County.

Pine Creek Limestone (in Conemaugh Group)

Pine Creek Limestone Member (of Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 32.

M. N. Shaffner, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 141. Pine Creek limestone in Conemaugh group, shown on generalized columnar section below Woods Run limestone and above Buffalo sandstone.

Named for Pine Creek, Allegheny County, Pa.

†Pine Creek Sandstone (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: J. P. Lesley, 1880, Pennsylvania 2d Geol. Survey Rept. $H_5$, p. xxi, 319.

Armstrong County.

Pinecrest Formation[1]

Lower Triassic: Central northern Utah.

Original reference: A. A. L. Mathews, 1929, Chicago Univ., Walker Mus. Mem., v. 1, no. 1, p. 1.

C. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 28. Thaynes formation, in Fort Douglas area east of Salt Lake, has been separated by Mathews on basis of fossil evidence, into Pinecrest and Emigration formations.

Named for Pinecrest Ridge, which lies between North and South Forks of Red Butte Creek in Fort Douglas area, east of Salt Lake City.

**Pinedale Glaciation, Drift, Till**

Pinedale glacial stage[1]

Pleistocene: Rocky Mountain region.

Original reference: E. Blackwelder, 1915, Jour. Geology, v. 23, p. 310, 324–340.

G. M. Richmond, 1953, Friends of the Pleistocene, Rocky Mountain Sec., [Guidebook] 2d Ann. Field Trip, Oct. 4–5, correlation chart. Pinedale stage comprises an early Pinedale substage, Pack Creek substage (new), and late Pinedale substage. Follows Lackey Creek stage (new) and precedes a Recent stage, the Castle Valley (new).

John de la Montagne, 1956, Wyoming Geol. Soc. Guidebook 11th Ann. Field Conf., p. 30. Glacial sequence in Jackson Hole area (ascending) Buffalo, Bull Lake, and Pinedale.

G. M. Richmond, 1957, Internat. Assoc. for Quaternary Research, 5th Cong., Madrid, p. 157. Pleistocene deposits in Rocky Mountain region are grouped into three stages: Buffalo (oldest), Bull Lake, and Pinedale, each with characteristic topographic expression and soil development. Pinedale stage consists of three substages whose moraines are youthful. Lower and middle substages, where superimposed, are separated by weak azonal soil. Upper substage (radiocarbon age slightly older than 6,170 240 years B. P.) probably represents subsidiary halt or minor readvance following the middle. Tills of all three substages, where not superimposed, have a moderately developed immature zonal soil, formed largely during post-glacial optimum.

G. M. Richmond, 1960, Geol. Soc. America Bull., v. 71, no. 9, p. 1371–1382. Discussion of glaciation of east slope of Rocky Mountain National Park, Colo. This area has been subjected to at least three Pleistocene glaciations, oldest to youngest correlated with Buffalo, Bull Lake, and Pinedale of Blackwelder (1915) in Wind River Mountains, Wyo. Deposits of Pinedale glaciation comprise three sets of moraines indicative of maximum advance of ice and two recessional halts or minor advances.

G. M. Richmond, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B223–B224. Discussion of correlation of alpine and continental glacial deposits of Glacier National Park and adjacent high plains, Montana. Deposits of two late Pleistocene alpine glaciations are correlated with Bull Lake and Pinedale glaciations of Wyoming. Pinedale glaciation consists of three advances separated by minor recessions. These are correlated with advances of classical Wisconsin glaciation of Illinois.

774–954—vol. 3—66——10

Named for moraines around lakes near Pinedale, on southwest side of Wind River Range, Wyo.

Pine Hill Quartzite[1]

Lower Cambrian: Southwestern Vermont.

Original reference: J. E. Wolff, 1891, Geol. Soc. America Bull., v. 2, p. 331–338.

Pine Hill is a short distance northwest of Rutland and a short distance southeast of Proctor, in Proctor Township, Rutland County.

Pine Hill Quartzite[1]

Silurian: Southeastern New York.

Original reference: E. C. Eckel, 1902, New York State Mus. 54th Ann. Rept., pt. 1, p. r144–r150.

Well developed in Pine Hill, east of Highland Mills, Orange County.

**Pine Island Shale**

**Pine Island Shale Member** (of Pearsall Formation)

Pine Island Formation

Pine Island Member (of Glen Rose Formation)

Lower Cretaceous (Comanche Series): Subsurface in Louisiana, Arkansas, and Texas.

George Weber, 1938, Oil and Gas Jour., v. 37, no. 4, p. 30. Pine Island member of Lower Glen Rose formation proposed by Shreveport Geological Society. Black and green shale, brown shale in lower part; limestone at base locally. Underlies Rodessa member; overlies Travis Peak formation.

A. F. Crider, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1665 (table 1), 1666–1667. Red, purple, and greenish shale, siltstone, and sand, with thin beds of calcareous shale and limestone, a part of which is fossiliferous, underlying lower Glen Rose, make up what is here called Pine Island formation. Has been called Travis Peak. In Bellevue Field, overlies Cotton Valley formation. Thickness 1,850 to 1,860 feet.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 32–33, cross sections. Pine Island formation was defined by Crider for beds here called Hosston. Pine Island was originally proposed by Shreveport Geological Society for beds above the Hosston (then called Travis Peak) and below James limestone lentil. The Society has further restricted Pine Island to dark shales with some interbedded limestone and sandstone lying above "Three Finger limestone" lentil and below James limestone member. Restricted Pine Island overlies Sligo formation (new); underlies Rodessa formation. Type section and boundaries of formation will be described by Nomenclature Committee of Shreveport Geological Society.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Lower member of Pearsall formation (new) in south Texas. Underlies Cow Creek member. Thickness about 100 feet. Occupies same stratigraphic position as Pine Island shale in Arkansas-Louisiana-east Texas area.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2340–2342. Herein defined as lowest member of Pearsall formation or its time-stratigraphic equivalent, including those rocks above top of Sligo formation and below base of James limestone member or its recognizable stratigraphic equivalents. Imlay (1940) published section which he termed Pine Island formation from Stanolind Oil and Gas Company's Dillon Heirs well No. 131, sec. 14, T. 21 N., R. 15 W. He selected top of Pine Island at 3,127 feet in this section. It is believed that in this well section called Pine Island formation by Imlay represents entire Pearsall formation. James limestone is not recognizable lithologic unit in this well. Imlay included in the Pine Island formation both the limestone and shale which are the time-stratigraphic equivalent of both the James limestone member and of the shale stratigraphically above James limestone member. James limestone member and lower part of Rodessa formation undergo facies change over Pine Island structure. They grade from characteristic lithologic type into black shale, dark calcareous shale, and thin beds of limestone. In Stanolind's Dillon Heirs well No. 1313, both lower Rodessa and James limestone member time-stratigraphic equivalents are lithologically similar to Pine Island shale member. Pine Island is not recognized beyond limits of either James or Cow Creek limestone members.

Type locality: Pine Island field, northwestern Louisiana. Formation completely penetrated in Dixie Oil Co.'s Dillon No. 92, sec. 13, T. 21 N., R. 15 W., Pine Island field, Caddo Parish, La., from a depth of 3,897 to 5,919 feet.

Pine Knob Sandstone

Lower Mississippian (Oil Lake) : Southwestern Pennsylvania.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Progress Rept. 126, p. 14–15. Name will probably be used following more definitive study of area for unit here termed Sandstone G and described as a sandstone and shale sequence. At type locality, unit is shaly at bottom, grading upward with slight unconformity into gray-brown sandstone. As a whole, it is thin bedded and indistinctly ripple marked. Thickness 35 to 75 feet; 42 feet at type locality. Disconformably underlies Sandstone H; conformably overlies Sandstone E (Linderman sandstone) or its equivalent, Conglomerate F (Hopwood conglomerate).

Type section: In highway cut at scenic lookout below Summit Hotel on Route 40 east of Hopwood, Fayette County.

**Pinelog Conglomerate**[1]

Lower Cambrian: Northwestern Georgia.

Original reference: L. LaForge, 1919, Georgia Geol. Survey Bull. 35, p. 40.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1383. Pinelog conglomerate of Bartow County is claimed by LaForge (1919) to be lower part of the Weisner quartzite, but the Pinelog appears to lie at base of Talladega series, where as the Weisner is the top of the Lower Cambrian arenaceous series.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 277. Basal conglomerate beds of Pine Log conglomerate of east end of Pine Log Mountain, which lies north of the Corbin granite and east of the fault [Cartersville] are derived from the Corbin granite and rest on that granite which is brought up in an anticline.

T. L. Kesler, 1950, U.S. Geol. Survey Prof. Paper 224, p. 9. For purposes of this report, Pinelog conglomerate is included in the Weisner formation.

First described in Cartersville district. Forms Pinelog, Pine, and eastern part of Brushy Knob and Signal Mountains.

Pine Mountain Complex[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1898, 1911–1913, pl. 1. Chief rock type is granite porphyry with abundant quartz phenocrysts; color varies, black, green, pink, and yellow. Porphyritic quartz syenite and granite occur locally. Composes an independent subsidiary stock; not part of main intrusion of Belknap Mountains. Assigned to White Mountain magma series, but age relative to other units in series unknown.

Occurs in Pine Mountain-Rocky Mountain area of Belknap Mountains.

Pine Mountain Formation[1]

Pine Mountain Group or Series

Precambrian(?): Central western Georgia.

Original reference: S. L. Galpin, 1915, Georgia Geol. Survey Bull. 30, p. 74–76.

G. W. Crickmay, 1935, *in* L. M. Prindle, Georgia Geol. Survey Bull. 46, p. 32. Pine Mountain series includes Hollis quartzite below and Manchester formation (new).

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 22–23. Discussion of crystalline rocks of Georgia. Rocks are grouped into 11 belts, in part using names proposed by Adams (1933, Jour. Geology, v. 41, no. 2). Pine Mountain series includes quartzites and schists of Pine and Oak Mountains in southwestern part of Wacoochee belt. Four formations recognized (ascending): Sparks schist, Hollis quartzite, Chewacla marble and Manchester schist. Chewacla marble (type locality Alabama) not known in Georgia. Adams believes that series is Paleozoic. It is here assigned to Precambrian.

J. W. Clarke, 1952, Georgia Geol. Survey Bull. 59, p. 6 (table). Referred to as Pine Mountain group. In Thomaston quadrangle, includes Hollis quartzite below and Manchester formation above. Overlies Woodland gneiss; underlies schist-gneiss migmatite. Precambrian(?).

Named for occurrence on Pine Mountain, from western part of Harris County to eastern part of Pike County.

†Pine Mountain Group (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: A. R. Crandall, 1889, Kentucky Geol. Survey Whitley County Rept.

Named for Pine Mountain.

Pine Mountain Porphyry

Precambrian: Central Arizona.

E. D. Wilson, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1129, 1139, pl. 11. Rhyolite porphyry which is typically a fine-grained porphyritic gray rock that weathers pale yellowish gray. Maximum width 1 mile. Occurs sparsely as dikes at various places in Yaeger greenstone and Alder series.

Prominent only in vicinity of Pine Mountain in central part of Mazatzal Mountains.

**Pine Nut Limestone Member** (of Gold Hill Formation)[1]

Cambrian: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

Exposed on Pine Nut claim, Manhattan district.

**Pine Plains Formation**

Upper Cambrian : Southeastern New York.

E. B. Knopf, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1212. Mainly dark impure dolomites; lower beds carry cryptozoon reefs, some edgewise conglomerate, and oolite. Thickness 1,300 feet. Occurs below Briarcliff dolomite (new) and above Stissing dolomite. Upper Cambrian.

E. B. Knopf, 1956, (abs.) Geol. Soc. America Bull., v. 67, pt. 2, p. 1817. Variable assemblage comprising dark, sandy, and argillaceous dolomites at three horizons with intervening heavier bedded and lighter colored dolomites accompanied by edgewise conglomerates, oolitic beds, and cryptozoon reefs. Upper (?) Cambrian.

J. D. Weaver, 1957, Geol. Soc. America Bull., v. 68, no. 6, p. 730–734, pl. 1. Described in Copake quadrangle as Pine Plains formation or group. Complete section not present in area, but group constitutes much of the carbonate belt. Presence of heterogeneous lithologies associated with much of the very dark-gray compact dolomite distinguishes it from other carbonate units. Thickness 406 feet to possibly as much as that given at type area. Upper Cambrian.

First described in Stissing Mountain area, Dutchess County.

**Pine Ridge Sandstone Member** (of Mesaverde Formation)[1]

Pine Ridge Sandstone (in Mesaverde Group)

Upper Cretaceous : Southeastern Wyoming.

Original reference: C. E. Dobbin and others, 1929, U.S. Geol. Survey Bull. 806, p. 140.

J. R. Bergstrom, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 114. Informally named Mesaverde group consists of (ascending) Allen Ridge formation (new) and Pine Ridge sandstone. Underlies Lewis formation. Thickness 400 feet.

Named for exposures in Pine Ridge, about 2 miles southeast of Rock River, Albany County.

**Pinery Limestone Member** (of Bell Canyon Formation)

Upper Permian (Guadalupe Series) : Western Texas and southern New Mexico.

P. B. King *in* A. K. Miller and W. M. Furnish, 1940, Geol. Soc. America Spec. Paper 26, p. 9. Incidental mention.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p 582–583, 585 (fig. 7), pl. 2. Consists of dark-gray fine-grained somewhat cherty limestone in thin straight beds, with several thicker lighter colored granular layers toward base At type locality and along foot of Reef escarpment, lies about 30 feet above base of formation and is 150 feet thick; southeastward in Delaware Mountains, and out in Delaware Basin, member thins to about 25 feet; here, dark thin straight-bedded limestones persist, the lighter gray beds are absent, and much sandstone is interbedded. Lies above the Hegler limestone member and below the Rader limestone member.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 55–56, pl. 3 [1949]. Mapped in New Mexico.

Type section: On slope above Pine Spring, 2½ miles east of Guadalupe Peak, Culberson County, Tex. Named for "The Pinery", an old stage stand on the Butterfield trail at Pine Spring.

Pinesburg Member (of Shippensburg Formation)

Middle Ordovician (Bolarian): Western Maryland and south-central Pennsylvania.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 715 (fig. 1), 718–722. Name proposed for basal member of formation. Described as dark-gray fine- to medium-grained limestone, cobbly below and platy above. Contains three metabentonites. At base in type section, is dark-gray to black medium-grained dark platy-weathering limestone with irregular partings; above is thicker unit consisting largely of dark-gray fine-grained cobbly blue-weathering limestone with prominent thick silty partings; at top is dark-gray fine- to medium-grained platy to slabby limestone. Similar lithologic zoning recognized throughout Cumberland Valley. Thickness 21 to 238 feet; 114 feet in type section. Conformably underlies Fannettsburg member (new); disconformably overlies "Stones River" limestone.

Type section: Exposure on south side of U.S. Route 30, 1 mile southwest of St. Thomas, Franklin County, Pa. Named for exposures along Western Maryland Railroad at Pinesburg Station, Washington County, Md.

**Pinesburg Station Dolomite** (in Beekmantown Group)

Lower Ordovician: Western Maryland.

R. H. Flower, 1956, Jour. Paleontology, v. 30, no. 1, p. 78. Incidental mention. Name credited to W. J. Sando.

W. J. Sando, 1956, Geol. Soc. America Bull., v. 67, no. 7, p. 935, 936. Formally proposed. Name applied to succession of dolomites overlying Rockdale Run formation (new) and underlying Row Park limestone. Top of formation is placed at base of lowest limestone bed in overlying Row Park formation. Thickness averages 450 feet.

W. J. Sando, 1957, Geol. Soc. America Mem. 68, p. 6 (table 1), 28–32, pls. 1, 3, 5. Consists of unfossiliferous cherty dolomite, most of which is laminated; mottled varieties occur throughout formation and are particularly common in lower half; chert nodules and irregular masses abundant. Thickness 372 to 503 feet.

Type section: On Suffecool Farm about 0.8 mile northwest of Pinesburg Station, Washington County. Total outcrop area is 2½ square miles; 75 percent of area is in western belt; eastern belt exposures are confined to narrow strip along northeast margin of Conococheague syncline.

**Pinetop Chert**[1]

Lower or Middle Devonian: Southeasten Oklahoma.

Original reference: H. D. Miser, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 8, p. 974, 975.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, chart 4. Included in Onesquethaw stage (new) [considered to be Lower or Middle Devonian].

Named for Pinetop School, sec. 5, T. 2 N., R. 15 E., about 20 miles south of McAlester, Pittsburg County.

Pine Valley Latite

Tertiary: Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 18, 63–69. An augite-biotite latite porphyry, hard and heavy, with a rough fracture surface. Varies in color from dark gray to red purple. Phenocrysts compose 60 percent of the rock. Well developed platy partings. Basal glass 10 to 150 feet thick averaging about 50 feet. Maximum thickness more than 2,000 feet. Basal contact unconformable. Generalized section of formation in area shows Pine Valley latite stratigraphically above Page Ranch formation (new) and below Eight Mile dacite and Culbert breccia (both New).

Exposed in upper parts of the northern Pine Valley Mountains, Washington and Iron Counties.

**Pine Valley Quartzite**

Cambrian: Northeastern Utah.

J. D. Forrester, 1937, Geol. Soc. America Bull., v. 48, no. 5, p. 638–639, pls. 2, 3. Conformably overlying Ophir shale in Uinta Mountains is the so-called Ogden (Ordovician) quartzite of Weeks (1907, Geol. Soc. America Bull., v. 18, p. 437). This unit, believed to be of Cambrian age, is here named Pine Valley quartzite. Thickness approximately 1,200 feet; tends to pinch out gradually to eastward. Underlies Mississippian limestones considered to be equivalent of Madison limestones of Wasatch Range; well defined angular unconformity.

A. A. Baker, J. W. Huddle, and D. M. Kinney, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 7, p. 1166 (fig. 3), 1168. About 400 feet thick in vicinity of Duchesne River where it overlies Ophir(?) shale.

N. C. Williams, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2738–2739. In western Uinta Mountains, two formations, Ophir and Pine Valley, heretofore assigned to Cambrian and thought to be conformable, are separated by a 20° angle of disconcordance. Plane of disconformity is proposed as proper position for Precambrian contact. Rocks earlier mapped as Ophir(?) are here named Red Pine shale. Name Pine Valley is superfluous, for if Pine Valley is lowermost Cambrian, as considered in this paper, it can be properly correlated, at least in part with the Tintic of the Oquirrh and Wasatch Mountains.

Named from exposures near Stewarts' Ranch on Provo River, Uinta Mountains. Present in discontinuous exposures as far east as Blacks Fork of Green River, Summit County.

Pineville Sandstone (in New River Group)

Pineville Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 211.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 241. Generally massive, grayish-white, coarse-grained. Thickness 30 to 50 feet. Locally its position in column is occupied by shale. Occurs below Little Fire Creek coal and above Pocahontas No. 9 coal. In New River group, Pottsville series.

Forms cliffs nearly 100 feet high at Pineville, Wyoming County.

**Piney Formation**[1]

Upper Cretaceous: Northern Wyoming.

Original reference: N. H. Darton, 1906, U.S. Geol. Survey Prof. Paper 51, p. 13, 59–60.

Named for exposures on Piney Creek, northwest of Buffalo, Johnson County.

**Piney Creek Alluvium**

Recent: North-central Colorado.

C. B. Hunt, 1954, U.S. Geol. Survey Bull. 996–C, p. 114–117. Alluvium well stratified; individual beds commonly several inches thick. Material largely silt but contains many thin layers of silty sand and some gravel. Contains a few pebbles or cobbles. Locally, especially in deep and narrow valleys like Lakewood Gulch, alluvium includes layers of coarse cobbly gravel in silt matrix. Layers of clean sand uncommon. Stratification rises toward mouths of tributaries, and composition of sediments varies according to kind of sediments furnished by tributaries. Charcoal, hearths, and stone artifacts found in alluvium. About 7 feet of alluvium exposed at the section. Overlies Wisconsin alluvium.

Type locality: Along Piney Creek, an eastern tributary to Cherry Creek in NW¼NW¼ sec. 25, T. 5 S., R. 66 W., in Denver area, Arapahoe County.

Piney Creek Conglomerate (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: D. White, 1895, Geol. Soc. America Bull., v. 6, p. 305–320.

On Piney Creek along New River.

**Piney Point Formation**

Eocene, upper: Subsurface in Maryland and Virginia.

E. G. Otton, 1955, Maryland Dept. Geology, Mines and Water Resources Bull. 15, p. 85–89, pls. 1, 5. 14. Name applied to glauconitic sands and interspersed shell beds of Jackson age that lie above Nanjemoy formation and below Calvert formation; contacts conformable. Occurs as a wedge shaped unit; attains maximum thickness of 60 feet in wells near Lexington Park and Breton Beach, Md.

Type well: St. M–Fe 24, drilled for Curtiss Steuart in 1950 near tip of Piney Point Peninsula 0.8 mile northeast of Piney Point lighthouse, St. Marys County, Md. Present in southern Maryland southeast of a line extending southwestward from Kenwood Beach across Calvert and St. Marys Counties to vicinity of Cobb Island in Charles County; recognizable in Northumberland and Westmoreland Counties, Va.

**Piney Ridge Sandstone Member** (of Chemung Formation)[1]

Upper Devonian: Central Pennsylvania.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 535.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Member of Chemung formation. A persistent bed about 50 feet thick, 30 to 200 feet above base of the Chemung. Allegrippis sandstone member occurs about 1,400 feet above the Piney Ridge.

Named for exposures along Piney Ridge, Huntingdon County.

**Pinkard Formation**[1]

Upper Cretaceous: Southeastern Arizona.

Original reference: W. Lindgren, 1905, U.S. Geol. Survey Prof. Paper 43.

Exposed in vicinity of Pinkard Gulch, west of Morenci, Clifton region.

†Pink Cliff series[1]

Eocene: Southwestern and central southern Utah.

Original reference: C. E. Dutton, 1880, Geology of High Plateaus of Utah, p. 143–159, 188–210.

Exposed at the Pink Cliffs, northern part of Kane County.

**Pinkerton Sandstone**[1] (in Pocono Group)

Lower Mississippian: Northeastern West Virginia.

Original reference: G. W. Stose and C. K. Swartz, 1912, U.S. Geol. Survey Geol. Atlas, Folio 179.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 101). Shown on correlation chart as sandstone in Pocono group. Underlies Maccrady formation; overlies Myers shale. Osagean series.

C. B. Read, 1955, U.S. Geol. Survey Prof. Paper 263, p. 10–11. On basis of paleobotanical studies, it seems that the age of the post-Hedges formations should be restudied. Lithologic evidence favors correlation of the Myers with Mauch Chunk, and Pinkerton with basal Pennsylvanian.

Occurs on Pinkerton Knob, W. Va.

Pinkerton Trail Limestone or Formation (in Hermosa Group)

Pennsylvanian (Atoka and Des Moines): Colorado and Utah.

S. A. Wengerd and J. W. Strickland, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2161 (fig. 2), 2167 (fig. 7), 2168–2169. Proposed to separate a limestone-dolomite-clastic sequence of Atoka and earliest Des Moines age from underlying Molas shale and overlying Paradox evaporite sequence. Widespread throughout Paradox Salt basin region as dark-gray fine to coarsely crystalline crinoidal and fusulinid-bearing limestone with some dark-gray shale. Thickness ranges from wedge-edge to more than 200 feet where intra-formational detrital section is best developed in Cedar Mesa anticline of Monument upwarp. Formerly referred to as "lower Hermosa member".

S. A. Wengerd, 1957, New Mexico Geol. Soc. Guidebook 8th Field Conf., p. 134, 135. Table shows Pinkerton Trail formation as lowermost unit in Hermosa group. Thickness at type locality 84 feet.

J. R. Clair, 1958, Rocky Mountain Assoc. Geologists Symposium on Pennsylvanian rocks of Colorado and adjacent areas, p. 34. In subsurface, stratigraphically restricted below to exclude unit herein named Lime Ridge formation.

Type locality: Pinkerton Trail near Denver and Rio Grande Railroad tracks, in sec. 26; T. 37 N., R. 9 W., approximately 12 miles north of Durango, Colo., on west side of U.S. Highway 550.

**Pinnacle Formation** (in Camels Hump Group)

Pinnacle Graywacke,[1] Arkose, or Formation

Cambrian(?): Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 225–226.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137, 140–143. Feldspathic sandstone containing much detrital magnetite and ilmenite; usually some shale of gray tinged with green. Well bedded; thickness of beds variable. Crossbedding prominent. Maximum thickness 400 feet. Underlies White Brook dolomite; overlies Call Mill slate. Type locality cited.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1135, 1136, 1141–1145. Extended to Vermont where known as Pinnacle formation because of lithologic variations. If a few feet of Call Mill slate are present in Vermont they are included in Pinnacle.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Precambrian(?).

J. B. Thompson, Jr., 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for field trips in New England, p. 16, 39. Pinnacle arkose makes up lower part of Mendon series of Vermont Valley sequence.

P. H. Osberg, 1959, New England Intercollegiate Geol. Assoc. Guidebook 51st Ann. Mtg, p. 47. Pinnacle formation of this report [Coxe Mountain area, Vermont] includes rocks called Mendon and Nickwaket.

Type locality: In Lot 1, Range 1, Dunham Township, Sutton quadrangle, Quebec, on north side of road and on western limb of same syncline that caps Pinnacle Mountain and Spruce Hill. Named for Pinnacle Mountain which has capping of graywacke.

Pinnacle[1] (System)

Cenozoic (pre-Pliocene): Southeastern Alaska.

Original reference: I. C. Russell, 1891, Nat. Geog. Mag., v. 3, p. 167–175.

D. J. Miller, 1953, Jour. Geology, v. 61, no. 1, p. 32. Deposits of system between Icy Bay and Yakutat Bay formerly thought to be either Pliocene or Pleistocene (Smith, 1939, p. 59), but collections of fossils made recently from some of the beds previously correlated with Pinnacle system probably not younger than Miocene.

Best exposed in cliffs of Pinnacle Pass and along northern and western borders of Samovar Hills, St. Elias region.

Pinnacle Point Beds or Formation

Miocene, upper: Southeastern Oregon.

E. M. Baldwin, 1959, Geology of Oregon: Ann Arbor, Mich., Edwards Bros., Inc., p. 108–109. Quartzose sandstone; locally interbedded with friable sandstone and siltstone. Sparsely fossiliferous. Unconformably overlies truncated or channeled Owyhee basalt; where Owyhee is missing, it is difficult to distinguish Pinnacle Point beds from Payette formation. Capped by Grassy Mountain basalt. Tentatively assigned to late Miocene (Barstovian).

Well exposed along eastern margin of Owyhee Reservoir from Burnt Ridge, Pinnacle Point, Dry Creek Butte, along margins of Oxbow Basin, Mitchell Brown and Vale Buttes.

Pinnacles Formation

Miocene, middle(?): West-central California.

Philip Andrews, 1936, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 24, no. 1, p. 19, 25, 26, map 1. Volcanic breccias and tuffs, chiefly rhyolite. Miocene(?).

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 217–218, 224 (fig. 3), pl. 4. In San Benito quadrangle, underlies Monterey group; overlies Gabilan limestone. Thickness as much as 2,600 feet. Middle(?) Miocene.

Named for exposures in Pinnacles National Monument, near King City, southeast of Salinas.

**Pinney Hollow Formation** (in Camels Hump Group)

Pinney Hollow Schist[1] or Formation

Lower Cambrian: East-central and west-central Vermont.

Original reference: E. L. Perry, 1927, Vermont State Geologist 15th Rept., p. 161.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 55–61, 116, geol. map. Formation described in eastern sequence in Green Mountain anticlinorium near Rochester and East Middlebury. Thickness 1,000 to 1,500 feet. Includes Hancock member (new) in middle part. Overlies Granville formation (new); underlies Ottauquechee formation. Cambrian.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 48–50, tables 2, 3. In Rutland area, overlies Grahamville formation (new); underlies Ottauquechee formation. Consists of three parts: lower, white green phyllite, green albitic phyllite and grit, thin black phyllite, middle, green white phyllite, thin greenstone, black phyllite; upper, green phyllite, finely banded green and gray siltstone. Thickness 3,500 to 4,000 feet. Cambro-Ordovician.

Type exposures in Pinney Hollow, Plymouth Township, Windsor County.

Pinnick Coal Member (of Mansfield Formation)

Pennsylvanian: South-central Indiana.

H. H. Gray, R. D. Jenkins, and R. R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 26–27. Important stratigraphic marker or key bed at top of lower unit of Mansfield. Average thickness about 1 foot. Coal named by D. W. Franklin (1939, unpub. thesis). Franklin's type section no longer exposed. Other good exposures noted.

Type section (Franklin): Mine on Pinnick property in SE¼SW¼ sec. 32, T. 2 N., R. 2 W., Orange County.

**Pinole Tuff**[1]

Pliocene: Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416 (table).

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 110 (table 24), 118–121, pls. 11, 12. Overlies Neroly sandstone. Type section designated because no type exposure had been designated previously; tuff exposed along Pinole Valley has been dropped by faulting and is not representative of the entire sequence. Thickness at type locality nearly 1,000 feet.

Type section: Exposures along shore of San Pablo Bay between Oleum and Rodeo; tuff exposed on both limbs of a synclinal fold. Named for exposures near town of Pinole, on San Pablo Bay, Contra Costa County.

†Pinos Altos limestones[1]

Ordovician: Southwestern New Mexico.

Original reference: C. R. Keyes, 1904, Am. Jour. Sci., 4th, v. 18, p. 360–362.

Probably named for town in Grant County.

Pinto Diorite[1]

Pinto Metadiorite

Precambrian: Central Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 56.

E. W. Heinrich, 1953, (abs.) Geol. Soc. America Bull., v. 64, no. 12, pt. 2, p. 1432. A number of post-Cherry Creek intrusives, all of which show varying degrees of metamorphism, include among others, Dillon granite gneiss, widespread in Beaverhead and Madison Counties, granite of Jardine district, and Pinto metadiorite in Little Belt Mountains.

Pinto Formation[1]

Pleistocene: Southern California.

Original reference: D. Scharf, 1935, Southwest Mus. Paper 9, p. 11–20.

Exposed in hill between Eagle Mountains and the Coxcombs and in Pinto Wash; also occurs in Pinto Basin, north-central part of Riverside County.

Pinto Gneiss

Precambrian: Southern California.

W. J. Miller, 1938, Geol. Soc. America Bull., v. 49, no. 3, p. 419 (fig. 2), 424–428. Comprises a complex of rocks, chief constituents of which are metamorphic facies of Gold Park gabbro-diorite (new) and Palms granite (new) and pegmatitic granite, together with some metasediments. Cut by White Tank monzonite (new).

Named because of its widespread, typical development in the Pinto Mountains, Riverside County.

†Pinto Limestone[1]

Upper Cretaceous (Gulf Series): Southwestern Texas.

Original reference: E. T. Dumble, 1892, Geol. Soc. America Bull., v. 3, p. 222, 229, 230.

Named for Pinto Creek, Val Verde County.

†Pinto Sandstone[1]

Cretaceous: Southwestern Utah.

Original reference: C. K. Leith and E. C. Harder, 1908, U.S. Geol. Survey Bull. 338, p. 37.

J. H. Mackin, 1954, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–14. Pinto sandstone, as defined by Leith and Harder (1908) included all sedimentary rocks between Homestake limestone and overlying Claron formation. The dominantly maroon sandstone and shale which forms lower part of Pinto, however, rests gradationally on Homestake and is separated by an unconformity from dominantly gray and brown sandstone, shale, and conglomerate that forms bulk of Pinto. Maroon beds beneath unconformity are now correlated with the Entrada. Term Pinto is abandoned, and portion of that formation between the Entrada and Claron designated Iron Springs formation.

Probably named for Little Pinto Creek, which appears to cross formation just south of Iron Springs quadrangle.

Pintoan series[1]

Lower Cambrian: Southeastern California and western Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 51, 53, 80.

Named for Pinto Mountains, near Waucoba Springs, in White Mountain Range, Calif.

Pinto Canyon Formation

Permian (Leonard and lower Guadalupe) : Southwestern Texas.

D. L. Amsbury, 1957, Dissert. Abs., v. 17, no. 9, p. 1981; 1958, Texas Univ. Bur. Econ. Geology Geol. Quad. Map. 22. Proposed for all Permian rocks above Alta formation in area. Divided into four unnamed members (ascending): regularly medium-bedded chert and limestone; irregularly bedded chert; regularly bedded chert and limestone with fossiliferous limestone lenses; thin-bedded siltstone with large limestone concretions. Thickness about 600 feet. Underlies Yucca formation.

Type section: In bed of Pinto Creek; base is three-sixteenth mile upstream from fourth creek crossing of Marfa-Ruidosa Road, Pinto Canyon area, Presidio County.

**Pinyon Conglomerate**[1]

Paleocene: Northwestern Wyoming.

Original reference: W. H. Weed, 1896, U.S. Geol. Survey Geol. Atlas, Folio 30.

J. D. Love, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 27. Consists almost entirely of rounded red, black, gray, and yellow pebbles, cobbles, and boulders of Precambrian quartzites and other hard Cambrian metamorphic and igneous rocks. Contains fragments of wood. In southeastern part of area, thickness ranges from 1,000 to more than 1,500 feet; near Turpin Meadows about 500 feet; on Gravel Mountain at least 2,000 feet. Rests on Upper Cretaceous sandstones, shales, and thin coal beds of Mesaverde age in southeastern part of area and on successively younger strata of Cretaceous age along outcrops to northwest. Paleocene.

J. D. Love, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1903, 1906. Uncomformably overlies Harebell formation (new) and unconformably underlies Colter formation (new).

Well exposed on Pinyon Peak, Yellowstone Park. Forms broad outcrops along eastern margin of Jackson Hole area, and is well developed along both forks of Fish Creek in Mount Leidy Highlands, and on Gravel Mountain.

Pinyon series[1]

Ordovician: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53.

Derivation of name not stated.

†Pinyon Mesa Group[1]

Eocene and older(?): Northwestern New Mexico and southwestern Colorado.

Original reference: W. H. Holmes, 1877, U.S. Geol. and Geog. Survey Terr. 9th Ann. Rept. 1875, p. 248, 249, 251.

Forms escarpment of Pinon Mesa in northwestern part of San Juan County, N. Mex.

†Pinyon Peak Conglomerate[1]

Eocene: Yellowstone National Park.

Original reference: A. Hague, 1899, U.S. Geol. Survey Mon. 32, pt. 2, p. 184.

**Pinyon Peak Limestone**[1]

Upper Devonian and Lower Mississippian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

K. C. Bullock, 1951, Utah Geol. and Mineralog. Survey Bull. 41, p. 11–14. In Lake Mountain area, crops out north of mouth of Rock Canyon in fault block that rests unconformably on Humbug limestone. Thickness 331 feet. Conformably underlies Gardner dolomite. Devonian.

T. S. Lovering and others, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1506. Stratigraphic location of Upper Devonian Pinyon Peak was incorrectly designated in original description as between Bluebell dolomite and Victoria quartzite. However, it lies above the Victoria and below the Gardner. As redefined, comprises beds formerly included in the three lower units of the Gardner dolomite, now known to contain an Upper Devonian fauna.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 11 (fig. 3), 13–14, pl. 1. In East Tintic Mountains, consists chiefly of thin-bedded, fine-grained, medium- to light-blue limestone seamed with veinlets and partings of buff- to brown-weathering clay and mudstone. Thickness 70 to 300 feet. Gradational with overlying Madison limestone, contact arbitrarily placed at base of thin bed of calcareous sandstone or sand-streaked limestone referred to as "sand-grain" or "ant-egg" marker by mining geologists of district. (Name Madison preferred to Gardner in this area). Loughlin (1919) did not recognize Pinyon Peak limestone in Tintic district where he believed Victoria formation to be of Mississippian age and to overlie an unconformity at base of Mississippian sequence. Consequently he included Pinyon Peak with his Gardner formation in this area. Data obtained since 1947 show that Pinyon Peak limestone occurs throughout East Tintic Mountains immediately above Victoria formation. Fossil evidence indicates that Devonian-Mississippian boundary is in upper part of Pinyon Peak; thus, age is considered to be Late Devonian and Mississippian(?).

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 38 (fig. 5), 39. In Stansbury Mountains, overlies Stansbury formation (new). Underlies Gardner dolomite. Thickness as much as 85 feet.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 152–153. Recognized in Fivemile Pass and North Boulter Mountains quadrangles where it is as much as 105 feet thick, conformably underlies Gardner formation and disconformably overlies Victoria formation.

Named for exposures on Pinyon Peak, Tintic district.

**Pinyon Ridge Granodiorite**

Jurassic(?): Southern California.

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Prevailingly dark granodiorite, varying to quartz diorite, commonly gneissic; intruded locally by quartz monzonite and pegmatite and at some places complexly by fine-grained white aplite. May be related to Pleasant View complex (new).

Type locality: Pinyon Ridge, Valyermo quadrangle.

Pioa Rhyolite (quartz trachyte) and Breccia

Pleistocene(?): Samoa Islands (Tutuila).

R. A. Daly, 1924, Carnegie Inst. Washington Pub. 340, p. 100, 106–108, 129–130. Rhyolite (quartz trachyte) dome and associated breccia. In

Tutuila, a long stage of basaltic development was followed by series of explosions that produced Pioa and Matafao breccias; this stage was followed by eruptions of Pioa rhyolite and Matafao, Papatele, Afono, and Vatia trachytes, which seem to have been erupted contemporaneously or nearly so.

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285–1286 (table 1), 1300–1302. Pioa trachyte plug is associated with Pago volcanic series (new). Pliocene and early Pleistocene(?).

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 191. Pleistocene(?). Late unit in Pago volcanic series; unconformably overlies basaltic tuffs, breccias, and flows forming floor of Pago caldera.

Occurs on Pioa Peak, east of Pago Pago Bay. Covers about 0.01 square mile.

**Pioche Shale**[1]

Lower and Middle Cambrian: Eastern Nevada, northwestern Arizona, eastern California, and western Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 9–12.

J. F. Mason, 1936, *in* A. W. Grabau, Paleozoic formations in the light of the pulsation theory, v. 1, Lower and Middle pulsation: 2d ed., Peiping, China, University Press, Natl. Univ. Peking, p. 274–276. Restricted to exclude two newly named units: Forlorn Hope shale and Comet shale. Restricted Pioche is 305 feet thick and includes "Combined Metals bed" of miners. Overlies Prospect Mountain quartzite.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1139, 1141 (fig. 3), 1143, 1154–1156, 1158 (fig. 6), 1159. Walcott's House Range, Utah, section emended. Here Pioche is 265 feet thick, overlies Prospect Mountain quartzite and underlies Tatow limestone (new). Westgate's (1932, U.S. Geol. Survey Prof. Paper 171) Highland Range, Nev., section emended. Here Pioche shale restricted to the 600 feet below Comet shale (redefined). Overlies Prospect Mountain quartzite. Lower-Middle Cambrian boundary placed at top of Pioche beneath the *Kochaspis liliana* zone at base of Comet shale. Term Forlorn Hope rejected in this report. Type locality of emended Pioche on north side of Lyndon (Shodde) Gulch, Nev.

H. E. Wheeler and D. W. Lemmon, 1939, Nevada Univ. Bull., Geology and Mining Ser., no. 31, p. 33, 34. Thickness in Pioche district 970 feet. Underlies Lyndon limestone; overlies Prospect Mountain quartzite. Mason's term Comet shale rejected.

H. E. Wheeler, 1943, Geol. Soc. America Bull., v. 54, no. 12, pt. 1, p. 1786, 1788–1789, 1790 (fig. 2), 1793, 1800, 1803, 1805, 1811–1815. Pioche shale is recognized from Eureka to western Grand Canyon and eastward throughout most of western Utah. In southeastern Nevada and northwesternmost Arizona, Pioche has been regarded as part of Bright Angel shale, and in western Utah it has been called Ophir and Cabin. Formation is both Lower and Middle Cambrian over most of Great Basin area, but it is Lower Cambrian at Eureka and Cave Valley(?), Nev., and in House and Deep Creek(?) Ranges, western Utah, and Middle Cambrian in Tintic and Sheeprock Ranges, central Utah.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 29. Uppermost 70 feet of beds previously assigned to Pioche shale in Wah Wah Range (Wheeler, 1943) are here assigned to Busby shale.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 28, 31–32, pl. 1. Mapped in Ivanpah quadrangle, California. Together with Prospect Mountain quartzite and Noonday dolomite, comprises what is termed western facies of the Cambrian.

A. R. Palmer, 1958, Jour. Paleontology, v. 32, no. 1, p. 154. At Pioche, Nev., includes Combined Metals member.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 668–669. Data presented in this report [northern Utah and southeastern Idaho] prove presence of Pioche formation throughout most of west-central and northern Utah and suggest its presence in the northern Wasatch, in part of Bear River Range, and in southeastern Idaho.

K. F. Bick, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1066. In Deep Creek Mountains, Utah, replaces name Cabin shale.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 32, 35–39. Included in Ophir group. Underlies Busby quartzite.

H. K. Stager, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B70–B71. At Mount Wheeler mine, Pine County, Nev., the Pioche overlies Prospect Mountain quartzite and is about 450 feet thick. Consists mainly of micaceous, siliceous, highly indurated shale but includes several beds and lenses of limestone. Thickest limestone bed, known locally as "Wheeler limestone," is about 50 feet above quartzite contact and may be equivalent to Combined Metals limestone at Pioche. It is 20 to 50 feet thick.

Type locality: Southeast of Pioche, Nev., on road to Panaca, Utah.

Pioneer Group

Upper Cretaceous (Chico): Northern California.

F. M. Anderson, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1863. Chico series subdivided into Pioneer, Panoche, and Orestimba groups. Maximum thickness of Pioneer group 7,500 feet.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 183, 185 (fig. 69) [preprint 1941]. Shown as lowest group in Chico series; underlies Panoche group; overlies Horsetown group.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 24, 32. Taliaferro and Anderson proposed divisions of Panoche group wherein Anderson's Pioneer group is approximately the equivalent of Taliaferro's Pacheco group and Anderson's Panoche and Moreno groups are inclusive of Taliaferro's Asuncion group. In area of present report [Ortigalita Peak quadrangle], both the Pacheco and Asuncion groups of Taliaferro or Pioneer and Panoche groups of Anderson are represented though they have not been satisfactorily separated.

Crops out in Cottonwood district and southward along the border of Sacramento Valley.

Pioneer Sandstone[1] (in Indian Bluff Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33–B, p. 18–19, 21, 22.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Assigned to Indian Bluff group (new). Top of sandstone forms Poteet Gap, where it is about 55 feet thick; in Cross Mountain section 50 to 60 feet thick; in Petros section 4 feet. Separated from underlying Indian Fork sandstone (new) by shale interval that is as much as 80 feet thick in some places; separated from overlying Armes Gap sandstone (new) of Graves Gap group (new) by a shale interval that contains the Jordan coal and Norman Pond coal.

Named from exposures at Old Pioneer, near Poteet Gap, Pioneer quadrangle, Campbell County.

**Pioneer Shale,[1] Formation, or Quartzite** (in Apache Group)

Precambrian: Central and southeastern Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

N. P. Peterson, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 100 (fig. 31). Shown as quartzite on columnar section of rocks in Globe-Miami district. Thickness 270 feet. Overlies Scanlan conglomerate; underlies Barnes conglomerate.

N. P. Peterson, C. M. Gilbert, and G. L. Quick, 1951, U.S. Geol. Survey Bull. 971, p. 15, fig. 3, pl. 1. Formation composed mainly of hard, fine-grained, reddish-brown arkosic sandstone in Castle Dome area. At least 165 feet thick. Mapped with Scanlan conglomerate.

Gordon Gastil, 1954, Am. Jour. Sci., v. 252, no. 7, p. 436–440. Pioneer rocks studied in southeastern Arizona consist of arkose grit and gravel conglomerate, feldspathic sandstone, argillaceous and feldspathic siltstone, silty mudstone, tuffaceous siltstone, and rhyolite tuff. At nine localities, sections consist predominantly of rhyolite tuff, and tuffaceous siltstone.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. Formation mapped in Globe quadrangle where it is about 270 feet thick, overlies Scanlan conglomerate and underlies Barnes conglomerate.

D. W. Peterson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–128. Thickness approximately 300 to 500 feet in Haunted Canyon quadrangle. Overlies Scanlan conglomerate; underlies Barnes conglomerate.

U.S. Geological Survey currently classifies the Scanlan Conglomerate as a bed in the Pioneer Formation on basis of a study now in progress.

Named for exposures at old mining settlement of Pioneer, just south of Globe quadrangle.

**Pipe Creek Shale Member** (of Java Formation)

Pipe Creek Member (of Hanover Shale)

Pipe Creek Shale Member (of Wiscoy Formation)[1]

Upper Devonian: Western and west-central New York.

Original reference: G. H. Chadwick, 1923, Geol. Soc. America Bull., v. 34, p. 69.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 15, pl. 3. In southwestern New York, considered member of Wiscoy sandstone. Overlies Nunda sandstone.

J. F. Pepper and Wallace de Witt, Jr., 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 37. Reallocated to member status in Hanover shale. Overlies Angola shale to west and Nunda sandstone to east. Maximum thickness about 20 feet in Springfield quadrangle and northern part of Arcade quadrangle; thins westward to 2 feet in Silver Creek quadrangle;

thins eastward and interfingers with gray shale until in western part of Hornell quadrangle it cannot be identified.

I. H. Tesmer, 1957, New York State Mus. Bull. 362, p. 5, 9, 13. In surface referred to as member of Chemung formation.

Wallace de Witt, Jr., 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1933–1934, 1935 (fig. 2). Redefined as basal member of Java formation (new) in western and west-central New York. Underlies Hanover shale member; overlies Nunda sandstone member of West Falls formation.

Type exposure in Pipe Creek Glen, West Falls, Erie County.

**Pipeline Shale Member** (of Brushy Canyon Formation)

Pipeline Shale

Permian: Southwestern Texas.

W. C. Warren, 1955, *in* P. B. King, N.D. Newell, and D. W. Boyd, Permian field conference to the Guadalupe Mountains: Soc. Econ. Paleontologists and Mineralogists, p. 11. Name suggested for a black shale that intervenes between Bone Spring limestone below and the Brushy Canyon sandstone above. Has been correlated with Cutoff member [of Bone Spring] and name is used to distinguish shale from the type Cutoff. Contains fusulinids. Apparently transitional in time between Leonard and Guadalupe and is a "starved basin" shale.

U.S. Geological Survey currently classifies the Pipeline Shale as a member of Brushy Canyon Formation on basis of a study now in progress.

El Paso Natural Gas and the Pasotex pipelines cross outcrop of Pipeline shale a short distance north of Highway 62 in Delaware Mountains, Culberson County.

**Piper Formation** (in Ellis Group)

Middle Jurassic: Montana.

R. W. Imlay and others, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 32. Defined to include all Middle Jurassic red beds, gypsum, and associated normal marine beds underlying Rierdon formation in eastern Montana east of Sweetgrass-Big Belt line of uplift. Basal part locally includes equivalents of type Gypsum Spring formation of central Wyoming as described by Love (1945); upper part includes beds that have been placed in lower part of lower Sundance in Wind River basin and central Wyoming. In Montana, consists of a lower red bed and gypsum member, a middle member of gray shale, limestone, and dolomite, and an upper red-bed gypsum member; these members grade into each other vertically, and to some extent the red beds grade laterally into middle marine member; upper member grades laterally into yellowish calcareous marine siltstone and sandstone. At type section, consists of (ascending) about 12 feet of massive white gypsum, 6 feet of brittle, chocolate-gray limestone, 57 feet of maroon and green siltstone and shale, 5 feet of gray, silty limestone, 9 feet of gray papery to chunky shale, and 4 feet of yellowish-gray sandy limestone. Thickness ranges from 0 to nearly 300 feet and varies considerably within short distances. Grades laterally into Sawtooth formation.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 967–968, chart 8C (columns 55, 57, 58, 60, 63, 64). Piper includes all Middle Jurassic beds underlying Rierdon formation in eastern Montana east of Sweetgrass-Big Belt-Bridger line of uplift. First identified as Gypsum Spring formation (Imlay, 1947) ; later fieldwork showed that Gypsum Spring of type area in central Wyoming represents only basal Middle Jurassic and correlates with lower member of Gypsum Spring, as employed by U.S. Geological Survey parties in Montana and parts of Big Horn Basin of Wyoming. This usage in Montana arose because it was practical in mapping and because Gypsum Spring was assumed to include all beds of Middle Jurassic age older than type Sundance. Because beds equivalent to type Gypsum Spring in Montana are not mappable, name Piper is used in that state for beds hitherto called Gypsum Spring. Middle member of Piper has furnished such ammonites as *Defonticeras* and *Teloceras*, which are of middle or upper Bajocian age; upper red-bed member grades laterally in western Montana into yellowish siltstone, sandstone, and limestone that contains *Arctocephalites* and *Procerites* and is considered of upper Bathonian age.

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 99–104, fig. 2. Subdivided to include (ascending) Tampico shale, Firemoon limestone, and Bowes members (all new). These units are recognized in subsurface and surface sections. In subsurface in Williston basin overlies Kline member of Nesson formation (both new).

T. P. Storey, 1958, Alberta Geol. Soc. Petroleum Geologists Jour., v. 6, no. 4, p. 90–104. Discussion of Jurassic of Williston basin and adjacent areas. On basis of faunal, environmental, and tectonic evidence, units are grouped into four major depositional sequences or stagelike intervals which Imlay refers to as Gypsum Spring (or Piper), Sawtooth, Rierdon, and Swift formations. Miscorrelation of type sections of these formations are result of variations in stratigraphic succession caused by sub-Swift and sub-Rierdon unconformities which correspond respectively to Arkell's (1956, Jurassic geology of the world: New York, Hafner Publishing Co.) Lower Callovian, and uppermost Callovian to Lower Oxfordian marine transgressions. Recognition of regional extent and significance of these unconformities suggests these are the following stratigraphic variations from those generally accepted: (1) the Lower Swift (Stockade Beaver-Hulett of Lower Sundance) is older than type Swift and younger than type Rierdon formations; and (2) Sawtooth is discrete stratigraphic unit which is younger than Piper or Gypsum Spring.

Type section: About 1 mile southwest of Piper on northwest corner of an escarpment due east of Bacon Ranch in sec. 17, T. 14 N., R. 20 E., Fergus County.

Pipes Fanglomerate[1]

Pliocene, upper, or Quaternary, lower: Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 379–380, map.

Named for occurrence near The Pipes, a watering place in San Bernardino County.

Pipestem Shale (in Bluestone Formation)[1]

Mississippian (Chesterian): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 294, 322.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 182, pl. 15. Geographically extended into Virginia and redefined as member of Bluestone formation. Thickness 10 to 20 feet. Overlies Pride shale member; underlies Glady Fork sandstone member. Chester series.

Type locality: In Tallery Mountain Road near foot of Davy Knob, about 1 mile northeast of Pipestem, Summers County, W. Va.

†Pipestone Quartzite[1]

Precambrian (Huronian): Southwestern Minnesota.

Original reference: N. H. Winchell, 1888, Minnesota Geol. Nat. History Survey Final Rept., v. 2, p. xxii.

Pipestone County.

Pipestone Canyon Formation

Eocene(?): Northwestern Washington.

J. D. Barksdale, 1948, Northwest Sci., v. 22, no. 4, p. 165, 175. Series of arkose, shale, and conglomerate. Basal member poorly sorted conglomerate of fairly well-rounded pebbles and boulders in massive bed approximately 20 feet thick. Succeeding sandstone is light gray to buff in color, in beds 6 inches to 4 feet thick interbedded with siltstones. These beds often tinged with purple. Upper part of formation shaly. Total thickness approximately 2,300 feet. Overlies Midnight Peak formation (new) unconformably.

Type locality: In Pipestone Canyon, Methow quadrangle.

†Pipestone Creek Beds[1]

Oligocene, lower: Western central Montana.

Original reference: E. Douglass, 1902, Am. Philos Soc. Trans., v. 20, new ser., pt. 3, p. 237–245.

On Pipestone Creek, just above Piedmont, Jefferson County.

Pipestone Springs Formation

Oligocene (Chadronian): Western central Montana.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 28, pl. 1. Pipestone Springs (also Pipestone, preoccupied, and Pipestone Creek), early Chadronian local fauna and inadequately described formation composed of confluent alluvial fans filling valleys in crystallines.

L. S. Russell, 1953, Billings Geol. Soc. Guidebook 4th Ann. Field Conf., p. 112. Pipestone Springs beds of Montana mentioned as approximately same age as Cypress Hills formation, Saskatchewan.

Present in Jefferson County.

†Piqua limestone member[1]

Pennsylvanian: Southeastern Kansas.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Bull. 328, p. 20.

Named for Piqua, Woodson County.

Piru Formation

Eocene: Southern California.

S. J. Kriz, 1955, Dissert. Abs., v. 15, no. 3, p. 393. Name given to Eocene sediments of area. Five members [unnamed] are differentiated. These range in age from early Maganos [Meganos] to late Domingene or Tejon. Uppermost member contains marine strata and unconformably underlies sediments of typical Sespe formation.

Area is Whitaker Peak-Reasoner Canyon in Ventura and Los Angeles Counties.

Piru Gorge Sandstone (in Ridge Basin Group)

Pliocene, middle: Southern California.

D. I. Axelrod, 1950, Carnegie Inst. Washington Pub. 590, p. 161, pl. 1. Made up of several massive, lenticular coarse-grained, crossbedded sandstones which range from 3 or 4 feet to as much as 30 feet in thickness. Unit as much as 150 feet thick. Underlies an unnamed shale zone below Peace Valley beds; overlies gray shales and blue-gray mudstones above French Flat sandstone (new).

Forms a conspicuous cuesta south of Pyramid rock on south bank of Piru Creek in Ridge Basin area along U.S. Highway 99, between Los Angeles and Bakersfield, in region from 5 miles north of Castaic to vicinity of Gorman.

**Piscataway Indurated Marl Member** (of Aquia Formation)[1]

Eocene, lower: Eastern Maryland and eastern Virginia.

Original reference: W. B. Clark and G. C. Martin, 1901, Maryland Geol. Survey, Eocene Volume, p. 58, 60–62.

R. A. Schmidt, 1948, Jour. Paleontology, v. 22, no. 4, p. 390, 392 (table 1), 393. The Piscataway indurated marl member below and Paspotansa greensand marl member above are present at type locality of Aquia formation. They cannot be distinguished on basis of their ostracods. Lower Eocene.

Named from Piscataway Creek which empties into the Potomac on Maryland bank about 10 miles below Washington, D.C.

†Piscataway Sands[1]

Eocene: Eastern Maryland

Original reference: A. Heilprin, 1884, Philadelphia Acad. Nat. Sci. Jour., 2d ser., v. 9, pt. 1, p. 120, 124–127.

**Pisgah Member** (of Kincaid Formation)[1]

Paleocene: Northeastern to southwestern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 535, 536, 540, 550.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 13. Middle member of formation in Texas. Overlies Littig glauconite member; underlies Tehuacana member. Consists of yellow, gray, green, and buff clay and glauconitic sand containing several limestone beds. Beds equivalent to Pisgah member crop out at many localities in southwestern Arkansas.

G. R. Kellough, 1959, Gulf Coast Geol. Soc. Trans., v. 9, p. 152–153. At Tehuacana Creek, section consists of 148 feet of strata divisible into 3 units: basal, 20 feet thick, gray slightly sandy shale; middle, 53 feet thick, gray slightly sandy shale or shaly sand interbedded with thin layers of sandy shale containing small amounts of coarse dark-green glauconite; and upper, 75 feet thick, gray sandy shale with small amounts of very fine-grained light-green glauconite. Overlies Littig member; underlies Tehuacana member.

Named for exposures on Pisgah Ridge, Navarro County, on road between Richland and Wortham, 6 miles north of Limestone County line.

**Pismo Formation**[1]

Miocene, upper, and Pliocene: Southern California.

Original reference: H. W. Fairbanks, 1904, U.S. Geol. Survey Geol. Atlas, Folio 101.

B. M. Page and others, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 16. Thickness about 3,200 feet. Overlies Monterey formation; underlies Paso Robles. Upper Miocene and Pliocene.

Named for exposures at town of Pismo, San Luis Obispo County.

**Pit Shale[1] or Formation**

Middle and Upper Triassic: Northern California.

Original reference: H. W. Fairbanks, 1894, Am. Geologist, v. 14, p. 28.

J. P. Albers, 1953, California Div. Mines Spec. Rept. 29, p. 7–8, pls. 1, 3, 4, 5. Formation, in Afterthought Mine district, Shasta County, is about 500 feet thick. Consists of shale and tuff, with tuff making up more than half of formation. Overlies Bully Hill rhyolite.

A. H. Coogan, 1957, (abs.) Geol. Soc. America Bull., v. 68, no. 12, pt. 2, p. 1821. Conformably overlies Dekkas formation (restricted).

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 5–7, pl. 1. Oldest formation exposed in area [southwest quarter Big Bend quadrangle, Shasta County]. Underlies Hosselkus limestone. Only upper part of formation studied. Middle Triassic.

A. H. Coogan, 1960, California Univ. Pubs. Geol. Sci., v. 36, no. 5, p. 243–255. Pit shale consists of black and gray siliceous shale which weathers to lighter shades of gray or white. Conformably overlies Dekkas formation of Bollibokka group (new). Owing to presence of middle Permian fusulinids in Dekkas and lack of diagnostic Triassic fossils in lower part of Pit, it is possible that Mesozoic-Paleozoic boundary is within Pit shale. [Spelled Pitt by J. P. Smith (1894), Jour. Geology, v. 2, p. 592, 601–604).]

Named for exposures at Silverthorns Ferry, on Pit River, Shasta County.

Pitcairn Gneiss Complex

Precambrian: Northeastern New York.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 15–17. A belt of heterogeneous rock comprising gneiss skarn, granulite, feldspathic quartzite, and rock resembling artertic migmatite.

Extends along northwest border of Diana complex from just southeast of Harrisville, Lewis County, for about 10 miles or more to northeast.

**Pitchfork Formation**

Eocene, middle: Northwestern Wyoming.

R. L. Hay, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1863–1898. Consists largely of detrital rocks—sandstones, siltstones, and conglomerates—containing volcanic debris from eruptive centers in Yellowstone Park-Absaroka volcanic province. Thickness 200 to about 1,200 feet; average about 1,000 feet. Interfingers northward with breccia; toward the south, pinches out against axis of Owl Creek Range. Almost everwhere underlain by Willwood and Tatman formations; overlain by basalt and equivalent breccia. West and south of Anchor post office, Masursky (1952, Wyoming Geol. Assoc. Guidebook 7th Ann. Field Conf., map) mapped beds equivalent to Pitchfork as Aycross formation. He showed Aycross strata extending as far south as Owl Creek Range, where, on axis of range, they pinch out between limestone of Paleozoic age and Tepee Trail formation. It is believed that use of Aycross for these beds is misleading because beds considered Aycross in Bighorn basin may never have been continuous with beds of Aycross south of Owl Creek

Range, in Wind River basin. As used here, Pitchfork formation includes beds in Bighorn basin named Aycross by Masursky. Vertebrate and plant remains indicate a probable middle Eocene age.

Name derived from Pitchfork post office in Greybull Valley. No single type section encompasses the lithologic variety of formation but exposures on cliff on east side of Francs Fork, in sec. 9, T. 47 N., R. 103 W., Park County, most nearly approach type section.

†Pithole Grit[1]

Mississippian: Northwest Pennsylvania.

Original reference: J. F. Carll, 1880, Pennsylvania 2d Geol. Survey Rept. $I_3$, p. 82, 93, 121, 130.

Well developed in and around Pithole, Venango County, and crops out along Allegheny River on south and along Oil Creek on west.

**Pitkin Limestone**[1]

Upper Mississippian: Northern Arkansas and eastern Oklahoma

Original reference: G. I. Adams and E. O. Ulrich, 1904, U.S. Geol. Survey Prof. Paper 24, p. 27, 109.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1939. In Arkansas, underlies newly defined Cane Hill member of Hale formation.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 71–75. Described on flanks of Ozark Uplift, northeastern Oklahoma, where it is conformable with the subjacent Fayetteville and unconformable with the overlying Hale formation. Maximum thickness 82 feet; average thickness 25 to 30 feet.

Named for exposures near Pitkin post office in Washington County, Ark.

Pitt Series[1]

Middle Triassic: North America.

Original reference: G. H. Ashley, 1923, Eng. Mining Jour.-Press, v. 115, p. 1106–1108.

Pittsburg Formation

Carboniferous: Central western Idaho and northeastern Oregon.

W. R. Wagner, 1945, Idaho Bur. Mines and Geology Pamph. 74, p. 4–5, pl. 1. Mainly conglomerates and sandstones with some argillaceous beds and here and there a dense tuffaceous bed. Conglomerates of subangular to rounded pebbles and boulders from 1 to 4 inches in diameter in coarse gray-green sandy matrix. Sandstones are coarse. Formation gray green to dark green in color and seems to have been formed mostly of debris eroded from Permian volcanics. Estimated thickness between 200 to 300 feet. Overlies Seven Devils volcanics.

Exposed near Pittsburg Landing on Snake River, Idaho County, Idaho. Covers area of approximately 1½ square miles on Idaho side of river and much larger but undetermined area on Oregon side.

†Pittsburg Formation[1]

Eocene: Western Washington.

Original reference: B. Willis, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 424–430.

Named for Pittsburg.

Pittsburg Formation

Pleistocene: Northern California.

C. F. Tolman, 1931, California, California Dept. Public Works, Div. Water Resources Bull. 28, p. 354, pl. D–IX, D–X. Fine clayey sandstone and tawny-yellow to brown and brownish-yellow sandy silt; obscurely bedded. Grades into material designated as recent alluvium. Thickness about 500 feet.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 106. Replaced by Montezuma formation; name Pittsburg preoccupied.

Occurs in upper San Francisco Bay region.

**Pittsburg Bluff Formation**

Pittsburg Bluff Sandstone[1]

Oligocene: Northwestern Oregon.

Original reference: L. G. Hertlein and C. H. Crickmay, 1925, Am. Philos. Soc. Proc., v. 64, no. 2, p. 254.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 112–113. Term Pittsburg Bluff sandstone originally was intended to include the fossiliferous beds at town of Pittsburg. This stratigraphic horizon is probably near middle of Oligocene section exposed in Columbia County. Total thickness of middle Oligocene between Pittsburg and Clatskanie, approximates 4,000 feet. Seems desirable that term Pittsburg Bluff formation be applied to entire middle Oligocene sequence in county and that type section be considered along Nehalem River, between Pittsburg and Mist. Overlies Keasey formation. Also referred to as Pittsburgh Bluff.

W. C. Warren and Hans Norbisrath, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 220 (table 1), 228–231. Formation, in upper Nehalem River basin, consists of firm, sparingly fossiliferous, tuffaceous sandstone and shale with beds of fine-grained white tuff; stratified cross-bedded sandstone with pebble bands and carbonaceous material; massive loosely consolidated brown-weathering medium-grained concretionary sandstone; gray fine-grained fossiliferous sandstone with calcareous beds. Thickness 700 to 850 feet. Disconformably underlies Scappoose formation (new); overlies Keasey formation; actual contact not observed, evidence suggests unconformity with angular discordance of several degrees. Middle Oligocene.

Named for exposures at Pittsburg Bluff, Columbia County.

Pittsburgh clay member

Pennsylvanian (Conemaugh Series): Eastern Ohio.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 65. Subjacent to Pittsburgh (No. 8) coal is a thin zone of clay or clay shale known as the Pittsburgh clay member; overlies Upper Pittsburgh limestone member. Top of this clay marks top of Conemaugh series in Ohio. Thickness 1 inch to 4½ feet.

Well exposed in Union Township, Morgan County.

Pittsburgh cyclothem

Pennsylvanian (Monongahela Series); Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 161–166. Lowest cyclothem in Monongahela series. Succeeded by Upper Pittsburgh cyclothem (new). In normal successsion, includes seven members (ascending): Lower Pittsburgh (Bellaire) shale and (or) sandstone, Lower Pittsburgh redbed, Upper Pittsburgh limestone, Pittsburgh underclay and shale, Pittsburgh (No. 8) coal, roof shale, and Pittsburgh "rider" coal. Thickness about 40½ feet. In area of this report, Monongahela series is discussed on a cyclothemic basis; 12 cyclothems are listed (ascending): Pittsburgh, Upper Pittsburgh, Redstone, Fishpot, Lower Sewickley, Sewickley, Benwood, Arnoldsburg, Lower Uniontown, Uniontown, Little Waynesburg, and Waynesburg.

Present in Athens County. Members of cyclothem are named from Pittsburgh (No. 8) coal, which was first described from exposures in Pittsburgh, Pa., area, but was formerly referred to in Athens County as Federal Creek coal bed.

†Pittsburgh Limestone (in Conemaugh Formation[1] or Group)

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology of Pennsylvania, v. 2, pt. 1, p. 628–635.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 34, 48. Pittsburgh limestone, first named by Rogers for its occurrence immediately below the Pittsburgh coal seam in western Pennsylvania and generally known as Upper Pittsburgh limestone in West Virginia, is widely distributed across southeastern Ohio. Member may consist of a single irregular layer of limestone separated from base of Pittsburgh coal by thin bed of clay, nodular limestone embedded in clay or clay shales, or several layers of limestone interstratified with calcareous argillaceous shale. Thickness of limestone and associated beds ranges from 2 feet to more than 20 feet, but the usual thickness is 4 or 5 feet. Conemaugh series.

M. N. Shaffner, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 141. Shown on columnar section as Pittsburgh limestone in Conemaugh group. Above Clarksburg coal and below Pittsburgh coal.

Named for its occurrence immediately below Pittsburgh coal in western Pennsylvania.

Pittsburgh Member (of Monongahela Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

Pittsburgh Red Beds, Red Shale, or Reds (in Conemaugh Formation[1] or Group)

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

[Original reference] (Pittsburgh red shale): I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 263–265.

M. T. Sturgeon, 1958, Ohio Geol. Survey Bull. 57, p. 130. Widespread variegated clays and shales occur at many places in Maryland, Ohio, Pennsylvania, and West Virginia in interval between Portersville (Friendsville) shale and limestone and Ames limestone. Thicknesses range up to 50 or even 100 feet. To these beds in Ohio, Condit (1912) gave name Round Knob. Elsewhere in northern Appalachian region these shales and clays are known as Pittsburgh red shale or redbed, a name given by White (1903) and a name which Condit deems unsatisfactory because of previous and general use of Pittsburgh for No. 8 coal and for its underlying limestone. Condit's opinion is valid, and name Round Knob is used for these beds in Ohio.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 69 (fig. 4). Pittsburgh redbed shown on generalized columnar section for Pennsylvanian of western Pennsylvania above Saltsburg sandstone and below Harlem coal. Conemaugh group.

Named for exposures along grade lines of many railroads at Pittsburgh, Pa.

Pittsburgh (Lower) Sandstone (in Conemaugh Formation)[1]

*See* Lower Pittsburgh Sandstone (in Conemaugh Formation)

**Pittsburgh Sandstone Member** (of Monongahela Formation)[1]

Pittsburgh sandstone member

Upper Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology of Pennsylvania, v. 2, pt. 1, p. 503–507.

Wilber Stout, 1954, Ohio Geol. Survey Open File Rept. 1, p. 26–27. Described in Ohio as Pittsburgh or Upper Pittsburgh sandstone member of Monongahela series. Scattered in its occurrence in eastern Ohio. Where best developed, it is gray to drab, medium fine in texture, and commonly marked by crossbedding planes.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 19. Upper Pittsburgh sandstone listed in summary of stratigraphic section of Monongahela formation in Harrison County. Thickness as much as 15 feet. Underlies Redstone limestone and overlies unnamed limy shale above Pittsburgh coal.

First described in Greene County, Pa.

†Pittsburgh Series[1]

Pennsylvanian: Central western Pennsylvania.

Original reference: H. D. Rogers, 1839, Pennsylvania Geol. Survey 3d Ann. Rept., p. 88–108.

G. H. Ashley, 1945, Jour. Geology, v. 53, no. 6, p. 374–389; M. N. Shaffner, 1946, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 55, p. 48, pl. 4. Discussion of Pittsburgh-Pottsville boundary. Pittsburgh series is equivalent to Monongahela, Conemaugh, and Allegheny groups.

Named for exposures in vicinity of Pittsburgh, Allegheny County.

Pittsburgh Underclay

Pittsburgh underclay and shale member

Pennsylvanian (Conemaugh Series): West Virginia and eastern Ohio.

J. B. McCue and others, 1948, West Virginia Geol. Survey, v. 18, p. 12. Pittsburgh underclay is topmost member of Conemaugh series. Thickness 2 to 12 feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 163. Pittsburgh underclay and shale member of Pittsburgh cyclothem in report on Athens County. Average thickness about 2 feet. Above Upper

Pittsburgh limestone member and below Pittsburgh (No. 8) coal member. Monongahela series.

Probably named for association with Pittsburgh coal.

Pittsfield Member of (of Littleton Formation)

Lower Devonian : Northern New Hampshire.

M. T. Heald, 1955, The geology of the Gilmanton quadrangle, New Hampshire: New Hampshire State Plan. Devel. Comm., p. 8, 10 (table 1), geol. map. Oldest unit of Littleton formation in Gilmanton quadrangle. Coarse-grained schists and gneisses. Underlies Jenness Pond member (new).

Good exposures at Sabattus Heights and along Pleasant Street in Loudon.

**Pittsford Shale** (in Salina Group)

Pittsford Shale Member (of Salina Formation)[1]

Upper Silurian : Western to east-central New York.

Original reference: J. M. Clarke, 1908, New York State Mus. Bull. 69, p. 867.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Pittsford shale at base of Salina group, Cayugan series. Underlies Vernon shale.

R. E. Griswold, 1951, New York State Water Power and Control Comm. Bull. GW–29, p. 10. Salina formation consists of (ascending) Pittsford shale, Vernon shale, Syracuse salt, Camillus shale, and Bertie limestone members. Of these, only the Vernon and Camillus have been recognized in Wayne County.

D. W. Fisher, 1957, New York State Mus. Bull. 364, p. 6, 11. Discussion of Vernon formation in its type locality. Name Pittsford shale is suppressed. It is not a widespread, clearly recognizable mapping unit. This discontinuous occurrence of greenish-black shale above Lockport dolomite is included within the Vernon.

Named for exposures in excavations in Erie Canal near Pittsford, Monroe County.

Pittsford Valley Dolomite

Cambrian : West-central Vermont.

G. W. Bain, 1938, New England Intercollegiate Geol. Assoc. [Guidebook] 34th Ann. Field Mtg., p. 8. Chiefly dolomite with about 30 percent graywacke beds occurring in cyclic series. Graywacke zones are about 10 feet thick and have buff-weathering dolomite "spacers" between. Thickness 800 feet. Overlies Florence dolomite (new).

Occurs in central Vermont marble belt, Rutland County.

Piutean series[1]

Pliocene : California.

Original reference : C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 80.

Well exposed under Piute Point, in Furnace Canyon, east of Death Valley, Inyo County.

**Placer Creek Formation**

Pleistocene : Southeastern Utah.

G. M. Richmond, 1956, Dissert. Abs., v. 16, no. 6, p. 1128. Consists of two members that comprise nine lithofacies, including till and various alluvial. colluvial, and eolian deposits. Till forms two sets of lower canyon end moraines. Weakly developed Porcupine Ranch soil is formed on lower member where it is overlain by the upper member. Moderately developed Castle Creek soil is formed on upper member and on deposits of lower member not overlain by the upper member. Older than Beaver basin formation (new); younger than Harpole Mesa formation (new).

Located in La Sal Mountains area.

Placerita Formation[1]

Pre-Cretaceous: Southern California.

Original reference: W. J. Miller, 1934, California Univ. at Los Angeles Pub. in Math. and Phys. Sci., v. 1, no. 1, p. 3–12, 63–65, 83, map.

G. B. Oakeshott, 1937, California Jour. Mines and Geology, v. 33, no. 3, p. 220–223, pl. 3. Crystalline limestone; graphite, biotite, sillimanite, and tremolite schist; quartzite and schistose conglomerate. No estimate of thickness in Little Tujunga quadrangle; at least 5,000 feet in Placerita Canyon district. Intruded by Rubio diorite. Carboniferous(?).

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 22 (fig. 2), 50–52, pls. 1, 2. Mapped as pre-Cretaceous. Intruded by Upper Jurassic(?)-Lower Cretaceous(?) granitic rocks. Occurs south of San Gabriel fault.

Named for exposures in Placerita Canyon, at west end of San Gabriel Mountains.

†Placer Mountain Group[1]

Upper Cretaceous: Central northern New Mexico.

Original reference: F. V. Hayden, 1869, U.S. Geol. and Geog. Survey Terr. 3d Ann. Rept. p. 90, 190.

Occurs in Placer Mountain, about 30 miles south of Santa Fe, Santa Fe County.

**Placid Shale Member** (of Brad Formation)[1]

Placid Formation

Placid Shale (in Brad Group)

Upper Pennsylvanian: Central Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 109–110, 115; 1922, Jour. Geology, v. 30, p. 24, 31, 35.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 111. Cedarton shale and Winchell member (including Clear Creek limestone of Drake and lower or limestone-bearing part of Placid shale member of Plummer and Moore) have been found to be included in typical Graford formation. Beds here included in "shale member" of Brad formation represent upper part of Placid shale member of Plummer and Moore.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Brad here raised to group status. Underlies Ranger limestone; overlies Winchell formation.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, April 17–19, p. 51 (columnar section). Shown on columnar section as member of Brad formation. Consists of shale, gray to brownish red to orange red, locally silty and sandy; contains local channel deposits of chert conglomerate and sand, and cherty limestone reefs; includes Corn Creek limestone member of Placid formation of Jenkins (1952, unpub. thesis).

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 66, pl. 27. Jenkins (1952, unpub. thesis) described Placid as a formation and, in

Mercury quadrangle, named persistent limestone beds in unit the Corn Creek limestone member. These beds can be traced north into Brown County to a point about 2 miles west of village of Brookesmith beyond which they are replaced by sandstone and conglomerate. In present report, the Placid is classified as basal member of Brad formation. Underlies Ranger limestone member; overlies Winchell limestone. Thickness 125 to 145 feet along Colorado River; about 95 feet in central and north-central parts of Brown County.

Named for town of Placid, McCulloch County.

Placita Marl[1]

Probably Miocene and Pliocene: Central northern New Mexico.

Original reference: E. D. Cope, 1875, Ann. Rept. Chief Engrs. U.S. Army, Rept. Secy. War to 44th Cong., v. 2, pt. 2, p. 997.

Occurs in region from Zandia [Sandia] Mountains to and beyond village of Placita [now Placitas], Sandoval County.

Placitos limestone[1]

Pennsylvanian: Central northern New Mexico.

Original reference: C. R. Keyes, 1903, Ores and Met., v. 12, p. 48.

In Sandia Mountains. Derivation of name not stated.

Plainfield Quartz Schist[1] or Quartzite

Plainfield Quartz Schist Member (of Putnam Series)

Pre-Triassic: Eastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 114, 132, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 69, pl. 1. Rank reduced to member. Occurs near base of Putnam series which is probably Precambrian in age.

John Rodgers and others, 1956, Preliminary geologic map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Includes local occurrences of fine-grained feldspathic gneiss which grades into aplitic phase of Sterling granitic gneiss. Pre-Triassic. Derivation of name stated.

C. B. Sclar, 1958, Connectcut Geol. Nat. History Survey Bull. 88, p. 10. Not mapped as separate unit in New London County.

R. M. Perhac, 1958, Connecticut Geol. Nat. History Survey Bull. 89, p. 8–9, pls. Plainfield quartzite described in Voluntown and Oneco quadrangles. Varies in texture and composition from fine-grained muscovite-quartz schist to fine-grained massive quartzite. Latter is definitely more abundant type. Bedding visible in many areas. Maximum possible thickness about 2,000 feet.

Named for town of Plainfield, Windham County.

†Plainfield Schist[1]

Ordovician: Western Massachusetts.

Original reference: R. Pumpelly, 1894, U.S. Geol. Survey Mon. 23, p. 29–30.

Named for occurrence in Plainfield Township.

†Plains Marl[1]

Miocene, Pliocene, and Pleistocene: Western Kansas.

Original reference: R. Hay, 1893, Kansas State Bd. Agric. 8th Bienn. Rept., p. 101.

J. C. Frye, 1952, Kansas Geol. Survey Bull. 99, p. 110. Listed with locally named units which are properly classed at least in part as Sanford formation.

Occurs on High Plains of western Kansas.

†Plains Series[1]

Pleistocene: Nebraska.

Original reference: A. L. Lugn, 1935, Nebraska Geol. Survey Bull. 10, 2d ser., p. 128, etc., charts.

A. L. Lugn, 1939, Am. Jour. Sci., v. 237, no. 12, p. 853 (fig. 1), 854. Surface of loess plain of south-central Nebraska, an area of more than 8,000 square miles, west of the till-covered area is underlain by yellowish Peorian loess and the Loveland formation (the Plains series), which increase in total thickness westward to a maximum of about 300 feet.

**Plainview Sandstone Member** (of South Platte Formation)

Lower Cretaceous: North-central Colorado.

K. M. Waagé, 1955, U.S. Geol. Survey Prof. Paper 274–B, p. 28–30, figs. 10, 11, 17, 19. Persistent unit which forms characteristic brown- to rusty-brown-weathering ledge of markedly tabular cross-laminated sandstone. Includes the black shale and conglomerate at the base of the formation. Thickness about 45 feet. Basal member of South Platte formation (new); disconformably overlies Lytle formation.

Named for exposures which occur in cut of Denver and Salt Lake Railroad (Moffat Tunnel Route) through the Dakota hogback at Plainview, NE¼NE¼ sec. 12, T. 2 S., R. 71 W., Jefferson County.

Plateau gravel phase[1]

Quaternary: Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 29, 35–42, 188.

Plateau Valley Beds[1]

Paleocene: Central western Colorado.

Original reference: B. Patterson, 1936, Geol. Soc. America Proc. 1935, p. 397.

G. G. Simpson, 1937, Cambridge Philos. Soc. Biol. Rev., v. 12, no. 1, p. 9 (footnote). Name Plateau Valley has been applied by Patterson to Paleocene part of the Ruby formation.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 28, pl. 1. Paleocene, Tiffanian. Member (?) of DeBeque formation.

C. L. Gazin, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 134 (fig. 1). Chart shows Plateau Valley beds in lower part of DeBeque formation. Tiffanian.

First mentioned in Mesa County.

Platte channel facies (of North Park Formation)

Miocene, upper: Central northern Colorado.

J. de la Montagne and W. C. Barnes, 1957, Rocky Mountain Assoc. Geologists Guidebook to geology of North and Middle Parks Basin, Colorado, p. 58, fig. 2. Crossbedded conglomerate and sandstone comprised mostly of rounded fragments of Precambrian rock and fragments of volcanic flow-rock. Angular fragments only rarely present. Although individual strata of this material not persistent for more than a few hundred yards along the valley, the mean size grade of volcanic fraction increases southward, passing from grit size at north end of valley to boulder size 60 miles to south near Independence Mountain. Interbedded with overbank facies of North Park formation in central part of valley.

Restricted to central parts of Saratoga Valley in North Park area.

†Platte Series[1]

Upper Cretaceous: From Rocky Mountains eastward.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 49.

Occurs in area of that segment of North American Interior Plateau which extends from Rocky Mountains eastward and constitutes the higher part of the Plains. Named for Platte River, which, in Colorado and Nebraska, cuts all divisions of the series.

†Platte Series[1]

Pleistocene: Nebraska.

Original reference: A. L. Lugn, 1935, Nebraska Geol. Survey Bull. 10, 2d ser., p. 88+, charts.

A. L. Lugn, 1939, Am. Jour. Sci., v. 237, no. 12, p. 853 (fig. 1). Shown on Pleistocene geologic map of Nebraska.

Platte shale[1]

Pennsylvanian: Southwestern Iowa and northwestern Missouri.

Original reference: C. R. Keyes, 1898, Am. Geologist, v. 21, p. 349.

Well exposed along Platte River of northwest Missouri. Named for exposures at mouth of Platte River at Nebraska-Iowa boundary.

Platte River Formation[1]

Upper Cretaceous or Eocene: Nebraska.

Original reference: H. Engelmann, 1876, Engr. Dept. U.S. Army, J. H. Simpson's Expl. of Great Basin of Terr. Utah, p. 247, 282–284.

On North Fork of Platte River.

**Platteville Limestone[1] or Formation**

Platteville Dolomite or Group

Middle Ordovician: Southwestern Wisconsin, northwestern Illinois, eastern Iowa, and southern Minnesota.

Original reference: H. F. Bain, 1905, U.S. Geol. Survey Bull. 246, p. 18–19.

C. A. Bays, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 269. Formation subdivided to include Mifflin limestone member which overlies Pecatonica member and underlies Magnolia member.

A. F. Agnew and A. V. Heyl, Jr., 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 9, p. 1585–1588. Formation subdivided to include Quimbys Mill member which overlies McGregor member and underlies Spechts Ferry shale member of Decorah formation.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, 10–11 (fig. 3). Considered a group in Dixon-Oregon area, Illlinois, where it includes (ascending) Pecatonica, Mifflin, Grand Detour (new), Nachusa (new), and Quimbys Mill formations, Underlies Galena group; overlies Ancell group (new).

M. P. Weiss and W. C. Bell, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 57–64. Restricted below to exclude Glenwood shale herein given formation status. In southeastern Minnesota, includes (ascending) Pecatonica, McGregor, and Carimona members. In Twin City area, includes Mifflin, Hidden Falls (new), and Magnolia members; McGregor is used where these three latter units are absent or insufficiently distinct to permit use of their names.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 274–285. In zinc-lead district of Wisconsin, Illinois, and Iowa, formation includes (ascending) Glenwood shale, Pecatonica dolomite, McGregor limestone, and Quimbys Mill members. At reference section in roadcut, U.S. Highway 151, NW¼NE¼ sec. 12, T. 2 N., R. 2 W., Grant County, Wis., formation is about 54 feet thick. In eastern part of mining district and farther east, strata of Platteville, Decorah, and Galena age are dolomite, and gross lithology of the three formations is somewhat similar. This eastern area is the type for Sardeson's (1896) Beloit formation. However, since term Beloit has been virtually forgotten and terms Platteville and Decorah have been used consistently since 1906, they are retained in this report.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1030–1033. Described in Fillmore County, Minn.

Reference section: Roadcut U.S. Highway 151, NW¼NE¼ sec. 12, T. 2 N., R. 2 W., Grant County, Wis.

†Platteville Stage[1]

Ordovician: Iowa.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 84.

Plattford Formation (in Scranton Shale)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 41, 58.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 30. Cotype locality designated. Here Plattford section is about 14 feet thick and includes the Vinland shale member. Westphalia limestone member is missing, and Tonganoxie sandstone member is recorded in the subsurface. Underlies Cass formation; Vinland shale in its outcrop areas in Cass County rests unconformably on the Stanton formation.

Type locality: In Platte River bluffs in west part of Plattford Township, Sarpy County. Cotype locality: In first and second Burlington quarries located northwest of South Bend, Cass County.

**Plattin Limestone[1]**

Plattin Group

Middle Ordovician: Eastern Missouri, central northern Arkansas, and western Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, v. 2, 2d ser., p. 111.

E. O. Ulrich, 1939, Kansas Geol. Survey Guidebook 13th Ann. Field Conf., p. 105–109. In sections near Cape Girardeau overlies Murfreesboro; underlies Kimmswick. Black River group.

J. G. Grohskopf, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 3, p. 351–365. Name Rock Levee proposed for rocks which underlie basal Plattin oolitic and conglomeratic limestone and overlie a chert zone which occurs in the "Joachim" dolomite. Thus, it restricts the "Plattin" and "Joachim" and contains a part of each. Overlapped by "Decorah".

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2041–2075. Rank raised to group. Comprises (ascending) Bloomsdale, Beckett, Hager, and Macy formations (all new). Overlies Rock Levee formation; underlies Decorah formation. Thins northward from about 400 feet at Cape Girardeau to about 125 feet in southern Lincoln County. Has been classified as Bolarian, Black River in age, and correlated with the Platteville of upper Mississippi Valley. Faunules from upper Macy suggest those beds are lower Trentonian. Lower formations resemble Bolarian.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 116. Underlies Barnhart formation (new).

Named for exposures near mouth of Plattin Creek, Jefferson County, Mo.

†Plattsburg Group[1]

Pennsylvanian: Northwestern Missouri.

Original reference: G. C. Broadhead, 1868, St. Louis Acad. Sci. Trans., v. 2, p. 317, 327.

Named for exposures at Plattsburg, Clinton County.

**Plattsburg Limestone** (in Lansing Group)[1]

Plattsburg Limestone Member (of Lansing Formation)[1]

Pennsylvanian (Missouri Series): Northwestern Missouri, eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: G. C. Broadhead, 1868, St. Louis Acad. Sci. Trans., v. 2, p. 317, 327.

N. D. Newell, 1935, Kansas Geol. Survey Bull. 21, p. 70–75. Includes (ascending) Merriam limestone, Hickory Creek shale, and Spring Hill limestone members. Basal formation of Lansing group; underlies Vilas shale; overlies Bonner Springs shale of Kansas City group.

Above is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 33–34. Thickness of formation 10 to 12 feet in Nebraska; 20 feet in Missouri; 20 to 24 feet in Kansas.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. Thickness of formation about 15 feet in Iowa. Members not recognized with certainty. Underlies Vilas formation; overlies Bonner Springs formation. Lansing group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 24, fig. 5. Formation in Lansing group. Exposed only in western Madison County where it is a highly fossiliferous gray to maroon nodular fine-grained algal limestone with interbedded red and green shale. Thickness about 4 feet. Overlies Bonner Springs shale; underlies Vilas shale.

Named for exposures at Plattsburg, Clinton County, Mo.

**Plattsmouth Limestone[1] Member** (of Oread Limestone)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

Original reference: C. R. Keyes, 1898, Am. Geologist, v. 21, p. 349, 350.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 149.

Plattsmouth limestone member of Oread formation; underlies Heumader shale member; overlies Leavenworth limestone member. This classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 419. Thickness about 5½ feet in measured section near Winterset, Madison County; consists of blue-gray uneven beds separated by thin shales, some black chert; lower 1 foot a persistent massive bed.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 41, pl. 1. Thickness about 18 feet in Douglas County where it is composed almost entirely of light-gray to nearly white wavy-bedded limestone which weathers a light gray to tan; scattered blue-gray chert nodules persistent near middle of bed.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 20–21, fig. 5. As exposed in quarries in Montgomery County, includes thin upper cherty limestone, thick section of shaly limestone containing abundant fusulinids, and lower unit containing less shale and fewer fusulinids. Thickness about 20 feet. In Cass County, thickness is about 13 feet and includes (descending) about 2 feet of thin-bedded limestone; 3 to 4 feet of fusulinid-bearing argillaceous limestone; 4 feet of calcareous olive shale weathering buff and containing abundant *Chonetes*, *Echinoconchus*, *Juresania*, *Neospirifer*, *Composita*, crinoid columnals, and large ramose bryozoans; and 3 feet of argillaceous to sublithographic cherty fossiliferous limestone. In Madison and Adair Counties, includes 4 feet of *Osagia*-bearing wavy-bedded sublithographic limestone, 2 to 3 feet of argillaceous shale, 3 to 4 feet of alternating dark-blue cherty limestone and platy shale, and 1½ feet of massive limestone containing *Ottonosia* at base. Overlies Heebner shale member; underlies Heumader shale member.

Type locality: In Missouri River bluffs in vicinity of Plattsmouth, Cass County, Nebr.

**Playas Peak Formation** (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 534, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 24–25, pl. 1. Sandstone and shale underlain in Eureka section by a basal conglomerate and capped by massive limestones. Basal conglomerate locally bouldery and unsorted. Thickness in Eureka section, where both contacts are disconformable, ranges from 800 to 2,000 feet; in Sylvanite section exposed section between 3,000 and 3,500 feet. In Eureka district, underlies Skunk Ranch conglomerate (new); overlies Corbett sandstone (new). Trinity age.

Named after Playas Peak in Eureka half of Little Hatchet Mountains.

**Pleasant Hill Limestone**[1]

Pleasant Hill Formation

Middle Cambrian: Central Pennsylvania.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 528, 534, 537.

J. L. Wilson, 1952, Geol. Soc. America Bull., v. 63, no. 3, p. 278. Thickness at type locality 600 feet; 350 feet at Williamsburg, upper part of section exposed; sandy layers, some siltstone and shale occur rather high in section. Underlies Warrior limestone.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation.

Named for exposures of upper part at Pleasant Hill Church, 1 mile northwest of Henrietta, Blair County.

Pleasant Lake Gabbro

Precambrian: Northeastern New York.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 59, 61. A folded sheet in limestone. Zone of basal contact with limestone is strongly injected by granitic pegmatite to form an arteritic migmatite. Intruded by a sheet of syenite in northern and uppermost part, as now exposed.

Crops out in an oval area about 2½ miles long and 1 mile wide just southeast of Pleasant Lake in Hammond quadrangle.

**Pleasanton Formation[1] or Group[1]**

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and northeastern Oklahoma.

Original references: E. Haworth, 1895, Kansas Univ. Quart., v. 3, p. 274, pl. opposite p. 290; 1895, Am. Jour. Sci., 3d, v. 50, p. 457, pl. opposite p. 466.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, p. 20, 25–26, pl. 5. Upper boundary of Henrietta group has been placed at approximate position of unconformity which separates the Des Moines and Missouri, and base of Pleasanton group has been raised to correspond. Underlies Hertha limestone of Kansas City group. Thickness 100 to 200 feet.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 26–27 (fig. 2). Thins northward from Missouri into Appanoose County, Iowa.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Columnar section, Jackson and Cass Counties, Mo., shows Pleasanton group comprises (ascending) Warrensburg channel sandstone, Sni Mills limestone, Dawson coal horizon, Wayside sandstone, Exline limestone, and Knobtown sandstone. Thickness 120 to 262 feet. Overlies Henrietta group; underlies Kansas City group.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2028, 2031 (fig. 4). According to interstate agreement, lowermost deposits of Missourian age, mostly clastic in nature, are to be called Pleasanton, a name first applied in stratigraphic sense by Haworth (1895) for rocks between uppermost Pawnee limestone and base of Hertha formation. Pleasanton was similarly used in Missouri until 1938 (McQueen and Greene) when it was revised to exclude Desmoinesian strata. In Kansas (Moore, 1932) and Nebraska (Condra, 1935), name was dropped. Now accepted definition, which was first used by McQueen and Greene, precisely corresponds to Bourbon formation or group as recognized in Kansas and Nebraska. Name Bourbon will be suppressed. Overlies Marmaton group; underlies Kansas City group.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 69–74. Group includes Hepler sandstone at base, Checkerboard limestone, and some massive sandstones known collectively as Knobtown sandstone. Thickness 35 to 150 feet along outcrop in Kansas.

C. M. Cade 3d, 1953, Tulsa Geol. Soc. Digest, v. 21, p. 130–133. Boundary between Missouri series and Des Moines series in area investigated [Nowata and Craig Counties, Okla.] is marked by erosional unconformity, with Seminole formation lying unconformably on Lenapah limestone. Two members of Pleasanton group, Checkerboard and Seminole were mapped.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 28–29, fig. 5. Group composed primarily of shale with some sandstone, thin limestones, and minor amounts of coal. Not subdivided into formations although distinctive units such as Exline limestone and Ovid coal are recognized. Top of Des Moines series is an erosional surface; hence, thickness of Pleasanton varies considerably. Thickness 19 feet in Madison County. Upper boundary at base of Hertha limestone.

Named for exposures at Pleasanton, Linn County, Kans.

**Pleasants Sandstone Member** (of Williams Formation)

Upper Cretaceous: Southern California.

W. P. Popenoe, 1937, Jour. Paleontology, v. 11, no. 5, p. 380. Named as upper member of Williams formation (new). Consists of light-colored shaly sandstones with intercalated beds of limy fossiliferous sandstone. Approximate thickness 320 feet. Unconformably underlies Eocene Martinez(?) formation; overlies Schulz member (new).

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166, 168 (fig. 2), 175. Member discontinuous in its distribution, being cut out of the section in many places by faulting and by overlap. Derivation of name given.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Shown on stratigraphic sections as underlying Silverado formation (new). In this report, name Schulz member has been altered to Schulz Ranch sandstone member.

Named for Pleasants Ranch at mouth of Williams Canyon, northern Santa Ana Mountains, Orange County.

Pleasant Valley Member (of Cuyahoga Formation)

Mississippian (Kinderhook): Central Ohio.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172. Included in Toboso conglomerate facies of the formation.

F. T. Holden, 1942, Jour. Geology, v. 50, no. 1, p. 48. Essentially a gray buff shale, about 16 feet thick, containing thin layers of medium-grained sandstone; base seldom exposed. Along Licking River, east of Newark, about 15 feet are exposed; here consists of massive tan siltstone, grading to tan and gray arenaceous shale with lenses of medium-grained sandstone. Underlies Black Hand conglomerate member. Derivation of name stated.

Named from exposures northwest of Pleasant Valley School on north valley wall of tributary of Clear Fork in SW sec. 5, T. 20 N., R. 19 W., Richland County.

**Pleasant View Complex**

Paleozoic and Mesozoic: Southern California.

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Name applied to a complex of deep-seated igneous intrusive and metamorphic rocks, some of which may be metasediments. Prevailing rocks are dark-gray quartz diorite gneiss and metadiorite. In large part probably represent San Gabriel complex.

Type locality: Pleasant View Ridge, Valyermo quadrangle.

Pleasant View Member (of Arapahoe-Denver Formation)

Tertiary: North-central Colorado.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 100 (fig. 23), 103–104, 105. Sediments vary from poorly bedded clays to arenaceous shales with occasional lenticular beds of gray friable medium- to coarse-grained sandstones, which are best developed in lower third. Dominantly light gray. Sandstones suggest channel deposits by their cross-laminated and poorly sorted composition. Thickness averages about 113 feet on Table Mountains. Base corresponds to Cretaceous-Tertiary boundary, and is marked by distinct color change from tan to light brown. Underlies Golden member (new).

Type section: On eastern extremity of South Table Mountain; NW¼ sec. 31, T. 3 S., R. 69 W., Morrison quadrangle. Recognized only on slopes of the Table Mountains, Jefferson County.

Pleasantview Sandstone Member (of Carbondale Formation)[1]

Pleasantview Sandstone (in Carbondale Group)

Pennsylvanian: Western and northern Illinois.

Original reference: H. R. Wanless, 1929, Illinois Geol. Survey Bull. 57, p. 49, 90–91, 124.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 95, 98, 190. Consists of two types: channel sandstone and nonchannel or sheet sandstone. Nonchannel ranges in thickness from 2 or 3 to 15 or 20 feet and is commonly very fine grained and blue gray or yellow gray. Major part of channel sandstones consists of lenticular massive beds, alternating with thin shaly beds. Thickness as much as 80 feet. In some areas, channel sands rest unconformably on all beds down to Colchester (No. 2) coal. Included in Summum cyclothem, Carbondale group. Name credited to W. V. Searight (unpub. ms.). Type exposure given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), 66, pl. 1. Assigned member status in Carbondale formation (redefined). Occurs above Purington shale member and below Kerton Creek coal member (new). Thickness about 18 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type exposure: Mill Creek, sec. 36, T. 2 N., R. 1 W., and sec. 31, T. 2 N., R. 1 E., vicinity of Pleasantview, Beardstown quadrangle, Schuyler County.

†Pleito Formation[1]

Oligocene and Miocene: Southern California.

Original reference: C. M. Wagner and K. H. Schilling, 1923, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 14, p. 235–252.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, fig. 14. Chart shows Pleito as occurring in upper Refugian and lower Zemorrian stages; thus, age is Oligocene and lower Miocene.

Exposed on Pleito Creek, Kern County.

Plum Bentonite (in Manning Formation)

Eocene: Central Texas.

H. B. Stenzel, 1953, Am. Assoc. Petroleum Geologists Guidebook Field Trips Houston Mtg., p. 45, 46. Name applied to bentonite bed in Manning formation. Thickness 1½ feet. Bentonite can be traced as separate lenses southwestward for 50 miles to region of Hells Gate on Guadalupe River in Gonzales County.

Named for occurrence in vicinity of village of Plum, Fayette County.

Pluma Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. and Min. Jour.-Press, v. 115, p. 793–799, 836–843, maps.

E. P. Rothrock, 1944, South Dakota Geol. Survey Bull. 15, p. 24. In vicinity of Homestake mine, consists of alternating beds of garnet schist and carbonaceous slates, some of which are pyritiferous. Thickness 4,000 feet. Overlies Garfield formation.

Named for exposures near Pluma, about 1½ miles east of Lead, Lawrence County.

Plumas Series[1]

Lower, Middle, and Upper Jurassic: Northern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, table opposite p. 217.

Plumas County.

**Plumb Shale Member** (of Wood Siding Formation)

Pennsylvanian (Virgil Series): Eastern Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Defined to include strata between Nebraska City limestone below and Grayhorse limestone above. Thickness at type locality about 20 feet; average thickness across Kansas 13 feet. Name credited to M. R. Mudge and R. H. Burton (work in preparation).

Type locality: In an east-west roadcut in SW¼SE¼SE¼ sec. 30, T. 14 S., R. 13 E., about 1½ miles west of Harveyville, Wabaunsee County. Name derived from Plumb Township.

Plum Brook Shale

Devonian: Northern Ohio.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 181. Proposed to replace Plum Creek shale of Grabau, 1917 (not Foerste, 1905, or Ulrich, 1917). Grabau derived his name from Plum Brook, 2 miles northeast of Prout Station, Sandusky quadrangle, but erroneously recorded the name as Plum Creek. The more accurate designation is therefore substituted.

E. C. Stumm, 1942, Jour. Paleontology, v. 16, no. 5, p. 549. Soft gray shale containing thin bands of argillaceous limestone. Exposed thickness (upper part) 20 feet; in wells 40 to 60 feet. Underlies Prout limestone.

K. V. Hoover, 1960, Ohio Geol. Survey Inf. Circ. 27, p. 8–15. Stratigraphic position and correlation of Olentangy shale discussed in detail. Here suggested that the Olentangy, Plum Brook shale, Prout limestone, Silica shale, and Ten Mile Creek are stratigraphically correlatable, with the reservation that the Olentangy is probably Upper Devonian. At various times and by different authors, the Plum Brook shale has been correlated with the Olentangy, and the so-called Prout limestone has been regarded as member of Olentangy. Olentangy stratigraphic interval is represented by Prout limestone and Plum Brook shale in northern Ohio. Regional information regarding thickness of Plum Brook shale-Prout limestone has not been worked out. Combined thickness of 36 feet of Plum Brook and Prout has been reported in outcrop area in Erie County. Eastward, this interval is represented by Plum Brook shale which has been reported to be 142 feet thick. Plum Brook is in apparent conformable contact with Huron shale.

Type locality: On Plum Brook, near Prout Station, Sandusky quadrangle, Erie County.

†Plum Creek Beds (in Chester Group)[1]

Mississippian: Southwestern Illinois.

Original reference: E. O. Ulrich, 1917, Mississippian formations of western Kentucky: Kentucky Geol. Survey, pt. 2, p. 44, 56, 230, pl. D.

J. M. Weller *in* Stuart Weller and J. M. Weller, 1939, Illinois Geol. Survey Rept. Inv. 59, p. 12; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 837. Name Baldwin formation proposed for preoccupied Plum Creek beds.

Occur in Randolph County.

Plum Creek Clay[1]

Plum Creek Member (of Brassfield Formation)

Silurian (Niagara): East-central Kentucky.

Original references: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145; 1906, Kentucky Geol. Survey Bull. 7, p. 10, 44, 61.

E. B. Branson and C. C. Branson, 1947, Jour. Paleontology, v. 21, no. 6, p. 549, 550 (fig. 1). Reallocated to member status in Brassfield formation. Underlies Oldham limestone; overlies dolomitic limestone in Brassfield formation.

Named for Plum Creek, Powell County.

Plum Creek Shale[1]

Middle Devonian: Northern Ohio.

Original reference: A. W. Grabau, 1917, Jour. Geology, v. 25, p. 337–343.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 181. Name Plum Brook shale proposed to replace Plum Creek shale. Grabau derived his name from Plum Brook, 2 miles northeast of Prout Station, Sandusky quadrangle, but erroneously recorded name as Plum Creek.

Locality is in Erie County.

**Plummer Limestone Member** (of Pawhuska Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: D. E. Winchester, 1918, U.S. Geol. Survey Bull. 686–C, p. 11–12.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 49–50. In Tps. 27, 28, and 29 N., northern Osage County, the Pawhuska is about 150 feet thick and contains six named limestone members (ascending): Lecompton, Plummer, Deer Creek, Little Hominy, Pearsonia, and Turkey Run. The Plummer limestone was not found south of center of sec. 35, T. 23 N., R. 7 E.

Named for exposures near house on Plummer Ranch, T. 26 N., R. 9 E., Osage County.

Plummer Hollow Mudstone Member (of Juniata Formation)

Upper Ordovician: Central Pennsylvania.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geology Contr. 3, 58 p. Consists of red silty mudstone with interbeds of red siltstone and sandstone. Overlies East Waterford red sandstone and shale member (new); underlies Run Gap red sandstone member. Thins eastward, and, at Waggoners Gap, beds lithologically referable to Plummer Hollow are not present and instead are about 360 feet of red sandstones of type that forms East Waterford member. [Swartz refers to his 1955 report *in* Pennsylvania Geologists Guidebook 21st Ann. Field Conf. Compiler was unable to locate this reference.]

Named for Plummer Hollow, in vicinity of Tyrone Gap.

**Plum Point Marl Member** (of Calvert Formation)[1]

Miocene, middle: Eastern Maryland.

Original reference: G. B. Shattuck, 1904, Maryland Geol. Survey, Miocene Volume, p. lxxiv.

Lincoln Dryden and R. M. Overbeck, 1948, Maryland Dept. Geology, Mines and Water Resources [Repts.] Charles County, p. 56–57. Upper member of formation. Overlies Fairhaven [diatomaceous earth] member; contact believed to occur just below oyster bed near south end of Calvert Cliffs. Contact with Choptank formation not definitely recognized, but it lies somewhere between Shattuck's "zones" 13 and 17. Thickness at least 50 feet and probably as much as 75 feet. Member believed to be present in Charles County near Hughesville, about 13 miles east of La Plata. Unit referred to here as Plum Point marls.

Named for Plum Point, Calvert County.

Pluto Limestone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 295, 334.

Named for association with Pluto coal in Summers County.

Pluto Shale (in Hinton Formation)[1]

Mississippian: Southern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1920, West Virginia Geol. Survey Rept. Webster County, p. 214, 219–220.

Occurs in Mercer and Summers Counties, W. Va., and in Tazewell County, Va.

**Plutos Cave Basalt**

Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 42–44, pl. 1. Uniform black vesicular olivine-rich augite basalt with fairly smooth crust marked by gentle swells and hollows. Oval schollendomes, a few feet to 20 feet high, scattered at random over surface of lower half of flow. Evidence concernimg thickness meager; thickest part probably median part that extends northwestward through Pluto's Cave; just north of cave approximately 290 feet of basalt encountered in well; locally may be 400 feet thick. Largest flow of any age in Macdoel quadrangle; seems to have issued from fissures near northeast base of Mount Shasta.

Seymour Mack, 1960, U.S. Geol. Survey Water-Supply Paper 1484, p. 20 (table), 41–43, pl. 1. Constitutes most prolific aquifer in Shasta Valley.

Occupies eastern half of Shasta Valley; covers more than 50 square miles and exceeds 20 miles in length. Named for Pluto's Cave, a large lava tube near its southern end. (Locality named The Caves on Williams' (1949) geol. map, pl. 1.)

Plymouth Conglomerate[1]

Lower Cambrian: Southeastern Vermont.

Original reference: C. H. Richardson, 1931, Vermont State Geologist 17th Rept., p. 220.

In Windham Township, Windham County.

**Plymouth Ferruginous Chert Member** (of Ironwood Iron-Formation)[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: W. O. Hotchkiss, 1919, Eng. Mining Jour., v. 108, p. 501, 502.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 105 (table 10), 106 (table 11), 107 (fig. 3). Underlies Yale member; overlies Palms quartzite. Thicknesses (taken from drill holes) 133 and 154 feet.

Named for Plymouth mine, Gogebic Range, Mich.

Plymouth Granite[1]

Late Paleozoic: Southeastern Vermont.

Original reference: E. L. Perry, 1929, Vermont State Geologist 16th Rept., p. 44–46.

Occurs on south slope of Morrison Hill in Plymouth, Woodstock quadrangle, about one-half mile northwest of Pinney Hollow road and an equal distance due west of Pinney Hollow Schoolhouse, east of road to abandoned Morrison Farm in Windsor County.

**Plymouth Marble**[1]

Plymouth Member (of Grahamville Formation)

Plymouth Member (of Hoosac Formation)

Lower Cambrian: East-central Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

J. B. Thompson, Jr., 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for field trips in New England, p. 41. Rank reduced to member in upper part of Hoosac formation. Has approximately same stratigraphic position as Turkey Mountain member which occurs south of outcrop area of the Plymouth. Cambrian or Lower Ordovician.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 47, 48, tables 2, 3. Reallocated to member status at top of Grahamville formation (new). Includes massive gray dolomite and white vitreous thinly bedded quartzite. Maximum thickness 100 feet, typically 10 to 20 feet. Underlies Pinney Hollow formation. Cambro-Ordovician. Outcrop area mentioned.

Well exposed in lower slopes of Ottauquechee and Black River valleys south of West Bridgewater in Rutland area. Crops out in Plymouth Township, Windsor County.

Plymouth Union Series

Cambrian(?) : Central Vermont.

H. E. Hawkes, Jr., 1941, Geol. Soc. America Bull., v. 52, no. 5, p. 653, 654–656, 657. A local unit consisting of quartz schists, quartzites, quartz conglomerates, and dolomitic marbles. Replaces Mendon series in this area. Clean massive quartzite at base. Several massive dolomite beds in upper part near Plymouth. North of Sherburne includes Sherburne conglomerate. Underlies Pinney Hollow schist with transition zone; overlies Pico Peak series (new).

Type locality: East side of Green Mountain Range in Plymouth and Bridgewater Townships, Windsor County.

**Plympton Formation** (in Park City Group)

Permian: West-central Utah and eastern Nevada.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2181–2184. Permian rocks in Confusion Range, Utah, above the Kaibab limestone are divisible into two formations, the older of which is herein named Plympton formation and the younger Gerster. Defined on basis of two partial sections, localities 7 and 8 of present report. Consists predominantly of dolomite and smaller amounts of chert. Five lithic zones differentiated. Aggregate thickness 690 feet. Park City group. Newell (1948, Geol. Soc. America Bull., v. 59, no. 10) applied name Phosphoria to all Permian rocks above the Kaibab. Term Phosphoria is herein considered inappropriate.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 93 (chart 1), 107–108. Geographically extended into east-central Nevada. In Pequop and Cherry Mountains and Ferguson Spring Mountains, the Plympton overlies Loray formation and underlies the Phosphoria. In Butte Mountains, overlies the Loray and underlies Gerster formation. Thickness 983 feet in Butte Mountains.

Has greatest areal extent in Millard and Plympton Ridges in Confusion Range, Utah. Locality 7 is 1.4 miles N. 60° E. of east end of Indian Pass. Locality 8 is 9 miles S. 20° W. of Granite Mountain. Section at locality 8 broken by several faults.

**Pocahontas Formation** (in Pottsville Group)[1]

Lower Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: M. R. Campbell, 1896, U.S. Geol. Survey Geol. Atlas, Folio 26, p. 3.

C. B. Read, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 273. Formation mentioned in discussion of Pennsylvanian floral zones and floral provinces.

Named for Pocahontas, Tazewell County, Va.

†Pocahontas Group (in Pottsville Group)[1]

Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: I. C. White, 1908, West Virginia Geol. Survey, v. 2A, p. 13.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 12, chart 6 (column 12). Pocahontas group, lower Pottsville series, southern West

Virginia, includes (ascending) Squire Jim coal, No. 2 Pocahontas coal, No. 3 Pocahontas coal, Pocahontas sandstone, No. 4 Pocahontas coal, and Flattop Mountain sandstone. Underlies New River group.

Named for Pocahontas, Tazewell County, Va.

Pocahontas Sandstone (in Lee Formation)

Pocahontas Sandstone (in Pocahontas Group)

Pocahontas Sandstones (in Pottsville Group)[1]

Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 224–232.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (columns 12, 19). Correlation chart shows Pocahontas sandstone in Pocahontas group in southern West Virginia and in Lee formation in Virginia.

Quarried at Pocahontas, Tazewell County, Va.

Pocatello Formation

Precambrian: Southeastern Idaho.

J. C. Ludlum, 1942, Jour. Geology, v. 50, no. 1, p. 89–92. Thick series of unfossiliferous metamorphosed sediments. Considerable variations in thickness and distribution of component sediments. Divided into two series: lower tillite series consisting of silicified sandstones, slates, intraformational limestone conglomerate, thin-bedded metamorphosed limestones, argillites, and tillites, approximately 1,100 feet thick; and an upper varved slate series consisting of alternating bands of dark and light slate with a few thin beds of sandstone in upper part, 350 feet thick. Underlies Blackrock limestone. Overlies Bannock volcanic formation of which it was formerly a part.

Exposed in Pocatello quadrangle.

**Pochnoi Volcanics**

Tertiary(?) or Quaternary: Alaska.

R. R. Coats, 1960, U.S. Geol. Survey Bull. 1028–0, p. 481–482, 486, 503–504, pl. 59. Sequence of tuff-breccia, lava, and agglomerate, and minor amounts of sandstone. Thickness in walls of caldera, 1,700 feet. Oldest rocks on island. Apparently erupted by volcano, which had approximately same dimensions as present island, whose center of eruption lay somewhere within area of present central depression.

Well exposed west and north of Pochnoi Point, Semisopochnoi Island, largest of young volcanic islands of western Aleutians. Exposed chiefly in northeast, south, and southwest parts of island, outside central lowland; elsewhere covered by products of later volcanic eruptions.

Pochuck Diorite[1]

Pochuck diorite phase (of Hudson Highlands Complex)

Precambrian: Eastern New York.

Original reference: C. P. Berkey and Marion Rice, 1919, New York State Mus. Bulls. 225–226, p. 51–52.

K. E. Lowe, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 143. Berkey and Rice (1919) showed oldest igneous representative distinguishable in Hudson Highlands as essentially a diorite but indicated that it is practically always intimately associated with Grenville metamorphics. Hornblende-plagioclase gneiss layers at Bear Mountain are believed to represent Grenville rocks reworked selectively by this diorite invasion. They correspond to Colony's (1921, New York State Mus. Bulls. 249–250) Pochuck-Grenville. Presence of a diorite parent rock of unquestionable magmatic origin could not be demonstrated in region, therefore, term "phase" is used for this earliest igneous interval. There is no intention to question the validity of the intrusive concept.

Report discusses area around Bear Mountain, a prominent summit of the Hudson Highlands, about 40 miles north of New York City.

**Pochuck Gneiss**

Pochuck Gabbro Gneiss[1]

Precambrian: Northern New Jersey and eastern Pennsylvania.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 439.

D. M. Fraser *in* B. L. Miller, D. M Fraser, and R. L. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–48, p. 163 (fig. 30), 175–187. Described in Northampton County, Pa. In Chestnut Hill exposure, conformably underlies Moravian Heights formation (new); both formations strike N. 50° E., and dip northwest at an angle of 59°. This superposition of Moravian Heights gives no indication of relative periods of origin as all rocks of Precambrian have been extensively disturbed. Pochuck may be older, younger, or interbedded with Moravian Heights. Intruded by Byram granite gneiss.

W. S. Bayley, 1941, U.S. Geol. Survey Bull. 920, p. 46, 47–49, pl. 5. Pochuck gneiss as heretofore defined includes two groups of dark gneisses of different age and different origin, one group comprising sedimentary gneisses that are older than the Byram and Losee types and of pre-Franklin age, and the other comprising igneous rocks that may be differentiates of Byram and Losee magmas. In this report name Pochuck gneiss is restricted to igneous rock; the older dark- and light-colored schists and gneisses and slaty rocks of sedimentary origin are mapped and described as Pickering gneiss. Formation to which name Pochuck gabbro gneiss is herein applied is a black or dark-gray rock with chemical composition of many diorites and gabbros, but differing from them mineralogically in containing orthoclase, microcline, and oligoclase rather than the more basic plagioclases. Considered to be older than the more granitoid Byram and Losee gneisses. Where the Pochuck is associated with Losee diorite gneiss, oligoclase is principal feldspar of the Pochuck; where it is closely associated with Byram gneiss, microperthite and microcline are prominent in the black gneiss and hornblende exceeds diopside.

Named for occurrences on east slope of Pochuck Mountain, N.J.

Pochuck Mountain Gneiss Series

Precambrian: Northern New Jersey.

J. M. Hague and others, 1956, Geol. Soc. America Bull., v. 67, no. 4, p. 468, 469, fig. 18. Sequence changes from thick series of oligoclase gneiss containing hornblende and microcline gneiss bands in Pimple Hills to interlayered hornblende gneiss, microcline gneiss, and biotite gneiss in Lake Lenape syncline, on Pochuck Mountain, and in Glenwood syncline. Thickness over 2,000 feet. Overlies Wildcat marble (new).

On Pochuck Mountain in Franklin-Sterling area.

Pocket Hollow Oolite (in Lutie Member of Theodosia Formation)

Lower Ordovician: Northern Arkansas and southern Missouri.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 31, pl. 2. Medium- to coarse-grained oolitic chert about 3 feet thick that occurs just below the top of the Lutie member. Lies stratigraphically above Hercules Tower sandstone bed (new) and separated from it by numerous beds of finely crystalline dolomite and "cotton rock".

Well exposed at the bottom of South Pocket Hollow in SE¼ sec. 29, T. 22 N., R. 14 W., Thornfield quadrangle, Ozark County. Mo.

**Pocono Formation,[1] Group,[1] or Sandstone**

Pocono Series

Lower Mississippian: Pennsylvania, eastern Ohio, western Maryland, Virginia, and West Virginia.

Original reference: J. P. Lesley, 1876, Pennsylvania 2d Geol. Survey Rept. L., app. E., p. 221, 222, pls.

C. A. Ashburner, 1885, Pennsylvania 2d Geol. Survey Rept. $R_2$, p. 104–105. Includes Benezette limestone.

M. R. Campbell, 1904, U.S. Geol. Survey Geol. Atlas, Folio 110. Includes Patton shale member (new).

Charles Butts, 1904, U.S. Geol. Survey Geol. Atlas, Folio 115. Includes Burgoon sandstone member (new).

G. W. Stose and C. K. Swartz, 1912, U.S. Geol. Survey Geol. Atlas, Folio 179. Group includes (ascending) Rockwell formation, Purslane sandstone, Hedges shale, Myers shale, and Pinkerton sandstone.

Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 573. Formation includes Peters Mountain sandstone (new).

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 17–18, pls. Formation, in south-central Pennsylvania, consists of 1,600 feet of sandstones and pebble beds. Comprises (ascending) Second Mountain (new), Peters Mountain, and Cove Mountain (new) members. Underlies Mauch Chunk red beds; overlies Catskill red beds.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 252, 283–294. Series consists of coarse reddish-brown micaceous sandstone, commonly crossbedded and conglomeratic, with brown, bluish-gray, and occasional red or green sandy shales, together with some impure and lenticular coals. Thickness 600 feet. Includes (ascending) Berea sandstone, shale and sandstone, Broad Ford sandstone, Merrimac coal, and sandstone and shale. Underlies Maccrady series; overlies Catskill series.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 336–337. Names Pocono and Price are practically synonymous. In this report, name Pocono is applied in northern Virginia as far south as western Alleghany County, where the formation occurs on high knobs along State line. Name Price is applied throughout region from southern Alleghany and western Botetourt Counties to Tennessee.

M. N. Shaffner, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 141. Group in Donegal quadrangle, includes Burgoon sandstone in upper part. Thickness not determined. Underlies Loyalhanna limestone. Base of surface section in area.

R. C. Bolger and H. V. Gouse, 1953, Pennsylvania Geol. Survey, 4th ser., Bull. M-36, p. 5-7, pl. 3. Group in Driftwood quadrangle is 396 to over 500 feet thick. Includes Patton shale member (or formation) and Burgoon sandstone member (or formation) near top. Occurs below Mauch Chunk red shale and above Oswayo formation.

T. W. Amsden, 1954, Maryland Dept. Geology, Mines and Water Resources Bull. 13, p. 23-24. Formation described in Garrett County, where it is exposed on flanks of Deer Park and Accident anticlines. Consists largely of sandstone interbedded with some siltstone and shale. Thickness about 1,080 feet. Overlies Hampshire formation, contact gradational; underlies Greenbrier formation, contact placed where noncalcareous sandstones of Pocono are overlain by calcareous shales or sandy limestones.

J. L. Dally, 1956, Dissert. Abs., v. 16, no. 12, p. 2425. Group, in West Virginia, represented by (from base upward) Marlinton formation (new), Sunbury shale, and Matoaka formation (new) in southern part of State; Manheim formation (new) and Burgoon formation in northern part; Rockwell formation, Purslane sandstone, and Hedges shale in eastern part. In southern and eastern areas, sequences are continuous and contemporaneous and range in age from early Kinderhook to late Osage, and intertongue laterally with Hampshire red beds; sequence in northern part of State is younger, ranges in age from upper part of Osage through Meramec, is vertically transitional with Hampshire red beds, and intertongues laterally with lower Greenbrier limestone in south and Myers red shale in east.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Field Trips Pittsburgh Mtg., p. 2-3. Formation rests unconformably on beds of Catskill formation in southern and western parts of anthracite region. Successively younger Catskill strata wedge in beneath Pocono in easterly and northerly directions. Contact between the two formations commonly placed at highest red bed of definite Catskill lithology. Pocono consists of 1,000 to 1,500 feet of conglomerate, sandstone, siltstone, shale, and coal beds. Sandstone and conglomerate are principal rock types. Color of beds light- to dark-gray olive, light-brown, and greenish-yellow. Formation appears to thin gradually to north and northeast in southern and western parts of anthracite region. Not certain that representatives of Burgoon and Griswold Gap conglomerates of central Pennsylvania are present in anthracite region. Unconformably overlies Mauch Chunk formation. Lower Mississippian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Group includes, in Appalachian Plateau, Burgoon, Shenango, Cussewago, Corry, and Knapp formations; includes part of "Oswayo" in Potter and Tioga Counties.

No type locality designated by Lesley. Later workers have assumed type area to be in Pocono Mountains of northeastern Pennsylvania.

Poe Evaporite Member (of Nesson Formation)

Jurassic: Subsurface in North Dakota and Montana, and Manitoba, Canada.

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 104-105, fig. 2. Basal member of Nesson formation (new). Underlies Picard shale member (new); unconformably overlies Triassic(?) Spearfish formation. In type section, consists of basal 65-foot bed of massive salt overlain by 53 feet of white to pink gypsum and anhydrite and dark-red shale with a few thin interbeds of gray to red dense dolomite; thin bed of buff to brown very finely crystalline to earthy limestone present at top. Thins eastward from type well and appears to merge in Bowdoin dome area with younger members of formation. Unit exhibits rapid facies changes on east flank of Williston basin where member overlaps Spearfish formation and Madison limestone and rests on pre-Mississippian sediments.

Type section: Interval 6,947 to 7,065 feet in Phillips-Skelly-Gulf No. 1 Hoehn (Poe Unit) well, center NE SE sec. 13, T. 152 N., R. 102 W., McKenzie County, N. Dak.

**Pogonip Group**

Pogonip Formation (in Mount Hamilton Group)

Pogonip Limestone[1]

Lower and Middle Ordovician: Eastern and southern Nevada, southeastern California, and western Utah.

Original references: C. King, 1876, U.S. Geol. Expl. 40th Par. Atlas, Map IV; 1878, U.S. Geol. Expl. 40th Par., v. 1, p. 187–195, 248.

C. W. Merriam and C. A. Anderson, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1682 (fig. 2), 1683–1684. Referred to as group. Pogonip limestone has been used broadly for strata in Great Basin lying between base of Eureka quartzite and top of Upper Cambrian Dunderberg shale (Eureka district). Following this interpretation, the Pogonip may embrace faunal zones ranging from Upper Cambrian to approximately Black River Middle Ordovician. In Antelope and Monitor Ranges, at least three recognizable formational units are present within vertical limits of the Pogonip. In Roberts Mountains, group is poorly represented and, even where best developed on west flank of Western Peak, shows little similarity to the thick section in Antelope and Monitor Mountains.

L. F. Hintze, 1951, Utah Geol. Soc. Guidebook 6, p. 38–42. Pogonip group geographically extended into Ibex area, Utah, where it underlies Swan Peak quartzite and overlies Upper Cambrian. Six lithologic units and 15 faunal zones recognized. Canadian and Chazyan.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 11–96. In western Utah and eastern Nevada, Pogonip group comprises (ascending) House limestone, Fillmore limestone, Wahwah limestone, Juab limestone, Kanosh shale, and Lehman formation (all new). Restricted to Ordovician; lower boundary is lithologic change below the *Symphysurina* faunal zone; in western Utah, underlying unit is Notch Peak formation; in central Utah and several Nevada localities underlying rocks are dolomitic. Two Middle Ordovician quartzites overlie group in western Utah. In this sequence, the lower (Swan Peak) quartzite, 390 feet in central Utah, thins in western Utah to disappear in eastern Nevada, grading into successively younger Pogonip zones westward; the upper (Eureka) quartzite persists to west, halfway across Nevada. Thins by convergence from about 3,000 feet at Ibex, Utah, to about 1,700 feet near Scipio.

L. F. Hintze, 1952, Utah Geol. and Mineralog. Survey Bull. 48, p. 48. Complete typical Pogonip Ordovician section has not been found in fault blocks of Ely Springs Range, Nev. In addition to hiatus of 200 to 500 feet of beds between top of Yellow Hill and bottom of Tank Hill (top of Ordovician sequence), there is also a gap, probably of 500 feet or more, at bottom of Ordovician.

R. L. Langenheim, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2087 (fig. 3), 2091. In Independence quadrangle, California, group includes Mazourka formation. Underlies Barrel Spring formation of Eureka group. Chiefly early Ordovician in age.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 23–29. In Eureka district, Nevada, group includes (ascending) Goodwin limestone, Ninemile formation (new), and Antelope Valley limestone (new). Overlies Cambrian Windfall formation (new) and underlies Eureka quartzite. As now defined, group may range in age from earliest Ordovician to Chazy or Middle Ordovician. Note on type locality.

M. S. Johnson and D. E. Hubbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 345–349, pls. 32, 33. Considered as a group, the Pogonip of Eureka area embraces several mappable formations falling between top of Cambrian system and base of Eureka quartzite. In Nevada proving grounds area [this report] latter definition is applied arbitrarily. Present study does not favor formal naming of formational divisions within group, though such procedure may eventually be called for. Hence provisional subdivision is used with nine minor units designated A through I in ascending order. Total thickness about 3,150 feet. Overlies unnamed upper Cambrian rocks; underlies Eureka quartzite.

C. W. Merriam and W. E. Hall, 1957, U.S. Geol. Survey Bull. 1061–A, p. 4 (table 1). In Inyo Mountains, Calif., group is about 1,350 feet thick; base not exposed; underlies Eureka quartzite.

Harald Drewes, 1958, Geol. Soc. America Bull., v. 69, no. 2, p. 227. Group described in Snake Range, Nev., where it is about 3,000 feet thick; not subdivided. Conformably overlies Corset Spring shale. As used here, group includes at least 550 feet of Upper Cambrian rocks which could not be separated from lithologically similar Ordovician part.

F. L. Humphrey, 1960, Nevada Bur. Mines Bull., v. 57, p. 16, 18 (fig. 7), 19–23, pl. 1. Formation included in Mount Hamilton group (new). Upper formation in group; overlies Goodwin formation; underlies Eureka quartzite. Comprises four members: member 1, about 400 feet thick, consists of alternating thin-bedded shale-parted limestone and massive medium-gray limestone beds from 1 to 3 feet thick; member 2, about 600 feet thick, consists of thin-bedded reddish-brown weathered limestone, commonly with thin reddish, but locally buff, shale partings; member 3, about 160 to 210 feet, fairly massive medium- to dark-gray medium-grained limestone; member 4, about 800 feet, thin-bedded limestone, most fossiliferous member of formation. Lower Ordovician. [Editor's note states that Pogonip formation of this paper equals Pogonip group of Nolan, Merriam, and Williams, (1956)].

Marshall Kay, 1960, Internat. Geol. Cong. 21st, Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). Underlies Gatecliff formation (new) in Toquima Range.

Type locality: Pogonip Ridge in White Pine or Hamilton district, about 30 miles southeast of Eureka, Nev. On Pancake Summit and Green Springs 15-minute topographic quadrangle of U.S. Geological Survey, Pogonip Ridge of King's usage is shown as Mount Hamilton of the White Pine Range.

†Pogonipan series[1]

Ordovician: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53, 80.

Pohakuloa Stage and Drift

Pleistocene: Hawaii Island, Hawaii.

C. K. Wentworth and W. E. Powers, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1942; 1941, Geol. Soc. America Bull., v. 52, no 8, p. 1207–1210. Four stages of glaciation, presumably correlative with Ice Age elsewhere, occurred on Mauna Kea. These are (beginning with latest) Makanaka, Waihu, Pohakuloa, and pre-Pohakula stages. Till 50 to 90 feet thick.

H. T. Stearns, 1945, Geol. Soc. America Bull., v. 56, no. 3, p. 269. Of glacial deposits described by Wentworth and Powers, only Makanaka deposits can be accepted as definitely glacial. Pohakuloa drift believed to be volcanic explosion deposits.

Drift occurs on walls of Pohakuloa Gulch between 8,750 and 9,500 feet.

**Pohono Granodiorite**[1]

Probably Cretaceous: East central California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 123.

Named for occurrence near Pohono Trail.

Poinsettan series[1]

Tertiary, upper: Illinois and Missouri.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 252.

Point Arena Beds or Formation

Miocene, upper: Northern California.

C. E. Weaver, 1943, California Div. Mines Bull. 118, p. 630–632; 1944, Washington [State] Univ. Pubs. in Geology, v. 6, no. 1, p. 4, 19, 21–22, pl. 2. Alternating units of interstratified grayish-brown clay shales, foraminiferal shales, diatomaceous shales, cherty shales strongly contorted, and units of thinly laminated sandstones and cherty shales and clay shales; occasional layers of sandstone 50 feet thick. Thickness 3,355 feet. Underlies terrace deposits; overlies Gallaway beds (new).

Exposed in sea cliffs almost continuously from Abalone Cove northward to Point Arena Lighthouse, a distance of about 30,000 feet. Point Arena-Fort Ross area, Mendocino County.

Point au Gres Limestone

Point aux Gres Limestone[1]

Mississippian: Eastern Michigan.

Original reference: C. C. Douglass, 1839(?), Michigan Leg. House Doc. 27, between p. 97 and 111.

G. H. Pringle, 1937, Michigan Dept. Conserv., Geol. Survey Div. Prog. Rept. 3, p. 14. At Point au Gres, 6 feet of Bayport limestone occur along lakeshore on west side of the point. This is limestone named Pointe aux Gres by Douglass.

G. M. Ehlers and W. E. Humphrey, 1944, Michigan Univ. Contr. Mus. Paleontology, v. 6, no. 6, p. 114–117. Description of fauna from Point au

Gres limestone at Grand Rapids. Thickness in Grand Rapids area 50 to 70 feet. History of nomenclature reviewed and reference made to work of Lane (1893, 1895, 1899, 1900, 1909). Concluded that Point au Gres instead of "Grand Rapids" or "Bayport" should be used. Usage is based on definition by Douglass (1841 [1849]). Continued reference to limestone as "Bayport" would be unfortunate since this name and also "Grand Rapids" were used only in casual manner by Lane.

Typically exposed at Point au Gres on western side of Saginaw Bay, Lake Huron.

Point aux Barques Lighthouse[1] (Sandstone)

Mississippian: Michigan.

Original reference: A. C. Lane, 1899, U.S. Geol. Survey Water-Supply Paper 30, p. 85.

In Huron County.

Point aux Barques Sandstone[1]

Mississippian: Michigan.

Original reference: A. Winchell, 1871, Am. Philos. Soc. Proc., v. 11, p. 60–66.

Saginaw Bay region.

Pointe aux Chenes Formation or Shale (in Salina Group)

Upper Silurian (Cayugan): Northern Michigan.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv. Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 26, 27, 33, 35–52 Proposed for strata which in recent reports have been designated by group term Salina. Consists of green and red shale with thin beds of dolomite of varied lithologic character and small irregular masses and thin beds of gypsum. Thickness varies from 8 to as much as 35 feet in outcrop sections; well records show between 500 and 600 feet on St. Ignace Peninsula. Occupies position between Middle Silurian Engadine dolomite and Upper Silurian St. Ignace formation (new). Further study may show that Salina group of Mackinac Straits area contains several formations and that the Pointe aux Chenes is its uppermost division. Pointe aux Chenes formation includes strata referred to Onondaga salt group by Hall (1851, Geological Reports pub. *in* pt. V. *of* Foster and Whitney report on Geology of Lake Superior Land District, U.S. Senate, Spec. Sess., March, 1851, Ex. Doc. no. 4) and Rominger (1873, Geology of the Upper Peninsula: Michigan Geol. Survey, v 1, pt. 3).

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 23–24. Most of strata are shales; hence, unit termed Pointe aux Chenes shale.

Named for exposures in area near Pointe aux Chenes, a headland on Lake Michigan about 9 miles northwest of city of St. Ignace.

Point Farfan diorite.

Miocene: Panamá.

[T. F. Thompson], 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 26. Grades regularly from coarse texture to fine grained and andesitic. Probably a small neck or intrusive plug. Pre-Pliocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 343–344. Augite-quartz diorite and presumably intrudes Panamá formation. Miocene.

Quarried at Point Farfan, near southern terminus of Thatcher Ferry, Point Farfan in on west side of Pacific entrance to Panamá Canal.

**Point Hey Member** (of Katalla Formation)

Point Hey Sandstone Member (of Redwood Formation)[1]

Oligocene: Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 773.

D. J. Miller, D. L. Rossman, and C. A. Hickcox, 1945, Preliminary report on petroleum possibilities in the Katalla area, Alaska: U.S. Geol. Survey, p. 7 (table), 12–13; 1945, Geologic and topographic map and sections of the Katalla area, Alaska: U.S. Geol. Survey War-Minerals Inv. Prelim. Map. Member of Katalla formation. East of long 144°19′ W. member consists of at least several hundred feet of gray to nearly black partly sandy shale and fine- to medium-grained gray sandstone. Sandstone beds range in thickness from 1 to 100 feet. Near long 144°19′ W., member is about 850 feet thick. West of long 144°19′ W., member includes a lower division mostly of shale which thickens westward to more than 2,000 feet and an upper division of thick sandstone beds and thin shale beds. Lies conformably between unnamed organic shale member below and Puffy member above. In unpublished manuscript by oil-company geologists, Point Hey shale and Point Hey sandstone are treated as two distinct units in Redwood formation.

Named for excellent outcrops in vicinity of Point Hey, Katalla district, Controller Bay region.

Point Lookout Granite[1]

Precambrian(?): Southwestern Virginia.

Original reference: A. I. Jonas, 1935, Geol. Soc. America Bull., v. 46, p. 49.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties Rept., p. 17. Described as biotite quartz monzonite. Intrudes a biotite gneiss injection complex, the oldest rock of which is the newly named Saddle gneiss. Cut by pink pegmatite.

Named from occurrence in Point Lookout Mountain, Grayson County.

**Point Lookout Sandstone** (in Mesaverde Group)[1]

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

Original reference: A. J. Collier, 1919, U.S. Geol. Survey Bull. 691–K.

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 90, 94, pl. 1. Described in Fort Defiance-Tohatchi quadrangle where it overlies Crevasse Canyon formation (new) and underlies Menefee formation. Made up of one thin and two thick units, totaling 320 feet. Northward, the thick units are separated by tongue of finer-grained material (Satan tongue of Mancos shale) so that combined thickness is about 400 feet; south of Crevasse Canyon, within 1 mile they thin abruptly and completely disappear within 2 miles. Lower cliff-making unit is here called Hosta sandstone tongue.

P. T. Hayes and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144. Described in Barker dome-Fruitland area, San Juan County, N. Mex., where it includes North Hogback tongue (new). Intertonguing relationships with Menefee discussed.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2156. Discussion of revised nomenclature of Mesaverde in San Juan basin, and term Point Lookout sandstone is extended throughout area. Point Lookout as a formation replaces Hosta sandstone member where that member is undivided and also replaces upper part of Hosta sandstone member where its lower part is absent or is separated from its upper part by tongue of Mancos. Hosta tongue of Point Lookout sandstone replaces lower part of Hosta sandstone member where that is present.

Well exposed in cliffs at Point Lookout, about 7½ miles southwest of Mancos, Montezuma County, Colo.

†Point of Rocks Group[1]

Upper Cretaceous (Montana): Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 47, 155.

Point of Rocks Station, Sweetwater County, Wyo.

Point of Rocks Sandstone

Point of Rocks Sandstone Member (of Tejon Formation)

Eocene, upper: Southern California.

R. D. Reed and J. S. Hollister, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 12, p. 1566 (fig. 9). Named on columnar section of upper Eocene strata in Devils Den area. Underlies Kreyenhagen and overlies "Tejon" shale.

Martin Van Couvering and H. B. Allen, 1943, California Div. Mines Bull. 118, pt. 3, p. 496, 497 (fig. 211). Described as tawny massive cavernous crossbedded medium to coarse quartzose sandstone; contains large chocolate-brown concretions in lower part; includes two thin silty claystone beds. Thickness 3,005 feet. Underlies Welcome formation; overlies Gredal formation (new).

H. H. Heikkila and G. M. MacLeod, 1951, California Div. Mines Spec. Rept. 6, p. 4 (table 1), 5 (table 2), 7, pl. 1. Described in Bitterwater Creek area, Kern County, as coarse- to medium-grained sandstone characterized by red-brown "cannonball" concretions of calcarinate sandstone up to 4 or 5 feet in diameter. Maximum thickness 600 feet; southeastward along strike there is a gradual decrease in apparent thickness due to progressive overlap by younger Santos shale member of Monterey formation and at one locality Twisselmann sandstone member (new) of the Monterey. In Antelope Valley, sandstone wedges out or is truncated by either the McDonald shale or Tulare sediments.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 10, 11, 19, 70, 101, 282. Report makes several references to Point of Rocks sandstone member of Tejon formation. At Media Agua Creek, bulk of Point of Rocks member was deposited during early Narizian, *Uvigerina churchi* time.

L. B. McMichael, chm., 1959, San Joaquin Geol. Soc. Guidebook Field Trip, May 9, p. 13, 14. Chart and columnar section of Chico-Martinez Creek area show Point of Rocks sandstone and shale member of Tejon formation unconformable below Salt Creek shale member of Tejon formation.

O. T. Marsh, 1960, California Div. Mines Spec. Rept. 62, p. 28. Conspicuous craggy sandstone at Red Man Rocks, Orchard Peak area, has been mapped as Eocene, usually as Point of Rocks whose type locality lies 4 miles southeast of Devils Den. Craggy sandstone in northeast corner of area has been regarded as Cretaceous. In present report, both exposures are mapped as Upper Cretaceous Red Man sandstone (new).

Type locality: T. 26 S., R. 18 E., Devils Den district, Kern County.

**Point Peak Shale Member** (of Wilberns Formation)

Upper Cambrian: Central Texas.

Frederick Romberg and V. E. Barnes, 1944, Geophysics, v. 9, no. 1, p. 88, fig. 7 (geol. map). Greenish shale underlying San Saba limestone member and overlying Morgan Creek limestone member (new). Name credited to Josiah Bridge and V. E. Barnes.

Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America v. 58, no. 1, p. 115–116, pls. 1, 2. Consists of well-bedded soft greenish calcareous shales with subordinate amounts of fine-grained compact dolomite; medium- to fine-grained glauconitic limestone; intraformational conglomerates; and near top, occasional beds of oolitic limestone and commonly extensive to scattered stromatolitic bioherms that locally coalesce to form biostromes. Average thickness 160 feet; at type section 270 feet; thins to 25 feet along Pedernales River in Blanco County. At type locality, underlies San Saba limestone member and overlies full but thin section of Morgan Creek limestone member. Locally in contact with Pedernales dolomite member. Top of the Point Peak drops abruptly southward in Sudduth area of Burnet County; bottom boundary likewise is not at a constant stratigraphic horizon, it ranges from 90 feet above base of formation on Point Peak to about 170 feet in Salt Branch section; difference in position of boundary probably due chiefly to facies change from shale to limestone.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 155, 188, 225, 254, 310 [1946]. Local stratigraphy described.

Type section: On south slope of Point Peak, an isolated hill about 4 miles northeast of Lone Grove, Llano County.

**Point Pleasant Formation**

Point Pleasant Limestone[1]

Middle Ordovician: Southwestern Ohio and northern Kentucky.

Original reference: J. S. Newberry, 1873, Ohio Geol. Survey, v. 1, p. 89 (table), 119–121.

M. P. Weiss and C. E. Norman, 1960, Ohio Geol. Survey Inf. Circ. 26, pl. 1. Chart shows development of stratigraphic classification of Ordovician rocks in Cincinnati region. Point Pleasant (Cynthiana) formation is below the Eden which is basal formation of Covington group, Cincinnatian series.

Named for exposures at Point Pleasant, Clermont County, Ohio.

Point Reyes Granodiorite

[Cretaceous]: Northern California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 9. Discussed in report dealing with potassium-argon determinations. Age given as 83.9 million years.

Crops out in vicinity of Point Reyes lighthouse and along northern shores of Point Reyes Peninsula toward Tomales Point at head of Tomales Bay. Dated specimen collected from quarry near old Government Landings.

Point Rock Shale Member (of Wilberns Formation)

Upper Cambrian: Central Texas.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart above Morgan Creek limestone member and below San Saba limestone and Pedernales dolomite members. [This may be lapsus for Point Peak shale member of Wilberns formation (Romberg and Barnes, 1944).]

Central mineral region.

**Point Sal Formation**

Miocene, lower and middle: Southern California.

C. R. Canfield, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 1, 66 (footnote). Name provisionally proposed for the Siltstone and Shell zone in Monterey formation.

W. P. Woodring, M. W. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1341 (table 1), 1344–1345; W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 11 (chart), 16–17, pls. 1, 3. Consists chiefly of dark-gray brown-weathering mudstone and siltstone. Includes thin beds of sandstone, limestone concretions, and diabase sills. Thickness ranges from 150 to 1,500 feet, thickest section being on south slope of Mount Lospe. In Point Sal area, appears to overlap the Lospe and to rest on Knoxville or Franciscan. On Mount Lospe, conformably overlies Lospe formation. Underlies Monterey formation. Type locality redesignated.

Type locality: As redesignated, on south slope of Mount Lospe, Santa Maria district. As designated by Canfield, on Point Sal Grade, approximately one-half mile east of old Point Sal Landing (Guadalupe quadrangle).

**Poison Canyon Formation**[1]

Paleocene: Southeastern Colorado.

Original reference: R. C. Hills, 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 148–164.

G. H. Wood and others, 1951, U.S. Geol. Survey Coal Inv. Map C–4 Described in Stonewall-Tercio area, Las Animas County, where several hundred feet of basal part of formation are exposed. Intertongues with underlying Raton formation. Paleocene.

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–146. Exposed over much of La Veta area where it is composed of approximately 2,500 feet of alternating beds of buff to red massive arkosic sandstone and conglomerate and thin beds of yellow shale. Overlies Vermejo formation (Raton formation not present in this area). Underlies Cuchara formation.

Well exposed in beds extending down Poison Canyon, west of Gardner, and across Muddy Creek to Promontory Bluffs, Huerfano County.

Poison Canyon Sandstone (in Westwater Canyon Sandstone Member of Morrison Formation)

Jurassic: Northwestern New Mexico.

R. T. Zitting and others, 1957, The Mines Magazine, v. 47, no. 3, p. 55, 57; L. S. Hilbert and A. F. Corey, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI-690, book 2, p. 370 (fig. 86), 371. Upper Westwater sandstone lens which intertongues with overlying Brushy Basin shale member of Morrison formation. Generally separated from main body of Westwater by a shale. Practically absent in parts of area and up to 100 feet thick in other places. Base of Poison Canyon consistently 160 feet below base of Dakota formation.

In Ambrosia Lake area, McKinley County.

†Poison Canyon Series[1]

Eocene: Southeastern Colorado.

Original reference: R. C. Hills, 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 148–164.

In Huerfano Basin, Huerfano County.

**Poison Creek Formation**[1] (in Idaho Group)

Pliocene: Southwestern Idaho.

Original reference: J. P. Buwalda, 1923, Idaho Bur. Mines and Geology Pamph. 5, p. 3.

U.S. Geological Survey currently classifies the Poison Creek as a formation in Idaho Group on basis of a study now in progress.

Type locality: At north end of Silver City Range at Poison Creek grade, Snake River valley.

Pokeberry cyclothem (in Carbondale Group)

Pennsylvanian: Western Illinois.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82 (fig. 22), 60, 113, 189, 190. Thickness 11 to 17 feet. Includes Pokeberry limestone. In sequence, occurs above Brereton cyclothem and below Sparland cyclothem. May be equivalent to Jamestown cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 56 (table 3). Replaced by Jamestown cyclothem.

Named from outcrops about 1 mile east of Pokeberry school in sec. 26, T. 2 N., R. 1 W., Beardstown quadrangle, Schuyler County.

Pokeberry Limestone Member (of Carbondale Formation)

Pokeberry Limestone (in McLeansboro Formation)

Pennsylvanian: Western Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 17, 98. Marine limestone in lower McLeansboro, between Danville (No. 7) coal above and Brereton limestone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11. Included in Jamestown cyclothem. Type locality designated.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 113. Blue-gray to greenish-gray limestone commonly 1½ to 2 feet thick. Columnar section shows Pokeberry limestone stratigraphically below Copperas Creek sandstone and above Sheffield shale. Included in Pokeberry cyclothem (new), Carbondale group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 48 (table), pl. 1. Rank reduced to member status in Carbondale formation (redefined). Occurs above Lawson shale member (new) and below

Copperas Creek sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NW¼ sec. 26, T. 2 N., R. 1 W., Schuyler County.

**Pokegama Quartzite**[1] (in Animikie Group)

Precambrian: Northeastern Minnesota.

Original reference: H. V. Winchell, 1893, Minnesota Geol. Survey 20th Ann. Rept., p. 123.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1042–1044. Base of Animikie group; lies on truncated pre-Animikie rocks—Archean greenstone, pre-Knife Lake granite, Knife Lake group, and Giants Range granite; overlain conformably, or nearly so, by Biwabik iron-bearing formation. Quartzite changes across strike from conglomerate at base through thin-bedded micaceous quartzite to very massive coarse-grained quartzite at top; succession fairly persistent where quartzite is thick; strike parallels Mesabi Range. Total thickness not more than 200 feet; commonly not over 75 feet.

Named for outcrops at Pokegama Falls on Mississippi River north of Grand Rapids, Itasca County.

Poland Limestone Member (of Denmark Formation)

Middle Ordovician (Mohawkian): East-central New York.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 599, 600–601, 603, 605; 1953, New York State Mus. Bull. 347, p. 45, 53–55. Name proposed for middle member of formation. Consists principally of dense fossiliferous limestone with intercalated calcareous shale southeastward to Newport, passing wholly into sparsely fossiliferous argillaceous calcilutite and shale of the "Dolgeville" facies at East Canada Creek, and ultimately into black shale at Canajoharie. Includes black dense resistant limestone at its base; not exposed at Trenton Falls. In various section contains a metabentonite near the base, two higher in unit, and a fourth at contact with overlying Russia limestone member (new). Contrasts with underlying Rathbun limestone member (newly defined) by lack of coquinal beds. Thickness about 60 feet.

Type section: At Trenton Falls on West Canada Creek near Oneida-Herkimer County line. Named for Poland, Herkimer County, southeast of Trenton Falls.

**Pole Canyon Limestone**

Middle Cambrian: East-central Nevada.

Harald Drewes and A. R. Palmer, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 1, p. 106 (fig. 2), 109 (fig. 4), 110–113, 118–119; Harald Drewes, 1958, Geol. Soc. America Bull., v. 69, no. 2, p. 224 (fig. 2), 225–226, pl. 1. Gray and white limestone, commonly massive. Total thickness about 2,000 feet. On west side of Snake Range, five alternating gray and white members are recognized (ascending): A, 415 feet thick; B, 630 feet; C, 160 to 320 feet; D, 220 to 380 feet; E, 340 feet. Conformably overlies Pioche shale; underlies Lincoln Peak formation (new). No complete type section available.

Named for Pole Canyon on west side of Mount Washington, on which most of formation is well exposed. Forms cliffs extending in broad, continuous outcrop band from Minerva district on west flank of Snake Range to Mount Washington and eastward into Big Wash drainage.

Pole Canyon Member (of Oquirrh Formation)

Pennsylvanian (Virgilian) : Northwestern Utah.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 121–126, pls. 1, 2. Interbedded and intercalated orthoquartzites, calcareous orthoquartzites, calcareous sandstones, crystalline limestones, cherty fossiliferous-fragmental limestones, and argillaceous to silty limestones, some of which contain chert nodules. Thickness 1,526 feet. Overlies Lewiston Peak member (new) ; underlies strata referred to as Wolfcampian(?).

Type locality: On east-trending spur in west side of Pole Canyon in secs. 2 and 11, T. 6 S., R. 3 W., Utah County. This is on west limb of Pole Canyon syncline (east limb of Ophir anticline).

Polecat Bench Formation

Paleocene: Northwestern Wyoming.

G. L. Jepsen, 1940, Am. Philos. Soc. Proc., v. 83, no. 2, p. 231–238. Proposed to replace name Fort Union for sediments in vicinity of Polecat Bench. Thickness about 3,500 feet. Bounded below by *Triceratops*-bearing (Lance?) beds and above by *Homogalax*-bearing (Gray Bull) beds. Composed of rocks, at Polecat Bench, mapped and described as Lebo and Tongue River by Stow (1938, Geol. Soc. America Bull., v. 49, no. 5, p. 731–762) and as Paleocene and Fort Union by Jepsen (1930, Am. Philos. Soc. Proc., v. 69, no. 7). Includes (ascending) Mantua lentil, Rock Bench quarry beds, Silver Coulee beds, and Clark Fork beds.

F. B. Van Houten, 1944, Geol. Soc. America Bull., v. 55, no. 2, p. 178. Underlies Willwood formation (new) ; in middle of Big Horn Basin, contacts are conformable; near basin's margin Willwood dips basinward and is locally nonconformable or overlaps Polecat Bench.

Well exposed at Polecat Bench, in Bighorn near Powell, Park County.

**Pole Creek Dacite**

Pliocene(?) : Northeastern Nevada.

R. R. Coats, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI–690, book 2, p. 304, 306–307. Medium-gray to black vitrophyre in form of small domical protrusions. Maximum thickness as much as 900 feet and maximum exposed length about 1½ miles; parts of masses concealed by gravels. Older than Gods Pocket dacite (new) ; younger than Robinson Creek vitrophyre.

Near eastern border of Jarbidge quadrangle.

**Poleo Sandstone Lentil** (in Chinle Formation)

Poleo Sandstone[1]

Upper Triassic: Central northern New Mexico.

Original reference: F. V. Huene, 1911, Neues Jahrb., Beilage-Bd. 32, p. 730–739, pl. 32.

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. Rank reduced to lentil in lower part of Chinle; overlies Salitral shale tongue (new). Prior to this survey, unit had been mapped as Senorito sandstone lentil of Chinle(?) in vicinity of Senorito Canyon and as Poleo sandstone in Mesa Poleo region.

Forms crest of Mesa Poleo.

Poleslide Member (of Brule Formation)

Oligocene: Southwestern South Dakota.

J. D. Bump, 1956, Am. Jour. Sci., v. 254, no. 7, p. 431–432. Unit formerly known as *Proteceras* beds (*Leptauchenia* beds) here designated Poleslide member. Subdivided into three units: lower zone includes approximately 100 feet of rather barren clays capped with light-gray clay band; middle zone, about 110 feet thick, is buff and gray clays where *Leptauchenia* nodules are developed and channel sandstones occur; upper unit, about 85 feet thick, is vertically weathered gray silty ash. Overlies Scenic member (new); underlies Arikaree white ash.

Standard section: NW¼ sec. 23, T. 43 N., R. 44 W., 8½ miles south of Scenic, and on south rim of Sheep Mountain Table, Shannon County.

†Polk Bayou Limestone[1]

Middle and Upper Ordovician: Northern Arkansas.

Original reference: H. S. Williams, 1899, Am. Jour. Sci., 4th, v. 8, p. 139–152.

Named for Polk Bayou, near Batesville, Independence County.

†Polk County Ash Bed (in Stanley Shale)[1]

Pennsylvanian: Southwestern Arkansas.

Original reference: J. F. Williams, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 375–376.

Named for exposures in Polk County.

**Polk Creek Shale[1]**

Upper Ordovician: Southwestern Arkansas and southeastern Oklahoma.

Original references: A. H. Purdue, 1909, Geol. Soc. America Bull., v. 19, p. 557; 1909, Slates of Arkansas, Arkansas Geol. Survey, p. 30, 36.

B. H. Harlton, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 4, p. 781 (fig. 2), 787. Described in Ouachita Mountains of southeastern Oklahoma where it is well developed at Black Knob Ridge and in the Potato Hills. In most exposures, shale is somewhat altered, hard, siliceous, and darker than the normal Sylvan; lower part is dark gray to black, dolomitic, and resembles "Normal Sylvan" of the Arbuckles; it includes the black bituminous type at its base, everywhre along south front of mountains east of Ardmore on Highway 77 and at Apache; the remainder, approximately 60 feet, consists of rather soft dark-greenish to greenish-gray platy shale, which is indistinguishable from the Sylvan of the Arbuckles. Unconformably overlies Big Fork chert; unconformably underlies Missouri Mountain shale. Silurian.

Named for Polk Creek, Montgomery County, Ark.

Pollack Quartz Latite

Tertiary, upper: Southwestern New Mexico.

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 39 (table 3), 47, pl. 1. Quartz latite ranges in color from a dominant pinkish brown to light red and purple. Attains maximum thickness of about 300 feet. Disconformable contacts with overlying Razorback formation and underlying Mimbres Peak formation. Late Tertiary.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 37. Described as purplish-gray rhyolite in Dwyer quadrangle. Underlies Santa Fe fanglomerates. Tertiary(?).

Type area: Along Taylor Creek which branches off to north of Pollack Creek. Named for exposures on Pollack Creek, Lake Valley quadrangle.

**Pololu Volcanic Series**

Pliocene(?) : Hawaii Island, Hawaii.

H. T. Stearns, and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 171, 176, 197; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 127. Predominantly olivine basalt with minor amounts of picrite-basalt and a few intercalated vitric tuff beds. At type section, consists of 450 feet of thin-bedded highly vesicular aa and pahoehoe primitive-type basalts dipping about 5° NE.; they extend an unknown distance below sea level; section is capped by flow of andesite of Hawi volcanic series (new). Maximum exposed thickness about 3,500 feet; 891 feet on southeast wall of Waipio Valley. Separated from overlying Hawi volcanic series by erosional unconformity.

Type section :Exposures on trail down northwestern wall of Poholu Valley. Composes lower slopes of much of Kohala Mountains at north end of island.

Polonio Sandstone Tongue (in McLure Shale)

Miocene, upper: Southern California.

O. T. Marsh, 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 32–33, pls. 1–2. Comprises alternating beds of siliceous quartz sandstone and interbeds of siliceous shale in approximately equal amounts. The massive sandstones crop out at prominent ledges and range in thickness from 1 foot to 36 feet; 10-foot-thick beds are common. Beds much broken by vertical closely spaced joints. Characteristic feature is intricate criss-crossing of thin siliceous veinlets which weather into sharp relief as ledges. Approximately every 20 feet along bedding are light-gray-brown lenticular concretions up to 3 by 5 feet which weather to brown.

Named for Polonio Pass at head of Antelope Valley [Kern County]. Tongue enters Orchard Peak area from northwest, thins southeastward and pinches out northwest of Hughes Ranch, near head of valley.

**Pomeroy Member** (of Naknek Formation)

Upper Jurassic: Central southern Alaska.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Comprises two facies. Sandstone facies approximately 400 feet thick on Oil Bay and 1,300 feet on south shore of Chinitna Bay. Sandstone beds on Oil Bay averaging 10 feet in thickness are interbedded with arenaceous siltstone beds averaging 1 foot in thickness. Sandstone is gray coarse grained arkosic grit. Conglomerate facies approximately 500 feet thick on east shore of Iniskin Bay. Lithology of conglomerate similar to that of conglomerate facies of Chisik member. Total thickness of member ranges from 600 to 1,300 feet. Conformable contacts with unnamed underlying siltstone member and overlying upper sandstone member.

Conglomerate facies forms northwest-facing cliff and hogback ridge extending from Iniskin Bay to Mount Pomeroy and eastward; on Iniskin Peninsula.

Pomeroy Quartz Monzonite[1]

Tertiary(?): Central Colorado.

Original reference: R. D. Crawford, 1913, Colorado Geol. Survey Bull. 4, p. 79.

J. W. Adams, 1953, U.S. Geol. Survey Bull. 982–D, p. 98, 103–104. Probably of Tertiary age.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 23. Name changed to Mount Pomeroy quartz monzonite because name Pomeroy was preempted.

Named for Pomeroy Mountain, Monarch district, Garfield quadrangle, Chaffee County.

Pomeroy Sandstone (in Monongahela Formation)[1]

Pomeroy sandstone member

Pennsylvanian (Monongahela Series): Southeastern Ohio and West Virginia.

Original reference: E. Lovejoy, 1888, Ohio Geol. Survey, v. 6, p. 630, 631, 635.

A. T. Cross and M. P. Schemel, 1956, West Virginia Geol. Survey, v. 22, pt. 1, p. 76 (figs. 1–70). Geologic section shows Pomeroy sandstone present in Guyandot quadrangle, Wayne County, W. Va. Thickness about 8 feet. Occurs above Redstone (Pomeroy) coal zone.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 71, geol. map. Pomeroy sandstone member (Monongahela series) underlies Fishpot limestone and shale member and overlies Redstone-Pomeroy (No. 8–A) coal. In early reports, Pomeroy coal was considered correlative of Pittsburgh (No. 8) coal, and term Pomeroy was applied to the overlying sandstone, which is the Upper Pittsburgh sandstone. With the recognition of the equivalency of the Pomeroy coal and the Redstone (No. 8–A) coal, term Pomeroy was applied in its present meaning. Ohio Geological Survey no longer considers the Fishpot sandstone correlative with the Pomeroy and has abandoned term Fishpot sandstone. In Morgan County, the Pomeroy member is a well-developed sandstone unit in many areas and a sequence of sandstones and shales in other areas. The massive phase locally extends upward to coalesce with the stratigraphically higher Lower Sewickley sandstone in areas where the Fishpot limestone, clay, and coal members are not present. The Pomeroy coalesces with the Upper Pittsburgh sandstone where Redstone coal and limestone members are absent. Where underlying Redstone (No. 8–A) coal and overlying Fishpot limestone members are present, the Pomeroy sandstone interval is 11 to 30 feet thick and averages 18 feet.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 170. Member of Fishpot cyclothem in report on Athens County. Term Pomeroy sandstone first used by Lovejoy (1888) for sandstone overlying Pomeroy or Redstone coal bed near Pomeroy, Ohio. Since that date, other names applied to this member include Redstone sandstone (Swartz and others, 1919) and Cedarville sandstone (Reger, 1916). Name Pomeroy has priority and is retained in this report. Thickness 0 to 30 feet; average thickness 12 feet. Underlies Fishpot redbed member; overlies roof shale at top of Redstone cyclothem. Monongahela series.

Named for Pomeroy, Meigs County, Ohio.

Pomfret Granite[1]

Devonian: Southeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Probably named for Pomfret Township, Windsor County.

Pomfret Phyllite[1]

Pomfret phyllite phase (of Hebron Gneiss)

Pre-Triassic: Northeastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 129.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey [Bull. 84]. Refers to Pomfret (Worcester) phyllite phase of the Hebron gneiss. Occurs at the eastern margin of the Hebron outcrop area. Pre-Triassic.

Typically developed in northeastern part of Pomfret [Township], Windham County.

Pompey Member (of Skaneateles Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 219, 220.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Overlies Delphi Station member (name replaces Delphi of Cooper, 1930); underlies Butternut shale member (name replaces Berwyn member of Cooper, 1930). Middle Devonian.

Type section: Upper 60 feet of section at top of Pratt Falls. Name is probably from village of Pompey, Onondaga County.

Pomponio Member (of Purisima Formation)

Pliocene: Northern California.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1325. Consists of about 2,300 feet of rhythmically interbedded siliceous mudstones and siltstones with a sandstone, siltstone, and mudstone facies locally developed. Overlies Tahana member (new); underlies San Gregorio member (new).

Area of report is in Santa Cruz Mountains, 30 to 40 miles south of San Francisco.

Ponca sandstone[1]

Upper Cretaceous: Northeastern Nebraska and northwestern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 148, 150.

Named for Ponca, Dixon County, Nebr.

**Ponce Limestone**

Ponce Chalky Limestones[1]

Oligocene, upper, and Miocene, lower: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 10, 17.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85, 2 sheets. Ponce limestone, in this report, comprises entire sequence of limestones overlying Juana Díaz formation; as mapped, is divided into a lower buff chalky limestone member and an upper hard white limestone member. Maximum thickness about 1,300 meters—between river valleys south of Peñuelas and west and southwest of Ponce. Uncomformable below undifferentiated Quaternary deposits.

R. C. Mitchell-Thome, 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 138. Includes Mercedita lentil (new) in lower part.

On south coastal plain, main outcrop of formation extends 55 kilometers, from hills 5 kilometers southeast of Juana Díaz to Ponce and westward from there to Bahia Montalva.

Poncho Rico Formation[1]

Miocene(?) and Pliocene: Southern California.

Original reference: R. D. Reed, 1925, Jour. Geology, v. 33, p. 591, 592, 605–607.

B. L. Clark, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1956–1957. Underlies King City formation (new).

J. E. Kilkenny, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 12, p. 2260–2261. Described in Salinas Valley where it consists of sands, silts, shales, and conglomerates, and contains Pliocene megafossil assemblage. Both conformable and unconformable on underlying Santa Margarita sand on Central fault block where it is generally less than 500 feet thick. Reaches maximum thickness of 900 feet in Cholame Hills where unconformable with underlying McLure shale. Unconformably underlies Paso Robles formation. Term Poncho Rico preferred here to Etchegoin because type section of former is in Salinas Valley, and type section of latter is in San Joaquin Valley. King City formation is limited in extent and for convenience is included in uppermost part of Santa Margarita formation.

Probably named for exposures along or near Poncho Rico Creek, Monterey County. [Now spelled on topographic map as Pancho Rico.]

Pond Limestone[1]

Mississippian (Chester): Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

Tishomingo County.

Pond Creek Coal Member (of Modesto Formation)

Pennsylvanian: Southeastern Illinois (subsurface).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1), pl. 1. Proposed for coal member reported at depth of 125 feet in drill hole. Occurs above DeGraff coal member (new) and below Lake Creek coal member (new). Coal has been referred to informally as 2d Cutler Rider coal. Piasa limestone and DeGraff, Pond Creek, and Lake Creek coals may be included in the complex West Franklin limestone member in eastern part of area. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Consolidated Coal Co. drill hole 91 in SW¼NE¼NE¼ sec. 21, T. 8 S., R. 3 E., Williamson County. Name derived from Creek that flows through northern part of township.

**Pondera Till**

Pleistocene: Central northern Montana.

J. F. Smith, Jr., I. J. Witkind, and D. E. Trimble, 1959, U.S. Geol. Survey Bull. 1071–I, p. 142, 153, pl. 10. Till is light brown but weathers chocolate brown to contrast markedly with light buff of underlying Lothair till (new) or the yellow of the intertill silt. Semiplastic and consists of clay that contains small amounts of unsorted pebbles, cobbles, and boulders of quartzite, limestone, dolomite, granite, and foliated metamorphic rocks. Rocks are rounded and average about half an inch in diameter. Thickness in most places about 30 feet; in a few exposures as much as 60 feet.

Named for exposures along north valley wall of Pondera Coulee in T. 29 N., Rs. 4 and 5 E., Liberty County. Best exposed on both sides of Marias River valley, in secs. 2, 10, and 11, T. 29 N., R. 5 E., and along north valley wall of Pondera Coulee in T. 29 N., Rs. 4 and 5 E.

Pond Hill Granite[1]

Upper Devonian or Upper Carboniferous: West-central New Hampshire.

Original reference: M. P. Billings, 1935, Geology of Littleton and Moosilauke quadrangles, New Hampshire: Concord, New Hampshire State Plan. Devel. Comm., p. 28, map.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 510, pl. 12. Discussed under New Hampshire magma series. Medium-fine gray granite. On map legend, Pond Hill granite is above Sugar Hill quartz monzonite and below Moody Ledge granite. However, relative ages of units of series have not been determined with complete satisfaction for in few places are they in contact.

Mapped on Pond Hill in northern part of Moosilauke quadrangle.

**Pondville Conglomerate[1]**

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134–141.

A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Interfingers with Wamsutta formation in southern part of quadrangle; partly older than "red beds" of Wamsutta and partly equivalent to them. Pennsylvanian.

A. W. Quinn, 1952, Bedrock geology of the East Greenwich quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad. Map [GQ–17]. Basal beds are chiefly white to buff coarse conglomerate with pebbles and boulders mostly of quartzite. These are interbedded with layers of gray to dark-gray sandstone. Bedding variable; crossbedded in part. Thickness generally 100 to 160 feet in Natick area. Underlies Rhode Island formation with gradational contact. Not recognized south of Greenwich Bay, R. I., where unit as mapped by Emerson (1917) is assigned to the Rhode Island formation.

Basal beds well exposed near Pondville Station on Walpole and Wrentham Railroad, Norfolk County, Mass.

Ponia (Poniya) Limestone

Pleistocene: Mariana Islands (Rota).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 345, 346 (correlation table) [English translation in library of U.S. Geol. Survey, p. 2, correlation table.] Poniya limestone shown on correlation chart below Mariana limestone and above Hirippo limestone. Pliocene(?).

S. Hanzawa, 1956, *in* Jacques Avias and others, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 53. Limestone complex. Forms foundations of successive terraces; consists of Foraminifera, calcareous algae, and fragmental reef-building corals; commonly thinly stratified. Dips toward sea at angle of 20°. Present in altitude less than 200 meters while Mariana limestone is found even in highest terrace of island, 470 meters in height. Sometimes unconformably overlain by Mariana limestone. In this case, it may be contemporaneous with one of Mariana limestone of higher terraces. Also considered forereef detrital facies of Mariana.

Type locality: Ponia, south coast of Rota Island.

Pontchartrain Clay[1]

Pleistocene: Southeastern Louisiana and southwestern Mississippi.

Original reference: L. C. Johnson, 1891, Geol. Soc. America Bull., v. 2, p. 24–25.

In region north of Lake Pontchartrain, La.

Pontiac Limestone (in McLeansboro Formation)[1]

Pontiac Limestone (in McLeansboro Group)

Pennsylvanian: Central eastern Illinois.

Original reference: J. E. Lamar, 1929, Illinois Geol. Survey Rept. Inv. 17, passim.

M. E. Ostrom, 1957, Illinois Geol. Survey Circ. 243, p. 4 (fig. 2), 7. Rank raised to formation in McLeansboro group. Lies approximately 150 to 200 feet above Lonsdale limestone and 250 to 300 feet below Millersville, LaSalle, and Livingston limestones.

Crops out southeast, northeast, and northwest of Pontiac, Livingston County.

**Pontotoc Group**[1]

Pennsylvanian and Permian: Central southern Oklahoma.

Original reference: G. D. Morgan, 1922, Oklahoma Geol. Survey Circ. 11.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Upper part of group mapped. Hart limestone member of Stratford formation of Pontotoc group at base in Pontotoc, Garvin, and Murray Counties. Permian.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, pl. 1. In Seminole County, comprises Vanoss formation below and Konawa formation above. Overlies Ada formation. Pennsylvanian (Virgil) and Permian.

Named for development in western part of Pontotoc County.

Pony Group, Metamorphics or Gneiss

Pony Series[1]

Precambrian (pre-Belt): Southwestern Montana.

Original reference: W. Tansley, P. A. Schafer, and L. H. Hart, 1933, Montana Bur. Mines and Geology Mem. 9, p. 8, map.

E. W. Heinrich, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1329. Cut by Blacktail granite gneiss (new).

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 20. Locally underlies Flathead sandstone.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 350, pl. 1. Group mapped and described in Lima region, Montana. Intruded by Dillon granite gneiss (term replaces Blacktail granite gneiss, preoccupied). Stratigraphic relations between Pony group and Cherry Creek group not clear in this area.

R. R. Reid, 1957, Montana Bur. Mines and Geology Mem. 36, p. 3–4, 14, geol. map. Metamorphics mapped and described in Tobacco Root Mountains. Within map area, Pony metamorphics are separated from Cherry Creek metamorphics by seemingly continuous greenish quartzite layer with only small isoclinal folds present within it. Foliation in Cherry Creek metamorphics appears to be everywhere parallel to that in Pony in vicinity of contact. Discordance suggested by Tansley and Schafer (1933) not observed. Most significant structural fact is that Cherry Creek metamorphics dip beneath Pony metamorphics. Unless some kind of large scale structural overturning has occurrred, the Cherry Creek metamorphics in Tobacco Root Mountains are older than Pony metamorphics (in range in which their type locality has been defined). This is contrary to generally accepted opinion.

Named for exposures at and in vicinity of town of Pony, Madison County.

**Pony Creek Shale Member** (of Wood Siding Formation)

Pony Creek Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, eastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 74, 81.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 41. Pony Creek shale was named by Condra (1927) to include too much section; it was redefined to a thickness of about 6 feet, which, at places, does not represent a natural formation and probably not a good member. Rank reduced to member status in Wood Siding formation (new); Pony Creek as restricted by Moore is not a good formation in Nebraska. Overlies unnamed sandstone and shale units; underlies Brownville limestone.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 13. New type locality selected.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Included in Wood Siding formation (redefined). Underlies Brownville limestone member; overlies Grayhorse limestone member.

P. B. Greig, 1959, Okla. Geol. Survey Bull. 83, p. 65–67. Described in Pawnee County where it is 60 to 75 feet thick. Overlies Brownville limestone member; underlies "Grayhorse" limestone member. Further southward continuation of unit appears likely but its extent is not known.

Type locality (Selected by Nebraska Survey): On Towle Farm 2½ miles southwest of Falls City, Richardson County, Nebr. Named for exposures east of Pony Creek, between Kansas-Nebraska line and 2 miles south of Falls City.

**Pony Express Limestone Member** (of Wanakah Formation)

†Pony Express Beds (in Morrison Formation)[1]

Pony Express Limestone Member (of Morrison Formation)

Upper Jurassic: Southwestern Colorado, New Mexico, and Utah.

Original reference: J. D. Irving, 1905, U.S. Geol. Survey Bull. 260, p. 56.

M. I. Goldman and A. C. Spencer, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1748 (fig. 2), 1750, 1752, (fig. 3), 1853 (table). Referred to as limestone member of Morrison. Underlies Bilk Creek sandstone member (new) ; overlies Entrada sandstone. [See La Plata sandstone.]

E. B. Eckel, 1949, U.S. Geol. Survey Prof. Paper 219, p. 27 (table), 28, 29. Described in La Plata district, Colorado, where it is reallocated to member status in Wanakah formation (redefined). In places, consists of single massive bed, and, in others, comprises three or more beds, each about a foot thick. In latter areas, upper beds are commonly massive and lower ones thinly laminated; most limestone bituminous. Thickness 6 inches to 30 feet; average 3 feet; variations in thickness probably due to irregularities in surface of Entrada upon which limestone was deposited. Underlies Bilk Creek sandstone member.

Named for occurrence in Pony Express mine, Ouray district, Colorado.

Pony Spring Siltstone Member (of Maroon Formation)[1]

Pony Spring Siltstone Member (of Minturn Formation)

Pennsylvanian or Permian: Central Colorado.

Original reference: D. B. Gould, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 7, p. 971–1009.

C. A. Arnold, 1941, Michigan Univ. Mus. Paleontology Contr., v. 6, no. 4, p. 59–70. Mentioned in discussion of some Paleozoic plants from central Colorado and their stratigraphic significance. Bath submember of Pony Spring has yielded *Walchia sp. Walchia* has been found in Pennsylvanian strata as well as in Permian and is, therefore, not a strict time marker, but rather a reflection of environment.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 43–44, 152–153, pls. 1, 8. Described in South Park area where, near Salt Creek, it is about 6,000 feet thick; conformably overlies Chubb siltstone member. At type locality, upper limit is Tertiary erosion surface formed before extrusion of Buffalo Peak flows; upper contact now concealed by lavas and talus. [Text states locality from which unit was named and refers to appendix for type section; however, sections in appendix are headed representative sections, but none agree exactly with locality from which unit was named. Most detailed section is on p. 152–153.].

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 820, 836–837. Pony Spring siltstone considered member of Minturn formation in this report [Permo-Pennsylvanian zeugogeosyncline, Colorado and New Mexico]. Overlies Chubb member and consists of 4,000 to 6,000 feet of greenish-gray and red siltstone and sandstone and was deposited in piedmont cyclothems. Contact of Minturn and Maroon formations lies in lower Pony Spring member at top of limy zone a few hundred feet above top of Bath sandstone (Gould, 1935) ; zone consists of gray shale and thin beds of limestone on Salt Creek and can be traced southward to Muleshoe Gulch where limestone is thinner. Zone lies about 2,700 feet above the gypsum [in Chubb member ] and about 4,300 feet above base of Pennsylvanian. Chubb siltstone assumed to be Desmoinesian because of position in section; on basis of correlations, basal Pony Creek is probably Desmoinesian.

Named for Pony Spring at west side of Pony Park, near NW cor. sec. 28, T. 12 S., R. 77 W., Park and Chaffee Counties. Representative section

(Stark and others, p. 152–153) is in secs. 20, 29, 32, and 33, T. 12 S., and sec. 16, T. 13 S., R. 77 W., [Park-Chaffee Counties].

Pooleville Member (of Bromide Formation)

Ordovician: Southern Oklahoma.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 120, 121. Name proposed for upper limy beds of formation. At type section, mostly a light-gray to nearly white limestone, thin-bedded except for top 15 feet which is massive. Thickness at type section about 250 feet. Overlies Mountain Lake member (new); unconformably underlies Viola formation.

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, p. 95, fig. 1. Pooleville apparently includes Ulrich's Criner and Webster (name preempted) formations. Corbin Ranch (new) of this report is the topmost lithographic limestone and calcareous shale section of Cooper's Pooleville.

Type section: On Spring Creek about on the line between secs. 8 and 17, T. 2 S., R. 1 W., Murray County. Name taken from Pooleville on west side of Arbuckle Mountains.

Pools Brook Limestone[1] (in Manlius Group)

Pools Brook Limestone Member (of Manlius Limestone)

Silurian(?): Central New York.

Original reference: Burnett Smith, 1929, New York State Mus. Bull. 281, p. 27, 31.

G. H. Davis 3d, 1953, New York State Mus. Circ. 35, p. 8, 10. Described as a member of Manlius limestone.

Named for exposure along southern rim of Pools Brook Valley, eastern Onondaga County.

Poorman Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. and Min. Jour.-Press, v. 115, p. 793–799, 836–843, maps.

J. A. Noble and J. O. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 944 (fig. 1), 945–946. Thickness possibly 2,000 feet or more; base not exposed. Underlies Homestake formation. Includes unit formerly termed De Smet formation.

Named for exposed section at junction of Poorman and Deadwood Gulches, along railroad track, Lead district, Lawrence County.

Poor Mountain Limestone Series,[1] or zone[1]

Cambrian(?): Northwestern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 6, 10.

Exposed from a high point on Poor Mountain to a low point on a dale of Rich Mountain. Named for exposures along Poor Mountain, Oconee County.

**Poor Valley Ridge Member** (of Clinch Sandstone)

Lower Silurian: Southwestern Virginia and northeastern Tennessee.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76 (2 sheets); 1954, Virginia Geol. Survey Bull. 71, p.

143–148, 188; R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 76–79, 122, 125–126, pl. 1. Fine- to medium-grained buff to greenish-white sandstone in beds a few inches to two feet thick, with partings and interbeds of green shale. Sandstone most massive in lower part; shale most abundant in upper part. Thickness 183 feet. Overlies Hagan member (new) ; underlies Clinton shale.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Lower Silurian.

Named for exposures along Louisville and Nashville Railroad cut in gap through Poor Valley Ridge near Hagan, Lee County, Va.

**Pope Chapel Sandstone Member** (of Atoka Formation)[1]

Pennsylvanian (Atoka Series) : Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 28–29. Hard calcareous greenish-gray to buff sandstone. Thickness 10 to 20 feet. Overlies unnamed shale above Coody sandstone member; underlies unnamed shale below Georges Fork sandstone member.

Named for exposure at Pope Chapel, sec. 24, T. 12 N., R. 19 E., Muskogee County.

Pope Creek Coal Member (of Abbott Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 45 (table 1), pl. 1. Assigned to member status in Abbott formation (new). Occurs above Tarter coal member and below Bernadotte sandstone member. Name Pope Creek sandstone discontinued. Coal named by Wanless (1931, Illinois Geol. Survey Bull. 60). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification retained but is independent of rock-stratigraphic classification.

Type locality: Center sec. 33, T. 14 N., R. 2 W., Mercer County.

Pope Creek cyclothem (in Abbott Formation)

Pope Creek cyclothem (in Tradewater Group)[1]

Pennsylvanian: Western, northern, and central Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 189, 192.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, pl. 1. Shown on correlation chart below Seville cyclothem and above Tarter cyclothem (new).

R. M. Kosanke, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2). In Abbott formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Named from exposures on south side of Pope Creek near center sec. 33, T. 14 N., R. 2 W., Alexis quadrangle, Mercer County.

Pope Creek Sandstone

Pennsylvanian: Western, northern, and central Illinois.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 63–64, 67–70, 192, 201, 204, 205. Pope Creek sandstone is commonly light gray, fine grained, very slightly micaceous, not very massive, and not well laminated. Thickness a few inches to 5 feet; average about 1 foot. Thickness of cyclothem as much as 17 feet. Bernadotte sandstone, in basal part of Seville cyclothem, truncates Pope Creek shale at several localities, and locally cuts out entire Pope Creek cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31. Name Pope Creek sandstone discontinued so that term Pope Creek may be retained for coal member.

Cyclothem named from exposures on south side of Pope Creek near center sec. 33, T. 14 N., R. 2 W., Alexis quadrangle, Mercer County.

†Pope Hollow Conglomerate[1]

Pope Hollow Conglomerate Member (of Venango Formation)

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: J. F. Carll, 1883, Pennsylvania 2d Geol. Survey Rept. $I_4$, p. 180–181.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 14, 243, 253. Prominent conglomerate band in middle part of Venango formation. Underlies Saegerstown shale member; overlies North Warren shale member. Upper Devonian.

Probably named for occurrence at Pope Hollow, Chautauqua County, N.Y.

Pope Springs Sandstone

[Upper Paleozoic]: Southeastern Wyoming.

C. M. Boos, 1941, (abs.) Colorado-Wyoming Acad. Sci. Jour., v. 3, no. 1, p. 25–26. Sand stratum close to the Satanka-Casper contact. Referred to also as Pope Spring sandstone.

In foothills of Laramie Mountains, a few miles east and south of town of Laramie, Laramie County, where there are a number of large springs.

**Poplar Mountain Gneiss**

Middle Paleozoic: North-central Massachusetts.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Described in Mount Toby quadrangle. Underlies Erving hornblende schist with gradational contact. Probably an eastern partially granitized facies of Amherst schist. Name credited to Robert Balk. Pre-Triassic.

Robert Balk, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–93. Described in type area as dark-gray well-foliated micaceous gneiss consisting of thin parallel black layers of biotite intercalated with fine-grained gray layers containing quartz and biotite in equal amounts. Lenses and beds of brittle light-gray well-stratified quartzite widespread; some actinolitic. Thickness of quartzite layers varies from less than 1 inch to 400 feet. Thin layers of typically dark-green to nearly black amphibolite common. Intermixed with Dry Hill granite gneiss. Represents sedimentary facies of the domelike gneissic complex termed Pelham granite by Emerson (1917, U.S. Geol. Survey Bull. 597). Middle Paleozoic.

Named for excellent exposures on Poplar Mountain 1 mile northeast of Millers Falls, Millers Falls quadrangle.

**Popo Agie Member** (of Chugwater Formation)

Popo Agie Beds[1]

Popo Agie Formation (in Chugwater Group)

Upper Triassic: Western Wyoming.

Original reference: W. C. Knight, 1901, Eng. and Min. Jour., v. 72, p. 359.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 43, 45. Allocated to member status in Chugwater formation. Underlies Gypsum Spring member; overlies Crow Mountain member (new). Thickness 297 feet. Area of report is southern margin of Absaroka Range.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 135–136. Rank raised to formation in Chugwater group. In Wind River Mountains, overlies Crow Mountain formation; underlies Wyopo formation (new). Thickness as much as 125 feet.

J. D. Love and others, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 17. Popo Agie, as used in this report [central Wyoming], is youngest member of Chugwater and is characterized by 100 to 200 feet of ocher-colored oolitic, siliceous, dolomitic claystones, limestone pellet conglomerates, purple and red shales, and red silty sandstones. Overlies Alcova limestone member. No consistent base for member has been found, either on surface or in subsurface. Underlies Nugget sandstone. Name Popo Agie used in this area in preference to Jelm.

Named from exposures on Popo Agie River, near Lander.

**Popotosa Formation**

Miocene, upper: Central New Mexico.

C. S. Denney, 1940, Jour. Geology, v. 48, no. 1, p. 77–84. Consists of debris eroded from volcanic rocks, plus small amount of tuff which was contributed by relatively small contemporaneous eruptions. Highly faulted. Estimated minimum thickness 3,000 feet; possible maximum 5,000 feet. Unconformably overlies volcanic rocks of Miocene(?) age to east of Silver Creek; underlies Santa Fe formation.

Well exposed in Silver Creek valley, T. 1 N., R. 2 W., San Acacia area, Socorro County. Named for Arroyo Popotosa.

Porcupine Beds[1]

Tertiary: Southwestern Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 197, 253.

Exposed on Porcupine River, between mouth of Driftwood River and head of the Ramparts, Yukon gold district.

Porcupine Group[1]

Ordovician and Silurian: Eastern Alaska, and northwestern Yukon, Canada.

Original reference: D. D. Cairnes, 1912, Canada Geol. Survey Summ. Rept. 1911, p. 26–32.

Yukon-Alaska boundary between Porcupine and Yukon Rivers.

Porcupine Ranch Substage

Pleistocene (Wisconsin): Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Sec. [Guidebook] 2d Ann. Field Trip, Oct. 4–5, correlation chart. Substage of Bull Lake stage. Occupies Iowan-Tazewell interval between Iowan subage and Tazewell sub-age.

Twin Lakes area.

**Porphyry Peak Rhyolite**[1]

Tertiary: Central southern Colorado.

Original reference: W. S. Burbank, 1932, U.S. Geol. Survey Prof. Paper 169.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 195, 196. In Greater Bonanza district, volcanics in order of succession are Rawley andesite, Bonanza latite, Squirrel Gulch latite, Porphyry Peak rhyolite, and Bremer [Brewer] Creek latite. In South Bonanza district, the volcanic sequence is roughly the same except Porphyry Peak rhyolite is missing and the Bonanza latite is replaced by Hayden Peak latite.

Exposed on slopes of Porphyry Peak, Bonanza district, Saguache County.

Porphyry Peaks Conglomerate

Pleistocene (?) : North-central Colorado.

R. L. Ives, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1049–1050. Poorly consolidated conglomeratic material. In two layers, separated in places by crossbedded sand. Most of the larger boulders are gray porphyry derived from the erosion of a steep-walled canyon through a porphyry dike near Pony Park. Top of conglomerate veneered with injection gneiss fragments which probably were washed from nearby moraines. Fills valley of Stillwater Creek to maximum depth of about 100 feet.

In valley of Stillwater Creek from Sleepy Hollow School to Pony Park in Monarch Valley, Grand County. In places nearly 1 mile wide.

Porphyry Peaks Rhyolite[1]

Tertiary : Central northern Colorado.

Original reference: L. E. Spock, Jr., 1928, New York Acad. Sci. Annals, v. 30.

Caps Porphyry Peaks and occurs on mountain tops on either side of Stillwater Creek farther south, in northeastern part of Grand County.

†Portage Group,[1] Formation,[1] or Shale[1]

Upper Devonian: New York, Maryland, Pennsylvania, and western Virginia.

Original references: J. Hall, 1840, New York Geol. Survey 4th Rept., p. 391–392, 452–455; L. Vanuxem, 1842, Geology of New York, pt. 3, p. 171, 172; J. Hall, 1843, Geology of New York, 4th dist., p. 224–249.

H. S. Williams, R. S. Tarr, and E. M. Kindle, 1909, U.S. Geol. Survey Geol. Atlas, Folio 169. Following the Genesee, and conformable with it, are beds of Portage formation. In this are included those beds which have been generally referred to by term Portage, or Portage group. Portage group was originally defined by Hall (1840) and applied to sandstones lying above Gardeau flagstone of Genesee Valley and distinct from the Gardeau, Ithaca, and Cashaqua groups which were named in same report. In this folio [Watkins Glen-Catatonk], rocks between the Genesee and Chemung are called Portage formation. Portage formation, which in typical region of Genesee Valley is composed of the Cashaqua, Gardeau, and "Portage" members, consists in Watkins Glen quadrangle of (ascending) Sherburne, Ithaca, and Enfield members.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 13–16. Upper Devonian begins with lowest beds of Portage group which in Juniata Valley are represented by remnant of Tully. This rests disconformably upon highest Hamilton, the Moscow shale, with its *Vitulina* zone. Top of Portage group lies approximately at base of Catskill red beds, of early Chemung age. Divisions of Portage recognized in Pennsylvania are (ascending) Rush formation (with Tully shale and limestone and Burket black shale) and Fort Littleton formation (with Harrell gray shale, Brallier sandstone and shale, Losh Run shale, Trimmers Rock sandstone, and Parkhead sandstone). Changes among members of group occur from Allegheny Front into eastern Pennsylvania. In the west, members are all shale except Tully and group is dominated by Brallier shale. From Susquehanna Valley east, dominant element of group is Trimmers Rock sandstone which has largely displaced Brallier shale. Tully is little known east of Susquehanna and is presumably displaced by Burket black shale.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. On Devonian correlation chart term "Portage" formation is used in column for east-central West Virginia. Portage shale is used in column for Genesee Valley, Portage is shown above the Letchworth and below the Wiscoy.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 385. Term Brallier shale replaces "Portage" shale as formerly used in West Virginia.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 392–396. Four formations, Grimes sandstone, Gardeau flags and shales, Nunda sandstone, and Wiscoy shale, overlie Naples group in Batavia quadrangle. No group name is applied to them, although they belong to Chemung stage. They had previously been included in Portage group but Chadwick (1933, Pan-Am. Geologist, v. 60) returned name Portage to formational status.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2821, 2826. Report presents revised correlations of lower Upper Devonian rocks in western and central New York. Sherburne flagstone member is excluded from Portage formation of Williams (1906, Science, new ser., v. 24) and Williams and others (1909) and assigned to Genesee formation. Ithaca shale member of Portage is redefined as Ithaca member of Genesee. In area south of Cayuga Lake, the Sonyea formation occupies the upper four-fifths of rock sequence that was designated Enfield shale member of Portage by Williams and others (1909).

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Unit mapped as marine beds (Dm) consists of gray to olive-brown shales, graywackes, and sandstones; contains "Chemung" beds and "Portage" beds including Burket, Brallier, Harrell, and Trimmers Rock; Tully limestone at base.

In 1843, Hall redefined "Portage or Nunda" Group to include older rocks, specifically Sherburne Flagstones, Cashaqua Shale, the Gardeau and Portage Groups of the annual reports. As redefined, Hall's Portage comprises all of the West Falls Formation, all of the Sonyea Formation, and upper two-thirds of Genesee Formation of de Witt and Colton (1959).

Named for exposures along banks of Genesee River in district formerly included in town of Nunda now Portage, Livingston County, N.Y.

†Portage Sandstone[1]

Upper Devonian: New York.

Original reference: J. Hall, 1843, Geology New York, div. 4, 4th dist., p. 226, 228–229, 248.

Well exposed in deep gorge below Portageville, Wyoming County.

**Portage Lake Lava Series**

Precambrian (Keweenawan): Northern Michigan.

W. S. White, 1952, Jour. Sed. Petrology, v. 22, no. 4, p. 190. First appearance of name. Credited to White, Cornwall, and Swanson, 1952 [1953].

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Name proposed to include the Eagle River, Ashbed, Central Mine, and Bohemian Range groups of old reports; these older subdivisions are quite arbitrary and depend on the continuity of individual flows or conglomerate beds for validity and are not useful for purpose of this report. A thick sequence of basalt and andesite flows with a few thin interbedded rhyolite conglomerates. Some flows are uniformly fine grained, but most increase in grain size from both the top and the bottom toward the center. Capping the massive lava that forms the bulk of each flow is a layer of amygdaloidal lava 1 to 75 feet thick (5 to 10 feet thick on most flows). Conglomerate and sandstone beds within the lava series composed primarily of rhyolitic material. The bulk of the clastic particles range in diameter from a small fraction of an inch to about 6 inches; pebbles and cobbles are generally well rounded. Most conglomerate beds or their equivalent horizons can be recognized for tens of miles northeast and southwest of this quadrangle. Tops of conglomerate beds, therefore, form excellent reference horizons for stratigraphic subdivisions of the series, and most of these beds, in consequence, have acquired names in local usage. Designated in ascending order these names are St. Louis conglomerate, the Old Colony and Wolverine sandstones, and the Kingston, Calumet and Hecla, Houghton, Allouez, Pewabic West, and Hancock conglomerates. Because of their exceptional thickness or economic interest, a few of the more persistent lava flows have acquired names in local usage, but most of the flows are nameless. Seven of the flows shown here are designated: the Greenstone, Kearsarge, Scales Creek (new), and Copper City (new) are noteworthy for their thickness; and the Ashbed, Iroquois (new), and Osceola flows, together with the Kearsarge, are of economic interest. Series represents oldest rocks in Ahmeek quadrangle; conformably underlies Copper Harbor conglomerate. Locally intruded by small body of rhyolite.

J. C. Wright and H. R. Cornwall, 1954, Bedrock geology of the Bruneau Creek quadrangle, Michigan: U.S. Geol. Survey Geol. Quad. Map [GQ–35]. Total thickness of 17,000 feet in Bruneau Creek quadrangle, including about 350 separate lava flows and approximately 20 thin beds of sedimentary rocks. Includes Bohemia conglomerate and Gratiot flow.

Other named units that have been assigned to the series are: the Ashbed, Calumet, Kearsarge, Medora, and Osceola amygdaloids and Lac la Belle conglomerate.

Named from Portage Lake, 10 miles southwest of the Ahmeek quadrangle, which was the site of one of Marvine's classic stratigraphic sections of the unit (Pumpelly, 1873, p. 47–89).

Portal Formation

Upper Devonian: Southeastern Arizona.

F. S. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 47, no. 3, p. 475–480. Consists of four members (ascending): alternating very thin beds of calcareous olive-colored shale and shaly aphanitic dark olive-gray limestone—93 feet thick at type section; hard fissile siliceous black shale—37 feet; alternating very thin beds of shale and limestone—153 feet; and alternating thick and very thick beds of bioclastic limestone—

59 feet. Total thickness ranges from 200 to 342 feet; 342 feet at type section. Overlies El Paso formation with disconformable contact; underlies Escabrosa limestone.

Type section: About 2½ miles northwest of village of Portal, from which name is derived. Exposed in SW¼ sec. 14, T. 17 S., R. 31 E., where formation forms ridge between Round Valley on north and Silver Creek on south.

Port Austin Sandstone[1]

Mississippian: Michigan.

Original reference: A. C. Lane, 1899, U.S. Geol. Survey Water-Supply Paper 30, p. 85.

Named for exposures at Port Austin, Huron County.

Port Byron Formation (in Coe Group)

Port Byron Limestone[1] or Dolomite

Port Byron Stage

Middle Silurian: Northwestern Illinois.

Original reference: T. E. Savage, 1926, Geol. Soc. America Bull., v. 37, p. 525–526, 531–533.

J. N. Payne, 1942, Illinois Geol. Survey Bull. 66, p. 191 (table 8). Shown on table of general classification of geologic time as Port Byron stage of Niagaran epoch.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as Port Byron dolomite; overlies Cordova dolomite (new). Niagaran and questionably Cayugan.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 18. Uppermost formation in Coe group (new).

Exposed in quarry at Port Byron, Rock Island County.

**Port Clarence Limestone**[1] (in Nome Group)

Lower and Upper Ordovician, Silurian, and Devonian: Northwestern Alaska.

Original reference: A. J. Collier, 1902, U.S. Geol. Survey Prof. Paper 2, p. 18, map.

R. M. Moxham and W. S. West, 1953, U.S. Geol. Survey Circ. 265, p. 2, 3. Probably mostly Silurian in age in Serpentine-Kougarok area.

Type locality: York Mountains, north of Port Clarence, Seward Peninsula.

**Port Deposit Gneiss**[1] or **Granite**

Lower Paleozoic(?) (Post-Glenarm): Northeastern Maryland, Delaware, and southeastern Pennsylvania.

Original reference: G. P. Grimsley, 1894, Cincinnati Soc. Nat. History Jour., v. 17, p. 112.

Ernst Cloos and H. G. Hershey, 1936, Acad. Nat. Sci., Philadelphia, Proc., v. 22, no. 1, p. 71–80. Port Deposit granite and Baltimore gabbro are intrusive into Glenarm series. Port Deposit granite and its associates, and Baltimore gabbro are not Precambrian, but Paleozoic (post-Conestoga).

Ernst Cloos, 1937, Maryland Geol. Survey [Rept.], v. 13, p. 33 (table 1). Included in Port Deposit granodiorite complex. Post-Lower Ordovician.

Norman Herz, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 980. Cuts Baltimore gabbro complex.

Port Deposit Granite or Gneiss cuts the Glenarm Series. U.S. Geological Survey currently designates age of the Glenarm Series as Lower Paleozoic(?).

Named for occurrences at Port Deposit, Cecil County, Md.

Port Deposit Granodiorite Complex

Post-Lower Ordovician: Northeastern Maryland, Delaware, and southeastern Pennsylvania.

Ernst Cloos, 1937, Maryland Geol. Survey [Rept.], v. 13, pt. 1, p. 13 (table 1). Includes, in addition to Port Deposit granodiorite, hornblende granodiorite, hornblende granodiorite with quartz diorite, pegmatite and aplite dikes, granite porphyry, and hornblende lamprophyre dikes. Post-Lower Ordovician.

H. G. Hershey, 1937, Maryland Geol. Survey [Rept.], v. 13, pt. 2, p. 109–148. Port Deposit granodiorite is part of Appalachian Piedmont complex in northeastern Maryland and northwestern Delaware. The Piedmont in these States, as elsewhere, is composed of metamorphosed sedimentary formations and intrusive igneous materials. In Maryland and Pennsylvania, metamorphism in this belt increases from northwest to southeast. Most of the igneous rocks are found in southeastern part, and of these the Port Deposit granodiorite complex is the largest. It is composed of three large and several small rock bodies, separated by schists, and extends over area about 30 miles long and 9 miles wide. Gabbro makes up parts of the north, west, and south boundaries of the complex. Rest of north boundary is composed of schists, probably of Glenarm series, and serpentine. A belt of metamorphic sedimentary rocks occurs north of the gabbro and south of the Paleozoic rocks. It is interrupted by a narrow, northeast-striking syncline of slate and conglomerates just north of Peach Bottom. Rest of south boundary is marked by overlap of unconsolidated Coastal Plain sediments and "Baltimore gneiss".

Porter Shale[1] or Formation

Oligocene, middle: Western Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 15, p. 10–22.

C. E. Weaver, 1937, Washington [State] Pubs. in Geology, v. 4, p. 110. Suggests abandoning name and retaining Lincoln formation for the middle Oligocene of Washington.

Exposed in cliffs on east and west sides of town of Porter along north side of Chehalis River near junction with Porter Creek [Thurston County].

Porterfield Stage

Middle Ordovician (Mohawkian): North America.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 8, chart 1 (facing p. 130). Mohawkian series divided into five stages (ascending): Whiterock, Marmor, Ashby, Porterfield, and Wilderness. Sequence of formations in type area of Porterfield is (ascending) Arline (new), Effna, Rich Valley (new), and Chatham Hill (new). Name credited to G. A. Cooper and B. N. Cooper.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 94, 95. Constitutes lower part of type Bolarian series and therefore lower part of stage is equivalent to upper Chazyan.

Named from Porterfield quarry 5 miles east of Saltville, Maccrady quadrangle, Virginia, and its environs where it is well represented.

**Porters Creek Clay**[1] or **Formation** (in Midway Group)

Paleocene: Western Tennessee, southwestern Alabama, southwestern Illinois, western Kentucky, eastern Mississippi, and southeastern Missouri.

Original reference: J. M. Safford, 1864, Am. Jour. Sci., 2d, v. 37, p. 361, 368.

F. S. MacNeil, 1946, U.S. Geol. Survey Mineral Inv. Prelim. Rept. 3–195, p. 10–12. In addition to typical clay facies, the Porters Creek includes Tippah sand lentil in lower part, in northern part of Tippah County, Miss., and Matthews Landing marl member at top, from Winston County, Miss., to Butler County, Ala. At outcrop in northern Mississippi, the Porters Creek is about 200 feet thick but thickens southward in subsurface to about 600 feet. Typical clay facies extends from southern Illinois and southeastern Missouri to Tombigbee River in western Alabama. Underlies Naheola formation; overlies Chalybeate member (new) of Clayton formation. Midway group. Paleocene. Name Sucarnooche clay, formerly used for entire Porters Creek in Alabama as well as for the calcareous clay east of Tombigbee River, has been abandoned.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 36–41. Described in Choctaw County, Ala., where it is about 350 feet thick and represents lowermost deposits of Midway group exposed in county. Includes Chalybeate limestone member (at base) and Matthews Landing marl member at top. Underlies Naheola formation.

T. W. Lusk, 1956, Mississippi Geol. Survey Bull. 80, p. 11–15. Described in Benton County where it is oldest outcropping formation. Only upper 70 to 80 feet exposed. Underlies Betheden formation.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 94–117. Described in Kemper County where it is about 500 feet thick. Consists of the typical clay facies, somewhat sandy and laminated at top. Includes Matthews Landing marl member at top. Conformably overlies Clayton formation (Chalybeate member at top); unconformably underlies Naheola formation. Midway group.

Named for exposures on Porters Creek, Hardeman County, Tenn., about 1½ miles west of railroad station at Middleton.

Portersville Limestone or fossiliferous horizon (in Conemaugh Formation)[1]

Portersville shale and limestone member

Pennsylvanian: Southeastern Ohio.

Original reference: D. D. Condit, 1912, Ohio Geol. Survey, 4th ser., Bull. 17, p. 20, 41.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 68, table 1. Portersville shale and limestone member listed as member of Anderson cyclothem in report on Perry County. Greater part of member is shale, but embedded fossiliferous limestone nodules are very conspicuous. Thickness 3 to 8 feet. Conemaugh series.

M. T. Sturgeon and others, 1957, Ohio Geol. Survey Bull. 58, p. 95 (table 11), 122–123. Shale and limestone member of Anderson cyclothem in report on Athens County. Average thickness 2⅓ feet. Occurs above Anderson coal and Cow Run sandstone member of Upper Bakerstown cyclothem. Conemaugh series.

Named for village in eastern part of Perry County.

**Port Ewen Limestone** (in Helderberg Group)

Port Ewen Limestone (in Oriskany Group)[1]

Lower Devonian: Eastern New York, New Jersey, Pennsylvania, Virginia, and West Virginia.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 21.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 50, 62–65, tables 13, 14. Becraft and Port Ewen shale occur as units to which these names can be applied only in eastern part of Monroe County. Table 13 shows Port Ewen shale in Nearpass quarries, New Jersey. Overlies Becraft limestone. Helderberg group.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1162, 1168, 1181. Thickness at Delaware Water Gap 136 feet; underlies Oriskany shale; overlies Becraft(?) limestone. Thickness 174 feet on Bushkill Road; overlies Becraft limestone; underlies Oriskany shale.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 97–110. Thickness in West Virginia 30 to 105 feet. Underlies Port Jervis limestone; overlies New Scotland limestone. Believed to comprise main part of "Shriver chert" of previous reports.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 190–195. Port Ewen beds consist of series of shaly limestones, above Alsen limestone and below Oriskany sandstone. Maximum thickness 6 to 8 feet in Coxsackie quadrangle [this report]. Maximum thickness in New York about 200 feet (Port Jervis area).

Carlyle Gray, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. As mapped, Helderberg formation consists of dark-gray calcareous thin-bedded shale (Mandata) at top, equivalent to Port Ewen shale and Becraft limestone in the east; dark-gray cherty thin-bedded fossiliferous limestone (New Scotland) with some local sandstones in the middle; and, at base, dark-gray medium- to thick-bedded crystalline limestone (Coeymans), sandy and shaly in places with some chert nodules.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 50. Thickness about 95 feet in Rockingham County. Overlies New Scotland limestone; underlies Port Jervis limestone.

Named for exposures in vicinity of Port Ewen, Ulster County, N.Y.

**Port Hudson Formation**[1]

Pleistocene: Southeastern Louisiana, southern Mississippi, and eastern Texas.

Original references: E. W. Hilgard, 1869, Am. Jour. Sci., 2d, v. 47, p. 77–88; v. 48, p. 332; Preliminary Report of a Geological Reconnaissance of Louisiana, 1869.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1714, chart 12. Shown on correlation chart as underlying Hammond terrace deposits and overlying Prairie member (Fisk, 1938).

Named for prominent development at Port Hudson, East Baton Rouge Parish, La.

Port Jervis Limestone (in Oriskany Group)[1]

Port Jervis Limestone and Chert (in Helderberg Group)

Lower Devonian: Southeastern New York, Maryland, Pennsylvania, Virginia, and West Virginia.

Original reference: G. H. Chadwick, 1908, Science, new ser., v. 28, p. 346–348.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 110–127, measured sections. Referred to as Port Jervis limestone and chert in Helderberg group. Geographically extended into West Virginia. At type locality, limestone is about 30 feet thick and consists of blue-gray partly siliceous or finely arenaceous limestone with specimens of *Dalmanites*, *Rensselaracria*, and *Homalonotus*. In central eastern Pennsylvania, formation disappears in an erosional unconformity between Oriskany sandstone and early members of Helderberg group. It is believed to reappear in Franklin County, southern Pennsylvania, and continues southward across Maryland, into West Virginia. In this belt, it occupies more of the Licking Creek limestone of Swartz (1938). Formation thins and is absent in Massanutten syncline of northern Virginia. Overlies Port Ewen limestone; underlies Ridgeley sandstone. Equivalent to part of Shriver chert or "Becraft limestone" of previous reports. Thickness as much as 90 feet.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 49, 50. Thickness about 10 feet in Rockingham County. Overlies Port Ewen limestone. Helderberg group.

Named for Port Jervis, Orange County, N.Y.

**Portland Arkose** (in Newark Group)

Portland Formation

Upper Triassic: Central Connecticut.

P. D. Krynine, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1919. Named as formation. Maximum thickness 4,000 feet. Overlies Meriden formation. A fluvial deposit similar to New Haven arkose.

P. D. Krynine, 1950, Connecticut Geol. Nat. History Survey Bull. 73, p. 30–31, 32, 69–70. Described as arkose. Consists of conglomerates, reddish-brown, purple, and grayish arkoses, fine-grained micaceous siltstones, and subordinate red and dark shales; these compose the normal sedimentary facies. Material becomes coarser from west to east; at the eastern margin in the vicinity of the Great Fault are coarse conglomerates and fanglomerates. Included in Newark group. Outcrop areas described.

E. P. Lehmann, 1959, Connecticut Geol. and Nat. History Survey Quad. Rept. 8, p. 8 (table 1), 25–30. In this report [Middletown quadrangle] Newark group comprises (ascending) New Haven arkose, Talcott basalt, Shuttle Meadow formation (new), Holyoke basalt, East Berlin formation (new), Hampden basalt, and Portland arkose. Except for small area in extreme southeast corner of quadrangle where pre-Triassic Bolton schist crops out, Portland arkose underlies entire eastern half of quadrangle; appears in northwest quarter as result of faulting. Estimated thickness 3,000 to 3,500 feet.

Best exposures in the Portland "brownstone" quarries near Middletown, Middlesex County.

Portland Clays[1]

Age(?) : Maine.

Original reference: C. H. Hitchcock, 1861, Rept. Geology Maine, p. 275–282.

At and around Portland, Cumberland County.

†Portland division (of Selma Chalk)[1]

Upper Cretaceous: Alabama.

Original reference: E. A. Smith, 1903, 58th Cong., 1st sess., S. Ex. Doc. 19, p. 12–20, map.

Along Tombigbee River from Pace's Landing nearly to Moscow, and along Alabama River from Elm Bluff to Old Lexington Landing. Named for exposures at Portland, Dallas County.

Portland (delta) Gravels[1]

Portland Sands and Gravels

Pleistocene: Western Oregon.

Original reference: J. P. Buwalda and B. N. Moore, 1930, Carnegie Inst. Washington Pub. 404, p. 21–22.

R. C. Treasher, 1942, Geologic map of the Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. Referred to on map legend as Portland terrace gravels. Correlates with Clackamas, Tualatin, and Willamette terrace deposits and glacial outwash.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 17–19. Portland gravels, sometimes referred to as Portland delta gravels, were deposited mainly by Columbia River during the Pleistocene. Base of gravels not known with certainty. Maximum thickness may be nearly 600 feet.

E. M. Baldwin, 1957, Northwest Sci., v. 31, no. 3, p. 114–115. Term Portland sands considered more appropriate than gravels.

Present in Willamette Valley in vicinity of Portland.

†Portland Quartzite[1]

Precambrian (Middle? Huronian): Central southern Wisconsin.

Original reference: T. C. Chamberlin, 1877, Geology Wisconsin, v. 2, p. 252–256.

Crops out in several places in town of Portland, Dodge County.

†Portland Shale[1]

Upper Devonian: Western New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 24, chart.

Probably named for exposures at Portland, Chautauqua County.

Portland Hills Silt Member (of Troutdale Formation)

Pliocene, upper, or Pleistocene, lower: Northern Oregon and southwestern Washington.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 10–13, pl. 2. In most roadcuts where silt has been exposed, it is structureless light-brown or yellowish-brown mass which in upper part may be mottled with gray streaks. In deep cuts, light-brown silt grades down into a reddish-brown, clayey silt. Surprisingly uniform in grain size, and suggestion of stratification noted in only few places. Scattered well-rounded quartzite pebbles occur in silt at elevation of 1,100 feet along crest of Portland Hills and attest to water-laid origin there. Thickness 300 to more than 700 feet. Uppermost member of formation.

E. M. Baldwin, 1957, Northwest Sci., v. 31, no. 3, p. 112–113. Rhinoceros tooth from the Portland Hills identified as form not known in North America beyond the Hemphillian. This strengthens Pliocene age for unit.

Forms thick cover over much of the Portland Hills in Oregon. Observed in clay pit west of West Pioneer, Wash. Traced eastward to Underwood Mountain on north side of Columbia River in Washington near Hood River, Oreg.

Portland Point Member (of Moscow Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 21, 229.

G. A. Cooper, 1933, Am. Jour. Sci., 5th, v. 26, p. 544, 550. In Schoharie Valley, overlies Panther Mountain shale and sandstone member (new).

R. S. Boardman, 1960, U.S. Geol. Survey Prof. Paper 340, p. 4 (fig. 2), 7. Basal limestone of Portland Point member extends westward [from type locality] and is considered equivalent of Menteth limestone member. Thickness 8½ feet at type locality.

Named for exposures at Portland Point (formerly Shurger Point), Cayuga Lake area.

**Portneuf Limestone Member** (of Thaynes Formation)

Portneuf Limestone (in Thaynes Group)[1]

Lower Triassic: Southeastern Idaho.

Original reference: G. R. Mansfield, 1915, Washington Acad. Sci. Jour., v. 5, p. 492.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 31–33, pl. 1. Limestone unconformably underlies Timothy formation where mapped in Ammon and Paradise Valley quadrangles. In Lanes Creek, Freedom, and Montpelier quadrangles farther east and southeast, the limestone contains a well-developed red-bed unit, which consists of interbedded red sandstones and shales and ranges from 200 to 1,000 feet in thickness.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 173, fig. 18. Described as member of Thaynes formation. Underlies Timothy sandstone member.

Named for Portneuf River, in Fort Hall Indian Reservation, at head of which the limestone is well exposed.

Port Orford Formation

Pliocene, middle: Southwestern Oregon.

E. M. Baldwin, 1945, Jour. Geology, v. 53, no. 1, p. 37–39. Name proposed for beds lying unconformably between Empire formation and overlying terrace deposits. Formation has been included with terrace deposits under name of Elk River beds, which are here restricted to exclude newly named unit. Formation consists of a basal bed of buff sand overlain by conglomerate and separated from it by a local unconformity; above the conglomerate is rusty sand that grades upward into blue-gray argillaceous sand which bears fossiliferous concretions; top of argillaceous sand has been truncated by the sea and Elk River beds have been deposited on this truncated surface; locally the sand pinches out and Port Orford conglomerate is difficult to distinguish from the gravels of the terrace deposits.

J. H. Van Voorthuysen, 1953, Jour. Paleontology, v. 27, no. 4, p. 604. Foraminiferal studies indicate an Amstelian age—oldest Pleistocene.

Exposed south of Cape Blanco within the Port Orford quadrangle, Curry County.

Portsmouth Conglomerate[1]

Carboniferous: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 328–329.

Exposed near Portsmouth Grove Station, in Portsmouth camp-meeting grounds, and elsewhere in that region of Newport County.

Portsmouth Member (of Black Hand Formation)[1]

Portsmouth Member (of Logan Formation)

Portsmouth Shale Member (of Cuyahoga Formation)

Lower Mississippian: Southern Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 758.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 1), 61. Included in Scioto shale facies (new) of Logan formation. Underlies Vinton sandstone member; overlies Buena Vista sandstone member; both contacts poorly exposed. In eastern Pike and Ross Counties, Portsmouth grades eastwardly into Byer sandstone member; along Ohio River, it is probable that upper part of Portsmouth is westward equivalent of the lower Vinton sandstone member of the adjacent Pretty Run facies. Maximum thickness 253 feet.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on generalized section of Ohio as middle member of Cuyahoga formation. Underlies Black Hand member; overlies Buena Vista member.

Named for Portsmouth, Scioto County.

**Portuguese Tuff Bed**[1] (in Altamira Shale Member of Monterey Shale)

Miocene, middle: Southern California.

Original reference: W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 2, p. 131.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 16–19. Basal part of Altamira. Thickness at least 280 feet. Below Miraleste tuff bed of Altamira. Type region redesignated.

Type region: Along Klondike Canyon, near Portuguese Bend, Palos Verdes Hills, Los Angeles County.

†Portville Conglomerate[1]

Devonian or Carboniferous: Southwesern New York.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 83.

On hills about Portville, Cattaraugus County.

Port Washington Stage[1]

Pleistocene: Southeastern New York.

Original reference: J. B. Woodworth, 1901, New York State Mus. Bull. 48, p. 621–663, pl. 1, map.

On northern and western extremity of Manhasset Neck, near Port Washington, Long Island.

Port Wing Brownstone Member (of Orienta Formation)

Cambrian: Northwestern Wisconsin.

G. O. Raasch, 1950, Illinois Acad. Sci. Trans., v. 43, p. 145 (fig. 8), 147. Critical examination of evidence on which Thwaites (1912) established his Chequamegon formation reveals that his Chequamegon brownstone formation is none other than the Port Wing brownstone member of the Orienta formation, repeated by faulting. [Thwaites' (1912 general section referred to Upper brownstone (of Port Wing); thickness 500 to 700 feet.].

Type locality not given. Thwaites referred to quarries at Port Wing, Bayfield County.

Portwood Formation (in New Albany Shale)

Upper Devonian: Eastern Kentucky.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 860 (fig. 4), 861, 862–866. Portwood formation *Hypothyridina* zone is basal stratum of the New Albany in eastern Kentucky and includes all beds between Middle Devonian limestone and Trousdale shale. Consists of Duffin dolomite, Harg calcareous shale (new), and Ravenna carbonaceous shale as members, which are regarded as coeval facies within the *Hypothyridina* zone. Generalized section of Estill County shows maximum thickness 22 feet; all three facies present.

Type locality and derivation of name not given.

Posey Formation

Quaternary, late: Western California.

P. D. Trask and J. W. Rolston, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1082. Firm sandy clay and sand as much as 50 feet thick. Underlies Merritt sand; overlies San Antonio formation.

Occurs in area around San Francisco-Oakland Bay Bridge. Named for the fact that it is well developed near Posey Tube between Alameda and Oakland.

Posideon Shale Member (of Graford Formation)[1]

Posideon Shale Member (of Palo Pinto Formation)

Pennsylvanian (Canyon Series): North-central Texas.

Original reference: F. B. Plummer and J. Hornberger, Jr., 1936, Texas Univ. Bull. 3534, p. 48–50, map.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in redefined Palo Pinto formation. Overlies Wynn limestone member (new).

Typically exposed in vicinity of Posideon, Palo Pinto County.

**Possum Sandstone Tongue** (of Revard Sandstone Member of Tallant Formation)

Possum Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series) : Northeastern Oklahoma.

Original reference: M. I. Goldman, 1920, U.S. Geol. Survey Bull. 686–W, p. 330, 332.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 32, 38, pl. 1. Rank reduced to bed in Tallant formation. More or less massive sandstone about 10 feet thick. Goldman (1920) identified it correctly as probably a tongue of the Revard sandstone.

Named for occurrence as a prominent ledge along sides of Opossum Creek in SE cor. T. 29 N., R. 11 E., Osage County.

Possumtrot Shale (in Bluefield Formation)[1]

Mississippian : Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 414.

Type locality: On west side of Indian Creek 1.6 miles northeast of Raines Corner and slightly north of Possumtrot Branch, Monroe County.

**Post Oak Conglomerate Member** (of Wichita Formation)

Permian : Southwestern Oklahoma.

G. W. Chase, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2028–2035. Proposed for conglomerate and arkose beds surrounding Wichita Mountains as a near-shore facies of lower part of Wichita formation. Composed of four distinct conglomerate facies: granite boulder conglomerate, rhyolite porphyry conglomerate, limestone boulder conglomerate, and conglomerate with zeolite-opal cement. This latter facies was named Tepee Creek (Merritt and Ham, 1941,). Tongues into Wellington formation.

W. E. Ham, C. A. Merritt, and E. A. Frederickson, 1957, Panhandle Geol. Soc. [Guidebook] May 2, 3, 4, p. 28. As now used, term Tepee Creek is applied to zeolite-opal sediments that were deposited as anorthosite conglomerates and sandstones unconformably on basic igneous rocks in central part of Wichita Mountain region. These sediments probably are coarse-clastic shoreward facies of shales in Wichita formation of Lower Permian age. Also included in this general classification are the limestone conglomerates, granite conglomerates, and arkoses which in eastern part of Wichita Mountains are called Post Oak conglomerate member of Wichita formation. General concept of Post Oak member must be revised to take into consideration rather extensive granite conglomerates and arkoses in overlying Hennessey formation that border granite hills in Quartz Mountain area near Lugert.

Name taken from Post Oak Creek in sec. 12, T. 2 N., R. 15 W., and from Post Oak Mission in NE cor. sec. 7, T. 2 N., R. 14 W., where the conglomerate is thick and well developed.

**Post Pond Volcanic Member** (of Orfordville Formation)

Post Pond Volcanics

Middle Ordovician (?) : Western New Hampshire and eastern Vermont.

J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle, (1:62,000) ; C. A. Chapman and others, 1938. Geologic map and structure sections of the

Mascoma quadrangle, New Hampshire (1:62,500): New Hampshire Highway Dept. Member consists of green chlorite-sericite schist in low grade metamorphic zone of Orfordville formation and amphibolite, amphibole gneiss, calcareous amphibole gneiss, fine-grained biotite gneiss, and gray quartz-mica schist in middle grade zone. Occurs near base of formation below Hardy Hill quartzite member (new). Middle Ordovician(?).

J. B. Hadley, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 119–121, 123–124. Thickness 2,000 to 4,000 feet.

R. J. Bean, 1953, Geol. Soc. America Bull., v. 64, no. 5, pls. 1, 2. Volcanics are mapped as separate unit underlying the Albee formation and overlying the Orfordville formation. Map legends show Upper(?) Ordovician age.

J. B. Lyons, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 113, 114–116, pl. 1. Stratigraphic revision of the Orfordville formation implies that the Post Pond and Sunday Mountain volcanic members are essentially equivalent; latter is not mapped separately. Assigned higher stratigraphic position; occurs above the Hardy Hill quartzite member.

Named for outcrops in vicinity of Post Pond, Lyme Township Grafton County, N. H. Outcrop belt extends southwestward into Vermont.

**Potapaco Clay Member** (of Nanjemoy Formation)[1]

Eocene, lower: Eastern Maryland and eastern Virginia.

Original reference: W. B. Clark and G. C. Martin, 1901, Maryland Geol. Survey, Eocene Volume, p. 58, 65–66.

D. J. Cederstrom, 1957, U.S. Geol. Survey Water-Supply Paper 1361, p. 2, 24. In York-James Peninsula, Va., the lower Eocene (Wilcox) part of Nanjemoy formation, Potapaco clay member, truncates Aquia formation. Downdip from the Fall Line the Aquia formation and Potapaco member, as well as basal pink Marlboro clay member of Nanjemoy, have been truncated by transgressive sea of middle Eocene time.

Potapaco is early name for Port Tobacco Creek, eastern Maryland.

Potato Sandstone[1]

Miocene(?): Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 374–375, map.

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 557. Conglomeratic Potato sandstone, which occupies several square miles in San Bernardino Mountains, was tentatively correlated with Puente formation by Vaughan (1922). Potato sandstone is arkosic, nonfossiliferous, and well indurated. Many of its pebbles are slabs of dark lustrous Pelona schist. Absence of Pelona shist fragments from conglomerates of Puente, indicates that the two formations, if contemporaneous, obtained their detritus from different and restricted areas.

Named for Potato Canyon, San Bernardino County. Forms the part of the ridge between Potato Canyon and Mill Creek east of Wilson Creek.

Potato Hill Andesite (in Buck Hill Volcanic Series)

Potato Hill Andesite (in Pruett Tuff or Formation)

Oligocene and younger(?): Southwestern Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Lavas intercalated with Pruett tuff (new) are (ascending) Crossen trachyte, Sheep Canyon basalts, and Potato Hill andesite (all new).

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1144 (fig. 3), 1155–1156, pl. 1. Dark-reddish-brown porphyritic flow and flow breccia in upper part of Pruett tuff. At Potato Hill, the andesite is 31 feet thick. It lies on about 50 feet of tuff which rests on Crossen trachyte. Andesite overlain by 25 feet of hard, dense, red tuff. North of Potato Hill, the andesite is 18 feet thick and is overlain by 29 feet of well-stratified tuff below Cottonwood Spring basalt. Eocene(?).

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 549–550, pl. 1. Described in Cathedral Mountain quadrangle where it is given rank of formation in Buck Hill volcanic series. Thickness 35 to 190 feet. Overlies Sheep Canyon basalt; underlies Cottonwood Spring basalt. Oligocene and younger(?).

Named for Potato Hill on Crossen Mesa, Buck Hill quadrangle, Brewster County.

Poteau Stage[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey. Unit is essentially the Boggy formation.

Name is from Poteau Mountains, Le Flore County, Oklahoma, and Segastian County, Arkansas.

**Poteet Limestone**

Middle Ordovician: Southwestern Virginia.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104 (2 sheets). Gray, brown, and tan, dense fine-grained limestone with abundant chert nodules; darker colored limestone predominant in lower part, and lighter colored limestone predominant in upper part; locally has zone of coarsely crystalline fragmental limestone at or near base, and one or more beds of dolomitic limestone higher up. Thickness 45 to 97 feet. Underlies Rob Camp limestone (new); unconformably overlies Dot limestone (new). Poteet limestone and Dot limestone shown as Murfreesboro limestone (after Butts) on U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table 1), 33–34, 37–39, pl. 1. Unconformably underlies Martin Creek limestone in areas where Rob Camp limestone is absent. Derivation of name given. Discussion of problems of correlation and summary of nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

Named from Poteet Ford, an old crossing of the Powell River in central part of Jonesville district, Lee County. Well exposed along a woods lane at base of bluff overlooking Powell River 0.2 miles north of suspension footbridge at Poteet Ford.

**Potem Formation[1]**

Lower and Middle Jurassic: Northern California.

Original reference: J. S. Diller, 1906, U.S. Geol. Survey Geol. Atlas, Folio 138.

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6 (figs. 3, 4), 14–16, pl. 1. In southwest quarter of Big Bend quadrangle, consists of argillites and fine-grained tuffaceous sandstone with small amounts of conglomerate, tuff, medium to coarse tuffaceous sandstone and a few beds of limestone and coarse pyroclastic material. Thickness about 1,000 feet. Intercalated with Bagley andesite. Underlies Montgomery Creek formation. Middle and Upper Jurassic (text) ; Middle Jurassic (map bracket).

Named for exposures on Potem Creek, Shasta County.

**Potlatch Anhydrite**[1]

**Potlatch Member** (of Three Forks Formation)

Upper Devonian: Subsurface in Montana, North Dakota, and South Dakota.

Original reference: E. S. Perry, 1928, Montana Bur. Mines and Geology Mem. 1, p. 4–6.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2322–2323, 2326. Designated member of Three Forks formation in area east of 110° meridian in Montana. In current informal subsurface usage, this unit is called "Potlatch". Wilson (1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf.) recognized that "Potlatch" represented only a small part of type Potlatch and used term Potlatch anhydrite (restricted). Used as member (as herein recommended), unit does not imply any redefinition or restriction of Perry's Potlatch anhydrite formation which is valid subsurface unit in its type area. From Little Rocky Mountains westward, upper part of Three Forks consists predominantly of green fossiliferous calcareous shale interbedded with thin beds of limestone and siltstone, and Potlatch member consists of anhydrite, dolomite, and dolomitic siltstone interbedded with calcareous and dolomitc shale.

Named for the fact that complete section is shown in cuttings of Potlatch-Adams No. 1 well on sec. 21, T. 34 N., R. 1 W., Toole County, Mont.

**Potomac Group**[1]

Lower and Upper Cretaceous : Virginia, Delaware, and Maryland.

Original references: W. J. McGee, 1886, Rept. Health Office, D.C., 1885, p. 19–21 ; Am. Jour. Sci, 3d., v. 31, p. 473–474.

N. H. Darton, 1951, Geol. Soc. America Bull., v. 62, p. 747, 752. Consists of (ascending) Patuxent, Arundel, and Patapsco formations. Group does not represent a large part of Lower Cretaceous. Structurally, a wedge-shaped mass lying on east-sloping floor of crystalline rocks; well records show that it thickens eastward to more than 1,000 feet. South of Fredericksburg, Aquia formation overlaps edge of Potomac group slightly, onto crystalline rock, and the Potomac in turn is overlapped by Miocene Calvert formation, Nanjemoy formation with its Marlboro clay member having thinned out or been eroded. In some areas, unconformably underlies Raritan formation.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2169 (fig. 1), 2173–2177. Lower Cretaceous. This assignment is made on basis of both floral and faunal evidence. Detailed discussion of probelm.

D. J. Cederstrom, 1957, U.S. Geol. Survey Water-Supply Paper 1361, p. 16, pl. 1. Early and late Cretaceous. In subsurface (in York-James Peninsula, Va.), underlies Mattaponi formation (new).

Type locality and derivation of name not stated. Unit crosses Potomac River near Chain Bridge, Virginia and District of Columbia.

**Potosi Dolomite**[1]

Upper Cambrian : Eastern and central Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 351, 355.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 30–32. Thick-bedded crystalline bluish-gray dolomite. Contains few fossils. Maximum thickness about 400 feet. Overlies Derby formation [compound term Derby-Doe Run not used in this report]; underlies Eminence dolomite. Upper Cambrian.

V. E. Kurtz, 1960, Dissert. Abs., v. 21, no. 3, p. 595. Overlies Doerun member of Elvins formation.

Named for Potosi, Washington County.

†Potosi Group[1]

Upper Cambrian and Lower Ordovician: Southeastern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 351, 355.

Probably named for Potosi, Washington County.

†Potosi Slates and Conglomerates[1]

Upper Cambrian : Eastern Missouri.

Original reference: F. L. Nason, 1901, Am. Jour. Sci., 4th, v. 12, p. 358–361.

Typically exposed near Elvins, St. Francois County.

**Potosi Volcanic Group**

Potosi Volcanic Series[1]

Tertiary, middle or upper : Southwestern Colorado.

Original reference : W. Cross, 1899, U.S. Geol. Survey Geol. Atlas, Folio 57.

E. S. Larsen, Jr., 1949, Am. Geophys. Union Trans., v. 30, no. 6, p. 863. Includes (ascending) Conejos andesite (quartz latite), Treasure Mountain rhyolite, Sheep Mountain quartz latite, Alboroto quartz latite (rhyolite), Huerto andesite (quartz latite), and Piedra rhyolite. Lavas of Potosi volcanic series followed those of Silverton volcanic series and were in turn followed by eruption of Fisher quartz latite.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 90–166, pl. 1. Series and units described in detail. Miocene.

T. A. Steven and J. C. Ratte, 1960, U.S. Geol. Sruvey Prof. Paper 343, p. 9–10, pl. 1. Middle or late Tertiary.

Named for exposures on Potosi Peak, Silverton quadrangle.

†Potsdam Limestone[1]

Upper Cambrian : New York.

Original reference: W. B. Dwight, 1886, Am. Jour. Sci., 3d, v. 31, p. 125–133.

In Dutchess County.

**Potsdam Sandstone**[1]

Upper Cambrian : Central and eastern New York and Vermont.

Original references: E. Emmons, 1838, New York Geol. Survey 2d Rept., p. 214–217, 230; 1840, New York Geol. Survey 4th Ann. Rept., p. 347.

John Rodgers, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1575. Potsdam forms lowest unit of New York Paleozoic section except for beds in thrust plates of Taconic orogeny. Base of Potsdam in this area is coarse sandstone approaching a conglomerate; it grades upward into fairly massive, clean sandstone. In Vermont, rock has been metamorphosed and is more properly quartzite. Thickness about 400 feet. At Whitehall, upper beds show transition into Little Falls through interbedded dolomite and sandstone. This transition facies has been called Theresa formation. At Shoreham, in Ticonderoga quadrangle, Little Falls is immediately underlain by 50 feet of massive quartzite without transition; beneath this is 50 feet of interbedded dolomite and sandstone, and then body of Potsdam. If these beds are equivalent to "Theresa" at Whitehall, they bear out suggestion by Emmons that upper Potsdam graded from sandstone in Champlain region to calcareous sediments in Saratoga region. Upper Potsdam as here used is Franconia; remainder is presumably Dresbach.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 795–814. Evidence presented to substantiate radical change in interpretation of Paleozoic stratigraphy of Saratoga Springs region. Previously accepted sequence (Potsdam sandstone, Theresa formation, Hoyt limestone, Little Falls dolomite, Amsterdam limestone, Trenton limestone, Canjoharie shale) is revised to read Potsdam sandstone, Galway formation, Hoyt limestone, Ritchie limestone (new), Mosherville sandstone (new), Gailor dolomite (new), Lowville limestone, Amsterdam limestone, Trenton limestone, and Canajoharie shale. Name Galway is reintroduced for strata younger than Potsdam and older than Hoyt. Term "Theresa" not applicable in area.

John Rodgers,1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America [Guidebook] for Field Trips in New England, p. 36 (table 2), 53. At Skene Mountain, the Potsdam underlies Dewey Bridge formation (new).

A. W. Postel, A. E. Nelson, and D. R. Wiesnet, 1959, U.S. Geol. Survey Geol. Quad. Map GQ–123. In Nicholville quadrangle, New York, Potsdam is divided into Nicholville conglomerate member (new) and upper unnamed orthoquartzite member. Unnamed member corresponds to Keeseville sandstone of Emmons (1842, Geology of New York, pt. 2). Upper member crops out in Hopkinton Brook, three-fourths mile north of Hopkinton. Upper and lower members may interfinger and may be locally unconformable.

C. W. Welby, 1959, New England Intercollegiate Geol. Assoc. Guidebook 51st Ann. Mtg., p. 23. Underlies Ticonderoga formation (new).

Named for occurrence at Potsdam County, St. Lawrence County, N.Y.

†Pottawatomie Formation[1]

Pennsylvanina: Eastern Kansas.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 92–94.

Named for Pottawatomie River.

†Pottawatomie Series[1]

Pennsylvanian: Iowa, Kansas, Missouri, Nebraska, and Oklahoma.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. Guidebook 5th Ann. Field Conf., correlation chart.

Potter Formation[1]

Pliocene: Texas.

Original reference: L. T. Patton, 1923, Texas Univ. Bull. 2330, p. 78–80.

In Panhandle

Potter parvafacies[1]

Upper Devonian: Southern New York and northern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 31.

L. V. Rickard, 1957, New York Geol. Soc. Guidebook 29th Ann. Mtg., fig. 2. Figure 2 shows Potter as part of Upper Devonian depositional facies in southern New York. Interfingers with Cattaraugus and Oswayo to southwest and Elkland to northeast.

Named for occurrence in Potter County, Pa.

**Potterchitto Member** (of Cook Mountain Formation)

Potterchitto Member (of Wautubbee Formation)

Eocene: Eastern Mississippi.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 53–57, profile C. Defined as middle member of Wautubbee formation eastern Mississippi. Lithology varies; all gradations from greensand to nonglauconitic sand are present; sands range from calcareous and marly to noncalcareous and from highly fossiliferous to nonfossiliferous and contain pellets, partings, interbeds, and lenses of carbonaceous clay and shale; bentonite and bentonic clay locally present; earthy siderite common. Thickness varies; 36 feet at type section. Overlies Archusa member (new) with contact conformable and gradational; underlies Gordon Creek shale member (new) with contact conformable and sharply defined.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Assigned to Cook Mountain formation.

Type locality: A series of roadcuts along the Newton-Decatur Highway (State Highway 15) on south side of valley wall of creek about 2 miles northeast of town of Newton, NE¼ sec. 26 and SE¼SE¼ sec. 23, T. 6 N., R. 11 E., Newton County. Named for outcrop near Potterchitto Creek.

**Potter Farm Formation**[1] (in Traverse Group)

Middle and Upper (?) Devonian: Northeastern Michigan.

Original reference: A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 524–526.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3), 590–593. Described in Thunder Bay region where composite section is about 65 feet thick. Overlies Norway Point formation. Separated from overlying Thunder Bay limestone by covered interval about 27 feet thick that includes two resistant members which are probably limestones. Included in Traverse group.

Type locality: Fred Potter Farm, E½ secs. 18 and 19, sec. 20, T. 31 N., R. 8 E., Alpena County.

†Pottsboro Subgroup[1]

Lower Cretaceous (Comanche Series): Northeastern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 121, 247, 270, 280–288.

Named for Pottsboro, Grayson County.

Pottstown Shale (in Newark Group)[1]

Upper Triassic: Southeastern Pennsylvania.

Original references: B. S. Lyman, 1893, Pennsylvania Geol. Survey geol. and topog. map of Bucks and Montgomery Counties; 1895, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 3, pt. 2, p. 2589–2638.

Exposed at Pottstown, Montgomery County.

**Pottsville Formation[1] or Group[1]**

Pottsville Series

Lower and Middle Pennsylvanian: Pennsylvania, Alabama, Georgia, Indiana, Kentucky, Maryland, Mississippi, Ohio, Tennessee, Virginia, and West Virginia.

Original references: J. P. Lesley, 1876, Pennsylvania 2d Geol. Survey Rept. L, app. E, p. 221–227; 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$, p. xxiii; C. A. Ashburner, 1877, Am. Philos. Soc. Proc., v. 16, p. 520, 535; David White, 1900, U.S. Geol. Survey 20th Ann. Rept., p. 749–953.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 212–251. Pottsville series divided into (ascending) Pocahontas, New River, and Kanawha groups. Only basal members of Kanawha present in area of this report. Overlies Mauch Chunk series of Mississippian age.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 408–435. Pottsville group includes (ascending) Lee formation, Norton formation, Gladeville sandstone, Wise formation, and Harlan sandstone (possibly of Allegheny age). Overlies Bluestone formation, as in Tazewell County, or Pennington formation as in Lee and Wise Counties.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 54–56. Formation in northwest Georgia contains Lookout sandstone and Walden sandstone. Thickness about 1,430 to 1,500 feet. Stratigraphically above Rockmart slate.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 20–39, table 1. Pottsville series in Ohio includes basal Harrison formation and cyclothems from the Sharon up through the Tionesta. Base of Homewood member of Brookville cyclothem of Allegheny series is considered boundary between Pottsville and Allegheny series. In this report [Perry County], the Pottsville is subdivided into 10 cyclothems. [For sequence see Anthony cyclothem].

G. H. Wood, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2669–2688. At type section and reference section, formation subdivided into (ascending) Tumbling Run, Schuykill, and Sharp Mountain members. Thickness 1,116 feet at reference section; 1,195 feet at type section (White, 1900). Overlies Mauch Chunk formation; underlies post-Pottsville rocks (Buck Mountain coal bed). Members crop out throughout Southern anthracite field and have been tentatively correlated with strata in parts of other anthracite fields.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanina geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1. Pennsylvania strata, Pottsville series, subdivided into nine groups (ascending): Gizzard, Crab Orchard Mountains, Crooked Fork, Slatestone, Indian Bluff, Graves Gap, Redoak Mountain, Vowell Mountain, and Cross Mountain.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey County Rept. 3, p. 68–71. Pottsville formation is uppermost Paleozoic unit cropping out in Madison County. Only lower part of formation present in county. Consists of about 85 feet of sandstone, shale, and coals. Unconformably overlies Pennington shale of Mississippian age.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 43–46, 49 (table 7). In northern Appalachian region, including Ohio, the Pottsville series has commonly been defined to include all Pennsylvanian strata from base of Brookville coal downward to underlying Mississippian formations. Flint (1951) and Merrill (1950, unpub. thesis) have included Brookville underclay and Homewood sandstone in Brookville cyclothem. If accepted, decision logically extends base of overlying Allegheny series to base of Homewood shale and sandstone. In Athens County [this report] only Tionesta cyclothem of Pottsville series is exposed for total thickness of about 15 feet.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 68–71. Pennsylvanian section subdivided into (ascending) Pottsville, Allegheny, Conemaugh, and Monongahela groups. Average thickness of Pottsville in western Pennsylvania about 240 feet. Only rocks of upper Pottsville age are represented, and, as in most areas of Pennsylvania, unconformably overlie Mississippian Mauch Chunk or Pocono formations. Throughout western Pennsylvania, the lower two-thirds of Pottsville rocks consists of relatively thick sandstones and a few thin coal beds, and the upper one-third consists of highly variable sequence of clays, shales, and sandstones. Sandstones comprise Connoquenessing formation; overlying beds are assigned to Mercer formation (contains Mercer coals, Mercer clay, and Homewood sandstone). In extreme western and northwestern Pennsylvania and in southwestern Pennsylvania, the Sharon conglomerate forms basal Pottsville but is thought to be absent in others.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as group with Tumbling Run, Schuylkill, and Sharp Mountain formations.

Type section: South of city of Pottsville along Pennsylvania Railroad cut on east side of water gap through Sharp Mountain, Schuylkill County, Pa. Reference section: About 150 feet east of type section, along east side of roadcut for U.S. Highway 122.

Potwisha Quartz Diorite

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 11, pl. 1. Dark gray in color with abundance of dark inclusions and schlieren. In gradational contact with Giant Forest pluton but mapped separately because of its distinctive color and mineral content.

Underlies about a square mile in vicinity of Potwisha Camp, Sequoia National Park.

Poudre Limestone Member (of Lykins Formation)

Permo-Triassic: Northern Colorado and eastern Wyoming.

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Underlies Stonewall Creek shale member (new); overlies Livermore shale member (new).

Extends northward beyond Horse Creek, Wyo., and as far south as Loveland, Colo.

†Poughquag Limestone[1]

Cambrian and Ordovician : Southeastern New York.

Original reference: J. D. Dana, 1872, Am. Jour. Sci., 3d, v. 3, p. 179–186, 250–256.

Exposed at or near Poughquag, Dutchess County.

**Poughquag Quartzite[1]**

Lower Cambrian : Southeastern New York and western Connecticut.

Original reference: J. D. Dana, 1872, Am. Jour. Sci., 3d, v. 3, p. 179–186, 250–256.

E. B. Knopf, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1212. Thickness about 250 feet in vicinity of Stissing Mountain, N.Y. Basal Cambrian carrying *Olenellus* and probably *Obolella* near Beacon, N.Y. Underlies Stissing dolomite; overlies Precambrian gneisses.

John Rodgers and others, 1956, Preliminary geologic map of Connecticut (1:253,400): Connecticut Geol. Nat. History Survey. Mapped as pre-Triassic. Massive or bedded vitreous quartzite, gray, white, or buff; locally small amounts of muscovite along bedding planes, or thin layers of muscovite schist between beds; most micaceous near top. In places, grades into feldspathic biotite gneiss, probably only near base of formation.

Named for exposures at Poughquag, Dutchess County, N.Y.

**Poul Creek Formation[1]**

Oligocene and Miocene: Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 753.

D. J. Miller, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–187, sheets 1, 2. Redefined to consist of approximately 6,100 feet of marine interbedded siltstone and sandstone strata that lie with apparent conformity on Kulthieth formation. As defined, formation includes in upper part most of the strata originally assigned to it at type locality on Poul Creek; also includes lower part of Yakataga Reef section, which was originally assigned to overlying Yakataga formation, and excludes beds described by Taliaferro as "glacio-fluvial conglomerates," here assigned to Yakataga formation. Age given in text as late Oligocene and early Miocene; mapped as Oligocene and Miocene.

Type locality: On Poul Creek, Yakataga district, Controller Bay region.

**Poultney Slate[1]**

Poultney Formation (in Poultney River Group)

Poultney Group

Lower Ordovician: Southwestern Vermont and New York.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 403.

George Theokritoff, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 53, 56. Name Poultney slate was applied by Keith (1932) to lowest Ordovician formation after "good exposures in town of Poultney at the boundary of New York, 7 miles southwest of Castleton." Poultney formation as used herein, includes beds of Ordovician section up to overlying red and bluish-green slates named Indian River. Formation is variable unit consisting typically of bluish-gray waxy-looking banded argillites, locally with indigo-colored patches replacing banding. Near base are local developments of finger-thick green and greenish-weathering black argillite and brown sandstones, and also black slates with limestone conglomerates and thin ribbon limestones. Overlies Hatch Hill formation. In Poultney River group.

J. G. Elam, 1960, Dissert. Abs., v. 21, no. 6, p. 1523–1524. Discussion of geology of Troy South and East Greenbush quadrangles, New York. Stratigraphic section has been subdivided into four groups, and the previously described dominant formational names have been elevated to group status. The groups are Bull (Lower Cambrian), Poultney (Lower Ordovician), and Normanskill (Middle Ordovician).

Named for exposures in town of Poultney, Rutland County, Vt., at boundary of New York, 7 miles southwest of Castleton.

Poultney River Group

Upper Cambrian to Middle Ordovician : Western Vermont.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 2. Six rock types recognized (ascending) : white-weathering black argillite with ribbon limestone and cherty beds; limestone-matrix limestone conglomerate; white-weathering green, gray, black, and rarely red argillite, with interbedded thin buff-weathering quartzite ("Poultney slate") ; black slate with interbedded brown-weathering ankeritic massive black quartzite with edgewise conglomerate, graded bedding, and channel filling abundant; soft red slate with thin dolomitic and quartzose beds ("Indian River") ; and black slate with massive black graywacke beds, commonly showing graded bedding and containing angular rock fragments. Units 1 and 3 are Dale's (1898, U.S. Geol. Survey Ann. Rept. 19, pt. 3, p. 188) Hudson white beds; unit 4 is Larrabee's (1939) Zion Hill quartzite; unit 5 is Keith's (1932) Indian River formation; unit 6 is Dale's (1898) Hudson grits. Thickness not more than 1,000 feet. Major unconformity probably separates group from West Castleton formation (new) ; this conclusion is based on overlap relations as well as gaps in stratigraphy ; an unconformity is present within group below unit 6.

Probably named for Poultney River.

Poundridge Granite[1]

Age (?) : Southeastern New York.

Original reference: G. K. Bell, Jr., 1936, Geol. Soc. America Proc. 1935, p. 65.

Occupies most of Poundridge (New York State Park) Reservation in northeast Westchester County.

Pounds cyclothem (in Caseyville-Abbott Formations)

Pounds cyclothem (in Caseyville Group)

Pennsylvanian : Southern Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39 ,no. 9, p. 1764 (table 2). Caseyville group includes (ascending) Lusk, Battery Rock, and Pounds cyclothems.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 5, 9, pl. 1. Includes (ascending) : Pounds sandstone (Makanda sandstone in restricted sense) and Reynoldsburg coal. Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 3), pl. 1. In Caseyville formation (redefined) and Abbott formation (new). Above Battery Rock cyclothem and below Grindstaff cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Secs. 35 and 36, T. 10 S., R. 8 E., Gallatin County.

**Pounds Sandstone Member** (of Caseyville Formation)

Pounds Formation (in Caseyville Group)

Lower Pennsylvanian: Southeastern and southwestern Illinois and western Kentucky.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 36, 38–39. Uppermost formation of group. Consists of a prominent sandstone below and a series of shaly beds above; sandstone has maximum thickness of more than 100 feet; shaly strata are poorly exposed and determination of their thickness depends upon recognition of overlying Grindstaff sandstone; the Grindstaff appears to lie from 40 to 60 feet above top of Pounds sandstone at most places, but locally the shaly beds have probably been cut out completely so that the Grindstaff or some younger sandstone is in direct contact with Pounds sandstone. Maximum thickness of formation 150 feet or more in eastern part of area; thins irregularly to west, and in places is not more than 50 feet thick. Probably unconformably overlies Battery Rock formation.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, pl. 1. Included in Pounds cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 29, 30, 44 (table 1), 61, pl. 1. Rank reduced to member status in Caseyville formation (redefined). Uppermost member of formation. In southeastern area, occurs above Gentry coal member (new); in southwestern area, occurs above Drury shale member. Thickness 80 feet at type section of Caseyville and about 100 feet at reference section of formation. In southwestern area, includes strata formerly considered to be lower part of Makando sandstone, which name is herein discontinued. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Along Pounds Hollow, sec. 35 and 36, T. 10 S., R. 8 E., Gallatin County.

Poverty Run Limestone (in Pottsville Formation)[1]

Pennsylvanian: Eastern Ohio.

Original reference: Wilber Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 65.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 22. On basis of fossil content, Morningstar (1922, Ohio Geol. Survey, 4th ser., Bull. 25) correlated Poverty Run limestone with Lowellville limestone as defined by Lamb (1910).

Exposed on Poverty Run, Muskingum County.

**Poway Conglomerate**[1]

Eocene, upper: Southern California.

Original reference: A. J. Ellis, 1919, U.S. Geol. Survey Water-Supply Paper 446.

G. J. Bellemin and Richard Merriam, 1958, Geol. Soc. America Bull., v. 69 no. 2, p. 199–220. Massive conglomerate of well-rounded pebbles and some boulders, consisting largely of rhyolitic tuff and porphyry; interbedded and crossbedded with sand lenses of coarse sand and fine silty clay; upper zones contain caliche. Ranges in thickness up to about 1,000 feet. Nearly horizontal, and in most places lies unconformably on Cretaceous Peninsular Range batholith and accompanying metamorphic rocks. Where Poway rests on La Jolla formation, contact is in most places conformable. Locally covered unconformably by more than 1,000 feet of soft-gray to yellow marine sands of Pliocene age termed San Diego formation. Upper Eocene; equivalent to Tejon formation.

Forms Poway Mesa and occurs in narrow belt extending from that mesa east of Witch Creek. Well exposed near town of Poway, and forms south wall of Poway Valley, San Diego County.

**Powderhorn Granite**[1]

Precambrian: Central western Colorado.

Original reference: J. F. Hunter, 1925, U.S. Geol. Survey Bull. 777.

Occurs in divide between Cebolla and Goose Creeks, north of Powderhorn, Gunnison County.

**Powell Limestone or Dolomite**[1]

Lower Ordovician: Northern Arkansas and southeastern Missouri.

Original reference: A. H. Purdue and H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 39. Includes Bull Shoals Mountain chert bed (new) at base. Notes on derivation of name.

Arkansas Geological and Conservation Commission, 1956, *in* Kansas Geol. Soc. Guidebook 20th Field Conf., columnar sections. Fine-grained gray argillaceous dolomite with thin beds of shale, sandstone and sandy dolomite at places. Thickness as much as 215 feet. Overlies Cotter dolomite; underlies Everton formation.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 23. Name Powell of Missouri-Arkansas area should not be extended into Appalachian Valley. At present there is no evidence to indicate that any beds in the Appalachian Valley of Tennessee are equivalent to the Powell formation of Ozark region.

Name derived from Powell Station, now abandoned, on Missouri-Pacific Railroad about 2 miles down Crooked Creek from present village of Pyatt, Marion County, Ark.

Powelton Shale (in Allegheny Formation)[1]

Pennsylvanian: Central southern Pennsylvania.

Original reference: I. C. White, 1885, Pennsylvania 2d Geol. Survey Rept. $T_3$, p. 61–62.

Named for village in Huntingdon County.

Powers Bluff Quartzite[1]

Precambrian (middle Huronian): Central northern Wisconsin.

Original reference: S. Weidman, 1907, Wisconsin Geol. Nat. History Survey Bull. 16, p. 82.

Forms main part of Powers Bluff, near Arpin, Wood County.

**Powwow Conglomerate Member** (of Hueco Limestone)[1]

Powwow Conglomerate

Permian (Wolfcamp Series): Western Texas and southeastern New Mexico.

Original reference: P. B. King and R. E. King, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 909, 911.

M. L. Thompson, 1954, Kansas Univ. Paleont. Contr. 14, Protozoa, art. 5, p. 17. In central New Mexico, Bursum formation is unconformably overlain by conglomerates and conglomeratic sandstones which commonly are referred to Abo formation but here are classed as belonging to Powwow conglomerate member of Abo.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Described in Wylie Mountains and vicinity. Consists of sequence of poorly consolidated conglomerate, sandstone, siltstone, and shale; marl and limestone beds present near top. Typically dark reddish brown. Thickness more than 200 feet where it fills former valleys; thins to about 20 feet over buried hills. Underlies Hueco limestone; unconformably overlies Precambrian Carrizo Mountain group.

Well exposed from 2 to 5 miles south of Hueco Canyon along main escarpment of Hueco Mountains, Tex. Name derived from Powwow Canyon 3½ miles south of Hueco Canyon; which is followed by El Paso-Carlsbad Highway.

Poxino [Poxono] Island Limestone (in Wills Creek Shale)[1]

Silurian: Northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. $G_6$, p. 146–147, 223–224.

Exposed only in steep bluff on Delaware River opposite Poxino Island.

Poxino Island Shale[1]

*See* Poxono Island Shale, correct spelling.

Poxono Island Shale[1]

Silurian (Cayugan Series): Northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. $G_6$, p. 77, 145–146.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1184–1187, measured sections. Consists of calcareous shale weathering light colored, greenish to buff. Interbedded with shale are local bands of Bloomsburg type. Near base of shale, at type locality, is bed of blue-gray limestone, about 5 feet thick—White's (1882) Poxono Island limestone—containing great numbers of Ostracoda. Thickness varies greatly; at Schuylkill River, absent or reduced to thickness of few feet. Gradually thickens northeastward; about 150 feet at Snyders; about 200 feet at Delaware Water Gap and type locality. Underlies Bossardville limestone; overlies and intertongues with Bloomsburg red sandstone. Poxono Island shale and Bossardville limestone are similar to, and homotoxial with, Wills Creek shale and Tonoloway limestone, respectively, of central

Pennsylvania and Maryland but lie in different province and the corresponding formations differ in their time limits. Both are believed to be later than Wills Creek shale.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Cayugan series.

Named for exposures in bluff of Delaware River in Middle Smithfield Township opposite Poxono Island.

**Pozo Formation**[1]

Pliocene (?) : Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 70.

Named for exposures in Pozo Canyon, Goldfield district.

**Prairie Formation**

Prairie member

Pleistocene: Central and southwestern Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 78 (fig. 6), 163–166. Series of Pleistocene deposits in Grant and La Salle Parishes is divided into four members, their names corresponding to the four distinct depositional terrace surfaces, Williana (oldest), Bentley, Montgomery, and Prairie. Prairie deposits, which in many areas are identical in appearance to those of the present flood plain, border the alluvial valley of the Mississippi and occur to greater distances flanking tributary streams than any of the older flood-plain materials. A typical section consists of an alternation of silty sands and silty clays, loamy material with some coarse sand lenses. Thickness 20 to 52 feet.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 182–183, pl. 1. Rank raised to formation. Described in Rapides and Avoyelles Parishes where it consists entirely of fresh-water clays, silts, sands, and basal graveliferous deposits; all but upper 20 feet of sequence is covered by Recent alluvium.

Named for Prairie Terrace typically developed near Aloha, sec. 16, T. 7 N., R. 4 W., Grant Parish, and at Nebo School, sec. 40, T. 7 N., R. 3 E., La Salle Parish.

**Prairie Formation** (in Elk Point Group)

Middle Devonian: Subsurface in Saskatchewan, Alberta, and Manitoba, Canada, and northeastern Montana and northwestern North Dakota.

A. D. Baillie, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 2, p. 444, 445 (fig. 1), 446 (fig. 2); 1953, Manitoba Dept. Mines and Nat. Resources Mines Br. Pub. 52–5, p. 11 (fig. 2), 12 (table 2), 24–25. Prairie evaporite formation proposed for salt and anhydrite beds that form upper unit of Elk Point group throughout most of Elk Point basin area. Beds range in thickness from more than 600 feet near center of basin to less than 50 feet around basin margins except on west side of map area where evaporite, as much as 450 feet thick, extend into Alberta. Thickness in type well 640 feet. Uppermost formation of group; overlies Winnipegosis formation; underlies Dawson Bay formation of Manitoba group.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2306–2307. Formation underlies deepest part of Williston basin northwestern North Dakota and northeastern Montana.

Thickness fraction of a foot to almost 500 feet. In center of basin, divided into two members: lower contains mostly anhydrite and dolomite interbedded with shale and thin beds of halite; upper is largely halite and is designated as salt member.

Type section: Interval between depths of 4,350 and 4,990 feet in Imperial Oil Co.'s Davidson well 1, in Lsd. 16, sec. 8, T. 27, R. 1 W. 3d Meridian, Saskatchewan, Canada.

**Prairie Bluff Chalk**[1] (in Selma Group)

Upper Cretaceous: Southwestern Alabama and Mississippi.

Original reference: A. Winchell, 1857, Am. Assoc. Adv. Sci. Proc., v. 2, p. 83, 84, 90.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Assigned to Selma group.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 68–78, pls. 1, 5, 6, 10. Described in Kemper County where it consists of massive hard brittle glaring white to blue-gray chalk. Thickness about 30 feet. Disconformably overlies Ripley formation; unconformably overlain by Chalybeate limestone member of Clayton formation.

N. F. Sohl, 1960, U.S. Geol. Survey Prof. Paper 331–A, p. 25–27. Consists dominantly of impure sandy chalk with subordinate amounts of clay, sand, and chalky limestone. Maximum thickness about 70 feet. Thickness 15 feet at type locality. Recognizable from southernmost Tippah County, Miss., to Bullock County, Ala., where it interfingers with Providence sand. In northeastern Mississippi, interfingers with Owl Creek formation; in northern Mississippi, overlain by Clayton formation. Overlies Ripley formation.

Named for exposures in Prairie Bluff, Wilcox County, Ala.

Prairie Creek Limestone Lentil (in Geuda Springs Shale Member of Wellington Formation)

Permian: Central Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 13. Uppermost 40 feet of the Geuda Springs consists of drab clays which weather greenish. They are delimited by 2 thin limestones separated by about 5 feet of shale. The limestones are rarely much more than 1 foot thick, but are almost invariably accompanied by prominent veins of secondary calcite which produce a honeycomb rock. Name Prairie Creek limestone lentil is proposed for these beds.

Named for occurrence along Prairie Creek, southeast of Furley, Sedgwick County. Have been traced from Gore Township (T. 30 S., R. 2 E.) northward to a point east of Furley in Lincoln Township (T. 25 S., R. 2 E.).

Prairie d'Ane Clay[1]

Pleistocene: Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 32–33, 46–47, 188.

Forms Prairie d'Ane at Prescott, Prairie de Roan at Hope, and Bois d'Arc Prairie, 10 miles south of Washington. Named for exposures in Prairie d'Ane at Prescott, Nevada County.

Prairie de Roan division[1]

Pleistocene: Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 29, 33.

Named for Prairie de Roan at Hope, Hempstead County.

Prairie Divide Glacial Stage

Pleistocene (pre-Wisconsin) : Northeastern Colorado.

Kirk Bryan and L. L. Ray, 1940, Smithsonian Misc. Colln., v. 99, no. 2, p. 28–29; L. L. Ray, 1940, Geol. Soc. America Bull., v. 51, no. 12, p. 1856–1857. Till and gravel of Prairie Divide represent widespread glaciation to which name Prairie Divide stage is applied. Oldest glacial deposit in Cache la Poudre drainage area. Probably correlative with Cerro glaciation of San Juan Mountains.

Till and gravel form surface of Prairie Divide, a broad mountain flat, with altitude of approximately 7,900 feet in T. 10 N., R. 72 W., Livermore and Home quadrangles.

**Prairie du Chien Group**[1]

Prairie du Chien Formation

Lower Ordovician: Southwestern Wisconsin, Illinois, Iowa, and southern Minnesota.

Original reference: H. F. Bain, 1906, U.S. Geol. Survey Bull. 294, p. 18.

R. L. Heller, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 29–40. Prairie du Chien group of most authors is revised to formation status. As thus defined, formation consists of (ascending) Oneota dolomite, New Richmond sandstone, and Shakopee dolomite. Name Root Valley sandstone, employed by some for sandstone facies of middle member in southeastern Minnesota is suppressed. As thus defined, the Prairie du Chien consists of a thick sequence of predominantly dolomitic rocks that occurs between the Jordan sandstone of Croixan age and St. Peter sandstone of Chazy age. Ranges in thickness from less than 100 feet in shoreward areas north and west of Minneapolis to 260 feet near Lanesboro, Minn. Canadian.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 272–273. In some areas, group is divisible into Oneota dolomite, New Richmond sandstone, and Shakopee dolomite. In some areas, no recognizable sandstone is found and threefold division cannot be made. Maximum thickness 240 feet. Underlies St. Peter sandstone.

Named for exposures in vicinity of Prairie du Chien, Wis.

**Prairie Grove Member** (of Hale Formation)

Pennsylvanian (Morrow Series) : Northwestern Arkansas and northeastern Oklahoma.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1935, 1940–1942. Name applied to upper member of formation. Described as a massive, variously sandy crossbedded, pock-marked limestone; lenses of relatively pure, crinoidal, highly fossiliferous limestone and oolitic limestone beds common. Thickness 60 to 200 feet. Overlies Cane Hill member (new) with angular discordance; underlies Bloyd shale.

Named for exposures in mountains east and south of Prairie Grove, Washington County, Ark. Member is distinguishable westward in Oklahoma to Arkansas River valley.

Prairie Hollow Member (of Prairie Mountain Formation)

Prairie Hollow Member (of Wildhorse Mountain Formation)

Mississippian: Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 857, 880. Variegated maroon and green shale, about 450 feet above base of Prairie Mountain formation (new).

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 49–51. Reallocated to Wildhorse Mountain formation. Thickness about 300 feet.

Type locality: In Prairie Hollow on west side of Round Prairie syncline at type locality of Prairie Mountain formation which is in sec. 25, T. 1 S., R. 12 E., Atoka County.

Prairie Mountain Formation (in Jackfork Group)

Mississippian: Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 857, 880–884. Defined to include strata underlying Markham Mill formation (new) and overlying Wildhorse Mountain formation (new). Consists of siliceous shale, commonly dark gray to gray, followed by alternating sandstones and shales. Includes the maroon and green shale Prairie Hollow member (new) about 450 feet above base. Thickness varies; in Round Prairie syncline approximately 1,350 feet; in Tuskahoma syncline about 4,300 feet. Jackfork group. Pushmataha series.

L. M. Cline, 1956, Tulsa Geol. Soc. Digest, v. 24, p. 101, 102. Harlton's map units extended into central Ouachitas. Restudy of type section of the Jackfork formation reveals that upper part of type Wildhorse Mountain formation duplicates an equivalent interval in lower type Prairie Mountain formation. By definition, Harlton's type Prairie Mountain formation includes type locality of Prairie Hollow maroon shale member. It has been found that the Prairie Hollow also occurs in midst of Wildhorse Mountain type section; the stratigraphic overlap is about 3,600 feet.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 43 (table 3), 51–54, pls. Formation in Ouachita Mountains overlies Wildhorse Mountain formation and underlies Markham Mill formation. Restricted to exclude Prairie Hollow shale member which is reallocated to member status in Wildhorse Mountain formation. Harlton lists thickness of 1,350 feet for formation at type locality, but when allowance is made for his error in including upper part of Wildhorse Mountain with the Prairie Mountain, the Prairie Mountain cannot be more than 400 or 500 feet thick in type area. Harlton's thickness of 4,300 feet in Tuskahoma syncline is believed to be too great. Maximum thickness less than 2,000 feet in Kiamichi Range. Mississippian (Meramecian and Chesterian).

Type locality: In Prairie Mountain, located in center of sec. 25, T. 1 S., R. 12 E., Atoka County.

Prairie River Granite[1]

Precambrian: Northeastern Minnesota.

Original reference: G. E. Culver, 1894, Minnesota Geol. Nat. History Survey 22d Ann. Rept., p. 102–114.

Exposed in SE¼SE¼ sec. 32, sec. 33, and sec. 34, T. 56, R. 25, Itasca County.

Prairie Rock Limestone[1]

Upper Cretaceous: Mississippi.

Original references: E. C. Eckel, 1905, U.S. Geol. Survey Bull. 243, p. 206–219; A. F. Crider, 1905, U.S. Geol. Survey Bull. 260, p. 510–521.

Quarried on southwest side of Bogue Chitto Creek, Neshoba and Kemper Counties; one-half mile east of Prairie Rock.

Prallsville Member (of Stockton Formation)

[Upper] Triassic: West-central New Jersey.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 53 (table). Shown on stratigraphic table as Lower Prallsville member and Upper Prallsville member, each consisting of thick-bedded medium to coarse arkose with red sandstone interbeds and separated one from the other by 136 feet of red and brown sandstone and red shale. Thickness of Lower Prallsville 474 feet, of Upper Prallsville 205 feet. Prallsville may or may not include overlying 373 feet of red and brown sandstone and underlying 447 feet of red sandstone [see Stockton formation]. Older than Cutalossa member (new); younger than Solebury member (new).

In area along Delaware River from Stockton northward to 3 miles west of Milford, Hunterdon County.

Pratt Ferry Formation

Middle Ordovician (Mohawkian): Central Alabama.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 75, 85–86, chart 1 (facing p. 130). Name proposed for somewhat bituminous calcarenite occurring in layers up to 4 inches or more in thickness. Total thickness about 8 feet. Underlies black shale of Columbiana formation (new); overlies limestone mapped as Lenoir but which had faunal similarities to Little Oak formation. Name attributed to B. N. Cooper and G. A. Cooper.

Occurs 0.2 mile southeast of Pratt Ferry.

**Pratt Point Member** (of Little Sitkin Dacite)

Quaternary: Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 182, pl. 23. A body of obsidian (chemically a rhyodacite). Rhyodacite ranges from light-gray to white glass, has many plagioclase and few pyroxene and hornblende phenocrysts, ranges from slightly to very vesicular, and, locally, contains small pink devitrification spherulites. Contact with surrounding low-silica dacite of Little Sitkin dacite extremely complex—apparently they were extruded contemporaneously from same vent.

Type locality: On north side of Pratt Point along coast of Little Sitkin Island, in Rat Islands group of Aleutian Islands. A long narrow body from 200 to 700 feet wide and about 2 miles long that extends from rim of Little Sitkin crater to coast north of Pratt Point.

Prattsburg Sandstone and Shale[1]

Upper Devonian: Western New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 25 and chart.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Table shows sandstone as youngest unit of Chemung stage in Canandaigua Lake area. Underlies Dunkirk shale; overlies Nunda sandstone.

Named for occurrence at Prattsburg, Steuben County.

**Praysville Porphyry**[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 81, 176, 177.

Occurs on Old Suffolk mining location, Praysville, Keweenaw Point.

**Preble Formation**

Middle or Upper Cambrian: North-central Nevada.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]; 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–15]. Schist, slate, and hornfels with crystaline limestone lenses a few hundred feet to over a mile long in lower part, partly dolomitized. Thickness at type locality may exceed 15,000 feet. In Winnemucca quadrangle, Cambrian(?) Osgood Mountain quartzite (new) and Preble formation are in thrust contact with other Paleozoic formations; in Golconda quadrangle, the Preble is apparently in normal contact with Ordovician Comus formation and is overlain unconformably by formations of Pennsylvanian age.

Type locality: Emigrant Canyon, near Preble Station, Golconda quadrangle.

**Prescott Diorite**[1]

Upper Carboniferous or post-Carboniferous: Western central Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, pl. 34.

Comprises Packard Mountain in Prescott, Hampshire County.

**Presidio Formation** (in Trinity Group)[1]

Lower Cretaceous (Comanche Series) : Western Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Min. Survey Bull. 8, p. 10, 11, 25–30.

C. P. Ross, 1943, U.S. Geol. Survey Bull. 928–B, p. 66–78, pl. 7. Five subdivisions recognized (ascending) : basal unit, 50 to 90 feet thick, of soft marl, clay, thin-bedded arenaceous limestone, calcareous sandstone and shell breccia; a conglomerate unit, 90 to 120 feet; tripartite unit, about 95 feet thick, of medium-bedded to massive limestone, calcareous sandstone, thin-bedded limestone, in part arenaceous, thin beds of shell breccia composed mainly of *Ostrea* sp. and a fairly massive sandstone, in part arenaceous; shell-breccia unit 110 to 165 feet thick; and cap rock of arenaceous limestone 30 feet thick. Underlies Shafter limestone (restricted) ; overlies Permain (Cibolo formation). Trinity age.

Named for exposures west of shaft of Presidio Mining Co., Presidio County.

**Presque Isle Granite**[1]

Precambrian (pre-Animikie) : Northwestern Michigan.

Original reference: R. C. Allen and L. P. Barrett, 1915, Jour. Geology, v. 23, p. 697.

N. K. Huber, 1959, Econ. Geology, v. 59, no. 1, p. 85 (table 1). Considered to be pre-Animikie (pre-Huronian of older reports).

Named for Presque Isle River.

Presque Isle Series[1]

Middle Devonian: Northeastern Michigan.

Original reference: E. R. Pohl, 1930, U.S. Natl. Mus. Proc., v. 76, art. 14, p. 4, 25.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 573. Presque Isle series or stage and its synonym, Long Lake series, are abandoned.

Occurs in Presque Isle and Alpena Counties. Derivation of name not stated.

Presque Isle Volcanics

Precambrian: Michigan and Wisconsin.

T. E. Hendrix, 1960, Dissert. Abs., v. 21, no. 3, p. 594. Incidental mention in discussion of structural history of East Gogebic Iron Range.

†Preston Formation (in Washita Group)[1]

Lower Cretaceous (Comanche Series): Northeastern Texas.

Original reference: R. T. Hill, 1894, Geol. Soc. America Bull., v. 5, p. 302, 303, 326.

Named for Preston, Grayson County.

**Preston Gabbro**[1]

Carboniferous or post-Carboniferous: Southeastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 74, 115, 153, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Mainly massive dark-green to purple or black medium- to coarse-grained gabbro, locally porphyritic. Dark speckled quartz-bearing gabbro at western border. Locally converted to coarse amphibolite by shearing; mylonite at contact. Pre-Triassic.

C. B. Sclar, 1958, Connecticut Geol. Nat. History Survey Bull. 88, p. 85–124, map. Preston gabbro is irregular plutonic mass approximately 18 square miles in area. Field evidence suggests that the gabbro is laccolithic mass whose floor is eastern contact and whose roof is western contact, respectively, of gabbro with Putnam gneiss. At least six distinct facies present.

Crops out in Preston Township, New London County.

Preston Hornblende Diorite[1]

Upper Paleozoic(?): Northwestern California.

Original reference: J. H. Maxson, 1933, California Jour. Mines and Geology, v. 29, nos. 1–2, p. 128, map.

J. C. O'Brien, 1952, California Jour. Mines and Geology, v. 48, no. 4, p. 265. Commonly a fine-grained gray rock closely cut by quartz veins. Green hornblende more characteristic than brown, though both are present. Intruded by Siskiyou granodiorite. Late Paleozoic(?).

Named for occurrence in Preston Peak, Siskiyou County.

Preston Limestone (in Wabaunsee Group)[1]

Pennsylvanian: Southeastern Nebraska.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 16, 26, 28.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 45. Preston limestone formation was named to include two limestones separated by a shale. This formation lies between the Willard and Auburn shales. When it was found that these beds represent the "Emporia" of older Kansas surveys, the Nebraska Survey accepted and used name Emporia for a few years, that is, until it was discarded by Moore (1936, Kansas Geol. Survey Bull. 22), when he revived names Elmont and Reading, gave the name Harveyville to shale located between these limestones, and ranked the three divisions each as formations. Although the authors [Condra and Reed] believe that these units represent only members of the Preston limestone their formational rank is accepted, and name Preston limestone is dropped.

Type locality: Near railroad bridge, west of Preston, Richardson County.

Presumpscot Formation

Pleistocene, upper: Southwestern Maine.

A. L. Bloom, 1959, Late Pleistocene changes of sea level in southwestern Maine: New Haven, Conn., Yale Univ., Dept. Geology, p. 55–80. Proposed for the late Pleistocene marine silty clay of southwestern Maine. Thickness 0 to more than 110 feet. Thickness changes rapidly within short distances as formation was deposited on surface of considerable relief. Overlies bedrock, till, or stratified drift.

Named from exposures in valley of Presumpscot River in cities of Portland and Westbrook and adjoining township of Falmouth; no single type section can be given.

Prettymarsh Diorite

Devonian: Southeastern Maine.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1796, 1797. Referred to as diorite and coeval diabase in list of formations. Older than Cadillac granite; younger than Ireson felsite. Devonian (post-Lower Devonian).

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 174, 176, 177. Described as trap or "black granite." Occurs in form of cupolas, chonoliths, laccoliths, and dikes. Texture variable; large masses very coarse grained.

Occurs on Mount Desert Island and nearby islands, Hancock County.

Pretty Meadow Glacial Stage

Pleistocene (Illinoian?): North-central Colorado.

R. L. Ives, 1953, Geog. Rev., v. 43, no. 2, p. 235–237, 238, 249 (table). Time covered by the deposition of the Pretty Meadow moraines. Glaciation also evidenced by a large abandoned melting basin, now known as Pretty Meadow, a smaller melting basin to the north, and several glacially smoothed surfaces at high levels near crest of main range. Older than Albion glacial stage (new).

In Silver Lake Valley near head of Boulder Creek in Boulder County.

Pretty Run sandstone facies (of Logan Formation)

Mississippian (Osage): Central Ohio.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172–173; 1942, Jour. Geology, v. 50, no. 1, p. 54 (fig. 3), 55–60. One of three facies distinguished in the formation. Includes Rushville shale, Vinton sandstone, Allensville conglomerate, Byer sandstone, and Berne conglomerate members; only latter four present at type locality. Lies to east of Scioto Valley shale facies.

Type locality: SE sec. 22, NE sec. 26, and NW sec. 25, T. 10 N., R. 19 W., Vinton County. Facies extends from eastern Scioto County northward into Wayne and Medina Counties.

**Preuss Sandstone[1] or Redbeds**

Upper Jurassic: Southeastern Idaho, north-central Utah, and western Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98, p. 76, 81.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, p. 1276 (fig. 8), 1277–1278, 1280 (fig. 10), strat. sections. Preuss redbeds present in western Uinta Mountains where they underlie Stump sandstone and overlie Twin Creek limestone. Measured sections show thicknesses of 669, 858, and 1,196 feet. East of Lake Fork, replaced by crossbedded Entrada sandstone.

R. W. Imlay, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1735–1753. Includes Wolverine Canyon limestone member (new), in Bingham County area, Idaho. Origin and distribution discussed.

Named for Preuss Creek in northeastern part of Montpelier quadrangle, about 12 miles northeast of Montpelier, Idaho. Occurs mainly in area of thrust faulting along Idaho-Wyoming border and in north-central Utah, extending from southern end of Teton Mountains west of Jackson, Wyo., southward to southern end of central Wasatch Mountains near Thistle, Utah.

Prewitt Sandstone Member (of Morrison Formation)

Upper Jurassic: Northwestern New Mexico.

C. T. Smith, 1951, *in* New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 13 (chart), 38. Massive conglomeratic crossbedded sandstone. Overlies Chavez member (new); underlies Brushy Basin member.

C. T. Smith, 1954, New Mexico Bur. Mines Mineral Resources Bull. 31, p. 16–17, pl. 1. Brown-weathering massive coarse-grained light-pinkish-red conglomeratic sandstone; near base is 4-foot purplish siltstone similar to underlying Chavez member; a similar purplish siltstone with great range of thickness occupies central part of member for many miles. Thickness 185 to 190 feet in type section (herein designated). Stratigraphic interval of Westwater Canyon sandstone member of Morrison in southeastern Utah and northeastern Arizona is approximately equivalent to position of the Prewitt in Thoreau quadrangle; some investigators have extended Westwater Canyon sandstone member into Thoreau quadrangle and applied it to all of sandy facies in upper part of Morrison.

J. A. Momper and W. W. Tyrrell, Jr., 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 23. Upper Jurassic.

Type section: South of Mount Powell in western part of Thoreau quadrangle in sec. 9. T. 14 N., R. 13 W. Named for exposures along cliffs north of U.S. Highway 66, north of Prewitt, McKinley County.

**Price Sandstone,[1] Formation, or Siltstone**

Mississippian: Southwestern Virginia.

Original reference: M. R. Campbell, 1894, Geol. Soc. America Bull., v. 5, p. 171, 177, pl. 4.

A. K. Miller, 1936, Jour. Paleontology, v. 10, no. 1, p. 69–72. At least lower part of Price formation is Kinderhook in age. Determination made on basis of goniatite specimen.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 336–350. Names Price and Pocono are practically synonymous. Name Pocono is applied in northern Virginia as far south as Alleghany County. Name Price is applied throughout region from southern Alleghany and western Botetourt Counties to Tennessee. Thicknesses: about 300 feet at Cumberland Gap and Little Stone Gap, Wise County; about 1,000 feet, Pine Mountain; 1,700 feet in Brush and Price Mountains; about 600 feet in Bland and Smyth Counties. Includes Cloyd conglomerate member (new). Underlies Maccrady formation (restricted).

B. N. Cooper, 1948, Jour. Geology, v. 56, no. 4, p. 258, 259. Supposed Osagean age of all of Price formation can no longer be affirmed. Although Keokuk age of upper part of Price seems reliably indicated, the lower parts of formation which contain fossils of early New Providence and Cuyahoga are probably Kinderhookian.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Price siltstone, in Duffield quadrangle, consists of about 400 feet of pale-olive to greenish-gray siltstone, which weathers to light olive gray; contains some interbedded shale. In other regions where Price is apparently coarser grained, it has been referred to as sandstone. Occurs above Big Gap siltstone and below Maccrady shale. Mississippian.

Named for Price Mountain, Montgomery County.

**Price River Formation** (in Mesaverde Group)[1]

Upper Cretaceous: Central and central eastern Utah and central western Colorado.

Original reference: E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, p. 445.

D. J. Fisher, 1936, U.S. Geol. Survey Bull. 852, p. 8–9 (table), 14. Traced eastward from Price River Canyon above Castle Gate, formation thickens greatly, and beyond Price River is divisible into four members (ascending): Castlegate sandstone, Sego sandstone, Neslen coal-bearing member (new), and Farrer non-coal-bearing member (new).

S. C. Schoff, 1938, Ohio State Univ. Abs. Doctors' Dissert. 25, p. 379. Underlies North Horn formation (new) in central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 130–132, fig. 15. Age fixed as Montana and probably late Montana. Unconformably overlies progressively older rocks from east to west.

E. M. Spieker, 1949, Utah Geol. Soc. Guidebook 4, p. 23–26. On west side of Wasatch Plateau, formation almost entirely conglomerate ranging from few tens of feet to over 2,000 feet in thickness. Conglomerate mostly gray to buff, but in northern part of Plateau and in Cedar Hills it is locally red. Unconformably overlies Indianola group.

H. E. Wheeler and V. S. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 10, p. 2413 (fig. 2), 2417. Includes Buck shale member in Colorado and Utah.

R. E. Hunt, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 1, p. 120. Overlies South Flat formation (new) in northern part of Gunnison Plateau. Thins and disappears westward in Chicken Creek Canyon and North Maple Canyon.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 186–188, figs. 2, 3, pl. 3. Comprises a western (Farrer) facies and an eastern (Neslen) facies. Members included in Neslen facies are (ascending) Castlegate, Sego, Corcoran (new), Cozzette (new), and Cameo (new). Geographically extended to Colorado. Thickness ranges from about 1,000 to 2,000 feet at western end of Book Cliffs in Utah and from 1,000 to 2,500 feet in western Colorado.

J. D. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332. p. 11 (table), 13, 14, pls. Restricted at base by removal of Castlegate sandstone which is herein raised to formation rank. Price River (restricted) extends eastward from type locality. South of type locality, it is widespread; to the west, it extends beyond divide between Price River and Spanish Fork of Provo River to valley of Spanish Fork where it forms part of a series of coarse-grained conglomerate beds. In western Book Cliffs, formation is sequence of gray shale beds, about 530 feet thick at Horse Creek. In western Book Cliffs, includes Bluecastle sandstone member at top.

Named for exposures in Price River Canyon, northwest of town of Castlegate, Utah, in Book Cliffs.

**Prichard Slate[1] or Formation[1]**

Precambrian (Belt Series) : Northern Idaho and northwestern Montana.

Original reference: F. L. Ransome, 1905, U.S. Geol. Survey Bull. 260, p. 277–285.

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 62, p. 29–32, pl. 11. Mostly argillite, blue-black to blue-gray, commonly showing distinct and regular banding. Considerable interbedded gray indurated sandstone. Upper part characterized by numerous alternations of argillaceous and arenaceous layers, and by shallow-water features. Thickness about 8,000 feet. Base not exposed. Underlies Burke formation.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 111, 112. Exposed at intervals from northwest corner of Montana to vicinity of Philipsburg, Mont.

R. E. Wallace and J. W. Hosterman, 1956, U.S. Geol. Survey Bull. 1027–M, p. 578–579, pl. 48. Described in western Mineral County, Mont. Contact with Burke and Revett formations undifferentiated is gradational. From junction of Clark Fork and Flathead Rivers southwest to Paradise Ferry across Clark Fork River, an airline distance of 5½ miles, an almost continuous section of the Prichard is exposed in Canyon walls of Clark Fork River and in railroadcuts and roadcuts along the canyons. Discounting unidentified faults, this section is nearly 17,000 feet thick. A few apparently minor faults were identified northeast of the ferry, and top of the section is truncated by a major fault.

J. W. Hosterman, 1956, U.S. Geol. Survey Bull. 1027–P, p. 728, pl. 57. In Murray area, Idaho, formation divided into two mappable units. Lower unit consists of about 75 to 80 percent dark-gray argillite and 20 to 25 percent light-brownish-gray fine-grained impure quartzites. Base of unit not exposed in area, but observed thickness in Bear Gulch about 9,000 feet. Upper unit forms transition zone between lower part and overlying Burke formation. Contains quartzite and argillite in roughly a 2 to 1 ratio. Quartzite ranges from thin bedded, impure, and greenish gray near base to thick bedded, pure, and light gray to white near top. Argillite is thinly laminated; dark-gray fine-grained material alternates with light-gray coarser grained material. Thickness of unit on ridge running northwest from Goose Peak about 1,800 feet.

Occupies almost entire drainage basin of Prichard Creek, Coeur d'Alene district, Idaho.

Prickly Pear Member (of Spokane Formation)

Precambrian (Belt Series) : Western Montana.

C. L. Fenton, and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1877, 1878, 1898. Occurs in typical Meagher facies (new) of Belt series. Contains argillites interbedded with sandstones and lenticular conglomerates. Mud cracks and ripple marks common. Thickness 3,000 to 4,500 feet. Underlies Empire member and overlies Greyson member.

Typical Meagher facies interpreted to be exposed along Prickly Pear Creek and in Belt Mountains, central western Montana.

**Prida Formation** (in Star Peak Group)

Middle Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Lithology variable; basal beds locally quartzitic sandstone, elsewhere conglomerate or coarse fanglomerate; above is 50 to 100 feet of interbedded clastics and brown dolomite and shale, then 100 to 200 feet of dark calcareous shale and thin-bedded limestone; at top thicker-bedded limestone. Average thickness about 250 feet. Unconformably overlies Koipato formation; conformably underlies Natchez Pass formation (new).

R. E. Wallace and others, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–220. Lower formation in Star Peak group. In Buffalo Mountain quadrangle, overlies Weaver rhyolite of Koipato group, angular unconformity; underlies Natchez Pass formation. Middle Triassic.

Type locality: East Range west of Prida Ranch, Winnemucca quadrangle.

Pride Shale (in Bluestone Formation)[1]

Pride Shale Member (of Bluestone Formation)

Mississippian (Chester): Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 294, 325.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 182, pl. 15. Redefined and renamed as member of Bluestone formation. In Burkes Garden quadrangle, Virginia, is basal member of formation. Average thickness about 100 feet. Underlies Pipestem shale member; overlies Princeton sandstone.

Type locality: At base of Bent Mountain, just south of Pride, Mercer County, W. Va.

**Pride Mountain Formation**

Upper Mississippian: Northern Alabama and northeastern Mississippi.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. At type locality, consists of relatively thick units of shale that alternate with thinner units of limestone, sandstone, and siltstone. Has maximum thickness of about 325 feet in Tishomingo County, Miss.; thins eastward to about 150 feet in eastern Lawrence County, Ala. In Colbert County, Ala., and Tishomingo County, Miss., formation is divisible into several members on basis of the alternation of sandy beds with beds of calcareous shale and limestone (ascending): Alsobrook, Tanyard Branch (new), Wagnon (new), Southward Spring sandstone, Sandfall (new), Mynot sandstone (new), and Green Hill (new). Southward Spring sandstone member not present at type locality. Underlies Hartselle sandstone; overlies Tuscumbia limestone.

Type locality: About 2 miles east of Pride, Ala., and ½ mile south of U.S. Highway 72 in SE¼ sec. 15, T. 4 S., R. 12 W. Named for exposure in roadcuts on northeastern slope of Pride Mountain in north-central Colbert County.

Priest Granite

Precambrian: Central New Mexico.

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1, p. 1138–1139. Coarse-grained rock composed chiefly of pink feldspar, quartz, and biotite. There are numerous irregular areas of pegmatite with gradational borders into finer grained granite. Contains many xenoliths of schist. Xenoliths of quartzites less common.

Named for occurrence at Priest Peak in Manzano Mountain. Forms northern abutment of belts of Sais quartzite and Blue Springs schist 1 mile north of Abo Pass and continues northward into heart of Manzano Mountains.

Priest Canyon Member (of Fremont Formation)

Upper Ordovician (Richmond): Central Colorado.

W. C. Sweet, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 2, p. 295–296, 302. Sequence of thin-bedded argillaceous fine-grained dolomite which overlies massive dolomite member throughout central part of outcrop area. In Canon City region, a persistent 4- to 8-foot bed of very finely laminated cherty dolomitic shale occurs at base of member, but not present in sections west of Canon City region. Thickness of 211 feet in Kerber Creek area near head of San Luis Valley, only 75 feet at type section, and becomes thinner on both north and south. Gradational contact with lower member; unconformably underlies Williams Canyon formation.

Type locality: In Priest Canyon, sec. 13, T. 18 S., R. 71 W., Fremont County.

Priest Hill Granite[1]

Upper Devonian: Northwestern New Hampshire.

Original reference: M. P. Billings and C. R. Williams, 1935, Geology of Franconia quadrangle, New Hampshire, p. 9.

C. R. Williams and M. P. Billings, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1023. Considered to belong to New Hampshire magma series, which is probably late Devonian. Considered younger than Bethlehem gneiss and Kinsman quartz monzonite, but older than Bickford granite.

Exposed on Priest Hill, Franconia quadrangle.

**Priest Pass Leucomonzonite**

Priests Pass Leucomonzonite

Upper Cretaceous: Southwestern Montana.

Adolph Knopf, 1957, Am. Jour. Sci., v. 255, no. 2, p. 81, 94–95, map facing p. 88. Monzonitic composition, nearly devoid of quartz, has only moderate content of biotite and hornblende.

Occurs at Priests Pass [Priest Pass, correct spelling], just south of Mullan Pass, Lewis and Clark and Powell Counties.

**Priest River Group**

Priest River terrane[1]

Precambrian: Northwestern Idaho and northeastern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 6, 7, 116°30′ to 117°30′.

C. F. Park, Jr., and R. S. Cannon, Jr., 1943, U.S. Geol. Survey Prof. Paper 202, p. 6, pl. 1. Group is complex sequence of metamorphic rocks that includes phyllites and schists, limestones, dolomites, quartzites, and volcanics in Metaline quadrangle, Washington. Underlies Shedroof conglomerate (new).

Outcrops at and to east of headwaters of Priest River, Idaho.

†Prieta Sandstone[1]

Upper Cretaceous: Central northern New Mexico.

Original reference: C. L. Herrick and D. W. Johnson, 1900, New Mexico Univ. Bull., v. 2, pt. 1, p. 3–63.

In Albuquerque quadrangle. Derivation of name not stated.

Primrose Sandstone (in Springer Group)

Primrose Sandstone Member (of Golf Course Formation)

Primrose Sandstone Member (of Springer Formation)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: E. Roth, 1928, Econ. Geology, v. 23, p. 45.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 900–901. Harlton (1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 8) proposed to subdivide Wapanucka into basal, middle, and upper units. It is now proposed to apply names Primrose and Limestone Gap (new) formations to unit designated as basal Wapanucka. Included by Taff (1902, U.S. Geol. Survey Geol. Atlas, Folio 79) in Chickachoc chert lentils. In frontal Ouachitas and north of Arbuckles, overlies Union Valley sandstone and underlies Limestone Gap shale. North of Arbuckles, Primrose has been known as Union Valley limestone. South of Arbuckles, overlies Lake Ardmore and underlies Limestone Gap shale. Springer group, Morrow series; Morrow is here included in the Bendian.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Shown on correlation chart as Primrose sandstone in Springer group.

M. K. Elias, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 70 (table 2), 97–99. In southern Arbuckles, underlies Gene Autry shale (new). Morrow series.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 138. Reallocated to member status at base of Golf Course formation (new). In Dornick Hills group.

Named for Primrose Ridge, in sec. 7, T. 4 S., R. 2 E., on which stand buildings of Primrose dairy farm.

**Prince Creek Formation** (in Colville Group)

Upper Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160 (table 1), 166–167, fig. 2. Includes all nonmarine beds above top of Niakogon tongue (new) of Chandler formation (new) and intertongues with marine Schrader Bluff formation (new). Like the Chandler, it is made up of sandstone, conglomerate, shale, and coal, but contains more bentonite and tuff than does the Chandler. Separated into Tuluvak tongue (new) below and Kogosukruk tongue (new) above. Underlies Sagavanirktok (new) and Gubik formations.

R. M. Chapman and E. G. Sable, 1960, U.S. Geol. Survey Prof. Paper 303–C, p. 69, 70, 126–127, pls. Exposures of formation in Utukok-Corwin region are restricted to cutbacks in Arctic coastal plain province and north edge of northern foothills section along Utukok and Kokolik Rivers, where they form dark-gray vertical cliffs. Formation includes sandstone, conglomerate, ironstone, coal, bentonitic clay, shale, and claystone. Total thickness not known. Maximum exposed thickness about 93 feet. Overlies Corwin formation; unconformably underlies unconsolidated deposits of Quaternary age.

Type locality: Prince Creek, a tributary to Colville River.

**Princes Anne Formation** (in Columbia Group)[1]

Pleistocene: Eastern Virginia, eastern Maryland, and eastern North Carolina.

Original reference: C. K. Wentworth, 1930, Virginia Geol. Survey Bull. 32, p. 81.

S. W. Lohman, 1936, U.S. Geol. Survey Water-Supply Paper 773, p. 13. Surface of Pasquotank and Camden Counties, in vicinity of Elizabeth City, N.C. is underlain by fine sands and sandy loams of the undifferentiated Pamlico and Princess Anne formations, which are lowermost terrace deposits along Atlantic coast and are youngest formations of Columbia group. Terrace deposits conceal marine beds of Pleistocene and Pliocene age or both.

Named for typical occurrence at village of Princess Anne, Princess Anne County, Va.

†Princeton Limestone[1]

Mississippian: Western Kentucky.

The original use of this name is said to be by Ulrich in Crittenden Press, Dec. 1890. This publication is not in U.S. Geological Survey Library nor in Library of Congress.

Probably named for Princeton, Caldwell County.

Princeton Quartz Monzonite[1]

Tertiary: Central Colorado.

Original reference: R. D. Crawford, 1913, Colorado Geol. Survey Bull. 4, p. 78.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 25. Now designated Mount Princeton quartz monzonite.

Named for Mount Princeton, north of Monarch-Tomichi district.

**Princeton Sandstone** (in Pennington Group)

Princeton Sandstone[1]

Upper Mississippian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487, 489.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 180–181, pl. 15. Described in Burkes Garden quadrangle where it is about 30 to 50 feet thick, overlies Pennington formation, and underlies Bluestone formation.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Upper Mississippian.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Assigned to the Pennington herein raised to group rank. Overlies Hinton formation; underlies Bluestone formation. Thickness about 50 feet in Duffield quadrangle, Virginia.

Named for Princeton, Mercer County, W. Va.

Princeton Series[1]

Precambrian (upper Huronian): Northwestern Michigan.

Original reference: R. C. Allen, 1914, Jour. Geology, v. 22, p. 571.

Named for Princeton mine, Gwinn district, Marquette County.

**Pringle Andesite**[1]

Tertiary: Central southern Colorado.

Original reference: W. Cross, 1890, Colorado Sci. Soc. Proc., v. 3, pt. 3, p. 276.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 197. In Silver Cliff-Rosita region, the volcanics, in order of decreasing age, consist of Rosita fragmental andesite, Bunker massive andesite, Fairview diorite in dike cutting earlier andesite, Bald Mountain dacite flows, rhyolite in dikes, eruptive channels and flows, Pringle andesite, trachyte flows, and Bassick agglomerate.

Forms upper part of Pringle Hill, west of Rosita, Silver Cliff-Rosita region.

**Proctor Dolomite**[1]

Upper Cambrian: Central and eastern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 366.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 236. Considered to be upper part of Eminence formation in certain areas.

Named for exposures on Proctor Creek, Morgan County.

Proctor Sandstone (in Greene Formation)[1]

Permian: Northern West Virginia.

Original reference: I. C. White, 1883, The Virginias, v. 4, p. 124.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 17 (table 2). Proctor sandstone in Greene formation listed in summary of stratigraphic sections of Dunkard group in Harrison County. Thickness 45 to 65 feet (full thickness not present). Overlies Windy Gap limestone.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Lower, Middle, and Upper Proctor sandstone listed at top of Greene series.

Named for occurrence below mouth of Proctor Creek, just south of Marshall-Wetzel County line.

Prospect Formation

Pleistocene: South-central Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 19 (fig. 3), 20–21, pl. 1. Silts, sands, and fine gravels similar to Martinsville formation (new) but more deeply weathered. Occurs as eroded terraces 20 to 50 feet above flood plain of present streams. Exposed thickness about 30 feet. Thickness 18 feet at type section (east of area of this report). Overlies most of bedrock formations of area; underlies parts of Martinsville formation; probably underlies windblown sand facies of Atherton formation (new) and probably intertongues with sand and gravel facies of Atherton. Early Wisconsin, Sangamon, or perhaps Illinoian. Name credited to W. J. Wayne (in preparation).

Type section: Along U.S. Highway 150, just west of village of Prospect, Orange County.

**Prospect Gneiss**

Prospect Porphyritic Gneiss[1]

Ordovician or Devonian: Southwestern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 59, 102–104, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey; John Rodgers, R. M. Gates, and J. L. Rosenfeld, 1959, Connecticut Geol. Nat. History Survey Bull. 84, p. 16. Age of Prospect gneiss designated pre-Triassic.

M. H. Carr, 1960, Connecticut Geol. Nat. History Survey Quad. Rept. 9, p. 14–17, pl. 1. Restricted to the dark-gray biotite augen gneiss; the interbanded schists are considered part of undifferentiated Hartland formation. Prospect gneiss always found at same stratigraphic position, that is, between The Straits schist member and the quartzitic member of Hartland formation.

Crops out in eastern part of Prospect Township, New Haven County.

†Prospectan series[1]

Cambrian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 51, 53, 80.

Prospect Hill Formation (in North Hill Group)

Prospect Hill Sandstone Member (of Hannibal Shale)[1]

Prospect Hill Siltstone Member (of Hannibal Formation)

Lower Mississippian: Southeastern Iowa and western Illinois.

Original reference: R. C. Moore, 1928, Missouri Bur. Geology and Mines, v. 21, 2d ser., p. 22, 23–24.

L. A. Thomas, 1949, Geol. Soc. America Bull., v. 60, no. 3, p. 408–409, 410. Referred to as siltstone member of Hannibal formation. Conodont assemblage indicates Lower Mississippian age.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 30. Included in North Hill group. In this report, name Prospect Hill formation is used for the siltstone that, in Adams and Hancock Counties, occupies stratigraphic position in North Hill group between McCraney limestone (below) and Starrs Cave limestone. Essentially light-gray to buff calcareous pyritic massive siltstone. From eastern limit, thickens westward to maximum of 29 feet.

First described at Prospect Hill, near Burlington, Des Moines County, Iowa.

†Prospect Mountain Limestone[1]

Middle Cambrian: Eastern Nevada.

Original reference: A. Hague, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 254–259.

Named for exposures on Prospect Mountain, Eureka district.

**Prospect Mountain Quartzite**[1]

Lower Cambrian: Eastern Nevada, eastern California, and western Utah.

Original reference: A. Hague, 1883, U.S. Geol. Survey 3d. Ann. Rept., p. 253, 254–259.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1139–1140, 1141 (fig. 5), 1142, 1156–1158. In House Range area, Utah, underlies Pioche shale. Thickness about 1,000 feet. In Highland Range, Nev., underlies Pioche shale; thickness about 450 feet.

H. E. Wheeler and D. M. Lemmon, 1939, Nevada Univ. Bull., Geology and Mining Ser., no. 31, p. 17–18, 33, 34. In Eureka district, underlies Eldorado formation; thickness 1,660 feet; base not exposed. In Pioche district, underlies Pioche shale; thickness 2,000 feet; base not exposed.

H. E. Wheeler, 1943, Geol. Soc. America Bull., v. 54, no. 12, pt. 1, 1786, 1788, 1792–1793, 1796–1797, 1808–1811. Prospect Mountain quartzite (Eureka district, Nevada) is present throughout entire region [Great Basin], ranging from Upper Algonkian(?) and Lower Cambrian in eastern Nevada and western Utah to lower Middle Cambrian in northwestern Arizona (Granite Gorge), central Arizona, northwestern Utah, and southeastern Idaho. The quartzite had been locally designated as Tapeats sandstone, Tintic, and Brigham quartzites. In Granite Gorge area, name Prospect Mountain substituted for term Tapeats.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 146–147 (fig. 2). On correlation chart of recommended revision of stratigraphic units in Great Basin region, Prospect Mountain quartzite is replaced by Stirling quartzite in Death Valley, Providence Mountains, and Nopah-Resting Springs Mountains, Calif.; by Tapeats sandstone in Grand Canyon; by Tintic quartzite in central Utah; and by Brigham quartzite in southeastern Idaho.

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, p. 30–31, pl. 2. In Providence Mountains, replaces preoccupied term Tough Nut quartzite (Hazzard, 1938). Underlies Latham shale (new) which replaces preoccupied term Kelso. Maximum thickness 1,085 feet. Unconformable above Precambrian granite, gneiss, and schist.

F. D. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 28, 29–31, 36 (fig. 6), pl. 1. Described in Ivanpah quadrangle (California-Nevada) where, together with the Noonday dolomite and Pioche shale, it makes up what is termed western facies of the Cambrian. Well exposed and underlies large areas in broad belt that extends from Clark Mountain 30 miles northwest to hills that lie 10 miles north of Kingston Range. Thickness 3,000 to 5,000 feet.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 6–7. Described in vicinity of Eureka, Nev., where total area of outcrop is about half a square mile. Forms discontinuous hook-shaped band that extends northward from west slope of Prospect Peak to south side of Ruby Hill and then swings southward along east side of ridge nearly to Eureka Tunnel; discontinuity due in part to transgression of outcrop band by Spring Valley fault. Total thickness unknown as base not exposed. Conformable below Pioche shale.

K. F. Bick, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1065–1066. In Deep Creek Mountains, Utah, stratigraphically restricted below to exclude 3,000-foot sequence of alternating quartzite and shale units here named Goshute Canyon formation. As restricted, Prospect Mountain is 3,000 feet thick and consists completely of quartzite. Underlies Pioche shale (Cabin shale).

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 159. In Ely area, overlies Piermont group (new).

Named for occurrence in Prospect Peak, Eureka district, Nevada.

Prospect Peak Basalts[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 682. Cenozoic.

Occur in Lassen National Park.

**Prosperity Limestone Member** (of Greene Formation)[1]

Permian: Southwestern Pennsylvania and southeastern Ohio.

Original references: F. G. Clapp, 1907, U.S. Geol. Survey Bull. 300, p. 13, 128; 1907, U.S. Geol. Survey Geol. Atlas, Folio 144; name suggested by M. J. Munn; 1907, U.S. Geol. Survey Bull. 318, p. 77.

Named for village of Prosperity, Washington County, Pa.

**Prosser Member** (of Galena Dolomite)

Prosser Limestone[1]

Middle Ordovician: Southeastern Minnesota, northwestern Illinois, and northeastern Iowa.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 368, 369, 524, 525, pl. 27.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29. Member of Galena formation. Underlies Stewartville member; overlies Decorah shale member. Chiefly hard compact drab limestone with subordinate amount of shale; some beds fairly thick, especially in upper middle part; several cherty horizons. Thickness 115 to 120 feet at type section herein designated.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 764, 765. In Minnesota, restricted at base to exclude interbedded limestones and shaly limestones here named Cummingsville member of Galena.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1029 (fig. 1), 1037–1039, 1054–1058, pl. 3. Described in Fillmore County, Minn., where it is middle member of Galena formation; overlies Cummingsville member; underlies Stewartville member. First reference to term Prosser was by Winchell and Ulrich (1897, Minnesota Geol. Nat. History Survey Final Rept., v. 3. pt. 2) when they diagrammed and described a section in Galena limestone from Prosser's ravine near Wykoff, Fillmore County, Minn. This section now known to be in valley of Mahood's Creek, and the real Prosser's ravine exposes only 25 feet of uppermost Stewartville rock. Winchell and Ulrich's section is similar to Part F of Mahood's Creek section (pl. 3) of present report, except that lower 37 feet is no longer accessible above mouth of Mahood's Creek. Member name was given by Ulrich (1911) who intended Prosser to be a formational name for a faunal zone. Stauffer and Thiel (1941) described a new measured section from valley of Mahood's Creek at Wykoff, although they still referred to it as Prosser's ravine. From about 180 feet of limestone bounded by *Prasopora* below and upper *Receptaculites* zone above, the Prosser is restricted in this report to limestone lying between very argillaceous limestone below and dolomitic limestone above. Both these boundaries in Fillmore County are delineated arbitrarily. Type section includes good exposure of member but no longer exposes its base. Concept of type section here expanded to include all exposures listed as parts of Mahood's Creek measured section (F192), and these include exposures of entire member with distance of half a mile. Thickness 51 feet at type locality. Toward the southeast, where lower Galena cannot be recognized as Cummingsville, the middle Galena is also unrecognizable as Prosser. The Cummingsville is not a phase or facies of the Galena. Name Prosser, whether restricted or not, is applicable only over relatively small part of upper Mississippi Valley. To give new name to strata in restricted Prosser of Weiss (1955) and present report would require suppression of name Prosser.

Type section (Stauffer and Thiel): Prosser Creek, 2½ miles west of Wykoff, Fillmore County, Minn.

Type section (Weiss): Mahood's Creek section compiled from several exposures in valleys of Spring Valley and Mahood's Creeks from about center of south edge of SE¼ sec. 8 southward to head of Mahood's Ravine along south edge of SE¼ sec. 20, T. 103 N., R. 12 W., Fillmore County.

Prout Limestone[1]

Prout Limestone Member (of Olentangy Shale)

Middle Devonian: Northern Ohio.

Original reference: C. R. Stauffer, 1907, Jour. Geology, v. 15, p. 592.

E. C. Stumm, 1942, Jour. Paleontology, v. 16, no. 5, p. 549–553. Prout limestone and underlying Plum Brook shale form bedrock along an arcuate line running from northeast to southwest through Erie County from Slate Cut, just south of shore of Lake Erie and 4 miles east of Sandusky, to Strong's Ridge, just northeast of Bellevue. The Prout is a hard, siliceous limestone 3 to 9 feet thick. Underlies Ohio shale.

R. E. Metter, 1953, Ohio Geol. Survey Rept. Inv. 18, p. 14. Prout limestone member of Olentangy shale underlies Huron shale in exposure at Slate Cut on U.S. Route 6, three-fourths mile east of new Cedar Point entrance.

K. V. Hoover, 1960, Ohio Geol. Survey Inf. Circ. 27, p. 8–15. Stratigraphic position and correlation of Olentangy shale discussed in detail. It is here suggested that the Olentangy, Plum Brook shale, Prout limestone, Silica shale, and Ten Mile Creek dolomite are stratigraphically correlatable, with reservation that Olentangy is probably Upper Devonian. At various times and by different authors, Plum Brook shale has been correlated with the Olentangy, and the so-called Prout limestone has been regarded as member of Olentangy. Regional information regarding Plum Brook shale-Prout limestone has not been worked out. Thickness of 36 feet for Plum Brook shale and Prout limestone has been reported in its area of outcrop in Erie County.

Type locality: Cut on B. & O. Railroad, 6 miles south of Sandusky and 1 mile north of Prout, Erie County.

Prout Series[1]

Middle Devonian: Northern Ohio.

Original reference: A. W. Grabau, 1915, Geol. Soc. America Bull., v. 26, p. 112.

Probably named for Prout, Erie County.

**Providence Limestone Member** (of Lisman Formation)

Providence Limestone (in McLeansboro Formation)[1]

Providence Limestone Member (of Dugger Formation)

Middle Pennsylvanian: Western Kentucky and west-central Indiana.

Original reference: L. C. Glenn, 1922, Kentucky Geol. Survey, ser. 6, v. 5, p. 98.

E. J. Harvey, 1956, U.S. Geol. Survey Water-Supply Paper 1356, p. 47, 55 (fig. 9), 64, 65, 67. Reallocated to member status in Lisman formation. In Henderson area, consists of gray fossiliferous strata that vary from massive and compact to thin and shaly. Thickness varies—maximum 10 feet. Overlain by No. 12 coal or, in places, by Anvil Rock sandstone member; basal member of formation, overlies No. 11 coal in Carbondale formation.

H. H. Murray, 1955, Indiana Geol. Survey Directory 3, p. 8 (fig. 1). Shown on stratigraphic column as member of Dugger formation in Indiana.

Well exposed in and about Providence, Webster County, Ky.

**Providence Sand** (in Selma Group)

Providence Sand Member (of Ripley Formation)[1]

Upper Cretaceous: Western Georgia and southeastern Alabama.

Original reference: Otto Veatch. 1909, Georgia Geol. Survey Bull. 18, p. 86.

C. W. Cooke and C. A. Munyan, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 791; C. W Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 34–39. Rank raised to formation. Unconformably overlies Ripley formation and transgresses across it in its extension to northeast in Georgia. Overlapped by Paleocene Clayton formation east of Flint River.

D. H. Eargle, 1948, Southeastern Geol. Soc. [Guidebook] 6th Field Trip, p. 44, 51–53; 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 105; 1955, U.S. Geol. Survey Bull. 1014, p. 69–83, pls. 1, 2. Subdivided to include Perote member (new) in lower part. At type locality of Providence, the variegated coarse sand of upper unnamed member is about 144 feet thick and overlies about 40 feet of fossiliferous fine sand of Perote member. In Alabama grades laterally westward into Prairie Bluff chalk. In Alabama, Providence included in Selma group.

Named for exposures on deep gullies at Providence, 8 miles west of Lumpkin, Stewart County, Ga. In Georgia, occurs in broad belt from Chattahoochee River in Clay and Quitman Counties northeastward to Flint River valley in Peach and Macon Counties; farther east, present in outliers in deeper stream valleys as far as Ocmulgee River valley. East of Ocmulgee River cannot be distinguished from underlying Cretaceous formations.

Providence Island Limestone or Dolomite

Lower Ordovician (Canadian) : Northwestern Vermont.

E. O. Ulrich. 1938, *in* E. O. Ulrich and G. A. Cooper, Geol. Soc. America Spec. Paper 13, p. 26, pl. 58 (columns 24, 27). Limestone which underlies Chazyan beds and overlies Cassin formation

R. B. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 11, 63, 92–93, pls. 1 2. Described on Isle La Motte and South Hero Island as a dark-blue and gray fine-grained generally massive dolomite. At type locality, underlies Day Point limestone. Type locality cited and several exposures described.

Type section said to be on Providence Island in Lake Champlain. Other exposures at extreme end of Isle La Motte and at southwestern end of South Hero Island in Lake Champlain.

Providence Mountains Limestone

Pennsylvanian: Southern California.

J. C. Hazzard, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 240. Listed as underlying Mount Edgar limestone (new), possible unconformity, and overlying Mississippian Monte Cristo limestone, possible unconformity. Thickness 825 feet.

Occurs near Kelso, in Providence Mountains, San Bernardino County.

†Provo Epoch[1]

†Provo Stage[1]

Provo Epoch is name applied to the time during which Lake Bonneville of Utah stood at the Provo Stage.

Terms have been abandoned by U.S. Geological Survey.

**Provo Formation** (in Lake Bonneville Group)

Pleistocene: West-central Utah.

K. C. Bullock, 1951, Utah Geol. and Mineralog. Survey Bull. 41, p. 21–22. Youngest of Lake Bonneville deposits—that is younger than Bonneville and Alpine formations. Divided into four units: gravel, sand, silt, and clay members; stratification and sorting well developed. Name credited to H. J. Bissell (unpub. thesis).

C. B. Hunt, H. D. Varnes, and H. E. Thomas, 1953, U.S. Geol. Survey Prof. Paper 257–A, p. 13, 21–25, pl. 1. Deposited during what Gilbert (1890, U.S. Geol. Survey Mon. 1) called Provo stage. In most of the valley, rests on Alpine formation; locally rests on glacial outwash or on pre-Lake Bonneville deposits. Thickness about 19 feet. Included in Lake Bonneville group.

Well developed at base of Wasatch Mountains in form of terraces, deltas, spits, bars, beaches, and deeper water deposits. Well developed on western side of Lake Mountain.

Pruett Formation (in Buck Hill Volcanic Series)

Pruett Formation (in Green Valley Volcanic Series)

Eocene(?) or Eocene, upper: Western Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Constitutes lower 900 feet of Green Valley volcanic series. Underlies Cottonwood Spring basalt (new). Includes intercalated lava flows (ascending): Crossen trachyte, Sheep Canyon basalts, and Potato Hill andesite. Overlies Boquillas limestone.

S. S. Goldich and C. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Oct. 29–31, p. 13, 14 (table 1), 17 (fig. 3), 18–19. Basal unit of Buck Hill volcanic series. [Authors make no reference to term Green Valley volcanic series.]

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1144 (fig. 3), 1145–1151, pl. 1. Chiefly tuff, gray to bluish-gray, but variegated and banded in many colors generally well lithified; commonly calcareous grading into fresh-water limestone; upper breccia, 6 feet thick; basal conglomerate and arkosic sandstone; includes intercalated lava flows as noted above. Thickness 900 to 1,000 feet. Unconformable above Boquillas limestone. Eocene(?). Derivation of name given.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 542–546, pl. 1. Described in Cathedral Mountain quadrangle. Intercalated lava flows are here treated as separate formations and name Pruett restricted to the tuff, sandstone, conglomerate, and limestone below Crossen trachyte. Thickness between 474 and 798 feet. Vertebrate fossils indicate late Eocene (Duchesne) age.

Named for Pruett Ranch, north-central Buck Hill quadrangle, Brewster County.

**Pryor Conglomerate Member** (of Cloverly Formation)[1]

Lower Cretaceous: Central southern Montana and central northern Wyoming.

Original reference: C. J. Hares; 1917, Washington Acad. Sci. Jour., v. 7, p. 429.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 42–43, pl. 1. Described in Bighorn Canyon, Hardin area, where it is composed of resistant sandstones, commonly with chert-pebble-bearing conglomerates at base. Ranges in thickness from about 30 feet at Soap Creek dome, where it is not conglomeratic, to 150 feet south of mouth of Bighorn Canyon. Occurs at base of formation. Where Pryor is absent, it is difficult to differentiate Cloverly from underlying Morrison.

Ralph Moberly, Jr., 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1143, 1145, 1147–1148, pl. 1. In this report [northern Bighorn Basin], Cloverly formation is redefined on lithogenetic basis. Name Pryor conglomerate retained for well-defined basal chert-pebble-conglomerate in northern part of area. Unit is of limited extent; unconformably overlies Morrison formation in outcrops from Sykes Mountain northwestward to Red Dome and at some exposures on west side of basin. Locally underlies Little Sheep mudstone member (new).

First described at base of Pryor Mountains, Carbon County, Mont.

Pryor Creek Shale (in Cherokee Shale)[1]

Pennsylvanian: Northeastern Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 13.

Well exposed in vicinity of town of Pryor Creek, Mayes County.

**Puckett Sandstone Member** (of Mingo Formation)[1]

Middle Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 40.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 99, 102, 104, 148. In Mingo formation between Wallins Creek coal (above) and Slater sandstone.

Named for Puckett Creek, Bell County, Ky.

**Puckmummie Schist**[1]

Post-Ordovician(?): Northwestern Alaska.

Original reference: P. S. Smith, 1910, U.S. Geol. Survey Bull. 433, p. 50, 62, map.

Well exposed on lower part of Puckmummie Creek and on rocky knob to east, in low hill northwest of Post Creek, and in a few scattered outcrops in Seward Peninsula.

Puckwunge Conglomerate[1]

Puckwunge Formation (in Keweenawan Group)

Precambrian: Northeastern Minnesota.

Original reference: N. H. Winchell, 1897, Am. Geologist, v. 20, p. 50–51.

G. M. Schwartz, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1003, pl. 1. Formation underlies Keweenaw Point volcanics; overlies Thomson slate.

G. M. Schwartz, 1949, Minnesota Geol. Survey Bull. 33, p. 18, 36, In Duluth area, consists of some conglomerate at base that grades upward into gray sandstone. Overlies Thomson slate. Thickness 100 to 200 feet.

F. F. Grout, H. P. Sharp, and G. M. Schwartz, 1959, Minnesota Geol. Survey Bull. 39, p. 13 (table 1), 29–30. Formation at base of Keweenawan group. Exposures along bluffs south of Pigeon River indicate thickness of at least 100 feet and maximum of 200 feet seems reasonable. Structurally conformable to Rove below and lava flows above. Area of report, Cook County.

Name derived from Puckwunge (Stump) River, a tributary of Pigeon River in T. 64 N., Rs. 3 and 4 E., Cook County.

†Puckwunge Slate[1]

Precambrian (upper Huronian): Northeastern Minnesota.

Original reference: N. H. Winchell, 1897, Am. Geologist, v. 20, p. 50–51.

Extends across Puckwunge Valley. Probably named for stream that enters Pigeon River from west to north of Grand Portage village, Cook County.

Pucro Sandstone

Pucro Sandstone Member (of Gatún Formation)

Miocene, middle: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no. 29, p. 132, 134 (correlation chart). Overlies Tuira formation; underlies Chucunaque formation. Contains typical Gatun fauna. Middle Miocene.

R. A. Terry, 1956, California Acad. Sci. Occasional Paper 23, p. 50, 51, 55. Uppermost member of Gatún formation. Thickness 1,500 to 2,000 feet.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 344. Miocene. Note on locality.

Río Pucro is southwestward flowing tributary of Río Tuira. American Geographical Society's sheet N. B–18 shows village of same name on Río Pucro.

Pueblan series

Cretaceous (Mid-Cretacic): New Mexico.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 2, p. 119 (plate 12); 1940, v. 74, no. 3, p. 213. The Cordilleran geosynclinal. Cretacic sediments on the east side of the Rocky Mountains include (ascending) Graneros shales, Greenhorn limestones, Carlile shales, Timpas limestones, and Apashapa shales.

Pueblo Formation[1]

Mesozoic or older: Southeastern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Type locality: Pueblo Mountains, southern part of Harney County.

**Pueblo Formation** (in Wichita Group)

Pueblo Formation (in Cisco Group)[1]

Pueblo Group

Permian (Wolfcamp): Central and central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

C. O. Nickell, 1938, *in* Wallace Lee and others, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 132–134. Formation includes (ascending) Camp Creek shale, Coon Mountain sandstone, Stockwether limestone, a series of shale beds with some sandstones and thin limestones, and Camp Colorado limestone members. Overlies Harpersville formation; underlies Moran formation of Wichita group. Pennsylvanian.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 91, 93. Rank raised to group and expanded below to redefined Permian-Pennsylvanian boundary (Wolfcamp-Cisco) which is placed at disconformity in Harpersville formation above Waldrip-Newcastle coal zone about 40 to 150 feet below Saddle Creek limestone. As redefined. includes (ascending) Saddle Creek, Stockwether, and Camp Colorado formations. Underlies Moran group; overlies Thrifty group (redefined).

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Formation includes beds lying between disconformity at base of Waldrip shale and top of Camp Colorado limestone. Average thickness in southern Coleman County 225 feet. Comprises (ascending) Waldrip shale, Saddle Creek limestone, Camp Creek shale, Stockwether limestone, Salt Creek Bend shale, and Camp Colorado limestone members. Underlies Moran formation; overlies Pennsylvanian Cisco group.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 267–270. Formation, in Brazos River valley, comprises (ascending) Waldrip shale, Saddle Creek limestone, Camp Creek shale, Stockwether limestone, Salt Creek Bend shale, and Camp Colorado shale members. Thickness 275 to 400 feet. Overlies Chaffin limestone member of Thrifty formation; underlies Watts Creek shale member of Moran formation. Locally, Chaffin and underlying shale members of Thrifty are absent and Pueblo rests on rocks as old as Breckenridge member of Thrifty. Boundary between Pueblo and Moran not mapped north of Elm Creek (east-central Throckmorton and west-central Young Counties); boundary difficult to discern because of probable absence of Camp Colorado limestone.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 75–76, pl. 27. Formation in Brown and Coleman Counties comprises (ascending) Waldrip shale, Saddle Creek limestone, Camp Creek shale, Coon Mountain sandstone, Stockwether limestone, Salt Creek Bend shale, and Camp Colorado limestone members. Overlies Chaffin limestone member of Thrifty formation. Permian. Only lower part of formation discussed in this report.

Named for exposures along valley of Battle Creek at Pueblo, Callahan County.

†Pueblo Limestone Member (of Pueblo Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Type locality of Pueblo formation: In Pueblo Mountains, southern part of Callahan County.

†Pueblo Quartzite[1]

Precambrian: Central northern New Mexico.

Original reference: J. W. Gruner, 1920, Jour. Geology, v. 28, p. 731–742.

Exposed at head of Pueblo Creek, Tps. 26 and 27 N., Rs. 14 and 15 E., Taos County.

Pueblo Mountain Series[1]

Tertiary, upper: Northwestern Nevada and southeastern Oregon.

Original reference: R. E. Fuller, 1931, Washington Univ. Pub. Geology, v. 3, no. 1, p. 14.

Occurs on Pueblo Mountain.

Pueblo Range Series[1]

Miocene, lower: Northwestern Nevada.

Original reference: J. C. Merriam, 1910, California Univ. Pub., Dept. Geol. Bull., v. 6, no. 2, p. 26–52, pl. 2.

On west side of Pueblo Range.

**Puente Formation**[1]

Miocene, upper: Southern California.

Original reference: G. H. Eldridge and R. Arnold, 1907, U.S. Geol. Survey Bull. 309.

M. L. Krueger, 1936, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1520. In Whittier Hills, underlies Sycamore Canyon formation (new).

M. L. Krueger, 1943, California Div. Mines Bull. 118, p. 363 (fig. 150). Upper part of Puente in Chino area divided into (ascending) Papel

Blanco shale, Blanco sandstone, Cubierto shale, Hunter sandstone and conglomerate, Peculiar shale, and Mahala sandstone and conglomerate (all new).

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 515, 516–517 (fig. 2), 519–523. Described in Puente and San Jose Hills where it is divided into three unnamed members: lower of shale and sandstone, middle of sandstone, and upper of shale, conglomerate, and sandstone. Delimitation of middle sandstone is key to threefold division. Thickness possibly 9,000 feet in Puente Hills; thinner in San Jose Hills. Krueger's (1943) subdivisions of upper Puente recognized in Slaughter Canyon and thicknesses measured. Overlain by sediments assigned to Repetto formation. In some areas, overlies Buzzard Peak conglomerate member (new) of Topanga formation.

S. N. Daviess and A. O. Woodford, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 83. In this report [northwestern Puente Hills], four divisions of Puente are recognized: lower siltstone member made up chiefly of interbedded siltstone and sandstone; sandstone member; upper siltstone member; and conglomeratic unit, Sycamore Canyon member. Krueger called this conglomeratic part of upper Puente the Sycamore Canyon formation. For purposes of this report, the unit is treated as local member of Puente because lower beds of conglomerate lens out within map area and in places interfinger with beds of upper siltstone member. Maximum thickness 8,500 feet or more. Underlies Repetto formation. Suggested that different plan of nomenclature for rocks herein assigned to the Puente may be desirable.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–154. Subdivided into (ascending) La Vida, Soquel, and Yorba (all new), and Sycamore Canyon members. Overlies El Modeno volcanics (new). On Burruel Ridge, Sycamore Canyon member is unconformably overlain by Repetto(?) formation. Late Miocene; correlative with Modelo formation of Santa Monica Mountains and with parts of Monterey formation.

R. F. Yerkes, 1957, U.S. Geol. Survey Prof. Paper 274–L, p. 326, pl. 46. In El Modeno area, strata of Puente formation rest with apparent conformity upon El Modeno volcanics. North of Santiago Creek and elsewhere strata overlap El Modeno volcanics, and Topanga, Vaqueros, and Sespe formations. Average thickness about 1,800 feet. In type area, to northwest of El Modeno, formation reaches thickness of about 11,000 feet.

Named for occurrence in Puente Hills, in southern part of Los Angeles County.

Puercan Age

Paleocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 8, pl. 1. Provincial time term, based on the Puerco formation of the San Juan Basin, northwestern New Mexico, type locality, Rio Puerco area. Covers the interval from Upper Cretaceous to Dragonian (Paleocene) time.

Above report defines 18 provincial time terms, based on mammal-bearing units, for the North American continental Tertiary. Paleocene: Puercan, Dragonian, Torrejonian, Tiffanian, and Clarkforkian; Eocene: Wasatchian, Bridgerian, Uintan, and Duchesnean; Oligocene: Chadronian, Orellan, and Whitneyan; Miocene: Arikareean, Hemingfordian, and Barstovian; Pliocene: Clarendonian, Hemphillian, and Blancan.

Most typical and only fossiliferous exposures, the escarpment running from northwest of Ojo Alamo about 25 miles to Arroyo Eduardo, east of Kimbetoh, [New Mexico].

Puercan series[1]

Upper Cretaceous: New Mexico.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, no. 4, p. 289.

**Puerco Formation** (in Nacimiento Group)[1]

Paleocene: Northwestern New Mexico.

Original reference: E. D. Cope, 1875, Ann. Rept. Chief Engrs. USA, Rept. Secy War to 44th Congress, v. 2, pt. 2, p. 1008–1017.

T. E. Reynolds, 1936, Jour. Paleontology, v. 10, no. 3, p. 202. Formation has limited exposure in New Mexico. Lower Paleocene.

H. E. Wood 2d and others. 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 29, pl. 1. Overlies Ojo Alamo formation; underlies Torrejon formation. Paleocene (Puercan).

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 272. Puerco and Torrejon are not recognizable except as faunal zones in San Juan basin; here this part of stratigraphic sequence is considered as single formation, the Nacimiento, containing Puerco and Torrejon faunas.

Named for occurrence in valley of upper Puerco River.

Puertecito Formation[1]

Lower Cretaceous(?) to base of Triassic: Northwestern New Mexico.

Original reference: E. H. Wells, 1919, New Mexico School Mines Bull. 3 [1920].

Christina Lochman-Balk, 1959, New Mexico Geol. Soc. Guidebook 10th Field Conf., p. 108. Sedimentary beds between Permian and Cretaceous. Purple-red and purple-gray sandstones, shales, and conglomerates. Thickness 1,150 to 1,250 feet. New Mexico Bureau Mines recommends abandoning term.

Puertecito district, Socorro and Valencia Counties.

**Puerto Ferro Limestone**[1]

Miocene: Puerto Rico.

Original reference: H A. Meyerhoff, 1933, Geology of Puerto Rico, p. 74.

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 337. Name given to Miocene deposits of island of Vieques, consisting of well-stratified limestone with some noncalcareous impurities, and containing numerous foraminifera, mollusca, and corals. Thickness about 200 feet. Rests discordantly on Cretaceous rocks.

Occurs on Vieques Island.

**Puffy Member** (of Katalla Formation)

Puffy Shale Member (of Redwood Formation)[1]

Oligocene: Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 773.

D. J. Miller, D. L. Rossman, and C. A. Hickcox, 1945, Preliminary report on petroleum possibilities in the Katalla area, Alaska: U.S. Geol. Survey, p. 7 (table), 13; 1945, Geologic and topographic map and sections of the Katalla area, Alaska: U.S. Geol. Survey War-Minerals Inv. Prelim. Map. Redefined as member of Katalla formation. Extends from base of lowest bed of shale-matrix conglomerate through the highest exposed Tertiary beds in Katalla area. Consists of dark-gray massive partly sandy shale, many beds of coarse- to medium-grained sandstone, and several thick beds and lenses of conglomerate. More than 3,700 feet thick. In unpublished manuscript by oil company geologists, Puffy conglomerate and Puffy shale treated as two distinct units in Redwood formation.

W. Waloweek and W. L. Norem, 1957, Jour Paleontology, v. 31, no. 3, p. 674–675. Miocene.

Named from exposures along Puffy Creek, Katalla district, Controller Bay region.

**Puget Group**[1]

Eocene and Oligocene(?): Western Washington.

Original reference: C. A. White, 1888, Am. Jour. Sci., 3d, v. 36, p. 443–450.

C. E. Weaver. 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 26, (table), 53-74. Thick series of massive sandstone, shales, interstratified sandstone, intercalated layers of carbonaceous shales, and coal seams; units vary in lithology from one locality to another, making it impossible to correlate details of any sequence at one locality with the stratigraphic columns at other adjacent places. The strata, which are all of continental origin, usually occur in shallow or closely compressed plunging anticlines synclines which in most localities have been displaced as the result of complex faulting. In Green River area, group includes (ascending) Bayne, Franklin, and Kummer formations; in Carbon River area includes (ascending) Carbonado, Wilkeson, and Burnett formations.

W. C. Warren and others, 1945, Preliminary map of the coal fields of King County, Washington: U.S. Geol. Survey. Described in King County where it overlies and interfingers with volcanic series of Eocene age; consists of sandstones, shale, and carbonaceous beds and is undifferentiated. In Newcastle-Issaquah area, group is 3,000 to 3,200 feet thick and is overlain by marine Oligocene beds. Southeast of Reton, group is overlain with slight angular discordance by marine beds of Oligocene and Miocene age. Farther east at Cedar Mountain, no Oligocene and Miocene sedimentary beds appear, but shales at top of group have increased in thickness from about 300 feet near Renton to about 1,200 feet at Cedar Mountain. Where well-exposed along Green River, group is at least 6,500 feet thick and base is not exposed. Top of group, as exposed in western part of Green River district, occurs in sec. 25, T. 21 N., R. 6 E., where Kummer syncline crosses river. In this syncline, the group is overlain by rocks of volcanic origin. Along east edge of Green River district, uppermost 500 feet of group includes tuffaceous sediments and tuff beds, which are not easily distinguished from tuffs in overlying Keechelus andesitic series. Relation of Puget group of Green River district to Puget group in northern coal fields of King County is uncertain. The two groups may be equivalent, or the Puget group in Green River district may be equivalent to the combined Cowlitz(?) formation, the overlying group of the northern area.

D. R. Crandell and L. M. Gard, Jr., 1960, U.S. Geol. Survey Geol. Quad. Map GQ–125. Oldest rocks exposed in Buckley quadrangle. Consists of light-gray to buff feldspathic and micaceous sandstone, siltstone, gray to black shale, and coal. Thin dark-brown bed of volcanic conglomerate in upper part of group. Group not differentiated. Underlies Keechelus andesitic series.

Occupies a large part of Puget Sound Basin and extends upon the west flank of the Cascade Range.

**Pugh Formation**[1]

Middle Pennsylvanian: Northeastern West Virginia.

Original reference: J. A. Taff and A. H. Brooks, 1896, U.S. Geol. Survey Geol. Atlas, Folio 34.

Named for exposures at Pugh post office, Webster County.

†Pulaski Formation (in Arago Group[1] or Series)

Eocene: Southwestern Oregon.

Original reference: J. D. Diller, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 319–320.

W. H. Twenhofel, 1943, Oregon Dept. Geology and Mineral Industries Bull. 24, p. 4. Sandstones, siltstones, and claystones. Possibly of continental origin. Underlies Coaledo formation; unconformably overlies Myrtle formation. In Arago series.

Forms hills about head of Pulaski Creek and Pulaski Arch, which separates Beaver Slough and Coquille coal basins.

**Pulaski Shale**[1]

Upper Ordovician: New York.

Original reference: L. Vanuxem, 1840, New York Geol. Survey 4th Rept., p. 373–374.

Rudolf Ruedemann, 1925, New York State Mus. Bull. 258, p. 149 (fig. 7), 154 (fig. 9). Pulaski shale comprises (ascending) Tremaines Bridge, Worthville, Sandy Creek, and Bennett Bridge beds.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 19). Shown on correlation chart as Pulaski shale in Lorraine group. Occurs above Whetstone Gulf shale and below Oswego sandstone.

Named for occurrence on Salmon River at Pulaski, Oswego County.

†Pulaski Shale[1]

Mississippian: Southwestern Virginia.

Original reference: M. R. Campbell, 1894, Geol. Soc. America Bull., v. 5, p. 171, 178, pl. 4.

In Pulaski, Wythe, and Montgomery Counties. Named for Pulaski, Pulaski County.

Pullen Formation (in Wildcat Group)

Miocene, upper, to Pliocene, lower: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 26–28, 102–105, pls. 1, 2. Diatomaceous mudstone with local basal sandstone. Thickness 600 to 1,100 feet. Thins from its southern outcrop northward and is overlapped by younger Tertiary beds; thins to south and east and is overlapped by Eel River formation (new). Overlies Yager formation (new) with angular unconformity.

Type section: Along west bank of Eel River, near Scotia, Humboldt County. Named for exposures at Pullen Ranch on Price Creek.

†Pulliam Formation[1]

Upper Cretaceous (Gulf Series) : Southern Texas.

Original reference: T. W. Vaughan, 1900, U.S. Geol. Survey Geol. Atlas, Folio 64, p. 2.

Named for Pulliam Ranch, on Nueces River, Zavalla [Zavala] County.

Pulpit Conglomerate (in Almy Conglomerate)

Paleocene: Northern Utah.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1), 842, 843, pl. 1. Coarse red cliff-making conglomerate. Thickness about 2,000 feet. Underlies Saw Mill conglomerate division (new); overlies Henefer formation (new).

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart), 142. Discussion of Frontier formation in Coalville area, Utah. Chart of nomenclature history of Cretaceous rocks of area shows column credited to Trexler (1955, unpub. thesis). On column, Pulpit conglomerate occurs above Henefer formation and below Knight formation. Text refers to Echo Canyon (formerly Pulpit) conglomerate. Echo Canyon conglomerate overlies Henefer.

Named for Pulpit Rock at mouth of Echo Canyon, Morgan County.

**Pulteney Shale Member** (of Sonyea Formation)

Upper Devonian: Western and west-central New York.

G. W. Colton and Wallace de Witt, Jr., 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–54. Consists largely of silty dark-gray and dark-brownish-gray shale; much very dark gray shale, finely interlaminated with lighter gray shale, present in lower part of member; numerous discrete beds of very dark gray shale and a few beds of brownish-black or black shale from 1 inch to 3½ feet thick present throughout member; most of these very dark shales are gradational into lighter colored shale above; layers of siltstone ranging from laminae a few hundredths of an inch thick to discrete beds 1½ feet thick are interbedded in member. Thickness 2 feet in southwestern Genesee County; 9 feet at reference section of the Sonyea south of Mount Morris; 162 feet at type exposure; thickens southward to about 250 feet in southeastern Yates County. Grades downward into Middlesex member through transition zone that ranges in thickness from a few inches in Genesee County to approximately 40 feet in Yates County; lower boundary arbitrarily placed at point above which dark-gray and dark-brown shale predominates over very dark gray, grayish-black, and black shale; locally in Ontario and Yates Counties, a bed of siltstone 2 to 10 inches thick in base of Pulteney marks the contact. In southern Genesee County and most of Livingston County, underlies Cashaqua shale member with boundary gradational through an interval of several feet; from eastern Livingston County to east edge of mapped area, overlain by Rock Stream siltstone member, boundary sharply marked.

Type exposure in Wagner Glen, one-half mile north of center of Pulteney, Pulteney Township, Steuben County.

**Pumpernickel Formation**

Pennsylvanian (?) : North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1951, Geology of the Winnemucca quadrangle, Nevada: U.S.

Geol. Survey Geol. Quad. Map [GQ–11]. Greenstone, dark chert, and dark argillite with interbedded limestone and clastic sediments. Greenstone varies from chlorite schist to recognizable andesitic lavas and breccias. Dark chert may be in part silicified ash or fine-grained tuff. Interbedded siliceous slate and phyllite, probably tuffaceous in part. May be identical with Leach formation. Thickness may exceed 6,000 feet. Underlies Havallah formation (new) with contact gradational Pennsylvanian(?).

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2847–2848. Probably Mississippian or older.

Named for Pumpernickel Valley on eastern border of Winnemucca quadrangle.

Pumpkin Creek Limestone Member (of Big Branch Formation)

Pumpkin Creek Limestone Member (of Dornick Hills Formation)[1]

Pennsylvanian (Des Moines Series): Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40–Z, p. 14.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum Geology of southern Oklahoma—a symposium, v. 1. Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig 2), 140. A member at top of Big Branch formation (redefined).

Named from outcrops on Pumpkin Creek in SE¼ sec. 19, T. 6 S., R 2 E., Carter County.

**Pumpkin Valley Member** (of Conasauga Shale)

**Pumpkin Valley Shale** (in Conasauga Group)

Middle Cambrian: Eastern Tennessee and southwestern Virginia.

Josiah Bridge, 1945, Geologic map and structure sections of the Mascot-Jefferson City zinc mining district, Tennessee (1:31,690): Tennessee Div. Geology. Named on may legend and mapped with Rome formation.

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 7–9. Pumpkin Valley shale formally proposed for 360 feet of shale which lies between typical Rome and typical Rutledge. Unit has commonly been included in the Rome. Derivation of name given. Report gives stratigraphic section at Lee Valley, Hawkins County.

John Rodgers, 1952, Geology of the Niota quadrangle, Tennessee (1:24,000): U.S. Geol. Survey Geol. Quad. Map. Southeast of Kennedy Ridge, in northwestern part of quadrangle, lower part of Conasauga shale differs from overlying main part of formation in being more silty, more purple in color, and in containing more siltstone but no limestone layers; particularly characterized by dull shales of green and purple and by monotonous uniformity that contrasts with underlying heterogeneous and varicolored Rome formation. In Hayes' original description of Rome and Conasauga formations, he classed these beds with the Conasauga, but in most of his mapping in northwest Georgia and Tennessee he mapped them as upper part of Rome. In this report, they are classed as Pumpkin Valley member of Conasauga shale. Member is exposed only in belt of Conasauga southeast of Kennedy Ridge. In other belts, member apparently does not reach surface. Thickness about 600 feet. Middle Cambrian.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1 (plates); pt. 2, p. 46 (fig. 3), 48, 49, 50 (table 4). In eastern Tennessee, the Conasauga varies in lithology and three phases are recognized; in northwestern phase, is termed Conasauga shale and the Pumpkin Valley is classed as a member; in central phase, Conasauga is termed a group and consists of six formations of which the Pumpkin Valley is the lowermost. Thickness 200 to 400 feet.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Pumpkin Valley shale described in Duffield quadrangle, Virginia. Thickness about 350 feet. Overlies Rome formation; underlies Rutledge limestone.

Named from Pumpkin Valley which lies between Cooper Ridge and Pine Ridge, Hawkins County, Tenn. Crops out along northwest side of valley and is typically exposed along State Highway 66.

### Puna Volcanic Series

Pleistocene, upper(?), and Recent: Hawaii Island, Hawaii.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 100 (table), 103–110. Series covers most of Kileauea volcano and was erupted in Recent and latest Pleistocene time. Rocks on western and southern slopes were mapped as Kamehame basalt, but this name includes lavas from both Mauna Loa and Kileau; hence, new name is used herein. Series includes a prehistoric member and an historic member. Prehistoric member ranges in thickness from a few feet in a flow on southern slope to more than 410 feet in Uwekahuna Bluff at western edge of Kilauea caldera where base is not exposed. Historic lava flows, erupted since 1750(?), differ only in degree of blackness from the late prehistoric flows. Historic flows are olivine basalts ranging from 1 to 20 feet in thickness on flanks of volcano; flows ponded in caldera are massive and columnar jointed. Correlative with Kau volcanic series on Mauna Loa as both series overlie Pahala ash. Wentworth's (1938) Keanakakoi formation is here treated as aa member of Puna volcanic series.

G. A. Macdonald, 1949, U.S. Geol. Survey Prof. Paper 214–D, p. 64–72. Includes Uwekahuna ash.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat. v. 6, Océanie, fasc. 2, p. 128. Late Pleistocene(?) and Recent.

Named for Puna district where rocks of series are most abundant.

### Punchbowl Formation

Miocene, upper: Southern California.

R. E. Wallace, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 790. Incidental mention as Punch Bowl formation.

L. F. Noble, 1953, Geology of the Pearland quadrangle, California: U.S. Geol. Survey Geol. Quad. Map [GQ–24]. Described in Pearland quadrangle as conglomeratic sandstone and siltstone with gypsiferous shale member in middle. Thickness about 1,600 feet. Deposit strongly faulted and folded. Unconformable on Vasquez formation and basement rocks; relationship to Pliocene Anaverde formation unknown. Present only south of San Andreas fault.

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Described in Valyermo quadrangle as consisting of two facies. The western, present

774–954—vol. 3—66——18

only north of San Andreas fault, corresponds in lithology to lower and middle member of formation as described in Pearland quadrangle; the eastern is divided into two members (mapped separately); upper member about 3,000 feet thick; lower member about 1,000 feet thick.

Type locality: Devils Punchbowl, Valyermo quadrangle.

**Punchbowl Volcanics**[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 55–60.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 128–129. Prominent cone of brown palagonitized tuff containing fragments of reef limestone and basalt of Koolau volcanic series, with minor amounts of black cinder and spatter and lava flow of nepheline basalt. Maximum thickness of tuff about 550 feet. Unconformably overlain by black ash of Tantalus and Sugar Loaf eruptions. Underlies reef limestone of plus 25-foot (Waimanalo) stand of sea and displaced a stream valley graded to the minus 60-foot (Waipio) stand of sea.

Named after Punchbowl Hill, the cone built by it. Exposed over area of about 0.7 square mile in Honolulu, on south side of Koolau Range about 13 miles west of Makapuu Head.

Puncheon Creek Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: I. B. Browning and P. G. Russell, 1919, Kentucky Geol. Survey, 4th ser., v. 5, pt. 2, p. 13.

Well developed along, and named for Puncheon Creek of Licking River, Magoffin County.

Punta de la Mesa Sandstone Member (of Mesaverde Formation)[1]

Upper Cretaceous: Central northern New Mexico.

Original references: C. L. Herrick, 1900, Am. Geologist, v. 25, p. 331–346; 1900, New Mexico Univ. Bull., v. 2, pt. 1, p. 3–63; pt. 2, p. 1–17.

Named for Punta de la Mesa, north of San Ignacio, Guadalupe County.

**Purcell Basalt**[1] (in Missoula Group)

Purcell Lava

Precambrian (Belt Series): Southeastern British Columbia and southwestern Alberta, Canada, and northwestern Montana.

Original reference: R. A. Daly, 1913, Canada Dept. Int. Rept. Chief Ast., 1910, v. 2, p. 207.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Dark-greenish-gray altered effusive basalt. In Glacier National Park, it is near base of Missoula group; but in other localities, mainly in Canada, it is reported in other stratigraphic positions.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 19 (table), 51–52, pl. 1. Purcell basalt included in lower part of Missoula group. Consists of dark greenish and purplish lava, much altered but originally basaltic. In Glacier National Park, principal flows are at or somewhat above top of Siyeh limestone of Piegan group and below Shepard formation. Thickness about 200 feet.

So named because maximum known thickness is in McGillivray division of Purcell Mountain system, British Columbia.

Purcell facies (of Belt Series)

Precambrian: Northern Idaho and northwestern Montana, and southern British Columbia, Canada.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1877. Within its northern basin, Belt series is divisible into facies that differ in lithology, stratigraphic sequence, thickness, recorded conditions of deposition, fauna, and flora. Purcell facies marked by abundant clastics throughout, with reduction of carbonate rocks. Quartzites, thick in lower parts, reach the known base of the Belt.

In Purcell Range.

Purcell Sandstone Lenses (in Hennessey Shale)[1]

Permian: Northern central Oklahoma.

Original reference: D. A. Green, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1465.

O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1546 (fig. 6). Sandstone lenses in Hennessey formation.

Present in vicinity of Purcell, Kingfisher County.

Purefoys Mill Series[1]

Precambrain or Lower Cambrian: Northern central North Carolina.

Original reference: W. H. Fry, 1911, Elisha Mitchell Sci. Soc. Jour., v. 27, p. 124.

L. R. Thiesmeyer and R. R. Storm, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1964. Series originated in fresh-water lakes. A stratigraphic position, similar to that of varved shales in the so-called Lower Cambrian of Virginia and of suspected varve horizons in the Hiwassee slates of Tennessee, implies that the Purefoys sediments may be approximately contemporaneous with either or both of these deposits. It is suggested that such sediments were formed from melt waters of valley glaciers near margins of Appalachia during general refrigerations which accompanied continental glaciation of northern hemisphere in latest Precambrian or early Cambrian time.

In Chapel Hill area. Derivation of name not given.

**Purgatoire Formation**[1]

Lower Cretaceous: Eastern Colorado, central northern and northeastern New Mexico, and western Oklahoma.

Original reference: G. W. Stose, 1912, U.S. Geol. Survey Geol. Atlas, Folio 186.

G. I. Finlay, 1916, U.S. Geol. Survey Geol. Atlas, Folio 203. In Colorado Springs area, includes Lytle sandstone and Glencairn shale members (both new).

S. L. Schoff, 1939, Oklahoma Geol. Survey Bull. 59, p. 54–57. In Texas County, includes Cheyenne sandstone member and shales tentatively identified as Kiowa member.

J. W. Stovall, 1942, (abs.) The Compass, v. 22, no. 4, p. 327. In Cimarron County, comprises Cheyenne sandstone member, 66 feet, and Kiowa shale member, about 50 feet.

Ernest Dobrovolny and C. H. Summerson, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 62. In Quay County, N. Mex., subdivided into (ascending) Tucumcari shale, Mesa Rica sandstone (new), and Pajarito shale (new) members. Overlies Morrison formation; underlies Graneros shale.

K. M. Waagé, 1952, Colorado Sci. Soc. Proc., v. 15, no. 9, p. 375 (fig. 1), 378 (fig. 3), 380–384. In Denver area, includes Lytle and Glencairn members. Overlies Morrison formation; underlies Dakota sandstone. Thickness 230 feet.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in Cimarron County with Cheyenne sandstone and Kiowa shale members.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 17 (table 3), 96–100. In Baca County, Colo., includes beds above Morrison formation and below Dakota sandstone. Subdivided into Cheyenne sandstone member below and Kiowa shale member above. Thickness 75 to 225 feet.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2007. Term Purgatoire abandoned in Tucumcari-Sabinoso area, New Mexico. Members of Purgatoire, as used by Dobrovolny and Summerson (1946) raised to formation rank.

Named for Purgatoire Canyon, in Mesa de Maya quadrangle, Colorado.

**Purgatory Conglomerate**[1]

Pennsylvanian: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 364–374.

Typically developed at Purgatory.

Purington Shale Member (of Carbondale Formation)

Purington Shale[1] (in Carbondale Group)

Pennsylvanian: Northern and western Illinois.

Original references: H. R. Wanless, 1931, Geol. Soc. America Bull., v. 42, p. 804; 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 94, 192, 197, 198. Light to medium gray; contains flattened oval ironstone concretions, which are most common in middle and lower parts. [In about half of area, the shale is cut out by channel deposits of the Pleasantview sandstone; in those areas where there is little or no truncation by the sandstone, it attains maximum thickness of about 50 feet.] In areas where shale attains its maximum thickness, upper 5 or 6 feet are silty to very fine sand and appears to grade upward into the Pleasantview sandstone; contact is abrupt where the sandstone is in channels. Overlies Oak Grove beds. Derivation of name credited to R. S. Poor (unpub. ms.). Occurs at top of Liverpool cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), 66, pl. 1. Rank reduced to member status in Carbondale formation (redefined). Occurs above Oak Grove limestone member and below Pleasantview sandstone member. Thickness about 15 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in

Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: SW¼ sec. 17, T. 11 N., R. 2 E., Knox County. Named for exposures at pits of Purington Paving Brick Co., East Galesburg.

**Purisima Formation**[1]

Pliocene: Western California.

Original reference: H. L. Haehl and R. Arnold, 1904, Am. Philos. Soc. Proc., v. 43, p. 16–53.

J. E. Allen, 1946, California Div. Mines Bull. 133, p. 18 (fig. 3), 38, pls. 1, 3. Described in San Bautista quadrangle as a conformable series of poorly consolidated clays, silts, sands, and gravels, predominantly marine towards base and continental in upper portion; highly variable in composition both vertically and laterally, fossiliferous in marine facies; folded, exhibits attitudes varying from horizontal to vertical. Thickness nearly 10,000 feet. Overlaps upon Santa Lucia granite, Franciscan, and Monterey; unconformably underlies Pleistocene Aromas red sands. Middle and upper Pliocene.

C. F. Tolman and J. F. Poland, 1940, Am. Geophys. Union Trans., v. 21, pt. 1, p. 26–27 (fig. 3). In Santa Clara County, underlies Santa Clara formation.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1325. Formation, in La Honda and San Gregorio quadrangles, subdivided into (ascending) Tahana, Pomponio, San Gregorio sandstone, Lobitos mudstone, and Tunitas sandstone members (all new). Maximum thickness 5,670 feet. Conformably overlies Monterey formation.

Named for exposures near Purisima and along Purisima Creek, San Mateo County.

**Purslane Sandstone** (in Pocono Group)[1]

Purslane Sandstone Member (of Pocono Formation)

Lower Mississippian: Northeastern West Virginia and western Maryland.

Original reference: G. W. Stose and C. K. Swartz, 1912, U.S. Geol. Survey Geol. Atlas, Folio 179.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 91–92. In PawPaw-Hancock area, the Pocono is considered to have group rank and is divided into five formations; in western Maryland where the five units cannot be differentiated, the Pocono is treated as a formation and the Purslane as a member. In West Virginia, member attains maximum thickness of 310 feet; in Maryland, uppermost beds have been eroded and thickest section is 144 feet. Consists of thick-bedded coarse white sandstone with interbedded conglomerate and with coal seams and red shales between the sandstones; contains a few plant remains. Overlies Rockwell member.

Purslane Mountain, Morgan County, W. Va., is formed of this sandstone. In Maryland, forms crest of Sideling Hill in Washington County and Town Hill in Allegany County.

Purvine Hills Basalt

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 132, pl. 15. Mentioned in discussion of

Capulin basalts in Des Moines quadrangle. [Most of discussion refers to basalts from Purvine Hills.]

Purvine Hills, a group of four small volcanic cones, on Purvine Ranch, Union County.

Purvine Mesa Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 120, 136 (table 4), 146 (fig. 23), pl. 1-b, 15. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined, but stratigraphic position of Purvine Mesa, Dunchee Hill, Sierra Grande, and Gaylord Mountain is not known.

Underlies several square miles of Purvine Ranch east of Folsom, Union County.

Pushmataha Series

Carboniferous (Bendian): Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 855–856. Bendian system (period) subdivided into two series, the older, the Pushmataha (new), and the younger, the Morrow. Series consists of Stanley group and most of Jackfork group. Comprises seven subdivisions (ascending): Tenmile Creek, Moyers, Chickasaw Creek, Wildhorse Mountain, Prairie Mountain, Markham Mill, and Wesley (all new). First three comprise what was formerly called the Stanley, and latter group are subdivisions of former Jackfork.

Name derived from Pushmataha County.

**Put-in-Bay Dolomite Member** (of Bass Islands Dolomite)[1]

Put-in-Bay Formation (in Bass Islands Group)

Upper Silurian: Southeastern Michigan and northern Ohio, and Ontario, Canada.

Original reference: W. H. Sherzer and A. W. Grabau, 1909, Geol. Soc. America Bull., v. 19, p. 546.

Wilber Stout, 1941, Ohio Geol. Survey, 4th ser., Bull. 42, p. 38, 40, chart facing p. 46. Put-in-Bay formation included in Bass Islands group in Ohio. Overlies Tymochtee formation; underlies Raisin River formation. Consists of fairly pure dolomite, thin to massive bedded, gray to drab to light brown in color. Thickness 50 to 250 feet.

C. K. Swartz, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows occurrence in Ontario, Canada.

Named for exposures on Put-in-Bay Island, Lake Erie.

**Putnam Formation** (in Wichita Group)[1]

Putnam Group

Permian (Wolfcamp Series): Central and central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31, 40.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 93. Rank raised to group. Includes Santa Anna Branch formation below and Coleman Junction formation above. Underlies Admiral group (redefined): overlies Moran group.

R. C. Moore, 1949, *in* M. G. Cheney, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, sheets 3, 4; R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as a formation about 140 feet thick. Includes Santa Anna Branch member below and Coleman Junction member above. Underlies the Admiral and overlies the Moran herein designated as formations.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 271. Formation, in Brazos River valley, is 140 to 210 feet thick and comprises Santa Anna Branch shale member and Coleman Junction limestone member. Overlies Moran formation; underlies Admiral formation. Wichita group.

Named for Putnam, Callahan County.

**Putnam Gneiss**[1]

Putnam Series

Pre-Pennsylvanian: Eastern Connecticut and southern Massachusetts.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 114, 129, 133, 134, 136, 140, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 67–73, pl. 1. Rank raised to series. Consists of five members: metamorphosed conglomerate, quartzite, quartz-biotite schist, hornblende schist and amphibolite, and limestone and dolomite. The quartzite is mapped as Plainfield quartz schist member. Probably Precambrian.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey; 1959, Connecticut Geol. Nat. History Survey Bull. 84, p. 55, 56. Age of gneiss designated pre-Triassic. Derivation of name given.

C. C. Sclar, 1958, Connecticut Geol. Nat. History Survey Bull. 88, p. 9–85. Bedrock in area of this report [New London County] consists of (1) a highly diverse group of metamorphic foliates known collectively as Putnam gneiss; (2) basic magmatic intrusive mass, the Preston gabbro; and (3) gneisses of granitic composition referred to as Sterling granitic gneisses. Plainfield quartzite not mapped as separate unit.

R. M. Perhac, 1958, Connecticut Geol. Nat. History Survey Bull. 89, p. 7–8. Putnam quartz-biotite schist underlies about 15 square miles in Voluntown and Oneco quadrangles. This rock constitutes a part of Putnam gneiss formation. Maximum possible thickness of schist about 2,000 feet. Plainfield quartzite not included in Putnam gneiss in present report.

Named for town of Putnam, Windham County, Conn.

Putnam Limestone (in Putnam Formation)[1]

Permian: Central northern Texas.

Original reference: O. F. Hedrick, E. Owens, and P. A. Meyers, 1929, Geologic map of Shackelford County, Texas (1:48,000): Texas Bur. Econ. Geology.

Shackelford County.

Putnam Sandstone (in Putnam Formation)[1]

Permian: Central northern Texas.

Original reference: O. F. Hedrick, E. Owens, and P. A. Meyers, 1929, Geologic map of Shackelford County, Texas (1:48,000): Texas Bur. Econ. Geology.

Probably named for town of Putnam, Callahan County.

**Putnam Hill Limestone Member** (of Allegheny Formation)[1]

Putnam Hill limestone member

Pennsylvanian: Eastern Ohio.

Original reference: E. B. Andrews, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 84–85.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 41–42, table 1. Member of Brookville cyclothem in report on Perry County. Average thickness 1½ feet. The limestone lies an average distance of 7 inches above Brookville coal, but the shale between the limestone and coal is nearly everywhere fossiliferous and is considered a part of Putnam Hill member. At most exposures, Putnam Hill member is overlain by sandy shale or interbedded fine- to medium-grained sandstone and shale of Clarion cyclothem. Allegheny series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 52–53. Uppermost member of Brookville cyclothem in Athens County. Average thickness about 2 feet. Occurs above Brookville (No. 4) coal member of Brookville cyclothem and below sandstone of Ogan cyclothem.

Named for Putnam Hill, Muskingum County.

**Putnam Peak Basalt**

Pliocene: Northwestern California.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 110 (table 24), 130–131, pl. 7. Dense black and vesicular basalt. Thickness 25 to 300 feet. Unconformably overlies Markley sandstone and San Pablo group; commonly has a low eastward dip.

Named from Putnam Peak in northeast Mount Vaca quadrangle, Solano County, where it covers slightly more than a square mile.

**Puyallup Formation, Interglaciation**

Puyallup Sand[1] or interglacial epoch[1]

Pleistocene, middle(?): Western Washington.

Original reference: Bailey Willis, 1898, Geol. Soc. America Bull., v. 9, p. 111.

J. E. Sceva, 1957, U.S. Geol. Survey Water-Supply Paper 1413, p. 19–20, pl. 1. In Kitsap County, conformably overlies Kitsap clay member (new) of Orting gravel. Maximum thickness about 300 feet.

D. R. Crandell, D. R. Mullineaux, and W. W. Waldron, 1958, Am. Jour. Sci., v. 256, no. 6, p. 390, 392–394. Puyallup sands of Willis redefined as Puyallup formation to include a thicker and laterally more extensive deposit characterized by coarse and fine alluvium, lacustrine sediments, and mudflows. Maximum thickness about 135 feet. Separated from older Alderton formation (new) by Stuck drift (new). [For Pleistocene sequence in area see 1958 entry under Orting glaciation.]

Typical occurrence on west side of Puyallup Valley, Pierce County.

**Puye Conglomerate** (in Santa Fe Group)

Puye Gravel (in Santa Fe Group)

Pliocene(?): North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103; 1938, Jour. Geology, v. 46, no. 7, p. 937 (fig. 4), 959. Quaternary formations in Abiquiu quadrangle comprise Canjillon till, Canones andesite, Vallecito basalt (all new), and Black Mesa basalt, which were poured out on high-level erosion surfaces, and Puye gravel (new), which overlies an erosion surface of intermediate level and is overlain, locally, by Bandelier rhyolite and Santa Clara basalt (both new).

E. H. Baltz and others, 1952, New Mexico Geol. Soc. Guidebook 3d Field Conf., p. 12. Ancha formation (new) is eastward extension of Puye gravel.

Brewster Baldwin, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 118 (fig. 2), 119. Mentioned in discussion of upper unit of Santa Fe group. Puye gravel, Ancha formation, and Tuerto gravel all rest with angular unconformity on deformed beds of Tesuque formation. These units of gravel are 500, 300, and 150 feet in maximum thickness, respectively. In Buckman area, Ancha formation appears to intertongue with Puye gravel. Early Pleistocene.

Mapped in valley of Chama River, Rio Arriba County.

Puyer Formation[1]

Eocene: Central Washington.

Original reference: J. Daniels, 1915, Geol. Soc. America Bull., v. 26, no. 1, p. 132.

Pierce County coal field.

P. W. A. Quarry Limestone Member (of Drum Formation)

Pennsylvanian (Missouri Series): Eastern Nebraska and south-central Iowa.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37. Basal member of formation. Thickness about 1 foot in Sarpy County, Nebr., and about 2 feet in south-central Iowa; this is a "middle" limestone zone and may not extend very far southward. Underlies Richfield Quarry shale member (new); overlies Quivira formation.

Type locality: P. W. A. quarry in Missouri River bluffs, east of Richfield quarry, Sarpy County, Nebr.

**Pyburn Limestone Member** (of Oliver Hill Formation)[1]

Lower Devonian: Western and central Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 685.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 288. Use of name, Pyburn limestone, is discontinued and all limestone formerly classed as Pyburn is included in Ross limestone member of Ross formation (new).

Named for exposures in Pyburn Bluff, Hardin County.

Pyramid conglomerate[1]

Upper Cretaceous: Southwestern (?) New Mexico.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 338.

Crops out in Pyramid Butte.

Pyramid shale[1]

Cretaceous (?): Eastern New Mexico.

Original reference: C. R. Keyes, 1905, Am. Jour. Sci., 4th, v. 20, p. 424.

Derivation of name not stated.

Pyramid Rock Basalt (in Honolulu Volcanic Series)

Pleistocene: Oahu Island, Hawaii.

H. T. Stearns, 1940, Hawaii Div. Hydrography Bull. 5, p. 50–51. Lava flow and feeder dike of nepheline basalt.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 129. Thickness unknown; Pyramid Rock has summit altitude of 100 feet, but lava extends below sea level. Overlain by reef of plus 25-foot (Waimanalo) stand of sea. Included in lower part of Honolulu volcanic series. Pleistocene.

Named for Pyramid Rock, a hill on Mokapu Peninsula that is composed of the lava and may mark vent from which it issued. Exposed over area of about 0.01 square mile at northwest corner of Mokapu Peninsula on northeast coast of Oahu, 13 miles northwest of Makapuu Head.

Pyrites Granite[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1929, New York State Mus. Bull. 281, p. 66, 71–73, 96.

Located just northeast of Pyrites, in southwestern corner of Canton quadrangle.

**Quabin Quartzite**[1]

Carboniferous: Western central Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 60. 72–75, map.

Composes large part of Quabin and Felton Mountains.

**Quadrant Quartzite**[1] or **Formation**[1]

Pennsylvanian: Wyoming and Montana.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110.

C. C. Branson, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1215–1217. Quadrant together with upper part of beds which Scott (1935) referred to as Amsden are herein regarded as attenuated edge of Tensleep sediments.

M. L. Thompson and H. W. Scott, 1941, Jour. Paleontology, v. 15, no. 4, p. 349–353. Lower part (beds 1 and 2) of Scott's (1935) section on Quadrant Mountain are Mississippian. In present report, Scott's section is revised: beds 1 and 2 are referred to Sacajawea(?) formation (Mississippian). Beds 3 to 21 are included in the Quadrant, and name Amsden is deleted from the section. At this locality, the Quadrant is 279 feet thick and underlies the Phosphoria. Fusulinids of type section discussed.

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2164–2165. Thickness 2,662 feet in Big Sheep Creek section, Beaverhead County, Mont. The east-to-west increase in thickness of the Quadrant may suggest post-Pennsylvanian erosion of formation on tectonically positive areas and its preservation in negative trends.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 20–22, pl. 1. Formation in southern Elkhorn Mountains consists of interbedded light-colored quartzitic sandstone and light-gray sugary and sandy dolomite. Thickness 225 to 325 feet. Overlies Amsden formation; underlies Phosphoria formation.

D. O. Peterson, 1959, Dissert. Abs., v. 20, no. 7, p. 2757. Discussion of regional stratigraphy of Pennsylvanian in northeastern Utah, western Wyoming, northwestern Colorado, and southeastern Idaho. Many nomenclatural problems exist. One of the suggested changes is that Quadrant and Casper formational names be abandoned and the Tensleep-Amsden-Sacajawea terminology extended to include strata formerly referred to by these names.

Named for Quadrant Mountain, in Gallatin Range, northwest corner of Yellowstone Park, Wyo. Forms bluff encircling the mountain.

**Quail Porphyry**[1]

Upper Cretaceous or lower Tertiary: Western central Colorado.

Original reference: S. F. Emmons, 1898, U.S. Geol. Survey Geol. Atlas, Folio 48.

Ogden Tweto, 1953, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-12. Fine-grained dark-gray monzonitic porphyry found only in a few dikes in eastern part of Pando area.

Largest sheet occurs under White Quail group of mines, Tenmile quadrangle. Pando area is in Eagle and Summit Counties.

Quajote Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 9–10, 16–17, pl. 27. Consists of following divisions (ascending): friable yellow and greenish-yellow sandstone, friable yellow sandstone, whitish and yellow-green shale and greenish sandstone with layers of dark-green limestone, weak drab limestone, hard brownish limestone, and light-buff streaked sandstone. Thickness 32 feet. Underlies Perilla member (new); overlies unnamed shale and sandstone division.

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Quakertown cyclothem

Pennsylvanian (Pottsville Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 8. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 23, table 1, geol. map. Includes (ascending): Quakertown shale and (or) sandstone, 8 feet thick, Quakertown clay, 1 to 5 feet; and Quakertown (No. 2) coal. Locally, the clay is replaced by Massillon sandstone. Overlies Huckleberry cyclothem; underlies Bear Run cyclothem. In area of this report, Pottsville series is described on a cyclothemic basis; 10 cyclothems are named. [For sequence see Anthony cyclothem.]

Exposed in western and northern Perry County.

Quakertown Fire Clay (in Pottsville Formation)[1]

Quakertown clay member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$, p. 332.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 23, table 1. Member of Quakertown cyclothem in report on Perry County. Plastic, sandy, and ferruginous at most outcrops. Commonly gray or dark gray. Thickness 1 to 5 feet. Underlain either by shale or sandstone and overlain by Quakertown coal. Locally clay replaced by Massillon sandstone.

†Quakertown Group (in Pottsville Formation)[1]

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. P. Lesley, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$, p. xxi–xxxvi, 319–333.

Quakertown Shale (in Breathitt Formation)

Pennsylvanian: Southeastern Kentucky.

R. E. Hauser, 1953, Kentucky Geol. Survey, ser. 9, Bull. 13, p. 11 (fig. 2), 14. Hard black fissile shale, 3 to 6 inches thick. Occurs from 6 to 18 feet above top of Lee formation. Underlies an unnamed shale 25 to 30 feet thick. In western part of area, a thin coal occurs in the position of the Quakertown; it may be that there is a lateral change from east to west of shale to coal.

This may or may not be a geographic extension of Quakertown shale listed below.

Occurs in Paintsville quadrangle.

Quakertown Shale (in Pottsville Formation)[1]

Pennsylvanian: Western Pennsylvania and western Maryland.

Original reference: I. C. White, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$, p. 66.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 54–55. Quakertown coal and shale mentioned in report on Fayette County. Coal and shale separate the Upper and Lower Connoquenessing sandstone. As much as 15 feet thick in places.

Occurs at the "Falls" on Quakertown Run, near Quakertown Station, Lawrence County, Pa.

Quakertown Slate (in Kanawha Formation)[1]

Pennsylvanian: Northern West Virginia and western Maryland.

Original reference: D. B. Reger, 1918, West Virginia Geol. Survey Rept. Barbour and Upshur Counties, p. 273.

Named for occurrence along Tygart Valley River in northern Randolph County, W. Va., where it lies just above Quakertown (Winifrede?) coal.

**Quall Limestone**[1]

Lower Devonian: Western and central Tennessee.

Original reference: C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 746.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 307. Erosion following flooding of Pickwick Lake has exposed section of 40 feet of Harriman limestone just across valley from old Quall place—type locality of Quall limestone. On basis of recent studies, it is concluded that Dunbar's Quall limestone is an unweathered phase of Harriman formation, and it is recommended that name Quall be discontinued.

Named for development on farm of Jim Quall, in valley of Dry Creek, a small stream entering Tennessee River near Walnut Grove, Hardin County.

Quanah Granite[1]

Precambrian: Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135, 137–138.

G. W. Chase, 1952, Oklahoma Geol. Survey Circ. 30, p. 11, 12. Makes up major part of the Quanah Mountain group and rests in a sill-like position on Lugert granite.

Named for Quanah Mountain in Wichita Mountains.

Quanah Gypsum[1]

Permian: Central northern Texas and southwestern Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 356 (footnote), 357.

In Hardeman County, Tex., and Greer County, Okla. Named for Quanah, Hardeman County, Tex.

**Quantico Slate**[1]

Upper Ordovician: Northeastern Virginia.

Original reference: N. H. Darton, 1894, U.S. Geol. Survey Geol. Atlas, Folio 13.

Named for Quantico Creek, Prince William County.

Quapaw Chert[1]

Mississippian: Northeastern Oklahoma.

Original reference: S. Weidman, 1932, Oklahoma Geol. Survey Bull. 56, p. 17.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey.

Named from Quapaw Village in Ottawa County.

Quapaw Sandstone (in Wann Formation)

Pennsylvanian: Central northern Oklahoma.

C. C. Branson, 1955, The Hopper, v. 15, nos. 10–11, p. 129. Name applied by F. C. Greene (1918, Am. Assoc. Petroleum Geologists Bull., v. 2, p. 122) to massive sandstone exposed at Quapaw. Revard is valid name for this unit.

Quapaw was small village in sec. 35, T. 25 N., R. 10 E., Osage County,

Quarry Conglomerate

Miocene and Pliocene: Southern California.

G. J. Bellemin, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 652 (fig. 1), 656–657. Named as one of five conglomerates interbedded in Miocene and Pliocene shales of the Puente Hills, Los Angeles County.

Named from an abandoned quarry on north side of Sycamore Canyon Road.

Quarry Creek Limestone[1]

Pennsylvanian: Southeastern Illinois.

Original reference: A. H. Worthen, 1875, Illinois Geol. Survey, v. 6, p. 10–17.

Named for Quarry Creek, 1½ miles east of Martinsville, Clark County.

Quarry Peak Rhyolite Complex

Tertiary: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 65–68, table 1, pl. 1. Flows, breccias, and tuffs of rhyolite composition. Most of sequence consists of holocrystalline equigranular aphanitic white or light-gray rhyolite which contains a few small inconspicuous phenocrysts of quartz and feldspar. Many of the breccias and tuffs are well bedded. Thickness about 1,000 feet. Overlies unnamed andesite with slight angular unconformity; disconformably underlies unnamed basalt.

Forms prominent peak west of Steins and north of Southern Pacific Railroad and State Highway 14. For convenience of this report, the peak above the abandoned quarry is called Quarry Peak from which sequence of rhyolitic rocks takes its name. The complex also crops out west and northwest of Quarry Peak and north of Steins, Hidalgo County.

Quartermaster Dolomite (in Quartermaster Formation)[1]

Permian: Western Oklahoma.

Original references: Noel Evans, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, no. 7, p. 706, 708; G. G. Suffel, 1930, Oklahoma Geol. Survey Bull. 49, p. 107, 114, 124, 128.

In Weatherford district, Custer County.

**Quartermaster Formation[1]**

Quartermaster Formation (in Custer Group)

Quartermaster Group

Permian: Southwestern and northwestern Oklahoma, southern Kansas, and northwestern Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 57.

Robert Roth, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 421–433. Mentioned in general discussion of extension into Texas and loose use of Kansas and Oklahoma formation names in Texas.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1526 (fig. 3), 1527–1528. Quartermaster used as group term to include Doxey shale and Elk City sandstone. Cloud Chief removed from Quartermaster and considered uppermost formation in underlying Whitehorse group.

Robert Roth, N. D. Newell, and B. H. Burma, 1941, Jour. Paleontology, v. 15, no. 3, p. 312–317. Age of Quartermaster formation of Oklahoma and Texas has been subject of controversy, being variously given as late Permian or Triassic(?). Fossils have been discovered in lower part of Doxey shale at base of Quartermaster. Some of the species recognized also characterize recently described Whitehorse fauna and indicate close relationship of enclosing beds with Whitehorse formation. If Whitehorse is Guadalupian (late Permian) in age, then fossiliferous Quartermaster beds probably are to be correlated with some part of Guadalupian or perhaps Ochoa of western Texas. Table shows Quartermaster formation as uppermost unit of Custer group.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 156–157. Permian beds above Day Creek dolomite are classified as belonging in Quartermaster group. They seem to be equivalent to lower part of Quartermaster formation of western Oklahoma and Panhandle of Texas. Maximum outcrop thickness in Kansas about 45 feet. Includes Taloga formation.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, formation includes Doxey and Elk City members.

Named for exposures along banks of Quartermaster Creek, Roger Mills County, Okla.

Quartz Spring Sandstone Member (of Lost Burro Formation)

Upper Devonian: Southern California.

R. L. Langenheim, Jr. and Herbert Tischler, 1960, California Univ. Pubs., Geol. Sci., v. 38, no. 2, p. 92, 94 (fig. 2), 134–135, 136. Consists of quartzite and interbedded sandy dolomite and limestone; contains fauna characterized by *Cyrtospirifer cf. C. monticola* Haynes. Thickness about 38 feet. Underlies Tin Mountain limestone.

Type locality: Exposures below type section of Tin Mountain limestone which is on southern slope of hills about 2½ miles southeast of Quartz Spring, Inyo County, and about 3,000 feet north of road to Rest Spring.

Quatal Formation

Quatal Red Clay Member (of Santa Margarita Formation)

Miocene, upper(?): Southern California.

W. E. Ver Planck, 1952, California Div. Mines Bull. 163, p. 35–37, pl. 33. Nonmarine facies of the upper Santa Margarita. Underlies a sandstone bed; overlies a gypsum bed stratigraphically above Caliente red beds. Total thickness of shale and sandstone above the gypsum is 75 to 100 feet. Occurs in Quatal Canyon gypsum deposit, Ventura County.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2978 (fig 3), 2996, 2997. Quatal formation is herein designated as the nonmarine claystone and sandstone, probably upper Miocene in age, that lies conformably between Caliente formation below and Morales formation above. At type locality, the formation, of probable lacustrine origin, is approximately 800 feet thick and consists of reddish-gray soft thin-bedded gypsiferous claystones weathering to reddish clay soil; contains basal bed of white massive gypsum that attains maximum thickness of 30 feet in Quatal Canyon. In southern part of Cuyama Badlands, formation thickens to about 2,700 feet and becomes mainly fluviatile pebbly sandstone of prevailing orange-buff color of which only basal 500 feet is lacustrine red claystone. West of mouth of Quatal Canyon, on west bank of Cuyama River, formation consists of about 600 feet of light brown sandstone-cobble conglomerate and sandstone which grades westward along strike into marine Santa Margarita sandstone. On northeast slope of Caliente Range adjoining Carrizo Plain, type Caliente redbeds are overlain conformably by about 700 feet of soft gray gypsiferous lacustrine claystone containing some thin-bedded hard sandstones in basal part; these claystones are believed to be correlative with Quatal red claystone of Cuyama Badlands but could belong to overlying Morales formation. Name replaces preoccupied Apache formation (Dibblee, 1947).

Type locality: Ballinger Canyon, Ballinger Canyon quadrangle. Named for exposures in Quatal Canyon.

Queantoweap Sandstone

Lower Permian: Northwestern Arizona.

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 515 (fig. 2), 525–526. Massive pink and gray ledge- and cliff-forming crossbedded sandstones which rest on Pakoon (new) and upper Callville limestones. Thicknesses: 393 feet, Hurricane Cliffs; 645 feet, North Grand Wash Cliffs; 400 feet Pakoon Ridge. Underlies Hermit formation with contact transitional in interval ranging from 5 to 50 feet. Not present in southwestern part of area where Supai is undifferentiated. Northward, could represent most, if not all, of massive-bedded tan, yellow, and pink sandstones of extreme northwest Arizona and southwest Utah that have commonly been referred to as "Supai."

Type section: On east side of Queantoweap Valley, Mohave County, between the upper and lower lava flows, near a well locally known as Gramps basin.

†Quebecan Substage (of Wisconsin Stage)[1]

Pleistocene: Great Lakes region.

Original reference: M. M. Leighton, 1931, Jour. Geology, v. 39, p. 51–53.

Named for Quebec, Canada.

Quebradillas Limestone[1]

Miocene: Puerto Rico.

Original reference: T. W. Vaughan, 1924, Geol. Soc. America Bull., v. 35, no. 4, table 3.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85. Quebradillas and Los Puertos limestones form an indivisible unit and in this report are termed Aymamón limestone.

**Quebrancha Limestone Member** (of Caimito Formation)

Quebrancha Limestone

Oligocene, upper: Panamá.

T. F. Thompson, 1944, Geological explorations in the vicinity of Río Quebrancha for the Panamá Cement Co.: Panamá Canal, Spec. Eng. Div., p. 17–20. The so-called Quebrancha limestone deposit consists of a 110 to 135 meter thick layer of variably argillaceous, sandy, or semicrystalline limestone. Separated from underlying Gatuncillo shale (new) by an interval of gritty sandstone, basalt, and conglomerate, and from overlying Río Duque shales (new) by interval by calcareous siltstone.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 234, 246 (fig. 2). Member of Caimito limestone. Thickness 350 to 450 feet. Grades upward into unnamed calcareous siltstone member; overlies, probably without marked discontinuity, volcanic member of Bohío formation.

Type region: On south limb of Quebrancha syncline; includes quarry of Panamá Cement Co.

**Queen Formation** (in Whitehorse Group or Artesia Group)

Queen Sandstone Member (of Chalk Bluff Formation)[1]

Permian (Guadalupe Series): Southeastern New Mexico and western Texas.

Original references: F. S. Prout, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 656; K. H. Crandall, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 8, p. 940–941.

R. K. DeFord and E. R. Lloyd, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 9. Whitehorse group of West Texas and New Mexico divided into (ascending) Grayburg, Queen, Seven Rivers, Yates, and Tansill formations.

W. C. Fritz and James Fitzgerald, Jr., 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 24–25. Includes Yoakum dolomite member (new) in subsurface.

N. D. Newell, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 43–46. Overlies Grayburg formation; underlies Seven Rivers formation. Lower boundary used herein is essentially that selected by Crandall (1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 982, 983, 987) on Queen Mesa, but top of formation is drawn above Shattuck member (new), a prominent sandstone approximately 100 feet thick over much of shelf area in Guadalupe Mountains, except near reef where it thins rapidly.

W. R. Moran, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1288. Crandall (1929) did not designate type locality. At type section herein designated, Queen is 421 feet thick and consists of alternating sandstone and sandy dolomite. At this section, Queen underlies Seven Rivers formation and overlies the Grayburg; Shattuck member is present in uppermost 100 feet of section.

P. T. Hayes and R. L. Koogle, 1958, U.S. Geol. Survey Geol. Quad. Map GQ-112. Formation described in Carlsbad Caverns West quadrangle which contains type section as designated by Moran. Overlies Grayburg formation; underlies Seven Rivers formation of Carlsbad group.

Term Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4) replaces terms Whitehorse and Chalk Bluff in New Mexico.

Type section (Moran): West wall of Dark Canyon, in SW¼ sec. 36, T. 24 S., R. 22 E., Eddy County, N. Mex. Named for exposures in vicinity of Queen post office, sec. 30, T. 24 S., R. 22 E., Eddy County.

**Queen City Sand Member** (of Mount Selman Formation)[1]

Queen City Sand or Formation (in Claiborne Group)

Eocene, middle: Northwestern Louisiana and eastern Texas.

Original reference: W. Kennedy, 1892, Texas Geol. Survey 3d Ann. Rept., p. 50–52.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 78–93 [1938]. Queen City sand described in Leon County where it is about 440 feet thick. Includes Omen glauconitic sand member at top and lower unit referred to as glauconitic sand at Venetia. Overlies Marquez shale member (new) of Reklaw formation; underlies Tyus marl member (new) of Weches formation.

H. B. Stenzel, 1953, Texas Univ. Bur. Econ. Geology Pub. 5305, p. 10 (fig. 3), 83–100. Formation described in Henrys Chapel quadrangle where it is youngest of Eocene formations present and is only incompletely preserved. Thickness 105 to 131 feet. Includes (ascending) Arp member, Omen glauconitic sandstone member, and unnamed upper sand member. Overlies Reklaw formation; underlies Pleistocene gravels.

C. R. Smith, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2517–2522. Three-fold division of Queen City as recognized on surface in Texas is also present in surface in Caddo Parish, La. Lower sand unit is correlative with Arp member; middle glauconitic member is correlative with Omen member; upper sand member is herein named Myrtis sand member. Underlies Weches formation. Present study shows that sand on surface at Queen City, Cass County, Tex., is equivalent to sand at type locality of Sparta sand. The sand occupying stratigraphic position between Reklaw and Weches formations, "Queen City" by name, has incorrect type locality and alternate type locality is herein suggested.

Alternate type locality: Exposures extending from town of Vivian north and west along old Vivian-Atlanta Road for 4 miles through secs. 23, 15, 10, and 4 to Myrtis Mill Creek, Caddo Parish, La. Well developed in vicinity of Queen City, Cass County, Tex., in which area it was described by Kennedy (1892).

**Queen Hill Shale Member** (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 44, 46, 47.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 154; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17. Queen Hill shale member of Lecompton formation; underlies Beil limestone member; overlies Big Springs limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24. Type locality and derivation of name stated.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 20, fig. 5. Dark to greenish gray and argillaceous in upper part; and black and fissile below. Thickness 4½ feet. Not identified farther northeast than Montgomery County.

Type locality: Queen Hill, a prominent point in Missouri River bluffs, northeast of Rock Bluff, Cass County, Nebr.

**Queenston Shale**[1]

Queenston Shale (in Richmond Group)

Upper Ordovician: Western New York, and Ontario, Canada.

Original reference: A. W. Grabau, 1908, Science, new ser., v. 27, p. 622–623.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 22 (fig. 6). Uppermost unit of Richmond group in Clyde and Sodus Bay quadrangles.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1981 (fig. 2), 1986. Discussion of stratigraphy of Silurian Medinan group. Queenston shale underlies the Whirlpool, basal formation of Medinan. In some areas the Queenston underlies the Grimsby.

Named for town of Queenston on Niagara River, opposite Lewiston, Niagara County, N.Y.

Queets Beds

Pleistocene, upper: Northwestern Washington.

S. L. Glover, 1940, Northwest Sci., v. 14, no. 3, p. 69–71. Name applied to late Pleistocene deposits on coastal area of Olympic Peninsula. Probably correlate with sediments of Vashon age in Puget Sound area. Beds are generally flat lying. Thickness about 15 feet. Overlies Taholah formation (new).

S. L. Glover, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2022–2023. Younger than Browns Point formation (new).

Well exposed on south bank of Quinault River near Indian village of Taholah, Grays Harbor County.

Quercan Sandstone[1]

Miocene: Central western California.

Original reference: C. E. Weaver, 1909, California Univ. Pub., Bull. Dept. Geology, v. 5, p. 251.

In San Pablo Bay region. Derivation of name not stated.

Quichapa Formation or Group

Oligocene(?): Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 18–24, 53–57. Group consists of three ignimbrite units in Pine Valley Mountains. Lowermost unit is hard dense welded tuff; pale red violet on fresh surfaces, weathers pale red brown; sparsely scattered through rock are angular red latite (?) fragments, averaging under 10 millimeters in diameter; ranges in thickness from less than 100 feet just east of Stoddard Mountain to about 800 feet near Pinto Peak; 5 to 20 feet of black glass containing angular red fragments at base of unit. Middle unit is a vitric rhyolite ignimbrite, consisting of strongly welded tuff, contains basal black glass, 10 to 20 feet thick, which unconformably overlies basal unit of group. Uppermost ignimbrite unit is red brown to purplish brown on fresh surfaces, weathers brown or dark brown; basal black glass of unit is as much as 35 feet thick; maximum thickness of unit in Pine Valley Mountains about 550 feet; conformably overlies middle unit. Thickness of group in Pine Valley Mountains ranges from a fraction of a foot to about 1,600 feet, the variation being due largely to an unconformity at top of group. In most exposures, lowermost unit of group appears to overlie Claron formation conformably. Underlies Rencher formation (new). Name credited to J. H. Mackin (personal commun.).

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 89, 97. Rank reduced to formation. Subdivided into (ascending) Leach Canyon tuff, Swett tuff, Bauers tuff, and Harmony Hills tuff members (all new). Underlies Rencher formation; overlies Isom formation (new).

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 37–40, maps 1 and 2. Formation, in Washington County, includes (ascending) Leach Canyon tuff, Bauers tuff, Little Creek breccia (new), and Harmony Hills tuff. Thickness 0 to 1,800 feet. Overlies Isom formation; underlies Rencher formation. Leach Canyon tuff has zircon age of 28 million years; this suggests that formation is Oligocene.

Named from exposures in Quichapa Canyon of the Harmony Hills, Iron and Washington Counties.

Quien Sabe Volcanics

Miocene, middle(?): West-central California.

N. L. Taliaferro, [1949], Geologic map of the Hollister quadrangle, California (1:62,500): California Div. Mines Bull. 143, pl. 1 [preprint?]. Shown on map legend as consisting of flows and agglomerates with plugs, dikes, and a sandstone member. Overlies Vaqueros formation.

C. J. Leith, 1949, California Div. Mines Bull. 147, p. 12 (fig. 2), 22–24, pl. 1. Described in Quien Sabe quadrangle. Thickness 4,000 feet. Unconformably underlies upper Pleistocene Peckham formation (new); unconformably overlies Vaqueros formation.

E. B. McKee, Jr., 1959, Dissert. Abs., v. 19, no. 11, p. 2913. In Pacheco Pass area, slightly folded erosional remnants of Quien Sabe group (late Cenozoic) locally lie with angular unconformity on Franciscan rocks.

Occurs in west-central part of Quien Sabe quadrangle and extend westward into Hollister quadrangle.

Quillayute Formation[1]

Miocene(?) or Pliocene: Northwestern Washington.

Original reference: A. B. Reagan, 1909, Kansas Acad. Sci. Trans., v. 22, p. 203.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 24 (chart), 195. Composed of medium- and coarse-grained pebbly sandstone, shaly sandstones, and sandy shales; prevailingly brownish gray. Maximum thickness probably under 1,000 feet; dips range between 5° and 15°. Rests with marked unconformity upon steeply dipping strata of older rocks which may be in part middle Miocene. Pliocene. Exposures noted.

Exposed in southwestern part of Clallam County in valley of Quillayute River near junction of Solduc and Bogachiel Rivers.

Quimbo Dolomite (in Joserita Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11. Ochre-colored dolomite, in places grades laterally into light-yellow calcareous shale. Underlies Saavedra member (new); overlies Corta sandstone (new).

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

**Quimbys Mill Member** (of Platteville Formation)

Quimbys Mill Formation (in Platteville Group)

Middle Ordovician: Southwestern Wisconsin, northern Illinois and eastern Iowa.

A. F. Agnew and A. V. Heyl, Jr., 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 9, p. 1585–1587. Proposed for "glass rock" beds that overlie McGregor limestone member of Platteville and underlie Spechts Ferry shale member of Decorah formation. Consists of limestone and dolomite in medium to thin beds which are separated by thin carbonaceous shale laminae. Thickness at type locality 12 feet; upper 6 feet is dolomite with carbonaceous shale partings; lower 6 feet is limestone. Unit thins toward northwest and thickens southeast becoming completely a dolomite in latter direction.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, 10 (fig. 3), 18 (fig. 9). Geographically extended into Dixon-Oregon area, Illinois, where it is considered a formation at top of Platteville group; includes (ascending) Hazel Green, Shullsburg, and Strawbridge members (all new). Overlies Nachusa formation (new). Underlies Guttenberg formation of Galena group.

A. F. Agnew, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1734. Geographically extended into eastern Iowa.

Type section: Quarry at Quimby's Mill, SE cor. sec. 11, T. 1 N., R. 1 E., Etna, Wis.

Quimper Sandstone

Oligocene, lower: Northwestern Washington.

J. W. Durham, 1942, Jour. Paleontology, v. 16, no. 1, p. 86–87. Massive-bedded sandstone 900 feet thick at type section. Underlies moderately well-bedded shale; overlies Townsend shale (new) or overlaps onto older rocks of Oligocene or Eocene age.

J. W. Wyatt, 1944, California Univ. Dept. Geol. Sci. Bull., v. 27, no. 5, p. 106. On Marrowstone Island, underlies Marrowstone shale (new). Here consists of nearly 700 feet of moderately well-bedded medium-grained arkosic sandstones; on south shore of Port Townsend Bay, section is approximately 800 feet thick; in this area, unconformity at base is well marked and Quimper overlies Lyre conglomerates, Townsend shale, and various parts of the Eocene section; rests successively on older rocks toward the northeast.

Type section: On east side of Kilisut Harbor, Marrowstone Island [Jefferson County], Quimper Peninsula.

**Quinault Formation**[1]

Pliocene: Northwestern Washington.

Original reference: R. Arnold, 1906, Geol. Soc. America Bull., v. 17, p. 451–468, map.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 191–194. On north side of Quinault River, consists of alternating layers of sandstone, shale, and conglomerate; on south side of river, consists of massive fossiliferous shaly sandstones. Thickness about 936 feet. At Cape Grenville, appears to rest unconformably upon a complex of basaltic lavas, tuffs, agglomerates and associated intrusive dikes which probably correspond to the Eocene Metchosin volcanics, a fault may separate these volcanics from the Quinault.

S. L. Glover, 1940, Northwest Sci., v. 14, no. 3, p. 70. Unconformably underlies newly defined lower Pleistocene Taholah formation.

T. J. Etherington, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 191. Chart shows Quinault formation stratigraphically above Montesano formation.

Occurs on Quinault Indian Reservation north and south of mouth of Quinault River between Cape Elizabeth and Point Grenville, Grays Harbor County.

**Quincy Amygdaloid**[1] (in Ashbed Group)

Precambrian (Keweenanwan): Northern Michigan.

Original reference: R. Pumpelly, 1893, Michigan Geol. Survey, v. 1, pt. 2. p. 21–25, 28.

Named for occurrence in Quincy mine, Houghton County.

**Quincy Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth)

Probably named for occurrence in Quincy mine, Houghton County.

**Quincy Granite**[1]

Mississippian(?): Eastern Massachusetts and Rhode Island.

Original reference: W. O. Crosby, 1876, Rept. on geol. map of Massachusetts, p. 1–42.

N. E. Chute, 1940, Massachusetts Dept. Public Works Bull. 1, p. 4, 11–12, pls. 2–A, 2–B. Devonian(?).

Alonzo Quinn, R. G. Ray, and W. L. Seymour, 1949, *in* Alonzo Quinn and others, Bedrock geology of the Pawtucket quadrangle, Rhode Island-

Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Mississippian (?).

Type area; In Quincy and Milton, Mass.

Quincy Syenite[1]

Precambrian: Massachusetts.

Original reference: C. H. Hitchcock, 1872, Am. Jour. Sci., 3d, v. 3, p. 47.

In Abington, Plymouth County.

**Quincy Pewabic Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, pl. 18.

Named for occurrence in Quincy and Pewabic mines, Houghton County.

**Quincy Pewabic Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, pl. 18.

Probably named for occurrence in Quincy and Pewabic mines, Houghton County.

**Quindaro Shale**[1] **Member** (of Wyandotte Formation)

Quindaro Member (of Iola Limestone)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook p. 92, 97.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 282. Member of Iola limestone; consists of gray calcareous shale 1 to 2 feet thick.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2033; 1949, Kansas Geol. Survey Bull. 83, p. 103. Quindaro shale member of Wyandotte formation; underlies Argentine limestone member; overlies Frisbie limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947. The Frisbie limestone, Quindaro shale, and Argentine limestone, which were indicated as members of the Iola limeston in western Missouri. are classified with overlying Island Creek shale and Farley limestone as members of the Wyandotte.

T. L. Welp. L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 420. Thickness 4 feet in vicinity of Winterset, Iowa

H. G. Hershey and others. 1960, Iowa Highway Research Board Bull. 15. p. 25, fig. 5. Member of Wyandotte. Top poorly defined. Argentine-Quindaro contact arbitrarily placed where limestone is subordinate and shale dominates section. In Madison and Union Counties, Quindaro shale consists of black fissile shale overlain by gray to live-gray fossiliferous shale and underlain by gray shale. Thickness about 3.7 feet. Overlies Frisbie limestone member. Although Condra and Upp (1933, Nebraska Geol. Survey Paper 4) did not recognize Quindaro in their Middle River traverse in Iowa it is recognized here.

Typically exposed in floor of Boyn's quarry, near NW cor. sec. 30, T. 10 S., R. 25 E., northeast of Welborn, Wyandotte County, Kans. Named for Quindaro Township.

Quinn Clay (in Harpersville Formation)

Pennsylvanian (Cisco) : North-central Texas.

F. B. Plummer *in* M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 7. Named in road log.

F. B. Plummer and H. B. Bradley, 1949, Texas Univ. Bur. Econ. Geology Pub. 4915, p. 5–17, pl. 3. Purplish-red, green, and maroon clay which occurs between Parks Mountain sandstone or its probable equivalent, the Cisco Lake sandstone, and upper Breckenridge limestone. Best described as the next to lowest clay in Harpersville formation, as defined by Plummer and Moore (1921, Texas Univ. Bull. 2132). Most conveniently mapped as the clay between the lower Crystal Falls limestone and the upper Breckenridge limestone. Average thickness 30 feet, maximum thickness 48 feet.

L. F. Brown, Jr., 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 41, p. 21–23. Quinn clay, according to Plummer and others (1949), is the clay between the Crystal Falls and upper Breckenridge limestone. Present study shows that this upper Breckenridge limestone in northern Stephens County is type Breckenridge and that no lower Breckenridge limestone occurs in subject area. Also correlation has not been demonstrated of type Quinn clay in northern Eastland County with Quinn clay mapped by Plummer and others in northern Stephens County. Quinn clay of present report (Stephens County) thins north of Clear Fork of Brazos River. Member is divided into upper clay and lower clay-shale units by thin sandstone south of Clear Fork of Brazos River and by a limestone north of the river. Clay contains several thin sandstone lentils, a limestone lentil, and a sandstone channel deposit. Thickness 30 to 50 feet.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 73. Beds that intervene between Breckenridge and Chaffin limestone members of the Thrifty in Brown County and north of Home Creek in eastern Coleman County are red clay containiing abundant hematite nodules and plant fossils. This is Quinn clay of Plummer and Bradley. In many places, lenticular beds of sandstone are present within unit, particularly near the base, and some channel-fill conglomerate is also present. Conglomerate may perhaps be correlated with Parks Mountain sandstone member of Thrifty.

Type locality: On north side of Eastland-Cisco Highway (U.S. Highway 80), 2 miles east of Cisco, Eastland County. Named for Quinn Ranch.

**Quinnesec Formation**

Quinnesec Greenstone[1]

Precambrian: Northern Michigan and northeastern Wisconsin.

Original reference: C. R. Van Hise and W. S. Bayley, 1900, U.S. Geol. Survey Geol. Atlas, Folio 62.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 33. Term Quinnesec formation applied to greenstone amphibolite and schist that form a belt in southernmost Dickinson County and adjacent parts of Wisconsin. These rocks were referred to as schists by Van Hise and Bayley (1900) who assigned them to the Archean and as greenstone by Leith, Lund, and Leith (1935) who assigned them to the middle Huronian. Recent mapping in the type area shows that rocks placed in the Quinnesec by previous workers comprise metavolcanic rocks and younger metagabbro sills. Term Quinnesec formation is retained for the metavolcanic rocks, which are clearly older than granitic rocks that form a mass of batholithic dimensions to the south. Relationships of Quinnesec formation and of the granitic rocks to known Animikie strata are not clear; the metavolcanic and granitic rocks are believed to be pre-Animikie; the younger metagabbro sills are intrusive into the formation and are younger than the granitic rocks to the south; they are tentatively correlated with the post-Animikie and metagabbro.

Quinnesec Falls, Dickinson County, Mich., is on some of the harder ledges of these rocks.

Quinnesec Ore-Formation[1]

Precambrian: Northern Michigan.

Original reference: C. L. Rominger, 1881, Michigan Geol. Survey, v. 4, pt. 2, p. 182.

Crops out at many localities along the range, especially north of the Norway, Quinnesec, and Chapin mines, Menominee iron region.

†Quinnimont Beds[1]

†Quinnimont coal group[1]

Pennsylvanian: West Virginia, western Pennsylvania, and southwestern Virginia.

Original reference: J. P. Lesley, 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$, p. xxii–xxiv.

Quinnimont Sandstone (in New River Group)

Quinnimont Sandstone (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 206.

P. H. Price, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 237–238. Hard, gray, massive, medium-grained, lenticular. As much as 70 feet thick. Underlies Beckley coal; overlies Quinnimont shale. New River group, Pottsville series.

Named for exposures in New River Canyon at Quinnimont, Fayette County.

Quinnimont Shale (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 206.

Named for exposures at Quinnimont, Fayette County.

**Quinnimont Shale Member** (of New River Formation)

Quinnimont Shale (in New River Group)

Quinnimont Shale (in Pottsville Group)[1]

Lower Pennsylvanian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell, 1896, U.S. Geol. Survey Geol. Atlas, Folio 29.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 238. Dark-gray siliceous to argillaceous laminated lenticular sandstone 5 to 40 feet thick. Underlies Quinnimont sandstone; overlies Fire Creek coal. New River group, Pottsville series.

U.S. Geological Survey currently classifies the Quinnimont Shale as a member of the New River Formation on basis of a study now in progress.

Named for exposures at Quinnimont, Fayette County, W. Va.

Quinto Formation (in Orestimba Group)

Quinto Member (of Moreno Group)

Upper Cretaceous (Chico Series): Northern California.

R. D. Reed, 1943, California Div. Mines Bull. 118, pt. 2, p. 109 (table 6) [preprint 1941]. Shown in table as Quinto formation in Orestimba group; underlies Garzas formation; overlies Moreno formation.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 185 (fig. 69), 186 [preprint 1941]. Middle member of Moreno group. Underlies Garzas member; overlies Moreno member of group.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 31. Quinto member described by Bennison (1941, unpub. map of late Upper Cretaceous deposits south of San Luis Creek, Merced and Fresno Counties) includes sandy shale and two beds of massive biotitic sandstone at Los Banos Creek and at Salt Creek, but units at Salt Creek are poorly exposed. Quinto discussed under heading of Panoche formation in this report [Ortigalita Peak quadrangle].

Has been traced at intervals from Los Banos Creek northward to Brentwood, Contra Costa County.

Quinto B reef beds

Upper Cretaceous: Central western California.

C. T. Smith, 1945, Jour. Paleontology, v. 19, no. 1, p. 37–38, 39 (table 1). Sandstones and sandy shales with some conglomerates. Contain almost exclusively *Glycymeris veatchii major*. Includes Los Banos Creek member. Discussion of biostratigraphy of *Glycymeris veatchii*. Name credited to Alan Bennison (unpub. thesis):

Exposed on Los Banos Creek, west of Los Banos, Merced County. Also crops out along Garzas Creek, Moreno Gulch, and other streams that flow into San Joaquin Valley.

Quitman Bed (in Trinity Group)[1]

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: J. A. Taff, 1891, Texas Geol. Survey 2d Ann. Rept., p. 728, 736.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Quitman formation shown on correlation chart above Mountain formation and below Glen Rose equivalents.

Named for Quitman Mountain and Quitman Gap, El Paso County.

†Quitman Limestone[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 54–55.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 204. Name preoccupied by Cretaceous formations in Texas.

Named for exposures at Quitman, Nodaway County.

Quitman Quartz Monzonite

Oligocene(?) : Western Texas.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 1034–1036, pl. 1. Chiefly quartz monzonite, includes some granodiorite; monzonite, syenite, and granite; holocrystalline, medium- and coarse-grained to porphyritic, generally pink or gray. Principal rock in Quitman pluton; and forms a discontinuous ellipse, elongated north-south, around volcanic rocks of area. Age of pluton cannot be dated exactly; youngest sedimentary rocks invaded are upper Washita [Lower Cretaceous] in age; also pluton cuts volcanic rocks which are presumably Eocene and Oligocene and is overlain by basin fill at least partly Pliocene; unlikely that pluton is later than Miocene; because it is comagmatic with the volcanic rocks, it is probably Oligocene.

Occurs in northern Quitman Mountains, Hudspeth County.

**Quivira Shale Member** (of Cherryvale Shale)

Quivira Formation (in Kansas City Group)

Quivira Shale (in Kansas City Formation)[1]

Pennsylvanian (Missouri Series) : Northeastern Kansas, southwestern Iowa, and northwestern Missouri.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 96–97. Quivira shale member of Cherryvale formation; overlies Westerville limestone member; underlies Cement City limestone member of Drum limestone. This classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma. However, Kansas proposed to deviate from the interstate classification by adopting Dewey instead of Cement City [see explanation under Cement City].

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37. In Nebraska, considered a formation in Kansas City group. Underlies P. W. A. Quarry limestone member (new) of Drum formation; overlies Westerville limestone member of Sarpy formation (new). Type locality stated.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 420. Thickness 5 feet in section measured near Winterset, Iowa.

H. G. Hershey and others, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Formation in Kansas City group. Thickness about 6 feet near Crescent, Pottawattamie County; here it is brownish calcareous fossiliferous shale containing thin coquina limestone seams. Thickness about 1 foot in Madison County. Underlies Drum limestone; overlies Westerville limestone.

Type locality: At Quivira Lake, near Kansas River east of Holliday, Johnson County, Kans.

**Quoddy Shale**[1]

Quoddy Formation

Silurian (Niagaran) : Southeastern Maine.

Original references: E. S. Bastin and H. S. Williams, 1913, Maine Water Storage Comm. 3d Ann. Rept., p. 168; 1913, Geol. Soc. America Bull., v. 24, p. 378, 379.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Listed as a formation.

Named for exposures at West Quoddy Head, Washington County.

Quoggy Joe Quartz Trachyte[1]

Age (?) : Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 109, 111, 164–168.

Forms entire mass of Quoggy Joe group of hills, Aroostook County.

**Rabbit Hill Limestone**

Lower Devonian : Eastern Nevada.

E. L. Winterer and M. A. Murphy, 1960, Jour. Geology, v. 68, no. 2, p. 134 (fig. 6), 135, 136. Consists of tan-weathering silty limestone and calcareous shale; lighter colored than underlying Roberts Mountains formation and more silty and more thinly bedded than overlying Nevada formation; both contacts appear to be conformable and gradational. Contains Helderbergian fauna. Name credited to C. W. Merriam.

U.S. Geological Survey currently designates the age of the Rabbit Hill as Lower Devonian on basis of a study now in progress.

Type section : Monitor Range, Horse Heaven Mountain quadrangle.

**Rabbit Spring Formation**[1]

Pliocene (?) : Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 71.

Exposed in bluffs above Rabbit Spring and in other places along edge of Maipais Mesa, Goldfield district.

Rabble Run Red Sandstone Member (of McKenzie Formation)[1]

Silurian (Niagaran) : Western Maryland and northern West Virginia.

Original reference: C. K. Swartz, 1923, Maryland Geol. Survey, Silurian Volume, p. 36.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 54, 118, 128, 154, 174. McKenzie formation includes Rabble Run sandstone near its base in Maryland. Throughout southern Pennsylvania and east-central Maryland, has red shale member near top; this red unit, Rabble Run member, although 80 feet thick north of Potomac near Hancock County, Md., thins rapidly southward and is represented in Morgan County, W. Va., by only 5 feet of red sandy shale; it has no other important representative elsewhere in West Virginia. It is believed that Rabble Run red bed thickens northeastward to coalesce with the eastern red, nonmarine facies (Bloomsburg) of the Cayugan group.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 76. Rabble Run sandstone member is present about 100 feet below top of formation. Member is as much as 100 feet thick in Bear Pond area and thins westward and disappears before reaching Cumberland. It appears first in Cacapon section southeast of Hancock and replaces gray shale and limestone toward east in Washington County. Beds resemble the overlying Bloomsburg red sandstone and shale member of the Wills Creek formation.

Named for exposures in Rabble Run in North Mountain, Washington County, Md.

Rabens Branch Bed (in Parkers Formation)

C. A. Malott, 1947, Indiana Acad. Sci. Proc., v. 57, pl. 132, 133 (fig. 2) [1948]. Fossiliferous clay band or ferrous carbonate band about 1 inch thick that overlies a thin coal bed near base of formation; horizon is about 20 feet below the Parkers coal and its black sheety shale.

Named from exposure on Rabens Branch, a small stream crossing the north-south road about one-quarter mile south of center of sec. 11, T. 5 S., R. 12 W., 1½ miles southwest of St. Wendells, Posey County.

Raber bed or member

Silurian: Northeastern Michigan.

W. A. Kelly, 1954, Michigan Geol. Soc. [Guidebook 18th] Ann. Field Trip, p. 21. Mentioned in notes on correlation of Silurian of Manitoulin Island with Silurian of Michigan. Bed contains corals identical with Fossil Hill member [formation]. Underlies Engadine dolomite.

Type locality and derivation of name not given. Town of Raber is in Chippewa County.

Raccoon Shale[1]

Raccoon Shale Member (of Cuyahoga Formation)

Mississippian (Kinderhook): Central Ohio.

Original reference: L. E. Hicks, 1878, Am. Jour. Sci., 3d, v. 16, p. 216, 219.

F. T. Holden, 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 46, 47. Raccoon shale member included in Granville shale facies of Cuyahoga formation. Lateral and vertical extent not well known. Underlies Black Hand siltstone member (emended); overlies Sunbury shale.

Named for exposures on Raccoon Creek, Licking County.

**Raccoon Mountain Member** (of Gizzard Formation)

Raccoon Mountain Formation (in Gizzard Group)

Lower Pennsylvanian; Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 4, 19, pls. 2, 3, 4, 12–D. Alternation of shales and sandstones with several coals. Includes all beds from base of Warren Point sandstone to base of Pennsylvanian which is recognized by lithologic contrast between Mississippian limestone and variegated (red, maroon, and green) shale and Pennsylvanian coals and plant bearing shales. Thickness in type locality 353 feet; elsewhere thickness varies, but formation is generally thick to east and thin to west. In northwest part of plateau, Warren Point sandstone thins, and the Raccoon Mountain, which cannot be differentiated, is included in lower part of Fentress formation. Basal formation of Gizzard group, Pottsville series.

U. S. Geological Survey classifies the Raccoon Mountain as a member of the Gizzard Formation on the basis of a study now in progress.

Type section: On a mine road beginning 0.4 mile northwest of Whiteside, Marion County, and leading to strip mines at head of Scratch Ankle Hollow, Shellmound quadrangle.

†Raccoon River Beds[1]

Pennsylvanian: Central southern Iowa and northwestern Missouri.

Original reference: H. F. Bain and A. G. Leonard, 1898, Geol. Soc. Amercia Bull., v. 10, p. 11–12.

Named for Raccoon River, Dallas County, Iowa.

Racer Canyon Tuff Member (of Cove Mountain Formation)

Tertiary: Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 44. Succession of rhyolitic ignimbrites with maximum thickness of about 1,500 feet. White, gray, pale-pink, or pale-yellow, nonwelded to moderately welded, vitric-crystal tuff in which red or purple lithic fragments are generally abundant. Weathers into spectacular "hoodoos." Overlies Willow Spring member (new); underlies Pilot Creek basalt member (new). Name credited to H. R. Blank (unpub. thesis).

Occurs in Washington County.

**Racetrack Dolomite**

Middle and Upper Cambrian: Southern California.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 3, 8–9, 14 (fig. 6), pls. 1, 2, 3. Name applied to oldest rock unit in sedimentary sequence of Quartz Spring area. Predominantly gray dolomite. Thickness about 1,900 feet; possible unmapped faults make questionable the measurements of lowest units of formation. Underlies Nopah formation. Base not satisfactorily defined because alluvium overlaps lowest exposures. Middle (?) Cambrian.

Type locality: In Last Chance foothills on western side of Racetrack Valley, about 3 miles west of Quartz Spring, Inyo County. Locality extends from southern tip of spur west of Hidden Valley Road junction, for roughly 7,000 feet to saddle north of U.S. Geological Survey bench mark at 5,330 feet above sea level. Named for Racetrack Valley, the long depression draining southward to the Racetrack playa from a low divide between Tin Mountain and Dry Mountain.

**Racine Dolomite**[1]

Racine Dolomite (in Coe Group)

Silurian: Southeastern Wisconsin and northeastern Illinois.

Original reference: J. Hall, 1861, Wisconsin Geol. Survey Rept. 1860, p. 1–7.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows that Racine dolomite underlies Guelph dolomite and overlies Manistique dolomite in eastern Wisconsin. Underlies Guelph dolomite and overlies Bellwood dolomite (new) in northeastern Illinois.

H. B. Willman, 1943, Illinois Geol. Survey Rept. Inv. 90, p. 29–30. Formation in Chicago area has maximum thickness of 250 to 300 feet; thinner in western part of region. Racine strata contains many coral reefs which consist predominantly of high-purity dolomite. Overlies Waukesha dolomite. Locally in Chicago area, overlies Joliet formation. Term Bellwood as used in Silurian correlation chart (Swartz and others, 1942) includes strata herein considered Waukesha and Racine.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 18. Coe group (new) comprises Waukesha, Racine, and Port Bryon formations, as Savage (1926, Geol. Soc. America Bull., v. 37, no. 4, p. 513) differentiated them in northwestern Illinois.

Named for exposures at Racine, Racine County, Wis.

Radcliff Formation[1] (in Telescope Group)

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 311, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p. 355, 372, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible the correlation of formations defined by Murphy (1930, 1932 [1933]) in Telescope Peak quadrangle with formations now commonly used in Death Valley region. Murphy tentatively assigned all rocks above Panamint metamorphic complex to Lower Paleozoic. Sentinel dolomite, Radcliff formation, and Redlands dolomite limestone are correlated with Noonday dolomite here assigned to Precambrian as defined in this report.

Occurs in southern part of Panamint Range, Inyo County.

**Rader Limestone Member** (of Bell Canyon Formation)

Upper Permian (Guadalupe Series): Western Texas and southern New Mexico.

P. B. King *in* A. K. Miller and W. M. Furnish, 1940, Geol. Soc. America Spec. Paper 26, p. 9. Incidental mention.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 583, 585 (fig. 1), pl. 2. Consists of massive light-gray limestone, with a few layers of thinner darker limestone. At type locality and elsewhere along foot of Reef escarpment, about 100 feet thick, and lies 225 feet above base of formation. Eastward into Delaware Mountains, thins to about 15 feet, massive beds disappear, and thinner darker beds predominate. Separated from overlying Lamar member by several hundred feet of predominantly sandstone beds. Lies above Pinery limestone member.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 56–57, pl. 3 [1949]. Mapped in New Mexico.

N. D. Newell and others, 1953, The Permian reef complex of the Guadalupe Mountains region Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 15. Lies below the McCombs limestone member (new).

Named for Rader Ridge, which projects from foot of Reef escarpment near Hegler Ranch, Culberson County, Tex.

**Raft Formation**

Raft Lake Beds[1]

Pleistocene, middle or upper: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 31, 48–50, pl. 4. Thickness about 200 feet. Overlie Rockland Valley basalt and, locally, Massacre volcanics. Middle(?) Pliocene. Geographical extent indicated.

H. T. Stearns and Andrei Isotoff, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 27. In Eagle Rock area, Raft lake beds extend under most of older alluvium on west side of Snake River and probably also for some distance under Cedar basalt. Upper Pliocene(?).

U.S. Geological Survey has amended the name to Raft Formation and designates the age as middle or late Pleistocene on basis of a study now in progress.

Type section: Exposures along Raft River near mouth, Cassia County.

Raft River Formation[1]

Pliocene(?): Northwestern Washington.

Original reference: A. B. Reagan, 1909, Kansas Acad. Sci. Trans., v. 22, p. 202.

Crops out on north side of Raft River, Grays Harbor County.

Ragg quartzite

Precambrian (Keweenawic): Iowa.

Charles Keyes, 1941, Pan-Am. Geologist, v. 75, no. 2, p. 99 (chart), 107. Name applied to quartzites (sandstones) about 10 feet thick. On chart appears below Hull porphyry and above Splitrock slates.

Ragged Valley Formation

Ragged Valley Shale Member (of Arroyo Hondo Formation)

Ragged Valley Shale Member (of Moreno Grande Formation)

Upper Cretaceous: Central California.

H. E. Vokes, 1939, New York Acad. Sci. Annals, v. 38, p. 27–28. Name proposed for unit described as Clay Shale member of Martinez(?) by Anderson and Pack (1915, U.S. Geol. Survey Bull. 603). Underlies an unnamed white sandstone member. Cantua member of Arroyo Hondo lies entirely within Ragged Valley shale, and a basal part of the shale, approximately 100 feet thick, appears to underlie Cantua throughout; hence, Ragged Valley shale overlies Moreno formation.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2). Shown as a member (or formation) in Panoche formation (or group). Underlies Brown Mountain sandstone; overlies Joaquin Ridge sandstone.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 31. Ragged Valley shale (*Pachydiscus* silt) included as lower member of Moreno Grande formation (new). Underlies Brown Mountain sandstone member; overlies San Joaquin sandstone member of Panoche formation.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 31. Ragged Valley shale and Brown Mountain sandstone, poorly defined stratigraphic units of late Upper Cretaceous, are included in uppermost part of Panoche formation of this report [Ortigalita Peak quadrangle].

Type locality: On Domengine Creek in Ragged Valley, north of Coalinga, Fresno County.

Raggedy Mountain Gabbro[1]

Raggedy Mountain Group

Precambrian: Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135, 136.

G. W. Chase, 1952, Oklahoma Geol. Survey Circ. 30, p. 11. Raggedy Mountain group is composed of anorthosite that grades downward into augite gabbro. Meers quartzite [oldest rock in region] and Raggedy Mountain group are cut by intrusions of olivine gabbro.

Named for Raggedy Mountains, Kiowa County.

**Ragland Sandstone**[1]

Middle Devonian: Eastern Alabama.

Original references: Charles Butts, 1927, Washington Acad. Sci. Jour., v. 17, p. 128–129; 1927, Am. Jour. Sci., 5th, v. 14, p. 365–380; 1927, U.S. Geol. Survey Geol. Atlas, Folio 221, p. 9, footnote.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1777, chart 4. Tentatively correlated with *Meristella*-Coral zone of Schoharie Valley sequence occurring about 250 feet above Onondaga limestone and containing "*Spirifer*" *venustus*. Shown on chart as younger than Frog Mountain sandstone.

Named for exposures in abandoned quarry 1½ miles south-southwest of Ragland, St. Clair County.

Raiff Limestone

Cambrian: Eastern Nevada.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 159–160. At type section, consists of 2,789 feet of limestones; lower A member, 1,456 feet thick, consists of medium-dark- to medium-light-gray aphanitic dolomite about 200 feet from light-gray aphanitic dolomite about 200 feet from top; B member, about 269 feet, composed of thin-bedded limestone and subordinate olive-drab shale; C member, 1,064 feet, characterized by two cliff-forming units. Overlies Monte Neva formation (new); underlies Dunderberg formation.

Type section: Northern Egan Range in NW¼ sec. 33, T. 22 N., R. 63 E. on divide north of Monte Neva Hot Springs. Name derived from Raiff siding on Nevada Northern Railroad, 3 miles east-northeast of type section.

Rail Cabin Formation

Upper Triassic: Northeastern Oregon.

W. R. Dickinson, 1960, Dissert. Abs., v. 20, no. 11, p. 4367. Upper Triassic sequence includes Begg, Brisbois, and Rail Cabin formations. Thickness of sequence, which is overlain by Lower Jurassic Graylock formation (new), is nearly 15,000 feet.

Type locality and derivation of name not stated. Report discusses Izee area, Grant County.

**Rail Canyon Sandstone Member** (of Vermejo Formation)[1]

Upper Cretaceous: Northeastern New Mexico.

Original reference: W. T. Lee, 1924, U.S. Geol. Survey Bull. 752.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10–b (column 21). Shown on correlation chart as occurring about middle of formation.

Named because of economic importance in making roof in Dawson mines, in Rail Canyon, Raton coal field.

Railroad Bridge Basalt[1]

Pliocene: Northwestern Nevada.

Original reference: R. E. Fuller, 1931, Washington Univ. Pub. Geology, v. 3, no. 1, p. 14.

Occurs in Thousand Creek Basin, south of Pueblo Mountain.

774–954—vol. 3—66——20

†Rainbow Beds[1]

Miocene or Pliocene: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 174–185.

Fresno and King Counties.

Rainbow Series[1]

Post-Franciscan: Northern California.

Original reference: W. Stalder, 1915, California State Mining Bur. Bull. 69, p. 447–449.

Humboldt County.

Rainbow Flat Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 294–295, geol. map. Metasedimentary rocks and migmatites north of El Dorado Ridge quartz diorite (new) are included in Rainbow Flat group; they are folded into approximately east trending anticlines and synclines and have been intruded by Stoddard Canyon quartz monzonite (new) to north of area studied. Relation to [Aurela Ridge] granulite (new) not ascertained.

Area studied is Cucamonga Canyon-San Antonio Canyon, Cucamonga quadrangle, San Bernardino and Los Angeles Counties.

Raine Ranch Formation

Miocene, upper: Northeastern Nevada.

Jerome Regnier, 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1191, 1195–1198, pl. 1. Consists of 2,000 feet of pumice lapilli tuff, volcanic breccia, lava flows, conglomerates, rhyolitic tuff, diatomite, shale, and limestone. Vertebrate fossils. In Pine Valley, rests unconformably and older Tertiary formations; normal fault separates formation from Paleozoic rocks of Pinon Range; in Susie Creek Valley rests in sedimentary contact on Paleozoic rocks. Underlies Palisade Canyon rhyolite (new); also underlies Carlin formation (new).

Named for Raine Ranch, sec. 6, T. 31 N., R. 52 E. Crops out in northern part of Pine Valley and valley of Susie Creek, vicinity of Carlin.

Raines Corner Limestone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 404.

Type locality: In bed of Indian Creek one-half mile northwest of Raines Corner, Monroe County, W. Va.

Raines Corner Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 409.

Type locality: On west side of Indian Creek along the State road, about 1½ miles northeast of Raines Corner, Monroe County, W. Va.

Rainer Lavas or Volcanics

*See* Mount Rainier Lavas.

**Rainvalley Formation** (in Naco Group)

Rainvalley Formation (in Snyder Hill Group)

Permian: Southern Arizona.

D. L. Bryant, 1955, Dissert. Abs., v. 15, no. 7, p. 1224. Uppermost formation of Snyder Hill group. Overlies Concha limestone (expanded).

W. D. Pye, 1959, Arizona Geol. Soc. Guidebook 2, p. 277. Thickness 400 feet. Gray-brown, red, and black limestone and dolomite with sandstone. Type area stated.

U.S. Geological Survey currently classifies the Rainvalley as a formation in the Naco Group on the basis of a study now in progress.

Type area: Mustang Mountains.

**Rainy Limestone Member** (of Arroyo Formation)

Rainy Limestone Member (of Clear Fork Formation)[1]

Permian (Leonard Series): North-central Texas.

Original reference: M. G. Cheney, 1929, Texas Univ. Bull. 2913, p. 27, pl. 1.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on chart as basal member of Arroyo formation. Older than Lytle limestone; younger than Lake Kemp formation.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Shown on correlation chart at base of Arroyo formation. Underlies Standpipe limestone member.

Type locality: Along Rainy [also spelled Rainey] Creek, 6 miles east of Abilene, Taylor County.

Rainy Mountain Limestone[1]

Lower Ordovician: Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135, 138–140.

Charles Schuchert, 1943, Stratigraphy of the eastern and central United States: New York, John Wiley & Sons, Inc., p. 871. Abandoned.

Named for Rainy Mountain, Kiowa County.

**Raisin River Dolomite Member** (of Bass Islands Dolomite)[1]

Raisin River Formation (in Bass Islands Group)

Upper Silurian: Southeastern Michigan and northern Ohio, and Ontario, Canada.

Original reference: W. H. Sherzer and A. W. Grabau, 1909, Geol. Soc. America Bull., v. 19, p. 546.

Wilber Stout, 1941, Ohio Geol. Survey, 4th ser., Bull. 42, p. 38 40, chart facing p. 46. Uppermost formation in Bass Island[s] group in Ohio. Overlies Put-in-Bay formation; unconformably underlies Oriskany formation. Consists of fairly pure dolomite, regularly bedded, layers commonly 2 to 6 inches thick, locally more massive; color bluish gray to brownish gray. Thickness about 50 feet. Limited to small areas west of Toledo.

J. E. Carman, 1960, Fieldiana: Geology, v. 14, no. 1, p. 1–5. In Lucas County, Ohio, fossiliferous Holland Quarry shale (new) occupies depression in Raisin River dolomite.

Named for exposures on Raisin River, Monroe County, Mich.

Raker Peak Pyroxene Andesites,[1] Dacite

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 287, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 682. Cenozoic.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, p. 77 (table 2), 79, 80 (table 4 and text), 81, 82. Listed on tables and mentioned in text in report on uranium geochemistry of Lassen volcanic rocks.

Raker Peak is in Lassen Volcanic National Park.

Rakes Creek Shale Member (of Tecumseh Shale)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska and southwestern Iowa.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, 2d ser., p. 47, 53.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 23. Top member of formation; overlies Ost limestone member. Thickness 6 to 10 feet in Nebraska and northern Kansas. In southern Kansas, lower boundary is not distinct. [Not treated as a subdivision of the Tecumseh by Kansas Geological Survey.]

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 19, fig. 5. Identified in quarry in sec. 15, T. 71 N., R. 43 W., Mills County where it consists of greenish-gray sandy shale with thin stringer near base. Thickness about 7 feet. Uppermost member of formation; overlies Ost limestone member.

Type locality: On Rakes Creek in NW¼ sec. 5, T. 10 N., R. 14 E., Cass County, Nebr.

Raleigh Graphite

Precambrian: Central North Carolina.

J. W. Harrington, 1947, Jour. Geology, v. 55, no. 6, p. 516–521. Name applied to several parallel tilted beds of earthy schistose graphite enclosed in the Precambrian schists and gneisses of Wake County.

All exposures mapped lie in belt 10 miles long and 2 miles wide; northern end is at town of Six Forks, 10 miles north of Raleigh; southern end may be 18 miles southwest of Raleigh.

**Raleigh Sandstone Member** (of New River Formation)

Raleigh Sandstone (in New River Group)

Raleigh Sandstone (in Pottsville Group)[1]

Lower Pennsylvanian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487, 493.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 234–236. Raleigh sandstone includes the Upper Raleigh and Lower Raleigh of White (1908, West Virginia Geol. Survey, v. 2a). The Upper Raleigh, 50 to 75 feet thick, underlies thin shale below Welch coal and overlies and is separated from Lower Raleigh sandstone by an interval containing shale and coal interval that includes Raleigh coals; locally coalesces with overlying Welch sandstone, cutting out Welch coal. Lower Raleigh sandstone, 50 to 100 feet thick, overlies Beckley coals above the Quinnimont sandstone. Both Lower and Upper Raleigh are included in New River group, Pottsville series.

U.S. Geological Survey currently classifies the Raleigh Sandstone as a member of the New River Formation on the basis of a study now in progress.

Named for exposures on road from Prince to Raleigh, Raleigh County, W. Va.

Ralston Formation[1]

Precambrian: Central northern Colorado.

Original reference: M. F. Boos and C. M. Boos, 1934, Geol. Soc. America Bull., v. 45, no. 2, p. 306.

In Boulder region.

Ralston Formation

Upper Jurassic: North-central Colorado.

W. A. Waldschmidt and L. W. LeRoy, 1944, Geol. Soc. America Bull., v. 55, no. 10, p. 1098. Underlies Morrison formation. Name credited to LeRoy (1944, unpub. thesis).

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 46–55. Represented by two lateral lithic variations: a shale-marlstone facies and a gypsiferous facies. Former facies essentially gray to maroon shales. Thin dense gray impure lithographic to sandy marlstones, and fine- to medium-grained yellow to buff calcareous sandstones and silts commonly present as minor components. Marlstones best developed near Mount Vernon Canyon where they are conspicuously laminated and arenaceous. Bedding moderately uniform. Thickness at type section 83 feet. Gypsiferous facies essentially of thin beds of white massive to fibrous gypsum and numerous thin layers of gypsiferous silt. Several conspicuous beds of hard massive yellow calcareous medium-grained sandstone and minor amounts of thin-bedded maroon shale in upper part of facies. Thickness at type section 67½ feet. Formation disconformably underlies basal sandstone of Morrison; overlies Lykins formation.

E. A. Frederickson, J. M. DeLay, and W. W. Saylor, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2120–2147. Four sedimentary facies recognized in Canon City embayment: conglomerate facies, sandstone facies, gypsum-shale facies and sand-shale facies. These are intergradational from west to east. Shale-marlstone and gypsum facies of Golden-Morrison area (of LeRoy) considered equivalent respectively to sand-shale and gypsum-shale facies of this paper. Thickness in embayment from fraction of a foot to as much as 180 feet.

Richard Van Horn, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 4, p. 755–756. Proposed that rocks that LeRoy (1946) described as Ralston formation be renamed Ralston Creek formation because the former name had been applied to two other units at the time LeRoy published his paper—one of which had its type locality only a few miles from LeRoy's type section. Late Jurassic.

Type section of shale-marlstone facies: Along irrigation ditch and water level on west side of Ralston Reservoir, Ralston Creek, 5 miles north of

Golden, sec. 5, T. 3 S., R. 70 W., Blackhawk quadrangle, Jefferson County. Facies prevalent between Bear Creek and Ralston Creek.

Type section of gypsiferous facies: On east side of Glennon Canyon, 1½ miles southeast of Morrison, NW¼ sec. 12, T. 5 S., R. 70 W., Morrison quadrangle, Jefferson County. Facies well exposed along west slope of Dakota hogback between Bear Creek and Turkey Creek.

†Ralston Formation[1]

Eocene, lower: Northern Wyoming.

Original reference: W. J. Sinclair and W. Granger, 1912, Am. Mus. Nat. History Bull., v. 31, p. 60–62.

Occurs on north side of Shoshone River in bluff opposite Ralston Station Bighorn Basin region.

Ralston Group[1]

Pennsylvanian and Permian: Central northern Oklahoma.

Original reference: C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910, Oklahoma State Univ. Research Bull. 3, p. 7, 13.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey. If validated, the name preoccupies name Ralston formation, Eocene, of Wyoming.

Named for Ralston, Pawnee County.

**Ralston Creek Formation**

Upper Jurassic: North-central Colorado.

Richard Van Horn, 1957. Am. Assoc. Petroleum Geologists Bull., v. 41, no. 4, p. 755–756. Name Ralston Creek formation used in place of name Ralston formation as described by LeRoy (1946). Change in name desirable to avoid confusion because Ralston formation has been used previously for several different formations. Encompasses same rocks that were described by LeRoy (1946) as Ralston formation. Consists of varicolored claystone, siltstone, and limestone and contains thin beds and disseminated nodules of moderate-red to dark-gray chalcedony. Underlies Morrison formation; overlies Lykins formation.

Richard Van Horn, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–103. Shale-marlstone about 110 feet thick in Golden quadrangle. At base of formation, a 5-foot-thick bed of grayish-red to light-gray fine- to medium-grained calcareous sandstone is exposed below highwater mark of Ralston Reservoir. This bed not indicated in sections measured by LeRoy (1946; p. 41, 51) of the Ralston and Lykins formations in Ralston Creek, and here tentatively assigned to Ralston Creek formation.

Type section: At the locality described by LeRoy (1946, p. 51), on south side of Ralston Creek in NW¼SW¼ sec. 5, T. 3 S., R. 70 W., Ralston Buttes quadrangle. [LeRoy, 1946, p. 51 gives type section of shale-marlstone facies of Ralston formation as sec. 5, T. 3 S., R. 70 W., Blackhawk quadrangle.]

†Ramona Formation[1]

Pennsylvanian: Northeastern Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 36.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey.

Named for Ramona, Washington County.

**Rampart Group**[1]

Mississippian (probably lower) : East-central Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 155–169.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000) : U.S. Geol. Survey. Name appears on map legend under Mississippian volcanic rocks.

Named for exposures in Lower Ramparts of the Yukon. Yukon-Tanana region.

Rampart Cave Member (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 19, 84–87. Consists almost entirely of gray or dark-gray aphanitic limestone with small amount of light-brown or tan silty mottling. Mostly thick bedded and massive, although thin beds found at top and bottom in many sections. In vicinity of Grand Wash Cliffs, maximum thickness about 160 feet. Thins to the east. Basal subdivision of Muav formation; overlies Flour Sack member (new) of Bright Angel shale.

Named from a cavern near base of member, a few miles east of Grand Wash Cliffs on south side of Lake Mead. In western half of Grand Canyon.

Ramp Creek Member (of Harrodsburg Limestone)[1]

Ramp Creek Member (of Warsaw Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1929, Indiana Acad. Sci. Proc., v. 38, p. 233–242.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 805. Reallocated to member status in Warsaw formation. Lowest member of formation; underlies Leesville member (reallocated).

Exposed in ravine tributary to Ramp Creek, southeastern part of Monroe County.

**Ramshorn Slate**[1]

Lower Ordovician: Southern central Idaho.

Original references: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth; 1934, Geol. Soc. America Bull., v. 45, p. 945.

C. P. Ross, 1937, U.S. Geol. Survey Bull. 877, p. 11, 14–17, pl. 1. In Bayhorse region, overlies Bayhorse dolomite and underlies Kinnikinic quartzite. Thickness 2,000 feet. Lower Ordovician.

Named for mine near head of Bayhorse Creek, Custer County.

†Ramshorn Volcanic Series[1]

Eocene, post-middle: Central Wyoming.

Original reference: D. Love, 1934, Wyoming Geol. Survey Bull. 24, pt. 4, p. 21–22.

J. D. Love, 1939, Geol Soc. America Spec. Paper 20, p. 79. Name preoccupied. Replaced by Wiggins formation.

Named for The Ramshorn, a mountainous ridge about 12 miles west of area studied (Owl Creek Mountains).

Rancheria Formation

Mississippian (Meramec): Western Texas. and central southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 9, 11, 17–19, 22, 34, 38. Sequence of cherty black bituminous argillaceous limestone beds that unconformably overlies Las Cruces formation (new) and unconformably underlies Helms formation (restricted) in Franklin Mountains of New Mexico. At type locality, section comprises (ascending) few inches of black, detrital, sandy shale; black, detrital quartz sandstone containing numerous plant fossils and considerable carbonaceous material; 8 feet of soft yellow to brown sandy siltstone; massive black bituminous detrital limestone made up largely of minute fragments of crinoidal material; and the remaining 235 feet of typical medium-bedded dense black silty limestone beds that weather brown and contain large amounts of brown-weathering porous chert. Thickness approximately 255 feet in type area; 215 feet at Rancheria Peak; thins by progressive overlap from south toward north in Sacramento Mountains and missing in northern part of range. Of Meramec age.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 19. Moorefield faunule present mostly in lower part, which was Laudon and Bowsher's evidence of Meramec age, but which would place it in upper Osage also, if section in Llano region were used for comparison. Probably upper part of Rancheria in Hueco and Franklin Mountains is of Meramec age.

Type locality: On southwest side of small south fork of shallow canyon that leaves west slope of Franklin Mountains, almost directly east of Vinton, Tex. (SW¼ sec. 67, S. Blk. 82, El Paso County, Tex.). Named for Rancheria Peak in Hueco Mountains where it is well exposed. Also present in parts of San Andres Mountains, New Mex.

Rancholabrean Age

Pleistocene, late: North America.

D. E. Savage, 1951, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 28, no. 10, p. 289. Provincial time term typified by Rancho La Brea (vertebrate) fauna. The Rancholabrean is post-Irvingtonian.

**Rancocas Formation[1] or Group[1]**

Paleocene and Eocene: New Jersey and Delaware.

Original references: W. B. Clark, 1894, New Jersey Geol. Survey Ann. Rept. 1893, p. 337–338; 1894, Jour. Geology, v. 2, p. 161–177.

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184. Group comprises (ascending) Hornerstown sand, Vincentown formation, and Manasquan formation.

Rancocas Creek, Burlington County, N.J., cuts through the formation, exposing its full sequence.

Rand Schist[1]

Precambrian (?): Southern California.

Original reference: C. D. Hulin, 1925, California State Min. Bur. Bull. 95, p. 23–29, map.

T. W. Dibblee, Jr., 1952, California Div. Mines Bull. 160, p. 12 (fig. 1), 13–14, pls. 1–3. Partial section of Rand schist, totaling about 2,000 feet, is exposed on north slope of Rand Mountains in Saltdale quadrangle. Schist is compressed into several folds, and uppermost layers are in contact with intrusive quartz monzonite; greenish-gray actinolite facies, which is abundant in Randsburg quadrangle, is not common in Saltdale quadrangle. Columnar section shows Rand schist older than newly defined Mesquite schist. Precambrian(?).

First described in Kern County where it composes bulk of Rand Mountains.

Randels Island Gneiss[1]

Age(?) : New York.

Original reference: R. P. Stevens, 1867, New York Lyceum Nat. History Annals, v. 8, p. 116–120.

Along southern shore of Spuyten-Duyvel Creek and Harlem River, Manhattan Island.

Randle Laharic Breccia-Conglomerate or deposit

Eocene-Oligocene : Northwestern Washington.

R. V. Fisher, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 127–132. Consists of three well-exposed massive volcanic breccia-conglomerate beds. Beds are poorly sorted and show no marked vertical or horizontal grading of fragment sizes, no preferred orientation of fragments, and no internal laminae. These characterictics indicate deposition by either lahars or pyroclastic flows but preclude deposition from air.

Occurs 1 mile west of Randle, eastern Lewis County.

Randlett horizon (in Duchesne River Formation)[1]

Eocene (Duchesnean) : Eastern Utah.

Original reference: J. L. Kay, 1934, Carnegie Mus. Annals, v. 23, p. 357–359.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 29, pl. 1. Underlies Halfway horizon; overlies Uinta formation. Eocene (Duchesnean).

Type locality : North and east of town of Randlett, Uintah County.

Randolph Granite[1]

Devonian : Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Quarried at Randolph, Randolph Township, Orange County.

Randolph Granite[1]

Upper Devonian or Upper Carboniferous : Northern New Hampshire.

Original reference: M. Billings, 1928, Am. Acad. Arts and Sci. Proc., v. 63, p. 82, map.

Type locality: In Ravine of the Castles, which lies south of Randolph Range and Randolph Township, 1 mile northwest of Mount Jefferson, in Mount Washington quadrangle.

Randolph Limestone[1]

Lower Cretaceous(?) : Southeastern Arizona.

Original reference: W. P. Blake, 1902, Tombstone and its mines.

Tombstone district.

Randolph Phyllite[1]

Middle Ordovician: Northeastern and southeastern Vermont.

Original reference: C. H. Richardson, 1924, Vermont State Geologist 14th Rept., p. 90.

Extends in north-south direction, entirely across Randolph Township, Orange County.

Rand Ranch Formation

Oligocene(?): Northeastern Nevada.

Jerome Regnier, 1960, Geol. Soc. America Bull., v. 60, no. 8, p. 1191, 1193, pl. 1. Consists of 1,700 feet of sandstones and conglomerates; basal 450 feet is gray volcanic-pebble conglomerate and gray and yellow volcanic sandstones; upper 1,250 feet is interbedded white, yellow, and red sandstones and Paleozoic-pebble conglomerates. Conformably overlies volcanic rocks of Cortex Mountains. Believed to be older than Safford Canyon formation (new) which unconformably overlies the volcanic rocks of Cortex Mountains. Nonfossiliferous; tentatively referred to Oligocene.

Named for Rand Ranch, SW¼ T. 30 N., R. 52 E., near Carlin.

**Randville Dolomite**[1] (in Chocolay Group)

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 9–16.

J. E. Gair and K. L. Wier, 1956, U.S. Geol. Survey Bull. 1044, p. 14 (table 2), 28–34, pl. 1, Exposed in south-central part of Kiernan quadrangle, near south shore of Michigamme Reservoir, and on east flank of Amasa oval (uplift). Has maximum thickness of about 1,800 feet on flanks of oval and consists largely of almost pure dolomite; locally contains phases of quartz-sericite slate, sericite and chlorite schist, feldspathic quartzite, and arkose. Unconformably overlies Margeson Creek gneiss (new); unconformably underlies Goodrich quartzite; in Dickinson County, Sturgeon quartzite commonly lies between the Randville and older granitic rocks; in Kiernan area, there is no equivalent quartzite in the section.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Uppermost formation in newly defined Chocolay group; in parts of Iron and Dickinson Counties is only representative of group.

Named for exposures near Randville, west-central Dickinson County.

Rangeley Conglomerate[1]

Devonian(?): West-central Maine.

Original reference: E. S. C. Smith, 1923, Am. Jour. Sci., 5th ser., v. 5, p. 147–154.

E. S. Pratt and H. W. Allen, 1949, Maine State Geologist Rept. 1947–1948, p. 23. Oldest rock in region [Franklin County]. Overlain by staurolite schist of varying composition.

Named for development near Rangeley and at southeast end of Rangeley Lake, Franklin County.

Rangely Tongue (of Mancos Shale)

Upper Cretaceous: Northwestern Colorado and northeastern Utah.

L. A. Hale, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 92, 93 (fig. 3). Equivalent to Black Butte tongue (new) of Rock Springs formation (or Mancos shale).

Rangely, Colo., to Vernal, Utah.

†Ranger Formation (in Canyon Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxvii.

Named for exposures in vicinity of Ranger, Eastland County.

**Ranger Limestone Member** (of Brad Formation)[1]

Ranger Limestone (in Brad Group)

Upper Pennsylvanian: Central and central northern Texas.

Original references: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133, 145; F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology 3801, p. 111–115. Upper member of Brad formation (redefined). Overlies an unnamed shale member which represents upper part of Placid shale member of Plummer and Moore, the lower part of which is here included in Winchell member of Graford. Ranger appears to be equivalent of Drake's (1893) Home Creek limestone at the type locality. As exposed on Home Creek, about 35 feet thick. It is massive bluish-gray noncherty limestone; upper part broken by bedding planes. At section measured on river bluff half a mile west of mouth of Home Creek, the Ranger is 70 feet thick. Because the limestone section of the Ranger passes into overlying Home Creek of northern Brown County by a series of relatively thin limestone beds interstratified with shale, it is difficult to place top of member and top of Brad formation. Along Colorado River, shale partings are so thin that it seems reasonable to place top of Ranger at top of unbroken limestone and to consider first thick shale as first bed of Caddo Creek formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Brad group. Underlies Hog Creek shale; overlies Placid shale.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 20. Underlies Colony Creek shale (new) which replaces name Hog Creek shale.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, April 17–19, p. 51. In Brown and Coleman Counties, member consists of limestone, pale yellowish brown to light gray, generally slabby, cherty; contains "seaweed" structures; locally abundant fusulinids and other foraminifers, brachiopods, and crinoid columnals. Reeflike in vicinity of Colorado River. Thickness about 20 feet. Overlies Placid shale member; underlies Colony Creek shale member of Caddo Creek formation.

Named for exposures west of Ranger, Eastland County.

Ranger Marble[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 622, 642.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included in Snowy Range series (new)

Exposed at various points northeastward to Brooklyn ranger station, Medicine Bow Mountains.

†Ranger Series[1]

Pennsylvanian: Central Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxvii, pl. 3.

Rapid Limestone[1]

Rapid Limestone Member (of Cedar Valley Formation)

Upper Devonian: Central eastern Iowa

Original references: C. [R.] Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 149; 1913, Iowa Acad. Sci. Proc., v. 20, p. 205, 206.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1751. Shown on correlation chart as middle member of Cedar Valley formation. Underlies Coralville limestone member; overlies Solon limestone member. Middle Devonian. Age of entire Cedar Valley is difficult to establish, and dating of some of its parts presents problems. Upper zone of the Rapid formation (*Atrypa waterlooensis*) probably should be correlated with part of the Callaway of Missouri.

W. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 157. Independence shale is stratigraphically below the Cedar Valley and above the Wapsipinicon. The Independence, by its fossils, is lower Upper Devonian; hence, Cedar Valley limestone is Upper Devonian in age and post-Independence.

Named for locality in Johnson County.

Rapid City Lens (in Newcastle Formation)

Upper Cretaceous: Western South Dakota.

R. M. Grace, 1952, Wyoming Geol. Survey Bull. 44, p. 14, 17. Primarily shale but containing 3 feet of sandstone. Maximum thickness about 27 feet. In this report, seven lenses are named in the Newcastle.

Named for exposure near Rapid City, Pennington County.

Rapides Shale or Formation (in Austin Group)

Cretaceous (Gulfian): Central Louisiana (subsurface).

J. M. Forgotson, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 117, 124. Proposed for sediments lying immediately below the base of either the Ector chalk or the Ector format and concordant with the sedimentary sequence making up the Austin group. Consists of dark gray shale, dark chalky shale, thin beds of chalk, shaly chalk, and thin limestones. In type well, occurs between electrical log depths of 9,055 and 9,245 feet. Formation has unconformity for basal boundary, therefore, concordant beds added below those encountered in type well are included in this definition.

Type well: Union Producing Company No. 1 Belgard, sec. 14, T. 4 N., R. 3 E., Rapides Parish.

†Rapids Schist[1]

Lower Paleozoic or older: Northern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 473.

Traversed by Chandler River in region of the rapids. Extends for several miles downstream nearly to West Fork in Chandler region.

†Rappahannock Series[1]

Lower Cretaceous: Eastern Virginia.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 321.

Rarden Shale Member[1] (of Cuyahoga Formation)

Rarden Shale Member (of Logan Formation)

Rarden Shale Member (of New Providence Formation)

Lower Mississippian: Southern Ohio and northeastern Kentucky.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 762.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 133. Rarden shale member of New Providence formation in Kentucky; included in Vanceburg facies of formation.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1950, Jour. Geology, v. 50, no. 1, p. 62–63. In Ohio considered a member of Logan formation; included in Vanceburg siltstone facies of formation.

Named for Rarden, Scioto County, Ohio.

†Raritan Clay[1]

Upper Cretaceous: New Jersey and eastern Maryland.

Original reference: T. A. Conrad, 1869, Am. Jour. Sci., 2d v. 47, p. 360–363.

Occurs along Raritan River, N.J.

Raritan fire clay[1] (in Raritan Formation)

Cretaceous: New Jersey.

Original references: G. H. Cook and J. C. Smock, 1877, New Jersey Geol. Survey may of district of Middlesex County; G. H. Cook, 1878, New Jersey Geol. Survey Rept. on clays, p. 34.

H. C. Barksdale and others, 1943, New Jersey State Water Policy Comm. [Spec. Rept. 8], p. 66, 140. Basal member of Raritan. Includes "Raritan potters clay" of earlier reports. Thickness 0 to 35 feet. Underlies Farrington sand member (new).

Crops out near Nixon, Bonhampton, Fords, Keasbey, and Milltown, Middlesex County.

**Raritan Formation**[1]

Upper Cretaceous: Eastern New Jersey, Delaware, and Maryland.

Original reference: G. H. Cook, 1888, Am. Geologist, v. 2, p. 260.

H. C. Barksdale and others, 1943, New Jersey State Water Policy Comm. [Spec. Rept. 8], p. 66–140. Formation, in Middlesex County, divided into several distinct mappable units. Clays of Raritan have been extensively used in ceramic industry and received informal names. The other members, composed dominantly of sands were not named but given numbers. In this report these are given member names. Thus, Raritan comprises from top to bottom Amboy stoneware clay, Old Bridge sand member (No. 3 sand of previous reports); South Amboy fire clay. Sayreville sand member (No. 2 sand of previous reports), Woodbridge clay, Farrington sand member (No. 1 sand of previous reports), and Raritan fire clay. Underlies Magothy formation. Upper Cretaceous.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 15–21. Evidence cited to substantiate Lower and

Upper Cretaceous age. Writers believe that the nonmarine beds lying below the Magothy in New Jersey and called Raritan are equivalent to nonmarine sediments in Delaware-Maryland-Virginia lying below the Magothy and referred to the "Raritan," Patapsco, Arundel, and Patuxent, and that the entire series should be considered as single unit.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2161–2184. Presentation of paleobotanical analyses and discussion bearing on age, correlation, and stratigraphic relationships of Cretaceous plant-bearing beds of Coastal Plain from New Jersey to South Carolina. In New Jersey, evidence is presented which challenges recent correlation by Spangler and Peterson, of greater part of plant-bearing Raritan formation with Potomac group of Maryland-Delaware, and assignment, by same authors, of major part of Raritan formation to Early Cretaceous. It is shown that both floral and faunal evidence indicates that none of the Potomac group can be correlated with any part of the Raritan formation of New Jersey. In Delaware-Maryland-Virginia area, assignment of Arundel and Patapsco formations of Potomac group to Late Cretaceous, as is done in two recent reports, is shown to be based on doubtful evidence. These formations are regarded as more reasonably assigned to Early Cretaceous, on evidence of both plants and vertebrates. The beds overlying the Potomac group in Maryland and Delaware are here considered correctly assigned to Raritan formation.

Well exposed in vicinity of Raritan River and Raritan Bay, N.J.

Raso Limestone[1]

*See* Lasso Limestone.

**Raspberry Formation**

Upper Triassic: North-central Nevada.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Gray, black, buff, or green slate, locally phyllitic; limestone lenses and limestone conglomerate, especially in lower part; quartzite lenses a few inches to 100 feet in thickness form about 5 percent of unit. Thickness in East Range approximately 3,000 feet; top and base not visible. In fault contact with older formations.

Type locality: Raspberry Creek, northwestern part of East Range.

Raspberry Mountain Granite[1]

Precambrian: Eastern Colorado.

Original reference: E. B. Mathews, 1900, Jour. Geology, v. 8, p. 214–240.

Named from its conspicuous development on Raspberry Mountain, Pikes Peak region.

**Rat Formation**

Tertiary or older: Alaska.

R. Q. Lewis, W. H. Nelson, and H. A. Powers, 1960, U.S. Geol. Survey Bull. 1028–Q, p. 558–560, pl 70. Porphyritic hornblende andesite lava flows and breccias, and conglomerates derived from them. No fossils found, and contact with Gunners Cove formation (new) not exposed; trace of contact trends north-south across high crest of island and is probably high-angle normal fault. Inferred to be older than Gunners Cove.

Limited to southeastern part of Rat Island which is on midpart of segment of Aleutian Ridge that includes Amchitka and southern Kiska Islands.

**Rat Creek Quartz Latite**

Rat Creek Quartz Latite (in Potosi Volcanic Series)[1]

Middle or late Tertiary: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull. 718.

Named for development on Rat Creek, Creede district.

Rathbun Limestone Member (of Denmark Formation)

Rathbun Member (of Shoreham Formation)

Middle Ordovician (Mohawkian): East-central New York.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 599–600. Name proposed for basal member of Denmark formation. Described at type section as brachiopod coquina, calcilutite, and calcareous shale. Contrasts with underlying Shoreham limestone by abundance of calcilutite; contrasts sharply with overlying Poland limestone member (newly defined) by presence of coquinal beds. Lithologically more similar to Shoreham than to Poland, but arbitrarily placed in Denmark formation because persistent basal calcarenite suggests subjacent disconformity. Maximum thickness 10 feet; 6 feet in type section. Persists along West Canada Creek but thins southeastward and is absent to the east at Little Falls.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p. 525–526. Reallocated to Shoreham formation because beds in West Canada Creek valley are faunal and lithologic equivalents of top Shoreham beds of Black River valley. Shales generally thicker and more calcareous than those in underlying part of Shoreham. Coquinal beds increase in number toward top. Thickness at type section about 9 feet.

Type section: On Rathbun Brook, a tributary of West Canada Creek, 1½ miles northwest of Newport, Herkimer County.

Raton Basalts

Quaternary: Northeastern New Mexico.

Helen Stobbe, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1354. Incidental mention only.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1022, 1027–1028, pl. 1; H. R. Stobbe, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1049, 1050. Medium- to dark-gray predominantly fine-grained vesicular olivine basalts. Some iddingsite. Rarely diabasic. Quaternary. Derivation of name and geographic distribution given.

G. H. Wood, Jr., S. A. Northrop, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–141 (sheet 2). Consists of two series of flows. Cumulative local thickness ranges from 100 to 500 feet.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 114–115. In Des Moines quadrangle, Raton basalts lie with apparent conformity on Ogallala formation. Topographically continuous with older Raton basalts mapped by Wood and others (1953) in Colfax quadrangle.

Named after Raton Mesa. Occurs in Colfax and Union Counties in Johnson Mesa, gap between Hunter and Johnson Mesas, Mesa Llargo, Hereford Park, Oak Canyon, Devoy Peak, mesa north of Valley post office, and Black Mesa.

**Raton Formation**[1]

Upper Cretaceous and Paleocene: Northeastern New Mexico and southeastern Colorado.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Colorado and New Mexico 3d Ann. Rept., p. 89–91.

G. H. Wood, Jr., S. A. Northrop, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–141. In Colfax County, N. Mex., formation is about 1,110 feet thick and consists of interbedded shale, siltstone, graywacke, arkosic or feldspathic sandstone, quartzose sandstone, conglomerate, and coal. Unconformably overlies Vermejo; in some areas overlies Trinidad sandstone. Upper Cretaceous and Paleocene.

R. B. Johnson and G. H. Wood, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 709 (fig. 2), 714–716. Crops out over most of Raton Mesa region; as much as 1,700 feet thick southeast of Spanish Peaks. Consists of thin basal sequence of gray to dark-purple-gray siliceous granule to pebble conglomerate or gray siliceous conglomeratic sandstone beds. Above basal sequence, formation is buff, gray, and olive-gray very fine- to coarse-grained arkose, graywacke, and quartzose sandstone beds; gray to dark-gray siltstone and silty shale beds; numerous coal beds. Intertongues and grades into Poison Canyon formation. Overlies Vermejo formation. Cretaceous and Tertiary.

Type area: In high mesa region between Trinidad, Colo., and Raton, N. Mex.

Ratonan series[1]

Eocene: New Mexico.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259.

†Raton Hills Group[1]

Upper Cretaceous and Eocene: Southeastern Colorado.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Colorado and New Mexico 3d Ann. Rept., p. 89–91.

Occurs in Raton Hills, Raton Mesa region.

Raton Pass coal group (in Raton Formation)[1]

Eocene: Eastern Colorado.

Original reference: R. C. Hills, 1899, U.S. Geol. Survey Geol. Atlas, Folio 58.

Elmoro region.

†Rattlesnake Beds[1] or Formation[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 41–54.

Named for Rattlesnake Mountain, Brewster County.

**Rattlesnake Formation**[1]

Pliocene and Pleistocene: Central northern Oregon.

Original reference: J. C. Merriam, 1901, California Univ. Pub. Bull. Dept. Geology, v. 2, no. 9, p. 310.

W. D. Wilkinson, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1534. Contains layer of welded tuff that stands in cliffs 50 to 75 feet high and extends from type locality near Picture Gorge eastward along both sides of John Day Valley to vicinity of town of John Day.

T. P. Thayer, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Maps MF–49, MF–50, and MF–51. In Aldrich Mountain quadrangle and Mount Vernon quadrangle, overlies Mascall formation with angular unconformity. In John Day quadrangle overlies Columbia River basalt with angular unconformity. Pliocene and Pleistocene(?).

T. P. Thayer, 1957, Some relations of later Tertiary volcanology and structure in eastern Oregon: Internat. Geol. Cong., 20th, Mexico, 1956. Consists of fanglomerate, boulder gravel, and welded rhyolite tuff. Gravels and about 15 feet of tuff near the center form a 650-foot bluff southeast of Dayville and extend below floor of valley. Tuff member has maximum thickness of about 110 feet. Vertebrate fossils below tuff date beds below tuff as lower Pliocene; beds above tuff range up to Pleistocene in age.

Type exposure: On Rattlesnake Creek about 1 mile west of Cottonwood, Malheur County.

Rattlesnake Granite[1]

Late Mesozoic: Southern California.

Original reference: F. S. Hudson, 1922, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 13, no. 6, p. 181, 207–209, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 485, table 4. Described under late Mesozoic plutonics. In plutonic sequence, central San Diego County, Rattlesnake granite is listed as youngest intrusive, younger than La Posta quartz diorite.

D. L. Everhart, 1951, California Div. Mines Bull. 159, p. 87–88, pls. 2, 3, 4. Mapped as Upper Cretaceous.

E. S. Larsen, Jr., 1958, U.S. Geol. Survey Bull. 1070–B, p. 44, 50. Lead-alpha age 117 million years.

Named for Rattlesnake Valley, Cuyamaca region, San Diego County.

Rattlesnake Point Granite

Precambrian: Southeastern Arizona.

F. F. Sabins, 1957, Geol. Soc. America Bull., v. 68, no. 10, p. 1322–1323, pl. 1. Coarse-grained with granitic-porphyritic texture. Fresh surfaces are greenish gray and weather light brown. Abundant large light-colored euhedral feldspar phenocrysts which have maximum dimensions of 15 by 25 mm. At Rattlesnake Point and other outcrops, there is pronounced flow-type preferred orientation of feldspar phenocrysts. Unconformably underlies Bolsa quartzite. Intrudes Pinal schist along west side of Bowie Mountain.

Crops out along northeast front of Chiricahua Mountains from vicinity of Emigrant Hills and Little Emigrant Canyon east to Rattlesnake Point from which granite takes its name, Cochise Head quadrangle, Cochise County. Also crops out along north flank of Blue Mountain, at Timber Mountain, and on southwest side of range in vicinity of Apache Pass.

Raul Canyon Basalt

Tertiary: Northwestern Utah.

G. H. Thomas, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 4, p. 14, pl. 1. Dark fine-grained porphyritic basalt. Mapped as Raul Canyon intrusive.

Named for exposures in Raul Canyon, Tooele County.

774–954—vol. 3—66——21

**Ravalli Group[1] or Argillite**

Ravalli Formation[1]

Precambrian (Belt Series): Northwestern Montana and northeastern Idaho.

Original reference: C. D. Walcott, 1906, Geol. Soc. America Bull., v. 17, p. 7, 9.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1880–1881. In Glacier National Park, Ravalli group represented by (ascending) Altyn formation, Appekunny formation, and Grinnell formation. Thickness 7,800 to 15,000 feet. Type locality cited.

C. E. Erdmann, 1944, U.S. Geol. Survey Water-Supply Paper 866–B, p. 47. Strata in Bad Rock Canyon on main Flathead River called Ravalli argillite.

Russell Gibson, 1948, U.S. Geol. Survey Bull. 956, p. 11–12, pl. 1. Formation in Libby quadrangle, Montana. Overlies Prichard formation; underlies Wallace formation. Thickness about 10,000 feet. Ravalli correlated with Burke formation, Revett quartzite, and St. Regis formation of Coeur d'Alene district.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 111–112. Term Ravalli group is used herein to include formations of Belt series that overlie or are believed to overlie Neihart and Prichard formations and are below Newland limestone of Piegan group or its stratigraphic equivalent. In and near Lincoln, Mineral and Sanders Counties, Mont., group contains Burke formation, Revett quartzite, and St. Regis formaton. In extreme northwestern part of Montana, maximum thickness may be 10,000 feet. In and south of Glacier National Park, group contains Altyn limestone, Appekunny argillite, and Grinnell argillite with aggregate maximum thickness of more than 12,000 feet. In Little Belt Mountains, Chamberlain shale (1,500 feet thick) is at present regarded as sole unit that can be correlated with Ravalli group.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 18–27, pls. 1, 2. Altyn limestone assigned to Ravalli group provisionally. May prove to be pre-Ravalli.

Type locality: Hills along Jocko River, near Ravalli, Mont.

Ravallian series[1]

Precambrian: Montana.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44.

Raven Member (of Montoya Dolomite)

Upper Ordovician: Southwestern New Mexico.

L. P. Entwistle, 1944, New Mexico Bur. Mines Mineral Resources Bull. 19, p. 18. Thick-bedded gray dolomite with some red chert. At base is a shell limestone. Thickness at Raven claim 120 feet. Overlies Par Value member (new); underlies Fusselman dolomite.

Typical exposures: On Raven claim, from which member is named, Boston Hill mining district, Grant County.

Ravenna Plutonic Series[1]

Mesozoic(?): Southern California.

Original reference: O. H. Hershey, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, pl. 1, map.

Probably named for occurrence at Ravenna Station, Los Angeles County.

Ravenna Shale Member or facies (of Portwood Formation)

Middle Devonian: Eastern Kentucky.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 863, 864, 865. Black fissile shale with lenses of black or brownish limestone; indistinguishable from overlying Trousdale shale. Considered a coeval facies with Harg shale facies (new) and Duffin dolomite.

Type section: One mile west of Ravenna, along railroad at southwest corner of Irvine, Estill County. Occurs only on eastern border of New Albany outcrop.

Raven Rock Member (of Stockton Formation)

[Upper] Triassic: West-central New Jersey.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 52 (table). Massive medium to coarse white and gray arkose. Thickness 293 feet. May or may not include overlying 724 feet of red and brown sandstone and underlying 787 feet of red and gray fine sandstone, red shale, and arkose [see Stockton formation]. Younger than Cutalossa member (new); older than Lockatong formation.

In area along Delaware River from Stockton northward to 3 miles west of Milford, Hunterdon County.

**Ravenswood Granodiorite**[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey, 1910, New York Acad. Sci. Annals, v. 19, p. 250.

Wallace de Laguna and M. L. Brashears, Jr., 1946, New York State Water Power and Control Comm. Bull. GW–13, p. 8 [reprinted 1948, p. 7]. Intrudes Fordham gneiss in many localities. Composition ranges from granite to diorite but term granodiorite is appropriate for most of it.

Named for typical development in Long Island City, a part of which is called Ravenswood.

**Rawley Andesite**[1]

Miocene (?): Central southern Colorado.

Original reference: W. S. Burbank, 1932, U.S. Geol. Survey Prof. Paper 169.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 195, 196. In Greater Bonanza district, the volcanics in order of succession are Rawley andesite, Bonanza latite, Squirrel Gulch latite, Porphyry Peak rhyolite, and Bremer [Brewer] Creek latite. In South Bonanza district, the volcanic sequence is roughly the same except Porphyry Peak rhyolite is missing and the Bonanza latite is replaced by Hayden Peak latite.

Exposed on slopes of Rawley Gulch and in Rawley mine, Bonanza district, Saguache County.

Rawlins Ash Bed (in Ash Hollow Member of Ogallala Formation)

Pliocene: Northwestern Kansas and southwestern Nebraska.

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 254. Name applied to volcanic ash bed. Thickness 3½ feet at type locality. Basal 2 feet relatively pure and massive; upper part interbedded with fine to medium sand. Lies about 10 feet above base of Ash Hollow member; lies stratigraphically below Fort Wallace ash bed (new).

Named from exposures at center of west line SW¼ sec. 4, T. 4 S., R. 34 W., Rawlins County, Kans.

Rawlinsian series

Cretaceous (Cretacic) : Northwestern Kansas.

[C. R.] Keyes, 1941, Pan-Am. Geologist, v. 76, p. 304 (chart). Series in the late Cretacic. Includes Arickaree formation. Occurs below the Eocene and above an unnamed interval above the Buckskinian series.

Rawls Basalt (in Buck Hill Volcanic Series)

Pliocene (?) : Western Texas.

S. S. Goldich and C. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Fall Field Trip Oct. 29–31, p. 14 (table 1), 22. Name applied to the thick flows above the Tascotal formation (new) ; flows are youngest rocks of Buck Hill series known to date. At least four flows 180 feet thick are included in the Rawls at Wire Gap; in southern part of Tascotal quadrangle contains eight flows at least 300 feet thick. Flows are separated by several beds of sandy tuff.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 555–558, pl. 1. Described in Cathedral Mountain quadrangle where it has a maximum thickness of 545 feet on Cathedral Mountain; at northernmost exposure—two outliers on butte west of McIntyre Peak—thickness is 30 and 75 feet respectively. Possibly early Pliocene.

Named for Rawls Ranch on Tascotal Mesa, Tascotal quadrangle, Presidio County.

Raymond Limestone (in Monongahela Formation)[1]

Pennsylvanian : Western West Virginia.

Original reference : I. C. White, 1882, The Virginias, v. 3, p. 142.

Exposed at Raymond City post office, Putnam County.

Raymond City Limestone[1]

Pennsylvanian : Western West Virginia.

Original reference : I. C. White, 1882, The Virginias, v. 3, p. 142.

Exposed at Raymond City post office, Putnam County.

Raymond Peak Andesites

Late Tertiary : Central eastern California.

H. G. Wilshire, 1957, California Univ. Dept. Geol. Sci. Bull., v. 32, no. 4, fig. 1. Named on map of Ebbetts Pass region. Older than Silver Peak andesites (new).

Ebbetts Pass region is in Alpine County.

Raymond Quarry Beds[1]

Devonian : Central eastern Iowa.

Original reference: M. F. Arey, 1906, Iowa Geol. Survey, v. 16, p. 420–448.

Blackhawk County.

†Raysor Marl[1]

Miocene, upper : Southern South Carolina.

Original reference : C. W. Cooke, 1936, U.S. Geol. Survey Bull. 867.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 182. Recommended that use of name Raysor marl be discontinued and the Miocene bed at Raysor Bridge be included in Duplin marl.

Named from Raysor Bridge, on Edisto River, 8 miles southwest of St. George, near which only known outcrops occur.

**Raytown Limestone Member** (of Iola Limestone)

Raytown Limestone Bed (in Kansas City Formation)[1]

Raytown Limestone Member (of Chanute Shale)

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, and eastern Kansas.

Original reference: H. Hinds and F. C. Greene, 1915, Missouri Bur. Geology and Mines, v. 13, 2d ser., p. 7, 27–28, 118.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, pl. 5. Member of Chanute shale. Thickness 5 to 8 feet. Overlies Muncie Creek shale member.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Member of Chanute shale. Underlies Liberty Memorial shale member (new).

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2032: F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vi (fig. 2), 13. Miscorrelation of Iola formation by Haworth and Bennett (1908) in tracing limestone in this part of section northeastward to Kansas City has been responsible for long standing error in nomenclature of Missourian units in northeastern Kansas and northwestern Missouri. Settlement of Iola problem has led to changes in Missouri Survey's classification of middle and upper Kansas City beds so as to bring interstate agreement in nomenclature. Paola limestone, Muncie Creek shale, and Raytown limestone, which were treated as members of Chanute shale, are recognized as belonging to Iola formation. Underlies Lane shale (redefined for Missouri).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Member of Iola limestone. As recognized in Middle River section in Madison County, is composed of a 9-foot sequence of light-gray wavy-bedded fossiliferous limestones separated into two or three units by thin shales. This unit differs from the Raytown of Condra and Upp (1933, Nebraska Geol. Survey Paper 4). They describe it as several thin limestone beds, all of which are quite fossiliferous and report a thickness of about 3 feet. Overlies Muncie Creek shale member; underlies Lane shale.

Named for Raytown, Jackson County, Mo.

Rayville Formation (in Kickapoo Creek Group)

Pennsylvanian (Lampasas Series): North-central Texas.

M. G. Cheney, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 207 (chart 1), 210–211. Proposed for bed from disconformity above Dennis Bridge limestone down to top of Parks formation. Includes approximately 1,000 feet of alternating limestone, blue and black shales, and sandstones. Outcropping members include Dennis Bridge limestone; an unnamed 100 to 125 foot section of shale, dolomitic limestones, and sandstone; Kickapoo Creek limestone; and Dickerson shale—a combined thickness of about 200 feet. Formation thins rapidly westward from type area, being less than 300 feet thick in Brown and Coleman Counties.

Type locality: Southwestern Parker County. Name derived from early settlement now almost abandoned, located 3½ miles southeast of Dennis and a like distance northeast of Kickapoo Falls.

**Razburg Sandstone Member** (of Pottsville Formation)[1]

Pennsylvanian: Northern central Alabama.

Original reference: C. Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175, p. 9.

Named for Razburg, Jefferson County.

Razorback Formation

Tertiary: Southwestern New Mexico.

F. J. Kuellmer and others, 1953, *in* New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 50 (map). Name appears on legend of map of Mimbres Valley. Referred to as andesite, trachyte, and latite.

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 39 (table 3), 47–48, pl. 1. In Lake Valley quadrangle, consists mainly of pyroxene andesites. Thickness 250 to 500 feet. On west side of White Rock Canyon, a 40-foot layer of fairly coarse grained well-sorted sandstone is interbedded with two of flows of formation. Underlies Bear Springs basalt (new); overlies Mimbres Peak formation. Flows of Razorback formation overlie Pollack quartz latite (new) along Taylor Creek.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 32–34. Formation consists of two superficially similar members, the lower andesite and the upper rhyolite that is close to being a trachyte or latite. Both are black or dark gray and fine grained. Total thickness of both members varies between 300 feet west of Mimbres Peak, at least 700 feet at Caballo Blanco, and 800 feet or more in Donahue Canyon. In northwest part of Dwyer quadrangle, it lies on an irregular surface of Caballo Blanco rhyolite; near Box Well, on Piloncillo sediments (new); in Mimbres fault zone, on Caballo Blanco rhyolite; and east of fault, on beveled rhyolites of Mimbres Peak and Caballo Blanco formations. Derivation of name.

Named after a mountain in sec. 36, T. 18 S., R. 11 W., Dwyer quadrangle.

Reading Gneiss[1]

Upper Cambrian: Southeastern Vermont.

Original reference: C. H. Richardson, 1929, Vermont State Geologist 16th Rept., p. 237, table opposite p. 288.

In Windsor and Windham Counties. Named for fact that its outcrops occupy whole of southern part of Reading, Windsor County.

**Reading Limestone Member** (of Emporia Limestone)

Reading Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: A. J. Smith, 1905, Kansas Acad. Sci. Trans., v. 19, p. 150.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Emporia limestone here recognized and used as originally defined. Underlies Harveyville shale member; overlies Auburn shale.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 56–57. Described in Pawnee County, where it is 15 to 26 feet thick. Underlies Harveyville shale member; overlies Auburn shale. Unit not easily traced and both northern and southern extremities in county are indistinct. Occurs south of Pawnee County, but southern extent not yet known.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 13, fig. 5. Geographically extended into southwestern Iowa where it is classified as formation in Wabaunsee group. Consists of two beds of gray crinoidal limestone which characteristically weather to deep brown; commonly fossiliferous with crinoid and brachiopod fragments. Thickness about 3 feet. Underlies Harveyville shale; overlies Auburn shale.

Type locality: In vicinity of Reading, Lyon County, Kans. Well exposed in roadcut near NW cor. sec. 33, T. 17 S., R. 13 E., 1 mile north of Reading.

†Reading Sandstone[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: E. V. D'Invilliers, 1883, Pennsylvania 2d Geol. Survey Rept. $D_3$, v. 2, p. 99–100.

Well exposed south of Reading, Berks County, in cuts of Philadelphia & Reading Railroad.

Readsboro Schist[1]

Upper Cambrian (?): Southwestern and southeastern Vermont.

Original reference: G. D. Hubbard, 1924, Vermont State Geologist 14th Rept., p. 282–288, 291, 294, map.

Named for extensive outcrops in Readsboro Township and around Readsboro, Wilmington quadrangle, Bennington County.

Ready Pay Member (of Percha Shale)

Upper Devonian or Lower Mississippian: Southern New Mexico.

F. V. Stevenson, 1944, Dallas Digest (Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Joint Ann. Mtg.), p. 94–95. Black fissile nonfossiliferous shale. In most sections, comprises lower two-thirds of total thickness of formation. Underlies Box member (new) with gradational contact. Possibly a different facies of Contadero formation (new).

F. V. Stevenson, 1945, Jour. Geology, v. 53, no. 4, p. 241, 243, figs. 2, 6, 13. Upper Devonian. Thickness 132 feet. Overlies Sly Gap formation in San Andres Mountains. Derivation of name given.

M. A. Stainbrook, 1947, Jour. Paleontology, v. 21, no. 4, p. 298. Basal black shale of Percha termed Silver by Keyes (1908). There is little doubt that the Silver and Ready Pay were proposed for identical division of Percha and there is little reason to replace earlier names. Percha of early Mississippian age.

Named after gulch which drains to south into Percha Creek, 400 yards east of a narrow canyon called "The Box", in vicinity of Hillsboro.

**Reagan Sandstone**[1] (in Timbered Hills Group)

Upper Cambrian: Central southern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55, 56. Basal formation in Timbered Hills group (new). Underlies Cap Mountain sandstone. Pebbly sandstone 500 feet thick; carries much glauconite and becomes calcareous at top. Separated from Precambrian by unconformity; Colbert porphyry and Tishomingo granite are oldest exposed rocks.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 18. Commonly rests unconformably on igneous rocks, but in one exposure about 98 feet of dense limestones separate it from igneous rocks. In some places, contact with overlying Honey Creek is fairly sharp; more commonly there is gradation zone at top, especially on northeast flank of Wichita Mountains. Here an alternation of sandstones and limestones make it impossible to choose distinct plane of separation between the two formations. Note on type section. Thickness 460 feet at type section.

E. A. Frederickson, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 7, p. 1349–1355. Two units, namely, the so-called Cap Mountain formation and the "basal limestone" are, on basis of faunal evidence and stratigraphic position, herein considered to be equivalents of all or parts of Honey Creek formation.

Type section: About 5 miles southwest of village of Mill Creek, Johnston County. Named from town of Reagan in Tishomingo quadrangle.

Reager Ash Bed (in Ash Hollow Member of Ogallala Formation)

Pliocene: Northwestern Kansas.

J. S. Carey and others, 1952, Kansas Geol. Survey Bull. 96, pt. 1, p. 9–13, 27. Name applied to volcanic ash bed. Approximately 10 feet thick. Lies near middle of member and stratigraphically above Calvert ash bed (new) and stratigraphically below an unnamed ash bed.

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 254. Listed in stratigraphic sequence as overlying Dellvale ash bed (new) and underlying Reamsville ash bed (new).

Type locality: NW¼NE¼ sec. 35, T. 2 S., R. 25 W., Norton County. Named for exposures 1 mile north of stop on Burlington Railroad in west-central part of county.

Reamsville Ash Bed (in Ash Hollow Member of Ogallala Formation)

Pliocene: Northwestern Kansas.

Ada Swineford, J. C. Frye, and A. B. Leonard, 1955, Jour. Sed. Petrology, v. 25, no. 4, p. 244 (fig. 1), 254–255. Highest named [volcanic] ash bed in Ogallala formation of central Great Plains. Thickness at type locality 3 feet; occurs in sequence of partly cemented sand and silty sand. Lies slightly above middle of Ash Hollow member and stratigraphically above Reager ash bed.

Named from exposures along Kansas Highway 8 in center of west line SW¼ sec. 32, T. 1 S., R. 14 W., Smith County, west-southwest of Reamsville.

**Recapture Shale Member** (of Morrison Formation)[1]

Upper Jurassic: Southeastern Utah, northeastern Arizona, southwestern Colorado, and northwestern New Mexico.

H. E. Gregory, 1938, U.S. Geol. Survey Prof. Paper 188, p. 36 (table), 58, pl. 15, strat. sections. Series of strongly colored shales and sandstones 100 to 300 feet thick. Shales are prevailingly dark red, but some are variegated—pink, ash, brown, and gray; many include firm strongly calcareous beds that break into slabs and friable imbricated gypsiferous beds that weather as tiny cliffs. Sandstones are white beds of glistening quartz cemented by lime, a few of them more than 1 foot thick or continuous for more than 1,000 feet. Overlies Bluff sandstone member; underlies Westwater Canyon sandstone member (new).

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 962–964, table 1. As interpreted here, type section of Recapture includes Salt Wash member as well as about 150 feet of overlying alternating sandstones and shales. The Salt Wash is thin and rests directly on the Entrada (Bluff), and the Summerville is absent. In Carrizo Mountains, distinction between Salt Wash and overlying part of Recapture is more clear cut, and term Recapture can best be used for the upper part only and is therefore a more restricted usage than Gregory employed. Gregory's description of the Recapture includes certain features of the Salt Wash; the two are very similar in gross lithologic characteristics but differ in type of sandstone and shale and in appearance and manner of weathering. [Also referred to as Recapture Creek shale.]

J. W. Harshbarger, C. A. Repenning, and R. L. Jackson, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 97. In Navajo country, Summerville formation, Recapture shale member, and Bluff sandstone member of Morrison formation grade laterally southward into distinct sand facies here named Cow Springs sandstone.

L. C. Craig and others, 1955, U.S. Geol. Survey Bull. 1009–E, p. 137–140. Member is present in northeastern Arizona, northwestern New Mexico, and small areas of southeastern Utah and southwestern Colorado. Unit was formed as large alluvial fan. To the north, member intertongues with and grades into Salt Wash member; upper part is most extensive and is recognized to south of Monticello, Utah. To the southwest, member pinches out along zero isopach line passing south of Gallup, N. Mex. Both at northwestern and southeastern extremities of this zero isopach, the line marks apparent limit of deposition, but in middle, south of Gallup, beds equivalent to Recapture have been removed by erosion; eastward extent of member in north-central New Mexico not known. Unit arbitrarily divided into three facies: conglomeratic sandstone; sandstone; and claystone and sandstone. Thick part of member is elongate curving area from northeastern Arizona into northwestern New Mexico; maximum thickness 680 feet in Arizona. Extension of Salt Wash as recognizable unit through southeastern Utah and into northeastern Arizona and northwestern New Mexico constitutes restriction of Gregory's original definition of the Recapture.

V. L. Freeman and L. S. Hilpert, 1956, U.S. Geol. Survey Bull. 1030–J, p. 313–314, 315 (fig. 60), 322, 325, 327, 328–329, 330–331, 333–334. In Gallup-Albuquerque area, member ranges from about 20 to as much as 276 feet in thickness, in general thinning southward. Consists largely of grayish-red sandy claystone and clayey sandstone with limy nodules and white clean fine- to medium-grained sandstone in alternating units 5 to 10 feet thick; the clean sandstone beds are most common in western part of area and probably represent tongues of Cow Springs sandstone. Clayey sandstone is dominant rock in eastern and southern parts of area. In most of area, conformable with underlying Bluff sandstone; to the north near Ysidro, rests directly on Summerville formation. Overlain by Westwater Canyon member.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 52–53. Gregory (1938) apparently included in type section some basal sands that are now correlated with Salt Wash member (Stokes, 1944). Usage in this paper [Navajo country] follows that of Stokes in considering as Recapture only the upper sandstone and shale at Gregory's type locality. Lower sandstone beds are referred to as Salt Wash member. Present in northeastern part of Navajo country;

intertongues with and grades into Salt Wash member where both members are present; intertongues with overlying Westwater Canyon member. Not present in northwestern part of area because Salt Wash sandstone member occupies entire Morrison interval. Not recognizable in southwestern part of area; where it grades into main mass of Cow Springs sandstone; the white sandstone tongue of Cow Springs, at base of Morrison, is only tongue of Cow Springs that can be separated from Recapture on regional scale. Near Fort Wingate, upper tongues of Cow Springs grade into Recapture, and Recapture is thicker toward east. Exclusive of white sandstone tongue but including all other tongues and lenses of Cow Springs that are present, Recapture is 483 feet thick at northern end of Chuska Mountains and thins to 215 feet at Todilto Park and 104 feet at Lupton, Ariz.; not recognizable at Black Rock, N. Mex.; 59 feet thick at Fort Wingate and thickens eastward to 207 feet at Thoreau, N. Mex.

Named for exposures near mouth of Recapture Creek, San Juan County, Utah.

Recapture Creek Shale Member (of Morrison Formation)

*See* **Recapture Shale Member** (of Morrison Formation).

Reclamation Group

Pennsylvanian (Des Moines): Eastern Wyoming and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 3, 28, 32. Consists mostly of limestones and shales colored shades of red, gray, and green. Comprises Division V of Hartville "formation" (Condra and Reed, 1935). Thickness 72 to 87 feet. Underlies Roundtop group (new); overlies Fairbank formation (new).

Type locality: Reclamation Hill, sec. 27, T. 27 N., R. 66 W., Platte County, Wyo.

Recreation Redbeds

Cretaceous: South-central Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 710 (fig. 2), 715–716, pl. 1. Series of uniformly brick-red fine-grained sandstones. Uniformity broken by conglomerate 5 to 30 feet thick. Thickness 1,265 feet at Gould Gulch. Underlies Amole arkose; overlies Cretaceous volcanics.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, pl. 1. Upper Cretaceous.

D. L. Bryant and J. E. Kinnison, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1235. Lower Cretaceous.

Named because of its color and occurrence in Tucson Recreational area. Practically confined to Red Hills and numerous small outcrops in zone of the great thrust east of Amole Peak, Tucson Mountains, Pima County.

Rector Formation

Lower Cretaceous (Shasta Series); Northern California.

M. A. Murphy, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 210–2105. Includes 20 to 400 feet of sandstone, conglomerate, and mudstone just above unconformity at base of Cretaceous section. Unit rests unconformably on igneous and metamorphic rocks of Klamath Mountains complex. Conformably underlies Ono formation (new), contact gradational.

Named for typical development along Rector Creek, a small tributary to the North Fork of Cottonwood Creek at Ono, Shasta County.

Red Amphitheater Breccia

Pliocene(?): Southern California.

C. A. Richards, 1958, *in* Pacific Petroleum Geologist, v. 12, no. 3, p. 4. Proposed for the masses of huge blocks, breccia, and minor amounts of fanglomerate that are exposed on the hills around Red Amphitheater. Believed to be derived from landslides, debris slides, or mass wasting from the rising Pyramid Peak fault block.

Area is part of the Funeral Mountains of the Amargosa Range, Death Valley National Monument.

**Red Bank Sand** (in Monmouth Group)[1]

Red Bank Formation

Red Bank Member (of Monmouth Formation)

Upper Cretaceous: New Jersey.

Original references: W. B. Clark, 1894, New Jersey Geol. Survey Ann. Rept. 1893, p. 337; 1894, Jour. Geology, v. 2, p. 165–166.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 8 (fig. 4), 28, 49–51. Rank reduced to member status in Monmouth formation. Conformably overlies Navesink member; conformably underlies Tinton member; toward south where Tinton is missing, Red Bank grades into overlying Hornerstown. Thickness in Monmouth County 125 feet; thins to southeast and not present south of Sykesville; decreases in thickness as sand member basinward or downdip and becomes more and more shaly and is inseparable from Hornerstown or Navesink.

S. K. Fox, Jr., and R. K. Olsson, 1955, [abs.] Jour. Paleontology, v. 29, no. 4, p. 736. Upper Cretaceous Navesink, Red Bank, and Tinton are formations with distinct microfaunas indicating time differences. Microfauna of Red Bank indicates correlation with latest Navarro of Gulf Coast section. Stratigraphic evidence indicates unconformity between Cretaceous and Tertiary formations. Hornerstown rests successively from northeast to southwest on Tinton, Red Bank, and Navesink.

H. W. Miller, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 722–736. Red Bank and Navesink formations (Cretaceous) interfinger at least locally, and Red Bank formation extends southwestward to Delaware as unit referred to as "middle greensand."

R. K. Olsson, 1959, Dissert. Abs., v. 19, no. 8, p. 2063. Subdivided into two members: Shrewsbury and Sandy Hook.

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184, B185. Uppermost formation in Monmouth group. Overlies Navesink formation; underlies Hornerstown sand of Rancocas group. Average dip southeast 35 feet per mile. Thickness 0 to 140 feet. Thickens in outcrop to northeast.

Well exposed in vicinity of Redbank, Monmouth County.

Red Beach Granite

Post-Silurian—pre-Upper Devonian: Southeastern Maine.

D. H. Amos, 1958, Dissert. Abs., v. 19, no. 5, p. 1053. All diorites and granites in area were emplaced in post-Silurian—pre-Upper Devonian interval. All but Red Beach granite were formed under relatively deep-seated conditions. Contact features establish that Red Beach granite is the youngest. [Other diorites and granites not named.]

Report discusses geology and petrology of Calais and Robbinston quadrangles.

**Red Bluff Clay**

Red Bluff Clay (in Vicksburg Group)[1]

Red Bluff Member (of Forest Hill Formation)

Oligocene, lower: Southern Mississippi and southwestern Alabama.

Original reference: E. W. Hilgard, 1860, Mississippi Geol. and Agric. Rept., p. 135.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1315 (fig. 1), 1318–1324. Cooke (1918) originally regarded Forest Hill sand as contemporaneous with Red Bluff clay but later accepted view of of Gulf Coast geologists that the Red Bluff comes in from east as wedge between Yazoo clay and Forest Hill sand. Concept derived from present study is that Forest Hill is deltaic equivalent of Red Bluff as Cooke originally believed. Vicksburg group is restricted below to exclude Forest Hill sand and Red Bluff clay. Chart shows Red Bluff clay overlies Yazoo clay and underlies Marianna limestone. Note on derivation of name.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1838 (fig. 6), 1839. Overlies Shubuta (clay) member (new) of Yazoo formation.

W. J. Hendy, 1948, Mississippi Geol. Soc. [Guidebook] 6th Field Trip, p. 27–28. Rank reduced to member status in Forest Hill formation. As restricted, consists of 10 to 14 feet of highly to slightly glauconitic fossiliferous dark-gray clay with one or more zones of argillaceous glauconitic limestone concretions.

C. W. Stuckey, Jr., 1953, Am. Assoc. Petroleum Geologists Guidebook Houston Mtg., p. 27. Included in Vicksburg group in this report.

Named for exposures at Red Bluff on Chickasawhay River just above railroad bridge 1½ miles south of Shubuta, Wayne County, Miss.

Red Bluff Epoch[1]

Pleistocene: California.

Original reference: O. H. Hershey, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, p. 1–29.

Name probably derived from Red Bluff, Tehama County.

Red Bluff Formation

Cenozoic: Southwestern Montana.

D. B. Andretta and S. A. Alsup, 1960, Billings Geol. Soc. Guidebook 11th Ann. Field Conf., p. 186, 189. Fine siltstone to coarse conglomerate and breccia. Beds chiefly deep red with purple, yellow, and white layers interspersed. Distinctly bedded, thoroughly indurated, and well sorted. Individual beds range from 3 inches to about 5 feet in thickness; each bed well defined and sharply differentiated from overlying and underlying beds. Appears to be deposited on topography of rolling relief on stripped Precambrian rocks. Middle Cenozoic.

Occurs between towns of Norris and Red Bluff along highway between Anceney and Norris, Madison-Gallatin Counties.

**Red Bluff Formation**[1]

Red Bluff Gravel

Pleistocene: Northern California.

Original reference: J. S. Diller, 1894, U.S. Geol. Survey 14th Ann. Rept., pt. 2, p. 413–416, pl. 44, map.

C. A. Anderson and R. D. Russell, 1939, California Jour. Mines and Geology. v. 35, no. 3. p. 235. Described as an alluvial deposit consisting largely of gravels with a minor amount of interbedded sand; commonly deep brick red in color. Thickness near Redding more than 100 feet. Overlies Tehama formation, locally overlies the Tuscan, and also overlaps upon the Cretaceous.

M. A. Murphy, chm., 1957, Sacramento Geol. Soc. [Guidebook] Ann. Field Trip, May 25–26, geol. map. Red Bluff gravel mapped in Ono quadrangle, Shasta County.

Named for exposures at Red Bluff, Tehama County.

Red Bluff Granite

Precambrian: Western Texas.

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 160. Name proposed for granite occurring in the Franklin Mountains.

T. S. Jones, 1953, Stratigraphy of the Permian basin of west Texas: West Texas Geol. Soc., p. 1. Underlies Lanoria quartzite.

Occurs at Red Bluff Park, in McKelligan Canyon, near El Paso.

†Red Bluff Sandstone (in Cimarron Group)[1]

Permian: Central southern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 40.

Named for exposures at former post office of Red Bluff, Comanche County.

**Red Branch Member** (of Woodbine Formation)

Upper Cretaceous: Northeastern Texas and southwestern Oklahoma.

H. R. Bergquist, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 98. Described at its type locality as consisting of tuffaceous sandstone, carbonaceous shale, and lignite; elsewhere also includes sandy shale and ferruginous sandstone, entire sequence being from 50 to 80 feet thick. Overlies Dexter member; downdip grades into material indistinguishable from overlying Lewisville and is classed with that member.

N. M. Curtis, Jr., 1960, Oklahoma Geology Notes, v. 20, no. 9, p. 240–244. Geographically extended into Bryan County, Okla.

Type locality: Near Red Branch community in northwestern Grayson County, Tex.

Red Bridge Limestone Member (of Liston Creek Formation)

Silurian (Niagaran): Northeastern Indiana.

Original reference: E. R. Cumings and R. R. Shrock, 1927, Indiana Acad. Sci. Proc., v. 36, p. 74–75.

Crops out along Mississinewa River at village of Red Bridge, Wabash County.

**Red Buttes Quartz Basalt** (in Tropico Group)

Pliocene(?): Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 137 (fig. 1), 138 (fig. 2), 142–143. Black basalt or mafic andesite consisting of several flows totaling about 360 feet in maximum thickness At Red Buttes, rests on pre-Tertiary quartz monzonite and unconformably underlies fanglomerate of probable Pleistocene age; in Kramer Hills, basalt overlies, probably unconformably, the lower part of the Tropico group and is overlain conformably by the upper part.

Type locality: Sec. 5, T. 8 N., R. 6 W., Kramer quadrangle, San Bernardino County. Also prominantly exposed in the Kramer Hills, Kramer and Barstow quadrangles. Name derived from Red Buttes.

Red Canyon Member[1] (of Lykins Formation)

Triassic(?): Southeastern Colorado.

Original reference: J. T. Duce, 1924, Colorado Geol. Survey Bull. 27, pt. 3, p. 81–82.

Probably named for exposures in eastern end of Red Rock Canyon, Las Amimas County.

Redcloud Dacite Flows, Lavas

Pleistocene: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 44, 49, 53, 63, 101, 138, pl. 1. Dacite lava flow that issued from vent on northern slope of former Mount Mazama and erupted after andesitic phase of Mazama's activity had ended. Watchman and Hillman vents were active before the vents of the Llao. Cleetwood and Redcloud dacite lavas younger than Mount Scott lavas. In section southwest of Wineglass, the steep margin of Redcloud flow (lava) presumably prevented Wineglass tuff from spreading farther south.

Redcloud Cliffs are on eastern side of Crater Lake.

**Red Cloud Sand and Gravel**

Pleistocene: Southern Nebraska.

C. B. Schultz, E. C. Reed, and A. L. Lugn, 1951, Science, v. 114, no. 2969, p. 548. Proposed that name Grand Island be restricted to the "Upper Grand Island" and name Red Cloud sand and gravel be applied to the "Lower Grand Island" of Condra and Reed (1950) which includes pro-Kansan sand and gravel. At type locality, consists of sand and gravel that grades from sand to medium-coarse gravel; gray in color throughout except for upper few feet which is strongly weathered to a yellowish brown, indicating a profile of weathering and unconformity at its top; thickness of 33 feet exposed in sand and gravel pit; occurs below Sappa formation and above Niobrara. Appears to be equal in age, at last in part, to pro-Kansan sand and silt (Atchison formation) in glaciated area of eastern Kansas and Nebraska.

Type locality: Red Cloud Township 2½ miles west-northwest of Red Cloud in E½ sec. 28, T. 2 N., R. 11 W., Webster County.

Red Cone Basalt Flow

Pliocene to Pleistocene, lower: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 32. Name applied to basalt flow on Red Cone. [See Timber Crater Basalt Flow.]

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 27. Here considered to be pre-Mazama.

Red Cone is in northwest corner of Crater Lake National Park.

**Red Creek Quartzite**[1]

Red Creek Complex

Precambrian: Northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 42, 62, 70, 137.

W. R. Hansen, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf. p. 23–25, 26 (fig. 3), pl. 1; 1957, U.S. Geol. Survey Geol. Quad. Map GQ–101. Consists mostly of rocks of moderately high metamorphic grade. Underlies Uinta Mountain group. Mapped in Cold Spring Mountain area, Colorado.

H. R. Ritzma, 1959, Utah Geol. and Mineralog. Survey Bull. 66, p. 17–18, geol. map. Because of diversity of rock types present in older Precambrian of area, whole assemblage is referred to as Red Creek complex. Most abundant rock type is quartzite with quartzose mica schist second most common type. Unconformably underlies Uinta Mountain group.

Named for exposures in Red Creek Canyon at head of Willow Creek. Red Creek Canyon separates Quartz Mountain and Mount Wheeler, northeast corner Uintah County, Utah.

**Red Desert Tongue** (of Wasatch Formation)

Eocene, lower: Southwestern Wyoming.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 100, 101 (chart). Sequence of coal beds, clay shale, siltstone, biotitic sandstone, and low-grade oil shale. Upper 400 feet contains many coal beds including Creston and Tierney coal zones. Only upper 400 feet of tongue exposed in central part of Great Divide Basin, but similar rocks on east flank of Rock Springs uplift are about 1,000 feet thick. Underlies Luman tongue (new) of Green River formation; unconformably overlies Fort Union formation. Intertongues with Battle Spring formation (new) to the north.

Named from exposures southwest of Red Desert Flat at Tipton Buttes and northeast of Red Desert Flat in NW cor. T. 21 N., R. 94 W., and adjoining parts of T. 21 N., R. 95 W., T. 22 N., R. 94 W., and T. 22 N., R. 95 W., Sweetwater County.

**Red Eagle Limestone** (in Council Grove Group)

Red Eagle Limestone Member (of Elmdale Formation)[1]

Red Eagle Limestone Member (of Konawa Formation)

Permian: Oklahoma, Kansas, Missouri, and Nebraska

Original reference: K. C. Heald, 1916, U.S. Geol. Survey Bull. 641, p. 24.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 167–168. Includes two limestones and a shale member. In southern Kansas, Red Eagle is a single ledge about 20 feet thick, but the two limestone members that are differentiated in central and northern Kansas can be identified in southern Kansas. Includes (ascending) Glenrock limestone, Bennett shale, and Howe limestone members. Underlies Roco shale; overlies Johnson shale. Council Grove group. Wolfcampian.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 87–89, Condra (1935, Nebraska Geol. Survey Paper 8) subdivided the Red Eagle into Glenrock limestone, Bennett shale, and Howe limestone members. These subdivisions have been recognized across Kansas and tentatively identified in Osage County, Okla. In north and central part of outcrop belt in Pawnee County, a threefold division of Red Eagle sequence is possible, but there is no sound basis for correlation with subdivisions in Kansas and Nebraska. For purpose of this report, Red Eagle is considered a single unit and defined as first persistent limestone zone above Long Creek limestone. Unit can be traced into Lincoln County. Consists of interbedded limestone and shale, thickening from less than 3 feet in north to more than 6 feet in south. Underlies Neva limestone.

A. E. West, 1960, Shale Shaker, v. 11, no. 3, p. 4–7. Described in Lincoln County, Okla., where it is classified as uppermost member of Konawa formation. Thickness 3 to 5 feet. Commonly made up of massive bed at base 2 to 3 feet thick with remainder of unit being thin-bedded limestones with shale partings. Overlies Long Creek limestone member. Overlain by redbeds.

Named for exposures near Red Eagle School, southwest of Foraker, Osage County, Okla.

†Red Eagle Shale (in Elmdale Formation)[1]

Pennsylvanian: Central northern Oklahoma.

Original reference: G. C. Clark and C. L. Cooper, 1927, Oklaholma Geol. Survey Bull. 40H.

Occurs in T. 22 N., Rs. 2 W.–5 E.

Redfield Formation

Eocene (Jacksonian): Southeastern Arkansas.

L. J. Wilbert, Jr., 1953, Arkansas Div. Geology Bull. 19, p. 80–87. Embraces the nonmarine Jacksonian deposits which overlie and are partially equivalent to the White Bluff formation. From north to south, the Redfield successively overlies the Pastoria and Rison members (both new) of the White Bluff; boundary is an erosion surface which is either subaerially exposed or is overlain by Pleistocene terrace deposits. Estimated maximum thickness 150 to 200 feet.

Name derived from village of Redfield in northern Jefferson County. Well exposed at White Bluff, 4 miles east of the village. Formation is restricted to northern part of Jacksonian outcrop area.

Red Gap Member (of Grinnell Argillite[1] or Formation)

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol Soc. America Bull., v. 48, no. 12, p. 1889. Argillites, dominantly red, but incidentally brownish or green; interbedded with pink, white, or greenish-white quartzites, brown sandstones, and sandy argillites. Recognized some places by thick beds of red argillite with flat mud-crack polygons. Maximum thickness 2,800 feet. Thins to 700 or 800 feet in Blackiston Valley. Intergrades with Rising

Bull member above and Rising Wolf member below. Type locality designated.

Type locality: Mountain between Red Gap and Ptarmigan Wall, Glacier National Park. Typically developed in Lewis Range, north of Many Glaciers.

Red Hill Complex

Carboniferous(?): East-central New Hampshire.

A. P. Smith and others, 1938, Geologic map and structure sections of the Mount Chocorua quadrangle, New Hampshire (1:62,500): New Hampshire Highway Dept. Includes gray to yellowish coarse-grained syenite, light-gray medium- to coarse-grained nephelite-sodalite syenite, gray to pink medium-grained syenite, white to brownish medium-grained quartz syenite, gray fine-grained quartz syenite, and gray to yellowish-gray fine-grained granite. Belongs to White Mountain magma series.

Occurs on and around Red Hill in southwestern corner of Mount Chocorua quadrangle.

Redhill sandstone[1]

Miocene: Southeastern California.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 61, 80.

Probably named for red sandstone mountain north of Ryan and east of Furnace Creek Wash, Inyo Canyon.

Red Hill Shale Member (of Lykins Formation)

Permo-Triassic: Northern Colorado.

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Uppermost member of formation; overlies Park Creek limestone member (new).

Red House Formation (in Magdalena Group)

Pennsylvanian: Southwestern New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 91–92, 255–256, figs. 2, 11. Consists dominantly of thin-bedded limestone and shale or claystone with limestone nodules and lenses. Color gray to dark gray. Massive cherty limestone beds present locally. A thin sandstone bed locally marks base of formation; a coarse-grained conglomeratic sandstone ledge is widely present in northern part of mountains near middle of section. Comprises about lower third of group. Thickness 362 feet. Conformably underlies Nakaye formation (new); unconformably overlies Cutter formation at type section; elsewhere it overlies Upham dolomite (new), Percha formation, and Nunn member of Lake Valley formation.

Type section: Along South Ridge in sec. 10, T. 15 S., R. 4 W., Sierra County. Named from Red House Mountain in southern part of Caballo Mountains area.

Redil Shale (in Panoche Group)

Upper Cretaceous: Central California.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec., Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Basal formation in group. White shale with silty and sandy interbeds. Includes Papanatas conglomerate member (new) at base. Thickness 5,325 feet. Underlies Benito sandstone (new). Fault contact with Franciscan. Name credited to D. W. Sutton (unpub. thesis).

Type locality: Papanatas Canyon, secs. 23 and 24, T. 14 S., R. 10 E., Fresno County. Name derived from Redil Canyon.

Red Knobs Formation

Middle Ordovician (Mohawkian) : Eastern Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 86, chart 1 (facing p. 130). A thick succession of red to pink calcarenites and limy ferruginous sandstones. Lower part consists of red to pink marble, the Holston marble of other authors. Upper beds, which yield a characteristically dark-maroon sandy regolith, are calcareous sandstones and ferruginous sandy calcarenites with partings of greenish-gray to buff shale. Maximum thickness 750 feet. Underlies Sevier formation; overlies Arline formation (new). Name attributed to B. N. Cooper and G. A. Cooper.

Named from exposures near and along the Blount-Loudon County line, near Meadow, on Meadow quadrangle.

Redlands Limestone[1] (in Telescope Group)

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 311, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July–Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p 355, 372, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible the correlation of formations defined by Murphy (1930, 1932 [1933]) in Telescope Peak quadrangle with formations now commonly used in Death Valley region. Murphy tentatively assigned all rocks above Panamint metamorphic complex to Lower Paleozoic. Sentinel dolomite, Radcliff dolomite, and Redlands dolomitic limestone are correlated with Noonday dolomite, here assigned to Precambrian as defined in this report.

Occurs in southern part of Panamint Range, Inyo County.

**Red Lion Formation[1]**

Upper Cambrian: Western Montana.

Original reference: F. C. Calkins and W. H. Emmons, 1913, U.S. Geol. Survey Prof. Paper 78.

E. N. Goddard, 1940, U.S. Geol. Survey Bull. 922–G, p. 165 (table). Thickness 225 to 350 feet in Philipsburg district. Overlies Hasmark formation; underlies Maywood formation.

L. L. Sloss and C. A. Moritz, 1951, American Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2146–2147. Described in extreme southwestern Montana. Thickness as much as 57 feet. Overlies Hasmark formation; underlies unnamed basal Devonian unit; upper contact marked by disconformity with varying amounts of formation removed by pre-Middle Ordovician and pre-Middle Devonian erosion. Term Snowy Range would be appropriate to area; however, Red Lion, named in Philipsburg area in 1913, is equivalent to Snowy Range (Dorf and Lochman, 1938). Hence, term Red Lion is favored for beds formerly assigned to "Dry Creek" in this area.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 17–19, strat. sections. In many areas of southwestern Montana, term Dry Creek has been applied to a mappable unit composed of beds equivalent to Red Lion and overlying unfossiliferous red mudstones and silty dolomites of Maywood formation of Devonian age. Lochman (1950) restricted term Dry Creek to Peale's original usage and as thus defined, it becomes lower shale member of Red Lion and Lochman's Sage pebble conglomerate member of Snowy Range formation becomes upper member of Red Lion. Terms Dry Creek and Sage members are applicable as far west as Philipsburg. In Philipsburg area, overlies Hasmark formation; in central and southwestern Montana, overlies Pilgrim formation. Underlies Maywood formation and locally Bighorn dolomite. Thickness 34 to 350 feet.

Named for mine at head of North Fork of Flint Creek, Philipsburg region, Granite County.

Red Man Sandstone

Upper Cretaceous: Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 26–28, pls. 1, 2. Massive concretionary cavernous-weathering arkose with two thin conglomerates; contains *Parapachydiscus, Inoceramus* prisms, and Foraminifera. Thickness at type locality 1,180 feet. Conformably overlies Moonlight formation (new) in Sawtooth Ridge syncline, along south limb of Devil's Den syncline, and west of Sawtooth Ridge. Elsewhere is faulted against other units. Underlies Moreno formation. Probably equivalent to Brown Mountain sandstone (Anderson, 1941). Unit has been mapped by some workers as Point of Rocks formation.

Type locality: South limb Devil's Den syncline, Sawtooth Ridge Quadrangle, Kern County. About 2 miles northwest of synclinal axis formation crops out in prominent crags which are here named Red Man Rocks.

Red Mesa Member (of Entrada Formation)

Upper Jurassic: Northeastern Arizona, southwestern Colorado, northeastern New Mexico, and southeastern Utah.

W. B. Hoover, 1950, New Mexico Geol. Soc. Guidebook 1st Field Conf., p. 77, 78 (fig. 1), 79 (fig. 2). Introduced for the crinkly shale and sandstone beds, 100 feet thick, between the Entrada proper (lower bed of Entrada) and Bluff sandstone member.

Well exposed at west end of Red Mesa, on Utah-Arizona line, about 17 miles west of the four corners.

Red Mountain Andesite[1]

Pliocene(?): Southern California.

Original reference: C. D. Hulin, 1925, California State Min. Bur. Bull. 95, p. 55–58, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 510, table 4. Overlies Rosamond beds; older than Black Mountain basalt. Probably Pliocene.

Named for its occurrence on Red Mountain, east of Randsburg, San Bernardino County.

Red Mountain Dacites

Quaternary: Northeastern New Mexico.

Helen Stobbe, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1355. Have built volcanic cones and occur as plugs and necks.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1021 (table 2), 1022, 1031–1033, pl. 1; H. R. Stobbe, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1066–1067. Series of intrusives and extrusives. Flows exhibit uniformly whitish to light-gray fine-grained nonvesicular hornblende dacite. Partly weathers pinkish-red; the balance of rock remaining gray, markedly displaying flow structure. Age, type locality, derivation of name, and geographic distribution given.

Type locality: Red Mountain (also called Bell Mountain), after which the dacites are named, on Johnson Mesa in eastern Colfax County. Other outcrop areas include Towndrow Peak, Green Mountain, Cunningham Butte, Laughlin Peak, Palo Blanco, Raspberry Peak, and Sierra Grande.

**Red Mountain Formation**[1]

Silurian: Northern Alabama and northwestern Georgia.

Original reference: E. A. Smith, 1876, Alabama Geol. Survey Rept. Prog. for 1876, p. 11, 23, 25, 42, 207–208.

G. W. Stose, 1952, Washington Acad. Sci. Jour., v. 42, no. 8, p. 243. In Murphree Valley anticline, Alabama, formation crops out near center of anticline and underlies Chattanooga shale and overlies Chickamauga limestone.

W. H. Robinson, J. B. Ivey, and G. A. Billingsley, 1953, U.S. Geol. Survey Circ. 254, p. 50. Sandstone, shale, and calcareous and siliceous iron-ore beds. Thickness 200 to 300 feet. Overlies Chickamauga limestone; underlies Frog Mountain sandstone.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey Rept. 3, p. 25–28. Described in Madison County, Ala., where it has maximum exposed thickness of about 30 feet and is composed of thin to moderately thick beds of limestone intercalated with thin beds of sandstone and shale. Lies unconformably upon rocks ranging in age from Cambrian to Ordovician or Upper Ordovician; contact with underlying rocks not exposed in county; unconformably underlies Chattanooga shale.

Named for development on Red Mountain (presumably East Red Mountain), east of Birmingham, Ala.

Red Mountain Gneiss

Precambrian: Central Texas.

Frederick Romberg and V. E. Barnes, 1949, Geophysics., v. 14, no. 2, fig. 2 (geol. map). Shown on map legend below Big Branch gneiss and above Town Mountain granite.

V. E. Barnes *in* V. E. Barnes, D. A. Shock, and W. A. Cunningham, 1950, Texas Univ. Bur. Econ. Geology Pub. 5020, p. 7. Description of rocks and type locality should have been given in text of Romberg-Barnes paper but were inadvertently omitted. Paige (1912, U.S. Geol. Survey Geol. Atlas, Folio 183) described granite at Red Mountain. Derivation of name given.

V. E. Barnes [1952?], Geologic map of the Blowout quadrangle, Blanco, Gillespie, and Llano Counties, Texas (1:31,680): Texas Univ. Bur. Econ. Geology. The two large outcrops of Red Mountain gneiss entering the quadrangle are continuations of area of gneiss forming Red Mountain. Age relation of Red Mountain gneiss and Big Branch gneiss not known. The two gneisses may be nearly of same age and derived from common source.

Named from Red Mountain in southeastern corner of Llano quadrangle, Llano County.

†Red Mountain Group[1]

Cambrian, Ordovician, Silurian, and Devonian: Northern Alabama.

Original reference: M. Tuomey, 1850, Alabama Geol. Survey 1st Bienn. Rept., p. 9, 10.

Named for Red Mountain, east of Birmingham, Jefferson County.

Red Mountain Leucogranodiorite

Lower Cretaceous(?) : Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 209–210, 235. Grayish rock characterized by scattered dark biotite clots. Intrudes Bald Mountain tonalite (new).

Exposed along ridge that trends northeast from summit of Red Mountain, Elkhorn Mountains [Grant County]. Forms part of Bald Mountain batholith.

Red Mountain Pyroxene Basalts,[1] Flows

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 274, 281, 285, geol. map.

Red Mountain is in Plumas County, in southern part of Lassen Volcanic National Park.

Red Mountain Rhyolite[1]

Tertiary : Central Colorado.

Original reference : J. V. Howell, 1919, Colorado Geol. Survey Bull. 17.

Probably named for Red Mountain, Chaffee County.

Red Mountain Rhyolite

Tertiary : Southwestern Montana.

D. B. Andretta and S. A. Alsup, 1960, Billings Geol. Soc. 11th Ann. Field Conf., p. 187. Red rhyolite with small quartz phenocrysts. Rests on Flathead quartzite. Apperas to be truncated by Cherry Creek fault. This flow was listed as "Tertiary volcanics" on Montana State geological map.

Caps Red Mountain which is on west side of Madison River opposite mouth of Cherry Creek, Madison County.

Redoak Granite[1]

Precambrian : Central southern Virginia.

Original reference: F. B. Laney, 1917, Virginia Geol. Survey Bull. 14, p. 35–36, map.

Named for occurrence at Redoak, Charlotte County.

Red Oak Member (of Dunleith Formation)

*See* Buckhorn Member of Dunleith Formation.

Redoak Hollow Formation

Redoak Hollow Sandstone Member (of Goddard Shale)

Mississippian (Chester) : South-central Oklahoma.

M. K. Elias, 1956, *in* Ardmore Geol. Soc. Petroleum Geology of southern Oklahoma—a symposium, Tulsa, Okla., Am. Assoc. Petroleum Geologists, v. 1, p. 70 (table 2), 83–85. Fossiliferous sandstone in lower part of Goddard shale.

M. K. Elias, 1957, Jour. Paleontology, v. 31, no. 3, p. 487–527. Fossils described from Redoak Hollow formation.

Name derived from Redoak Hollow, a westward-draining valley in S½ sec. 19, T. 2 S., R. 1 W., Carter County.

Redoak Mountain Group

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 11, 19, pls. 2, 3, 4, 6, 8. Includes all strata between top of Graves Gap group (new) below and base of Vowell Mountain group (new) above, that is, between top of Windrock coal and top of Pewee coal. Thickness 300 to 440 feet; in Cross Mountain section 345 feet. Includes (ascending) shale interval, Caryville sandstone (new), shale interval, Fodderstack sandstone (new), shale interval, Silvey Gap sandstone (new), and Pewee coal.

Type locality: Cross Mountain, Lake City quadrangle, Anderson County. Name derived from Redoak Mountain in southwestern part of quadrangle, beds of group being exposed on south end of mountain above Graves Gap.

**Redonda Formation**

Redonda Member (of Chinle Formation)

Upper Triassic: Northeastern New Mexico.

Ernest Dobrovolny and C. H. Summerson, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 62. Member consists of variegated red shale, argillaceous limestone, and red or buff sandstone, and siltstone. Overlies lower unnamed member; underlies Wingate(?) sandstone. Thickness 25 to 425 feet.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2004–2006. Rank raised to formation. Consists of alternating beds of clayey siltstone and fine-grained sandstone. Thickness of beds of each lithologic type ranges from about 2 to 10 feet; greater part of unit is siltstone. Siltstone beds predominantly brownish red and commonly marked with thin streaks and spots of grayish green; sandstone beds distinctively orange red. Thickness ranges from zero at points where truncated to about 225 feet at section 18 miles west of Tucumcari; thickness commonly about 50 feet. Unconformably overlies Chinle formation; unconformably underlies Entrada sandstone. Absent over large areas owing to pre-Entrada erosion. Probably of latest Triassic age as indicated by presence of tracks of bipedal dinosaurs and a phytosaur skull. Derivation of name given.

Name taken from Redonda (also spelled Redondo) Mesa, about 15 miles south of Tucumcari, Quay County.

Redondo sandstone

Mesozoic (Early Cretacic) : New Mexico.

Charles Keyes, 1940, Pan-Am; Geologist, v. 74, no. 2, p. 105 (chart), 153. Lowest unit of Tucumcarian series. Underlies Pyramid shales; overlies Dixie shales unconformably. Thickness 250 feet.

**Red Peak Member** (of Chugwater Formation)

Red Peak Formation (in Chugwater Group)

Triassic: Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 12, 44. Red shales and sandstones, about 566 feet thick. Underlies Crow Mountain member (new); overlies Dinwoody formation. Thickness changes considerably even in adjacent sections, owing to lack of persistent beds at top of member.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 134–135. Referred to as Red Peak formation in Chugwater group. In Wind River Mountains, consists of 600 to 1,000 feet of commonly designated "red" siltstone. Overlies Dinwoody formation; underlies Alcova dolomite.

T. C. Woodward, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 230–231. Described in Deadman Butte area where it is basal member of formation, underlies Alcova limestone member, and overlies Dinwoody formation. Consists of series of pale to moderate reddish-brown siltstones with minor number of thin interbedded yellowish-gray sandstones. Thickness 600 to 875 feet.

S. S. Oriel and L. C. Craig, 1960, *in* Guide to the geology of Colorado: Denver, Rocky Mountain Assoc. Geologists, p. 45. Adoption of name Goose Egg formation by many geologists in Wyoming has resulted in restriction of names Red Peak and Chugwater to beds above Little Medicine tongue of Dinwoody formation. Red Peak member, therefore, now includes only rocks of Early and possibly of Middle Triassic age. Age designation is based primarily on intertonguing relations westward with well-dated marine Thaynes limestone in western Wyoming.

Named after Red Peak, a few miles east of Red Creek, southern margin of Absaroka Range.

Red Pine Shale (in Uinta Mountain Group)

Precambrian: Northeastern Utah.

N. C. Williams, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2736 (fig. 1), 2737 (fig. 2), 2738, 2740 (fig. 3). Mottled-brown, greenish-brown, and gray thinly bedded micaceous shale. Thickness variable due to irregular surface on which unit was deposited; 1,775 feet at mouth of Red Pine Creek; 1,200 feet, 2 miles westward in same canyon; decreases westward to South Fork basin, where it is locally absent. Conformably overlies Mutual quartzite; unconformable below Tintic quartzite (Pine Valley of previous works); where Tintic and overlying formations are absent, underlies Madison limestone. Unit has been referred to as Ophir.

R. E. Cohenour, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 34, 37 (fig. 2), 38. In this report [Uinta-Wasatch Mountain junction and part of central Utah], Red Pine shale and Mutual formation not included in Uinta Mountain group.

Type section: Along Red Pine Canyon, a tributary to Smith and Morehouse Creek, Summit County. Forms uniform slope ascending from lower contact in bottom of canyon to base of Paleozoic cliff-making formations.

**Red River Formation**[1] (in Bighorn Group)

Upper Ordovician: Surface and subsurface in Manitoba, Canada, and subsurface in Montana, North Dakota, South Dakota, and Wyoming.

Original reference: A. F. Foerste, 1929, Denison Univ. Bull., v. 29, no. 2, Sci. Lab. Jour., v. 24, p. 35, 37.

V. H. Kline, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 3, p. 345. Geographically extended into subsurface in North Dakota.

A. D. Baillie, 1952, Manitoba Dept. Mines and Nat. Resources Mines Br. Pub. 51-6, p. 14–18, geol. map. Formation consists of predominantly carbonate strata between underlying shales and sandstones of Winnipeg formation and overlying argillaceous limestones and dolostones of Stony Mountain formation. Strata comprising formation were first described by Dowling (1900, Canada Geol. Survey Ann. Rept. 1898, pt. F) who divided them into three divisions: Lower Mottled, Cat Head, and Upper Mottled. Foerste (1929) introduced term Red River formation for these strata and designated three members, Dog Head, Cat Head, and Selkirk, to correspond with the three divisions of Dowling. Thickness about 250 feet in outcrop and in wells.

H. D. Erickson, 1954, South Dakota Geol. Survey Rept. Inv. 74, p. 43. Names Trenton, Decorah, and Platteville have been used for strata now termed Red River. Present in subsurface in South Dakota.

R. J. Ross, Jr., 1957, U.S. Geol. Survey Bull. 1021–M, p. 446 (fig. 68), 447–448. Discussion of Ordovician fossils from wells in Williston basin, eastern Montana. Red River formation is basal unit of Bighorn group. Underlies Stony Mountain formation. Overlies Winnipeg formation. Members not differentiated. Upper Ordovician.

M. R. McCoy, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 27 (fig. 1), 29. Geographically extended into Powder River Basin, Wyoming, where, in most areas, it overlies Roughlock siltstone. Where Stony Mountain formation is not present, the Red River is overlain by Lodgepole formation or farther south by either Pahasapa limestone or Englewood shale.

Crops out on western and southern shores of Lake Winnipeg, Manitoba, Canada. Red River flows through southern part of outcrop.

†Red River Group[1]

Upper Cretaceous (Gulf Series): Northeastern Texas.

Original reference: B. F. Shumard, 1860, St. Louis Acad. Sci. Trans., v. 1, p. 583, 589.

Named for exposures along Red River, northeastern Texas.

Red River Loess[1]

Pleistocene: Southwestern Arkansas, Louisiana, southeastern Oklahoma, and northeastern Texas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 29–32, 188.

Named for exposures in Red River Valley at Fulton, Hempstead County, Ark.

**Red Rock Channel Sandstone**[1]

Pennsylvanian: Central southern Iowa.

Original reference: C. R. Keyes, 1891, Am. Jour. Sci., 3d, v. 4, p. 273–276.

Named for Red Rock, Marion County.

Red Rock Limestone

Triassic: Central Nevada.

F. N. Johnston, 1941, Jour. Paleonotology, v. 15, no. 5, p. 448. Massive limestone, badly jointed fractured and veined with calcite. Thickness 800 feet.

In South Canyon, New Pass or Desatoya Range. So named because it is believed to be equivalent to the "Red Rocks" at the head of Congress Canyon, West Humboldt Range.

Red Rock member[1]

Precambrian (Keweenawan) : Northeastern Minnestoa.

Original reference: A. H. Elftman, 1898, Am. Geologist, v. 21, p. 90–109, 175–188.

Named for its persistent red color.

Red Rock Rhyolite (in Yavapai Group)

Precambrian : Central Arizona.

E. D. Wilson, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 112; 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1118 (table 1), 1120–1121, pl. 10. Dominantly rhyolitic rocks, consisting of flows and minor amounts of agglomerate, breccia, and intrusives. Characteristically massive, with flow banding or bedding apparent only in places. Intrusive masses not readily distinguishable from flows. Typical rhyolite is grayish-brown to reddish-brown dense rock that breaks with splintery fracture; in places porphyritic. Thickness apparently exceeds 1,000 feet. Middle member of group; in fault contact with Yaeger greenstone (new) below and Alder series (new) above.

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (table 2). Placed stratigraphically above Alder series; unconformably underlies Deadman quartzite.

Named from typical occurrence in Red Rock Butte, in central segment of Mazatzal Range. Also crops out prominently in Pine Creek, eastern Tonto Basin, and southern Black Hills areas.

†Red Rock Canyon Beds[1]

Pliocene, lower : Southern California.

Original reference: J. C. Merriam, 1919, California Univ. Pub., Dept. Geol. Bull., v. 11, no. 5.

In Red Rock Canyon at Ricardo, eastern part of Kern County.

**Redrock Canyon Sandstone Member** (of Santa Margarita Formation)[1]

Miocene, upper : Southern California.

Original reference: W. A. English, 1916, U.S. Geol. Survey Bull. 621, p. 191–215.

Named for occurrence in small area in Redrock Canyon, Cuyama Valley, southwestern part of Kern County.

Red Shale Butte Complex

Pleistocene : Northern California.

C. A. Anderson, 1941, California Univ. Dept., Geol. Sci. Bull., v. 25, no. 7, p. 364–365. Made up of a number of coalescing flows characterized by andesitic lavas.

Occurs in Medicine Lake Highland, approximately in center of Modoc Lava Bed quadrangle.

**Red Spring Sandstone Member** (of Hignite Formation)[1]

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 43.

Named for association with Red Spring coal in Cumberland Gap coal field.

Redstone Clay (in Monongahela Formation)[1]

Redstone underclay member

Pennsylvanian: Western Pennsylvania and eastern Ohio.

[Original reference]: M. G. Wilmarth, 1938, U.S. Geol. Survey Bull. p. 1789.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 70. Redstone clay member (Monongahela series) recognized in several exposures in Union Township, Morgan County.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 169. Underclay member of Redstone cyclothem in report on Athens County. Average thickness 1 foot. Monongahela series.

Redstone cyclothem

Pennsylvanian (Monongahela Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 167–170. Embraces interval between Upper Pittsburgh cyclothem (new) below and Fishpot cyclothem (new) above. Except for locality where Upper Pittsburgh cyclothem is developed, the Redstone includes rock units from top of Pittsburgh roof shale to top of Redstone roof shale. Wherever Redstone cyclothem extends downward to top of Pittsburgh roof shale, all members common to Monongahela cyclothems are present; normal sequence includes six members (ascending): Upper Pittsburgh shale and sandstone, Redstone redbed, Redstone limestone, Redstone underclay, Redstone (Pomeroy) (No. 8a) coal, and roof shale. Where base of Redstone rests on Upper Pittsburgh coal, thickness of cyclothem is 25 feet; where base overlies Pittsburgh roof shale, which is commonly the case, average thickness is 35 feet. In area of this report Monongahela series is discussed on a cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Present in Athens County.

Redstone Granite[1]

Pre-Triassic: Southeastern Connecticut and southwestern Rhode Island.

Original reference: L. H. Martin, 1925, Connecticut Geol. Nat. History Survey Bull. 33.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Pre-Triassic. Derivation of name stated.

Named for Redstone Ridge north of Westerly, R. I., and Pawcatuck, Conn.

**Redstone Limestone Member** (of Monongahela Formation)[1]

Redstone Limestone (in Monongahela Group)

Redstone limestone and shale member

Upper Pennsylvanian: Western Pennsylvania, western Maryland, Ohio, and northern West Virginia.

Original reference: F. Platt and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$, p. 55–104, 286.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. M–26, p. 119. Included in Monongahela group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 70–71, geol. map. Redstone limestone and shale member (Monongahela series) occupies interval between Upper Pittsburgh sandstone and shale member and the Redstone (Pomeroy) (No. 8–A) coal. In Morgan County, the Redstone is represented only locally by limestone; the usual exposure consists of calcareous shales, whose boundaries are indefinite. In many areas, Redstone limestone and shale interval is occupied by the merging Upper Pittsburgh and Pomeroy sandstones. Superjacent Redstone (No. 8–A) coal present only locally; hence, summit boundary indefinite in areas where Pomeroy sandstone is not well developed or where that unit is represented by thin limestones and shales. Where boundaries of Redstone limestone and shale member can be determined, a thickness of 10 to 18 feet is indicated.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 169. Redstone limestone member of Redstone cyclothem in report on Athens County. Average thickness 5 feet. Monongahela series.

Named because it occurs immediately below Redstone coal, which outcrops along Redstone Creek, Fayette County, Pa.

Redstone Member (of Monongahela Formation)[1]

Redstone redbed member

Pennsylvanian: Western Pennsylvania and eastern Ohio.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 169. Member of Redstone cyclothem in report on Athens County. Thickness 3 to 20 feet. Wherever Upper Pittsburgh sandstone is exceptionally thick, Redstone redbed member may be missing, its interval occupied by sandstone. Monongahela series.

†Redstone Quartzite[1]

Precambrian: Central southern Minnesota.

Original reference: F. W. Sardeson, 1908, Geol. Soc. America Bull., v. 19, p. 221–242.

Composes Redstone Hill in Courtland Township, midway between towns of New Ulm, Brown County, and Courtland, Nicollet County.

Redstone Sandstone (in Monongahela Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 567–596.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 119 (table 1). Table of classification and nomenclature lists Redstone sandstone in Monongahela series. Equivalent to Fishpot limestone.

Probably named for its relation to Redstone coal.

Redstone Ridge Group[1]

Silurian: Central Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 2, p. 823.

Probably named for Redstone Ridge.

**Red Tanks Member** (of Madera Limestone)

Pennsylvanian: West-central New Mexico.

V. C. Kelley and G. H. Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. Lower part of member consists of dark-red-brown siltstone, sandstone, and shale. Locally, as in Carrizo Arroyo, base contains buff sandstone and limestone conglomerate. Upper part consists mostly of cement-gray thin-bedded nodular limestone and gray shale. Most prominent limestone generally at top of member. Thickness 200 to 300 feet. Some intertonguing of marine sediments of Red Tanks member with continental beds of overlying Abo formation. Conformably underlain by Atrasado member (new) of Madera limestone.

Forms continuous belt along eastern side of Los Vallos from Breach Canyon on north to west floor of Monte de Belen on south. Also exposed in wide fork extending south from Carrizo Arroyo where the most complete section of the member is exposed. Crops out in several places in tributaries of Red Tanks Arroyo, for which member is named, located in secs. 4 and 5, T. 3 N., R. 3 W., Valencia County. Also crops out in Comanche Arroyo.

Red Top Limestone[1] (in Stevens Series)

Middle Cambrian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 80, map.

C. D. Campbell, 1947, Geol. Soc. America Bull., v. 58, no. 7, p. 602 (table 4), 611, pl. 1. Remapping of northeastern Stevens County and discovery of Cambrian and Ordovician fossils are thought to justify adoption there of formation names established by Park and Cannon (1943) for the Metaline quadrangle. Correlative with the Middle Cambrian Metaline limestone are most of Weaver's Northport limestone, Republican Creek limestone, Red Top limestone, and Deep Lake argillite, and part of Boundary phyllite.

Probably named for occurrences on Red Top Mountain, Stevens County.

**Redwall Limestone**[1]

Mississippian: Northern Arizona, New Mexico, and Utah.

Original reference: G. K. Gilbert, 1875, U.S.G. and G.S.W. 100th M., v. 3, p. 162, 177–186, 197, figs. 81, 82.

A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 495. At Jerome, Ariz., unconformably overlies Devonian Jerome formation; disconformably underlies Permian Supai. Thickness 300 feet.

R. C. Gutschick, 1943, Plateau, v. 16, no. 1, p. 1–11. In Yavapai County, comprises four unnamed members (ascending): white crystalline oolitic limestone; fine-grained cherty porous limestone; massive coarsely crystalline limestone; gray micro-oolitic dense limestone. Thickness about 285 feet. Overlies Jerome formation; underlies Supai formation. Kinderhook and Osage.

E. D. Koons, 1945, Geol. Soc. America Bull., v. 56, no. 2, p. 154. In Grand Canyon, east of Toroweap fault, overlies Temple Butte formation; underlies Supai formation. Thickness 600 feet.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 28). Correlation chart shows age range (southwestern Utah) Kinderhook-Chester.

A. N. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 515 (fig. 2), 518. Section from South Hurricane Cliffs to a little beyond Peach Springs Canyon, Ariz., shows Redwall limestone underlying tongue of Callville formation; southeastward underlies Supai red beds. Laterally equivalent to Rogers Spring limestone.

J. W. Huddle and Ernest Dobrovolny, 1952, U.S. Geol. Survey Prof. Paper 233–D, p. 77 (fig. 14), 81 (fig. 19), 86–90, geol. sections. Thin limestone of Mississippian age in central Arizona is equivalent of Redwall limestone of northwestern Arizona and Escabrosa limestone of southeastern Arizona. Name Redwall extended for use in central Arizona as it has priority over Escabrosa. Consists of lower impure dark-gray limestone, 50 to 70 feet thick; a middle massive cliff-forming limestone; and an upper thin- to medium-bedded cherty limestone. North of Salt River these divisions tend to disappear, and formation there consists of loose blocks of limestone, surrounded by red sandy mudstone, and a few solid limestone beds. Thickness as much as 552 feet. Overlies Devonian Martin formation; underlies Pennsylvanian Naco formation.

G. W. Crosby, 1959, Brigham Young Univ. Research Studies, Geology Ser., v. 6, no. 3, p. 20–21, 52. In Millard County, Utah, disconformably overlies Cove Fort quartzite (new).

Type locality: Shinumo drainage basin, on north side of Grand Canyon. Named for red appearance of its escarpment on either side of Grand Canyon.

**Red Warrior Limestone**[1]

Silurian (?) and Devonian (?) : Southwestern Utah.

Original reference: B. S. Butler, 1913, U.S. Geol. Survey Prof. Paper 80.

J. J. McFarlane, 1955, Brigham Young Univ. Research Studies, Geology Ser., v. 2, no. 5, p. 19 (fig. 1), 21. Although formation was thought to be Silurian and Devonian, it actually includes representatives of Ordovician, Silurian, and Devonian systems. Lower Red Warrior limestone was correlated with Ordovician Fish Haven dolomite of northern Utah. Chart shows Red Warrior limestone above Morehouse quartzite and below Mowitza shale.

Type locality: Red Warrior mine, southeast of Frisco district.

Red Wash Formation

Lower Triassic: Northeastern Utah and northwestern Colorado.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 477, 478. As Woodside, Thaynes, and Ankareh (restricted) formations are traced eastward along flank of Uinta Mountains, each becomes thinner, and in vicinity of Whiterocks Canyon the Thaynes disappears completely. Red beds east of that point are in part equivalent to Ankareh (restricted) sandstone and shale and in part to Woodside shale. Since none of the terms Woodside, Ankareh, or Moenkopi can appropriately be applied to these beds, name Red Wash formation is proposed. Thickness at type locality 1,080 feet. At type section, overlies Park City formation and underlies Shinarump conglomerate, both contacts unconformable.

B. F. Curtis, 1951, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 39. Stratigraphic column shows Red Wash formation present in vicinity of Vermillion Creek, Colo. Occurs below Stanaker formation and above Phosphoria formation. Permian and Triassic.

W. F. Scott, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 101–102. Discussion of stratigraphy of Triassic sequence in Wasatch and Uinta Mountains. William's introduction of name Red Wash rather than Moenkopi does not seem justified.

Type section: In Red Wash Canyon north of Dinosaur quarry in Dinosaur National Monument, Utah; section measured on Brush Creek along traverse beginning near mouth of Brush Creek Gorge in sec. 3, T. 2 S., R.

22 E., Uinta Base and Meridian, and running southward to base of Shinarump conglomerate.

**Redwater Shale Member** (of Sundance Formation)

Upper Jurassic: Southwestern South Dakota and northwestern Wyoming.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 259–264, geol. sections. Consists of 80 to 190 feet or more of greenish-gray to gray soft fissile shale that includes some soft glauconitic sandstone in lower 20 to 30 feet and some thin beds of coquinoid or oolitic limestone in upper half. At type section, lower 18 feet consists of alternating beds of gray shale and soft yellow sandstone; upper 118 feet consists mainly of soft dark-gray shale but contains lenses of sandy limestone at several levels and many limestone concretions in upper half. Overlies Lake member (new); underlies Morrison formation, contact gradational through an interval of 10 to 15 feet.

Type section: Bluff one-half mile north of Redwater Creek, near mouth of Crow Creek, 9 miles northwest of Spearfish, in S½ sec. 2, T. 7 N., R. 1 E., Butte County, S. Dak.

Redwood Formation[1]

Oligocene: Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 770–782.

Occurs between Redwood and Burls Creeks and ridge between Cave and Hey Point, Katalla district, Controller Bay region

Redwood Creek Schist

*See* Kerr Ranch Schist.

Ree Beds[1]

Eocene or Oligocene: South Dakota.

Original reference: E. D. Cope, 1892, Am. Assoc. Adv. Sci. Proc., v. 40, p. 285.

Ree Heights is in Hand County.

**Reed Dolomite**[1]

Precambrian(?): Eastern California.

Original reference: E. Kirk, 1918, U.S. Geol. Survey Prof. Paper 110.

C. R. Longwell, 1952, Washington Acad. Sci. Jour., v. 42, no. 7, p. 42. In view of a study made of lower limit of the Cambrian in the Cordilleran region, it is believed that Reed dolomite should be carried under the heading of "age unknown." Designation of definitely Precambrian does not seem warranted by evidence now available.

Named for exposures along east side of Reed Flat; best section in canyon at head of Wyman Creek, in sec. 7, T. 6 S., R. 35 E., Inyo Range.

Reed Formation[1]

Upper Mississippian: Central northern Utah.

Original reference: F. F. Hintze, Jr., 1913, New York Acad. Sci. Annals, v. 23, p. 109.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 136. Reed (or Reade) and Benson formations are approximately equivalent to

Brazer and Madison, respectively; not certain that boundaries between formations correspond.

Exposed in Big Cottonwood Canyon at north end of Reade and Benson Ridge, which separates Big Cottonwood Canyon from Day's Fork, central Wasatch Mountains.

Reed Canyon Silt Member (of Tejon Formation)

Eocene, upper: Southern California.

J. G. Marks, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1922. Listed as upper member of Tejon formation in type area of Tejon. Thickness 160 feet. Shown as unconformably underlying continental deposits of Oligo-Miocene age and overlying Metralla sandstone member (new) of Tejon formation.

J. G. Marks, 1943, California Div. Mines Bull. 118, pt. 3, p. 535, 536 (fig. 232), 537 (fig. 233). Shale, glauconitic silt, and fine sand. Shown on stratigraphic column as unconformably underlying Tecuya formation.

Type locality: Reed Canyon, Tehachapi Mountains, Kern County.

†Reeder Sandstone[1]

Uppper Cretaceous: Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 381, 382.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Dakota formation as herein defined contains stratigraphic units formerly called "Rocktown channel sandstone," "Ellsworth formation," "Solomon formation," "Reeder sandstone," "Marquette sandstone," "Spring Creek clay," and others.

Named for exposures in upper valley of Medicine Lodge River near post office at Reeder. Town of Reeder now abandoned. Upper valley of Medicine Lodge River is in Kiowa and Barber Counties.

Reedian series

Precambrian (Protozoic): Eastern California.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 4, p. 307 (chart). Listed as a series consisting of 2,500 feet of dolomites. Unconformable below Deepian series and above Wymanian series.

Occurs in Death Valley region.

Reeding Sandstone

Permian: Western Oklahoma.

Henry Schweer *in* O. E. Brown, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1553 (fig. 9). Shown on cross section a little above middle of Hennessey formation.

Type locality and derivation of name not given.

Reeds Creek Andesite

Eocene, middle, to Oligocene, lower: Northern California.

B. L. Clark and C. A. Anderson, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 935 (fig. 2), 938, 940–941. Andesitic conglomerates and breccias. Rests in part on basement complex and is in part intercalated with or lies above Ione formation.

Occurs in Sacramento Valley near Wheatland, Yuba County.

**Reeds Spring Chert Member** (of Boone Formation)

**Reeds Spring Limestone**[1]

Reeds Spring Formation

Reeds Spring Member (of Chouteau Formation)

Lower Mississippian : Southwestern Missouri and northeastern Oklahoma.

Original reference: R. C. Moore, 1928, Missouri Bur. Geology and Mines v. 21, 2d ser., p. 143–145, 161–163, 169, 170, 190, 191, 193.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 184 (fig. 28), 196–199, 202–204. Report refers to Reeds Spring limestone and quotes extensively from unpublished manuscript by Clark (1941) who classed Grand Falls chert as member of the Reeds Spring. Report also refers to Reeds Spring member of Chouteau formation.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 43–44, pls. Formation described in northeastern Oklahoma where it is as much as 175 feet thick and consists of nearly equal amounts of thin alternating fine-grained dense thin-bedded limestone and dark-gray to blue-gray chert. Unconformably overlies St. Joe, Chattanooga, and St. Clair formations; unconformably underlies Keokuk formation. Osagean.

C. H. Behre, Jr., and A. V. Heyl, Jr., 1958, Deutschen Geol. Gesell., Zeitschr., v. 110, pt. 3, p. 517 (fig. 2). Chart shows Reeds Spring member in lower part of Boone formation. Thickness 30 to 45 feet.

Named for exposures in vicinity of Reeds Spring, Stone County, Mo.

**Reedsville Shale**[1]

Upper Ordovician: Central Pennsylvania, eastern Tennessee, and southwestern Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 27.

Charles Butts and E. S. Moore, 1936, U.S. Geol. Survey Bull. 855, p. 43–45, pls. 1, 3. In Bellefonte quadrangle, Pennsylvania, 1,000 feet thick and consists of dark calcareous shale with thin layers of fossiliferous limestone. Thick-bedded calcareous sandstone at top, 40 feet thick, carrying *Orthorhynchula* and *Byssonichia; Orthorhynchula* zone. Overlies Trenton limestone; underlies Oswego sandstone.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 2, p. 114. Restricted below to exclude about 400 feet of dark brownish-weathering shale herein named Antes shale.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, pls. Mapped in eastern Tennessee where, east of Kingston fault, it overlies unit 4 of Chickamauga limestone; thickness 250 to 400 feet. Underlies Sequatchie formation. In folio mapping the Reedsville was largely ignored though Hayes (1894, folio 4; 1895, folio 20) called it Athens shale and Keith (1901, folio 85) thought it represented featheredge of Sevier shale.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 71–73, measured sections. Described in Jonesville district, Lee County, Va., where it conformably overlies Trenton limestone and conformably underlies Sequatchie formation. Thickness 282 to 460 feet.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geology Contr. 3, 58p. From Tyrone Gap to Susquehanna Gap, underlies Bald Eagle sandstone (Centennial School member, new, in western part of area).

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 7, pl. 1. Reedsville of central Pennsylvania is equivalent to Martinsburg formation of eastern Pennsylvania. Transitional with underlying Trenton limestone; underlies Bald Eagle formation. Thickness approximately 1,000 feet.

Named for exposures at Reedsville, Mifflin County, Pa.

**Reef Ridge Shale**[1]

Reef Ridge Shale Member (of Monterey Formation)

Miocene, upper: Southern California.

Original reference: W. F. Barbat and F. L. Johnson, 1933, Pan-Am. Geologist, v. 59, no. 3, p. 239.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 165. Treated as a member of Monterey formation.

S. S. Siegfus, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 1, p. 24–44. Restricted at its type locality to exclude brown shales and silts in lower part of the originally defined Reef Ridge shale because that part of the section has been included in McLure shale by Henney (1930). As thus restricted, formation corresponds more nearly with the "caving blue shale" of Kettleman Hills. Thickness about 300 feet. Underlies Jacalitos formation; overlies McLure shale; upper and lower contacts gradational at type locality.

Exposed on Reef Ridge, west of Kettleman Hills, Fresno and Kings Counties.

Reel Limestone Member (of Bond Formation)

Reel Limestone (in McLeansboro Group)

Pennsylvanian: Southeastern and eastern Illinois.

G. H. Cady and others, 1955, Illinois Geol. Survey Rept. Inv. 183, p. 7 (fig. 3), 8–9. Fine-grained compact fossiliferous limestone faintly mottled in shades of dove to gray with irregular reddish-brown spots; weathers grayish yellow. Identification of limestone not based upon lithologic characteristics but upon its relative position and the absence of other limestone beds for some distance above and below; 1 foot of dark-gray to black shale underlies limestone and overlies a coal bed 7 to 10 inches thick. Columnar section shows Reel limestone stratigraphically below Friendsville limestone and above Mount Carmel sandstone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), pl. 1. Rank reduced to member status in Bond formation (new). Occurs above Flannigan coal member and below Livingston and Millersville limestone members. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Sec. 8, T. 1 S., R. 12 W., Wabash County. Named from exposures on Emmanual Reel Farm.

**Reelsville Limestone**

Reelsville Limestone[1] (in West Baden Group)

Reelsville Limestone Member (of Paint Creek Formation)

Mississippian (Chester Series): Southwestern Indiana and northern and central Kentucky.

Original reference: C. A. Malott, 1919, Indiana Univ. Studies, v. 6, no. 40, p. 7–20.

R. E. Stouder, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 3, p. 268 (fig 1), 269, 270 (fig. 2), 274 (fig. 3), 275–276. Paint Creek is used here to include group of formations above Sample sandstone and below Cypress sandstone between Ohio River and southern end of Hardin and Breckinridge Counties, Ky. The three formations of the Paint Creek are correlatives of three formations of Indiana (ascending): Reelsville limestone, Elwren sandstone and shale, and Beech Creek limestone. Names Reelsville and Elwren are here proposed for two lower members of the Kentucky formation; term *Productus inflatus* zone is used for upper member. Thickness of Reelsville 28 feet near Germantown, Breckinridge County; in Gasper River region, thickens and rests on underlying Renault with no apparent break in sedimentation.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 828; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 76). Considered member of Paint Creek formation in Indiana.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations in southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7, 26–27. Paint Creek of standard Chester column has triple expression in southern Indiana (ascending): Reelsville limestone, Elwren sandstone, and Beech Creek limestone. Each of these is a distinct stratigraphic unit in parity with other formations of the Chester and deserves name in its own right. At designated type section, Reelsville limestone is 2⅔ feet thick. Truncated and overlapped by Pennsylvanian Mansfield sandstone and not present north of Reelsville. Putnam County.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 24–25, pl. 1. In Indiana, Reelsville limestone is less than 10 feet thick and commonly is exposed as a single massive bed in which entire thickness is represented; locally absent and stratigraphic interval represented by clastic rocks. Underlies Elwren sandstone; overlies Sample sandstone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 45–46, pl. 1. Included in West Baden group (redefined). Thickness 0 to 7 feet. Underlies Elwren formation; overlies Sample formation.

Type section: Near center sec. 21, T. 13 N., R. 5 W., along highway downhill, south bluff of Walnut Creek, just south of Reelsville, Putnam County, Ind.

**Reese Formation**[1]

Eocene(?): Central southern Montana.

Original reference: W. R. Calvert, 1912, U.S. Geol. Survey Bull. 471, p. 412.

Type locality: Reese Creek, Park County.

**Reeve Meta-Andesite**[1]

Pennsylvanian: Northern California.

Original reference: J. S. Diller, 1908, U.S. Geol. Survey Bull. 353.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California Westwood sheet (1:250,000): California Div. Mines. Mapped with Permian marine sedimentary and metasedimentary rocks.

Named for unidentified locality near Genesee, east of Taylorsville, Plumas County.

Reformatory Granite[1]

Precambrian: Southwestern Oklahoma.

Original reference: C. H. Taylor, 1915, Oklahoma Geol. Survey Bull. 20.

C. A. Merritt, 1958, Oklahoma Geol. Survey Bull. 76, p. 33–38, pl. 1. Described in Lake Altus area as coarsely crystalline reddish granite, locally containing xenoliths of gabbro, andesite or aplite. Considered to include unit formerly termed Flat Top granite, that occurs on Flat Top and Soldier's Spring Mountains.

Exposed in Quartz Mountain-Headquarters Mountain area. Named after the quarry rock at the State Reformatory near Granite, Greer County.

Refugian Stage[1]

Oligocene: California.

Original reference: H. G. Schenck and R. M. Kleinpell, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 2, p. 215–225.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 99–103, fig. 14 (correlation chart). Stage nearly everywhere occurs conformably above beds considered age equivalents of Upper Tejon formation, although irregular contacts are reported in some areas. Subjacent to lower Miocene Zemorrian stage.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 73. Refugian stage occurs conformably above beds of Narizian age nearly everywhere.

Type locality: Canada de Santa Anita, on south side of Santa Ynez Mountains, Santa Barbara County, about 5 miles west of Gaviota Pass. Name derived from the Spanish land grant "Nuestra Senora del Refugio".

Reisner Limestone Member (of Mattoon Formation)

Pennsylvanian: Central and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 41, 51 (table 1), pl. 1. Proposed to replace name Newton limestone; name Newton preempted. Uppermost member of formation; stratigraphically above Woodbury limestone member. Thickness about 9 inches. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NE¼ sec. 16, T. 7 N., R. 10 E., Jasper County. Named for Reisner School 1½ miles southwest of type outcrop.

**Reklaw Member** (of Mount Selman Formation)[1]

Reklaw Formation (in Claiborne Group)

Eocene, middle: Eastern Texas and northwestern Louisiana.

Original reference: A. C. Ellisor, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 1339–1346.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 65–78 [1938]. Rank raised to formation in Claiborne group. Thickness about 80 feet. Comprises Newby glauconitic sand member below and Marquez shale member above (both new). Unconformably overlies Carrizo sand; underlies Queen City sand.

B. W. Blanpied and R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 128 (correlation chart). Correlation chart shows Reklaw formation includes Arp sand member (new).

H. B. Stenzel, 1950, Texas Univ. Bur. Econ. Geology Pub. 5019, p. 23–27, pl. 1. Recent work indicates that the Reklaw, as described by Wendlandt and Knebel (1929, American Assoc. Petroleum Geologists Bull., no. 10) that is, the 20 to 40 feet of brown to dark-blue micaceous sandy clay, does not belong in Reklaw because it interfingers with and grades laterally into Carrizo sand and is separated from Reklaw glauconites by regionally continuous disconformity. Reklaw, as restricted here, consists of two divisions, a lower glauconite 4 to 15 feet thick and an upper brown shale as much as 100 feet thick. These two divisions are precisely the two members described by Stenzel (1939) [1938] in Leon County.

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 243–C, p. 37. Because of similarity of their stratigraphic position above Carrizo sand and similarity of ferruginous beds partly composing them, Reklaw and Bigford members of Mount Selman formation have been regarded as contemporaneous. Geographic and stratigraphic positions of fossiliferous ferruginous sandstones north of Leming, Atascosa County, suggest that they represent eastward extension of the Bigford from Frio County; if the Leming and Scruggs Creek localities should prove to represent the same zone, then on assumption that the conglomerate is basal part of the Reklaw, it would appear that the Bigford is not exact equivalent of the Reklaw, but is older and intervenes between the Carrizo sand and the Reklaw.

H. B. Stenzel, 1953, Texas Univ. Bur. Econ. Geology Pub. 5305, p. 34–83. Described in Henrys Chapel quadrangle where it includes Newby glauconitic sand member and Marquez shale member. Thickness about 40 feet. Overlies Carrizo sand; underlies Arp member of Queen City formation.

Well exposed at Reklaw, Cherokee County, Tex.

Relay Quartz Diorite[1]

Ordovician [?]: Northeastern Maryland.

Original reference: E. B. Knopf and A. I. Jonas, 1929, Maryland Geol. Survey Baltimore County Rept., p. 104.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 43 (table 7), 63. At least three periods of granite formation are recognized in Maryland rocks. The oldest are the probable migmatites associated with Baltimore gneiss; those of second period cut the Glenarm series; the Relay quartz diorite is among representatives of the second period. Table lists unit under Ordovician with comment, age uncertain.

Occurs at Relay on Patapsco River, Baltimore County.

**Relay Creek Dolomite Beds** (in Marlow Formation)

Relay Creek Dolomite[1]

Relay Creek Dolomite or Dolostone Member (of Whitehorse Formation)

Permian: Northwestern Oklahoma and southern Kansas.

Original reference: N. Evans, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4, p. 405–432.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1803, 1804–1805. Dolomite member of Whitehorse sandstone. In Kansas, Whitehorse sandstone is divided into four members: Marlow, Relay Creek dolomite, an even-bedded sandstone member, and an upper shale member. In Oklahoma, Relay Creek dolomites are regarded as being upper part of Marlow.

L. V. Davis, 1955, Oklahoma Geol. Survey Bull. 73, p. 64. Relay Creek dolomite beds included in upper part of Marlow formation. Consists of two thin beds separated by 15 to 20 feet of red sandy shale.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as Relay Creek dolostone member of Whitehorse formation.

Named for exposures both north and south of Relay Creek in T. 15 N., R. 12 W.

**Relief Quartzite**[1]

Mississippian: Northern California.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey Geol. Atlas, Folio 66.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 15). Shown on correlation chart above Kanaka formation and below Cape Horn slate.

Named for exposures at Relief, Colfax quadrangle.

Relizian Stage[1]

Miocene, middle: California.

Original reference: R. M. Kleinpell, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 3, p. 376–378.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 117–121, fig. 14 (correlation chart). Superjacent to Saucesian stage and subjacent to Luisian stage. Comprises two zones: *Siphogenerina hughesi* and *Siphogenerina branneri*. Systematic catalogue.

Type locality: Reliz Canyon, Monterey County.

**Remick Tonalite**[1] (in New Hampshire Plutonic Series)

Upper Devonian(?): Northwestern New Hampshire.

Original reference: M. P. Billings, 1935, Geology of Littleton and Moosilauke quadrangles, New Hampshire, p. 28, maps.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 507–508, pls. 1, 12. Included in New Hampshire magma series. Distribution on map indicates it is younger than Albee and Ammonoosuc formations.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Included in New Hampshire plutonic series whose age is Upper Devonian(?).

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 54. Derivation of name.

Named for Remick Park, a municipal park in Littleton, Grafton County.

Remmel Granodiorite[1]

Jurassic(?): Central northern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

Probably composes the cliffs of Mount Remmel, Wash., 5 miles south of international boundary.

**Renault Formation**[1]

Renault Formation (in New Design Group)

Upper Mississippian (Chester Series): Southwestern and southeastern Illinois, southern Indiana, western and central Kentucky, and southeastern Missouri.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 122.

R. E. Stouder, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 3, p. 268 (fig. 1), 269, 270 (fig. 2), 271–273. In Meade, Hardin, and Breckinridge Counties, Ky., Renault formation consists of (ascending) unnamed limestone ranging in thickness from 0 to 23 feet, Mooretown sandstone, and Beaver Bend limestone members; the latter two names being geogphically extended from Indiana. Overlies Ste. Genevieve limestone; underlies Sample sandstone.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 824–826. Renault formation assigned to New Design group (new). In standard Mississippian section, overlies Aux Vases sandstone and underlies Bethel sandstone. In southwestern Illinois, underlies Yankeetown chert. Locally in southern half of Monroe County, Ill., overlaps Aux Vases and becomes basal member of Chester series. In Johnson, Pope, and Hardin Counties, Ill., and adjacent parts of Kentucky, formation is divisible into two members which are locally unconformable; the lower, or Shetlerville member, is typically developed in Hardin County, Ill. Eastward in Kentucky, shaly layers of Renault become less conspicuous, and formation consists of a limestone that cannot be distinguished from Paint Creek formation where Bethel sandstone is absent; from Todd to Grayson County, this limestone unit is known as Girken limestone. In Indiana, consists of three members (ascending): Paoli, Mooretown, and Beaver Bend. Also present in Ste. Genevieve County, Mo.

Elwood Atherton, 1947, Illinois Acad. Sci. Trans., v. 40, p. 129, 130 (fig. 7), 131 (fig. 8). In Hardin County, Ill., formation comprises Shetlerville member below and Downeys Bluff member (new). Overlies Levias member of Ste. Genevieve formation.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7. Renault formation of standard Chester column has triple expression in Indiana (ascending): Paoli limestone, Mooretown sandstone, and Beaver Bend limestone. Each of these is a distinct stratigraphic unit in parity with other formations of the Chester and deserves a name in its own right.

Named for Renault Township, Monroe County, southwestern Illinois. Typically developed in valley of Horse Creek and its tributaries in eastern part of Township.

Rencher Formation

Tertiary: Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 18–25, 57–59. Complex assemblage of welded tuff and tuff-breccia, breccia, air-fall tuff, bedded tuff-breccia, volcanic sandstone, and lenticular limestone and conglomerate. Maximum thickness of 600 feet. Overlies

Quichapa group (new) unconformably; underlies Atchinson formation (new).

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 92 (fig. 2), 97, 98. Overlies Quichapa formation; underlies Page Ranch formation. Zircon age dating suggests that Rencher-Page Ranch period of extrusive-intrusive igneous activity is late Oligocene or early Miocene.

Type locality: Vicinity of Rencher Ranch at north end of Grass Valley, Pine Valley Mountains, Washington and Iron Counties.

†Renfroes Marl[1]

Upper Cretaceous: Western Georgia.

Original reference: J. O. Veatch, 1909, Georgia Geol. Survey Bull. 18, p. 86–89.

Named for exposures at Renfroes, Chattahoochee County.

**Rennie Shale**[1]

Middle Cambrian: Northern Idaho.

Original reference: E. Sampson, 1928, Idaho Bur. Mines and Geology Pamph. 31, p. 9.

C. E. Resser, 1938, Smithsonian Misc. Colln., v. 97, no. 3, p. 2–3. Consists of soft olive argillaceous shale, sometimes micaceous. Thickness 50 to 75 feet. Overlies Gold Creek quartzite; underlies Lakeview limestone.

Crops out in stream along west side of Rennie Ridge, a spur on south side of Packsaddle Mountain, Pend Oreille district.

Rennix Limestone[1]

Upper Ordovician (Richmond): Southeastern Kentucky.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 435.

Named for Rennix Creek, Cumberland County.

Reno Member (of Franconia Formation)

Upper Cambrian: Eastern Minnesota and southwestern Wisconsin.

R. R. Berg, 1951, Minnesota Geologist, v. 8, no. 4, p. [2]; 1953, Jour. Paleontology, v. 27, no. 4, p. 555; 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 864–865, measured sections. Consists of beds of wormstone with high glauconite content, separated by thinner beds of crossbedded greenstone; thin beds of greenstone conglomerate are common; top of member is marked by a 1- to 6-foot bed of dolomitic, flat-pebble conglomerate. Thickness at type locality 116 feet. Overlies Tomah sandstone member (new); interfingers with Mazomanie member (new).

Type locality: In Hell Hollow, 1½ miles north of Reno, SE¼ sec. 23, T. 102 N., R. 4 W., Houston County, Minn.

**Rensselaer Graywacke**[1]

Lower Cambrian(?): Eastern New York.

Original reference: T. N. Dale, 1893, U.S. Geol. Survey 13th Ann. Rept., pt. 2, p. 301–340, map.

Rudolf Ruedemann, 1942, New York State Mus. Bull. 327, p. 1–17. Discussion of supposed occurrence of *Oldhamia* in Rensselaer grit. It is apparent that *Oldhamia occidens* of the Nassau beds and the supposed *Oldhamia* of the grit are of entirely different nature and origin and the

Rensselaer grit "*Oldhamia*" can not be used for correlation of the Rensselaer with the Nassau beds or any other Cambrian formation.

Theodore Arnow, 1951, New York Water Power and Control. Comm. Bull. GW–25, p. 8 (table 1), 11, pl. 2. Only outcrop of Rensselaer graywacke in Columbia County is small outlier in northern part of county. Thickness of outlier not known but believed to approximate the 1,400 feet assigned to main body of Rensselaer graywacke plateau that lies north of Columbia County. Lower Cambrian(?). Considered to have been deposited at same time Schodack and Nassau formations were deposited. Underlies Stockbridge limestone.

Named for exposures on upper part of east side of Renssalaer grit plateau, eastern New York; also the southeastern, western, and northern faces of the plateau.

**Renwick Shale Member** (of Genesee Formation)

Renwick Shale (in Ithaca Shale)

Renwick Shale Member[1] (of Middlesex Shale)

Upper Devonian: South-central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 202.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4. Shale reallocated to base of Ithaca shale. Underlies Six Mile shale; overlies Cornell shale and sandstone.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2814 (fig. 3), 2815, 2817 (fig. 4), 2821, 2827. At Cayuga Lake, Sherburne flagstone member of Genesee is overlain by a 5- to 40-foot unit of black and very dark brown shale containing siltstone scour channels. Base of unit is sharply defined, but upper boundary is gradational. This unit of dark shaly rock was informally named Ithaca *Lingula* shale by Williams (1906, Science, new ser., v. 24) and was apparently named Renwick shale member of Middlesex shale by Caster (1933). Caster's Renwick was proposed in an abstract, and type area and boundaries were not described. Name Renwick shale member of Genesee formation is herein adopted for stratigraphic unit above Sherburne. Thickness at reference section (herein designated) 38 feet. Underlies Ithaca member; boundary placed at top of beds of dark-brown shale above which rocks are gray silty shale and thin beds of dark-gray siltstone. Renwick extends westward to vicinity of Keuka Lake where member is present as thin tongue of black shale in middle of Penn Yan shale member.

Reference section: In Renwick Brook on east side of Cayuga Lake, 0.3 mile north of Ithaca, Tompkins County.

Repettian Stage

Pliocene: Southern California.

Manley Natland, 1953, Pacific Petroleum Geologist, v. 7, no. 2, p. 2. Lowermost of four stages, based on foraminiferal assemblages, in the Pliocene and Pleistocene of southern California. Occurs below the Venturian stage. In western part of Ventura Basin, lower and middle Repettian are absent and the upper Repettian lies apparently conformably on Delmontian upper Miocene.

†Repetto Formation[1] or Siltstone[1] (in Fernando Group)

Pliocene, lower: Southern California.

Original reference: R. D. Reed, 1932, 16th Int. Geol. Cong. Guidebook 15, p. 31.

M. L. Krueger, 1936, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1520. In Whittier Hills area, underlies Sycamore Canyon formation (new).

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof Paper 207, p. 40–42, pl 1. In type region, formation consists of 2,000 to 3,000 feet of siltstone and rests conformably on diatomaceous shale referred to upper Miocene. Farther east in Puente Hills, the Repetto includes thick beds of conglomerate and sandstone. In Palos Verdes Hills [this report], the Repetto consists entirely of siltstone, and term Repetto siltstone is used. Siltstone is about 150 feet thick and disconformably overlies Malaga mudstone member of Monterey shale. Underlies Lomita marl in type region of Lomita. Lower Pliocene.

G. B. Oakeshott, 1950, California Jour. Mines and Geology, v. 46, no. 1, p. 51 (table 1), 54 (table 2), 55–56. Name Repetto formation is used in this report [Placerita oil field, Los Angeles County] for lower Pliocene sedimentary rocks, including basal Elsmere member and Repetto siltstone member. Relationship between Elsmere and siltstone members not certain. Elsmere member is used for lower Pliocene beds including typical Elsmere fauna described by Grant and Gale (1931, San Diego Soc. Nat. History Mem., v. 1). The two members may be in part contemporaneous although siltstone member probably overlies Elsmere. Thickness of Elsmere about 100 feet; thickness of siltstone 300 feet. Unconformably overlies Mint Canyon formation; unconformably underlies Pico formation; in some areas unconformably underlies Sunshine Ranch member (new) of Pico formation.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 22 (fig. 2), 23 (fig. 3), 75–78, pl. 1. Formation described in San Fernando quadrangle where it is distributed in discontinuous belt along western and southern margin of San Gabriel Mountains for 13½ miles, as far east as Sunland and Tujunga. Maximum thickness 3,000 feet, measured in Lopez Canyon (south of San Gabriel fault) from top of underlying Modelo contact to base of overlying Saugus formation. South of San Gabriel fault, includes Elsmere member, which reaches maximum thickness of 1,400 feet, from its contact on pre-Tertiary crystalline rocks to overlying base of Pico formation, in upper Elsmere Canyon. North of San Gabriel fault, thickness of formation, from top of Modelo to base of Saugus formation, in Humphreys syncline, is about 500 feet.

D. L. Durham and R. F. Yerkes, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–195. Included in Fernando group. Basal formation of group; underlies unnamed formation that constitutes upper part of group. In eastern Puente Hills, conformably overlies Sycamore Canyon member of Puente formation. Maximum thickness of 1,600 feet exposed on ridge south of Olinda.

U.S. Geological Survey has abandoned the term Repetto.

Type locality: In Repetto Hills, along west side of Atlantic Boulevard, Los Angeles.

Republic Chert[1]

Pennsylvanian: Southwestern Missouri.

Original reference: E. M. Shepard, 1898, Missouri Geol. Survey, v. 12, pt. 1, p. 125–126, 141.

Named for Republic, Greene County.

Republic Conglomerate

Precambrian: Northern Michigan.

R. M. Dickey, 1938, Jour. Geology, v. 46, no. 3, p. 331–334. Named in discussion of Ford River granite (new) of Southern Complex of Michigan.

Named for occurrence south of town of Republic, Marquette County. Upper part of principal exposure is near Republic baseball park near State Highway 95.

†Republic Formation[1]

Pre-Cambrian (Huronian): Northwestern Michigan.

Original reference: M. E. Wadsworth, 1890, Lake Superior along the south shore, by Julian Ralph, p. 77–99; 1891, 2d ed.

Named for occurrence at Republic, Marquette County.

Republic Granite[1]

Precambrian: Northern Michigan.

Original reference: C. A. Lamey, 1933, Jour. Geology, v. 41, no. 5, p. 487–500.

C. A. Lamey, 1937, Jour. Geology, v. 45, no. 5, p. 487–510. Two granites, one of Archean age and one of post-Huronian, possibly Killarnean, are now generally recognized as present in Southern Complex. Agreement does not exist regarding relative amounts of these granites nor the criteria by which their extent should be judged. Evidence is cited to show that granite at Republic is younger than a conglomerate there which has been described as containing granite fragments. Believed that there is sufficient evidence to warrant conclusion that northern part of Southern Complex, extending from about 5 miles west of Republic to at least 3 miles east of Palmer, is a post-Huronian granitic unit to which name Republic granite is applicable. Republic granite is probably continuous with more northern intrusions, thus making northern part of Southern Complex a post-Huronian unit.

R. M. Dickey, 1938, Jour. Geology, v. 46, no. 3, p. 321–335. Granite-porphyry, herein named Ford River granite, is post-Lower Huronian and pre-Middle Huronian. It has been considered post-Huronian and called Republic granite by Lamey. Term Republic granite is not desirable, since known post-Huronian granite is exposed only in small quantities in vicinity of Republic. Since name Republic is established in literature, it is retained as designation for port-Huronian granite found in some abundance about margins of Southern Complex.

Named for exposures in vicinity of Republic, Marquette County.

Republic Quartzite[1]

Precambrian (Huronian): Northwestern Michigan.

Original reference: M. E. Wadsworth, 1893, Michigan Geol. Survey Rept. 1891–1892, p. 63–64, 84–85, 102–127.

Probably named for occurrence at Republic, Marquette County.

Republican Creek Limestone[1] (in Stevens Series)

Middle Cambrian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 78, map.

C. D. Campbell, 1947, Geol. Soc. America Bull., v. 50, no. 7, p. 602 (table 4), 611. Remapping of northeastern Stevens County and discovery of Cambrian and Ordovician fossils are thought to justify the adoption there of formation names established by Park and Cannon (1943) for the Metaline quadrangle. Correlative with the Middle Cambrian Metaline limestone are most of Weaver's Northport limestone, Republican Creek limestone, Red Top limestone, and Deep Lake argillite, and part of Boundary argillite.

Extends from head of Republican Creek southwest past north end of Deep Lake, Stevens County.

†Republican River Formation[1]

Pliocene, lower: Northern Kansas and central southern Nebraska.

Original reference: H. F. Osborn, 1907, Am. Mus. Nat. Hist. Bull., v. 23, p. 250, 251; W. B. Scott, 1907, Textbook of Geology, p. 724.

A. L. Lugn, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1271–1273. Exposures generally referred to the Republican River beds in southwestern Nebraska and parts of Kansas are now known to belong to lower part of Ogallala group, that is, they are equivalent to upper part of Valentine formation and lower part of Ash Hollow formation.

Exposed along Republican River.

Resendez Shale Member (of Fayette Formation)

Eocene (Jackson): Western Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 267–268. Proposed for series of shaly beds with local developments of argillaceous sandstone and oyster streaks. Underlies Roma sandstone tongue and overlies Salineno sandstone tongue. Thickness about 80 feet in Roma area; apparently grades northward into nonmarine bentonitic red and green shale.

Named from Resendez ranchhouse, 1 mile northwest of Roma, Roma quadrangle, Starr County.

Reserve Shale Member[1] (of Falls City Limestone)

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 5, 9.

Type locality: In upland near State line, northwest of Reserve, Brown County, Kans.

Reservoir Formation

Pliocene(?) and Quaternary, lower: Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 45–46. Mentioned in discussion of "Muddy Creek" formation. Name credited to H. R. Blank (unpub. thesis).

Present in Washington County.

Reservoir Granite[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey and Marion Rice, 1919, New York State Museum Bull. 225, 226, map and passim.

K. E. Lowe, 1950, Geol. Soc. America Bull., v. 63, no. 3, p. 143. In place of Canada Hill, Reservoir, and Mahopac granites described by Berkey and Rice (1919), the term Canada Hill granite phase of Hudson Highlands complex is used here to include all rocks representative of granitic igneous activity in the Hudson Highlands after the Pochuck diorite phase and earlier than the Storm King granite intrusion.

Type locality: At north end of Boyd Corners Reservoir, Putnam County.

Reservoir Hill Granite[1]

Precambrian: Northwestern New York.

Original reference: H. P. Cushing and D. H. Newland, 1925, New York State Mus. Bull. 259, p. 42–47.

Reservoir Hill, southeast of Gouverneur, St. Lawrence County.

**Resolution Dolomite Member** (of Minturn Formation)

Pennsylvanian: Colorado.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 199–201, 215–216. Consists of lower dolomite bed 35 to 40 feet thick, middle shale and grit unit 15 to 35 feet thick, and upper dolomite bed 15 to 22 feet thick. Separated from overlying Robinson limestone member by a 400-foot section of grayish clastic rocks. Separated from underlying Hornsilver dolomite member (new) by interval, about 800 feet thick, of grit, conglomerate, shale, and dolomite. About 3,700 feet above base of formation.

Named for the fact that it caps Resolution Mountain, an 11,927-foot peak on the divide between Resolution and Wearyman Creeks, Pando area.

**Resting Springs Formation**

Pleistocene(?): Southern California.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 2, 102–103, pl. 1. Succession of limy sandstone, conglomerate, and pumice at least 1,000 feet thick, deposited upon remnants of a thrust plate of late Pliocene age.

Occurs in Pahrump Valley, Inyo County, near Resting Springs.

Rest Island Granite[1]

Precambrian: Minnesota, and Ontario, Canada.

Original reference: I. H. Cram, 1932, Jour. Geology, v. 40, no. 3, p. 270–278.

Named for the granite of Rest Island batholith, in Rainy Lake area.

Restoration Point horizon[1]

Oligocene: Northwestern Washington.

Original reference: B. L. Clark, 1930, Geol. Soc. America Bull., v. 41, p. 751–770.

Restoration Point Member (of Blakeley Formation)

Miocene, lower: Northwestern Washington.

C. V. Fulmer, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1341. At type section of Blakeley, Restoration Point member consists of approximately 4,000 feet of marine hard massive gray-tan siltstone interbedded with thin hard fine-grained sandstone; soft limonitic-stained sandstone largely covered by beach gravels; and massive dark-gray, silty shale; contains the typical Blakeley molluscan faunule. Overlies Orchard Point member; underlies an unnamed lithologic unit consisting of approximately 4,650 feet of massive nonmarine conglomerates interbedded with thin gray sandstone and soft carbonaceous siltstones.

Named for occurrence at Restoration Point near entrance to Bremerton Inlet, Kitsap County.

**Rest Spring Shale**

Mississippian and Pennsylvanian (?) : Southern California.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 3, 14 (fig. 6), 25–26, pls. 1, 2, 3. Characteristically an argillaceous shale grading into siltstone; basal shale contains discoidal concretions 2 to 6 inches in diameter shale grades upward into siltstone, fine-grained sandstone and in some places thin isolated beds of light-gray quartzite; some sandstone is conglomeratic in thin inconspicuous beds. Thickness about 310 feet. Underlies Tihvipah limestone (new) ; overlies Mississippian Perdido formation (new).

J. F. McAllister, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–95. In long exposure from western side of Ubehebe Peak stock to northern side of [Ubehebe Peak] quadrangle, outcrop width of nearly vertical, highly sheared Rest Spring shale ranges from 200 to 1,000 feet; on flank of open fold west of Lee Flat the thickness is about 300 feet. Overlies Perdido formation; underlies Bird Spring (?) formation.

Type locality: Extends from head of gulch 2,000 feet south of Rest Spring northward to within 200 feet of top of hill that is 2,000 feet northwest of Burro Spring, Inyo County. Named from extensive exposures around Rest Spring.

**Retort Phosphatic Shale Member** or **Tongue** (of Phosphoria Formation)

Permian: Southwestern Montana, eastern Idaho, northeastern Utah, and western Wyoming.

R. W. Swanson, 1956, *in* V. E. McKelvey and others, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2832 (fig. 3), 2836 (fig. 4), 2850–2851; 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 29–30, pls. 2, 3. Upper phosphatic shale member of Phosphoria formation, provisionally called D member in recent preliminary reports on area in Montana and Wyoming, is here named Retort phosphatic shale member. At type locality, divided into three principal zones: lower phosphatic zone, 26 feet thick; middle somewhat calcareous mudstone, 15 feet thick, lower 10 feet of which includes oil shale beds; upper phosphatic zone, 19 feet thick. Thickness of member 55 to 90 feet. Thins progressively northward from Retort Mountain to about 30 feet near Melrose, 20 feet near Philipsburg, 10 feet near Maxville, and 3 to 5 feet in Garrison region where it is composed almost wholly of phosphorite; east of Ruby River, thins abruptly to generally less than 10 feet; in Centennial Mountain about 20 feet; 35 feet or less in Jackson Hole region; thins to the north; probably in large part by facies change to chert, and toward the southwest in Idaho where it intertongues with and grades laterally into cherty shale member. Overlies Rex chert member; underlies Tosi chert member (new) ; both contacts appear conformable. Also intertongues with Franson member (new) of Park City formation and Shedhorn sandstone (new).

T. M. Cheney, 1957, Utah Geol. and Mineralog. Survey Bull. 59, p. 28. Geographically extended into northeastern Utah.

Type locality: Small Horn Canyon, just northwest of Retort Mountain in sec. 23, T. 9 S., R. 9 W., about 10 miles south of Dillon, Beaverhead County, Mont. Retort Mountain was named from retort built there nearly 40 years ago in attempt to recover oil from the shale.

**Retreat Group**

Silurian and Devonian: Southeastern Alaska.

Fred Barker, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–100. Dominant rock types are fine-grained gray to greenish-gray sericite schist, sericite-chlorite-albite schist, medium-grained quartz-muscovite schist, fine-grained green chlorite-albite-epidote schist, black graphitic quartzose pyrite-bearing slate, and black graphitic slate. Gray fine- to medium-grained graywacke and silvery sericte schist form minor part of group. Gray to buff marble with dark-gray laminae in beds 0.5 foot to more than 100 feet thick exposed at several localities. Individual beds of all above-mentioned rock types are a few inches to a few hundred feet thick. Thickness of group at least 6,000 feet. In contact with Barlow Cove formation (new) along a bedding plane fault. On southwest limb of Shelter syncline.

U.S. Geological Survey currently designates the age of the Retreat Group as Silurian and Devonian on basis of a study now in progress.

Underlies western part of Mansfield Peninsula from Point Retreat to south boundary of Juneau (B–3) quadrangle.

Reusens Migmatite

Reusens migmatite facies (of Moneta Gneiss)

Precambrian: South-central Virginia.

W. R. Brown, 1951, (abs.) Virginia Jour. Sci., new ser., v. 2, no. 4, p. 346. Complex of quartz monzonite gneiss and dark hornblendic gneisses. Unconformably underlies Rockfish conglomerate. Grades into Lovingston quartz monzonite gneiss.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1). Precambrian. Type locality designated.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 12–16, pl. 1. Facies of Moneta gneiss which is included in Virginia Blue Ridge complex (new). In most typical development, it consists of from two to four distinct interbanded and interlensed phases, ranging from almost black hornblende gneiss to white basic pegmatite.

Type locality: In vicinity of Reusens on James River 2 miles northwest of Lynchburg, Campbell County. Lynchburg quadrangle.

**Revard Sandstone Member** (of Tallant Formation)

Revard Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Central northern Oklahoma.

Original reference: D. E. Winchester, K. C. Heald, and others, 1918, U.S. Geol. Survey Bull. 686–G, p. 60–64.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 119–120. Reallocated to member status in Tallant formation (new). Stratigraphically above Bigheart sandstone member.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 36–37, 38. Thickness commonly 18 to 22 feet; locally (west of Okesa), thickens to between 35 and 40 feet. Base commonly falls between two-fifths and one-half of the way from the bottom to the top of formation. South of Caney River, Hulah sandstone member appears in upper part of the Revard and would seem to be an equivalent of the latter; elsewhere the bed named Hulah appears as a lens between the Bigheart and Revard members.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 14–15, 22–24, pls. Limits of Revard are obscure even at type locality, and consequently the unit is of doubtful stratigraphic value. Name is applied to persistent sandstone normally present in upper part of Tallant. Lenticular nature of upper Missouri sandstones makes it doubtful if the "Revard" of one locality is exact equivalent of the "Revard" of adjacent localities unless beds can be continuously traced. Revard of Pawnee County [this report] is a massive crossbedded sandstone containing thin lenses of red shale and white siltstone. Thickness 35 feet. Separated from underlying Bigheart sandstone member by 100-foot unnamed shale interval. Underlies unnamed red shale sequence.

Type locality : Revard Point, sec. 13, T. 26 N., R. 10 E., Osage County.

**Revett Quartzite** (in Ravalli Group)[1]

Precambrian (Belt Series) : Northeastern Idaho and northwestern Montana.

Original reference: F. L. Ransome, 1905, U.S. Geol. Survey Bull. 260, p. 277–285.

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 62, p. 35–36, pl. 11. White quartzites, commonly rather thick bedded; interstratified with subordinate amounts of micaceous sandstone. Thickness about 1,200 feet. Overlies Burke formation; underlies St. Regis formation.

F. C. Calkins, 1909, U.S. Geol. Survey Bull. 384, p. 38. Middle formation in Ravalli group.

J. W. Hosterman, 1956. U.S. Geol. Survey Bull. 1027–P, p. 729, pl. 57. Described in Murray area, Shoshone County, Idaho, where it is approximately 2,200 to 2,400 feet thick. Except for transition zone with underlying Burke formation, uniform throughout section; consists of fine- to medium-grained almost white; pure quartzite; beds commonly 1 to 6 feet thick; a few thin greenish-gray argillite beds. Underlies St. Regis formation.

Named for exposures surrounding Revett Lake, Coeur d'Alene district, Idaho.

Revuelto formation or shales

Mesozoic (Early Cretacic) : Northeastern New Mexico.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 3, p. 209; v. 74, no. 4, p. 306–307. Name presented as a substitute for Pyramid shales, the latter name found to be preoccupied. Included in the Tucumcarian series. Thickness 50 feet. Overlies Redondo sandstone.

Name derived from Revuelto Mesa, Cerro Tucumcari region.

**Reward Conglomerate Member** (of Owens Valley Formation)

Reward Conglomerate[1]

Permian : Eastern California.

Original reference : E. Kirk, 1918, U.S. Geol. Survey Prof. Paper 110.

C. W. Merriam and W. E. Hall, 1957, U.S. Geol. Survey Bull. 1061-A, p. 8, 10. Rank reduced to member status in Owens Valley formation (new). Permian.

Named for exposures south of Reward mine, Inyo Mountains.

**Rex Chert Member** (of Phosphoria Formation)[1]

Permian: Northeastern Utah, eastern Idaho, southwestern Montana and southwestern Wyoming.

Original reference: R. W. Richards and G. R. Mansfield, 1912, Jour. Geology, v. 20, p. 683-689.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2847-2849; 1959, U.S. Geol. Survey Prof. Paper 313-A, p. 25-28. Richards and Mansfield did not publish description of section from Crawford Mountains; only section of Rex described by them is one measured in sec. 12, T. 10 S., R. 44 E., a few miles west of Phosphoria Gulch. Because they described the section near Phosphoria Gulch (which has chert as dominant constitutent), in preference to Crawford Mountain section (where beds of Rex age are mainly carbonate rock), it is assumed that they intended Phosphoria Gulch to be type locality for Rex chert member as well as of Phosphoria formation as a whole. Adoption of alternate interpretation—that they meant Rex Peak to be type locality—would require displacing name Rex with new name for chert member in southeastern Idaho, if rules of stratigraphic nomenclature were adhered to strictly. Because Rex chert is known internationally as name of main chert in Phosphoria, its displacement by new name seems undesirable. Richards and Mansfield described the Rex in Phosphoria Gulch as consisting of 100 feet of gray limestone and black chert in lower part, 60 feet of red-stained black chert in middle, and 80 feet of dark cherty shale in upper part. Latter unit has been recognized over wide area and in recent reports has been separated from Rex and referred to as "upper shale member"; this separation is continued here, and name Rex is restricted to hard resistant dark chert above Meade Peak phosphatic shale member. North, east, and south from typical area, upper part of Rex passes into carbonate rock of Franson member (new) of Park City formation; lower part continues as far as southwestern Montana, western Wyoming, and north-central Utah, where it passes into the Franson. North-northwest of typical area, Rex passes into cherty mudstone, which composes entire upper part of Phosphoria in Portneuf quadrangle and Fort Hall Indian Reservation and is designated as separate member.

Type locality: Phosphoria Gulch, 2½ miles northwest of Meade Peak, Bear Lake County, Idaho. Measured in sec. 12, T. 10 S., R. 44 E. Named for Rex Peak in Crawford Mountains, 4 miles east of Randolph, Rich County, Utah, where chert forms an anticlinal cap.

**Rexroad Formation**

Rexroad Member (of Ogallala Formation)

Pliocene, upper: Kansas and Oklahoma.

H. T. U. Smith, 1940, Kansas Geol. Survey Bull. 34, p. 95-99, 112. At localities where diagnostic fossils have been found, formation consists of alternating beds of gray to reddish mudstone, buff sandy silt, rusty sand and gravel, and a few thin seams of lignite. Has been mapped as Ogallala, and some Rexroad beds are indistinguishable from typical Ogallala. Base not exposed in Meade County; hence, complete thickness is problemmatical. Individual exposures do not exceed 35 feet, but it is probable that thickness is at least as great as local relief of topography, which is about 80 feet. Contact with overlying Ogallala not exposed. In some areas, as in Clark County, underlies Kingsdown formation (redefined).

J. C. Frye and C. W. Hibbard, 1941, Kansas Geol. Survey Bull. 38, pt. 13, p. 395 (fig. 2), 399 (table), 400 (fig. 3A), 407–410. Smith (1940) named the Rexroad from exposures along tributary to Crooked Creek on Rexroad Ranch, in same general locality from which Rexroad fauna was collected by Hibbard (1938, Kansas Acad. Sci. Trans., v. 40). Choice of type locality was unfortunate because only uppermost part of formation is here exposed. Top of formation was not defined by Smith, although it is exposed in this area, and beds of Pleistocene sand and gravel, which unconformably overlie Pliocene beds, were not clearly excluded from the Rexroad. Beds called Rexroad by Smith are here designated Rexroad member (upper Pliocene) of Ogallala formation. Thickness 50 to 250 feet. Lower and thicker part of Rexroad member does not crop out at surface in Meade basin area; hence, thickness and character of member are known only from test-hole samples and well logs. Upper beds of member, which are exposed at surface, consist of blue-gray, tan, and gray sand, silt, and clay. Where entire member is present, it is about 200 feet thick, but in deepest part of basin it may attain maximum thickness of 250 feet, and east of Crooked Creek fault it is only about 30 feet thick. Unconformably overlain by basal sand or gravel of Meade formation (redefined) of Pleistocene age.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no. 5, p. 91–105. Includes XI member (new) in lower part. Overlies Laverne formation, angular unconformity.

C. W. Hibbard, 1950, Michigan Univ. Mus. Paleontology Contr., v. 8, no. 6, p. 113–192. Treatment of Rexroad formation by many authors working in different areas of western Kansas has been varied. This report traces development of the term Rexroad formation and Meade formation and relationship of Rexroad fauna to other known faunas.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 65. Blanco formation has its maximum development in southwestern Kansas where formation attains maximum thickness of more than 250 feet. In this area, Smith (1940) described and named Rexroad formation from exposures now classed as Blanco formation. Frye and Hibbard (1941) redescribed these beds as Rexroad member of Ogallala.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55, 56. Underlies Angell member of Ballard formation (both new). Rexroad formation was included in Blanco formation of former State Geological Survey of Kansas classification. Position of Rexroad formation was discussed at Pleistocene conference held in Lawrence, Kans., but decision on it was deferred. Formation is now recognized as older than Meade group. It is here considered to be of late Pliocene age.

Named from exposures along tributaries of Crooked Creek on Rexroad Ranch, in sec. 22, T. 33 S., R. 29 W., Meade County, Kans.

**Reynales Limestone** (in Clinton Group)

Reynales Limestone Member (of Clinton Formation)[1]

Silurian: Western New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as formation in Clinton group. Occurs above Maplewood shale and below Sodus shale.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. In Clinton group. Occurs above Neahga shale; interfingers with Brewer Dock limestone to east and overlies Maplewood shale. Unconformable below Irondequoit limestone. Name Wallington limestone proposed for limestone formerly regarded as Reynales at Rochester and eastward. This limestone is younger than type Reynales of Niagara and Clinton Counties. Middle Silurian.

Named for exposures at Reynales Basin (also spelled Reynolds), 8 miles east of Lockport.

Reynolds Limestone (in Bluefield Formation[1] or Group)

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 301, 426.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County p. 255, 264. In Greenbrier County, a shaley blue to yellowish-blue fossiliferous limestone, 15 to 40 feet thick. Underlies a yellow to olive shale beneath the Droop sandstone; separated from underlying Webster Springs sandstone by a yellow sandy shale which may be the equivalent of the Bickett shale of Reger (1926). Mauch Chunk series.

Type locality: In public road 0.3 mile eastward from Reynolds School and 0.6 mile northwest of Knobs village, Monroe County.

**Reyolds Sandstone Member** (of Hignite Formation)[1]

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 43.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 12, 111, 119, 125, 149. Massive locally conglomeratic sandstone. In Hignite formation between High Splint coal above and Fossil limestone.

Named for Hanging Rock of Reynolds Mountain, Bell County, Ky.

Reynoldsburg Coal Member (of Abbott Formation)

Pennsylvanian: Southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1), pl. 1. Assigned to member status in Abbott formation (new). Occurs at base of formation below Grindstaff sandstone member. Coal named by J. M. Weller (1940, Illinois Geol. Survey Rept. Inv. 71).

Type locality: North of Cedar Creek, W½ sec. 32, T. 11 S., R. 4 E., Johnson County.

†Reynosa Formation,[1] Limestone,[1] or Caliche

Pleistocene: Northern Mexico and southern Texas.

Original reference: R. A. F. Penrose, Jr., 1890, Texas Geol. Survey 1st Ann. Rept., p. 57, 58, 63.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull. ,v. 29, no. 12, p. 1695 (fig. 1), 1715. Referred to as Reynosa caliche. Covers parts of Fleming and Goliad formations.

Named for occurrence at Reynosa, Tamaulipas, Mexico.

†Rhems Shale[1]

Eocene, lower: Eastern South Carolina.

Original reference: E. Sloan, 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 449, 451, 452, 453.

Type locality: Perkins Bluff, Black River, 5 miles from Rhems, Williamsburg County.

**Rhinestreet Shale Member** (of West Falls Formation)

Rhinestreet Shale[1] (in Naples Group)

Upper Devonian: Western and west-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19. p. 23, chart.

J. F. Pepper, Wallace de Witt, Jr., and George W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Chart OC–55. Rank reduced to member status in West Falls formation (new). In Lake Erie area, underlies Angola shale member and overlies Cashaqua shale; in Genesee River valley-Letchworth Park area, underlies Gardeau shale member and overlies Cashaqua shale, in Naples-Hammondsport area, underlies Hatch shale member and overlies Cashaqua shale. Thins eastward; 195 feet on Eighteen Mile Creek; 19 feet at Conklin Gully.

G. W. Colton and Wallace de Witt, Jr., 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–54. Overlies Cashaqua shale member of Sonyea formation.

R. G. Sutton, 1960, New York State Mus. Bull. 380, p. 18–19. Included in Naples group. Overlies Rye Point member (new) of Cashaqua formation; underlies Hatch formation. Term Attica shale abandoned and Rhinestreet understood to be applicable westward to Lake Erie. Thickness 4 to 152 feet.

Named for exposures along Rhinestreet north from Naples, Ontario County.

Rhinoceros Hill Beds (in Ogallala Formation)[1]

Rhinoceros Hill Beds (in Ash Hollow Formation)

Pliocene, lower: Western Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7, p. 159–163.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 144–145. Included in Ash Hollow formation (Ogallala group). Consist of about 10 to 15 feet of unconsolidated sand with mammalian remains and a 6- to 7-foot deposit of white diatomaceous marl (above) that contains plant remains and fresh-water fishes. Occur a few tens of feet above Edson beds. Rhinoceros Hill sands may belong in the channel of the same late Tertiary river system as the Wray beds and the Long Island beds and are probably nearly or quite contemporaneous with them.

Named from Rhinoceros Hill in northwestern part of Wallace County.

Rhoda Creek Formation

Pennsylvanian (Springer Series): South-central Oklahoma.

M. K. Elias, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 70 (table 2), 91–95. Uniformly gray shale; ferruginous concretions (at several horizons) that are locally concentrated in zones or lentils. Thickness at type locality 140 feet. At type locality, overlies Sand Branch member (new) of Caney shale with angular unconformity and underlies an unexposed and unnamed shale interval, which in turn underlies Union Valley formation.

Type locality: NW¼ sec. 8; T. 2 N., R. 7 E., about 1 mile northwest of Frisco; Pontotoc County. Name derived from Rhoda Creek, largest eastern tributary to Clear Boggy Creek.

**Rhode Island Formation**[1]

Pennsylvanian: Eastern Rhode Island and southeastern Massachusetts.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 159–201.

A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts; U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Interfingers with Wamsutta formation in southern part of Pawtucket quadrangle, partly younger than "red beds" of the Wamsutta and partly equivalent to them.

A. W. Quinn, 1952, Bedrock geology of the East Greenwich quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad. Map [GQ–17]. Underlies large part of East Greenwich quadrangle. Overlies Pondville conglomerate with gradational contact. Wamsutta formation and Pondville conglomerate, as mapped by Emerson (1917) south of Greenwich Bay, R.I., are assigned to this unit. Subdivision of formation in this quadrangle not possible.

D. R. Nichols, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–91. Two units of formation mapped in Narragansett Pier quadrangle, Rhode Island; may include some of Pondville conglomerate south of Pettaquamscutt River. Beds of schistose conglomerate and pebbly sandstone occur on the mainland and on Dutch Island. These are described as glossy gray to dark-gray rocks with intercalated muscovite schist and meta-anthracite. Bedding is variable with crossbedding locally. Pebbles of quartz and quartzite greatly elongate. Stratigraphically higher is the soft fissile phyllite exposed on Conanicut Island. Phyllite is black to light gray and greenish gray with a silvery luster; bedding usually indeterminate.

Named for fact that it includes graphite coal beds of Rhode Island.

Rhodes Canyon Formation

Devonian: Southern New Mexico.

R. H. Flower, 1958, Roswell Geol. Soc. Guidebook, 11th Field Conf., p. 74. Comprises 75 feet of soft shale, the lower part with white marly beds, middle with silty beds, and top with soft thin clay shale. Overlies Thoroughgood formation (new).

F. E. Kottlowski, 1959, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec., and Roswell Geol. Soc. Guidebook Joint Field Conf. Apr. 17–18, p. 265–266. Thoroughgood and Rhodes Canyon formations are informal units not yet properly defined. The "Rhodes Canyon" consists of 50 feet of interbedded light- to dark-gray silty fissile shale and dark-gray to brownish-gray micaceous siltstone with some thin tan sandstone beds in Hembrillo Canyon (called Contadero in 1956) and 75 feet of pale- to dark-olive-gray calcareous silty micaceous shale with a few lenses of gray or olive-gray calcareous micaceous siltstone in Rhodes Canyon (called Percha in 1956).

In Rhodes Canyon [San Andres Mountains, Sierra County].

**Rhododendron Formation**[1]

Miocene, upper: Central northern Oregon.

Original reference: E. T. Hodge, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 157.

D. E. Trimble, 1955, (abs.) Geol. Soc. America Bull., v. 66, no. 12, pt. 2, p. 1667. Formation is now known to overlie middle Miocene Molalla formation of Harper and underlie Troutdale formation of Hodge, originally designated as Pleistocene but referred to lower Pliocene by Chaney in 1944. In northeast-trending outcrop belt about 5 miles wide and 25 to 30 miles long southeast of Portland, formation ranges from about 100 to about 500 feet thick and consists predominantly of hypersthene andesite tuff breccias. Weathering of pre-Troutdale age suggests that Rhododendron formation is no younger than upper Miocene.

Columbia River Gorge. Derivation of name not given.

Rhyolite Canyon Formation

Rhyolite Canyon Series

Cenozoic: Southeastern Arizona.

H. E. Enlows, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 105–107. Series is volcanic sequence made up of rhyolite flows and tuffs. Composite thickness of 1,025 to 1,405 feet. Underlies Sugarloaf series (new); unconformably overlies Faraway Ranch series (new).

H. E. Enlows, 1955, Geol. Soc. America Bull., v. 66, no. 10, p. 1218–1236, pl. 1. Referred to as formation. Most of the rhyolite deposits of Cenozoic age in Chiricahua National Monument, heretofore termed flows, are more correctly classified as welded rhyolite tuff or ignimbrite, the result of many eruptions of nuess ardentes. Beds of formation are pale brown to pinkish gray, darkening to pale brown or grayish red on exposure. All are porphyritic containing phenocrysts of quartz and sanidine. Consists of nine unnamed members of which all but the uppermost member are rhyolites. Upper member of black to medium-dark-gray rhyodacite. Thickness of formation 1,900 feet. [Presumably includes rocks described as Sugarloaf series (Enlows, 1951).] Unconformably overlies Faraway Ranch formation. Traced southward into main portion of Chiricahua Mountains, and apparently crops out all along central and western parts of range, extending eastward into Portal area. Raydon (unpub. thesis) named 4,500 feet of rhyolite tuffs and welded tuffs which cap section in Cave Creek area, the Cave Creek formation, and states they are probably correlative with those of Chiricahua National Monument.

Best exposed in Rhyolite Canyon from which it is named, Chiricahua National Monument, Cochise County.

Ribbon Gneiss[1]

Precambrian (?): Central Washington.

Original reference: A. Waters, 1927, Jour. Geology, v. 35, p. 159–160.

Named for Ribbon Rock, Ribbon Cliff, and Ribbon Mesa, Douglas County.

Rib Hill Formation or Sandstone

Pennsylvanian or Permian: Eastern Nevada.

E. N. Pennebaker, 1932, Mining and Metallurgy, v. 13, no. 304, p. 164. Series of sandstone and sandy limestone about 3,200 feet thick. Lower 1,100 feet consists of medium- and fine-grained sandstone weathering yellow and buff with local patches of red; succeeding 800 feet are made up of lenticular sandy limestone beds; upper part predominantly sandstone. Overlies Ely limestone with no apparent unconformity; underlies Arcturus limestone. Formerly included in Ely limestone. Name credited to Roland Blanchard.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). Age of Rib Hill sandstone shown as Permian.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2170. Pennebaker (1932) in report on Robinson (Ely) mining district, separated a predominantly sandstone unit of Permian age, which he called Rib Hill formation, from beds that were previously mapped at Rib Hill as Ely limestone by Spencer (1917). Present writers [Hose and Repenning] believe that in vicinity of Rib Hill, where exposures are poor, inclusion of this predominant sandstone sequence in the Ely by Spencer was inadvertent and that it should have been included in Arcturus formation.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 102–103. Preoccupied name Rib Hill abandoned. Pennebaker's Rib Hill lies stratigraphically above Spencer's (1917, U.S. Geol. Survey Prof. Paper 96) Ely limestone and within Lawson's (1906) Arcturus limestone. Pennebaker placed upper boundary of Rib Hill 2,000 feet above base of previously named Arcturus limestone. Basal 1,000 feet, predominantly sandstone, is distinctive mappable unit. This basal sandstone member of Pennebaker's Rib Hill is herein named Riepetown sandstone.

Present in Robinson mining district west of Ely, White Pine County. Derivation of name not given.

**Rib Hill Quartzite**[1]

Precambrian (middle Huronian?) : Central northern Wisconsin.

Original reference: S. Weidman, 1907, Wisconsin Geol. Nat. History Survey Bull. 16, p. 41.

Exposed on Rib Hill, southwest of Wausau, Marathon County.

Ribolt Clay Shale[1]

Ribolt Member (of Crab Orchard Clay Shales)

Silurian (Niagaran) : Northeastern Kentucky and southwestern Ohio.

Original reference: A. F. Foerste, 1931, Kentucky Geol. Survey, ser. 6, v. 36, p. 171, 172, 173, 189, 202.

R. N. Thomas, chm., 1955, Kentucky Geol. Soc. [Guidebook] Field Trip 1955, p. 31 (fig. 11). Shown on generalized section of Serpent Mound region, Adams and Highland Counties, Ohio, as Ribolt member of Crab Orchard clay shales. Shales with thin dolomite lenses; thickness about 50 feet. Overlies Estill member; underlies Bisher formation.

Type exposure: Ribolt, Lewis County, Ky., 10 miles west of Vanceburg.

**Ricardo Formation**[1]

Pliocene, lower : Southern California.

Original reference: J. C. Merriam, 1914, California Univ. Pubs., Dept. Geol. Bull., v. 8, p. 276, 278.

H. S. Gale, 1946, California Jour. Mines and Geology, v. 42, no. 4, p. 326, 335, 338–350, pl. 52. Described in Kramer borate district where it is divisible into three units or members, post-borate conglomerate (at top), "lake bed" deposits, and Saddleback basalts, which form the base on which the borate-bearing lake beds rest. Approximate thickness 1,500 feet. Unconformably underlies older alluvium; unconformably overlies Rosamond formation.

T. W. Dibblee, Jr., 1952, California Div. Mines Bull. 160, p. 12 (fig. 1), 25–30, pls. 1, 2, 3. Described in Saltdale quadrangle where it is well developed on northwest flank of El Paso Mountains extending from Redrock Canyon northeast through Last Chance Canyon to Black Hills. Consists of a series of continental and lacustrine sediments containing lava flows and tuff of supposed Pliocene age. Maximum exposed thickness 7,000 feet; northeast of Last Chance Canyon, thins to less than 1,000 feet in Black Hills. Separated from underlying Goler formation (new) by pronounced angular unconformity; overlapped by Black Mountain basalt.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 142. Unit defined as Saddleback basalt in Ricardo formation by Gale (1946) is here redefined as formation in Tropico group (new).

Occurs in vicinity of Ricardo, Kern County.

Rices Mudstone Member (of San Lorenzo Formation)

Oligocene (Refugian and Zemorrian): Western California.

E. E. Brabb, 1960, Dissert. Abs., v. 21, no. 5, p. 1163. Overlies Twobar shale member (new). This is type Oligocene of California, although it does not correspond to Oligocene of Europe.

Type section: Along Kings Creek, Big Basin area, Santa Cruz Mountains. Derivation of name not stated.

**Riceville Shale**

Riceville Shale Member (of Chemung Formation)[1]

Upper Devonian: Northwestern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $Q_4$.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1352. In Crawford County, Riceville shale, which is equivalent to uppermost part of Chagrin shale of Ashtabula County, Ohio, consists of interbedded gray silty shale, greenish-gray to tan semifissile to massive mudrock, and white to tan thin- to thick-bedded fossiliferous siltstones. The siltstones are lenticular and cannot be correlated between adjacent exposures. Underlies Cussewago sandstone; where the Cussewago is absent, the Riceville is capped by Corry sandstone.

Well exposed on Oil Creek in bluff just west of Riceville, Crawford County.

Riceville Stage[1] or monothem[1]

Upper Devonian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, table opposite p. 61.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Prog. Rept. 126, p. 11. Riceville stage listed in Conewango series. Unit termed Sandstone D of Riceville stage will probably be named Jumonville sandstone when more definitive study of area is published.

Riceville is in Crawford County.

**Richard Sandstone Member** (of Pierre Shale)[1]

Upper Cretaceous: Central northern Colorado.

Original reference: M. W. Ball, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, p. 81–87.

G. R. Scott and W. A. Cobban, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 128–129. Olive-gray massive fine-grained sandstone is characteristic. Large orange-brown calcareous sandstone concretions common. Thickness about 60 feet at Richard Lake and Round Butte.

Exposed along north bank of Richard Lake, sec. 30, T. 8 N., R. 68 E., Larimer County.

Richardson Subgroup[1] (of Wabaunsee Group)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas, northwestern Missouri, and northern Oklahoma.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 4, 5, 9.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035, 2037 (fig. 6); 1949, Kansas Geol. Survey Bull. 83, p. 188; G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 12–15; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 20–21. The subgroups named (ascending) Sacfox, Nemaha, and Richardson by Condra (1935) have been included in the interstate classification agreed upon by the Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma. As thus defined the Richardson subgroup in standard section includes (ascending) Wamego shale, Maple Hill limestone, Langdon shale, Dover limestone, Dry shale, Grandhaven limestone, Friedrich shale, Jim Creek limestone, French Creek shale, Caneyville limestone, Pony Creek shale, and Brownville limestone. Nomenclature in the several States may deviate from this by a combination or omission of terms where certain named rock units are not recognizable.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2277. Nemaha-Richardson boundary lowered to base of Tarkio limestone herein reduced to member status in newly proposed Zeandale formation. This change has been agreed to by the Nebraska and Kansas Geological Surveys which are chiefly concerned. As herein redefined, the Richardson subgroup comprises five formations (ascending): Zeandale limestone, Pillsbury shale, Stotler limestone, Root shale, and Wood Siding formation (with Brownville limestone member at top).

Type locality: Big Nemaha Valley of southern Richardson County, Nebr., between points south of Humboldt and southwest of Falls City.

**Rich Butt Sandstone**

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 953 (fig. 2), 955 (table 1), 956 (fig. 3), 960. In type area, characteristic rock is light feldspathic sandstone, medium- to fine-grained and medium- to thick-bedded, that contains sharply contrasting pelitic layers; on Rich Butt Mountain, sandstone is coarser grained and thicker bedded and contains a few lenses of very coarse feldspathic sandstone and fine arkosic conglomerate; locally contains dark argillaceous rocks that are generally thinly and evenly layered and in places are interbedded with fine reddish-weathering ankeritic sandstone. Conformably overlies and somewhat intertongues with Pigeon siltstone of Snowbird group; top of formation cut off by Greenbrier fault; along Big Creek about 3,000 feet of formation is preserved beneath the fault, on Rich Butt Mountain about 1,800 feet.

Type section: Southeast of Mount Cammerer on Big Creek, above community of Mount Sterling, [Cocke County]. Named for Rich Butt Mountain, a northwestern spur of Mount Cammerer, near northeast end of Great Smoky Mountains.

**Richfield Member** (of Lucas Formation)

Middle Devonian: Michigan (subsurface).

K. K. Landes, 1951, U.S. Geol. Survey Circ. 133, p. 7. Term applied to porous dolomite at base of Lucas. In center of basin and on west flank, contains beds of sandstone. Thickness as much as 80 feet.

Named for Richfield (now Au Sable) Township in northern Roscommon County.

Richfield Quarry Shale Member (of Drum Formation)

Pennsylvanian (Missouri Series): Eastern Nebraska and south-central Iowa.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37. Consists of grayish shale and dark fissile shale. Thickness 1 to 1½ feet in Sarpy County, Nebr., and south-central Iowa, and may pinch out southward. Underlies Cement City member; overlies P. W. A. Quarry limestone member (new).

Type locality: Richfield quarry located in Platte Valley bluffs 2½ miles south of Richfield, Sarpy County, Nebr.

Rich Fountain Formation (in Jefferson City Group)

Lower Ordovician: Northern Arkansas and southern Missouri.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 15, 17–24, pl. 2. Massive to thin-bedded white to buff to gray fine-grained argillaceous to coarsely crystalline dolomite; thin buff to brown dolomitic sandstone lenses and layers abundant; chert commonly dull white to brown massive or nodular to thin lenticular; lower part predominantly thick-bedded coarsely crystalline dolomite here named School Mine ledge bed; upper part predominantly argillaceous dolomite. Thickness 140 to 180 feet. As defined, name replaces the Jefferson City (restricted) of Grawe and Cullison (1931, Jour Geology, v. 39, no. 4) except that slightly younger rocks are included in new unit; also includes lower part of Jefferson City dolomite of Winslow (1894). Unconformably underlies Theodosia formation (new); unconformably overlies Roubidoux formation.

Type section: Near Rich Fountain, Osage County, Mo.

**Rich Hill Limestone Member** (of Cherokee Shale)[1]

Pennsylvanian (Des Moines Series): Central western Missouri.

Original reference: F. C. Greene and W. F. Pond, 1923, Missouri Bur. Geology and Mines, v. 19, 2d ser., p. 37, 51–53.

Named for occurrence at Rich Hill, Bates County.

**Richland Formation** (in Conococheague Group)

Richland Member (of Conococheague Formation)

Upper Cambrian: Southeastern Pennsylvania.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Geologic map of the Richland quadrangle, Pennsylvania (1:24,000): Pennsylvania Geol. Survey, 4th ser., Atlas 167–D. Dolomite sequence that stratigraphically overlies Millbach member (new); top is drawn at base of first thick bed of medium-light-gray limestone containing crinoid fragments and other fossils; contact with Ordovician Stonehenge formation concealed. Basal part of member consists of thick-bedded medium-light- to medium-dark-gray finely crystalline dolomite that is in part laminated and contains beds of edgewise conglomerate and calcarenite; *Cryptozoon* present at two horizons in lower 120 feet of beds. Chert, which is frequently oolitic, and oolitic medium-gray limestone interbeds occur in the more limy center of member. Upper part of member reflects cyclic sedimentation, medium-gray siliceous dolomites are repeated at least 12 times; these beds are usually overlain by limy dolomite, magnesian limestone, or banded limestone and dolomite; the bands are often broken into conglomerate; above this are typically medium-gray to light-gray dolomites with shaly partings or bands; the cycle then begins again with siliceous dolomite. Total thickness of member probably in excess of 1,300 feet; approximately 1,264 feet at type section with base not exposed.

Carlyle Gray and D. M. Lapham, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 148–150. Upper Cambrian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Conococheague group.

Type section: Along Reading Railroad about one-fourth mile east of Richland and along road immediately west of Sheridan, Lebanon County.

Richland Limestone and Flint[1]

Mississippian: Southeastern Ohio.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, pl. opposite p. 933.

Probably named for Richland, Vinton County.

Richland Loess

Pleistocene (Wisconsinan): Northern Illinois.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 7, 11. Name applied to loess that lies on Shelbyville till and successively younger Woodfordian moraines. Thickness about 8 feet; lower 3 feet calcareous and fossiliferous. Woodfordian substage. Has been commonly referred to as Tazewell loess.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 546. Classification presented of Wisconsin glacial stage of north-central United States. Consideration also given to other classifications including one proposed by Frye and Willman. Name Richland loess proposed by Frye and Willman considered superfluous.

Named from exposures in east bluff of Illinois Valley north of Richland Creek in roadcut in NW¼SE¼SW¼ sec. 11, T. 28 N., R. 3 W., Woodford County.

†Richland Sandstone[1]

Pennsylvanian: Central Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxv, pl. 3.

Named for Richland Creek, San Saba County.

†Richmond earth[1]

Miocene: Eastern Virginia and eastern Maryland.

Original reference: W. B. Clark, 1897, Maryland Geol. Survey, v. 1, p. 197.

Can be traced from Eastern Shore of Maryland entirely across the State and thence southward into Virginia. Probably named from its wide occurrence in vicinity of Richmond, Henrico County, Va.

**Richmond Group**[1] or **Formation**

Richmond Formation (in Cincinnati Group)

Upper Ordovician: Indiana, Illinois, Kentucky, Michigan, Missouri, southwestern Ohio, and West Virginia.

Original reference: N. H. Winchell and E. O. Ulrich, 1897, Minnesota Geol. and Nat. History Survey Final Rept., v. 3, pt. 2, p. ciii.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 17–23. Group, in Clyde and Sodus Bay quadrangles, contains Queenston shale; base of Queenston not exposed in area. Underlies Whirlpool sandstone and Grimsby sandstone of Silurian Albion group.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., p. 110, 113–114, chart facing p. 108. Group in Ohio comprises (ascending) Arnheim, Waynesville, Liberty, and Whitewater formations. Thickness about 265 feet. Overlies Maysville group; underlies Silurian Medina group (top of which is Elkhorn formation).

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 201–239. Discussion of pre-Chattanooga stratigraphy in central Tennessee. Richmond group comprises (ascending) Arnheim formation, Sequatchie formation, Fernvale limestone, and Mannie shale. Overlies Maysville group; underlies Brassfield limestone of Silurian Medinan series.

H. P. Woodward, 1951, West Virginia Geol. Survey, v. 21, p. 27, 28, 32, 113, 327, 330. Group comprises Oswego sandstone and Juniata formation. Overlies Maysville group which here includes Martinsburg formation. Rock units here called Juniata and Oswego have previously been described in West Virginia reports as "Red Medina" and "Gray Medina," respectively.

R. C. Hussey, 1952, Michigan Dept. Conserv., Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14. Richmond comprises (ascending) Bills Creek, Stonington, and Big Hill members. Some beds formerly included in Bills Creek are included in Haymeadow Creek member (new) of Trenton formation.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Group comprises (ascending) Waynesville, Liberty, Saluda, Whitewater, and Elkhorn formations. Overlies Maysville group, top of which is Arnheim formation; underlies Medina group (Brassfield formation). Cincinnatian series.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 66, no. 3, p. 247–298, chart 2; Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–33. Cincinnatian series comprises (ascending) Edenian, Maysvillian, Richmondian, and Gamachian stages.

A. M. Gutstadt, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 3, p. 518–521. Term Cincinnati group revived to include (ascending) Eden shale, Maysville formation, and Richmond formation.

W. N. Melhorn, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 819 (fig. 1). As shown on generalized stratigraphic section of Southern Peninsula, Mich., Richmond formation comprises (ascending) Utica shale, Lorraine shale, and Queenston shale. Underlies Cataract formation.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1029–1030. In Cincinnati region, Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations [of Richmond group] define Richmond stage of the Cincinnatian. Richmond stage succeeds Maysville stage. Covington group contains standard sections of both Eden and Maysville stages.

Named for Richmond, Ind.

Richmond or Richmondian Stage

*See* **Richmond Group** or **Formation.**

Richmondville Sandstone[1]

Mississippian: Michigan.

Original reference: A. C. Lane, as reported by M. E. Wadsworth, 1893, Michigan Geol. Survey Rept. 1891–1892, p. 66.

Named for exposures at Richmondville, Sanilac County.

Rich Mountain Conglomerate (in Pottsville Group)[1]

Pennsylvanian: Northern West Virginia.

Original reference: D. B. Reger, 1918, West Virginia Geol. Survey Rept. Barbour and Upshur Counties, p. 292.

Named from its exposure along Rich Mountain Range.

Rich Valley Formation

Middle Ordovician: Southwestern Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 86–87, chart 1 (facing p. 130). Consists of black and chocolate-brown shales, which contain graptolites, brachiopods, and trilobites. Ranges in thickness from a few feet to 350 feet. Overlies Arline formation (new); underlies Chatham Hill formation (new). Beds herein defined as Rich Valley are the lower and characteristic part of a unit widely identified by Butts, Decker, and others as Athens shale. Rich Valley corresponds to lower part of Liberty Hall black limestone-black shale succession of central western Virginia. Name credited to B. N. Cooper and G. A. Cooper.

Type section: Immediately south of Porterfield quarry and Worthy mine of Mathieson Chemical Corp., about 7 miles east-southeast of Saltville on Maccrady quadrangle, Smyth County.

Richville Formation

Pleistocene, upper: Northeastern Arizona.

G. K. Sirrine, 1959, Dissert. Abs., v. 19, no. 8, p. 2064. Incidental mention.

Springerville-St. Johns area, Apache County.

Rickard facies (of Schoharie Formation)

Lower or Middle Devonian: East-central New York.

J. H. Johnsen, 1957, Dissert. Abs., v. 17, no. 10, p. 2247. Schoharie formation redefined. Includes Carlisle Center (lower) facies, Rickard facies (new), and Leeds facies. Richard facies overlies Carlisle Center facies and corresponds to Schoharie formation of Vanuxem (1840). Rickard facies passes eastward into Leeds facies.

**Rickenbach Dolomite** (in Beekmantown Group)

Rickenbach Formation (in Beekmantown Group)

Lower Ordovician: Southeastern Pennsylvania.

J. P. Hobson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 12, p. 2713, 2715–2719. Proposed for thick- to thin-bedded fine-grained and coarse-grained dolomite overlying Stonehenge limestone and underlying interbedded limestone and dolomite here referred to as Epler formation. Upper and lower contacts transitional. Consists of two unnamed members, an upper fine-grained and a lower coarse-grained. Total thickness about 580 feet. Type sections for both members given.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Geologic map of the Richland quadrangle, Pennsylvania (1:24,000): Pennsylvania Geol. Survey, 4th ser., Atlas 167–D. Described in Lebanon County where it is about 335 feet thick, base not exposed.

Type sections: Lower member, cut along west side of Reading Co.'s railroad tracks beginning about 1,000 feet south of crossing at Rickenbach, Berks County; upper member, on southwest bank of Schuylkill River one-half mile east by northeast of Epler School.

Ricker Limestone

*See* Ricker Station Limestone.

**Ricker Sandstone Member** (of Mineral Wells Formation)[1]

Ricker Conglomerate

Middle Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 386.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 92–94, 98. Ricker member, on State Highway 7, 6 miles east of Brownwood, near type locality, consists of 6 feet of conglomerate and an estimated 20 feet of sandstone beneath it. Conglomerate is irregularly stratified, coarse sandstone and conglomerate grading upward into brown sandstone; contains some dense hard fossiliferous limestone pebbles 3 inches or less in diameter, and many small pebbles of chert—red, brown, yellowish, white, purple, gray, black, and green. In Brownwood area; separated from overlying Capps limestone member by 30 feet of gray shale, near base of which is small coral reef.

M. G. Cheney, chm., 1949, Abilene Geol. Soc. [Guidebook], p. 8 (chart), 17. At Stop No. 5, Ricker conglomerate, 5 feet thick, overlies about 25 feet of sandstone. Type locality of Ricker conglomerate is on hill about 1.3 miles to the southeast. About 100 feet below Ricker conglomerate and one-fourth mile southwest of Ricker Station is a 3-foot limestone with abundant fusulinids and other fossils. Correlation of Ricker conglomerate with Brazos River conglomerate and Ricker Station limestone with Goen limestone of Palo Pinto County appears plausible.

M. G. Cheney, chm., 1950, Abilene Geol. Soc. Guidebook Nov. 2–4, p. 13. Road log refers to Ricker conglomerate (Drake's bed no. 23 [Ricker bed]) which is correlated with Brazos River sandstone and conglomerate.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 61, pl. 27. Drake's Ricker bed, which he placed at top of his Strawn division, is separated from underlying Ricker Station limestone of Cheney by 50 to 70 feet of interbedded gray shale and sandstone. Drake (1893) stated that the sandstone and conglomerate of his Ricker bed caps an isolated butte north of Ricker Station, 5½ miles east of Brownwood. Other exposures, he said, were along west side of Steppes Creek and along crest of high escarpment west of Pecan Bayou. Nickell (1938) correlated a bed of sandstone along Colorado River, 5 to 9 miles east of Winchell, with this unit. In his stratigraphic section in Brownwood area, Nickell placed the Ricker sandstone in Mineral Wells formation. Best exposure of basal sandstone of Ricker bed of Drake is in cut on recently relocated Fort Worth division of Gulf, Colorado, and Santa Fe Railroad, 5 miles east of courthouse at Brownwood and 0.3 of a mile south of U.S. Highway 84 in spur in west valley wall of Steppes Creek. At this locality, the bed is a 25- to 35-foot brown sandstone containing chert pebbles. It irregularly overlies 17 feet of greenish-gray shale. Lower part of the Ricker in this cut locally occupies channels cut 10 to 12 feet into underlying shales. Top of the conglomeratic Ricker sandstone member is in face of a borrow pit north of crossing of Santa Fe Railroad on military road to Camp Bowie, 2 miles south of this junction with U.S. Highway 84. Shales of Ricker sandstone member of Nickell is separated from Capps limestone lentil of Moore and Plummer by gray silty shale.

Named for Ricker post office, near Brownwood, Brown County.

Ricker Station Limestone (in Lone Camp Group)

Ricker Station Limestone Member (of Grindstone Creek Formation)

Pennsylvanian: Central Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Ricker limestone shown on correlation chart as member at top of Grindstone Creek formation (Goen limestone-Ricker limestone). Occurs above Santo limestone member.

Gayle Scott and others, 1941, *in* West Texas Geol. Soc. [Guidebook] Spring Field Trip, p. 24. Following correlation now seems well established both by paleontology and well-log cross sections: Ricker Station limestone (Colorado River Valley) with Goen-Santo limestone (Brazos River Valley). In the column, Ricker Station limestone occurs below Ricker-Rochelle conglomerate which is said to rest on limestone of Big Saline group, 70 miles southwest of Palo Pinto County.

M. L. Thompson, 1945, Am. Jour. Sci., v. 243, no. 8, p. 453. Collection made from highly arenaceous limestone near depot at Ricker. This limestone, commonly known as Ricker limestone, occurs immediately below Ricker conglomerate sandstone, that is, in lower part of Drake's (1893, Texas Geol. Survey, 4th Ann. Rept. pt. 1) Ricker bed.

M. G. Cheney and others, 1949, Abilene Geol. Soc. [Guidebook], p. 8 (chart), 17. About 100 feet below Ricker conglomerate and one-fourth mile southwest of Ricker Station is a 3-foot limestone with abundant fusulinids and other fossils. Correlation of Ricker conglomerate with Brazos River conglomerate and Ricker Station limestone with Goen limestone of southeastern Palo Pinto County appears plausible.

M. G. Cheney, chm., 1950, Abilene Geol. Soc. Guidebook Nov. 2–4, p. 14. Stop No. 2 on road log is at Ricker Station limestone; thickness 2 feet; contains fusulinids and gastropods. Overlies a well-bedded sandstone. This thin limestone and sandstone section evidently belongs in Drake's (1893) Indian Creek shale (No. 22). Type locality mentioned.

M. G. Cheney and D. H. Eargle, 1951, Geologic map of Brown County, Texas (1:62,000): Texas Univ. Bur. Econ. Geology. Columnar section shows Ricker Station limestone in Lone Camp group below Ricker sandstone.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 60, pl. 27. Limestone unit that Cheney called Ricker Station limestone was listed by him (1940) as Ricker limestone in his table of Paleozoic strata but not described. He listed it again in 1949 in a similar table but called it Ricker Station limestone apparently to avoid confusion with Ricker bed described by Drake (1893). The limestone, although discontinuous, is an important stratigraphic unit. It is lowermost limestone bed of Strawn group in Colorado River valley. Outcrop of the Ricker Station limestone is indicated by scattered blocks of limestone as much as 3 feet across in a pasture 0.1 mile south of road crossing at Ricker Railroad siding, 5½ miles S. 76° E. of courthouse at Brownwood on the Gulf, Colorado, and Santa Fe Railroad. Limestone traced discontinuously for 5 miles southwest of this locality but has not been found to northeast. Where well exposed on face of cuesta locally called Six-Mile Mountain (6 miles southeast of Brownwood Courthouse), the unit is a 4-foot-thick bed of grayish-brown limestone containing fine-grained sand; fusulinids abundant. Limestone is overlain by 12 feet of greenish-gray clay. Drake's Ricker bed, which he placed at top of his Strawn division, is separated from underlying Ricker Station limestone by 50 to 70 feet of interbedded gray shale and sandstone.

Type locality: Three and one-half miles northeast of Stop No. 2, Brown County. [This would be approximately at Ricker.]

**Rico Formation**[1]

Rico Member (of Cutler Formation)

Pennsylvanian and Permian: Southwestern Colorado, northwestern New Mexico, and southeastern Utah.

Original reference: W. Cross, 1899, U.S. Geol. Survey Geol. Atlas, Folio 57.

A. A. Baker and J. B. Reeside, Jr., 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 11, p. 1420, 1423, 1424, 1441, 1443, 1446. Underlies Halgaito tongue or member (new) of Cutler formation.

W. S. Burbank and E. N. Goddard, 1937, Geol. Soc. America Bull., v. 48, no. 7, pl. 3. Discussion of thrusting in Huerfano Park region, Colorado. Stratigraphic column for region shows "type of sediments like Rico formation" overlying "type of sediments like Hermosa formation."

L. G. Henbest, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1329–1330. Species of *Fusulina* in Rico indicates middle, or possibly upper, Des Moines age. *Triticites* sp. from Rico of Moab region. Utah indicates that Rico of that region is of upper Pennsylvanian age. Thus, evidence indicates that type Rico is of Des Moines age and the transition facies of the Rico rises in time scale toward west and southwest.

S. A. Wengerd, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 5, p. 1041–1042, 1044 (fig. 5). In San Juan Canyon, Utah, gradationally overlies Hermosa formation. Considered transitional from Late Pennsylvanian to early Permian.

S. A. Wengerd and J. W. Strickland, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2174–2175. Rico, transitional between Hermosa marine strata below and Cutler continental strata above is here considered basal member of Cutler. It is not a mappable unit of any stratigraphic constancy over a wide area and probably should not be called a formation.

George Herman and S. L. Sharps, 1956, Intermountain Assoc. Petroleum Geologists [Guidebook] 7th Ann. Field Conf., p. 81. Writers disagree with Wengerd and Strickland (1954) in considering Rico as basal facies of Cutler. It is unfortunate that type section lies within area of continuous sedimentation across Permo-Pennsylvanian boundary because, in center of embayment where time break is present, the so-called transition series lies beneath unconformity. In Rico quadrangle, the unit is of Des Moines age, equivalent to post-salt Des Moines upper Hermosa of southern part of embayment and to uppermost saline and penesaline sequence in northern part of Paradox Salt embayment.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 212, no. 9, p. 2054, 2056 (fig. 3). New terminology shows Rico transition facies at base of Cutler group. Transitional between Hermosa group below and Halgaito formation.

D. W. Bolyard, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1911. Discussion of stratigraphy in Sangre de Cristo Mountains between La Veta Pass and Westcliffe, Colo. Name Madera replaces Hermosa and Rico formations of Burbank and Goddard (1937) in south-central Colorado, and restricts these terms to southwestern Colorado west of San Luis-Uncompahgre highland.

Named for exposures in Rico Mountains, Colo.

**Riddle Formation** (in Myrtle Group)

Upper Jurassic: Southwestern Oregon.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2774–2782. Introduced for clastic sedimentary rocks of Late Jurassic (Portlandian) age in southwestern Oregon. Consists mostly of medium- to dark-gray siltstone in which pebble lenses are common. Where well exposed, divisible into two members: a lower, of medium- to dark-gray siltstone in which pebble lenses and limestone lenses are common, chert conglomerate locally at top; conglomerate and metavolcanics locally at base; and an upper, dominantly medium-gray siltstone, sandstone beds fairly common; limestone lenses few; conglomerate of chert and graywacke common at top. Thickness about 1,088 feet. Underlies Days Creek formation (new) with probable disconformity; overlies Rogue formation near Days Creek and in valley of Myrtle Creek; overlies Dothan formation in Dutchman Butte, Roseburg, and Bone Mountain quadrangles. Name Riddle replaces Jurassic part of Knoxville formation as used by Diller and Kay (1924, U.S. Geol. Survey Geol. Atlas, Folio 218) in southwestern Oregon.

Type section: About 10 miles east of Riddle along South Umpqua River from ½ to 1 mile above mouth of Days Creek in E½ sec. 16 and W½ sec. 15, T. 30 N., R. 4 W., Douglas County. Named for town of Riddle. Well exposed in valley of South Umpqua River and its tributaries, Days

Creek, Cow Creek, and Myrtle Creek, in Days Creek, Canyonville, Roseburg, and Dutchman Butte quadrangles.

**Riddlesburg Shale Member** (of Pocono Formation)[1]

Mississippian: Western Pennsylvania and southwestern Virginia.

Original reference: D. B. Reger, 1927, Geol. Soc. America Bull., v. 38, p. 156–157, 397–410.

W. M. Laird, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 161–163. Name Riddlesburg shale extended to cover basal Mississippian beds along Allegheny front from Altoona, Pa., southward to U.S. Route 30.

Type section: One and one-half miles north of Riddlesburg, Bedford County, Pa.

**Ridenhower Shale**[1]

Ridenhower Member (of Paint Creek Formation)

Upper Mississippian (Chester Series): Southeastern Illinois and western Kentucky.

Original reference: Charles Butts, 1917, Mississippian formations of western Kentucky: Kentucky Geol. Survey, pt. 1, p. 73.

Elwood Atherton and D. H. Swann, 1948, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 32, no. 2, p. 300. Lower Chester formations are correlated in western Illinois, the subsurface of southeastern Illinois basin, Hardin County, Ill., and Indiana. Paint Creek of southern and western Illinois is divided into three members: upper limestone and shale zone, named Ridenhower member and correlated with "Paint Creek" of southeastern Illinois; middle sandstone and shale zone correlated with Bethel sandstone of southeastern Illinois; and a lower "pink crinoidal limestone" correlated with upper part of "Renault" formation and called Downeys Bluff member in southeastern Illinois. Correlations credited to F. E. Tippie (unpub. ms.).

A. H. Sutton and W. A. Oesterling, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1786. Paint Creek was named by Weller (1913) from exposures in southwestern Illinois. Name Ridenhower was applied by Butts (1917) to same part of Chester section, the shale between the Bethel and Cypress sandstones in Fluorspar district.

Named for Ridenhower, Johnson County, Ill.

Ridge Formation

*See* Ridge Route Formation.

Ridge Basin Group

Miocene, upper, and Pliocene: Southern California.

D. I. Axelrod, 1950, Carnegie Inst. Washington Pub. 590, p. 161, 165–168, pl. 1. Name applied to a section of sediments, about 22,000 feet thick, that crop out on U.S. Highway 99 between Los Angeles and Bakersfield. Wide variety of clastics is represented, ranging from marginal fanglomerates to finely bedded calcareous shales. Sediments form an asymmetrical syncline plunging northwestward, with the axis lying just east of the highway. Apparently includes (ascending) French Flat sandstone (new), Piru Gorge sandstone (new), Peace Valley beds, and Hungry Valley formation.

J. C. Crowell, 1954, California Div. Mines Bull. 170, map sheet 7. In mapped area, includes Violin breccia (new), 27,000 feet thick, and Hungry Valley formation, 4,500 feet thick. Conformably overlies Castaic formation (new) with interfingering contact that is marked by an abrupt upward increase in the proportion of sandstone beds.

Well exposed in region 5 miles north of Castaic to vicinity of Gorman about 20 miles northwestward, Los Angeles County.

**Ridgeley Sandstone** (in Oriskany Group)[1]

Ridgeley Sandstone Member (of Oriskany Formation)

Lower Devonian: Eastern West Virginia, central Pennsylvania to central western Virginia.

Original reference: C. K. Swartz and others, 1913, Maryland Geol. Survey Lower Devonian vol., p. 92, table facing p. 30.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 130–132, pl. 14. Thickness about 4 feet in Burkes Garden quadrangle. Overlies Rocky Gap sandstone; underlies Huntersville chert.

H. P. Woodward, 1948, West Virginia Geol. Survey, v. 15, p. 32, 130–149, 278–306. Ridgeley sandstone replaces Oriskany "sandstone" of previous reports. Maximum thicknesses—275 to 350 feet—occur in Hampshire and Morgan Counties. Overlies Port Jervis limestone of Helderberg group. Underlies Huntersville chert or in some areas Needmore shale.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept. 14] Washington County, p. 86–87. Member of Oriskany formation. Overlies Shriver chert member. Underlies Romney shale.

F. G. Lesure, 1957, Virginia Polytech. Inst. Bull., Expt. Sta. Ser. 118, p. 52–53, pl. 1. Described in Clifton Forge district. Thickness 2 to 25 feet. Overlies Licking Creek sandstone; underlies Needmore shale.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Oriskany formation, as mapped, includes Ridgeley sandstone at top and Shriver chert below.

Named for Ridgeley, W. Va.

Ridge Route Formation

Miocene, upper, or Pliocene, lower: Southern California.

Thomas Clements, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 2, p. 217 (fig. 1), 218. Continental beds consisting of rather well-bedded sandstones and shales with many beds of conglomerate. Overlies Modelo with slight angular discordance; underlies Saugus formation.

L. R. David, 1945, Jour. Paleontology, v. 19, no. 3, p. 315. Paleontological evidence indicates that age may be Pliocene or upper Miocene.

Peter Dehlinger, 1952, California Div. Mines Spec. Rept. 26, p. 6–8, pl. 1. Ridge Route formation, as exposed in area of study, consists of about 5,050 feet of sediments. Contact with underlying Modelo is not a sharp break. Ridge Route beds have been folded concordantly with the Modelo strata into the northwestward plunging Ridge Basin syncline.

Occurs in southeastern part of Tejon quadrangle.

**Ridgetop Shale**[1]

Lower Mississippian: Western Tennessee.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 29.

C. W. Wilson, Jr., and E. L. Spain, Jr., 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 6, p. 805–809. From stratigraphic and paleontologic evidence, it is believed that "Ridgetop shale" is not separate formation and that strata previously assigned to the "Ridgetop" are only a phase of the New Providence. If beds of Kinderhook age (other than probably the Chattanooga shale) are present in central Tennessee, they are not represented in beds formerly separated as "Ridgetop shale."

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 164. New Providence and Ridgetop shales, as locally recognized, appear to be slightly different developments of beds of same age.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 33. At type locality, overlies Maury formation.

Type section: Outcrops along Louisville and Nashville Railroad between Bakers Station in Davidson County, and Ridgetop in Robertson County.

†Ridgway shale member[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 202.

**Ridgway Till**[1]

Ridgway Conglomerate

Ridgway Glacial Epoch[1]

Paleocene: Southwestern Colorado.

Original reference: W. W. Arnold, 1915, U.S. Geol. Survey Prof. Paper 95, p. 16, map.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 14, 58, 59. Near Ridgway, the till is made up of two members; lower, as much as 100 feet thick, is typical glacial till; upper overlies erosional surface of lower and is clay with small pebbles. In all areas, overlies Mancos shale or older rocks; in Ridgway area, underlies Telluride conglomerate; near Gunnison, underlies San Juan tuff or other volcanic rocks. Now considered to be Paleocene.

F. B. Van Houten, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 385–388. Referred to as Ridgway conglomerate. On stratigraphic evidence, the Ridgway is a general correlative of the Upper Cretaceous and lower Paleocene Animas formation; on lithologic evidence, it is as reasonably a mudflow and stream deposit as it is a tillite.

Type locality: One mile west of Ridgway, Ouray County.

**Ridley Limestone** (in Stones River Group)[1]

Middle Ordovician: Central Tennessee.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 258–267.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 2 (fig. 1), 34–39. Predominantly gray limestone that is locally bluish or dove color; beds are massive, many ranging from 4 inches to 4 feet in thickness; between 20 and 35 feet above base of formation is a thin-bedded member about 10 feet thick that consists of beds ½ to 4 inches in thickness; chert is common and consists of (1) stringers, nodules, and blebs of dense black or dark-brown chert and (2) irregular masses of brown to light-brown or white chert. Thickness at type locality—herein designated—95 feet; in southern part of Rutherford County 115 feet. Underlies Lebanon limestone; overlies Pierce limestone.

Type section: Beginning in river bluff a short distance downstream from Davis mill and continuing across Jefferson-Lascassas Road and along secondary road to south and up hill on west side of road behind first house on right. Safford named limestone for exposures at Judge Ridley's mill near old Jefferson. Name has now been changed to Davis mill which is located 0.7 mile east of Jefferson on Jefferson-Lascassas Road in north-central Rutherford County.

Ridley Park Granodiorite

Age unknown: Southeastern Pennsylvania.

A. W. Postel, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2004–2005; 1941, Acad. Nat. Sci. Philadelphia Proc., v. 92, p. 125–133. Igneous rocks in Wissahickon schist in Philadelphia region originated in two ways: definite magmatic intrusions into Wissahickon and hydrothermal replacement of Wissahickon by potash and soda-rich solutions. Ridley Park granodiorite and Springfield aplitic granodiorite are products of magmatic intrusion; Springfield porphyroblastic granodiorite is product of hydrothermal reaction. Precise chronological position cannot be assigned as age of Wissahickon is in doubt. Relative age sequence is considered to be (oldest to youngest) metagabbro, Springfield porphyroblastic granodiorite, Springfield aplitic granodiorite, and Ridley Park granodiorite. Ridley Park occurs typically as conformable bodies from 2 to 100 feet in width, intrusive into Wissahickon schist parallel to the schistosity.

Area mapped is roughly rectangular, bounded on northwest by Narbeth, on northeast by Manayunk, on southwest by Chester, and on southeast by Philadelphia. Town of Ridley Park is in Delaware County.

Riepe Spring Limestone

Permian (Wolfcampain): East-central Nevada and western Utah.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 93 (chart 1), 102. Name given to massive coralline and fusulinid-bearing limestones originally included in Ely limestone by Spencer (1917) and by Pennebaker (1932) but restricted from Ely in present paper at type locality. Riepe Spring is 410 feet thick and is underlain by South Ridge sandstone (new) and overlain by Riepetown sandstone (new). On north side of Rib Hill, in Ruth mining district, upper 300 feet of Ely limestone, as described by Spencer (1917), is assigned to Riepe Spring; here unit rests disconformably on Ely (restricted) with no development of South Ridge sandstone separating the formations. Recognized in Carbon Ridge area south of Eureka, unit is 618 feet thick and rests on unnamed sequence of calcareous silts and mudstones and is overlain by Riepetown sandstone. Beds here assigned to Riepe Spring, plus underlying silts and mudstones, and overlying sands of Riepetown and limestones of Pequop formation were named Carbon Ridge formation by Nolan (1956). Riepe Spring is present in Confusion Range, Utah, where it was included in Ely limestone by Hose and Repenning (1959). In Tooele County, Utah, overlies Oquirrh formation.

Type section: At north end of Ward Mountain, SE¼ sec. 7, T. 15 N., R. 63 E., White Pine County, Nev. Name derived from Riepe Spring in SE¼SE¼ sec. 36, T. 16 N., R. 62 E.

Riepetown Sandstone (in Carbon Ridge Group)

Permian (Wolfcampian) : East-central Nevada and western Utah.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 93 (chart 1), 103. Name applied to basal sandstone member of Pennebaker's (1932) "Rib Hill" formation (herein abandoned). Thickness 1,008 feet at type locality where it consists of pale yellowish-gray, very fine to medium-grained, rounded to subrounded, platy to thick-bedded quartz sandstone which weathers brownish red and yellowish tan. Overlies Riepe Spring limestone (new) ; underlies Arcturus formation. At Moorman Ranch, Riepetown is about 1,200 feet thick, conformably overlies Riepe Spring limestone and underlies Moorman Ranch facies of Pequop formation. Identified in Utah. Hose and Repenning (1959) did not apply "Rib Hill" to beds in Confusion Range, but used Lawson's Arcturus limestone for those rocks stratigraphically above Riepe Spring limestone (referred to as Ely by them) and below Kaibab formation.

Type section: At Rib Hill, NW¼ sec. 21, T. 16 N., R. 62 E., White Pine County, Nev. Name derived from village of Riepetown, about 2 miles north-northwest of Rib Hill.

**Rierdon Formation** (in Ellis Group)

Rierdon Formation (in Sundance Group)

Upper Jurassic: Montana, South Dakota, and Wyoming.

W. A. Cobban, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 9, p. 1264 (fig. 1), 1277–1281, strat. sections. Name applied to group of alternating gray limy shales and limestones overlying Sawtooth formation (new) and disconformably underlying Swift formation (new). At type locality, consists of (ascending) 20½ feet of medium-gray chunky limy shale containing a few dense gray nodular limestones, 33½ feet of dark-medium-gray fissile calcareous to almost noncalcareous shale containing thin beds of gray dense nodular limestone, 43½ feet of medium-gray chunky shale containing a few thin beds of limestone in lower part, and 39 feet of alternating 4- to 6-inch limestone layers and thicker beds of medium-gray chunky limy shale. At type locality, lower part of formation is of upper Bathonian age and rest lower Callovian. Basal beds are younger on flanks of South arch than along Rocky Mountain front.

R. W. Imlay and others, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 32. In south-central Montana, overlies Piper formation (new).

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 466 (table 2), 475–477, 482. Swift-Rierdon nomenclature of Ellis group in Montana is applied in eastern Wyoming to formational units of Sundance group. Indications are that names are applicable to the marine Upper Jurassic throughout most of Wyoming and western South Dakota, but term Sundance should be retained because of historical significance. Section of Rierdon, measured northeast of Newcastle, Wyo., gives thickness 212 feet; formation includes (ascending) Stockade Beaver shale, Hulett sandstone, and Lak members. Overlies Gypsum Spring formation; underlies Swift formation. In some Black Hills areas, formation includes a fourth member, Canyon Springs, at base.

T. P. Storey, 1958, Alberta Soc. Petroleum Geologists Jour., v. 6, no. 4, p. 90–104. Discussion of Jurassic of Williston basin and adjacent areas. On basis of regional extent and significance of sub-Swift and sub-Rierdon unconformities, a different stratigraphic interpretation is presented. Swift is divided into Lower, Middle, and Upper units. Lower Swift in Williston basin is equivalent to Stockade Beaver and Hulett members of Sundance and unconformably overlies Rierdon, which has been considered equivalent to the Stockade Beaver and Hulett. Rierdon herein corresponds essentially to type Rierdon of Sweetgrass arch where it occurs with notable unconformity, both below Middle and Upper Swift and above Sawtooth and older Gypsum Spring beds. Lower Swift of Williston basin is absent over Sweetgrass arch and over most of western Montana, where it is overlapped by Swift formation of Cobban.

Type locality: Rierdon Gulch, sec. 23, T. 24 N., R. 9 W., Teton County, Mont.

Rifle Member (of De Beque Formation)

[Tertiary] : Colorado.

D. B. Kitts, 1956, Am. Mus. Nat. History Bull., v. 110, Art. 1, p. 47, 49, 51. Incidental mention in fossil locality data.

Type locality and derivation of name not stated.

Rift Shale (in Pocahontas Group)

Rift Shale (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series) : Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 217.

H. R. Wanless, 1939, Geol. Soc. America Special Paper 17, p. 100; P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 217, 244. Included in Pocahontas group, Pottsville series.

Named for exposures at Rift, McDowell County.

†Riga Schist[1]

Ordovician : Northwestern Connecticut and southwestern Massachusetts.

Original reference: W. H. Hobbs, 1893, Jour. Geology, v. 1, p. 717–736, 780–802.

Typically developed on Mount Riga Peak, Conn.

Riggs Formation

Paleozoic(?) : Southern California.

D. H. Kupfer, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 187, 194–196, 199, pls. 1, 2. Name provisionally applied to carbonate rocks of unknown age that compose Riggs thrust plate. Stratigraphic section not worked out and structure only partially known. Formation consists of interbedded recrystallized limestone and dolomite with a few thin beds of orthoquartzite and other clastic rocks. Estimated thickness about 2,500 feet; measured sections are of little help in estimating true thickness because structure is not understood and formation is locally dolomitized; sections may not give minimum thickness because area is highly faulted and repetitions could occur; several sections could fit together to give composite section many thousands of feet thick. No fossils found and little is known of stratigraphic position of formation. It may have been unconformable on Pahrump group before thrusting. Unconformably overlain by Tertiary(?) rocks. Formation may represent part of geologic column hitherto unidentified in this region. Tentative correlations suggest formation is younger than Crystal Spring formation (late Precambrian). Best evidence for age is Paleozoic(?). If future work should establish an unmetamorphosed correlative of Riggs rocks with a more nearly complete and structurally less complicated section, name Riggs should not be considered as having priority over any name given to new section.

Caps major peaks and ridges and is well exposed along Riggs Ridge north of Riggs silver mine and in Hill 2979 just east of Riggs Ridge (pl. 1). Area of report is Silurian Hills, San Bernardino County, 15 miles southeast of Death Valley.

**Riley Formation**

Upper Cambrian: Central Texas.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 154–155 [1945]; Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 111–112, pl. 2; P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 29, 225, 253, 290, 309 [1946]. Proposed to include all Cambrian strata in central Texas beneath Wilberns formation. Includes, from base to top, rocks formerly known as Hickory sandstone, Cap Mountain formation, and Lion sandstone member of Cap Mountain formation. Contacts of these rock units intergrade laterally, crossing faunal zones. They are here considered to be members of the Riley. Thickness in Moore Hollow area 780 feet. Riley as here defined is distinct from and not a revival of Riley series (Comstock and Dumble, 1890).

Named from Riley Mountains, southeastern Llano County, where included members are typically exposed.

†Riley Series[1]

Upper Cambrian: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxi, 286–289, pl. 3.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 154–155 [1945]; Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 111–112, pl. 2; P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 29, 225, 253, 290, 309 [1946]. Riley formation as herein defined is distinct from, and not a revival of Riley series of Comstock and Dumble (1890).

Named for Riley Mountains, Llano County.

**Riley Creek Glaciation**

Pleistocene: Central southern Alaska.

Clyde Wahrhaftig, 1953, *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 8, 13 (table 1); Clyde Wahrhaftig, 1958, U.S. Geol. Survey Prof. Paper 293–A, p. 18, 45–47, pls. 2, 3, 5. Four distinct glacial advances separated by marked ice withdrawals recognized along Nenana River. Riley Creek succeeded Healy glaciation (new). Drift much better preserved than older deposits. End moraine forms ridge along south bank of Riley Creek near its mouth at McKinley Park station. Lateral moraines and ice-contact deposits traced several miles up valleys of Yanert Fork and Nenana Rivers. Ground moraine has well-preserved drumlinoid hills, medium moraine ridges; and numerous lakes. Outwash plain extends downstream as set of terraces.

In Nenana River valley area.

Rillito Andesite

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 736, fig. 2, pl. 1. On fresh surfaces, red to brown and contains numerous prominent feldspar crystals, most about one-half centimeter in length. Weathers drab to brown. Dense and breaks into angular blocks which retain their angularity and smoothness until a late stage of weathering. Maintains smooth surfaces on weathered outcrops. Thickness 450 feet west of Safford Peak. Underlies Safford tuff (new). Separated from underlying Cretaceous volcanics by poorly exposed conglomerate.

A prominent cliff-former extending from cliffs west of Safford Peak to Silver Bell pass, near north end of Tucson Mountain Range, Pima County.

**Rimroad Gravel**

Oligocene or Miocene: Eastern Montana.

A. D. Howard, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 578; 1960, U.S. Geol. Survey Prof. Paper 326, p. 16 (table 2), 17, pl. 1. Fluvial sands and gravels, similar to younger Flaxville gravel. Average thickness 30 feet.

Distributed along high divide between Yellowstone River and parallel-flowing Redwater Creek to west, Dawson and Prairie Counties. Town of Rimroad is in southwestern Dawson County.

Rim Rock Sandstone (in Mesaverde Group)

Upper Cretaceous: Northwestern Colorado and northeastern Utah.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 111–114, pls. 1, 2, 3. At type locality, gray medium- to fine-grained sandstone, cross-bedded in some places, thinly bedded in others, and containing a few beds of shale that are tongues from main body of Mancos; varying amounts of black chert grains. Thickness at type locality 416 feet; at Rangely anticline 580 feet; at north end Asphalt Ridge 112 feet. Overlies Asphalt Ridge sandstone (new), contact gradational. In western part of area, at lower boundary a thin tongue of Mancos shale separates it from underlying Asphalt Ridge; upper boundary at base of Williams Fork formation is marked by green or gray shale overlain by brackish-water brown thin-bedded sandstones interbedded with pink, purple, white, and black shale and thin coal beds.

Type locality: At the Rim Rock, 9 miles east of the Green River, Uintah County, Utah. Continuous outcrops from Asphalt Ridge to Rio Blanco County, Colo., as hogback ridge called the "Rim Rock."

Rincon Limestone[1]

Upper Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 469, 471, 472, 480–482.

D. L. Bryant, 1952, Arizona Geol. Soc. Guidebook 2, p. 37, figs. 6, 7. Composed of 40 feet of thick-bedded massive coarse-grained pink limestone containing abundant trilobite fragments in Picacho de Calera Hills. Disconformably underlies Picacho de Calera formation. Type section cited.

Type locality: Rincon Mountains, 25 miles southeast of Tucson. Type section: near Colossal Cave in Whetstone Mountains.

**Rincon Shale[1] or Mudstone**

Rincon Claystone

Miocene, lower: Southern California.

Original reference: P. F. Kerr, 1931, Econ. Geology, v. 26, no. 2, p. 156, 157.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 33, 38 (fig. 2), pls. In southwestern Santa Barbara County, Rincon claystone is about 1,500 feet thick. Conformably overlies Vaqueros sandstone except in Tranquillon Mountain ridge where it lies unconformably on Espada formation (new), the Vaqueros having buttressed out. Conformably underlies Monterey shale except where Tranquillon volcanics (new) intervenes. Lower third of Rincon carries upper Zemorrian (lower Miocene) foraminiferal fauna; upper two-thirds carries Saucesian (upper lower Miocene) fauna.

J. E. Upson, 1951, U.S. Geol. Survey Water-Supply Paper 1108, p. 14. Consists of massive dark-bluish-gray mudstone which develops a dark-greenish-black mucky soil. Characterized by discontinuous bands of ovoid calcareous concretions, usually limonitic and yellowish-brown in color. Thickness about 1,700 feet. Overlies Vaqueros sandstone; underlies Monterey shale; both contacts conformable. Lower Miocene.

P. C. Orr, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 113–115. On Santa Rosa Island, Rincon shale underlies Garanon member of Santa Rosa Island formation (both new).

Type section: Along Los Sauces Creek east of Rincon Mountain, Ventura County.

Rinconada Schist Member or phase (of Ortega Quartzite)

Precambrian (Proterozoic): Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 22, pl. 2. Consists of gray to buff quartz-muscovite schist, which in many places has interbedded quartzite members. Most of the schist is more or less even textured. Some is conglomeratic. In one area, it directly overlies Hopewell series (new).

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 6, 8 (fig. 2), 12–19, pl. 1. Rinconada schist member consists of four distinctive and mappable units: andalusite-biotite hornfels, staurolite gneiss and schist, quartzite, and muscovite-quartz-biotite-garnet phyllite. Total thickness estimated to be 1,800 feet. Lies between a lower quartzite member and the upper Pilar phyllite member (new). Derivation of name given.

Named for settlement of Rinconada 2 miles north of Dixon in the Rio Grande Canyon. Occurs in Picuris Mountain area, Taos County.

Rincon Valley Granite

Laramide: Southern Arizona.

C. J. Acker, (abs.) 1958, Arizona Geol. Soc. Digest, p. 47. Massive blocks of Paleozoic sedimentary rocks have been thrust from a southerly direction over an irregular surface of Rincon Valley granite of Laramide age.

In Colossal Cave area, Pima County.

**Rindgemere Formation**[1]

Pennsylvanian (?) : Southeastern New Hampshire and southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 199.

Occupies broad area in Rochester, N.H., and Acton and Lebanon Townships, Maine. Named for exposures at Rindgemere Station, East Rochester, Strafford County, N.H.

**Ringbone Shale** (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 532, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 18–19, pl. 1. Comprises a basal conglomerate, containing boulders as large as 2½ feet in diameter, followed by dark shale, subordinate sandstone, and here and there a bed of black limestone. Thickness of any single bed rarely exceeds 5 feet. Upper 150 feet composed of tuffaceous sandstone and shale containing two purer volcanic members, one a basalt flow and one an andesite breccia, each approximately 50 feet thick. Maximum total thickness about 650 feet. In vicinity of Ringbone Ranch, formation is interfingered with conglomerate of the underlying Broken Jug limestone (new); thins out southward against old surface of Broken Jug limestone; underlies Hidalgo volcanics (new). Trinity age.

Named from Ringbone Ranch, near which formation is best exposed, Eureka district in Little Hatchet Mountains.

**Ringold Formation**[1]

Pleistocene, middle to upper: Northeastern Oregon and southeastern Washington.

Original reference: J. C. Merriam and J. P. Buwalda, 1917, California Univ. Pub., Bull. Dept. Geology, v. 10, no. 15, p. 255–266.

R. C. Newcomb, 1958, Am. Jour. Sci., v. 256, no. 5, p. 328–340. Type section of formation consists of about 620 feet of horizontally bedded continental sediments lying between river level [Columbia River] and the tops of the White Bluffs, from about 340 to 960 feet in altitude. Uppermost 505 feet of section composed largely of lacustrine sand and silt; lower part is a weakly indurated conglomerate that was deposited by river currents; the conglomerate extends below river level, down to an altitude of about 290 feet; it is underlain by 100 to 290 feet of lacustrine silt, clay, and sand, and some gravel. This lower lacustrine composite, commonly called the "blue clays," is here considered a part of the Ringold; it overlies the basalt bedrock.

Type locality: White Bluffs of Columbia River, Franklin and Benton Counties, Wash. Named for Ringold post office which is situated at base of White Bluffs.

Río Conglomerate[1]

Upper Cretaceous: Puerto Rico.

Original reference: H. A. Meyerhoff, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 278.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 60 (table 7). Thickness 300 feet. Underlies Luquillo formation; overlies La Muda limestone.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 9 (fig. 3). Table shows Río conglomerate (Meyerhoff and Smith, 1931) is possibly equivalent to Figuera volcanics of present report.

J. D. Weaver, 1956, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 338. Upper Cretaceous. Type locality stated.

Type locality: At Barrio Río, about 8 miles south of San Juan. Also crops out near Aguas Buenas and along railway west of Trujillo Alto. Conglomerate stands as prominent ridge which crosses the Río Piedras-Caguas Highway at northern limit of La Muda, Fajardo district.

Río Blanco Formation

Río Blanco Series[1]

Upper Cretaceous: Puerto Rico.

Original reference: B. Hubbard, 1923, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 1, p. 26.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2). Thickness about 7,000 feet. Underlies Río Yauco series; overlies Río Culebrinas series. Term "series" is taken from original surveys, but is misnomer.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, no. 1, p. 200. In Yauco area, a complex, more than 9,000 meters thick, of volcanic flows with interbedded marine limestones, mudstones, tuffs, and sedimentary rocks derived from the volcanic rocks, is divided into eight formations: Sabana Grande, El Rayo, Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara (new). Río Blanco and Río Yauco formations in a northern basin are considered to have been deposited penecontemporaneously with deposition of Ensenda in a southern basin. Complex ranges in age from Senonian to late Paleocene, possibly Eocene.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 344–345, pl. 1. In Mayagüez, contains massive tuffaceous volcanic rock with tongues of lava and breccia near top, bottom, and middle of unit. Includes Las Marías limestone member. Occurs between Yauco mudstone and Río Culebrinas map unit and dips generally 60° to 70° SW. Attitudes are conformable with map units above and below. Thickness 4,700 meters, of which 2,700 is measured in Mayagüez area, and 1,200 in San Sebastián area. Structural position of Yauco mudstone indicates that the Río Blanco should be stratigraphically below Yauco if the two units are conformable. Age determinations show that the Río Blanco is equivalent to or younger than the Yauco. If the Yauco is in fault contact with the Río Blanco, the age relationship may be satisfied, but there is no evidence of faulting. At present time, a fault is assumed.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 47–56. In area of this report, Río Blanco formation crops out in Ponce, Peñuelas, and Adjuntas quadrangles. Consists of unknown thickness of pyroclastic rocks alternating with andesite flows. Lenses of massive limestone and lenses of calcareous mudstone, thin-bedded argillaceous limestone, and calcareous tuff present locally. Mattson included rocks assignable to Río Yauco formation in his Mayagüez. Formation along northern border is brought in contact with middle Eocene Jacaguas group (new) by Cerrillos-Descalabrado fault. To the west, interfingers with Río Yauco formation. To east of the Río Guayo, formation is covered by sediments of "undeformed sequence." Inasmuch as the Río Yauco and Río Blanco formations interfinger, the Río Blanco should be included in Mayagüez group.

Named from exposures along Río Blanco, Lares district.

Río Chiquito Formation

Upper Cretaceous: Puerto Rico.

E. A. Pessagno, Jr., 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 84. Consists of unknown thickness of pyroclastics alternating with andesite flows. Locally contains lenses of limestone that correlate lithologically and faunistically with massive limestones of Mattson's (1960) San Germán formation. Relationship of Río Chiquito with Río Yauco formation to west not precisely known. Cover of Oligocene and younger sediments obscures relationship of the Río Chiquito with other Cretaceous rocks to east. Intruded by Tibes diorite (new). Footnote states that name Río Chiquito is no longer used. Unit currently assigned to Río Blanco formation.

In Ponce-Coamo area, south-central part of island.

Río Culebrinas Formation

Río Culebrinas Series[1]

Cretaceous: Puerto Rico.

Original reference: B. Hubbard, 1923, New York Acad. Sci. Scientific Survey of Porto Rico and Virgin Islands, v. 2, pt. 1, p. 25.

M. D. Turner, 1958, (abs.) Caribbean Geol. Conf., 1st, Antigua, British West Indies, 1955, p. 25. In San Sebastián area, the Older Series is made up of (1) tuffaceous rocks, agglomerates, and associated sedimentary rocks known as Río Culebrinas series and (2) stratigraphically younger massive volcanic flows, agglomerates, and tuffaceous rocks termed Río Blanco series. Thickness of each series about 1,000 meters. The Río Culebrinas is tightly folded and both Cretaceous units are cut across by faults.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 103. Río Culebrinas formation may interfinger with Augustinillo formation (new).

Named for exposures in Río Culebrinas Valley, Lares district.

Río de la Plata Series[1]

Lower Cretaceous: Puerto Rico.

Original reference: E. T. Hodge, 1920, New York Acad. Sci. Scientific Survey of Porto Rico and Virgin Islands, v. 1, pt. 2, p. 130.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 39, 40, 41. Predominantly tuffs. Thickness about 2,000 feet. Recent fossil discoveries help to substantiate Lower Cretaceous age. Term "series" is taken from original survey but is misnomer.

Named for Río de la Plata River which flows across the rocks, Coamo-Guayama district.

Rio Dell Formation (in Wildcat Group)

Pliocene, middle to upper: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 31–33, 107–111, pls. 1, 2. Massive mudstone, alternating thin sandstone and mudstone, "phantom-banded" mudstone, and very fine grained sandstone. In Ferndale quadrangle, divided into: upper member—mudstone; middle member—alternating sandstones and mudstones; lower member—mudstone with sandstones; units not distinguished to the east where there is more very fine grained sandstone in upper part. Thickness 3,000 to 6,000 feet; thins northward. Underlies Scotia Bluffs formation (new); unconformably overlies Eel River formation (new); top of Rio Dell arbitrarily taken as lowermost buff-weathering sandstone of Scotia Bluffs; base of Rio Dell chosen as a thin glauconite mudstone or fine-grained sandstone overlying a cut surface of upper Eel River mudstone.

Type section: East bank Eel River north of Scotia and west bank of river west of Scotia, Humboldt County.

Río Descalabrado[s] Member (of Naranjo Formation)

Río Descalabrados Series[1]

Eocene: Puerto Rico.

Original reference: E. T. Hodge, 1920, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 2, p. 161.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 54. Name Río Descalabrado[s] series discarded and name Cañas Arriba formation adopted.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 78–85. Member of Naranjo formation (new). Hodge applied name Río Descalabrado[s] series to these rocks. He overlooked the possiblity of Cretaceous sequence being repeated by faulting and mistakenly included Upper Cretaceous rocks belonging to the units now named Ildefonso and Robles formations in his "Río Descalabrado[s] series." Term "series" is here amended to member. Consists of marls, argillaceous limestones, and calcareous siltstones together with lenses and beds of Coamo Springs and Guayo conglomeratic sandstone. Thickness 0 to 7,600 feet. Interfingers with Guayo conglomeratic sandstone member (new) to west and is completely covered by alluvium east of Salinas. Lower part interfingers with Coamo Springs limestone member. Where Coamo Springs member is absent, the Río Descalabrado[s] rests directly on Miramar member (new) or on underlying Upper Cretaceous rocks.

Type area: West and north of village of Las Ollas.

Río Duque Shales

Eocene: Panamá.

T. F. Thompson, 1944, Geological explorations in vicinity of Rio Quebrancha for the Panama Cement Company: Panama Canal, Spec. Eng. Div., p. 21–23. Fine-grained silty dark-gray locally carbonaceous soft shales with thin sandstone beds. Thickness probably more than 600 meters. Believed that Río Duque and Vamos formations are identical and that age of both are either lower Miocene or uppermost Oligocene.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 345. Synonym of Gatuncillo formation. Eocene.

Río Duque is a small tributary of Río Agua Sucia in Panamá immediately west of the Quebrancha syncline.

Rio Grande Drift[1]

Pleistocene: Southwestern Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Min. Survey Bull. 8, p. 41.

Shafter district, Presidio County.

Rio Grande Gravels[1] or Beds

Tertiary: New Mexico.

Original reference: C. L. Herrick, 1898, Am. Geologist, v. 22, p. 26–43.

Kirk Bryan and F. C. McCann, 1937, Jour. Geology, v. 45, p. 807. Instead of Santa Fe formation, Bryan (1909, New Mexico Univ. Bull., Geol. Ser., v. 3, no. 1) used term "Rio Grande beds," which should be abandoned.

Occurs in vicinity of Albuquerque.

Rio Grande Loess[1]

Tertiary, upper: Central northern New Mexico.

Original reference: C. L. Herrick, 1898, Am. Geologist, v. 22, p. 26–43.

Rio Grande Marl[1]

Probably Miocene and Pliocene: Central northern New Mexico.

Original reference: A. B. Reagan, 1903, Am. Geologist, v. 31, p. 87, 89.

Occurs in inner valley of Rio Grande.

†Rio Grande series[1]

Pennsylvanian: New Mexico.

Original reference: C. R. Keyes, 1903, *in* Report of the Governor of New Mexico to the Secretary of the Interior.

Rio Grande Series[1]

Tertiary, upper: Central northern New Mexico.

Original reference: C. L. Herrick, 1898, Am. Geologist, v. 22, p. 26–43.

In Albuquerque region.

**Río Guatemala Group**

Oligocene: Puerto Rico.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 85. Cibao marl, Lares limestone, and San Sebastián formation are largely facies equivalents showing rapid lateral transition; term "Río Guatemala group" is introduced to refer to the whole sedimentary complex. Names Cibao, Lares, and San Sebastián are retained to designate, respectively; predominantly marl and chalky limestone, predominantly reef-type limestone and predominantly clastic facies of the group. Maximum thickness about 700 meters in area between Río Camuy and longitude line through San Sebastián.

Named from the Río Guatemala, which flows its entire course in outcrop belt of group north and west of San Sebastián. Group crops out in belt extending from vicinity of Moca on west to vicinity of Bayamón on east.

Río Jueyes Series[1]

Eocene, middle(?)-upper: Puerto Rico.

Original reference: E. T. Hodge, 1920, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 2, p. 149.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 51, 52. In Coamo-Guayama district underlies Coamo Springs series; unconformable above Guayama series. Thickness 3,500 feet. On basis of fossil evidence age is considered to be Eocene, probably upper-middle. Term "series" is taken from original surveys, but is misnomer.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 24, 44. Toa Vaca formation (new) includes Río Jueyes and Guayama series of Hodge. Part of Hodge's Río Jueyes series also included in Ildefonso formation (new).

Named from river which flows over central exposures, Coamo-Guayama district.

Río Loco Formation

Upper Cretaceous (Cenomanian) : Southwestern Puerto Rico.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, no. 1, p. 200, 201. In Yauco area, a complex, more than 9,000 meters thick, of volcanic flows with interbedded marine limestones, mudstones, tuffs, and sedimentary rocks derived from volcanic rocks. is divided into eight formations: Sabana Grande (new), El Rayo (new), Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara (new). The Río Loco is considered to intertongue with Río Yauco formation.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 197; 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 324–329, pl. 1. Redefined to include bronzite andesite near Parguera and Guanica and to exclude a large fairly continuous mudstone unit considered Yauco mudstone. Contains bronzite andesite porphyry lavas, more than half with pillow form, and subordinate tuff, breccia, hornblende andesite, dacite(?), and limestone. Thickness about 300 meters in northern exposures; no thicknesses measured elsewhere. Lies between Mayagüez group (new) and Bermeja complex (new).

E. A. Pessagno, Jr., Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 23. Underlies Robles formation in Barranquitas quadrangle.

Occurs on flanks of Las Mesas-Fraile anticline and in southeastern part of Mayagüez area.

**Río Matón Limestone Member** (of Robles formation)

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 144, 145. Occurs sporadically at base of formation from central Puerto Rico southward to a point near south coast where it lies unconformably on volcanic breccia of volcanic complex. In part a reef and in part a near-reef accumulation; consists of both massive and bedded limestones; in southernmost outcrops, interbedded with volcanic sandstone and contains volcanic debris. Fossils indicate Senonian (Coniacian-Campanian) age. Name credited to Berryhill and Glover (in press).

H. L. Berryhill, Jr., and Lynn Glover 3d, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I–319. Underlies Cayey siltstone member (new). Thickness about 50 meters at type locality.

Type locality: Just west of Highway 1, at point 2.7 kilometers S.65°W. of Cayey Plaza, Cayey quadrangle. Named for exposures on south side of Río Matón.

Rio Tinto Formation

Carboniferous(?): Northeastern Nevada.

A. E. Granger and others, 1957, Nevada Bur. Mines Bull. 54, p. 116, pl. 14. In Elko County, a thrust fault crops out south of Rio Tinto mine and divides Paleozoic rocks into two groups of formations which cannot as yet be correlated. Rio Tinto formation is lowest exposed rock of lower plate sequence and forms wall rock of Rio Tinto mine. Predominantly fine-grained quartz-sericite schist, shale, and locally fine-grained dark quartzite and dense black chert containing poorly preserved Radiolaria. Estimated minimum thickness 4,000 feet (Nolan, unpub. rept.). Stephens (unpub. rept. )gives 2,085 feet. Unconformably underlies Banner limetone (new). Age not established. Mapped as Carboniferous(?).

Named for occurrence at Rio Tinto mine, Elko County.

Río Yauco Formation or Shale

Río Yauco Series[1]

Upper Cretaceous: Puerto Rico.

G. J. Mitchell, 1922, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 3, p. 249. Strongly bedded black shale about 1,200 feet thick exposed on upper Río Yauco, Ponce district. Conformably interbedded with San Germán limestone considered to be Upper Cretaceous.

Bela Hubbard, 1923, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 1, p. 25, 29–35. In southern part of Lares district, Río Yauco series is named from the Río Yauco shale, a term applied by Mitchell to black shales which form a prominent part of this series between Mayagüez and Consumo. In this area sequence is Río Culebrinas series (oldest), Río Blanco series, and Río Yauco series. In Río Yauco series, about 6,000 feet of shales and tuffs are exposed along Mayagüez-Las Marías Road from kilometer 13 to kilometer 19; traverse across series northeast from Rincon shows total thickness of over 8,000 feet; allowance made for duplication of strata by folding and faulting.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 60 (table 7). Thickness of shale in Ponce district about 7,000 feet; thickness of series in Lares district also 7,000 feet. Heading on table 2 (stratigraphic table for Puerto Rico) reads Upper(?) Cretaceous; however text and other table headings do not qualify the Upper Cretaceous.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, no. 1, p. 200–201. In Yauco area, a complex, more than 9,000 meters thick, of volcanic flows with interbedded marine limestones, mudstones, tuffs, and sedimentary rocks derived from the volcanic rocks, is divided into eight formations: Sabana Grande, El Rayo, Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara (new). Río Yauco and Río Blanco formations are considered to have been deposited in a northern basin penecontemporaneously with deposition of Ensenada in a southern basin. The Río Yauco and Ensenada overlie the Sabana Grande and El Rayo formations unconformably and are separated from overlying San Germán and Jicara formations, at least locally by unconformities. Complex ranges in age from Senonian to late Paleocene, possibly Eocene.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p.

55–62. Name Río Yauco shale first used by Mitchell (1922). Slodowski (1956, unpub. thesis, [1958, Dissert. Abs.]) proposed that term shale be replaced by formation inasmuch as sequence is composed of many lithic types. Mitchell (1922) used name Peñuelas shale for rocks correlated with Río Yauco formation of present report. Mattson [1960] includes rocks assignable to Río Yauco formation in his Mayagüez group. In area of present report, Río Yauco formation is exposed in western part of Peñuelas quadrangle. Consists of heterogeneous marine assemblage of mudstone, tuffs, tuff breccias, limestones sedimentary breccias, and basalt flows. Thickness unknown; Slodowski (1956) estimated 4,500 feet. Interfingers with Río Blanco formation

Named for exposures on upper Río Yauco, Ponce district.

**Ripley Formation**[1] (in Selmá Group)

Upper Cretaceous; northern and central Mississippi, Alabama, Georgia, western Kentucky, and western Tennessee.

Original reference: E. W. Hilgard, 1860, Mississippi Geol. and Agric., p. 3, 62, 83–95.

B. Wade, 1917, Johns Hopkins Univ. Circ., new ser., no. 3, Whole No. 203, p. 74, 101. Includes Coon Creek tongue (new).

W. H. Monroe, 1941, Alabama Geol. Survey Bull. 48, p. 103–129. In this report, base of formation in eastern Alabama is placed at base of a thick deposit of coarse sand and gravel rather than at contact of *Exogyra ponderosa* and *Exogyra costata* zones as was proposed by Stephenson and Monroe (1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12). This further restricts the Ripley by about 50 feet, but gravel bed rather than faunal zone contact is more logical base for formation. Proposed restriction has advantage in that base of Ripley is at very nearly the same stratigraphic position from Chattahoochee River to Sumter County. Conformably overlies Demopolis member of Selma chalk from Mississippi State line through Lowndes County, but, in eastern part of Sumter County, uppermost part of Demopolis chalk merges laterally toward the east into sand which is included in Ripley; in western part of Montgomery County, Ripley rests on westward-extending tongue of Cusseta sand; unconformably underlies Prairie Bluff chalk; in some areas overlapped by Providence sand.

D. R. Stewart, Lyle McManamy, and H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources 62d Bienn. Rept., app. 3, p. 9. Represented in Stoddard County, Mo., by McNairy member.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Included in Selma group.

D. H. Eargle, 1955, U.S. Geol. Survey Bull. 1014, p. 54–69. In Alabama, name Ripley is used in western Sumter County for chalky sand and clay beds essentially contemporaneous and continuous with Ripley of Mississippi. Farther east in Alabama, successively lower parts of Demopolis chalk grade laterally into a sand and clay facies that is designated Ripley. In eastern Alabama, the Ripley includes all strata between underlying Blufftown formation and overlying Prairie Bluff chalk or its correlative, the Providence sand. Coarse sandy beds at base of Ripley in eastern Alabama, designated Cusseta sand member, represent western featheredge of Cusseta sand of Georgia. In Georgia, name Ripley is applied to sand and sandy clay that contain fossils in upland areas. The strata, originally described as Renfroes marl (Veatch, 1909), lie between

Cusseta sand and Providence sand. Detailed description of outcrops in Georgia.

L. W. Stephenson, 1955, U.S. Geol. Survey Prof. Paper 274–E, p. 98, 100, 101. In this report, McNairy member is raised to formational rank in Missouri and Illinois. [Hence the Ripley is geographically restricted.]

F. F. Mellen, 1958, Mississippi Geol. Survey Bull. 85, p. 49–54. Includes Chiwapa sandstone member (new).

N. F. Sohl, 1960, U.S. Geol. Survey Prof. Paper 331–A, p. 9–22. Formation discussed in Tennessee and Mississippi. Thickest in northern areas of outcrop, where, in vicinity of Tennessee-Mississippi State line, it is close to 350 feet thick; thins southward until near Alabama-Mississippi State line, it is about 60 feet thick. In northern Mississippi, divided into (ascending) transitional clay, Coon Creek tongue, McNairy sand member, sand of upper part of Ripley, and Keownville limestone member (new). Base of formation is gradational downward to Demopolis chalk through transitional clay. In Tennessee and northernmost Mississippi this clay unit lies entirely within *Exogyra cancellata* zones, but, south of southern Tippah County, the transitional clay lies in part above that zone. This clay, along with rest of formation, grades into sandy chalk in Noxubee County, Miss. Upward, clay becomes increasingly sandy and grades into highly fossiliferous sand units of Coon Creek tongue. In Pontotoc and Kemper Counties, Miss., McNairy sand member is absent, and greater part of formation cannot be divided. In Noxubee County, Miss., whole formation grades into chalk facies. Unconformity at top of Ripley varies locally in magnitude. In some places, Keownville limestone member appears to be entirely eroded off, and overlying Prairie Bluff chalk rests on sand of middle part of Ripley.

W. S. Parks, 1960, Mississippi Geol. Survey Bull. 87, p. 22 (table 2), 26 (fig. 4), 61–68, pl. 4. Ripley formation of this report [Prentiss County] refers to all beds above Demopolis chalk and consists of three units: transitional clay, Coon Creek tongue, and McNairy sand member. Disconformably underlies Owl Creek and Prairie Bluff formation. Maximum thickness about 300 feet.

Named for Ripley, Tippah County, Miss.

Ripleyan series[1]

Upper Cretaceous: Mississippi.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 252.

Ripogenous (Ripogenus) Series[1]

Silurian: North-central Maine.

Original reference [name appears as Ripogenous series]: F. W. Toppan, 1932, Geology of Maine, Contr. Dept. Geol. Union Coll., Schenectady, p. 71–72.

Bradford Willard, 1945, Jour. Paleontology, v. 19, no. 1, p. 67. Series revised to include Chesuncook limestone and Ripogenus volcanics (both new).

Exposed in Ripogenous [Ripogenus] Gorge, where it is intruded by Katahdin granite, just below prominent rock known as the "Little Heater," Piscataquis County.

Ripogenus Volcanics

Lower or Middle Silurian: North-central Maine.

Bradford Willard, 1945, Jour. Paleontology, v. 19, no. 1, p. 67. Named as a subdivision of the Ripogenus series: intrudes sediments of the series. Name credited to L. W. Fisher (written commun. 1941). Age not stated.

A. J. Boucot, 1954, Am. Jour. Sci., v. 252, no. 3, p. 144–145. Discussion of stratigraphic relationships near contact of Katahdin granite. Oldest stratum exposed on west side of Ripogenus Dam is basalt. Fisher (in Willard. 1945) suggested term Ripogenus volcanics be applied to the basalt. Name Ripogenus is preoccupied by Toppan's Ripogenous [Ripogenus] series. Katahdin granite cuts the basalt. No new name is suggested for the basalt.

Named from Ripogenus Dam at south end of southeast arm of Chesuncook Lake, Piscataquis County.

Ripple Quartzite[1]

Precambrian: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 7.

Forms summit of Mount Ripple, British Columbia.

Ripton Conglomerate[1]

Precambrian: Northwestern Vermont.

Original reference: W. G. Foye, 1919, Vermont State Geologist 11th Rept., p. 84–85.

In Brandon quadrangle, Addison County.

Risco Formation

Upper Cretaceous(?): Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 12–16, pls. 2, 3. Massive greenish-gray concretionary graywacke, forming rugged cliffs; lower half contains six tuffaceous sandstones; conglomerate present at base of formation west of Polonio Pass fault. At type locality, formation is roughly divisible into three parts in approximate thickness ratio (from bottom to top) of 2:3:5. Upper and lower parts consists of massive concretionary coarse sandstone, sandwiching a group of thin finer-grained sandstones relatively free of concretions. Roughly the same ratio holds in Three Peaks anticline, despite thinning and facies change. Thickness 2,965 feet at type locality; 4,400 feet north of Antelope Pumping Station; 1,650 in Three Peaks anticline; thinning is toward the northeast; unit pinches out on north limb of Three Peaks anticline. Conformably underlies Johnson Peak formation (new); overlies Badger shale (new), at type locality, contact is a thrust, but elsewhere contact is conformable. No diagnostic fossils.

Type locality: Comprises upper parts of both Risco Canyon and next adjacent canyon to west, west of Orchard Peak, Annette quadrangle, Kern County. Formation extends as nearly continuous band of outcrop from northwest corner of Orchard Peak area southeastward, then eastward almost to Devil's Den where it ends abruptly against Hex thrust.

Rising Bull Member (of Grinnell Argillite[1] or Formation)

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1889–1890. Thickness 600 to 1,100 feet. Argillites, quartzites, and mud breccias forming initial transition between Grinnell and Siyeh. Type locality designated.

Type locality: Upper cliffs of Mount Rockwell (Rising Bull of the Blackfeet), south of Upper Two Medicine Lake, Glacier National Park.

Rising Wolf Member (of Appekunny Argillite)[1]

Rising Wolf Member (of Grinnell Formation)

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1889. Thickness 200 to 700 feet. Reassigned to Grinnell Formation. Type locality designated.

Richard Rezak, 1957, U.S. Geol. Survey Prof. Paper 294–D, p. 137. Discussion of stromatolites of Belt series. Rising Wolf member of Fenton and Fenton (1937) is represented by *Collenia undosa* zone 1 in Grinnell argillites.

Type locality: Southern slopes of Rising Wolf Mountain, Glacier National Park.

Rison Clay Member (of White Bluff Formation)

Eocene (Jacksonian): Southeastern Arkansas.

L. J. Wilbert, Jr., 1953, Arkansas Div. Geology Bull. 19, p. 39–40, 70–80. Defined to include all marine Jacksonian beds developed above the Caney Point member in the southern part of the outcrop area of the White Bluff. Typical lithology—silts and blocky clay containing arenaceous foraminifers, molluscan molds, local thin lenticular concretions of molluscan molds. Maximum thickness of about 140 feet attained in eastern Cleveland County; member thins to a featheredge at southern margin of outcrop area. Overlies Caney Point marl member; interfingers with and is overlapped by Redfield formation.

Type locality: Along U.S. Highway 79, near junction with Arkansas State Highway 35, west of Rison city limits, Cleveland County.

Risser Beds

Silurian: Central western North Dakota (subsurface)

Saskatchewan Geological Society, 1958, Report of the Lower Palaeozoic names and correlations committee: Saskatchewan Geol. Soc., p. 16, 17, charts A and B. Buff to cream-colored dense to chalky microcrystalline dolomites; porous in part; occasional fossil fragments. Characteristically with reddish sandy development at base (13,120 to 13,174 feet in type well). Maximum known thickness 556 feet near center of Williston Basin (in west-central North Dakota). Everywhere truncated by a pre-Middle Devonian surface of unconformity; rest with possible unconformity on Hanson beds (new). No fossil evidence of Silurian age; may be in part Devonian. Name credited to unpublished Shell Oil Co. usage.

Type locality: Amerada No. 1 Risser (center SW¼ SE¼ sec. 12, T. 149 N., R. 96 W., McKenzie County) between 12,615 and 13,174 feet; Williston Basin.

Rita Blanca deposits

Pleistocene: Western and northwestern Texas.

G. L. Evans and G. E. Meade, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 493. Lacustrine deposits in part equivalent to Blanco beds. Basal contact not exposed. Lowermost exposed strata consist of 30 feet or more of dark distinctly laminated clays containing plant remains and small fossil fish. Some sand beds and thin uniform layers of fresh-water dolomite are interbedded in the shales. Overlying the laminated clays is section, 50 feet or more thick, consisting mainly of sands, bentonitic clays, and thin-bedded calcareous sandstone.

Exposed along Rita Blanca Creek and its tributaries about 8 miles west of Channing, Hartley County.

Ritchie Limestone

Upper Cambrian or Lower Ordovician: East-central New York.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 797 (fig. 1), 799 (fig. 2b); 803 (fig. 3), 804–806. Massive very thick bedded ash-white weathering gray-blue calcilutite only slightly dolomitized. Contains black chert nodules and *Rhachopea*(?). Thickness 43 feet. Formation exposed by faulting; measured thickness may be excessive. Apparently unconformably underlain by noncherty dark-gray coarse-grained dolomite of upper Hoyt and unconformably overlain by 7 feet of conglomerate composed of dolomite cobbles in a sand matrix. Latter grades laterally into a coarse sandstone with well-rounded quartz grains, which grades abruptly upward into cherty arenaceous blue-gray dolomite with Lower Ordovician fauna. Coarse clastic layer is interpreted as Mosherville sandstone (new) and dolomite as Gailor dolomite (new). Upper Cambrian or Lower Ordovician.

John Rodgers, 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for Field Trips in New England, Nov. 10–12, p. 34 (table 1). Listed on table as Lower Ordovician. Age is uncertain; may be facies of beds above or below.

Type locality: Just south of Petrified Sea Gardens, owned by Mr. Ritchie, about 3 miles west of Saratoga Springs, Saratoga County. This is only known exposure.

Ritchie Red Beds (in Monongahela Formation)[1]

Ritchie redbed member

Pennsylvanian: Northern West Virginia and eastern Ohio.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 30, 44.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 181. Member of Lower Uniontown cyclothem in report on Athens County. Composed of variegated clay shale with calcareous inclusions. Thickness about 10 feet. Above Arnoldsburg shale and sandstone member; below Lower Uniontown limestone member. The Ritchie is also considered a member of Uniontown cyclothem wherever upper boundary of Lower Uniontown cyclothem is lost. Monongahela series.

Named for exposures in Ritchie County, W. Va.

Ritito Conglomerate

Miocene(?): Central northern New Mexico.

Fred Barker. 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 3, 38, 42–43, pl. 1. Consists commonly of rounded to subangular pebbles and small boulders of fine-grained to pebbly quartzite, amphibolite, and metarhyolite. Most amphibolite fragments are weathered and very friable. Matrix of conglomerate is quartzose and composed of poorly sorted, subangular to subrounded grains. Generally the rock is weakly cemented and typically has medium-gray color. Maximum thickness of 400 feet on east side of Ritito Creek and in Escondido Canyon; pinches out entirely a mile to east of Canada del Oso. Lies directly upon Precambrian rocks along lower Vallecitos Valley.

Named after exposures in Ritito Canyon, in secs. 11 and 14, T. 27 N., R. 7 E. Other exposures 2 miles southeast and 1 mile west to south of Canon Plaza, along northeast side of Vallecitos Valley from Canon Plaza to Jarosita Creek, and along parts of Escondida and Felipito Canyons.

Rittman Conglomerate Lentil (of Cuyahoga Formation)[1]

Rittman Conglomerate Submember (of Armstrong Sandstone Member of Cuyahoga Formation)

Rittman Member (of Cuyahoga Formation)

Lower Mississippian: North-central Ohio.

Original reference: G. W. Conrey, 1921, Ohio Geol. Survey, 4th ser., Bull. 24, p. 56.

F. T. Holden, 1942, Jour. Geology, v. 50, no. 1, p. 41 (table), 49, 51. Termed Rittman conglomerate submember of Armstrong sand member of Cuyahoga formation in area of River Styx conglomerate facies. Unit consists of a layer of about 2 feet of brown and tan coarse conglomerate which is fossiliferous and rather friable, overlying a dark olive medium- and coarse-grained sandstone containing considerable mica. Not traceable throughout facies.

E. J. Szmuc, 1958, Dissert. Abs., v. 18, no. 6, p. 2109. Rank raised to member of Cuyahoga formation. Overlies Meadville member; underlies Armstrong member. Lower Mississippian.

Well exposed at Rittman, Wayne County.

River Glacial Stage

Pleistocene (Iowan): North-central Colorado.

R. L. Ives, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 75. Younger than Stillwater glacial stage (new); older than Arapaho glacial stage (new). Evidenced by terminal moraine.

R. L. Ives, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1057–1058, 1062. Time covered by the deposition of a terminal moraine across mouth of Arapaho Creek which was mapped as moraine two. Ice and moraines of River stage dammed the Colorado River for short time, and some morainal material of this age was deposited in Colorado Valley on northwest side of river opposite Arapaho Creek.

In Monarch Valley, Grand County.

Riverbank Formation

Pleistocene, middle: Central California.

S. N. Davis and F. R. Hall, 1959, Stanford Univ. Pub. Geol. Sci., v. 6, no. 1, p. 6, 12, 16–20, pls. 2, 3. Composed of clays, silts, and sands; distinctive feature is a resistant silica hardpan in lower part of soil profile. Thickness at type section 53½ feet; however, thickness cannot be given with certainty because of difficulties in picking lower contact in subsurface; probable thickness as shown on geologic cross section (pl. 3) 150 to 200 feet. Overlies Turlock Lake formation (new); underlies Modesto formation (new). Modesto and Riverbank formations together represent the

Victor formation, and they can be traced northward into the Mokelumne area.

Type section: NW¼NE¼ sec. 26, T. 2 S., R. 9 E., Riverbank quadrangle, San Joaquin County. Exposures are in south bluff of Stanislaus River just north of intersection of Jackson and Topeka Streets in Riverbank. Exposed in a northwest-southeast trending belt of variable width that lies just west of Turlock Lake formation and east of towns of Modesto and Turlock.

**River Portal Mica Schist**[1]

Precambrian (Gunnison River Series): Central western Colorado.

Original reference: J. F. Hunter, 1925, U.S. Geol. Survey Bull. 777.

Named for excellent exposures in vicinity of the river portal of Gunnison Tunnel, Gunnison River region.

†River Quarry Beds[1]

Middle Ordovician: Southwestern Ohio.

Original reference: E. Orton, 1873, Ohio Geol. Survey, v. 1, p. 370–387.

Named for river quarries at Cincinnati.

Riverside Sand[1]

Miocene(?): Northwestern Iowa.

Original reference: H. F. Bain, 1896, Iowa Geol. Survey, v. 5, p. 255, 277–279.

Named for Riverside, Woodbury County.

Riverside Sandstone[1]

Lower Mississippian: Western and southern Indiana.

Original reference: T. C. Hopkins, 1896, Indiana Dept. Geology and Nat. Resources 20th Ann. Rept., p. 196, 317, pl. 9.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 1. Riverside sandstone listed in Riverside facies of Edwardsville formation.

First described in Fountain County. Quarried at Riverside.

Riverside sandstone facies (of Edwardsville Formation)

Lower Mississippian: Southeastern Indiana.

P. B. Stockdale, 1931, Indiana Div. Geology Pub. 98, p. 76, 293–300. Edwardsville formation is differentiated into following facies: Stewarts Landing, Springler Knob, Medora Knob, Allens Creek, Bear Wallow, and Riverside sandstone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Riverside sandstone facies listed in Edwardsville formation. Includes Riverside sandstone.

Exposed in Fountain and Warren Counties along Wabash River. Probably named for quarries at Riverside, Warren County.

River Styx conglomerate facies (of Cuyahoga Formation)

Mississippian (Kinderhook): Northeastern Ohio.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 43 (fig. 2); 50–51. One of seven facies distinguished in the formation. Includes Black Hand conglomerate and Armstrong sandstone members. Merges with Tinkers Creek shale facies (new) on the northeast and the Killbuck shale facies (new) on the southwest.

Occurs in Medina and Wayne Counties.

Riverton Formation or cyclothem (in Cherokee Group)

Riverton Formation (in Krebs Group)

Pennsylvanian (Des Moines Series) : Southeastern Kansas and southwestern Missouri.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 21; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 196. Cherokee group is divided into 15 cyclic formational units. Riverton, first in the sequence (ascending), occurs below the Neutral formation (cyclothem) and unconformably overlies eroded surface of the Mississippian. Average thickness 38 feet. Includes Riverton coal, 3 to 10 inches thick. [For complete sequence see Cherokee group this entry.].

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Riverton formation in Krebs group. Underlies Warner formation.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 10–11. In Jasper County, Mo., formation is about 17 feet thick. Underlies Warner formation and overlies Boone chert. Krebs group. Derivation of name given.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 29–32. Described in southeastern Kansas as formation in Krebs subgroup of Cherokee group. Thickness 10 to 20 feet; average 15 feet. Consists of a basal shale 4 or 5 feet to 13 feet thick, an underclay 2 to 4 feet thick and Riverton coal. Overlies leached chert rubble derived from underlying Mississippian rocks. As presently defined, it is in part equivalent to McCurtain shale of eastern Oklahoma.

Name derived from Riverton coal in Cherokee County, Kans.

**Riverton Iron-Formation** (in Paint River Group)

Precambrian (Animikie Series) : Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 38. Consists dominantly of interbedded chert and siderite. Thickness ranges from less than 100 feet in western part of district to about 600 feet in eastern part. Locally upper part of formation is absent due to erosion prior to deposition of overlying Hiawatha graywacke. Overlies Dunn Creek slate (new).

Name derived from Riverton mine at Iron River, Iron County, first site of mining in district 75 years ago. Formation is visible in walls of the caved workings of the old mine.

Riverview terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703 (fig. 8), 1710, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Riverview is applied to terrace deposit younger than and lying about 8 feet below First Street; a bench about 6 feet lower is designated as Riverview No.

2. Like First Street and Beaumont (Sixth Street) deposits, it is composed of dark-weathering silt overlying limestone gravel.

Type locality: Junction of Riverview and Chicon Streets, Austin, Travis County.

Rivoli Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 24, figs. 3, 12. Argillaceous dolomite about 5 feet thick. Shown on columnar section as underlying Sherwood member (new) and overlying Mortimer member (new).

Occurs in Dixon-Oregon area.

Roach Creek Sandstone (in Graves Gap Group)

Pennsylvanian (Pottsville Series): Southeastern Kentucky and eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio]; p. 11, 19, pls. 2, 3, 4. Thickness near Roach Creek 60 feet; in western part of Cumberland Mountains 20 to 80 feet; thins to southeast; 20 to 25 feet near Fonde, Ky. Separated from overlying shales of Redoak Mountain group (new) by a shale interval 50 to 90 feet thick that contains Craig coal and Windrock coal; separated from underlying Armes Gap sandstone (new) by a shale interval 60 to 130 feet thick that contains Pioneer coal.

Named from exposures above Roach Creek, near Dean, Block quadrangle, Scott County, Tenn.

†Roan Gneiss[1]

Precambrian: Eastern Tennessee, northern Georgia, western North Carolina, and northwestern South Carolina.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 2.

T. L. Kesler, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 756, 775–781. Near Kings Mountain, mica schists and gneisses, previously mapped as Carolina gneiss, and hornblende gneisses, previously mapped as Roan gneiss, actually constitute metamorphosed upper part of Gaffney. Similar rocks in Beaver Creek area are apparently stratigraphically higher. Evidence in other parts of Carolina Piedmont indicates that intrusive diorite and possibly recrystallized mafic volcanic rocks have been included in the Roan and possibly recrystallized felsic volcanic rocks in the Carolina gneiss. Names Carolina and Roan have lithologic but not stratigraphic significance.

F. D. Eckelmann and J. L. Kulp. 1956, Am. Jour. Sci., v. 254, no. 5, p. 291, 314. In Spruce Pine district, interlayered with Carolina gneiss, and the two types of rocks grade into each other along and across the strike. The Roan-Carolina sequence appears to be a single sedimentary unit with varying lithology, complicated by intense isoclinal folding and plastic deformation. Roan-Carolina complex is interlayered with Cranberry and Henderson gneisses. These formations are in a consistent and conformable stratigraphic position below the Carolina-Roan complex as seen in Cranberry, Roan Mountain, and Mount Mitchell quadrangles where the granitic gneisses are distributed about borders of the Roan-Carolina rocks which form the central part of the southwest-plunging Spruce Pine synclinorium.

Named for development on Roan Mountain, Carter County, Tenn.

Roaring Branch Sandstone (in Pocono Formation)[1]

Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $G_5$, p. 56–57, 235.

Occurs along Roaring Branch.

Roaring Branch Shales (in Pocono Formation)[1]

Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $G_5$, p. 56–57, 235.

Occurs along Roaring Branch.

†Roaring Creek Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian: Eastern West Virginia.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 462.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 100. Massive sandstone; uppermost member of Kanawha group.

Well developed along Roaring Creek, a branch of Tygart Valley River, Randolph County.

**Roaring Fork Sandstone** (in Snowbird Group)

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 954–956. Thick unit of dark sandstone and interbedded pelitic rocks; in vicinity of Roaring Fork, somewhat less that half of formation consists of massive light-greenish-gray sandstone beds 5 to 50 feet thick, which ar fine to medium grained, highly feldspathic, and moderately well sorted; interbedded with them are thick- to thin-bedded finer grained sandstone, siltstone, and argillaceous rocks; current bedding common especially in finer grained and thinner bedded sandstone. At type locality, about 8,000 feet of Roaring Fork sandstone conformably underlies Pigeon siltstone, but base is cut off by faults; on Pigeon River, where complete section is present, formation is 2,700 feet thick; this decrease is interpreted as resulting from intertonguing eastward with Longarm quartzite (new) through an interval of several thousand feet.

Typical section: On Roaring Fork, 1 to 3 miles southeast of Gatlinburg, Sevier County.

Roaring River Sandstone Member (of Noel Shale)

Upper Devonian: Southwestern Missouri.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 91–92. Light gray to pale buff on fresh exposures; medium or dark reddish brown on weathering. At type locality, consists of two irregular beds 9 to 12 inches thick. Basal part of Noel. Rests unconformably on several formations involved in a surface that appears to have presented very slight relief. Most common underlying rock is Cotter dolomite; in some areas, overlies Fortune formation.

Type locality: About center of east side sec. 34, T. 22 N., R. 27 W., along Missouri State Highway 112, Barry County. Name derived from Roaring River.

Roaring River Tongue (in Ono Formation)

Lower Cretaceous; Northern California.

M. A. Murphy, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2103, 2111. Conglomerate, sandstone, and mudstone. Typical section along Roaring River consists of four beds of massive cobble. Beds range in thickness up to 40 feet and are lenticular along the strike. Interbeds are massive sandstone with minor amounts of mudstone in lower part of tongue; upper part is predominantly graywacke with increasing amounts of mudstone toward top; approximately 850 feet thick on Roaring River; thickness differs greatly along strike.

Named from Roaring River, a tributary of Cottonwood Creek, Shasta County.

Robbers Roost Formation

Permian (Wolfcamp): South-central Nevada.

J. S. Berge, April 1960, Brigham Young Univ. Research Studies, Geol. Ser., v. 7, no. 5, p. 11 (fig. 3). Named on correlation chart. Overlies Butte formation (new). Name credited to G. P. Lloyd (unpub. thesis).

North end of White River valley, White Pine County.

Robbers Roost Gravel

Quaternary: Northwestern Arizona.

Donaldson Koons, 1948, Plateau, v. 20, no. 4, p. 54 (fig. 1), 58. Composed of poorly rounded and sorted pebbles of limestone, sandstone, and chert of local derivation. Rests on steep bedrock slopes. Interpreted as a talus or alluvial cone deposit.

Name derived from Robbers Roost Mesa, Coconino County, near which the unit is well exposed.

**Robbins Shale Member**[1] (of Stranger Formation)

Robbins Shale

Pennsylvanian (Virgil Series): Southeastern Kansas and southeastern Nebraska.

Original reference: R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 146, 153–156.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 29. Stranger age beds are exposed in three small areas on Table Rock-Richfield anticlines in Cass and Sarpy Counties in North Branch Weeping Water Creek valley, Eightmile Creek valley and Platte River bluffs in vicinity of South Bend. Well logs show that these beds extend subsurface through Forest City basin and rise to surface in outcrop areas of Missouri and Kansas. Stranger section in Cass County is Robbins shale above and Cass formation below. Robbins shale is about 3 feet thick in Burlington quarries near South Bend. Rests conformably on Haskell member of Cass formation, but its upper boundary is at post-Stranger unconformity below the Lawrence formation.

H. C. Wagner and L. D. Harris, 1953, U.S. Geol. Survey Oil and Gas Inv. Chart OC–48. Described in Fredonia quadrangle, Kansas, where it is more than 120 feet thick in southern part of quadrangle, thins to 50 feet in northern part. Predominantly a light-olive-gray slightly silty shale that is characterized by beds and lenses of small ironstone concretions. Overlies Haskell limestone member; underlies Ireland sandstone member of Lawrence shale.

Type locality: Robbins Farm, sec. 11, T. 26 S., R. 15 E., southwest of Yates Center, Woodson County, Kans.

**Rob Camp Limestone**

Middle Ordovician: Northeastern Tennessee and southwestern Virginia.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104 (2 sheets). Very massive bedded very dense cryptocrystalline, tan and dove-gray limestone with abundant small patches of white crystalline calcite; zones of thinner bedded limestone containing chert nodules present in eastern part of area. Thickness as much as 150 feet. Unconformably underlies Martin Creek limestone (new); overlies Poteet limestone (new). Same as Mosheim limestone (after Butts) on map by Miller and Fuller (1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76).

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table), 33–34, 39–43, 105, 107, 109, pl. 1. Further described; typical section and derivation of name given. Rob Camp probably correlates with Five Oaks limestone of Cooper and Prouty (1943) in Tazewell County. Summary of nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

Named from exposures one-half mile north of Rob Camp Church in Rose Hill district. Church is in northwest corner of Hancock County, Tenn., 3 miles south of Lee County line.

Roberta Sandstone Member (of Barnwell Formation)

Eocene, upper: Central and northeastern Georgia.

J. F. L. Connell, 1958, Southwestern Louisiana Jour., v. 2, no. 4, p. 321–322, 329, 343 (fig. 15). Name applied to the argillaceous red sands composing the typical Barnwell, that is above and outside the area of outcrop of the Irwinton and Upper Sand members. Thickness 15 to 40 feet. In extreme northeastern Georgia, beds occur higher in the section than the other members; in Crawford and possibly Peach County, occur unconformably upon uppermost Twiggs clay member.

Type locality: At Rich Hill, a prominent topographic feature 6 miles east of Roberta, Crawford County. Present also in Glascock and Jefferson Counties.

Roberts Formation[1]

Precambrian: East-central California.

Original reference: J. H. Maxson, 1934, Pan-Am. Geologist, v. 61, no. 4, p. 311.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 280 (fig. 4). Thickness about 2,500 feet. Underlies Wyman formation.

In Wyman Canyon, Inyo Range.

Roberts Sand[1]

Miocene(?): Southwestern Alabama.

Original reference: W. H. Dall and J. Stanley-Brown, 1894, Geol. Soc. America Bull., v. 5, p. 167, 170.

Named for exposures at Roberts, Escambia County.

**Roberts Mountains Formation** or **Limestone**

Middle Silurian: Eastern Nevada and western Utah.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 11–12, pl. 1. Formation lies between the light-gray dolomites of Lone Mountain (restricted) and Ordovician Hanson Creek formation (new). Predominantly limestone, well-bedded and dark slate gray. Thickness at type section 1,900 feet; at Lone Mountain 741 feet. Lower contact drawn at base of laterally persistent belt of bluish-black chert 560 feet above Eureka quartzite; at Lone Mountain, same type of chert beds occur 318 feet above the Eureka. Partial equivalent of this formation at Lone Mountain was included in Lone Mountain limestone by Hague (1892; U.S. Geol. Survey Mon. 20).

R. W. Rush, 1956, Utah Geol. and Mineralog. Survey Bull. 53, p. 12 (fig. 3), 20–21, 22 (fig. 5). Geographically extended into Millard County, Utah, where it is 369 feet thick, underlies Jack Valley formation (new) and overlies Fish Haven dolomite.

E. L. Winterer and M. A. Murphy, 1960, Jour. Geology, v. 68, no. 2, p. 134 (fig. 6), 135, 136. Underlies Rabbit Hill formation (new).

Type section: West side Roberts Creek Mountain, about 30 miles north of Eureka, Eureka County, Nev.

Robertson Formation (in Mowich Group)

Lower Jurassic: East-central Oregon.

R. L. Lupfer, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 238–239, 241–242. Includes, in most places, two lithologic facies: (1) a basal section of conglomerate and coarse greenish-gray sandstone upon truncated beds of the Upper Triassic, and (2) an overlying reef limestone. Average thickness 250 feet; maximum about 500. Underlies Suplee formation (new).

W. R. Dickinson, 1960, Dissert. Abs., v. 20, no. 11, p. 4367. Lower Jurassic sequence in Izee area, Grant County, includes Robertson, Supple, Nicely, and Hyde formations. Uppermost unit in Triassic sequence is Graylock formation (new).

Type area: Along headwaters of South Fork of Beaver Creek, 7 miles Southeast of Suplee post office, in secs. 26, 27, 28, and 29, T. 18 S., R. 26 E. Named for Robertson Ranch in sec. 28, T. 18 S., R. 26 E., Crook County.

Roberts Ranch Member (of Dagger Flat Formation)

Upper Cambrian: Southwestern Texas.

J. L. Wilson, 1954, Jour. Paleontology, v. 28, no. 3, p. 251, 252; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 12, p. 2465. Principally shale with thin beds of dark sandy finely crystalline limestone and calcareous micaceous graywacke sandstone. Thickness 225 to 570 feet. Overlies Buttrill Ranch member (new); underlies Marathon formation.

Type locality: Dagger Flat, Brewster County. Crops out along crest of Marathon anticlinorium which is traversed by Roberts Ranch Road.

Robeson Conglomerate

Triassic: Southeastern Pennsylvania.

D. B. McLaughlin, 1939, Michigan Acad. Sci. Arts, and Letters, Papers, v. 24, pt. 4, p. 60, 73. Name applied to a thick succession of conglomerates and coarse sandstones with almost no shale that occur in an alluvial fan in the Triassic. Considered to be stratigraphic equivalent of Lockatong and Brunswick formations. Dip and width of outcrop indicate thickness of approximately 15,000 feet.

Named from Robeson Township, Berks County.

Robinson Diorite[1]

Miocene or Pliocene: Central southern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 56.

Occurs on west of main summit of Castle Mountain, between Robinson and Blackhawk, Meagher County.

**Robinson Formation**[1]

Pennsylvanian: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California, Westwood sheet (1:250,000): California Div. Mines. Mapped with Permian marine sedimentary and metasedimentary rocks.

Named for exposures on Robinson Ranch near Taylorsville, Plumas County.

**Robinson Limestone Member** (of Minturn Formation)

Robinson Limestone Member (of Battle Mountain Formation)

Robinson Limestone Member (of Maroon Formation)[1]

Pennsylvanian: Northwestern Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1886, U.S. Geol. Survey Mon. 12, p. 69, 198, 279, 598, 646; 1898, U.S. Geol. Survey Geol. Atlas, Folio 48.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1376 (fig. 1), 1378 (fig. 2), 1380–1383, 1384. Reallocated to member status in Battle Mountain formation (new). Overlies Belden shale member (new); underlies Jacque Mountain member.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 201–202, 211–215. Reallocated to member status in Minturn formation. Overlies Resolution dolomite member (new); underlies Elk Ridge limestone member. Thickness 300 to 400 feet; comprises three to five beds of gray limestone separated by clastic rocks; limestone beds are 3 to 31 feet thick and 40 to 85 feet apart. Limestones contain fusulinids classed as Des Moines in age. Work in Pando area has proved that Lime Cliffs group of limestones of Minturn quadrangle are equivalent to Robinson limestone, and bed that Brill designated Robinson limestone in his type section of Battle Mountain formation, along Turkey Creek, in southern part of Minturn quadrangle, is in reality the bed here called Hornsilver dolomite member.

Named for fact it forms ore-bearing horizon of Robinson mine in Tenmile district.

†Robinson Quartzite[1]

Lower Cambrian : Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann Rept., pt. 3, p. 620–622.

Probably named for town of Robinson, Juab County.

†Robinson Shale[1]

Mississippian : Central eastern Nevada.

Original references: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52; 1924, Pan-Am. Geologist, v. 41, p. 78.

Ely district.

Robinson Branch Formation or coal cycle (in Cabaniss Group)

Robinson Branch Formation (in Cherokee Group)

Pennsylvanian (Des Moines Series) : Southwestern Missouri, and southeastern Kansas, northeastern Oklahoma.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Robinson Branch formation. Underlies Fleming formation; overlies Mineral formation. Included in Cabaniss group.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as Robinson Branch coal cycle in Senora formation, Cabaniss group in Oklahoma.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 39. Top is Robinson Branch coal bed. In lower part, in places in Vernon and Bates Counties, Mo., in southeastern Kansas, and in northeastern Oklahoma, contains a bed of black calcareous shale containing *Marginifera muracatina*, *Linoproductus cora*, gastropods, and pelecypods. Sporadic limestone in lower part, in western Missouri, southeastern Kansas, and northeastern Oklahoma, is called Doneley limestone in Oklahoma. Upper limestone was named Ardmore (Gordon, 1893), and entire limestone and shale succession was included in the Ardmore by Cline (1941). The prominent ledge of limestone in Vernon County, Mo., is known as "diamond rock," and name Rich Hill has been applied to it (Greene and Pond, 1926).

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 62–66, 105. A formation in Cabaniss subgroup of Cherokee group. Includes (ascending) limestone and calcareous shale (cap rock of Mineral coal), dark shale, fine-grained sandstone, underclay, and Robinson Branch coal. In eastern Labette County, Kans., and Craig County, Okla., the limestone forms an almost continuous bed, averaging 18 inches in thickness; in Cherokee and Crawford Counties, Kans., ranges in thickness from featheredge to 3 feet; Branson (1952) [1954] applied name Russell Creek to this limestone in Craig County, Okla. Overlies Mineral formation; underlies Fleming formation. Derivation of name given.

Named from Robinson Branch coal, which in turn is named for Robinson Branch, a stream in Vernon County, Mo. Complete succession was formerly exposed in strip pits northeast of Walker, SW¼ sec. 2, T. 36 N., R. 30 W., Vernon County.

Robinson Creek Vitrophyre

Pliocene: Northeastern Nevada.

R. R. Coats, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI–690, Book 2, p. 307. Several small gray vitrophyric perlite domes, characterized by labradorite, hypersthene, augite, magnetite, and apatite. Maximum exposed thickness of any one dome about 200 feet and greatest length about three-fourths of a mile; generally bases on which domes were extruded not visible.

Near northeastern border of Jarbidge quadrangle.

Robinson Mountain Basalt or flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 121–122, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined. Robinson Mountain is fifth in known sequence; younger than Bellisle Mountain and older than Jose Butte.

Robinson Mountain, a prominent, deeply eroded vent is about 5 miles west-northwest from Capulin Mountain and 3 miles west of Union County line.

**Roblar Leucogranite**

Cretaceous: Southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 97, pl. 1. Flesh-colored and aplitic; shows a little biotite and white feldspar. In most places, shows poor outcrops; exposures are of a friable sandy nature; where better exposed, yields small angular blocks due to the closely spaced sheeting. Younger than Woodson Mountain granodiorite.

Named for its exposures in Roblar Canyon, San Luis Rey quadrangle.

**Robles Formation**

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 143–147. Three facies recognized. Sandstone-siltstone facies of central and south-central part of island includes Río Matón, Lapa lava, and Las Tetas lava members (all new); this facies interfingers northward into pillow-lava-volcanic-breccia facies that intertongues to northeast with impure limestone-volcanic-breccia-conglomerate facies. Thickness of formation and probable equivalent strata ranges from approximately 3,000 feet in southern part of island to about 4,000 feet in central part; equivalent strata may be as much as 8,000 feet thick in northeastern part of island. Unconformably overlies volcanic complex in southern part of island; in central part, appears to lie conformably on lavas equivalent to Fajardo formation; underlies Cariblanco formation (new). Probably ranges from late Coniacian to early Campanian in age. Name credited to Pease and Briggs (in press).

H. L. Berryhill, Jr., and Lynn Glover 3d, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I–319. In Cayey quadrangle, consists of five distinct members and a sixth unnamed member which lies at base of formation in places south of Proyecto Vazquez. Named members (ascending) Río Matón limestone, Lapa lava, Cayey siltstone (new), Las Tetas lava, and Collao (new). Maximum thickness about 1,000 meters.

M. H. Pease, Jr., and R. P. Briggs, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I–320. Described in Comerío quadrangle which contains type area.

Includes Río Matón limestone, Lapa lava, and Las Tetas lava members. Maximum composite thickness more than 1,000 meters. Overlies unit termed formation K; underlies formation L.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 21–24. In Ponce-Coamo area, crops out south of Cerrillos-Descalabrado fault in Coamo and Río Descalabrado quadrangles. Includes Lapa andesite member. Underlies Ildefonso formation (new); base not exposed. Thickness about 3,000 feet in Barranquitas quadrangle; here it overlies Río Loco formation and unconformably overlies Ildefonso formation.

Type area: Barrio Robles of Municipio of Aibonito, Comerío quadrangle.

**Roca Shale**[1] (in Council Grove Group)

Permian: Southeastern Nebraska, northeastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 86, 88.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Defined to exclude Legion shale and Sallyards limestone. Consists of gray, red, and green shale, and thin impure limestone. Thickness 15 to 20 feet. Underlies Sallyards limestone member of Grenola limestone; overlies Howe limestone member of Red Eagle limestone. Wolfcamp series.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 90–94. Roca shale, as used in this report, includes rocks between Red Eagle and Neva limestones. In essence, this is original definition of unit proposed by Condra (1927). Condra's definition has been modified by establishment of Grenola formation (Condra and Busby, 1933) which, except for Neva limestone, consists of beds formerly included in upper part of Roca. Definition of Roca as restricted by Condra and Busby is the one currently followed in Kansas and Nebraska. In Pawnee County, top of Kansas Roca is indeterminate, and only Neva limestone member of Grenola can be recognized with assurance. Hence, Roca of this report includes in its upper part a section representative of all but Neva limestone member of Grenola formation of Kansas. Thickness 80 to about 120 feet in Pawnee County.

Named for Roca, Lancaster County, Nebr.

**Rochdale Limestone** (in Beekmantown Group)[1]

Lower Ordovician: Southeastern New York.

Original references: W. B. Dwight, 1887, Am. Jour. Sci., 3d v. 34, p. 32; Vassar Bros. Inst. Trans. Sci. Sect., v. 4, pt. 2, p. 213.

E. B. Knopf, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1212. Consists of limestones and dolomites carrying *Lecanospira* and orthoceratite cephalopods. Thickness about 400 feet. Overlies Halcyon Lake calc-dolomite (new). Discussion of stratigraphy of lower Paleozoic rocks surrounding Stissing Mountain, Dutchess County.

Named for exposures near village of Rochdale, Dutchess County.

Rochelle Conglomerate (in Canyon Group)

Rochelle Conglomerate (in Graford Formation)[1]

Rochelle Conglomerate Member (of Garner Formation)

Pennsylvanian: Central Texas.

Original references: R. S. Tarr, 1890, Texas Geol. Survey 1st Ann. Rept., p. 204, 205; Am. Geologist, v. 6, p. 147–153.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1) ; 90–91. Shown on chart as member at top of Garner formation. Rochelle conglomerate, Capps and Adams Branch limestones have been miscorrelated between their type localities in Colorado River district and Brazos River district; this fact should be borne in mind in using early literature. Rochelle conglomerate can be traced northward below Capps limestone; hence it is now considered at least as old as Brazos River conglomerate. Strawn series.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 93–94, pl. 20. Lowest division of Canyon group in Llano region. Thickness 8½ to 18 feet. Underlies Brownwood shale; east of Rochelle, unconformably overlies dark-gray and dark-maroon sandy shale of Strawn age; southwest of Rochelle overlaps on Marble Falls limestone.

J. W. Shelton, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1515–1524. Discussion of Strawn-Canyon boundary.

L. F. Brown, Jr., 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2866–2871. Discussion of problems of stratigraphic nomenclature and classification. Upper Pennsylvanian, north-central Texas—erecting series from groups, suppression of formations, redefining and raising rank of rock-stratigraphic units, time-stratigraphic boundaries versus lithographic contacts.

Type locality: Four miles east and 1.3 miles north of Rochelle-San Saba Road, near top of prominent escarpment.

Rocher Member (of Salem Limestone)

Mississippian (Valmeyer Series) : Southwestern Illinois.

J. W. Baxter, 1959, Dissert. Abs., v. 19, no. 11, p. 2910, 2911. Salem limestone is subdivided into four members [sequence not stated] to which names Kidd, Fults, Chalfin, and Rocher are assigned. Rocher member is a skeletal calcarenite in which the tests of *Endothyra* are a prominent element; commonly more or less oolitic.

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 2–3, 10–11, 13, 27–30, pl. 1. Consists of thick limestone beds separated by more thinly bedded strata. Maximum thickness about 60 feet near Prairie du Rocher; thins to north to 10 to 15 feet near Valmeyer, Overlies Chalfin member; underlies St. Louis limestone.

Type section: Above spring, 1 mile south of Monroe-Randolph County line at site of a limestone mine in T. 5 S., R. 9 W. Named from exposures in northern Randolph County less than 1 mile north of town of Prairie du Rocher.

Rochester Biotite Granite[1]

Devonian(?) : Southeastern New Hampshire.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 148, 149.

Probably named for exposures at Rochester, Stafford County.

Rochester Quartzite[1]

Precambrian: Vermont.

Original reference: W. G. Foye, 1919, Vermont State Geologist 11th Rept., p. 87.

Exposed along the Mine Railroad in Rochester, Windsor County.

**Rochester Rhyolite** (in Koipato Group)

Rochester Trachyte[1]

Permian: Northwestern Nevada.

Original reference: A. Knopf, 1924, U.S. Geol. Survey Bull. 762.

R. E. Wallace and others, 1959 U.S. Geol. Survey Mineral Inv. Field Studies Map MF-220. Rhyolite included in Koipato group in Buffalo Mountain quadrangle. Consists of rhyolite tuff-breccia in heterogeneous intertongued pile; relatively few masses that are true flow rocks; predominantly devitrified glass, containing sparse small phenocrysts, metacrysts of tuffaceous fragments of feldspar and quartz. Thickness not uniform probably exceeding 2,000 feet in places. Older than Weaver rhyolite. Permian.

Named for occurrence in Rochester Canyon, Rochester district.

**Rochester Shale** (in Clinton Group)

Rochester Formation

Rochester Member (of Mifflin Formation)

Rochester Shale Member (of Clinton Formation)[1]

Middle Silurian: Maryland, New York, Pennsylvania, and West Virginia, and Ontario, Canada.

Original reference: T. A. Conrad, 1839, New York Geol. Survey 3d Rept., p. 62–63.

C. K. Swartz and F. M. Swartz, 1931, Geol. Soc. America Bull., v. 42, no. 3, p. 624, 627–628, 630, 632. Geographically extended into Pennsylvania where it includes Keefer sandstone member. Thickness 70 feet. Underlies McKenzie formation; overlies Rose Hill formation.

E. R. Cumings, 1939, *in* Geologie der Erde, North America, v. 1, p. 595, 597. In Ontario, Clinton group includes Reynales and Irondequoit limestones and Rochester shale. Decew waterlime bed, formerly included in the Lockport, is here made upper member of Rochester formation. It is overlain by Gasport dolomite. Thickness 70 feet in Niagara Gorge.

W. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 8, 106–116. Rochester shale described in West Virginia where it is as much as 30 feet thick. Overlies Keefer sandstone and underlies McKenzie formation. This usage indicates general correlation of Rochester shale with the so-called "upper Clinton shale" of previous Survey county reports. Middle Silurian, Niagaran series.

H. L. Alling, 1946, Rochester Acad. Sci. Proc., v. 9, no. 1, p. 52–53. Term Gates is a rock facies and retention of name as formation or member of the Rochester is inadvisable.

D. W. Fisher, 1959, New York State Mus. Sci. Service Map and Chart Ser. 1. There is variance of opinion as whether time break exists between Lockport group and underlying Rochester shale. Some claim that Brownsport, Waldron, and Laurel fill this "gap." Evidence is not conclusive inasmuch as apparent faunal differences may be due to ecological control. There seems to be physical break between Decew and Gasport in western New York, but no physical break is evident from Rochester eastward. The Rochester in Clinton group grades imperceptibly upward into Decew, which is transferred to Tonwandan stage (new). Grades eastward into Herkimer sandstone; overlies Irondequoit limestone.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 5–6, 20, 23. Rank reduced to member status in Mifflin formation (new). Underlies McKenzie member; overlies Keefer member. Thickness 30 to 40 feet in central Pennsylvania. In Mount Union section referred to as formation. Thickness 40 feet. Overlies Keefer formation; underlies McKenzie formation. Silurian.

Named for exposures at Rochester, Monroe County, N.Y.

Rociada limestone[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 10.

In Solitario Mountain district, northwest of Las Vegas, San Miguel County.

Rockaway Conglomerate Beds (in Lutie Member of Theodosia Formation)

Lower Ordovician: Northern Arkansas and southern Missouri.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 25, 27, pls. 2, 6. Name applied to chert conglomerate and breccia beds that mark the base of the Lutie; number of beds vary from place to place and are commonly separated by "cotton rock" or crystalline dolomite. Beds are stratigraphically below the Hercules Tower sandstone (new) and are immediately overlain by a massive, crystalline dolomite, commonly more or less chert free.

Named from Rockaway Beach, Lake Taneycomo, Taney County, Mo.

Rock Bench Quarry Beds (in Polecat Bench Formation)

Paleocene; Northwestern Wyoming.

G. L. Jepsen *in* W. B. Scott, 1937, A history of land mammals in the Western Hemisphere: New York, Macmillan Co., p. 99; 1940, Am. Philos. Soc. Proc., v. 83, no. 2, p. 234–236, 238 (table). Proposed for rocks yielding the *Ptilodus-Elphidotarsius-Plesiolestes-Ancondon* fauna. A coarse buff sandstone, 9 to 31 feet thick, that occurs about 200 feet above base of formation and about 70 feet above top of Mantua lentil (new); stratigraphically below Silver Coulee beds (new).

Rock Bench is local name for part of the Polecat Bench, in Big Horn basin, near Powell, Park County.

**Rock Bluff Limestone Member** (of Deer Creek Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 43, 50.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5). Rock Bluff limestone member of Deer Creek limestone; underlies Larsh shale member; overlies Oskaloosa shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947; classification is subject to modifications imposed by lateral variations of deposits.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 157–158. Dense blue limestone; commonly a single massive stratum 1 to 2 feet thick. In Kansas, underlies Larsh-Burroak shale member.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17. In Missouri, underlies Larsh-Burroak shale member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 18, fig. 5. Dark blue to gray, dense; commonly one massive bed, but locally weathers into two layers. Thickness 1½ to slightly more than 2 feet. Underlies Larsh shale member; overlies Oskaloosa shale member.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 45–46, pl. 1. In Douglas County, consists of single bed of hard dense to fine-grained dark-blue-gray limestone about 2 feet thick. Overlies Oskaloosa shale member; underlies Larsh-Burroak shale member.

Named for exposures high in Missouri River bluffs northeast of Rock Bluff, Cass County, Nebr.

Rock Branch Coal Member (of Modesto Formation)

Pennsylvanian: Southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1), pl. 1. Name applied to coal previously called Scottville so that latter name can be restricted to Scottville limestone. Stratigraphically above Piasa limestone member and below Athensville coal member (new). Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: SW¼SW¼NW¼ sec. 21, T. 8 S., R. 9 W., Macoupin County. Named for exposures along Rock Branch in northwestern part of county.

Rock Candy Agglomerate and Latite (in Bullion Canyon Series)

Tertiary: Central Utah.

P. F. Kerr and others, 1957, Geol. Soc. America Spec. Paper 64, p. 14, 15 (fig. 6), pl. 12. Rock Candy agglomerate, 600 feet thick, underlies Rock Candy latite 50 to 500 feet thick.

Mapped in vicinity of Big Rock Candy Mountain, Marysvale area.

†Rock Canyon Conglomeratic Member (of Moenkopi Formation)[1]

Lower Triassic: Northwestern Arizona and southwestern Utah.

Original reference: H. Bassler and J. B. Reeside, Jr., 1921, U.S. Geol. Survey Bull. 726–C, p. 90–92.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 54. Abandoned as stratigraphic term. Rock Canyon conglomerate at its type locality is substantially equivalent to Harrisburg gypsiferous member of Kaibab.

Named for Rock Canyon, 5 miles north of Antelope Spring, Mohave County, Ariz.

**Rockcastle Conglomerate Member** (of Lee Formation)[1]

**Rockcastle Sandstone** (in Lee Group)[1]

Rockcastle Conglomerate (in Crab Orchard Mountains Group)

Lower Pennsylvanian: Eastern Tennessee, northern Georgia, and east-central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 3.

V. H. Johnson, 1946, Coal deposits of Sand and Lookout Mountains, Dade and Walker Counties, Georgia: U.S. Geol. Survey Prelim. Map. Geographically extended into northern Georgia where it is exposed on Lookout Mountain and overlies Vandever shale.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4, 19, pls. 2, 3, 4, 12–A. Youngest unit in Crab Orchard Mountains group (new). Term conglomerate considered more appropriate than sandstone in this area. In type area (as used in this report), conglomerate is 160 feet thick; maximum thickness 300 feet; in general, greatest thickness is along Eastern Escarpment; thins progressively southward. Along Piney River in Rhea County, the massive conglomeratic sandstone splits eastward to form a sequence of thin sandstones and shales. Contains Nemo coal. Overlies Vandever formation; underlies Dorton shale (new). Pottsville series.

Type locality: Rockcastle Cove, near Jamestown, Fentress County, Tenn.

†Rockcastle Group (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: A. R. Crandall, 1889, Kentucky Geol. Survey Rept. Whitley County.

Named for Rockcastle River.

†Rock City Conglomerate[1]

Pennsylvanian: New York.

Original reference: J. P. Lesley, 1875, Pennsylvania 2d Geol. Survey Rept. 1, p. 96.

Named for erosional feature locally called "rock cities," Cattaraugus and Chautauqua Counties.

†Rock Creek Beds[1]

Pleistocene: Western Texas.

Original reference: J. W. Gidley, 1903, Am. Mus. Nat. Hist. Bull., v. 19, p. 622, 625.

G. L. Evans and G. E. Meade, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 494. Same as Tule formation (Cummins, 1893).

Named for Rock Creek, Swisher County.

†Rock Creek Conglomerate Member (of Maroon Formation)

Permian(?): Northwestern Colorado.

C. F. Bassett, 1939, Geol. Soc. America Bull., v. 50, no. 12, pt. 1, p. 1864. Whole thickness consists of pink to red coarse sandstone and arkosic grits and conglomerates highly crossbedded. Lower part contains a few thin interbedded gray shales and limestones. Thickness approximately 1,224 feet. Underlies State Bridge siltstone member (new); conformably overlies McCoy formation. Permian(?). Name credited to Donner (unpub. thesis).

H. F. Donner, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1223. Name abandoned and beds included in McCoy formation of Pennsylvanian age in McCoy area. Derivation of name given.

Named for its fine exposures along west bank of Rock Creek north of McCoy. In Eagle and Routt Counties.

Rock Creek Granodiorite,[1] Gabbro,[1] and Diorite[1]

Jurassic: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1913, Canada Dept. Int. Rept. Chief Ast., 1910, v. 2, p. 401.

Named for occurrence near forks of Rock Creek, British Columbia.

**Rock Creek Limestone** (in McLeansboro Group)

Rock Creek Limestone Member (of McLeansboro formation)[1]

Middle and Upper Pennsylvanian: Central western Illinois.

Original reference: A. H. Worthen, 1873, Illinois Geol. Survey, v. 5, p. 309, 312, 314, 315.

U.S. Geological Survey classifies the Rock Creek as a formation on the basis of the fact that the McLeansboro is given group status in Illinois.

Named for outcrops along Rock Creek, Menard County.

Rock Creek Limestone Member (of Vamoosa Formation)

Rock Creek Limestone (in Nelagoney Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: F. C. Greene 1918, Am. Assoc. Petroleum Geologists Bull., v. 2, p. 122.

C. C. Branson, 1955, The Hopper, v. 15, nos. 10–11, p. 126–127. Referred to as Rock Creek limestone member of Vamoosa formation. Name Rock Creek is synonym and not in good standing.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 108. Abandoned by Oklahoma Geological Survey. Name was earlier used for a Pennsylvanian limestone in Illinois, for Pleistocene beds in the Texas Panhandle, and for a gabbro in British Columbia. Bowen (1918) named the same limestone Labadie and this is accepted name.

Well developed in T. 26 N., R. 10 E., Osage County. Rock Creek is small tributary of Sand Creek and flows through sections 3,4, 9, 10, and 15.

Rockcut Formation

Lower Paleozoic: Northeastern Washington.

J. L. Barlow, 1958, U.S. Atomic Energy Comm. [Pub.] RME–2068, p. 7. Oldest rocks in district are biotite-amphibole schists, gneisses, limestones, and quartzites which Weaver (1920) designated Orient gneiss and tentatively assigned a Precambrian age. Hougland (1933, unpub. thesis) subdivided this sequence and assigned name Rockcut formation to include two lower quartzite and limestone members of Lower Paleozoic(?) age; he also used term amphibole schist to include all basic medium- to fine-grained, more or less metamorphosed rocks in area. These schists are intercalated within the Rockcut. No evidence for establishing age of these rocks has been found; they are referred to as lower Paleozoic complex.

Report covers northern Ferry County.

Rockdale Dolomite

Silurian (Niagaran): Northeastern and northwestern Illinois.

T. E. Savage *in* C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Name appears on correlation chart. Underlies Joliet dolomite (restricted).

Type locality and derivation of name not given.

Rockdale Drift[1]

Pleistocene (Wisconsin) : Northeastern Illinois.

Original reference: D. J. Fisher, 1925, Illinois Geol. Survey Bull. 51, p. 17.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. 16th Ann. Field Conf., p. 12 (fig. 4). Shown on columnar section of Pleistocene deposits in Dixon-Oregon area above Minooka drift and below Manhattan drift.

Named for village of Rockdale, 2 miles southwest of Joliet, Will County.

Rockdale Formation (in Wilcox Group)[1]

Eocene: Eastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 583.

W. M. Beckman and F. E. Turner, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 608–621. Seguin formation, as originally defined, straddles boundary between Midway and Wilcox groups. Members of Seguin, Solomon Creek clays, and Caldwell Knob sands, are redefined so that base of Wilcox is placed at disconformity marking top of Solomon Creek clays and base of Caldwell Knob sands. Where it is possible to recognize the divisions as redefined, Caldwell Knob beds should be regarded as basal member of Rockdale formation and Solomon Creek member should be regarded as member of Wills Point formation.

R. L. Folk, leader, 1960, Texas Univ. Geol. Soc. Tertiary Field Trip, Dec. 10 strat. section. Includes (ascending) Hooper clay, Simsboro sand, Butler clay, and Calvert Bluff members. Overlies Seguin formation; underlies Sabinetown. Wilcox group.

Type locality: Exposures in central Milam County, in vicinity of Rockdale.

**Rockdale Run Formation** (in Beekmantown Group)

Lower Ordovician: Western Maryland.

R. H. Flower, 1956, Jour. Paleontology, v. 30, no. 1, p. 77, 78. Incidental mention in discussion of cephalopods from Canadian of Maryland. Name credited to W. J. Sando.

W. J. Sando, 1956, Geol. Soc. America Bull., v. 67, no. 7, p. 936. Formal proposal of name. Applied to interbedded limestones and dolomites overlying Stonehenge limestone. Lower two-thirds of formation is predominantly limestone; upper third mostly dolomite. Average thickness about 2,450 feet. Underlies Pinesburg Station dolomite (new); top is placed at top of highest limestone bed beneath the dolomite.

W. J. Sando, 1957, Geol. Soc. America Mem. 68, p. 21–28, geol. sections 2, 3, 4, 5, 8, and 10, pl. 1. Includes three lithologic zones: a cryptozoon chert zone confined to lower 100 to 200 feet of formation; a concentration of oolitic limestones about 100 to 200 feet thick about 200 feet above cryptozoon chert zone; dolomite in upper third. Detailed description of type section.

Type section: On Robinson and Seibert Farms just south of Rockdale Run between 1 and 1½ miles west of Hicksville, Washington County. Outcrops constitute 58 square miles.

**Rockdell Limestone**

Middle Ordovician: Southwestern Virginia.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66, p. 135 (fig. 11), 137–139, 240 (geol. section 139), pls. 9, 18, 23. Includes the 100 to 300 feet of beds between the Lincolnshire below and Benbolt limestone above; includes Perry and Ward Cove limestones of Tazewell County, and name Rockdell is used where these two formations cannot be differentiated. Consists of coarse-grained light gray high-calcium limestone with a few beds of dark-gray cherty limestone. Along northwest base of Clinch Mountain upper two-thirds of unit is dark-gray granular cherty limestone and lower division coarse grained light-gray and free from chert; in Rosedale belt upper part is nodular-weathering earthy limestone containing *Nidulites* and lower part, generally thicker, is light-gray to pinkish coarse-grained limestone with distinctly clastic texture. Thickness at type locality 248 feet.

Type locality: Near Elk Garden, Russell County. Also crops out in small elliptical area south of Rockdell.

Rock Falls Series[1]

Mississippian: Eastern Michigan.

Original reference: A. C. Lane, 1900, Michigan Geol. Survey, v. 7, pt. 2, p. 252–253.

In Huron County. Derivation of name not stated.

**Rockfish Conglomerate**[1]

Rockfish Member (of Lynchburg Gneiss)

Precambrian: Western Virginia.

Original reference: W. Nelson, 1932, Washington Acad. Sci. Jour., v. 22, no. 15, p. 456–457.

A. I. Jonas and G. W. Stose, 1939, Am. Jour. Sci., v. 237, no. 8, p. 575, 578 (fig. 2), 589, 593. At many places in Catoctin Mountain-Blue Ridge and Mount Rogers anticlinoria, the Rockfish conglomerate, which at type locality and elsewhere contains pebbles and boulders of granite and gneiss derived from the Lovingston granite gneiss and granite of the injection complex, underlies Lynchburg gneiss.

H. B. Cooke, Jr., 1952, (abs.) Virginia Jour. Sci., v. 3, new ser., no. 4, p. 336. Rockfish conglomerate divided into two members: Rockfish conglomerate (restricted) and Mount Jefferson sandstone (new).

R. O. Bloomer and H. J. Werner, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 583–585, pl. 1. Referred to as Rockfish member of Lynchburg. Occurs in base of Lynchburg in lenticular bodies as much as 2 miles long and 1,000 feet across at outcrop. Grades downward 10 to 100 feet into basement complex with diminution in number of clasts and disappearance of bedding. The granite clasts were doubtlessly derived from the Lovingston and Pedlar formations, and the biotite clasts probably from skialiths of basement complex gneiss.

Type locality: On Rockfish River, Nelson County.

**Rockford Limestone**[1]

Lower Mississippian (Kinderhook Series): Southeastern Indiana.

Original reference: F. B. Meek and A. H. Worthen, 1861, Am. Jour. Sci., 2d, v. 32, p. 167–177.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 88–89. Immediately underlies New Providence shale of Borden group and overlies New Albany shale throughout southern Indiana outcrop belt between New Albany on the Ohio River at south and Bartholomew County to north; absent in Kentucky. Thickness 1 to 3 feet, commonly 2 feet.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 855–856. Overlies Jacobs Chapel shale (new).

Typically exposed in bed of White River at Rockford, Jackson County.

†Rockford Shale[1]

Upper Devonian : Central northern Iowa.

Original reference : S. Calvin, 1878, Am. Jour, Sci., 3d, v. 15, p. 460–462.

Named for Rockford, Floyd County.

Rockfordian series[1]

Upper Devonian : Iowa.

Original reference : C. R. Keyes, 1933, Pan-Am. Geologist, v. 60, no. 3, p. 226.

Rock Grove Member (of Shell Rock Formation)

Rock Grove Substage[1]

Upper Devonian : Central northern Iowa.

Original reference : C. H. Belanski, 1927, Am. Midland Nat., v. 10, no. 10.

M. A. Stainbrook, 1944, Illinois Geol. Survey Bull. 68–A, p. 187. Shellrock formation comprises (ascending) Mason City, Rock Grove, and Nora members.

Named for development in Rock Grove Township, Floyd County.

Rockhill Limestone (in Graford Formation)[1]

Pennsylvanian : Central northern Texas.

Original reference : E. Böse, 1918, Texas Univ. Bull. 1758, p. 14–16.

Forms the flat top of the long, narrow ridge (Rock Hill) that extends southwest from southern end of Lake Bridgeport Dam in Wise County.

**Rockhouse Shale**[1] (in Linden Group)

Rockhouse Limestone Member } (of Ross Formation)
Rockhouse Shale Member }

Lower Devonian : Western and central Tennessee.

Original reference : C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 736.

G. A. Cooper and others, 1942. Geol. Soc. America Bull., v. 53, no 12, pt. 1, chart 4. Rockhouse shale shown on correlation chart as Silurian.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 280 (fig. 83), 283–287, 292. Rockhouse shale member and Rockhouse limestone member comprise the basal unit of newly defined Ross formation through its known outcrop belt and unconformably overlie Decatur limestone. Shale member is restricted to south-central Hardin County where its average thickness is about 25 feet; conformably underlies Ross limestone member. Limestone member is widely distributed in northern Hardin and Wayne Counties where its average thickness is about 12 feet; conformably underlies Birdsong shale member; includes basal 8 to 10 feet of Birdsong shale as described by Dunbar (1919, Tennessee Div. Geology Bull. 21). Cooper and others (1942) place Rockhouse shale in Silurian. If Rockhouse shale is Silurian, then entire Ross formation including Ross limestone member and Birdsong shale member are likewise Silurian because they bear a close relationship to the Rockhouse shale member and Rockhouse limestone member.

Named for Rockhouse, a hunters' clubhouse on Horse Creek, 5 miles northwest of Lowryville, Hardin County.

Rockingham Schist[1] or Mica Schist

Paleozoic: East-central and southeastern New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1890–1892. On older geological maps, the crystalling schists of Belknap Mountains were divided into two groups, "Rockingham mica schist" and the "Montalban series." Present study has revealed no real difference between schists in different parts of area, and they are here treated as single unit, Rockingham mica schist. Age unknown.

M. P. Billings, 1953, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 43. Part of unit which lies southeast of the Fitchburg pluton included in Merrimack group of Silurian (?) age.

Widely exposed in Rockingham [County].

Rock Island Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33. 45 (table 1), 63, pl. 1. Assigned to member status in Spoon formation (new). Present at base of formation. Occurs below Seville limestone member. Thickness 2½ to 3 feet in type section of Abbott. Coal named by Worthen (1868 *in* Geology and Paleontology, v. 3, Illinois Geol. Survey). Presentation of new rock stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification retained but is independent of rock-stratigraphic classification.

Type locality: Southwest bank of Spoon River, SW¼SW¼ sec. 23, T. 6 N., R. 1 E., Rock Island County.

**Rock Lake Shale Member** (of Stanton Limestone)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 41, 59, 156, 157.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 51 Rock Lake shale was named in Nebraska but was named Victory Junction shale by Newell (1935) from exposures in Kaw Valley area, Kansas. On basis of subsequent studies, it is agreed that original name is valid.

R.C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 119. Rock Lake shale member of Stanton formation; underlies South Bend limestone member; overlies Stoner limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32. Average thickness 6 feet in Nebraska; 3 to 4 feet in northwestern Missouri; 3 to 8 feet in Kansas. Old type locality now badly covered; co-type locality designated.

Type locality: Exposures in vicinity of Rock Lake located in SW sec. 13, T. 12 N., R. 10 E., Sarpy County, Nebr.; co-type locality is in Platte River Bluffs just east of south gate of State Fish Hatcheries across Platte River northeast of South Bend.

**Rockland Formation**[1]

Cambrian or Ordovician : South-central Maine.

Original reference: E. S. Bastin, 1908, U.S. Geol. Survey Geol. Atlas, Folio 158.

H. W. Allen, 1951, Maine State Geologist Rept. 1949–1950, p. 79. Sequence of metamorphosed sedimentary rocks in Rockland quadrangle is (ascending) Ilesboro formation containing Combs limestone member at top; Battie quartzite; Penobscot formation; and Rockland formation consisting of Weskeag quartzite member at base, a siliceous limestone member above the quartzite, and Rockport limestone member at top.

Well developed just west and southwest of Rockland, Knox County.

Rockland Formation[1]

Middle Ordovician (Trentonian): Ontario, Canada, and northern New York.

Original references: P. E. Raymond, 1914, Canada Geol. Survey Summ. Rept. 1912, p. 348: 1916, Harvard Coll. Mus. Comp. Zoology Bull., v. 56, p. 255, 260; 1921, Canada Geol. Survey Mus. Bull. 31, p. 1.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 251–255. Rockland limestone is lowermost formation in Trenton group. In type section, Rockland has been described as consisting of 40 feet of heavy-bedded limestones, separated from "Lowville" limestone by 18 feet of "Leray beds of the Black River." These "Leray beds" of Ottawa district carry a fauna in which *Doleroides ottawanus* Wilson is abundant; a similar fauna directly overlies Watertown limestone, the top of the Black River group, at Watertown, N.Y. Believed that the "Leray beds" at Rockland are post-Watertown rather than pre-Watertown Leray limestone of New York. Rockland, at its type section, is revised to include these "Leray beds." In southeastern Ontario and northwestern New York, beds characterized by *Doleroides ottawanus* constitute a separable member of the formation herein designated Selby member. Upper part of formation is herein named Napanee member. Thickness at Dexter, N.Y., about 64 feet. Overlies Chaumont formation; underlies Hull formation. Other formations of Rockland age are: Coboconk and Cloche Island limestones (type areas in Ontario), and Amsterdam and Isle la Motte limestones.

G. M. Kay, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 599. Type section of Rockland is east of Ottawa. It has been described as consisting of the "Leray," comprising 9½ feet of "Leray proper" and 8½ feet of "transition beds," overlain by 40 feet Rockland limestone. The writer [Kay] 1937 stated that the "Leray beds" at Rockland are post-Watertown. Restudy of section shows that only the "transition beds" are post-Watertown, and that the 9½ feet of "Leray proper" is Chaumont. That the Rockland above the "transition beds" is equivalent to the Napanee is strongly suggested by the fauna and the fact that each is overlain by limestones containing Hull crinoid fauna. Lithology, as well as fauna, of "transition beds" resembles that of Selby member of Rockland, which is post-Chaumont.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 599. Stratigraphic column of Trenton group on West Canada Creek, N.Y., shows Rockland limestone, 10 feet thick, above Lowville limestone of Black River group and below Kirkfield limestone; both contacts disconformable. Term Kirkfield used in preference to "Hull" of previous reports.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1411–1412. Summarizes Middle Ordovician bordering Allegheny synclinorium. Lower Trentonian formations of northwestern New York and eastern Ontario, Rockland and Kirkfield limestones, disconformably overlap Black River rocks, lying locally on Canadian and Cambrian along the Mohawk River, and on Precambrian in Ontario; the Rocklandian and Kirkfieldian are considered to be stages.

Type locality: At Rockland, Ontario, 30 miles east of Ottawa.

†Rockland Sandstone[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane, 1911, Michigan Geol. and Biol. Survey Pub. 6, geol. ser. 4, p. 610.

Named for occurrence at Rockland, in Ontonagon County.

†Rockland Sandstone[1]

Miocene(?): Eastern Texas.

Original reference: E. T. Dumble, 1901, Geology of Beaumont oil field.

Named for Rockland, Tyler County.

Rocklandian (Rockland) Stage or Substage

Middle Ordovician (Trentonian): Eastern North America.

G. M. Kay, 1936, Geol. Soc. America Proc. 1936, p. 82. Rockland and Hull are earliest stages of Trenton group.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 251–261, 293, 298. Discussion of stratigraphy of Trenton group and list of formations of Rockland age. Early Trenton was fundamentally a time of advancing seas that progressively submerged margins of lands. In Rockland stage, oldest sediments were limited to more medial parts of Ontario basin, in Thousand Islands region and northwestward into Ottawa Valley. In late Rockland time, the seas overlapped Adirondack arch in narrow strait somewhat north of Mohawk Valley. Hull stage is essentially a continuation of this overlap.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1411–1412. Lower Trentonian formations of northwestern New York and eastern Ontario, the Rockland and Kirkfield or Hull limestones, disconformably overlap Black River rocks, lying locally on Canadian and Cambrian along Mohawk River, and Precambrian in Ontario; the Rocklandian and Kirkfieldian are considered stages.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 86, 91, 94 (table 3). Raymond's (1914, Canada Geol. Survey Summ. Rept. 1912) "formations" in Trenton were zones he thought time-defined by fossils; subsequently the lithologies were distinguished, but Rockland limestone and Rocklandian stage are identical at Rockland, Ontario. Other formations in the stage have lithic differences or were named as an incident to their isolation. Younger than Chaumontian stage of Blackriveran series.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30. Rocklandian and Kirkfieldian substages included in Nealmontian stage.

Named derived from Rockland, Ontario, Canada, for which Rockland limestone is named.

**Rockland Valley Basalt**[1]

Pliocene, middle(?): Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 31, 47–48, pl. 4. Series of even-bedded blue and black basalts about 250 feet thick. Interbedded with them is one bed of clay 15 feet thick. Shown on stratigraphic column above Massacre volcanics and below Raft lake beds.

Named for exposures on north side of Rockland Valley, Power County.

Rockledge Conglomerate (in Woods Corners Group)

Rockledge Limestone Breccia

Upper Cambrian: Northwestern Vermont.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1021, 1045, 1049–1052. Name Rockledge limestone breccia proposed to replace Corliss conglomerate except at its type locality. Described as breccia composed mainly of small pieces of blue slabby limestone and sandy dolomite, cemented by lime or dolomite with abundant sand grains. Thickness 0 to 40 feet. Underlies Georgia formation conformably; overlies Hungerford formation (new) disconformably.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Incidental reference to Rockledge conglomerate.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 542–543, 546, pl. 1. Schuchert's (1937) Rockledge limestone conglomerate has generally been shortened to Rockledge conglomerate. Included in Woods Corners group (new). Schuchert misinterpreted structure and believed Rockledge to overlie Hungerford. Detailed mapping has proved that Rockledge underlies Hungerford. Maximum thickness 100 feet; because of lensing no applicable figure can be given for thickness. Overlies Skeels Corners slate. Regarded as southern equivalent of Saxe Brook dolomite but separate names are retained because of lithologic differences between the two units. Note on type locality.

Type locality: On Rockledge Estate, 4.4 miles north of center of St. Albans, on west side of Highgate Road, in Franklin County. Large bioherm from which estate takes its name is not in Rockledge conglomerate but in top of underlying Skeels Corners slate. Formation extends northward from type locality in unbroken outcrop to point 1¾ miles S. 20° W. of Highgate Falls. Southward, crops out in discontinuous lenses.

Rock Levee Formation

Middle Ordovician: Eastern Missouri.

J. G. Grohskopf, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 3, p. 360–362. Proposed for those rocks which underlie the basal Plattin oolitic and conglomeratic limestone and overlie a chert zone which occurs in the Joachim dolomite; thus, it restricts the Plattin and Joachim and contains a part of each. Consists of dense gray limestone or buff dolomites with some interbedded shale. Thickness in type area (determined from wells) 270 feet.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2042 (fig. 1), 2044–2046. Underlies Bloomsdale formation (new) of Plattin group.

Type locality: 0.2 mile east of junction of U.S. Highway 61 and Missouri Highway 74, Cape Girardeau County. Name derived from siding on St. Louis-San Francisco Railway, in NW¼NW¼NW¼ sec. 24, T. 30 N., R. 13 E. Surface distribution is closely allied with the basal Plattin.

Rocklin Granodiorite

[Jurassic]: Northern California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 6. Discussed in report dealing with potassium-argon age determinations. Age given as 131 million years.

Occurs in Rocklin pluton, an elliptical mass of approximately 150 square miles, which crops out in foothill belt of Sierra Nevada in western part of Auburn quadrangle. Pluton intrudes Mariposa formation and is unconformably overlain by marine beds equivalent in age to Campanian stage of Upper Cretaceous. Dated sample obtained from Rocklin quarry in Placer County.

Rockmart Slate[1]

Mississippian: Northwestern Georgia.

Original reference: C. W. Hayes, 1891, Geol. Soc. America Bull., v. 2, p. 143; 1894, Geol. Soc. America Bull., v. 5, p. 469–470, 478.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 52–54, geol. map. Succeeds Newala limestone with an erosional unconformity. Predominantly a clay rock which includes thin beds of sandstone and at one horizon a stratum of thinly bedded, slightly fossiliferous chert about 80 feet thick. Estimated thickness 1,200 to 3,000 feet; bedding is most everywhere steeply inclined and cut by slaty cleavage; no recognizable beds or horizons have been detected that would serve as datum planes for measurement. Rockmart has hitherto been regarded as a facies of Stones River group and correlated with the Chickamauga of older usage. It is here considered Mississippian and a correlative facies of the Floyd shale.

Named for Rockmart, Polk County.

Rock Mesa Lava Flow

Rock Mesa Obsidian Flow

Recent: Southwestern Oregon.

E. T. Hodge, 1925, Oregon Univ. Pub., v. 2, no. 10, p. 54 (fig. 34), 55, 57 (fig. 40). Discussion of Mount Multnomah, ancient ancestor of the Three Sisters. Rock Mesa lava flow is term applied to flow that makes up Rock Mesa.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, no. 3, p. 53, 54, 58, pl. 12(b). Referred to as Rock Mesa obsidian flow in report on volcanoes of Three Sisters region. May be among youngest rocks of region.

Rock Mesa is southwest of South Sister Mountain and north of Le Conte Crater.

**Rock Point Member** (of Wingate Sandstone)

Upper Triassic: Northeastern Arizona, southwestern Colorado, northwestern New Mexico, and southeastern Utah.

G. A. Kiersch, 1955, Mineral Resources Navajo-Hopi Indian Reservations, Arizona-Utah, v. 2, p. 4 (fig. 1), 5. Consists of reddish-orange, parallel, and thin-bedded siltstone and sandstone. Thickens southward from Kayenta (350 feet) to 700 feet in Hopi Buttes country where it intertongues with upper Lukachukai member (new). Overlies Chinle formation. Name credited to Harshbarger and others (in press).

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 8–10. Type locality designated. Formerly the "A" division of Chinle formation (Gregory, 1917, U.S. Geol. Survey Prof. Paper 93). At type locality, consists of sequence of pale reddish brown beds forming ledges of silty sandstone and slopes of siltstone; thickness 344 feet; underlies Lukachukai member; conformably overlies Chinle formation.

Type locality: The lower, slope-forming unit exposed in Little Round Rock, a prominent butte, 15 miles south of Rock Point School, Ariz.

Rockport formation[1]

Upper Cretaceous: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 61–62, 280, 301.

Named from hamlet of Rockport, Summit County.

Rockport Limestone (in Greene Formation)[1]

Permian: Western West Virginia.

Original reference: C. E. Krebs, 1911, West Virginia Geol. Survey Rept. Jackson, Mason, and Putnam Counties, p. 102.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Table shows Lower, Middle, and Upper Rockport limestones in Greene series. Lower Rockport is above Nineveh coal and below Nineveh "A" coal; Middle Rockport is below Taylor sandstone; Upper Rockport is below Gilmore limestone.

Named for occurrence at Rockport, Wood County.

Rockport Limestone[1] (in Traverse Group)

Middle Devonian: Northeastern Michigan.

Original reference: R. A. Smith, 1916, Michigan Geol. and Biol. Survey Pub. 21, Geol. Ser. 17, p. 172–175.

B. F. Hake and J. B. Maebus, 1938, Michigan Acad. Sci., Arts, and Letters, Papers, v. 23, p. 447–461. Included in Traverse group in central Michigan.

G. A. Cooper and A. S. Warthin, 1941, Washington Acad. Sci. Jour., v. 31, no. 6, p. 260. Preoccupied Rockport limestone replaced by Rockport Quarry limestone.

Named for exposures at Rockport, Alpena County.

**Rockport Limestone Member** (of Rockland Formation)[1]

Cambrian or Ordovician: South-central Maine.

Original reference: E. S. Bastin, 1908, U.S. Geol. Survey Geol. Atlas, Folio 158, p. 3–4.

H. W. Allen, 1951, Maine State Geologist Rept. 1949–1950, p. 79. Member at top of Rockland. Overlies an unnamed siliceous limestone member.

Named for exposures on eastern shore of Rockport Harbor, Knox County.

Rockport Sandstone[1]

Pennsylvanian: Southwestern Indiana.

Original reference: E. T. Cox, 1871, Indiana Geol. Survey 2d Ann. Rept., p. 169.

Probably named for Rockport, Spencer County.

Rockport Shales[1]

Pennsylvanian: Northwestern Missouri.

Original reference: C. R. Marbut, 1904, The State of Missouri, p. 69.

**Rockport Quarry Limestone** (in Traverse Group)

Middle Devonian: Northeastern Michigan.

G. A. Cooper and A. S. Warthin, 1941, Washington Acad. Sci. Jour., v. 31, no. 6, p. 260. Proposed to replace Rockport limestone of Smith, 1916 (not Bastin, 1908; Krebs, 1911; or Marbut, 1904).

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3), 580–581. Section at Rockport consists predominantly of gray and brown limestone with minor amounts of shale; thickness about 41 feet. Overlies Bell shale; underlies Ferron Point formation. Included in Traverse group.

Type section: Quarry of Kelly Island Rock and Transport Co. at Rockport in northeast corner Alpena County. Also exposed in Presque Isle County and at some places along shore of Lake Huron.

Rock Prairie Sandstone (in Jackson Group)

Eocene: East-central Texas.

A. A. L. Mathews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 5, geol. map. Basal sandstone of group. Composed of thick and thin beds of medium- to coarse-grained marly fossiliferous dark-red sandstone which weathers to dark brown; many beds are porous, almost cavernous, while others are dark buff, platy, and friable; some thick beds are slightly crossbedded coarse-grained clear quartz sandstone with uniform quartz grains; other beds are made up of irregular and nodular iron sandstone seams which thicken and thin laterally. Approximately 60 feet thick. Underlies Caddell formation; unconformably overlies Cockfield formation.

Type locality: About 2 miles east of the road where pipelines of Humble Oil Co. cross Carter's Creek Road, Brazos County. Name derived from community of Rock Prairie on Highway 6, 3½ miles south of corner of campus of A & M College of Texas. Section is composed of the compilation of the outcrops along the road, and those exposed in the branches on either side of the road.

Rock Riffle limestone member

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 131–133. Fresh-water limestone in Harlem cyclothem. Lies beneath Harlem underclay member and above Round Knob redbed member. Typically gray, weathering greenish gray; nodular to bedded and enclosed in greenish gray clay shale. Thickness about 4½ feet.

Named for exposures along Rock Riffle Run, a small tributary on south side of Hocking River, Athens Township, Athens County.

Rock River Formation[1] or Dolomite

Upper Cambrian: Northwestern Vermont, and southeastern Quebec, Canada.

Original reference: H. W. McGerrigle, [1931], Vermont State Geologist 17th Rept., p. 182, 184, 185.

J. A. Dresser and T. C. Denis, 1944, Quebec Dept. Mines Geol. Rept. 20, v. 2, p. 396, 397. Lowest formation of Philipsburg series. Thickness about 500 feet.

Exposed from northern part of St. Albans quadrangle, Vermont, across the international border for about 20 miles into Quebec.

Rock Run Limestone[1]

Upper Ordovician (Richmond) : Northeastern Illinois.

Original reference: J. R. C. Evans, 1926, Chicago Univ., Abs. Theses, Sci. ser., v. 2, p. 199–200.

Type locality not stated.

Rock Springs Beds

Miocene and Pliocene : Central Arizona.

C. S. St. Clair, 1957, Plateau, v. 30, no. 2, p. 36, 37, fig. 2. Volcanic flow rocks and tuffaceous and clastic sandstones. Flow rocks are olivine basalt, hornblende basalt, and hornblende andesite. Tuffaceous sandstones made up mostly of fine-grained pumice with small amounts of rounded sand grains of quartz and feldspar and dark minerals. Locally in sequence are boulder conglomerates probably of fluviatile origin. Beds have been extensively eroded but represent Cenozoic rocks that may have been up to 2,000 feet thick. Underlie Pleistocene gravels.

Sequence is east of Bradshaw Mountains near Rock Springs, south-central Yavapai County.

**Rock Springs Formation** (in Mesaverde Group)[1]

Upper Cretaceous : Southwestern Wyoming and northeastern Utah.

Original reference : A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

W. R. Hansen and M. G. Bonilla, 1954, Colorado Sci. Soc. Proc., v. 17, no. 1, p. 4 (fig. 1), 9–10. Geographically extended into Daggett County, Utah, where it underlies Erickson formation and overlies Blair formation. Thickness 1,090 feet in Flaming Gorge area; 100 feet in Clay Basin. Intertongues with Hilliard shale toward east.

W. R. Hansen, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–101. Described in Clay Basin quadrangle, Utah, as interbedded pale-grayish-orange to light-brown fine-grained sandstone and gray Hilliard-like shale becoming punky toward top; capped by massive pale-grayish-orange to white very fine grained cliff-forming sandstone. Contact with underlying Hilliard shale mapped arbitrarily at base of a grayish-orange fine-grained sandstone bed, 24 feet thick, that separates a predominantly shale sequence below from interbedded shale, sandy shale, and sandstone above.

Present in Rock Springs uplift, Sweetwater County, Wyo.

**Rock Stream Siltstone Member** (of Sonyea Formation)

Rock Stream Flagstone Member (of Cashaqua Shale)

Upper Devonian : Western New York.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 12–13, pl. 3. Name proposed for flagstone member in upper part of Cashaqua shale. Consists of sequence of alternating flagstones and shale.

Thickness 180 feet. Underlies Parrish limestone lentil; overlies lower unnamed shale with sharply defined contact.

G. W. Colton and Wallace de Witt, Jr., 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–54. Redesignated as Rock Stream siltstone member of Sonyea formation. Is eastern lateral equivalent of large part of Cashaqua shale member. Throughout its extent in area studied, the Rock Stream is underlain by Pulteney shale member (new) and overlain by Cashaqua shale member. Not present west of eastern Livingston County. At westernmost exposure, near Hemlock Lake, consists of two beds of siltstone, from 2 to 5 inches thick, separated by 4 feet of silty gray shale. Thickens eastward. About 217 feet thick along Hamilton Creek 2½ miles west of Watkins Glen.

R. G. Sutton, 1960, New York State Mus. Sci. Service Bull. 380, p. 14–17, 54, 55–56. Member of Cashaqua formation. Overlies Sawmill member (new). After submission of this paper for publication, Colton and de Witt (1958) proposed name Pulteney for unit herein named Sawmill Creek; former name thus has priority.

Named from exposures on Rock Stream in northwestern part of Watkins quadrangle, Reading Township, Schuyler County.

**Rocktown Channel Sandstone Member** (of Dakota Sandstone)[1]

Rocktown Sandstone Member (of Ellsworth Formation)

Upper Cretaceous: North-central Kansas.

Original reference: W. W. Rubey and N. W. Bass, 1925, Kansas Geol. Survey Bull. 10, p. 16, 57–65.

R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]. Reallocated to member status in Ellsworth formation (new) of Dakota group. Overlies Terra Cotta shale member (new).

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Dakota formation, as herein defined, contains stratigraphic units formerly called "Rocktown channel sandstone," "Ellsworth formation," "Solomon formation," "Reeder sandstone," "Marquette sandstone," "Spring Creek clay," and others.

Named for exposures at and near the large group of "hoodoos" or houselike blocks of sandstone in NW¼ sec. 4, T. 13 S., R. 11 W., locally known as Rocktown, Russell County.

**Rockvale Sandstone Member** (of Vermejo Formation)[1]

Upper Cretaceous: Eastern Colorado.

Original reference: W. T. Lee, 1917, U.S. Geol. Survey Prof. Paper 101, p. 163–169.

Named for typical development near Rockvale, Fremont County.

Rockville Conglomerate[1]

Tertiary or Quaternary: Northeastern Iowa.

Original reference: W. J. McGee, 1891, U.S. Geol. Survey 11th Ann. Rept., pt. 1, p. 304.

S. D. Tuttle and R. C. Northup, 1955, Iowa Acad. Sci. Proc., v. 62, p. 366–372. Rockville conglomerate should be updated in age to Tertiary-Quaternary and extended to include a new outcrop at Olin, Jones County.

Named for Rockville, Delaware County.

Rockville Granite

Rockville Quartz Monzonite (in Stearns Magma Series)

Precambrian (middle Keweenawan) : Central Minnesota.

Eleanor Tatge, 1939, Am. Mineralogist, v. 24, no. 5, p. 303–316. Unusually coarse-grained granite with abundant microcline phenocrysts and very little secondary alteration. Rockville granite has been used as a trade name for granite quarried near St. Cloud [and Rockville].

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1002, 1006. Quartz monzonite and porphyritic quartz monzonite; typically pink, ranges to dark reddish gray. Included in Stearns magma series; grades into St. Cloud red facies of series.

Crops out between St. Cloud and Richmond, Stearns County. Most characteristic exposure is at Rockville.

†Rockville Member (of Skaneateles Formation)[1]

Middle Devonian : Eastern Pennsylvania.

Original reference: Bradford Willard and A. B. Cleaves, 1933, Geol. Soc. America Bull., v. 44, no. 4, p. 768, 781.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 16, 138. Pre-occupied name Rockville replaced by Fort Hunter sandstone.

First studied at Rockville, on Susquehanna, in Dauphin County.

†Rockville Sandstone[1]

Upper Devonian : Southwestern New York.

Original reference: H. S. Williams, 1887, U.S. Geol. Survey Bull. 41, p. 51, 73.

Exposed at old Rockville, which is 1 mile west of present Rockville, Allegany County.

**Rockwell Formation**[1] (in Pocono Group)

Rockwell Member (of Pocono Formation)

Lower Mississippian : Northeastern West Virginia and western Maryland.

Original reference: G. W. Stose and C. K. Swartz, 1912, U.S. Geol. Survey Geol. Atlas, Folio 179.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources, p. 91. In PawPaw-Hancock area, the Pocono is considered to have group rank and is divided into five formations; in western Maryland, where the five units cannot be differentiated, the Pocono is treated as a formation and the Rockwell as a member. Consists of greenish to gray crossbedded arkosic sandstone, fine conglomerate, and buff shales with some dark shales that locally contain coal seams. Thickness 540 to 550 feet on Sideling Hill, Washington County, Md. Underlies Purslane member.

Named for exposures in Rockwell Run, Morgan County, W. Va.

**Rockwood Formation**[1]

Lower and Middle Silurian : Eastern Tennessee and northwestern Georgia.

Original reference : C. W. Hayes, 1891, Geol. Soc. America Bull., v. 2, p. 143.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pls. 11, 12, 13. At Rockwood, the formation, if the Sequatchie is removed, is entirely lower Silurian, but in other areas middle Silurian and perhaps even higher rocks are present. Clinch sandstone and Rockwood formation are mainly contemporaneous phases of lower and middle Silurian and, in areas intermediate between the two type localities, grade into each other, though in any one section the sandstone lies chiefly below. Underlies Hancock limestone; overlies Sequatchie formation.

Named for Rockwood, Roane County, Tenn.

Rockwood Oolite[1] Member (of Bangor Limestone)

Mississippian: Northwestern Alabama.

Original reference: W. B. Jones, 1928, Alabama Geol. Survey Circ. 8, p. 13–15.

W. B. Jones, 1939, Econ. Geology, v. 34, no. 5, p. 575, 576–577. Thickness at type locality about 55 feet. Overlies Spout Spring oolite member (new).

Type locality: Near Rockwood, Franklin County.

†Rockwood Sandstone[1]

Silurian: Northwestern Georgia.

Original reference: C. W. Hayes, 1894, U.S. Geol. Survey Geol. Atlas, Folio 2.

East of Chattooga Valley.

Rockwood Sandstone (in Chester Group)[1]

Mississippian: Southwestern Illinois.

Original reference: S. Weller, 1913, Illinois Geol. Survey Bull. 22, p. 31.

Probably named for Rockwood, Randolph County.

Rocky Branch bone bed (in Jeffersonville Limestone)

Middle Devonian: Southeastern Indiana.

J. W. Wells, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 282–283. Name applied to bone bed near top of Jeffersonville limestone.

Crops out on Rocky Branch, northwestern Jennings County.

Rocky Butte Volcanics

Pleistocene: Northern Oregon.

R. C. Treasher, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2034. Name applied to a series of volcanic flows that capped many hills in Portland area prior to or during early stages of continental glaciation.

Rocky Canyon Granite[1]

Jurassic or Cretaceous: Northwestern Nevada.

Original reference: C. P. Jenney, 1935, Nevada Univ. Bull., v. 29, no. 6, p. 37–42.

Crops out over 6 square miles in lower Rocky and Wright's Canyons and elsewhere in Humboldt Range.

Rocky Cedar Limestone

Rocky Cedar Creek Limestone Lentil (in Kincaid Formation)[1]

Eocene: Northeastern Texas.

R. A. F. Penrose, Jr., 1890, *in* E. T. Dumble, Texas. Geol. Survey 1st Ann. Rept., p. 19–20. At Rocky Cedar Creek, is deposit of shell limestone, composed almost entirely of shells of lower Eocene fossils. It is traceable up and down Rocky Cedar Creek for 7 miles, and underlies divide between Rocky Cedar and Muddy Cedar Creeks, a distance of 4 miles. Section of well on this divide shows: lower shell limestone 3 to 4 feet thick, coarse sand, 1½ to 2 feet, shell limestone, 3 to 4 feet, gray and yellow clay (Basal Clays), 9 feet, gray and buff sand, 3 feet. About 1 mile below point where Texas Pacific Railroad crosses Rocky Cedar, an outcrop 15 feet thick of this limestone is present, and as it still forms bed of the creek, its thickness here must be still greater than that. Village of Elmo is situated on Muddy Cedar, and just beyond is black prairie region showing Cretaceous fossils. Consequently Rocky Cedar limestone is probably lowermost bed of Tertiary series in this part of State.

Lentil typically exposed in Ola quarry, 1 mile south of Ola and along Rocky Cedar Creek between Ola and Wills Point, Kaufman County.

†Rocky Comfort Chalk[1]

Upper Cretaceous (Gulf Series) : Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72, 89–95, 188.

Named for exposures at Rocky Comfort, Little River County.

**Rock Flats Alluvium**

Pleistocene (Nebraskan or Aftonian) : Northeastern Colorado.

G. R. Scott, 1960, Geol. Soc. America Bull., v. 71, no. 10, p. 1541, 1542 (table 1). Name applied to oldest widespread alluvium recognized in Denver area. Where typically exposed, occurs as a sheet, 10 to 40 feet thick, of reddish-brown poorly sorted stony coarse sand that unconformably overlies Mesozoic bedrock on a pediment about 1,600 feet below level of a subsummit surface on the Front Range. Occurs 100 feet above next younger alluvium here named Verdos.

Typically exposed in gravel pit at east edge of Rocky Flats in NW¼SW¼ sec. 23, T. 2 S., R. 70 W., Golden quadrangle.

Rockyford Ash Member (of Sharps Formation)

Miocene: Southwestern South Dakota.

J. C. Harksen, 1960, Geology of the Sharps Corner quadrangle, South Dakota (1:62,500) : South Dakota Geol. Survey. Consists of as much as 38 feet of silty volcanic ash and ashy silt layers that are white, buff, tan, and reddish brown. Conformably underlies upper part of formation and conformably overlies Brule formation. Name credited to John Nicknish (unpub. thesis).

Type locality and derivation of name not given.

Rocky Gap Sandstone (in Helderberg Group)[1]

Lower Devonian: West Virginia and southwestern Virginia.

Original reference: F. M. Swartz, 1929, Pennsylvania Acad. Sci. Proc., v. 3, p. 80.

P. H. Price and H. P. Woodward, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 11, p. 1987. Present in vicinity of Bluefield where it has locally been mistaken for Oriskany sandstone.

Well exposed in Rocky Gap, W. Va.

**Rocky Hill Volcanics** (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull 30, p. 74–75.

G. A. Macdonald and D. A. Davis *in Jacques* Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 130. Thickness of lava probably 40 feet; Rocky Hill cone 130 feet high, base not exposed. Overlain by Sugar Loaf basalt and by sand and coral of the plus 25-foot (Waimanalo) stand of sea. Extent noted.

Named for Rocky Hill, largest of the four cinder cones. Exposed over area of about 0.1 square mile in lower end of Manoa Valley, on south side of Koolau Range about 11 miles west of Makapuu Head.

**Rocky Mound Limestone Member** (of Graham Formation)[1]

Rocky Mound Limestone (in Graham Group)

Upper Pennsylvanian: Central northern Texas.

Original reference: Wallace Lee *in* Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 40–45.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, p. [16], [17], fig. 4. Shown on generalized columnar section as Rocky Mound limestone in Graham group; occurs below Wayland shale and above Upper Gunsight limestone. Limestone is possibly a bioherm; consists mainly of crinoid fragments and a few fusulinids bound together with algal filaments.

Well exposed on southwest slope of Rocky Mound, 3 miles northeast of Graham, Young County.

Rocky Point Beds

Rocky Point Formation

Oligocene, upper: Northwestern Oregon.

F. W. Libbey, W. D. Lowry, and R. S. Mason, 1945, Oregon Dept. Geology and Mineral Industries Bull. 29, p. 8–9. Name Rocky Point beds applied to marine sandstones exposed in eastern Washington County, in Portland Hills area in Multnomah County, and along Dixie Mountain Road between Shady Brook School and Wallace School in sec. 18 and SW¼ sec. 5, T. 2 N., R. 2 W., and in numerous cuts along the Rocky Point Road which leads east from Skyline Boulevard to U.S. Highway 30. In most places, sandstones seem to occupy windows in overlying Columbia River basalt. Fossil evidence indicates that beds are upper Oligocene or somewhat younger.

M. L. Steere, 1955, Geol. Soc. Oregon Country News Letter, v. 21, no. 10, p. 85. Name Rocky Point formation proposed for Cowlitz formation in northwest Oregon. Type locality designated. Name credited to R. J. Deacon (unpub. thesis).

Type locality: On Rock Creek in vicinity of Keasey Station, Columbia County.

Rocky Point Conglomerate (in Deese Formation or Group)

Pennsylvanian (Desmoinesian): Southern Oklahoma.

C. W. Tomlinson, 1937, Ardmore Geol. Soc. [Guidebook] Field Trip, March 13, Road log, p. 1, 2, geol. map. Chert conglomerate in upper Deese formation.

Lynn Jacobson, 1959, Oklahoma Geol. Survey Bull. 79, p. 28 (fig. 11), 35. Rocky Point member of Deese group is about 1,400 feet above Arnold limestone. Maximum thickness 70 feet; much of thickness is sandstone. Much of outcrop covered by Lake Murray.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc. Petroleum Geology of southern Oklahoma—a symposium, v. 2: Tulsa, Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 32–33. Rocky Point conglomerate, in Deese group, is about 1,600 feet below Camp Ground member (new). Desmoinesian. Name credited to Guthrey and Milner (unpub. ms.).

Occurs in area south of Ardmore.

**Rocky Ridge Sandstone Member** (of Pierre Shale)[1]

Upper Cretaceous: Central northern Colorado.

Original reference: M. W. Ball, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, no. 1, p. 81–87.

G. R. Scott and W. A. Cobban, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf. Symposium, p. 128, 129 (fig. 3). Olive-gray fine-grained massive sandstone; contains large calcareous sandstone concretions that weather dark brown. Thickness 97 feet. Separated from overlying Larimer sandstone member by 163 to 187 feet of soft yellowish-gray sandstone and sandy shale with gray sandstone concretions; separated from older Terry sandstone member by 511 to 604 feet of sandy and nonsandy shale.

Named for exposures on north and east banks of Rocky Ridge Reservoir 6 miles north of Fort Collins, Larimer County. Makes prominent ridge at many places between Round Butte and Berthoud. Forms west escarpment of Fossil Ridge.

**Rocky Ridge Sandstone Member** (of Pottsville Formation)[1]

Pennsylvanian: North-central Alabama.

Original references: C. Butts, 1926, Alabama Geol. Survey Spec. Rept. 14; 1927, U.S. Geol. Survey Geol. Atlas, Folio 221.

Named for fact it forms Rocky Ridge, east and northeast of Chaba pumping station in northwestern part of Vandiver quadrangle.

Rocky Run Conglomerate[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 2, p. 1553.

Crops out on Rocky Run, Montour Township, Pike County.

Rocky Woods Conglomerate[1]

Carboniferous: Southeastern Massachusetts.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, table.

In the Great Rock area in Rehoboth, extends eastward to Rocky Woods, near Taunton, Bristol County.

Rod Club Sandstone (in Springer Group)

Rod Club Sandstone Member (of Springer Formation)[1]

Pennsylvanian (Springer Series): Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40–Z, p. 12, 13.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, p. 143. Overlies Goddard shale (new).

M. K. Elias, 1956, *in* Petroleum geology of southern Oklahoma, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 70 (table 2), 89. Rod Club sandstone overlies Goddard shale. Springer series.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 10. Thickness 250 to 400 feet. Consists chiefly of shales; these typically contain several ledges of sandstone, each from 2 to 25 feet thick. Occurs above Goddard shale and 800 to 1,000 feet below Overbrook sandstone. In Springer group which here includes Chesterian and Springeran series. Basal unit of Springeran series as here defined.

Named for outcrops at smaller Rod and Gun Club Lake in NW¼ sec. 7, T. 4 S., R. 2 E., Carter County, on southeast plunging nose of Caddo anticline.

**Rodeo Shale** (in Monterey Group)[1]

Miocene, middle: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 69 (table 14), 71, pls. Occurs in southern Carquinez and Mare Island quadrangles. Apparently conformable upon Hambre sandstone where it is exposed in band 1,000 feet wide that extends from San Pablo Bay southwestward in Concord quadrangle. Underlies Briones sandstone. Average thickness 670 feet.

G. D. Robinson, 1956, U.S. Geol. Survey Quad. Map GQ–88. Described in Hayward quadrangle as arenaceous shale, locally porcelaneous, and shaly biotitic arkosic sandstone, with thin but persistent beds of siliceous rocks and limestone. Thickness varies irregularly from less than 100 feet to more than 300 feet; in general thickens southeastward. Overlies middle sandstone and shale of Monterey group; disconformably underlies Briones sandstone.

Named for exposures along Rodeo Creek, in northwest part of Concord quadrangle, Contra Costa County.

**Rodessa Formation** (in Trinity Group)

Rodessa Member (of Glen Rose Formation)

Lower Cretaceous (Comanche Series): Subsurface in Louisiana, Arkansas, Mississippi, and Texas.

W. B. Weeks, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 8, p. 961 (fig. 4), 970. Lower Glen Rose is divided into Pine Island member below and Rodessa member above. Trinity group, Comanche series. Thickness about 500 feet. Name proposed by Shreveport Geological Society.

R. W. Imlay, 1940, Arkansas Geol. Survey Circ. 12, p. 33–35, cross sections. Rodessa formation includes oolitic to coquinoid limestone, calcareous shale, and two anhydrite beds. Overlies James limestone; underlies Ferry Lake anhydrite. Contains number of members, lentils, and tongues.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Rodessa formation employed as catch-all for beds between James limestone and Ferry Lake anhydrite in subsurface of Arkansas-Louisiana-east Texas area.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2350–2354. Formation redefined as those rocks between base of Ferry Lake anhydrite and base of Young zone (or its stratigraphic equivalent) as recognized in Rodessa field. Type well designated.

Type well: Union Producing Co.'s Caddo Levee Board No. B–1, sec. 26, T. 23 N., R. 16 W., Caddo Parish, La. Interval on electrical log from 5,320 to 5,805 feet represents Rodessa.

**Rodman Limestone** (in Black River Group)[1]

Rodman Member (of Nealmont Limestone)

Middle Ordovician: Central Pennsylvania.

Original reference: Charles Butts, 1918, Am. Jour. Sci., 4th ser., v. 46, p. 525, 533, 537.

Charles Butts and E. S. Moore, 1936, U.S. Geol. Survey Bull. 855, p. 39–40, pls. 1, 3. In Bellefonte quadrangle, overlies Lowville limestone and underlies Trenton limestone. Thickness 10 to 50 feet. Black River group.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Type Rodman included in Nealmont limestone of Trenton group.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 192. Termed member of Nealmont.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 2, p. 97, 101, 104–105. Further described as uppermost member of Nealmont limestone. Composed of impure, brownish-weathering limestone, darker than rest of Nealmont, and thin beds of white-weathering dense limestone; frequently has nodular chert in lower part. Thickness about 30 feet in type area; 26 feet in section near Tusseyville. Overlies Centre Hall member; underlies cobbly beds below metabentonite 0 of Salona limestone. Lower limit gradational and cannot be defined readily; essential conformity exists between Nealmont and Salona, though angular unconformity found locally. Type section designated.

Type section: Along Highway 322, 1 mile west of Tusseyville, 3 miles south of Centre Hall and 6 miles east of Oak Hall, Centre County. Named at Rodman Station, near Roaring Springs, Blair County.

Rodriquez Tank Sandstone

Ordovician: Western Texas.

W. B. N. Berry, 1960, Texas Univ. Bur. Econ. Geology Pub. 6005, p. 20. White to buff quartzose sandstone 20 to 50 feet thick. Occurs between Marathon limestone and Fort Pena formation. Graptolites characteristic of uppermost part of the Marathon were collected 3 inches below the sandstone, and graptolites diagnostic of basal beds of Fort Pena were collected 1 inch above the sandstone; thus stratigraphic position was determined from paleontological evidence. Alsate shale commonly present between Marathon, and Fort Pena is absent in this area.

Type locality: Northern part of the Solitario, Brewster County. Named for outcrops near Rodriquez Tank. Sandstone is a continuous unit and commonly stands out forming a low ridge in area of Ordovician outcrop in the Solitario and a prominent bench in old Jones Ranch (now Slaughter Ranch) locality. Outlines recumbent anticline below Cretaceous rim in Jones Ranch area.

**Roger Park Basaltic Breccia**

Pliocene(?): Southwest-central Utah.

Eugene Callaghan, 1939, Am. Geophys. Union Trans. 20th Ann. Mtg., pt. 3, p. 439 (fig. 2), 440 (fig. 3), 446–447. Flows near top of formation are dark gray with distinctly basaltic appearance; breccias are various shades of gray or red, and fragments commonly vesicular. Maximum thickness in mapped area as much as 2,000 feet. Position of Roger Park in volcanic sequence of region not clear. Breccia overlain by latite grouped with Dry Hollow latite (new) and underlain by latites and breccia of Bullion Canyon volcanics (new). May be facies of Bullion Canyon volcanics. Tertiary.

The U.S. Geological Survey currently considers the Roger Park to be Pliocene(?) in age. This designation is made on the basis of restudy of Bullion Canyon Volcanics, now considered to be Miocene(?).

Occurs in Marysvale region. Derivation of name not stated.

Rogers Chalk Lens (in Taylor Marl)[1]

Upper Cretaceous (Gulf Series) : Northern central Texas.

Original reference: W. S. Adkins and M. B. Arick, 1930, Texas Univ. Bull. 3016, p. 65.

Type locality: On a small creek from about 1 mile to 1¼ miles south and a little west of Rogers, Bell County.

**Rogers City Limestone** or **Formation**

Middle Devonian: Northeastern Michigan.

G. M. Ehlers and R. E. Radabaugh, 1937, Michigan Acad. Sci., Arts, and Letters, Sec. Geology and Mineralogy [Guidebook] 7th Ann. Field Excursion [p. 8–9]. Name applied to limestone overlying Dundee limestone and disconformably underlying Bell shale of Traverse group. Thickness 69½ to 72½ feet.

G. M. Ehlers and R. E. Radabaugh, 1938, Michigan Acad. Sci., Arts, and Letters, Papers, v. 23, p. 441–445. As proposed, name Rogers City is applied to limestone and dolomite strata formerly considered part of the Dundee which is here restricted to lower 140 feet of section. Lower 8 to 9 feet of Rogers City is dolomite; upper part is limestone. Rogers City fauna is distinctive from that of Dundee.

Type locality: Quarry of Michigan Limestone and Chemical Co., at Rogers City, Presque Isle County.

**Rogers Creek Member** (of Schrader Bluff Formation)

Upper Cretaceous: Northern Alaska (subsurface and surface).

C. L. Whittington, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 249, 250, 251, fig. 5. About two-thirds of member is medium-gray to medium-light-gray clay shale in type section. Listed in order of importance, rocks interbedded with the clay shale are tuff, siltstone, silt shale, sandstone, and bentonite. Thickness about 700 feet in vicinity of Umiat, 585 to 595 feet at type section. Lowest named member of formation. Rogers Creek member and overlying Barrow Trail member (new) defined to include rocks overlying Tuluvak tongue of Prince Creek formation that were formerly included in Tuluga member of Schrader Bluff formation. Very poorly exposed in Umiat area but is expressed as areas of subdued topography enclosed by cuestas formed by Barrow Trail member.

Type section: Gubik test well No. 1 from 295 to 890 feet and Gubik test well No. 2 from 555 to 1,140 feet. Named from upper part of Rogers Creek, about 10 miles S. 80° W. of Umiat Mountain where subdued topography is typically developed.

Rogers Gap (division) Member (of Cynthiana Formation)[1]

Middle Ordovician: Central Kentucky.

Original reference: A. F. Foerste, 1912, Denison Univ. Sci. Lab. Bull. 17, p. 19, 23, 42, 44.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1642. Division of Cynthiana. Thin- to medium-bedded limestone and shale with distinctive fauna. Overlies Nicholas limestone; underlies Fulton shale. Gratz shale division includes Rogers Gap in its upper part. Pre-Cincinnatian.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 18. All subdivisions of interval between top of Benson limestone and base of Eden formation should be referred to as members of the Cynthiana. This includes the lithologic and paleontologic units heretofore defined as Brannon, Woodburn, Greendale, Millersburg, Nicholas, Rogers Gap, Bromley, and Gratz.

L. H. Lattman, 1954, Am. Jour. Sci., v. 252, no. 5, p. 257, 268. Rogers Gap [member of Cynthiana formation] formation, uppermost member of the Mohawkian, and the overlying Fulton shales, lowermost member of the Cincinnatian, are faunally indistinguishable in this area [Ohio Valley around Cincinnati]; they appear to be lithologic facies of same time-rock unit. The Rogers Gap and Fulton rest northwardly on the Nicholas and southwardly on the Greendale; they are not present over top of Jessamine dome; Fulton (shale phase) is absent in some places toward center of dome, and the Million (Eden) rests directly on the Rogers Gap. The faunal and lithologic evidence indicates the advisability of extending the Cincinnatian series downward to embrace the Cynthiana formation, rather than including this formation in Mohawkian as has been the common practice.

Probably named for Rogers Gap, Scott County.

Rogersian series[1]

Precambrian: Montana, and Alberta, Canada.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44.

Derivation of name not stated.

**Rogers Spring Limestone**[1]

Mississippian: Southeastern Nevada.

Original references: C. R. Longwell, 1921, Am. Jour. Sci., 5th ser., v. 1, p. 46; 1928, U.S. Geol. Survey Bull. 798.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, no. 5, p. 930 (table 1). Chiefly gray crystalline limestone with some cherty zones. Thickness about 600 feet. Underlies Bluepoint limestone; overlies Muddy Peak limestone Mississippian.

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 518–519. Lower Mississippian. Thickness Virgin Mountain section 577½ feet.

Ben Bowyer, E. H. Pampeyan, and C. R. Longwell, 1958, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–138. Mapped as Mississippian.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). In Virgin Mountains, underlies Illipah formation.

Well exposed along Rogers Spring fault scarp, Clark County.

Rogersville Limestone (in Greene Formation)[1]

Permian: Southwestern Pennsylvania.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 97, 106.

In Greene County.

**Rogersville Shale**[1] (in Conasauga Group)

Middle Cambrian: Northeastern Tennessee, western North Carolina, and southwestern Virginia.

Original reference: M. R. Campbell, 1894, U.S. Geol. Survey Geol. Atlas, Folio 12, p. 2.

John Rodgers, 1943, Geologic map of Copper Ridge district, Hancock and Grainger Counties, Tennessee (1:24,000): U.S. Geol. Survey Strategic Minerals Inv. Prelim. Map. Includes Craig limestone member (new). Overlies Rutledge limestone; underlies Maryville shale.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1 (plates); pt. 2, p. 46 (fig. 3), 48–51. In eastern Tennessee, Conasauga varies in lithology and three phases are recognized; in central phase (between Knoxville and Morristown, and north of Clinch Mountain), the Conasauga is considered a group consisting of six formations of which the Rogersville shale is third in sequence (ascending). Underlies Maryville limestone; overlies Rutledge limestone. Thickness 0 to 250 feet.

Named for exposures at and near Rogersville, Hawkins County, Tenn.

**Rogue Formation**

Upper Jurassic: Southwestern Oregon.

F. G. Wells and G. W. Walker, 1953, Geology of the Galice quadrangle, Oregon: U.S. Geol. Survey Geol. Quadrangle Map [GQ–25]. Name given to a sequence of metavolcanic rocks and small related intrusives of Upper Jurassic age. Sequence consists of intimately intermixed fine- to coarse-grained tuffs, agglomerates, flow breccias, and flows and their metamorphic equivalents. These types can be differentiated only in extensive waterworn exposures. Estimate of thickness depends on an assumption as to the thickening due to folding; thickness at type locality probably 15,000 feet. Bounded on west by Dothan formation; both formations dip steeply eastward; evidence indicates that volcanic rocks of the Rogue were deposited on sedimentary rocks of the Dothan prior to deformation; Galice formation lies to the east of the Rogue.

Type section: Along Rogue River, Galice quadrangle. Formation almost continuously exposed along Rogue River from confluence of Whiskey Creek to Almeda mine, along lower 5 miles of Grave Creek and along lower reaches of Reuben Creek.

Rogue River Flows, Pumice Flows

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 81, 90–92, pl. 19 (fig. 2). Rogue River flows (pumice flows) were products of glowing avalanche that followed Rogue River and its tributaries. The flows united near confluence with Union Creek, and composite flow continued for 20 miles to point 1½ miles above present site of village of McLeod. End of flow lies 35 miles from former summit of Mount Mazama. Glowing avalanches of pumice were part of final activity of Mount Mazama and followed what is termed main pumice fall.

Rogue River is west of Crater Lake.

Rogue River Group[1]

Cretaceous: Southwestern Oregon.

Original reference: T. Condon, 1902, The two islands.

Named for Rogue River valley.

Rohnerville Formation

Pleistocene, upper (?) : Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 63, pls. 1, 2. Warped terrace deposit, predominantly gravel with lesser amounts of sand, silt, and clay; unfossiliferous. Thickness 10 to 25 feet. Overlies Carlotta formation (new) with angular unconformity. No positive statement regarding age can be made; it is post-Hookton and thus probably upper Pleistocene.

Formation is of limited extent; restricted to surface upon which Rohnerville and Fortuna are built and to isolated surface known as Grizzly Bluff, Humboldt County.

Rolling Fork Limestone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 152, pl. 25. Upper member of Brodhead formation, Athertonville facies (new). Dense and siliceous to crinoidal cherty limestone about 60 to 80 feet thick. Underlies Floyds Knob formation; overlies Ginseng siltstone member (new) of Brodhead formation.

Well exposed along road leading up hill west of old Ginseng post office, southeastern Larue County. Probably named for Rolling Fork of Salt River which forms boundary between Larue and Nelson Counties.

**Rollins Sandstone Member** (of Mesaverde Formation)[1]

**Rollins Sandstone Member** (of Mount Garfield Formation)

Upper Cretaceous: Central western Colorado.

Original reference: W. T. Lee, 1909, U.S. Geol. Survey Bull. 341, p. 320 (table), 322.

C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851, p. 23 (table), 40, 41, 44. In Book Cliffs coal field, Colorado, Rollings sandstone is basal member of Mount Garfield formation (new). Thickness 71 feet at Book Cliff mine. In Grand Mesa region, the Rollins is basal member of Mesaverde.

E. C. Dapples, 1939, Econ. Geology, v. 34, no. 4, p. 371. In Anthracite-Crested Butte quadrangles, strata near village of Baldwin that Lee identified as Bowie are believed to underlie Rollins sandstone forming part of a new member herein called Baldwin sandstone. Hence, the Rollins overlies the Baldwin sandstone member and underlies Paonia shale member.

J. D. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 19. Southeast of Colorado River, beds of lower part of Mount Garfield formation below Rollins sandstone member pass into marine shales indistinguishable from Mancos shale, and the Rollins becomes basal member of the Mesaverde. Rollins sandstone member was said by Lee to rest on Mancos shale throughout Grand Mesa area. Paonia member rests, according to Lee, on Rollins sandstone member in western part of Grand Mesa area, but toward east the Bowie member appears and gradually increases in thickness eastward. According to Boyer (written commun.), Lee misidentified his units in Grand Mesa field. Upper member of Sego sandstone of present report was mistaken for Rollins, and strata between the upper Sego and Rollins were referred to Bowie shale member.

Forms conspicuous cliff at Rollins mine, north of Delta, Delta County.

Roll Quarry Limestone[1]

Age(?): West-central Vermont.

Original reference: E. J. Foyles, 1929, Vermont State Geologist 16th Rept., p. 283.

Rolls Ford Shale Member (of McLeansboro Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1915, Illinois Geol. Survey Bull. 20, p. 99–107.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 100. Marine shale and impure limestone in lower McLeansboro, probably above Danville (No. 7) coal.

Exposed at Ralls Ford (Rolls Ford) on Sangamon River, 4 miles northwest of Springfield, Sangamon County.

Roma Sandstone Member or Tongue (of Fayette Formation)[1]

Eocene, upper: Southern Texas, and Tamaulipas, Mexico.

Original reference: W. G. Kane and G. B. Gierhart, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 9, p. 1376, 1383, 1387.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 268. Thickness of tongue (or member) 250 to 300 feet at Roma. Thins northward and wedges out completely near Laredo. Composed almost entirely of massive and crossbedded medium- to fine-grained sandstones which are fossiliferous; large calcareous sand concretions common throughout member. Overlies Resendez shale tongue (new); underlies Gorgora shale member (new).

Exposed at International Bridge, San Pedro de Roma on Mexican side of Rio Grande from Roma, Starr County, Tex.

Romance Arkose[1]

Precambrian: Northwestern Vermont.

Original reference: W. G. Foye, 1919, Vermont State Geologist 11th Rept., p. 84.

Probably named for Romance Mountain, in western part of Rochester quadrangle, in Addison County.

**Rome Formation**[1]

Lower Cambrian: Northwestern Georgia, northern Alabama, western North Carolina, eastern Tennessee, and southwestern Virginia.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. on Cahaba coal field, p. 149.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51–A, p. 8. Ivanhoe limestone member of Shady dolomite herein considered basal member of Rome formation.

B. N. Cooper, 1939, Virginia Geol. Survey Bull. 55, p. 8–10, pl. 2. In Draper Mountain area, Virginia, overlies Shady formation; underlies Elbrook formation. Consists of red, green, and yellow shales and siltstones; many intercalations of argillaceous dolomite. Thickness 2,000 feet.

P. B. King and others, 1944, Tennessee Div. Geology Bull. 52, p. 14–16. Described in connection with manganese deposits in northeastern Tennessee. Lower and Middle Cambrian.

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 4–7. Underlies Pumpkin Valley shale (new); shale was formerly included in Rome formation. Stratigraphic section at Lee Valley, Hawkins County given; here 513 feet of Rome is exposed.

T. L. Kesler, 1950, U.S. Geol. Survey Prof. Paper 224, p. 12–17, pl. 1. In Cartersville district, Georgia, the Rome overlies Shady formation, or where Shady is absent, the Weisner formation. In extreme western part of the district, formation consists largely of crystalline dolomite and limestone whose maximum thickness is about 1,800 feet. In southeastern part, consists largely of metashale whose thickness is at least 2,000 feet. Carbonate rocks and metashale intergrade. Some dolomite formerly included in the Shady are here included in the Rome. Underlies Conasauga formation.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1 (geol. maps); pt. 2, p. 43–45. Summary discussion of usage of name. [See bibliography entry for Hayes and Keith, this report.] Rome formation as mapped herein [eastern Tennessee] includes Apison shale member but excludes overlying "Rome shale" as used by Hayes and Keith which belongs to Conasauga group. In this usage, Rome corresponds to Safford's (1869, Geology of Tennessee) Knox sandstone. Formation is a heterogeneous and variegated mixture of sandstone, siltstone, shale, dolomite, and limestone; proportions vary greatly. Stratigraphy of the Rome is one of major problems of east Tennessee stratigraphy; Rome occurs chiefly just above major thrust faults, is commonly folded and imbricated, and shows no base; fossils are comparatively rare. Thickness in northeast Tennessee 1,200 feet or more; elsewhere, base is missing, and thickness is unknown but is more than 700 feet in many places. Fossils of both Lower and Middle Cambrian are reported from the formation, but it is believed that the Middle Cambrian fossils come from the "Rome shale" unit; hence, most if not all of the Rome as mapped here is of Lower Cambrian age.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 40. Formation conformably overlain by Honaker limestone in Hot Springs area and occurs as single small patch in northernmost part of window.

Named for exposures at Rome, Ga.

†Rome Sandstone[1]

Lower Cambrian: Northwestern Georgia and southeastern Tennessee.

Original reference: C. W. Hayes, 1894, U.S. Geol. Survey Geol. Atlas, Folio 2.

Probably named for exposures south of Rome, Ga.

Romeo Member (of Joliet Formation)

Silurian (Niagaran): Northern Illinois.

D. L. Graf, 1952, Illinois Geol. Survey Rept. Inv. 161, p. 2, 3 (table 1). Very fine grained dolomite; widespread.

Occurs in Chicago area. [Graf (p. 2) states that he obtained his samples from Willman. Willman (1943, Illinois Geol. Survey Rept. Inv. 90, p. 26–27) divides Joliet formation into five unnamed members, A to E; on

p. 27 he [Willman] mentions locality at Romeo but name is not applied to any of his units].

Romero Conglomerate Lentil (in Debris Dam Sandstone)

Upper Cretaceous: Southern California.

B. M. Page, J. G. Marks, and G. W. Walker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1730 (fig. 2), 1733 (fig. 3). 1741. Lenticular conglomerate beds in Debris Dam sandstone (new). Well cemented; pebbles and cobbles are largely siliceous types mostly 2 to 8 inches, with some as much as 14 inches in diameter; matrix is dark arkose, which also occurs as interbeds between gravel layers of member. Although lenticular in detail, conglomerate is persistent in general, where one gravel layer tapers out another begins above or below it. Thickness, if intervening sandstone beds are included, ranges up to 2,000 feet. South of Santa Ynez fault, disconformably (?) underlies Juncal formation (new).

Occurs south of Santa Ynez River, northeast of Santa Barbara, Santa Barbara County.

**Romney Shale**[1]

Middle Devonian: Eastern West Virginia, western Maryland, southern Pennsylvania, and northern Virginia.

Original reference: N. H. Darton, 1892, Am. Geologist, v. 10, p. 13, 17.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 305–308. Romney shale restricted. Millboro shale, as named and as here used, includes only the Marcellus and Naples (basal Portage) shales of original Romney. In Frederick and Shenandoah Counties, Romney (restricted) includes at base much black and gray fissile shale, which rests normally upon Onondaga shale. This shale is overlain by a commonly fossiliferous mass of rock, the Hamilton, composed largely of compact very fine-grained olive-green argillaceous sandstone. Upper part of Romney (restricted) is dark-colored to black sandy fossiliferous Naples shale with *Paracardium* and *Probeloceras*, extending up to the light-greenish shale of succeeding Brallier.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 245–253. In its reports describing eastern counties (1916–39), the West Virginia Geological Survey abandoned term "Romney," indicating that its several horizons were individually recognizable. Name Romney is without adequate support because it cannot be used for any precise chronological position. Name must either be entirely redefined or abandoned. It is suggested that Romney be hereafter used to designate the black-shale Devonian facies of whatever age. In terms of this proposal, Romney black shale stands for rocks of this facies wherever they occur in geologic column of Appalachian Devonian.

Ernst Cloos. 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 87–89. Romney shale, in Maryland, comprises (ascending) Onondaga shale, Marcellus black shale, and Hamilton members. Overlies Ridgeley sandstone member of Oriskany formation; underlies Jennings formation.

F. G. Lesure, 1957, Virginia Polytech. Inst. Engineering Expt. Sta. Ser. 118, p. 18 (table 1), 20 (table 2). Described in Clifton Forge iron district where it includes Needmore shale member below and Millboro shale member above. Overlies Ridgeley sandstone; underlies Brallier formation. Thickness 800 to 1,200 feet. Includes most of Middle Devonian and probably includes a little of the Upper Devonian.

Named for exposures at Romney, Hampshire County, W. Va.

**Rondout Limestone**

Rondout Limestone (in Cayuga Group)[1]

Rondout Limestone (in Keyser Group)

Rondout Limestone Member (of Manlius Formation)

Upper Silurian and Lower Devonian: New York and Pennsylvania.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

G. H. Chadwick, 1940, New York Geol. Assoc. 16th Ann. Mtg. Field Guide Leaflets, p. 2. In Catskill area, includes Fuyk sandstone member (new). Thickness 2 to 40 feet. Underlies Manlius (Olney limestone); overlies Normanskill.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1182–1184, 1160. Included in Keyser group. White's (1882) Stormville section reexamined. Rondout limestone includes unit correlated with Stormville hydraulic cement bed. Rondout overlies Decker sandstone. Underlies Manlius. Silurian.

H. P. Woodward, West Virginia Geol. Survey, v. 14, p. 175–176. Beds overlying Williamsport ("Bloomsburg") sandstone and below Tonoloway ("Bossardville") limestone in eastern West Virginia, although previously described as "Rondout," are here identified with Wills Creek limestone of Maryland and are treated under that name.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 44, 45–58 [1946]. Rondout waterlime includes Fuyk sandstone locally, and Glasco limestone lentil (new) near top. Underlies Manlius (Olney); overlies Normanskill. Upper Silurian.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Formation included in Helderbergian series. Underlies Thacher member (new) of Manlius formation.

Colgate University staff and students, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 2 (columnar section), 4, Referred to as member of Manlius formation. Overlies Cobleskill limestone member; underlies Olney limestone member. Columnar section (p. 2) shows Rondout member of Manlius group.

L. V. Rickard, 1956, Dissert. Abs., v. 16, no. 1, p. 102. Base of Devonian system of New York is apparently not at base of Coeymans of eastern part of State where it has been placed for many years. Present information indicates that underlying Rondout and Cobleskill formations are probably also Devonian in age.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Chart shows upper part of Chrysler (Rondout) waterlime as Devonian; lower part is Upper Silurian.

U.S. Geological Survey currently designates the age of the Rondout Limestone as Upper Silurian and Lower Devonian on the basis of a study now in progress.

Named for development in cement quarries at and near Rondout County, N.Y.

**Ronkonkoma Stade, Drift**

Ronkonkoma Substage[1]

Pleistocene: Southeastern New York.

Original reference: A. C. Veatch, 1903, Jour. Geology, v. 11, p. 766–776.

Occurs on eastern end of Long Island. Probably named for town and lake of Ronkonkoma.

Roodhouse Coal Member (of Carbondale Formation)

Pennsylvanian: Southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 47 (table 1). Member of Carbondale formation. Lies between Shawneetown coal member and Summum (No. 4) coal member. Recognized only in vicinity of type locality.

Type locality: NW¼ sec. 21, T. 12 N., R. 11 W., Roodhouse quadrangle, Greene County.

Rooney Chert (in Hannan Limestone)

Rooney Chert Member[1] (of Madison Limestone)

Rooney Limestone

Mississippian (Kinderhook and (or) Osage): Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 14, 47.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 2 (col. 38). Shown on correlation chart as being in Hannan limestone. Underlies Monitor Mountain limestone and overlies Dean Lake chert, both in Hannan limestone, Osagean.

J. M. Andrichuk, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 89. Hall (1952, unpub. thesis) proposed that Deiss' Rooney chert be recognized as a formation and be designated Rooney limestone. The Rooney at type section includes about 550 feet of crinoidal limestone, varying to microcrinoidal or sparsely crinoidal in lower part, with interbeds of gray bedded dense fine-grained limestone. Upper boundary is erosional surface, but about 50 miles to southeast, the Rooney is reported by Deiss to be 292 feet thick and overlain by Monitor Mountain limestone. Upper Kinderhook and possibly lower Osage age.

Type locality: On south slope of top of Lone Butte, in SE¼ sec. 23, T. 23 N., R. 13 W., about 15 miles from Pentagon Mountain.

Roop Sandstone Member (of Alhambra Formation)

Eocene, upper: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 54–55, pls. 2F, 3A, 4A. Proposed for 115 feet of brownish-gray medium-grained poorly stratified sandstone with 5 percent of interbedded silty shales; nonfossiliferous. Overlies Castro shale member (new); lies stratigraphically below Pereira shale member (new). May represent a local lens in formation but is well-marked lithologic unit at type locality; term Roop sandstone should be used as a lithologic unit only in type area.

Type section: West limb of Pacheco syncline in cuts along Santa Fe Railway east of east portal of Muir Tunnel, near Martinez, Contra Costa County.

Roosevelt Member (of Apache Group)

Precambrian (Algonkian) : South-central Arizona.

N. E. A. Hinds, 1936, Carnegie Inst. Washington Pub. 463, p. 32. Seventh [upper] member of group. Chert and dark-reddish and purplish siliceous shales. Maximum thickness 30 feet. Underlies Troy quartzite and overlies a vesicular basalt flow south of Roosevelt Dam.

Present locally at and near Roosevelt Dam, Gila County.

Roosville Formation[1]

Roosville Member (of Miller Peak Formation)

Precambrian (Belt Series) : Southeastern British Columbia, Canada.

Original reference: R. A. Daly, 1912. Canada Geol. Survey, Dept. Mines Mem. 38, Map 2, 114°30′ to 115°.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1902. Designated a member of Miller Peak formation in Belt series. Underlies Mount Rowe member (new) ; overlies Kintla member. Type locality given.

Type locality: Three miles east-northeast of Phillips Creek cascade, near Roosville, British Columbia.

**Root Shale** (in Wabaunsee Group)

Pennsylvanian (Virgil Series) : East-central Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Defined to include strata between Wood Siding formation above and Stotler limestone (new) below. Thickness ranges from about 30 to 90 feet and averages 60 feet. Comprises (ascending) Friedrich shale, Jim Creek limestone, and French Creek shale members.

M. R. Mudge and H. R. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 15 (table 2), 30–33. Originally, strata comprising Root shale was included in McKissick Grove shale member of Wabaunsee group by Condra (1927, Nebraska Geol. Survey Bull. 1, 2d ser.). Moore (1936, Kansas Geol. Survey Bull. 22) discarded name McKissick Grove and divided strata into 11 formations of which 3, Friedrich shale, Jim Creek limestone, and French Creek shale, are now classified as members of Root shale. Average thickness 38 feet in Wabaunsee County [this report].

Type section: In a roadcut along east-flowing stream near center of N½SE¼ sec. 20, T. 21 S., R. 11 E., Lyon County. Name derived from Root Station on Atchison, Topeka, and Santa Fe Railroad.

Root Valley Member (of Prairie du Chien Formation)

Root Valley Sandstone

Ordovician (Beekmantown) : Southeastern Minnesota and northwestern Iowa.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 59–63. Medium- to fine-grained, white to buff, yellow, or brown rather even-bedded sandstone with hard quartzitic masses that have appearance of arenaceous chert. Thickness 35 to 40 feet. Underlies and is interbedded with Shakopee dolomite; overlies Oneota dolomite. In older geologic literature horizon was known as New Richmond beds or sandstone.

L. A. Thomas and C. A. Balster, 1949, Iowa Acad. Sci. Proc., v. 56, p. 236 (table 1). In discussion of micropaleontological zones in Iowa, Root Valley is shown as member of Prairie du Chien formation. Occurs above Oneota member and below Willow River member.

R. L. Heller, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 31–33. Detailed studies of the Root Valley sandstone and the New Richmond sandstone indicate that these two units are one and the same. Based on priority of the name New Richmond, the name Root Valley should be suppressed.

Typically exposed along highway above State Fish Hatchery west of Lanesboro, along river bluff at Preston, in Whitewater State Park, where highway descends from St. Charles, Winona County, Minn.

†Rosalie Granite[1]

Precambrian : Central northern Colorado.

Original reference : S. H. Ball, 1906, Am. Jour. Sci., 4th v. 21, p. 383.

Forms ridge between Mount Evans and Mount Rosalie, Georgetown quadrangle.

†Rosamond Series[1]

Miocene : Southern California.

Original reference: O. H. Hershey, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, pl. 1, map.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 135–136. Since Hershey's description, name Rosamond has been applied by later workers to Tertiary stratified rocks exposed in widely separated areas in Mojave Desert, as far north as Ricardo and as far east as Newberry. Many of these exposed sections called Rosamond were found to be of different ages, with one as old as Paleocene and another as young as Pliocene. Hence, the sequence of rocks exposed in Rosamond Hills and originally described by Hershey as Rosamond series, together with probable correlative rocks of Tertiary age exposed in vicinities of Kramer borate area and in Kramer Hills are here named Tropico group.

Type section : Near Rosamond Station, Kern County.

Rosebud Beds[1]

Rosebud facies

Miocene, lower and middle : Central southern South Dakota.

Original reference: W. D. Matthew and J. W. Gidley, 1904, Am. Mus. Nat. History Bull., v. 20, p. 241–246.

A. L. Lugn, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1270–1271. Rosebud is name applied to about 500 feet of pinkish sandstone and silty clay, the "lower Miocene of southern South Dakota," and has been used to some extent for bluff-forming layers of eastern part of the Pine Ridge, mainly in Sheridan County, Nebr. Matthew tentatively correlated the Rosebud with lower Miocene of western Nebraska, that is, with the Harrison. The Rosebud in northern Sheridan County encompasses all that is present of following formations: Gering, Monroe Creek, Harrison (old lower Harrison) and at least lower part of Marsland formation (old upper Harrison). Hence, term Rosebud, as far as Nebraska is concerned, is obsolete. However, Rosebud might be retained in northern Nebraska and South Dakota as an inclusive term for correlative formations where they are too indistinct for differentiation.

J. C. Harksen, 1960, Geology of the Sharps Corner quadrangle, South Dakota (1:62,500) : South Dakota Geol. Survey. Rosebud strata of type locality are traceable southwestward into three (Gering, Monroe Creek, and Harrison) formations of Arikaree group and possibly into part of overlying Marsland formation. However, the "Rosebud" in mapped area is unlike typical Marsland of Nebraska and is here informally called "Rosebud facies" pending further study. In area of report, consists of light-tan to brown interbedded calcareous sands, silts, and clays with large amounts of layered tabular concretions and cemented ledges. At Porcupine Butte, 3 miles east of southern (Manderson) quadrangle, upper contact of the Rosebud with overlying Ash Hollow formation is exposed; in this area, the Rosebud is 235 feet thick.

Well exposed along Little White River in vicinity of Rosebud Agency, Todd County.

Rose Canyon Latite-Andesite Volcanics

Oligocene: Northern Utah.

R. E. Marsell and R. L. Threet, 1960, Geologic map of Salt Lake County, Utah (1:62,500); supplement to Bull. 69 [not yet published]: Utah Geol. and Mineralog. Survey. Named on map legend. Occurs above Butterfield andesite flows (new) and below South Mountain andesite flows (new).

Mapped in southern part of Salt Lake County. Rose Canyon is in unit as mapped.

Rose Canyon Shale[1]

Rose Canyon Shale Member (of La Jolla Formation)

Eocene, lower and middle: Southern California.

Original reference: M. A. Hanna, 1926, California Univ. Pub., Dept. Geol. Sci. Bull., v. 16, no. 7, p. 187–246.

L. G. Hertlein and U.S. Grant 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 66–67. Uppermost member of La Jolla. Attains maximum thickness of at least 300 feet and is most widely distributed member of formation. Unconformably overlies Torrey sand member or overlaps the sand and rests unconformably on Black Mountain volcanics or Cretaceous sandstones. Underlies Poway formation.

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Shown on chart as shale member of La Jolla formation. Lower and middle Eocene.

G. B. Oakeshott, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 254 (table). Table lists Rose Canyon shale (formation). Overlies Torrey sand; underlies Poway conglomerate.

Named for exposures at big bend in Rose Canyon, La Jolla quadrangle, San Diego County.

Rosefield Formation

Oligocene: Eastern Louisiana.

J. F. L. Connell, 1960, Southeastern Geology, v. 2, no. 2, p. 59, 115. Listed in catalog of type localities of coastal plain stratigraphic units. Name credited to Delaney (unpub. thesis).

H. V. Andersen, 1960, Louisiana Dept. Conserv., Geol. Bull. 34, p. 100–101. Delaney (1958) in an investigation of Louisiana Vicksburg equivalents restudied Mosley Hill type locality. He reported presence of three mappable units (two silty clay units separated by a sand) between the Danville Landing and the Catahoula. He restricted the Mosley Hill to the basal unit; the overlying sand he named Sandel formation; the uppermost fossiliferous clays and siltstones he named Rosefield formation. Rosefield at its type locality carries a Vicksburg fauna.

Type locality: Exposures at Rosefield cemetery, near junction of Louisiana State Highways 112 and 126, northwestern Catahoula Parish.

**Rose Hill Formation**[1]

Rose Hill Formation (in Clinton Group)

Middle Silurian: Maryland, Pennsylvania, and northern Virginia.

Original reference: C. K. Swartz, 1923, Maryland Geol. Survey Silurian vol., see index.

H. P. Woodward, 1941, West Virginia Geol. Survey [Repts.], v. 14, p. 55–91. Geographically extended into West Virginia where it underlies Keefer sandstone and overlies the Tuscarora sandstone. Thickness 200 to 600 feet.

Ernst Cloos and C. H. Broedel, 1943, Geol. Soc. America Bull., v. 54, no. 9, p. 1379 (table 1). Shown on stratigraphic column of Harrisburg, Pa., area as including Keefer sandstone; thickness 700 to 750 feet. Occurs below Bloomsburg red beds and above Tuscarora sandstone.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 112 (fig. 4), 114–119. Described in Burkes Garden quadrangle, Va., where it is 228 feet thick; underlies the Wills Creek sandstone and overlies the Clinch sandstone. Contains no Keefer or Rochester beds. White sandstone, formerly called Keefer in this area, is a part of the Rose Hill.

F. M. Swartz and H. J. Hambleton, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 21. Rose Hill shale and sandstone, in Clinton group, contains Center iron sandstone member (new).

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 6, 20, 23, 30–31, pl. 1. Greenish-gray and grayish-red fossiliferous shale and sandstone. Thickness 650 to 850 feet. Underlies Mifflin formation (new); overlies Tuscarora formation. Includes Burnt Ridge member (new) in middle.

Named for exposures on Rose Hill, Cumberland, Md.

Rose Island Arkose[1]

Carboniferous: Southern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 308, 380.

Occurs on Rose Island, one of Newport Harbor Islands.

**Roseland Anorthosite**

Roseland Anorthosite (in Virginia Blue Ridge Complex)

Precambrian: Central Virginia.

C. S. Ross, 1941, U.S. Geol. Survey Prof. Paper 198, p. 2–6. Name applied to anorthosite in Roseland district. Consists of antiperthitic andesine. It is cut by numerous quartz veins, dikes rich in ferromagnesian minerals, and large lenticular bodies of a rock called nelsonite; intrudes gneissic quartz monzonite that forms dominant country rock of region. Unit has been referred to as pegmatite and syenite by earlier workers.

R. O. Bloomer and H. J. Werner, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 582, pl. 1. White or green, coarse-grained, locally granulated, granulose, monomineralic rock consisting of oligoclase-andesine. Along margins are large tabular grains and veins of blue quartz and inclusions of basement complex gneiss oriented parallel to regional foliation; nelsonite forms dikelike bodies along contact of Roseland with Marshall formation In Piedmont is surrounded by Marshall formation; in Blue Ridge is surrounded by Pedlar formation.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 9. Included in Virginia Blue Ridge complex (new).

Named from exposures near Roseland, Nelson County. Length of mass is about 13 miles, greatest width about 2½ miles, and total area about 22 square miles.

**Rosendale Limestone Member** (of Salina Formation)[1]

Upper Silurian: Eastern New York.

Original reference: J. Hall, 1893, New York State Mus. 46th Ann. Rept., p. 156, 159.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. In southern half of Rosendale quadrangle. Rosendale waterlime overlies Accord shale (new). Upper Silurian.

Named for exposures at Rosendale, Ulster County.

Rosett Bed (in Midway Formation)

Tertiary, lower: Central Texas.

R. H. Cuyler and A. W. Weeks, 1940, *in* Geol. Soc. America [Guidebook] 53d Ann. Mtg., p. 24. Named in road log.

Near Larremore oil field, Caldwell County.

**Rosewood Shale**[1]

Lower Mississippian: Southeastenn Indiana and western and northern Kentucky.

Original reference: Charles Butts, 1915, Kentucky Geol. Survey, 4th ser., v. 3, pt. 2, p. 150.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 143–144. Name abandoned. Holtsclaw Hill facies (new) of Brodhead formation (new) comprises the two units "Rosewood shale" and "Holtsclaw sandstone" proposed by Butts (1915).

Type locality: Village of Rosewood, Harrison County, Ind.

**Rosiclare Sandstone Member** (of Ste. Genevieve Limestone)[1]

Rosiclare Member (of Ste. Genevieve Limestone)

Upper Mississippian: Southern Illinois, southern Indiana, and western Kentucky.

Original reference: E. O. Ulrich and W. S. T. Smith, 1905, U.S. Geol. Survey Prof. Paper 36, p. 24, 40.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 816. Underlies Levias (formerly Lower Ohara) member; overlies Fredonia member.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 20–21, pl. 1. Because Rosiclare generally contains more limestone than sandstone and in places consists partly or mostly of shale, Indiana Geological Survey uses name Rosiclare member. Thickness 1 to 15 feet.

Named for Rosiclare, Hardin County, Ill. Typical development in Ohio River bluff just below town.

**Rosita Andesite**[1]

Eocene : Central southern Colorado.

Original reference: W. Cross, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 285.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 197. In Silver Cliff-Rosita region, the volcanics, in order or decreasing age, consist of Rosita fragmental andesite, Bunker massive andesite. Fairview diorite in dikes cutting earlier andesite, Bald Mountain dacite flows, rhyolite in dikes, eruptive channels and flows, Pringle andesite, trachyte flows, and Bassick agglomerate.

Chief occurrence in beneath and about town of Rosita, from which unit is named, Silver Cliff-Rosita region, Custer County.

**Roslyn Formation**[1]

Roslyn Arkose

Eocene : Central Washington.

Original reference: I. C. Russell, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 2, p. 100–137, map.

C. E. Weaver, 1937, Washington [State] Pub. in Geology, v. 4, p. 26 (table), 51–52. Massive yellowish-brown sandstone and subordinate quantities of clay shales and carbonaceous shales including coal seams. Thickness 2,000 to 3,500 feet. Overlies Teanaway basalt. Middle to upper Eocene. Areal distribution noted.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 101 (table 1), 108–110, pl. 1. Roslyn arkose in area of this report [northern parts of Mount Stuart and Snoqualmie quadrangles] concordantly underlies Teanaway basalt and is in contact with two younger rocks, post-Roslyn rhyolite and Yakima basalt; the Yakima overlies Roslyn with angular unconformity. Just south of area of this report the Roslyn is deformed into asymmetrical syncline with steep limb on southwest side; west side of syncline is tightly folded and faulted. C. T. Bressler (1951, unpub. thesis) divided Roslyn into three units: basal beds—200 feet or less of red clastic rocks that grade upward into nearly white clastic rocks; 2,300 feet of largely massive yellowish-gray arkosic medium-grained sandstone with darker interbedded fine-grained sandstone and siltstone; upper 1,500 feet composed of eight major coal beds interbedded with medium- to fine-grained sandstone and siltstone. Considered middle and (or) upper Eocene on basis of one fossil fish and two turtle carapaces, which together with leaves, are only fossils found in Roslyn to date.

Best exposed on northern side of Yakima Valley between Swauk Creek and Lake Cle Elum on eastern side of Cascade Mountains. Largest area is in drainage basin of Teanaway River and southward in vicinity of Cle Elum and Roslyn, Kittitas County.

Ross Formation

Lower Devonian : Central Tennessee.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 280-302, fig. 2. In this report [Pre-Chattanooga stratigraphy of central Tennessee]. Dunbar's 1919 (Tennessee Div. Geology Bull. 21) classification of the Lower

Devonian is modified. Ross formation is defined to include all beds overlying Decatur limestone and underlying Flat Gap or Harriman formations. As thus defined, includes Birdsong shale member, Bear Branch facies. Ross limestone member, Rockhouse shale member, Rockhouse limestone member. Decaturville zone, and Bryozoan zone. Cooper and others (1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1 chart 4) placed Rockhouse in the silurian, leaving Ross the oldest unit of Devonian; no reasons were given for this shift in classification, but presumably it resulted from recent analysis of fauna of Rockhouse. However, if Rockhouse is Silurian, then entire Ross formation, including Ross limestone member and Birdsong shale member, are likewise Silurian. In one respect, such a shift would clear up matter of occurrence of unique bulbs of *Camarocrinus* in a Niagaran formation and in a Devonian formation; proposed change would limit range of these fossils to the Silurian.

Type locality not given.

**Ross Limestone Member** (of Olive Hill Formation)[1]

Ross Limestone Member (of Ross Formation)

Lower Devonian: Western Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 579, 685.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 280, 287–290. In this report (Pre-Chattanooga stratigraphy of central Tennessee, Dunbar's 1919 (Tennessee Div. Geology Bull. 21) classification is modified. Ross formation, which is defined to include all beds overlying Decatur limestone and underlying Flat Gap or Harriman formations, includes Birdsong shale member, Bear Branch facies, Ross limestone member, Rockhouse shale and limestone members, Decaturville zone, and Bryozoan zone. It is believed here that original separation of Pyburn from Ross was not justified, nor was separation made by later workers justified; hence, name Pyburn limestone is discontinued, and all limestone formerly classed as Pyburn is included in Ross limestone member of Ross formation. Ross limestone member, as used here, would be represented at all localities mentioned in preceding work of Foerste, Dunbar, Miser, and Jewell. Ross member conformably overlies Rockhouse shale member in areas along Tennessee River and Horse Creek to south and overlies Rockhouse limestone member in outliers in Hardin and Wayne Counties; member (and its local Bear Branch facies) unconformably underlies Flat Gap limestone or Harriman formation; northward Ross member grades into Birdsong shale member. Thickness in northern part of outcrop area 35 to 45 feet; southward thickens to about 60 feet at Chalybeate Spring and 90 feet along Dry Creek.

Named for exposures on Ross Farm, near Sulphur Spring, Hardin County.

**Ross Fork Limestone** (in Thaynes Group)[1]

Lower Triassic: Southeastern Idaho.

Original reference: G. R. Mansfield, 1915, Washington Acad. Sci. Jour., v. 5, p. 492.

G. R. Mansfield, 1952, U.S. Geol Survey Prof. Paper 238, p. 17, 31–32, pl. 1. Mapped in Ammon and Paradise Valley quadrangles where it consists of grayish and yellowish limestone, shale, and sandstone.

Named from Ross Fork Creek, in Fort Hall Indian Reservation, in upper waters of which this limestone is well exposed.

Rossian series[1]

Precambrian: Cordilleran region.

Original reference: C. R. Keyes, 1917, Iowa Acad. Sci. Proc., v. 24, p. 56.

Rossie Dioritic Series

Rossie Intrusive Complex[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1929, New York State Mus. Bull. 281, p. 81–86, 89.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 67–71. Referred to as Rossie dioritic series; varies from augite diorite to biotite-oligoclase quartz diorite, with local variations toward monzodiorite.

Well displayed in town of Rossie, St. Lawrence County.

Rossland Monzonite[1]

Mesozoic; Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly. 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 8.

Named for occurrence at Rossland, British Columbia, just north of international boundary.

Rossland Volcanic Group[1] or Formation

Carboniferous(?) to Cretaceous: Southern British Columbia, Canada, and northeastern Washington.

Original references: R. G. McConnell and R. W. Brock, 1904, British Columbia West Kootenay Sheet (1:253,440): Canada Geol. Survey; R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, p. 320–334, maps.

Mapped at and around Rossland Mountains, British Columbia, just north of international boundary.

Ross Mine Formation

Permian (Guadalupe): Southwestern Texas.

C. C. Rix, 1952, Geologic map of Cinati Peak quadrangle, Presidio County, Texas (1:48,000): prelim. ed., Texas Univ. Bur. Econ. Geology; 1953, West Texas Geol. Soc. [Guidebook] Spring Field Trip, May 28–30, p. 1, 5 (chart), 14, 20. Sandstone, shale, chert, and limestone. Occurs above Cibolo formation and below Mina Grande formation (new).

Type locality and derivation of name not stated. Probably named for Ross mine which is in Shafter mining district.

Rossville Shales and Sandstone[1]

Pennsylvanian: Northeastern Kansas.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 31.

Probably named for Rossville, Shawnee County.

Rota Limestone

Pleistocene or early Holocene: Mariana Islands (Rota).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, pt. 57, table 4 [English translation in library of U.S. Geol. Survey, p. 68, 69]. Named on correlation chart. Correlated with Chatcha [Chacha] limestone of Saipan, Asuncion [Sonson] limestone of Tinian. Peleliu limestone on Palau and Fais limestone, and Barigata [Barrigada] limestone on Guam. Pleistocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 54. Raised coral reef limestone; elevated as much as 20 meters above sea level in general and 30 meters on southwest coast. Mostly coralliferous, but *Halimeda*-bearing near Sonson, Taipincot, southwest of island and only geomorphologically distinguished from Mariana limestone. Early Holocene. Name credited to S. Sugawara (unpub. ms.).

Type locality: Rota Island. Developed as belt surrounding island.

Rothwell Shale Member (of Muldraugh Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 217–219, pl. 16. Shale, very clayey; dark blue gray, olive gray, green gray, and purple. Forms basal unit of Olive Hill facies (new) of formation. Thickness as much as 30 feet. Overlies Floyds Knob formation; overlain by impure limestone beds which constitute upper part of formation. The combined Rothwell shale and the Indian Fort shale member (new) at the top of the Brodhead formation, Irvine and Morehead facies (both new), constitute the Morris Mountain shaly member of the Logan formation of Butts (1922)

Type section: Along State Highway 40 between Rothwell post office and top of hill 1 mile east-northeast, Menifee County.

Roubaix Group

Precambrian: Southwestern South Dakota.

J. R. Berg, 1946, South Dakota Geol. Survey Rept. Inv. 52, p. 4, 6–7, 14–19, map (on page following title page). Varied in lithology, including more than two lithologically mappable units. Basal part in places a blue-gray quartzite; in other places may be described as gray to brown quartzose schist. Interbedded with upper parts of the quartzose schists and quartzite are black quartzose schists of similar lithology, differing only in color. Where less resistant and more schistose the aluminous sediments show biotite prophyroblasts, or segregations of biotite. Mapped as part of Lead system; group is younger than and overlies rocks of the Lead system.

Mapped in vicinity of Roubaix, Galena-Roubaix district, in the Black Hills. Biotite schist lithology most characteristic northeast and southwest of Hay Creek, east of Roubaix (secs. 33 and 34, T. 4 N., R. 4 E.; and secs. 3, 4, and 5, T. 3 N., R. 4 E.) Biotite porphyroblast type of rock well developed in N½SW¼ sec. 28 and in S center sec. 32, T. 4 N., R. 4 E.

**Roubidoux Formation[1] or Dolomite**

Lower Ordovician: Eastern and central Missouri.

Original reference: F. L. Nason, 1892, Missouri Geol. Survey, v. 2, p. vii, 12, 93, 114–115.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 47–50. Interbedded sandstones and dolomites; variable in character; in some places is almost entirely sandstone; whereas in others it is mainly dolomite. Basal sandstone irregular in thickness, ranging from less than 1 foot up to 30 feet; color reddish-brown or sometimes gray. Thickness 160 to 170 feet. Fossiliferous; main fossil zone 60 to 70 feet above base. Overlies Gasconade formation; unconformably underlies Jefferson City formation.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2. p. 15. Unconformably underlies Rich Fountain formation (new) of Jefferson City group.

R. L. Heller, 1954, Missouri Geol. Survey and Water Resources, 2d ser., v. 35, 118 p. As originally defined, Roubidoux did not have specific type section. Type section is herein designated. Thickness 150 feet at type section. Here formation overlies the Gasconade and underlies Rich Fountain formation of Jefferson City group. May rest unconformably on Gasconade, but there is little field evidence to support this view; Roubidoux-Rich Fountain contact appears to be one of conformity. Systematic description of fauna.

Type section (Heller): Along southeast-facing hillside above Roubidoux Creek in SE¼NW¼SW¼ sec. 10, T. 33 N., R. 12 W., Texas County. Widely distributed throughout most of Ozark uplift in Missouri.

Rough Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374–383.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 76. In ascending order, 150 feet sandstone; 50 feet blue sandy clay; 25 to 40 feet sandstone, partly massive. Commonly massive and containing considerable conglomerate, especially at top. Overlies Hamm Valley beds; underlies Buffalo Creek bed.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Rough Creek, Mills County.

†Rough Creek Shale Member (of Tesnus Formation)[1]

Pennsylvanian: Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Bose, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 45

Named for exposures on Rough Creek in Dove Mountain quadrangle.

Roughlock Siltstone

Middle Ordovician: Western South Dakota.

M. R. McCoy, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 44, 45, 46. Pale-gray-green to cream siltstone 25 to 30 feet thick. Conformably underlies Whitewood dolomite; conformably overlies Ice Box formation (new).

Type section: In Spearfish Canyon, 2.4 miles above Maurice [Lawrence County], several hundred yards up canyon wall. Name taken from Roughlock Falls.

Rough Mountain Conglomerate Lentil (in Brownwood Shale)

Pennsylvanian: Central Texas.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 95, pl. 20. Small lentil that varies in thickness from 6 to 20 feet. At thickest part, on east side of Rough Mountain, made up of alternating beds of gravel exhibiting crossbedding like that found in stream terraces; foreset beds dip at angles ranging from 10° to 30°. Northward from Rough Mountain and northward along base of Adams Branch escarpment, conglomerate thins and grades into a coarse-grained crossbedded sandstone.

Extends from point where Rochelle-Cowboy Road leaves the Rochelle-San Saba Road north a distance of about 3 miles to a water tank on Baker's Ranch, McCulloch County.

Roulet Conglomerate[1]

Upper Devonian: Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1880, Pennsylvania 2d Geol. Survey Rept. $G_3$, p. 97–104.

Probably named for Roulette [Roulet], Potter County.

Round Knob Shale Member or horizon (in Conemaugh Formation)[1]

Round Knob clay shales member

Round Knob redbed member

Pennsylvanian (Conemaugh Series): Eastern Ohio and western Pennsylvania.

Original reference: D.D. Condit, 1912, Ohio Geol. Survey, 4th ser., Bull. 17, p. 35.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 49, 50. Clay shales member of Conemaugh series in report on Morgan County. Farm Condit's description, it would appear that Round Knob shale and Saltsburg [Saltzburg] sandstone are contemporary units, or the names are applied to different facies of same unit. The Round Knob member overlies the Saltsburg sandstone in some areas in Morgan County, and in others, occupies same interval between Barton and Harlem coals as does the Saltsburg. Term Round Knob is applied to shaly phase of this interval where strata are highly colored, and term Saltsburg is applied to sandy phase. Round Knob shales are pinkish to red or chocolate red.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 130–131. Redbed member of Harlem cyclothem in report on Athens County. Widespread variegated clays and shales occur at many places in Maryland, Ohio, Pennsylvania, and West Virginia in interval between Portersville (Friendsville) shale and limestone and Ames limestone. Thicknesses range up to 50 or even 100 feet. To these beds in Ohio, Condit gave name Round Knob. Elsewhere in northern Appalachian region, these clays and shales are known as Pittsburgh red shale or redbed, a name given by White (1903, West Virginia Geol. Survey, v. 2) and a name which Condit considered unsatisfactory because of previous and general use of Pittsburgh for the Number 8 coal and its underlying limestone. Average thickness about 17 feet. Conemaugh series.

Named for Round Knob, a hill in Madison Township, Columbiana County, Ohio.

Round Mountain Member (of Little Valley Formation)

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Upper member of formation. Overlies Leesville member (new); underlies Baldy Mountain member of Davis Creek formation (both new). The Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Round Mountain Silt[1]

Round Mountain Silt Member (of Temblor Formation)

Miocene, middle: Southern California (subsurface and surface).

Original reference: A. Diepenbrock, 1933, California Oil Fields, Div. Oil and Gas, v. 19, no. 2, p. 14, 16, pl. 2.

A. M. Keen, 1943, San Diego Soc. Nat. History Trans., v. 10, no. 2, p. 26 (fig. 1), 28 (fig. 2), 29–35. Mapped as Round Mountain silt in Kern River area near Round Mountain. Considered member of Temblor. Thickness about 90 feet. Underlies Santa Margarita; overlies Olcese sand member of Temblor.

Otto Hackel and K. F. Krammes, 1958, San Joaquin Geol. Soc. [Guidebook] Spring Field Trip May 17, p. 3, 4. Overlies Olcese sand; underlies Mon Bluff formation (new); north of Poso Creek underlies Kern River formation. Mainly brown, somewhat bedded organic siltstone. Diatomite member present about 100 feet below top in outcrop. Middle Miocene.

Type locality: At west edge of Mount Poso oil field, northeast of Bakersfield, Kern County, in Ohio Oil Co. well no. "Glide" 1, sec. 13, T. 27 S., R. 27 E.

Round Prairie Formation

Pennsylvanian (Morrow): Southern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 895–900. At type locality, section includes lower boulder bed, which overlies Union Valley sandstone, separated from an upper bouldery shale by 2 or 3 beds of sandstones. Some of these sandstones are highly calcareous and fossiliferous and are approximately 25 feet apart. The upper bouldery shale is overlain by 10 to 15 feet of jet black fissile fossiliferous shale, locally siliceous, with seams of chalcedony. Underlies Barnett Hill formation. Thickness 400 to 800 feet. Formation has been described as Johns Valley shale; term Johns Valley is herein abandoned.

B. H. Harlton, 1959, *in* The geology of the Ouachita Mountains, a symposium: Dallas Geol. Soc. and Ardmore Geol. Soc., p. 131 (fig. 1), 137. Formation consists of approximately 425 feet of soft gray bouldery shale generally with two interbeds of dark-gray to black shale and thin sandstone layers. Basal boulder bed, which ranges in thickness up to 275 feet, is succeeded upward by persistent interval, about 50 feet thick, of dark-gray to black shale and intercalated thin-bedded sandstone. This zone is succeeded upward by two bouldery shale beds, separated near middle by zone of dark-gray to black flaky shale with occasional sandstone lentils. Entire thickness of this three-unit zone is a little more than 100 feet. Formation, as thus described, is more restricted term than that defined in 1938. Underlies Barnett Hill; overlies Johns Valley shale of published reports.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 62–63. Because of uncertainties concerning use of terms Caney, Mississippian Caney, Pennsylvanian Caney, Ouachita Caney, and Johns Valley, Harlton (1938) proposed that name Johns Valley be abandoned and name Round Prairie be adopted. Subsequent workers have not followed Harlton in use of term Round Prairie, preferring instead the older term Johns Valley.

Type locality: NE¼NE¼SE¼ sec. 2, T. 2 S., R. 12 E., Round Prairie syncline.

**Round Rock Member** (of Esmeralda Formation)[1]

Miocene, upper, and pliocene, lower: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

Exposed in vicinity of Round Rock, about 1 mile north of Manhattan, Nye County.

Roundtop Flow, Lava

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 32, 62. Bulk of flow consists of porphyritic andesite marked by pronounced slabby jointing parallel to banding. In places, thickness no less than 500 feet. Rests on bouldery till. Summit polished and scratched by glacial action. Lies to east of Palisade flow (new). Was part of main andesitic cone of former Mount Mazama. Wineglass welded tuff may once have been continuous over entire top of Roundtop lava. [Diller and Patton, 1902, U.S. Geol. Survey Prof. Paper 3, described Roundtop andesite area.]

Roundtop is on northeast rim of Crater Lake.

Roundtop Group

Pennsylvanian (Des Moines): Eastern Wyoming and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 3, 33–34, 44. Consists mostly of shale, mudstone, and thin limestone colored various shades of red, green, and gray. Comprises Division IV of Hartville "formation" (Condra and Reed, 1935, Nebraska Geol. Survey Paper 9). Thickness 149 feet. Underlies Hayden group (new); overlies Reclamation group (new).

Type locality: Roundtop Mountain, sec. 22, T. 27 N., R. 66 W., Platte County, Wyo.

**Round Valley Limestone**

Lower Pennsylvanian: Northeastern Utah and northwestern Colorado.

Walter Sadlick, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 50 (chart), 52, 56–57. In Uinta Mountains, Morgan formation has been subdivided into two members. Upper member consists mainly of reddish-brown clastics that are overlain by Weber sandstone. In these aspects, the upper member is correlative with type Morgan. Lower member consists of light-gray limestones that have no counterpart in type Morgan as defined by Blackwelder (1910). Name Round Valley is here proposed for essentially Morrowan beds of typically light-gray limestone, in part dolomitic and cherty, having an average thickness of 300 to 350 feet. Thickness 481 feet in Sols Canyon. Underlies Morgan formation (restricted); overlies Manning Canyon formation.

Walter Sadlick, 1957, Intermountain Assoc. Petroleum Geologists Guidebook 8th Field Conf., p. 69–70, pl. 1 (fig. 1). In Uinta Mountains, the Round Valley typically forms resistant ledges of light-gray limestone. Formation can be traced laterally along flanks of Uintas and as far east as Juniper Mountains, Colo. At latter locality, Abrassart and Clough (1955) published detailed section of Morgan (unrestricted). Their middle Morgan member is at least partially equivalent to Round Valley limestone. At type section herein stated, disconformably overlies Great Blue limestone.

Type section: In Round Valley about 3 miles east of Morgan, Morgan County, Utah; measured in NW¼ sec. 29, T. 4 N., R. 3 E. Traced in Wasatch Mountains from Dry Bread Hollow, east of Huntsville, Utah, southward to west of Heber, and from Salt Lake City to northwestern Colorado along flanks of Uinta Mountains. Well exposed approximately 1 mile north of U.S. Route 30S on west side of Round Valley, in approximately sec. 20, T. 4 N., R. 3 S., Morgan County, Utah.

**Rove Slate**[1] (in Animikie Group)

Precambrian: Western Ontario, Canada, and northeastern Minnesota.

Original reference: J. M. Clements, 1903, U.S. Geol. Survey Mon. 45, index.

D. A. White, 1954, Minnesota Geol. Survey Bull. 38, p. 3 (table 1), 4. In Gunflint district, the three units of Animikie group corresponding to Pokegama, Biwabik, and Virginia formations of Mesabi district are called respectively Kakabeka, Gunflint, and Rove formations.

Named for Rove Lake, just north of international boundary.

Rowe Formation (in Cherokee Group)

Rowe Formation or coal cycle (in Krebs Group)

Pennsylvanian (Des Moines Series): Southwestern Missouri, southeastern Kansas, and northeastern Oklahoma.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Rowe formation. Includes Rowe Coal. Underlies Drywood (Dry Wood) formation (new); overlies Warner formation. Included in Krebs group.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 6. Referred to as Rowe coal cycle in Savanna formation, Krebs group, in Oklahoma.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 14, 18, 20. Rowe formation exposed in Barton and Vernon Counties, Mo. Thickness as much as 14 feet in Vernon County. Overlies Warner formation; underlies Drywood formation. Krebs group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 35–37, 101. Formation in Krebs subgroup of Cherokee group. Thickness in Kansas as much as 22 feet. Overlies Warner formation; underlies Drywood (Dry Wood) formation. Derivation of name given.

Named from Rowe coal, which has been extensively mined in southeastern Kansas and western Missouri.

**Rowe Schist**[1]

Lower Cambrian(?): Western Massachusetts, eastern New York, and southern Vermont.

Original references: B. K. Emerson, 1898. U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 76–78, 158, pl. 34.

D. M. Larrabee, 1939, Eng. Mining Jour., v. 140, no. 12, p. 49 (fig. 3), 50–51. Area of report is about 10 miles southwest of Rutland, Vt. Rowe schist borders eastern edge of slate belt, from where it extends into Taconic Mountains. In map area, it is nowhere a true schist but is instead a phyllite, locally a phyllitic quartzite, and grades westward into purple and green slates. There is no sharp contact between the slates and phyllites; it is a zone of variable width—usually less than three-fourths mile—in which slates, quartzites, and phyllites are interbedded. Cambrian slates [Mettawee] grade eastward in Rowe schist. Lower Cambrian.

R. V. Cushman, 1950, New York State Water Power and Control Comm. Bull. GW–21, p. 9 (table 2), 10, 11, pl. 2. Crops out in Rensselaer County, N.Y. Thickness not determined. Lower Cambrian(?).

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Berkshire schist as mapped in this report [Cheshire quadrangle, Massachusetts] includes some rocks mapped as Berkshire, Hoosac, and Greylock by Pumpelly, Wolff, and Dale (1894, U.S. Geol. Survey Mon. 23) and Hoosac, Normanskill, and Rowe by Prindle and Knopf (1932, Am. Jour. Sci., 5th ser., v. 24).

Named for occurrence at town of Rowe, Franklin County, Mass.

Rowes Agglomerate[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1910–1911, pl. 1. Unbedded explosion agglomerate filling a volcanic vent over 1 mile long and almost one-half mile wide. On Hill 1560 are rounded to angular fragments, a few inches to a few feet across, enclosed in a dense dark-gray matrix which is largely fragmental and composed of small grains of feldspar and quartz. Included fragments of Meredith porphyritic granite are most common; a few of Sawyer quartz syenite, Belknap syenite, and Conway granite also present. Assigned to White Mountain magma series; youngest member of series with possible exception of some dikes which do not cut the agglomerate.

Exposed on Rowes Hill in Belknap Mountains. Best exposures are the broad ledges at summit of Hill 1560, 1½ miles slightly northeast of Gilford village, Belknap County.

Rowlandville Granite[1]

Age(?): Northeastern Maryland.

Original reference: G. P. Grimsley, 1894, Cincinnati Soc. Nat. History, v. 17, p. 79, 81, 88.

At Rowlandville, Cecil County.

Rowlesburg Sandstone (in Chemung Formation)[1]

Upper Devonian: Northern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Preston County, p. 97, 194.

At Rowlesburg, Preston County.

Rowley Creek Slate[1]

Precambrian: Central southern Wisconsin.

Original reference: A. Leith, 1935, Kansas Geol. Soc. Rept. 9th Ann. Field Conf., p. 329–330, fig. 216.

Named for small creek that flows through eastern part of Baraboo syncline, Sauk County.

**Row Park Limestone** (in St. Paul Group)

Middle Ordovician: Western Maryland, southern Pennsylvania, and northern West Virginia.

R. B. Neuman, 1951, Geol. Soc. America Bull., v. 62, no. 3, p. 278–284, pls. 1, 2. Proposed for beds forming lower formation of St. Paul group (new). Typical Row Park contains four limestone types: (1) calcarenite, formed of pebbles and sand of limestone and dolomite in light crystalline matrix; (2) dove vaughanite, usually containing some white, crystalline calcite; (3) granular limestone that varies in color from almost white to dark gray; and (4) dolomitic limestone. Thickness at type locality 162 feet. Underlies New Market limestone. Base of Row Park cannot be traced along a line that corresponds exactly to a bedding plane in either underlying Beekmantown dolomite or to one within itself; beds or lenses of dolomitic limestone are interbedded with nonmagnesian limestone through a zone as much as 50 feet thick; the thickest variable zone corresponds to thickest Row Park section, and this zone thins as formation thins to south. Where Row Park is thickest, southwest of Marion and at Welsh Run, Pa., limestones are interbeded with the Beekmantown dolomite 40 to 50 feet below the stratum thought to represent base of Row Park.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 80. Neuman named an 800-foot sequence of "Stones River" the Row Park formation. Cooper and Cooper had previously identified this sequence as Whistle Creek on the basis of contained fossils. Below the New Market of Cooper and Cooper, Neuman discovered granular limestone containing abundance of *Rostricellula*. It is postulated here that both identifications of the New Market are correct but that the Row Park is a partial facies of the New Market and also the Whistle Creek.

F. M. Swartz and R. R. Thompson, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 5. In Franklin County, Pa., subdivided into Social Island limestone member below and Browns Mills limestone member above. Overlies Beekmantown dolomite.

Type section: In pastures 0.2 mile northwest of Row Park, Washington County, Md. Limestone forms a wedge whose thin edge lies in West Virginia, thickening northward into southern Pennsylvania.

Roxana Silt

Pleistocene (Wisconsinan): Southwestern Illinois.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 2 (fig. 1), 5, 10, 12. Succession of silts below Peoria loess and above a well-developed buried soil. Basal part locally contains gray noncalcareous colluvial silts with some sand and rare pebbles; gradationally above this colluvial zone (or in its absence, as basal unit) is gray noncalcareous massive silt, locally containing humus streaks in upper part. This gray silt unit is overlain by weakly calcareous pink to pinkish-tan massive silt containing sparse fauna of large snail shells. Pink silt unit grades upward into weakly calcareous massive gray silt, sparsely fossiliferous in lower part, which in turn is overlain by another pink massive silt, noncalcareous in upper part and commonly noncalcareous and nonfossiliferous throughout. Thickness at type section 47 feet. Altonian substage.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 535–536, 538, 546. Roxna silt of Frye and Willman is not single rock unit but a composite of Farmdale and Peorian. In type section of Roxana silt, Frye and Willman included in its basal part 4 feet of Farmdale loess and above it 43 feet of Peorian loess, lower part of which is undoubtedly Iowan. They have 15 feet of Peorian loess at top to be designated as Peorian. Instead, this uppermost unit may posibly be correlative of Bignell loess of Doniphan County, Kans.

Type section: Exposures at Pleasant Grove School, center SE¼ sec. 20, T. 3 N., R. 8 W., southeast of Roxana, Madison County.

**Roxbury Conglomerate**[1] (in Boston Bay Group)

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: Edward Hitchcock, 1861, Am. Jour. Sci., 2d ser., v. 31, p. 377.

M. P. Billings, F. B. Loomis, Jr., and G. W. Stewart, 1939, Geol. Soc. America Bull., v. 50, no. 12, pt. 1, p. 1868, 1869–1870, 1877–1881. Described as a heterogeneous mixture of conglomerate, sandstone, shale, andesitic and basaltic flows, tuffs, and breccias. Minimum total thickness in Hingham area 3,440 feet. Carboniferous; possibly Pennsylvanian, probably Permian.

Named for exposures in Roxbury, Boston area.

Roxbury Granite Gneiss

Pre-Triassic: Western Connecticut.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as white granite gneiss composed of microcline, albite, quartz, and muscovite. Some gneiss layers are aplitic.

R. M. Gates, 1959, U.S. Geol. Survey Geol. Quad. Map GQ–121. Replaced by Mine Hill granite gneiss. Name Roxbury preoccupied.

Named for town of Roxbury, Litchfield County.

†Roxton beds[1]

Upper Cretaceous (Gulf Series): Northeastern Texas and Southwestern Arkansas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 114, 340.

Crops out near Roxton, Lamar County, and Honey Grove, Fannin County, Tex., and at base of White Cliff section on Little River, Ark.

**Roxy Formation** (in Little Butte Volcanic Series)

Oligocene, lower(?): Southwestern Oregon.

F. G. Wells, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–89. Sequence of flows, flow breccias, and coarse agglomerates that comprises lower part of Little Butte volcanic series. Base of formation is irregular and transitional with flows and water-laid pyroclastics in upper part of Colestin formation (new); hence, base is defined as top of uppermost layer of water-laid pyroclastics that is succeeded by at least 100 feet of flows with or without interlayered nonwater-laid pyroclastics. Underlies Wasson formation (new); transitional with underlying Colestin formation.

Named after Rosy Ann, a well-known knob east of Medford, Jackson County.

Royal Formation[1]

Pennsylvanian: Southern West Virginia.

Original references: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487, 490.

Named for Royal, Fayette County.

Royal Shale (in Pocahontas Group)

Royal Shale (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western Mercer and Summers Counties, p. 366.

H. R. Wanless, 1939, Geol. Soc. America Special Rept. 17, p. 100; P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 217, 244. Included in Pocahontas group, Pottsville series.

Occurs at Royal, Raleigh County.

†Royalton Formation[1]

Mississippian: Northeastern Ohio.

Original reference: C. S. Prosser, 1912, Ohio Geol. Survey, 4th ser., Bull. 15, p. 33, 72, 144, 493.

Named for exposures in Royalton Township, Cuyahoga County.

**Royer Marble**[1] or **Dolomite** (in Arbuckle Group)

Upper Cambrian: Central southern Oklahoma.

Original reference: E. O. Ulrich, 1927, Oklahoma Geol. Survey Bull. 45, p. 28.

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55. Royer marble (dolomite) included in Arbuckle (here raised to group status). Underlies Signal Mountain limestone; overlies Fort Sill limestone.

W. E. Ham, 1949, Oklahoma Geol. Survey Circ. 26, p. 50–58. Royer dolomite mapped for this report (Mill Creek-Ravia area, Johnston County) consists mostly of massive-bedded coarsely crystalline, nearly pure dolomite about 550 feet thick; apparently conformable contacts with underlying Fort Sill formation and overlying Butterly dolomite.

Type section: SE cor. sec. 36, T.1 S., R. 1 E., Murray County. Named for old Royer Ranch on west side of East Timbered Hills in Arbuckle Mountains.

Royston Formation[1]

Permian: Central northern Texas.

Original reference: M. G. Cheney, 1929, Texas Univ. Bull. 2913, p. 26, pl. 1.

Type locality: Royston, Fisher County.

Roystone Coquinite (in Conewango Group)

Roystone Coquinite Member[1] (of Oswayo Shale or Riceville Formation)

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

Original references: B. K. Emerson, 1898. U.S. Geol. Survey Geol. Atlas, 71, p. 61, 97, table.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Generalized succession for marine Upper Devonian of northwestern Pennsylvania and southwestern New York lists Roystone member at base of Riceville formation. Underlies Oswayo member.

C. R. Fettke, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. M–21, p. 33. Report gives section of Oswayo formation near Knapp Creek, N.Y. The bed of limestone 23 feet above base of section probably is limestone which Ashburner (1880) called the Marvin Creek. Caster (1934) renamed this limestone the Roystone, stating that Ashburner was not sufficiently exact in his definition of type locality and that the limestone which Ashburner saw along Marvin Creek is one of calcareous horizons in lower part of Knapp formation. Writer [Fettke] does not accept this interpretation of Ashburner's use of term and states reasons. Term Marvin Creek used in this report.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 14 (tables 3, 4), 278. Table 3 shows Roystone coquinite in Oswayo shale. Footnote states that Caster (1934, Bulls. Am. Paleontology, v. 21, no. 71) renamed this coquinite Flatiron, but Roystone is in good standing. Table 4 shows Roystone coquinite at base of Riceville formation, below Oswayo shale. Page 278 lists Roystone coquinite in Conewango group, below Oswayo shale and above Cattaraugus red shale.

Named from exposures on Roosevelt Highway between Roystone and Ludlow, McKean County, Pa.

Rubio Diorite or Diorite Gneiss

Rubio Diorite and Metadiorite[1]

Pre-Tertiary (Late Paleozoic? or Precambrian): Southern California.

Original reference: W. J. Miller, 1934, California Univ. at Los Angeles Pub. Math. and Phys. Sci., v. 1, no. 1, p. 7–12, 49–65, 83, map.

G. B. Oakeschott, 1937, California Jour. Mines and Geology, v. 33, no. 3, p. 223–224. Rubio diorite is for the most part a rather dark, medium-grained gneiss containing abundant hornblende, little quartz, and with the composition of diorite. Age not conclusively determined; several considerations suggest late Paleozoic. The Rubio has been intruded by Upper Jurassic(?) granodiorite which, in a number of places, cuts across secondary gneissic banding. Diorite has intruded and metamorphosed Placerita limestone. There can be no doubt of post-Placerita (Carboniferous?) and pre-granodiorite (Upper Jurassic?) age of the Rubio. Improbable that it is Triassic or Lower Jurassic. Assigned to late Paleozoic, possibly Permian or Pennsylvanian.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 465, table 4. Placerita formation, Rubio diorite, Echo granite, and combinations of all three (San Gabriel complex) are believed to be early Precambrian in age. Rubio diorite is younger than the Placerita.

G. B. Oakeschott, 1948, California Div. Mines Bull. 129, p. 250, 251. Summary of geology of crystalline rocks in western San Gabriel Mountains lists Rubio diorite-gneiss under heading pre-Tertiary, Late Paleozoic(?).

Named for typical occurrence in large area extending from Rubio Canyon into Eaton Canyon, San Gabriel Mountains.

**Rubio Peak Formation**

Miocene(?): Southwestern New Mexico.

R. M. Hernon, W. R. Jones, and S. L. Moore, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 120. Listed in table of formations for Santa Rita quadrangle. Gravels and pumiceous tuffs with interbedded flows of andesitic basalt. Thickness as much as 600 feet. Underlies Lucky Bill formation (new); unconformably overlies Wimsattville formation (new). Miocene(?).

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 39, 40–44. Of late Tertiary age.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 18–23, pl. 1. Purple, brown, gray and green andesite and latite flows, flow breccia, agglomerate, and tuffs in Dwyer quadrangle. Interfingers with Sugarlump rhyolite near Mimbres Peak. Thickness, 600 to about 5,000 feet. Derivation of name given.

Named after prominent butte located in secs. 9, 10, 15, and 16, T. 19 S., R. 10 W., (as shown on pl. 1), Dwyer quadrangle.

Ruby Diorite

Age not stated: Southeastern Arizona.

G. M. Fowler, 1938, Arizona Bur. Mines Bull. 145, Geol. Ser. 12, p. 121, pl. 32. Darker, finer grained, and denser than the younger diorites, Sidewinder and Blue Ribbon. Includes fragments of conglomerate and is cut by dikes of Sidewinder and Blue Ribbon formations.

Named from mine settlement of Ruby, Santa Cruz County. Exposed in and around the Montana mine.

†Ruby Formation[1]

Eocene: Western Colorado.

Original reference: W. Cross, 1892, Am. Jour. Sci., 3d, v. 44, p. 21–33.

G. G. Simpson, 1937, Cambridge Philos. Soc. Biol. Rev., v. 12, no. 1, p. 9 (footnote). Name Plateau Valley has been applied by Patterson to Paleocene part of the Ruby.

Named for Ruby Peak, near Irwin, Gunnison County.

Ruby Limestone and Gneiss[1]

Precambrian: Southwestern Montana.

Original reference: E. Douglass, 1905, Carnegie Mus. Annals. v. 3, p. 407–428.

Exposed in Ruby Canyon, west of Old Baldy, and on east slope of Ruby Mountains, east of Dillon, Beaverhead County.

Rubyan series[1]

Middle Cambrian: Nevada.

Original references: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53; 1924, Pan-Am. Geologist, v. 41, p. 38, 78.

Well exposed on Ruby Hill at Eureka, Eureka County.

Ruby Road Formation

Age not stated: Southern Arizona.

B. P. Webb and K. C. Coryell, 1954, U.S. Atomic Energy Comm. RME–2009, p. 7. Gray intermediate(?) lavas and tuffaceous rocks. In places, has appearance of an intrusive rock. Underlies Montana Peak formation (new).

Exposed along Ruby Road on southwest flank of the Atascosa Range, Ruby quadrangle, Santa Cruz County.

**Ruddell Shale**

Upper Mississippian: Northeastern Arkansas.

Mackenzie Gordon, Jr., 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 11, p. 1631–1634. Proposed for the section of fissile clay shales lying between the top siliceous limestone bed of the Moorefield formation (herein restricted) below and the base of the Batesville sandstone above. Typically dark-gray to greenish-gray fissile clay shale that weathers red; lower 30 to 40 feet contain arenaceous and calcareous beds some of which are platy; upper half of this interval contains dark-gray to black limestone concretions which contain a goniatite assemblage; above this interval, shale is very fissile. Thickness at type locality 125 feet, here unit is exposed near the axis of a small anticline close to the Pfeiffer fault; a complete section 165 feet thick is exposed near Batesville.

Type locality: West end of Ruddell Hill, in Ruddell civil township near Ruddell's mill, Independence County. Section is almost completely exposed along the Batesville-Bethesda Road in the NE¼NE¼ sec. 13, T. 7 N., R. 13 W., starting in a gully a few feet below the culvert three-eighths of a mile northwest of Ruddell's mill and continuing east and south to the crown of Ruddell Hill.

Rudolph Quartzite[1]

Precambrian (middle Huronian): Central northern Wisconsin.

Original reference: S. Weidman, 1907, Wisconsin Geol. Nat. History Survey Bull. 16.

Largest area is immediately east of Rudolph, Wood County.

Ruffner Fire Clay (in Allegheny Formation)

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1914, West Virginia Geol. Survey Rept. Kanawha County, p. 202.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 100. In Allegheny formation below Lower Freeport coal.

Named for Ruffner, 2 miles east of Charleston, Kanawha County.

Rugg Brook Dolomite or Formation

Rugg Brook Dolomite Conglomerate[1] or Dolomite Breccia

Lower or Middle Cambrian: Northwestern Vermont.

Original reference: Charles Schuchert, 1933, Am. Jour. Sci., 5th ser., v. 25, p. 356, 359, 365, 366, 368.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1014, 1021, 1039–1040. Described as a dolomite breccia and conglomerate.

C. E. Resser and B. F. Howell, 1938, Geol. Soc. America Bull., v. 49, no. 2, p. 203. Lower Cambrian.

B. F. Howell, [1939], Vermont State Geologist 21st Rept., p. 97–101. Redefined as a sandy, sometimes conglomeratic, salmon-brown- to buff-brown-weathering gray-to buff-colored dolomite. Maximum thickness about 75 to 100 feet. Lower or Middle Cambrian.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1136, 1151–1153. In Oak Hill sequence, Rugg Brook formation, 0 to 40 feet thick, overlies Parker slate and underlies Skeels Corners slate. Lower Cambrian(?).

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 534–536. Rugg Brook dolomite described in St. Albans area where it is 100 to 300 feet thick. Overlies Parker slate; underlies St. Albans slate. Middle Cambrian. In Milton quadrangle, Cady (1945, Geol. Soc. America Bull., v. 56, no. 5) mapped the Rugg Brook as Winooski dolomite. Term Winooski should be dropped and name Rugg Brook applied in both northwestern and west-central Vermont.

Type locality: On Rugg Brook less than 3 miles southwest of St. Albans, Franklin County.

Rugged Crest Flow

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 38, 49. Name applied to flow at Rugged Crest. Overlapped by Wineglass dacite flow (new). [See Sun Creek Dacite Flow.]

Rugged Crest is on north rim of Crater Lake.

**Ruin Granite**[1]

Precambrian: Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. Mapped in Globe quadrangle. Typically a coarse-grained porphyritic quartz monzonite containing large phenocrysts of pale-pink orthoclase 1 to 3 inches long. Outcrops generally light brown and deeply weathered.

D. W. Peterson, 1960, U.S. Geol. Survey Geol. Quad. May GQ–128. Underlies much of northwestern part of Haunted Canyon quadrangle and occurs in scattered outcrops throughout remainder of northern half. Table 1 shows Ruin granite below Scanlan conglomerate of Apache group and above Pinal schist.

Occurs in Ruin Basin, Globe quadrangle.

**Rulo Limestone Member** (of Scranton Shale)[1]

Rulo Limestone (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 8, 14, 25.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 49 (fig. 11), 213. Rank raised to formation in Wabaunsee group. Term Scranton abandoned. Underlies Silver Lake shale; overlies Cedar Vale shale. Average thickness about 2 feet.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2277. Rank reduced to member status in Scranton shale, here reintroduced as a formation with stratigraphic span as assigned to it by Haworth and Bennett (1908). Underlies Silver Lake shale member; overlies Cedar Vale shale member.

Type locality: Two and one-half miles north of Rulo, Richardson County, Nebr.

†Ruma Formation (in Chester Group)[1]

Ruma Formation (in Homberg Group)

Mississippian (Chester Series): Southwestern Illinois.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 126.

J. M. Weller *in* Stuart Weller and J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 135; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 833. In Randolph and Monroe Counties, mostly shale and locally attains thickness of 75 feet. Shales are variegated and contain reddish and purplish beds similar to some of Renault shales. Arenaceous strata, mainly thin-bedded and shaly sandstones, occur in middle part of formation and locally in upper part. Sandstone beds in midst of Ruma are undoubtedly equivalent to Cypress sandstone of standard section. Parts of underlying and overlying shaly strata may be equivalent to upper and lower parts of the Paint Creek and Golconda formations where the intervening Cypress sandstone is more typically developed. Overlies Paint Creek limestone; underlies Okaw limestone. Included in Homberg group (new).

Named for Ruma, Randolph County. Exposed in tributaries of Horse Creek.

Rumsy Ridge Sandstone Member (of Fish Creek Shale)

Rumsy Ridge Shale (in Medina Group)

Lower Silurian: Western New York, and southern Ontario, Canada.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1988. Name proposed for fossiliferous light-bluish-gray calcareous sandstone. Occurs 6 feet above base of Fish Creek shale (new) in Niagara Gorge and closer to base at Lockport, N.Y.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Rank raised to formation to include green shales and thin interbedded gray siltstones lying above Whirlpool sandstone and beneath Cabot Head shale in Niagara Gorge. Locally underlies Grimsby sandstone. Replaces preoccupied name Fish Creek shale.

Named from populated part of Niagara Escarpment which overlooks village of Lewiston, Niagara County, N.Y.

Run Gap Red Sandstone Member (of Juniata Formation)

Ordovician: Central Pennsylvania.

F. M. Swartz, 1948, Pennsylvania Geologists Guidebook 14th Ann. Field Conf., supp., diagram (following p. 4), fig. 3. Incidental mention as red sandstone in upper part of Juniata. Underlies Tuscarora sandstone: overlies red siltstone and sandstone members of Juniata red beds.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geology Contr. 3, 58 p. At top of Juniata formation, in Tyrone Gap area, are thin red sandstones that appear to represent westerly extension of Run Gap red sandstone member that is about 250 feet thick and finely and sparingly conglomeratic at Run Gap. Overlies Plummer Hollow mudstone member (new); eastward from vicinity of Lost Creek Gap, overlies East Waterford red sandstone member (new). [Swartz refers to his 1955 report *in* Pennsylvania Geologists Guidebook 21st Ann. Field Conf. Compiler was unable to locate this reference.]

Extends from area of Jacks Mountain, north of Lewistown in Mifflin County, to area of Shade Mountain at Lost Creek Gap. Run Gap is located in Tuscarora Mountain along boundary of Juniata and Perry Counties.

Runningwater Formation

Miocene: Northeastern Nebraska and eastern Wyoming.

H. J. Cook, 1960, Internat. Geol. Cong. 21st, Copenhagen, pt. 12, p. 204 (section), 205. Name applied to deposits above lower stages of the Marsland (which were originally named Upper Harrison beds) and below Sheep Creek beds of Matthew and Cook. Generalized section shows the Runningwater below Sheep Creek group.

Name derived from local name of river on which deposits occur.

Runnymede Sandstone Member (of Ninnescah Shale)

Permian: South-central Kansas.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, p. 1773–1774. Blue-green to gray shaly sandstone 7 to 8 feet thick, with intercalated layers of red shale and sandstone. Topmost bed of the Ninnescah at its northernmost outcrop.

Named from Runnymede, Harper County.

Rush Formation[1] (in Susquehanna Group)

Upper Devonian: Central Pennsylvania.

Original reference: Bradford Willard, 1935, Geol. Soc. America Bull., v. 46, no. 8, p. 1199.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Middle Devonian.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3. Included in Susquehanna group. Comprises Burket shale member and Tully limestone member.

Named for Rush Township, Northumberland County.

Rush Member (of Tully Limestone)[1]

Upper Devonian: Central Pennsylvania.

Original reference: B. Willard, 1934, Pennsylvania Acad. Sci. Proc., v. 8, p. 57–62.

Exposed in roadcut east of small brook one-half mile from railway station at South Danville (Riverside), in Rush Township, Northumberland County.

**Rushford Sandstone[1]**

Rushford Member (of Canadaway Formation)

Rushford Sandstone (in Canadaway Group)

Upper Devonian: West-central New York.

Original reference: D. D. Luther, 1902, New York State Mus. Bull. 52, p. 619.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Overlies Caneadea member of Perryburg formation (new).

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 17. Member of Canadaway formation. Overlies Caneadea member;

underlies "Machias" member of Canadaway. Upper boundary not well established.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook Ann. Mtg., p. 17 (table 2), 18. Listed as Rushford sandstone in Canadaway group. Overlies Caneadea shale; underlies "Machias" shale.

Well exposed in Caneadea Gorge, 3.3 miles east of Rushford, Allegany County.

Rush Run Sandstone (in Greene Formation)[1]

Permian: Northern West Virginia.

Original reference: R. V. Hennen, 1909, West Virginia Geol. Survey Rept. Marshall, Wetzel, and Tyler Counties, p. 191.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 17 (table 2). Listed in summary of stratigraphic sections of Dunkard group in Harrison County. Thickness about 25 feet. Top of unit about 495 feet above Waynesburg coal.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). In Greene series.

Named for Rush Run, which empties into Fish Creek, three-fourths mile southeast of Hundred, Wetzel County.

**Rush Springs Sandstone** or **Formation** (in Whitehorse Group)

Rush Springs Member (of Whitehorse Sandstone)[1]

Permian: Southwestern Oklahoma and north-central Texas.

Original reference: R. W. Sawyer, 1929, Oklahoma Geol. Survey Bull, 40-HH.

D. A. Green, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1454, 1473. Rank raised to formation; unit has unconformity at base and top. Cloud Chief gypsum is grouped with the Quartermaster rather than with Rush Springs in the Whitehorse.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Geographically extended into north-central Texas where it is given formational rank in Whitehorse group. Includes Dozier sandstone member (reallocated). Underlies Cloud Chief gypsum; overlies Marlow formation.

L. V. Davis, 1955, Oklahoma Geol. Survey Bull. 73, p. 68–75, pl. 1. In present report, the Rush Springs is classed as a formation in Whitehorse group. Conformably overlies Marlow formation; unconformably underlies Cloud Chief formation. Thickness 136 to 300 feet in Grady and Stephens Counties. Sawyer did not specify a type locality, but stated that his Rush Springs is the Whitehorse sandstone of Reeves (1921, U.S. Geol. Survey Bull. 726). Reeves mentioned a Whitehorse sandstone cliff which forms river bluffs 1 mile north of northeast corner of Tonkawa Township. This description places the locality in sec. 36, T. 7 N., R. 10 W., Caddo County, where almost the full thickness of formation from base upward is exposed and texture and bedding are typical. This location is considered acceptable as a type locality.

Type locality: Cliffs on river bluffs northeast of Tonkawa Township, sec. 36, T. 7 N., R. 10 W., Caddo County, Okla.

Rushville Group[1]

Rushville Shale Member (of Logan Formation)

Lower Mississippian: Central Ohio.

Original reference: E. B. Andrews, 1879, Am. Jour. Sci., 3d, v. 18, p. 137.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 1, p. 41 (table 2), 60. Rushville shale member included in Pretty Run sandstone facies (new) of Logan formation. Overlies Vinton sandstone member; locally underlies Pennsylvanian sandstone. Lower Mississippian.

Probably named for Rushville near eastern border of Fairfield County.

Rusk Formation (in Trinity Group)

Cretaceous (Comanche Series): Subsurface in northeastern Texas and northern Louisiana.

J. M. Forgotson, Jr., 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 92, 94 (chart); 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2332 (fig. 2), 2355–2357. Defined as those rocks and their stratigraphic equivalents below top of Glen Rose limestone as recognized in subsurface of northeastern Texas and above top of Ferry Lake anhydrite. In type well, occupies interval from 5,785 to 7,265 feet; consists of alternating beds of nonporous dense crystalline limestone, earthy limestone, and gray to black shale; contains thin stringers of anhydrite in basal part. Occupies stratigraphic interval termed upper Glen Rose formation and Paluxy formation. Revision of Trinity nomenclature by Shreveport Geological Society eliminated term "lower Glen Rose" as formational unit; term upper Glen Rose formation became orphaned and reference to it as Glen Rose formation became a misnomer since it was equivalent only to part of Glen Rose as defined on outcrop.

Type well: Skelly Oil Co.'s G. W. Weatherby Well 1, Williams McIlvane Survey, southwest Rusk County, Tex.

Russell Feldspathic Gabbro

Precambrian: Northeastern New York.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 53–54, 260–267. Name applied to the gabbro in the Russell sheet. In area of this report, only northern half of mass was studied; here the east-northeast half consists of normal gabbro and the west-southwest half of a feldspathic gabbro; junction between the two is sharp.

North end of gabbro sheet lies about 3 miles south-southwest of Russell, Russell quadrangle, St. Lawrence County.

†Russell Formation[1]

Lower and Middle Cambrian: Southwestern Virginia and southeastern Kentucky.

Original reference: M. R. Campbell, 1894, U.S. Geol. Survey Geol. Atlas, Folio 12, p. 2.

Named for Russell County, Va.

†Russell Formation[1]

Upper Cretaceous: Central and western Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 49.

Named for exposures at Russell, Russell County.

†Russell Slate

Upper Cambrian: Northwestern Vermont.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1055. Local name; abandoned in favor of Hungerford slate (new).

Rudolf Ruedemann, 1947, Geol. Soc. America Mem. 19, p. 164, 165. Name Russell slate referred to in description of graptolites *Dictyonema schucherti* and *Dictyonema vermontense.*

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 547. Ruedemann (1947) referred to this formation [Hungerford] as Russell slate, but name is not necessary and is probably not valid, for it was not defined.

Occurrence: Small road-metal quarry 1 mile northwest of Highgate Center, Franklin County.

Russell Creek Limestone Member (of Senora Formation)

Pennsylvanian (Des Moines Series): Northeastern Oklahoma, southeastern Kansas, and southwestern Missouri.

C. C. Branson, 1954, Oklahoma Acad. Sci. Proc., v. 33, p. 191 (table 1). Name applied to limestone that forms cap rock of the Mineral coal; underlies Broken Arrow coal.

C. C. Branson, 1955, The Hopper, v. 15, no. 12, p. 137. Ferruginous clayey carbonaceous gray limestone, 10 inches to 2 feet thick in one bed; contains fusulinids.

Type section: On Leep Farm on east bank of Russell Creek where it is flowing south in NE¼SW¼ sec. 15, T. 29 N., R. 20 E., Craig County, Okla.

Russellville Shale (in Atoka Formation)[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans, v. 15, p. 51.

Probably named for Russellville, Pope County, Ark.

Russia Limestone Member (of Denmark Formation)

Middle Ordovician: Central New York.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598–601; 1953, New York State Mus. Bull. 347, p. 55–57. Defined at Trenton Falls as extending from top of Poland member (new) through 70 feet of shaly limestone to a local disconformity 2 feet below a ferruginous bed in base of Upper High Falls. Lower 50 feet lithologically similar to the Poland but relatively barren platy calcilutite and shale form upper 20 feet. Underlies Rust member (new) of Cobourg formation. Facies discussed.

Typically developed in Trenton Falls George along west line of Russia Township.

Rust Limestone Member (of Cobourg Formation)

Middle Ordovician (Mohawkian): East-central New York.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 601–602, 604. Name proposed for lower member of formation in Utica quadrangle and vicinity. Described as argillaceous and coquinal limestone. Slump breccias at Prospect Bridge occur near top. Thickness 115 feet. Underlies newly defined Steuben member; overlies newly defined Russia member of Denmark formation.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 59–61. Further described. Includes shaly limestone, conglomerate, calcilutite and shale in type section.

Type section: At Trenton Falls on West Canada Creek near Oneida-Herkimer County line. Named from Rust Farm in Herkimer County 1 mile east of type section.

**Rustler Formation[1] or Limestone[1]**

Permian (Ochoa Series): Western Texas and southeastern New Mexico.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 44.

L. R. Page and J. E. Adams, 1938, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1709; 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 62–63. In eastern Midland basin, underlies Dewey Lake formation (new).

J. E. Adams, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 11, p. 1612–1615. Lang (1938, New Mexico State Engineer 12th and 13th Bien. Rept.) measured section of Rustler in Eddy County, N. Mex. He divided section into 11 members (descending 1–11). Unit 2, a 30-foot gypsiferous dolomite is here named Magenta member; unit 6, a 35-foot dolomite is here named Culebra member. Overlies Salado formation; underlies Dewey Lake formation.

G. E. Hendrickson and R. S. Jones, 1952, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 3, p. 22–23. Formation described in Eddy County. Unconformably overlies Salado formation in most of area east of Pecos River and Castile formation and Whitehorse group or its equivalents west of Pecos. In northern part of county, overlies Chalk Bluff formation. Underlies red beds (Pierce Canyon red beds) and sandstones of Dockum group. Thickness 200 to 500 feet.

Named for exposures in Rustler Hills, Culberson County, Tex.

Rustler Canyon Basalt

Tertiary: Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1). Black vesicular basal or olivine andesite flows and flow breccias. Maximum thickness 50 feet. On west side of Box Canyon, a single amygdaloidal flow about 18 feet thick is separated from Box Canyon rhyolite (new) by covered zone about 55 feet thick. In one place, 15 feet of basalt breccia is exposed beneath flow which is covered by Piloncillo sediments (new). In one locality, occurs between Kneeling Nun and Caballo Blanco rhyolites.

Named after Rustler Canyon in northwest corner of Dwyer quadrangle. Confined to two localities: on west side of Box Canyon, for about one-quarter mile north of Box Well graben, and in secs. 20 and 21, T. 18 S., R. 11 W.

†Rustler Springs Formation[1]

Permian: Western Texas.

Original reference: J. A. Udden, 1915, Am. Jour. Sci., 4th, v. 40, p. 151–155.

Named for Rustler Springs, Culberson County.

Rusty beds[1]

Rusty zone (in Pierre Formation)

Upper Cretaceous: Central and eastern Colorado, central southern Montana, and central and northern Wyoming.

Original reference: C. W. Washburne, 1908, U.S. Geol. Survey Bull. 340, p. 350.

M. O. Griffitts, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 12, p. 2012, 2014, 2015, 2017. Dane, Pierce, and Reeside (1937, U.S. Geol. Survey Prof. Paper 186–K) subdivided Pierre shale in Colorado and used Sharon Springs member for basal zone and informal terms (ascending) rusty zone, tepee zone, and transition zone for remainder of formation. These zone terms are recognized and used as formal stratigraphic terms in this report. Thickness of zone about 1,200 feet.

Rusty Beds Member (of Thermopolis Shale)

Lower Cretaceous: Central northern Wyoming.

Arthur Mirsky, 1960, Dissert. Abs., v. 21, no. 4, p. 850. Nonmarine section between marine Sundance formation (Late Jurassic) and definitely marine Thermopolis shale (Early Cretaceous) is divisible into four mappable units. Unit 4 (basal Thermopolis) is a black paper-thin shale, interbedded with thin lenticular tan cross-laminated siltstone and fine-grained sandstone. It has been informally known as "Rusty Beds" for a long time, and term is ingrained in the literature. Unit has been placed in uppermost Cloverly or lowermost Thermopolis by previous investigators. It is here proposed that it be formally named Rusty Beds member of the Thermopolis.

Area of report is southern Big Horn Mountains.

†Ruth Limestone[1]

Pennsylvanian: Eastern Nevada.

Original reference: A. C. Lawson, 1906, California Univ. Pub., Bull. Dept. Geology, v. 4, no. 14, p. 292.

Named for Ruth mine, Robinson mining district, Egan Range, White Pine County.

**Rutland Dolomite**[1]

Lower Cambrian: Southwestern and west-central Vermont and northwestern Massachusetts.

Original reference: J. E. Wolff, 1891, Geol. Soc. America Bull., v. 2, p. 331–338.

E. C. Jacobs, [1937], Vermont State Geologist 20th Rept., p. 71, 98–100. Geographically extended into northwestern Massachusetts.

Named for exposures in valley in vicinity of Rutland, Vt.

†Rutledge Limestone (in Midway Group)[1]

Eocene, lower: Southern Alabama.

Original reference: E. A. Smith, 1892, Sketch of geology of Alabama: Birmingham, Ala., Roberts & Son, pamph. of 36 p.

Probably named for exposures at Rutledge, Crenshaw County.

**Rutledge Limestone**[1] or **Dolomite** (in Conasauga Group)

Middle Cambrian: Northeastern Tennessee, western North Carolina, and southwestern Virginia.

Original reference: A. Keith, 1896, U.S. Geol. Survey Geol. Atlas, Folio 27, p. 2.

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 7, 9–10. In Lee Valley, Hawkins County, Tenn., Ruthledge Limestone overlies Pumpkin Valley shale (new); underlies Rogersville shale. Thickness 320 feet.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1 (plates); pt. 2, p. 46 (fig. 3), 49–51. In eastern Tennessee, the Conasauga varies in lithology and three phases are recognized; in central phase (between Knoxville and Morristown, and north of Clinch Mountain) the Conasauga is considered a group consisting of six formations of which the Rutledge is second in sequence (ascending). Overlies Pumpkin Valley shale; underlies Rogersville shale. Thickness 100 to 500 feet.

Named for exposures in valley of Rutledge, Grainger County, Tenn.

Ryan Formation

Tertiary: Southeastern California.

D. I. Axelrod, 1940, Jour. Geology, v. 48, no. 5, p. 528. Unconformably overlies Furnace Creek formation (new). Furnace Creek is Miocene or Pliocene. Name credited to H. D. Curry.

In Furnace Creek Wash area, central Death Valley region.

Ryan Sandstone[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: J. R. Bunn, 1930, Oklahoma Geol. Survey Bull. 40PP, p. 10.

Typically exposed in scarps southeast and northwest of Ryan, Jefferson County.

Ryans Ford Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Central eastern Illinois.

Original reference: J. E. Lamar and H. B. Willman, 1934, Illinois Geol. Survey Bull. 61, p. 129–138.

Coles and Cumberland Counties.

**Rye Formation**

Rye Gneiss[1]

Probably Ordovician and Silurian: Southeastern New Hampshire and southwestern Maine.

Original reference: Alfred Wandke, 1922, Am. Jour. Sci., 5th ser., v. 4, p. 141, 143–144.

M. P. Billings, 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for Field Trips in New England, p. 23, 24, 29, 44. Includes an upper metavolcanic member, fine-grained biotite gneiss and amphibolite, and a lower metasedimentary member, feldspathic mica schist. Latter represents several metamorphic zones. Thickness about 4,000 feet. Conformably underlies Merrimack group. Paleozoic, probably Silurian and perhaps Ordovician also.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State, Plan. Devel. Comm., p. 38–39. Ordovician(?).

U.S. Geological Survey currently designates the age of the Rye Formation as probably Ordovician and Silurian on the basis of a study now in progress.

Named for development in Rye Township, Rockingham County, N.H.

774–954—vol. 3—66——31

Ryegate Granite[1] or Granodiorite

Upper Devonian(?): Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table facing p. 288.

W. S. White and M. P. Billings, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 662, 665–667, pl. 1. Medium- to coarse-grained light-gray quartz monzonite, granodiorite, and quartz diorite. Granodiorite most abundant type; porphyritic in vicinity of Blue Mountain. Some foliation present. Forms complex of small plutons. Assigned to New Hampshire magma series.

Named for quarry in northeastern part of Ryegate Township, Caledonia County. Occurs in two general areas, Blue Mountain and Groton, in vicinity of Ryegate in Vermont part of Woodsville quadrangle, Vermont-New Hampshire.

Rye Point Member (of Cashaqua Formation)

Upper Devonian: Western New York.

R. G. Sutton, 1960, New York State Mus. Sci. Service Bull. 380, p. 17–18, 53, 55, figs. 2, 5. Proposed for fossiliferous gray calcareous shales that overlie Rock Stream member. Includes red and green nodular limestone bed known as Parrish limestone lentil (Clarke and Luther, 1904). Thickness 15 to 113 feet; thins eastward and disappears in Ithaca region. Underlies Rhinestreet black shale.

Type locality: Small stream on east side Keuka Lake, 3 miles northeast of Hammondsport and 1½ miles northeast of Rye Point, Steuben County.

Rykert Granite[1]

Jurassic(?): Northern Idaho and Washington, and British Columbia, Canada.

Original reference: R. A. Daly, 1912, Canada Dept. Mines Mus. Mem. 38, p. 284.

**Rysedorph Conglomerate**[1]

Middle Ordovician: Eastern New York.

Original reference: R. Ruedemann, 1901, New York State Mus. Bull. 42; 1901, New York State Mus. Bull. 49.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 276–277. Discussed under heading of formations of Sherman Fall age, Trenton group.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16), 119. Correlation chart for Vermont shows Rysedorph conglomerate in Taconic sequence below Tackawasick limestone and above Normanskill formation. May represent the horizon of Middle Ordovician unconformity.

Also referred to as Rysedorph Hill Conglomerate.

Named for occurrence in Rysedorph [Rysedorf] Hill (locally called Pinnacle or Sugar Loaf Hill), 2 miles southeast of Rensselaer, across river from Albany.

Saanich Formation[1] or glacial deposits

Pleistocene: Western Oregon and northwestern Washington, and British Columbia, Canada.

Original reference: R. Arnold and H. Hannibal, 1913, Am. Phil. Soc. Proc., v. 52, p. 565–595.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 24 (table). Described as formation consisting of post-glacial marine terrace deposits exposed in Puget Sound area together with poorly consolidated clays, sands, and gravels along the coast of Oregon and Washington.

Probably named for occurrences north of Victoria and Saanich Peninsula, Vancouver Island.

Saavedra Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11, 15–16, pl. 27. Consists of following units (ascending): detritus, white sandstone, light-brown sandstone, gray arenaceous limestone, Barata limestone (new), buff sandstone, Arkill limestone (new), soft white sandstone, yellow limestone, Chapparal sandstone (new), light-colored shales and sandstones, dense gray limestone, green shale, argillaceous limsetone, shale, light-brown sandstone, and calcareous sandstone. Thickness 218 feet. Underlies unnamed limestone and sandstone division; overlies Joserita member (new).

In standard section of Lowell formation in the Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Sabana Grande Andesite (in Mayagüez Group)

Sabana Grande Formation

Upper Cretaceous: Southwestern Puerto Rico.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 197; 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 329, 330, 338–339, pl. 1. Sabana Grande andesite was defined by Slodowski (unpub. thesis) as Sabana Grande formation. The mudstone in Sabana Grande of Slodowski is correlated with the Yauco mudstone in area of this report [Mayagüez]. Unit is composed of andesite breccia, flow breccia, and tuff, with minor basalt lava; lateral changes of texture and lithology common. No fossils identified; from its position between Parguera (new) and Yauco formation, the Sabana Grande can be dated as Turonian to Campanian.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, no. 1, p. 200. In Yauco area, a complex, more than 9,000 meters thick, of volcanic flows with interbedded marine limestones, mudstones, tuffs, and sedimentary rocks derived from the volcanic rocks, is divided into eight formations: Sabana Grande, El Rayo (new), Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara (new). Sabana Grande and El Rayo formations unconformably underlie Ensenada and Río Yauco formations. Complex ranges in age from Senonian to late Paleocene, possible Eocene.

Largest exposures are on routes 348 and 119 connecting Mayagüez, Rosario, and San Germán.

Sabanita (Sabanitas) Formation

(?) Miocene, middle: Panamá.

[T. F. Thompson], 1943, Panama Canal Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 5, p. 7. Continental gravels, tuffs, and clays. Masks the contact of Gatún formation with basement complex.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 906, 920. Considered middle Miocene(?) continental facies of basal part of Gatún formation. Typically a tuff-conglomerate unconformably overlying pre-Tertiary basement complex. Over wide exposures, weathering has altered it to a weathered ash and gravel. Unsorted and massive in type exposure.

Type exposure: Along Boyd-Roosevelt Highway northeast of Sabanitas, vicinity of Gatún Lake.

Sabattus Formation

Sabattus Garnet Schist (in Tacoma Series)

Sabattus Shale

Silurian: Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Listed in table of formations as garnet schist. Uppermost unit in Tacoma series (new). Older than post-Silurian pegmatites, aplites, and granites; younger than Minwah limy gneiss (new).

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. In Lewiston area are seven formations (ascending): Danville injection gneiss (new), Androscoggin gneiss, Bates crystalline limestone, Deer Rips lime-silicate gneiss (new), Thorncrag biotite-sillimanite gneiss, Tacoma lime-silicate series, and Sabbatus quartz-sillimanite-biotite schist.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 125–130, pl. 1, table 1 (facing p. 112). Described as a formation consisting of quartz-mica schist with garnet and sillimanite and marble lenses. Only quartz-muscovite-sillimanite schist can be traced for considerable distance. Thickness 3,000 feet. Conformably overlies Androscoggin formation. Silurian. Type locality described.

R. L. Miller, 1945, Maine Geol. Survey Bull. 2, p. 9. Referred to as shale.

Type locality: Outcrops on or near Sabattus Mountain for which it is named. Crops out in area extending from Lewiston to Waterville.

Sabetha Limestone (in Council Grove Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 232, 234.

Named for exposures on Omaha-Tulsa Highway, 1 mile north of Sabetha, Nemaha County, Kans.

†Sabine Formation[1] or Group

Sabine Stage

Eocene, lower: Eastern Texas, Alabama, Arkansas, and Louisiana.

Original references: A. C. Veatch, 1905, Louisiana Geol. Survey Bull. 1. pt. 2, Rept. 1905, p. 84, 85, 88, Letter of transmittal of Louisiana Director to Governor dated Dec. 9, 1904; U.S. Geol. Survey Water-Supply Paper 114, on Louisiana and southern Arkansas, p. 180, 184–185, ms. sent to Govt. Ptg. Office, Aug. 2, 1904.

W. D. Chawner, 1936, Louisiana Dept. Conserv., Geol. Bull. 9, p. 54–64. Sabine group in Louisiana crops out over broad area in northwestern part of State where it is brought to surface by Sabine uplift. History of usage of term discussed. [Most of usage of term Sabine group in Louisiana is in reports dealing with subsurface stratigraphy.]

G. E. Murray, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 5, p. 687. Term Sabine stage recommended as time-rock term for post-Midwayan and pre-Claibornian deposits of Coastal Plain province. This is similar to original usage of Veatch (1905, 1906). As such, it is synonymous with Wilcox group used as a time-rock term. Stage includes all deposits in Gulf and Atlantic Coast province formed during the stand of early Eocene sea, beginning with initial deposition of widespread *Ostrea thirsae-Ostrea multilirata*-containing beds of East Texas, Louisiana, Mississippi, and Alabama, and their equivalents, and ending up with initial invasion of Claibornian sea. Sabine age includes all time involved in deposition of these deposits. Includes at least two substages based on cyclic alternations of regional nature.

G. G. Varvaro, 1957, Louisiana Dept. Conserv., Geol. Bull. 31, p. 63–64, pl. 4. Term Sabine stage used in discussion of subsurface stratigraphy in Evangeline and St. Landry Parishes. Includes Wilcox group.

Formation named for typical fossiliferous development on Sabine River in Sabine County, Tex., and Sabine Parish, La., and from exposures at Sabinetown Bluff.

†Sabine River Beds[1]

Eocene: Eastern Texas.

Original reference: E. T. Dumble and R. A. F. Penrose, Jr., 1890, Texas Geol. Survey 1st Ann. Rept., p. xxxvi, 17, 22, pl. 3.

Named for Sabine River.

Sabinetown Formation (in Wilcox Group)[1]

Eocene, lower: Eastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 574, 601, 634.

W. M. Cowan, 1942, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 51, p. 2. In Wilson County, overlies Rockdale formation and underlies Carrizo sand.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 47 (fig. 1), 56, 63–64. In original definition, Plummer included both the beds at Pendleton Ferry and those at Sabinetown in Sabinetown formation. Term Sabinetown is herein restricted to those beds lying above High Bluff member of Pendleton formation and below Carrizo sand. Includes Pearson glauconite member at base, and an upper member that consists of silty, laminated, lignitic shale with glauconitic crossbedded fine-grained sand. Thickness about 52 feet. Note on type locality.

Type locality: Bluff on Texas side of Sabine River about one-fourth mile below old ferry landing. Named from village of Sabinetown, Sabine County, Tex.

Sabula dolomite[1]

Silurian (Niagaran): Central eastern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 149, 150.

Named for Sabula, or Sabula Junction, Jackson County.

Sac Limestone[1]

Lower Ordovician (Beekmantown): Southwestern Missouri.

Original reference: E. M. Shepard, 1898, Missouri Geol. Survey, v. 12, pt. 1, p. 49, 74–77.

Named for outcrops on Sac River, Greene County.

Sacajawea Formation[1] (in Montchauve Group)

Mississippian: Wyoming and Montana.

Original reference: C. C. Branson, 1936, Geol. Soc. America Proc. 1935, p. 391.

C. C. Branson, 1937, Jour. Paleontology, v. 11, no. 8, p. 650–660. Lower part of Amsden is Mississippian in age and is here described and named Sacajawea formation to separate it from upper part of Amsden (Pennsylvanian). At type section, formation (units 14 and 15 of measured section) consists of basal unit, 2 to 11 feet thick, of red and buff sandstone and shaly sandstone, breccia in places, shale cave filling in places; and upper unit, 43 feet thick, of massive crystalline light-gray cherty limestone, with Ste. Genevieve fauna in lower 20 feet. Beds 10 to 13 (possibly Chester in age) in section are set off by unconformity above and are possibly separated from Sacajawea by unconformity below; these beds may be added to the Sacajawea if favoring evidence appears. Disconformable on Madison limestone. Fauna described.

C. C. Branson, 1939, Geol. Soc. America Bull., v. 50 no. 1, p. 1203, 1204, 1211, 1212. Measured sections show Sacajawea formation underlies Tensleep formation (redefined); locally separated from the Tensleep by limestone interval referred to as beds of Chester(?) age.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 126 (fig. 2), 130–131. Columnar section of formations exposed in and near Wind River Mountains shows Sacajawea formation, 100 to 200 feet thick, above Madison formation and below the Tensleep. Text states that on Bull Lake Creek 60 feet of laminated limestone without fossils lies with irregular contact on the Sacajawea and is overlain disconformably above. This sequence may constitute another formation, possibly of Chester age. Term Amsden not used in area of this report.

W. F. Scott and P. C. Wilson, 1953, (abs.) Geol. Soc. America Bull., v. 64, no. 12, pt. 2, p. 1554. Distinctive red-bed sequence, usually considered basal part of Amsden formation, constitutes persistent lithostratigraphic unit over much of Montana and Wyoming. In most areas, this unit rests disconformably upon Madison limestone. In central Montana, it overlies Heath formation of Big Snowy group. Underlies typical Amsden carbonates except in western Montana, where Amsden is absent and unit underlies Quadrant quartzite, and in eastern Wyoming, where Amsden lithologies have not been separated from the Hartville and Minnelusa. Thicknesses vary, without apparent pattern, from 5 feet in central Wyoming to 230 feet in Big Snowy Mountains. Name Sacajawea, which has been applied to Mississippian part of the Amsden in northwestern Wyoming, should be restricted vertically to include only the red beds, and extended laterally throughout area where these beds are recognizable. Term Amsden should be retained for the limestone and dolomites between the Sacajawea (restricted) and the typical sandstones of the Tensleep or its equivalents.

J. D. Love, 1954, Tentative diagrammatic correlation of Tensleep, Amsden, Casper, and Hartville formations in Wyoming *in* Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf. [chart in pocket]. Correlation chart shows that Sacajawea formation at type locality extended upward to base of Darwin sandstone member of Amsden formation.

A. B. Shaw and W. G. Bell, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 3, p. 333–337. Discussion of age of Amsden formation on basis of new collection of fossils made at Cherry Creek, Wind River Mountains, Wyo. Use of name Sacajawea formation at Cherry Creek is not justifiable because Mississippian beds in this area do not constitute a mappable unit under present standards; in this the writers [Shaw and Bell] disagree with Branson (1937). Possibly such terms as Sacajawea fauna or Sacajawea beds used in colloquial sense, may be applicable.

A. B. Shaw, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 60, 61 (fig. 1), 62. As originally defined the Sacajawea did not include all of the Amsden below the Darwin sandstone, but only the *Spirifer welleri* zone. Love (1954) extended type section upward to include all post-Madison and pre-Darwin rocks; this makes the Sacajawea an objectively recognizable lithologic unit rather than a named faunal zone, but it may not serve the original purpose of separating the *Spirifer welleri* zone from overlying Pennsylvanian rocks. Whichever designation of the Sacajawea is used, the beds so designated contain in their lower part a large and distinctive fauna which Shaw and Bell (1955) regarded as Chesteran.

J. W. Strickland, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 51, 53. Term Sacajawea should be adopted throughout western Wyoming for strata of Chester age below the Darwin and above top of Madison group.

C. A. Burk, 1956, Stratigraphic summary of the pre-Niobrara formations of Wyoming, *in* Wyoming stratigraphy, pt. 1, Subsurface stratigraphy of the pre-Niobrara formations in Wyoming, Casper, Wyoming: Wyoming Geol. Assoc., p. 92. Suggests name be abandoned.

J. W. Strickland, 1957, Wyoming Geol. Assoc. Guidebook 12th Ann. Field Conf., p. 20, 21, 23–25. Sacajawea problem discussed. Confusion in interpretation and usage of term Sacajawea believed to have arisen largely as a result of original miscorrelation of type Sacajawea with Cherry Creek section and failure of most workers, including writer [Strickland], to recognize it. Believed that term Sacajawea should be used only for upper member of Upper Madison but should include the thin-bedded limestone and dolomites directly underlying Darwin sandstone and above the "massive crystalline limestone" of Branson (1937). This conclusion seems warranted on the basis of lithologic similarity with beds in unquestionable Madison strata and comment by Branson that beds referred to as Lower Amsden formation may be added to the Sacajawea if favoring evidence appears. This conclusion differs from those of earlier workers including the writer's (Strickland, 1956) who considered the term Sacajawea interchangeable with beds referred to as Lower Amsden. Type section described. Type Sacajawea as originally defined embraces only lower 50 feet or so of an 80- to 100-foot sequence of strata between the Darwin sandstone and typical looking Madison limestone.

T. W. Todd, 1959, Dissert. Abs., v. 20, no. 6, p. 2230–2231. Sacajawea formation, Amsden formation, and Tensleep sandstone are products of marine transgressive-regressive cycle that took place on Wyoming cratonic shelf during Pennsylvanian period as one phase in development of eastern Cordilleran geosyncline. Name Montchauve group is suggested for these formations.

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Discussion of stratigraphy of Pennsylvanian in northeastern Utah, western Wyoming, northwestern Colorado, and southeastern Idaho. Suggested that Quadrant and Casper formational names be abandoned and the Tensleep-Amsden-Sacajawea terminology be extended to include strata formerly referred to by these names and that term Sacajawea be accepted as formational name applicable to the red clastic sequence between Madison limestone or equivalent and Amsden carbonates.

Type locality (Strickland, 1957): In SE¼NW¼NE¼ sec. 11, T. 2 N., R. 4 W., along hogbacks in middle of valley above Bull Lake, Wind River Mountains, Wyo. Name derived from Mount Sacajawea at head of Bull Lake Creek. A store and inn of that name are on Yellowstone Park Highway near mouth of Bull Lake Creek. Word is Shoshone name of Bird Woman, guide of the Lewis and Clark expedition.

Sacandaga Quartzite[1]

Precambrian: Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199, p. 94, 121.

Type locality: Sacandaga River, Sacandaga mine, Day Township, Saratoga County.

Sacator Quartz Diorite

Paleozoic(?) or Mesozoic(?): Southern California.

W. J. Miller and R. W. Webb, 1940, California Jour. Mines and Geology, v. 36, p. 354–355, 356, 378 (fig. 31), pl. 2. Quartz-diorite varying to diorite, dark-colored and even-grained. Intrudes the Summit gabbro.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 512. Noted as cutting both Kernville series and Summit gabbro.

Named from exposures in Sacatar Canyon in northeastern part of Kernville quadrangle, Kern County.

Sacate Formation

Eocene, middle or upper: Southern California.

F. R. Kelley, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 1, p. 3 (fig. 2), 4 (fig. 3), 10–11. Succession of sandstones and interbedded silty and shaly strata. Thickness about 875 feet. Formation varies laterally. In Sacate Canyon, three well-defined massive sandstones crop out and are separated by sandy shales. These sandstones lose their identity toward the east and west. Conformably underlies Gaviota formation; conformably overlies Cozy Dell formation. Sandstone has been called "Coldwater" since evidence indicated it to be the probable equivalent of the Coldwater sandstone of the Ventura region.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 28–29, 38 (fig. 2). Thickness given as 1,000 to 1,500 feet. Overlies Cozy Dell; underlies Gaviota; upper and lower contacts gradational. Upper Eocene.

Type locality: Sacate Canyon, western Santa Ynez Mountains, Santa Barbara County.

Sacchi Beach Beds

*See* **McIntosh Formation.**

Sacfox Subgroup[1] (of Wabaunsee Group)

Pennsylvanian (Virgil Series) : Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 4, 5, 10–11.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 2036, 2037 (fig. 6) ; Kansas Geol. Survey Bull. 83, p. 169–171; G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 18–20; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 19–20. The subgroups named (ascending) Sacfox, Nemaha, and Richardson by Condra (1935) have been included in the interstate classification agreed to by the Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma. As thus defined, the Sacfox subgroup in standard section includes (ascending) Severy shale, Howard formation, White Cloud shale, Happy Hollow limestone, Cedar Vale shale, Rulo limestone, and Silver Lake shale. Nomenclature in the several States may deviate from this by combination or omission of terms where certain named rock units are not recognizable.

Type locality: In Missouri River bluffs in southeastern Richardson County, Nebr., and adjacent part of northeastern Kansas, that is, between southeast of Rulo, Nebr., and White Cloud, Kans. Name derived from the Iowa-Sac-Fox Indian Reservation in northeastern Kansas and southeastern Nebraska.

Sachuest Arkose[1]

Carboniferous: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 284–288, 379.

Composes west and south shores of Sachuest Neck, north shore at Flint Point, and a small exposure offshore at a headland one-fourth mile south of Flint Point, Newport County.

†Sacramento Formation[1]

Middle Devonian: Northern California.

Original reference: J. P. Smith, 1894, Jour. Geology, v. 2, p. 591, 592.

In Sacramento Canyon, Redding region.

**Sacramento Porphyry** or **Porphyrite**[1] (in Gray Porphyry Group)

Tertiary, lower: Central Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1883, U.S. Geol. Survey Leadville Atlas, cross-section sheet; 1886, U.S. Geol. Survey Mon. 12, p. 81.

C. H. Behre, Jr., 1953, U.S. Geol. Survey Prof. Paper 235, p. 50–52, 57, pl. 1. Distinguished from similar rocks of Gray porphyry group by following megascopic features: coarser and less equigranular than Evans Gulch porphyry; lacks large orthoclase phenocrysts such as are common in Johnson Gulch porphyry; relative abundance of ferromagnesian minerals and relatively small proportion of orthoclase phenocrysts and euhedral quartz distinguish it from typical Lincoln porphyry. In igneous sequence, intrusion of quartz diorite porphyry was followed by intrusions of Evans Gulch and Sacramento porphyries and typical Lincoln porphyry; relative ages of these porphyries not determinable. Older than Iowa Gulch porphyry. Igneous rocks that are younger than Precambrian in area of this report [west slope of Mosquito Range] are either wholly or mainly Tertiary and only possibly in part late Cretaceous or early Pleistocene in age.

Ogden Tweto, 1956, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–34. Mapped as early Tertiary in Tennessee Pass area, Eagle and Lake Counties, where it consists of gray, greenish-gray, or dark-orange-buff quartz monzonite porphyry characterized by abundant stout feldspar phenocrysts, predominantly plagioclase in most bodies but mostly orthoclase in some, and by abundant biotite flakes. Considered younger than Elk Mountain porphyry because some faults that offset bodies of Elk Mountain do not appear to run through the Sacramento.

Named for occurrence under Gemini Peaks, between heads of Big and Little Sacramento Gulches, vicinity of Leadville, Lake County.

Sacramento Tuff and Sand Member (of Tuscan Formation)

[Pliocene]: Northern California.

R. C. Treasher, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1257. Tuscan formation is subdivided into five members. Sacramento tuff and sand is youngest in sequence. Overlies Iron Canyon agglomerate member.

Occurs at Iron Canyon dam site near Red Bluff, Tehama County.

Sacramento Hill Porphyry

Lower Cretaceous: Southeastern Arizona.

W. G. Hogue and E. D. Wilson, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 21. Porphyry, ranging from granitic to monzonitic in composition. Forms numerous dikes and sills and Sacramento Hill stock. Intruded Paleozoic and older rocks.

G. W. Bain, 1952, Econ. Geology, v. 47, no. 3, p. 305, 306, 308. Described as quartz porphyry. Appears to have been intruded before deposition of Lower Cretaceous strata. If porphyry is later than Dividend fault and older than Glance conglomerate, then it is of very early Lower Cretaceous age.

Forms the stock of Sacramento Hill in Bisbee or Warren district, Cochise County.

Sacred Heart Granite (in Minnesota Valley Granite Series)

Precambrian: Southwestern Minnesota.

E. H. Lund, 1956, Geol. Soc. America Bull., v. 67, no. 11, p. 1482, 1483–1484. Massive, medium-grained, pinkish-gray to red granite. Inclusions common but concentrated in swarms, rather than being everywhere present as in Morton gneiss. Inclusions commonly a few feet or less across but some measure more than 100 feet across. Appears to be younger than nearby Morton gneiss but age relationship not certain. May represent younger phase of magma that produced Morton gneiss and Fort Ridgely granite (new).

Crops out in vicinity of Sacred Heart, Renville County.

**Saddle Gneiss**

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carrol and Frederick Counties Rept., p. 17, 18. Oldest rock of the injection complex, a highly metamorphosed biotite gneiss with layers of biotite schist and quartzite. Intruded by Cattron diorite (new).

A. J. Stose and G. W. Stose, 1957, Virginia Geol. Survey Bull. 72, p. 22–25, pl. 1. Comprises quartzite, biotite, schist, gneiss and garnetiferous facies with and without sillimanite. Quartzite in places contains graphite. Individual layers of these rocks, nowhere more than few feet thick, alternate with each other in every outcrop to such an extent that different kinds of rock could not be mapped separately. No sequence in the rock determined. Garnetiferous biotite gneiss is medium-to fine-grained banded rock composed of fine quartz grains, grayish-green feldspar, and bronze biotite flakes. Highly garnetiferous variety occurs 1 mile east of Cattrons Mill. Quartzite abundant in Saddle gneiss in several narrow zones which lie north of and along U.S. Route 58 from Baxter Ferry on New River southwestward to Independence. Quartzite that is interlayered with biotite gneiss is found chiefly in belt northwest of Fries overthrust and south of Striped Rock granite and north of Elk Creek village. Oldest known rocks of district. Derivation of name given.

Named from Saddle Creek in southwestern part of Gossan Lead district, Grayson County. Well exposed at intersection of Saddle Creek and U.S. Route 58. Best exposures at several places along U.S. Route 58 on State Highway 95, and on U.S. Route 21 south of its junction with State Highway 95.

**Saddleback Basalt** (in Tropico Group)

Saddleback Basalt (in Ricardo Formation)

Pliocene(?): Southern California.

H. S. Gale, 1946, California Jour. Mines and Geology, v. 42, no. 4, p. 326, 339, 346–350. Name applied to basaltic lavas which form base on which borate-bearing lake beds (Kramer Lake beds) rest. They rise in dip slope outcrops around northern borders of basin where borates occur. Flows vary in thickness from 600 feet maximum to where they pinch out and disappear in an area along the southern border of the basin. Present in Ricardo formation only in Kramer borate district.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 137 (fig. 1), 138 (fig. 2), 142. Redefined as local formation in Tropico group (new). At type section, rests on quartz monzonite but elsewhere rests with probable slight unconformity on lower part of Tropico group. In Kramer borate district, these underlying rocks were referred to as Rosamond formation by Gale (1946). The Saddleback is overlain unconformably by the borate-bearing shale of upper part of Tropico in Kramer district in the borate mines and unconformably by fanglomerate of probable Pleistocene age at the surface. Pliocene(?). Type locality designated.

Type locality: Saddleback Mountain in S¼ sec. 9, T. 11 N., R. 7 W., 4 miles north of Boron, Boron quadrangle, San Bernardino County. From Saddleback Mountain, basalt crops out as scattered exposures in low isolated hills toward northwest for 6 miles, and west about 10 miles.

Saddlebag Lake Conglomerate

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1033–1034. Basal conglomerate composed almost entirely of greenstone fragments in a schistose matrix of greenstone debris. Unconformably underlies Dike Lake slate (new); unconformably overlies Ely greenstone. Name credited to V. G. Sleight. [Fig. 4 shows Moose Lake conglomerate occupying stratigraphic position assigned to Saddlebag Lake conglomerate in text.]

Named for exposure on shores of Saddlebag Lake in sec. 13, T. 65 N., R. 6 W., in Vermilion district.

Saddle Bayou Lentil (in Verda Member of Yazoo Clay)

Eocene (Jackson): Central Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv., Geol. Bull. 10, p. 78 (fig. 6), 102–103. Series of massive fossiliferous sands averaging 20 feet in thickness. Sands are medium grained, well rounded, poorly indurated, and locally cemented by limonite. Lentil grades downward and interfingers laterally with typical Verda lignitic clays; grades laterally, eastward, into a series of unnamed sandy shales.

Exposed in cuts along a secondary road crossing a tributary of Saddle Bayou in the NW¼ sec. 20, T. 9 N., R. 2 W., Grant Parish.

**Saddle Creek Limestone Member** (of Pueblo Formation)

Saddle Creek Formation (in Pueblo Group)

Saddle Creek Limestone Member (of Harpersville Formation) [1]

Permian: Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 416.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 91. Rank raised to formation and reallocated to the Pueblo here redefined, given group status and assigned to the Permian. Underlies Stockwether formation. Redefined Pennsylvanian-Permian boundary is placed at disconformity in Harpersville formation above Waldrip-Newcastle coal zone about 40 to 150 feet below Saddle Creek limestone.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as limestone member of Pueblo formation. Consists of thin irregular layers of brittle fine-grained blue-gray limestone 4 to 5 feet thick. Underlies Camp Creek shale member; overlies Waldrip shale member.

Well exposed 1 to 2 miles south of mouth of Saddle Creek, south of Colorado River, McCulloch County.

**Saddlehorse Gypsum Lentil** (in Quartermaster Formation)[1]

Permian: Texas.

Original reference: C. N. Gould, 1907, U.S. Geol. Survey Water-Supply Paper 191, p. 16–20.

Saddle Mountain Lavas

Age not stated: Northern California.

Howell Williams, 1932, California Univ. Pub. Bull. Dept. Geol. Sci., v. 21, no. 8, p. 274. Flat-lying lavas older than Harkness lavas.

Saddle Mountain shown on map in Shasta and Plumas Counties, Lassen Volcanic National Park.

Saddle Mountain Porphyry[1]

Saddle Mountain Rhyolite

Precambrian: Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135, 136.

R. E. Denison, 1959, (abs.) Oklahoma Acad. Sci. Proc. 1958, p. 124. Saddle Mountain rhyolite is typically granophyric, and recent investigation indicates that it is gradational phase of Lugert granite.

Occurs near Saddle Mountain, in and around sec. 36, T. 5 N., R. 15 W., Wichita Mountains.

**Sadlerochit Formation**

Sadlerochit Sandstone[1]

Permian and Lower Triassic: Northern Alaska.

Original reference: E. D. Leffingwell, 1919, U.S. Geol. Survey Prof. Paper 109, p. 103, 113, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Cited as formation on map legend.

In Sadlerochit Mountains, Canning River region.

Saegerstown Member (of Cattaraugus Formation)

Saegerstown Shale[1]

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

Original reference: G. H. Chadwick, 1925, Geol. Soc. America Bull., v. 36, p. 457–464.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Saegerstown [shale] shown on correlation chart above Salamanca and below Woodcock. Upper Devonian.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 33. Extended into Chautauqua County, N.Y., where it is considered member at top of Cattaraugus formation. Consists of shales and siltstones. Thickness about 100 feet. Overlies Salamanca member; underlies Oswayo formation. Upper Devonian.

Named for exposures along French Creek, in village of Saegerstown, Crawford County, Pa.

Safford Dacite

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 739–740, pl. 1. Consists of three varieties of rock: fresh porphyritic dacite with groundmass of minute spherulites; porphyritic border facies with clear glass groundmass; and chalky porphyritic dacite. Chalky white to light gray when fresh and gray to light drab on weathered surfaces. Flow structure nearly vertical and parallel to its borders. The dacite pierces the Rillito andesite (new) and the Safford tuff (new). The mass is regarded as an eroded volcanic neck.

Largely confined to core of Safford Peak, Tucson Mountains, Pima County. Area of peak is elliptical, the long axis of which is 2,800 feet and short axis is 1,500 feet.

Safford Tuff

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 731–733, fig. 2, pl. 1. Consists of a coarse stratified but poorly sorted volcanic breccia or tuff near Safford Peak. Farther south it is usually fine grained and well stratified to thin bedded. Its materials range from sand to boulders 3 feet in diameter. Ranges through various shades of red and brown and is chalky white where altered. Thickness at least 340 feet. Rests concordantly on Rillito andesite (new) near Safford Peak, but to the southeast rests directly on Cretaceous volcanics with marked angular unconformity and is overlain by later basalts with another angular unconformity.

Named from exposures in cliffs near Safford Peak. Occurs throughout Tucson Mountain Range, Pima County.

Safford Canyon Formation

Oligocene, upper, and Miocene, lower(?): Northeastern Nevada.

Jerome Regnier, 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1191, 1193–1195, pl. 1. Consists of 700 feet of water-laid vitric tuffs and tuffaceous volcanic sandstones and conglomerates which form an open north-plunging syncline in northern end of Pine Valley. Lower part is 50-foot bed of coarse volcanic-pebble conglomerate which rests in sedimentary contact (slight angular unconformity) on volcanic rocks of Cortez Mountains; remainder of formation is interbedded tuffs, conglomerates, and a 20-foot bed of limestone. Occupies same stratigraphic position as Rand Ranch formation (new), between the volcanic rocks and upper Miocene Raine Ranch formation (new): not considered facies of Rand Ranch but believed to be younger than that formation. Nonfossiliferous.

Named for tributary of Humboldt River southwest of Palisade, vicinity of Carlin. Section measured from NE¼ sec. 11, T. 31 N., R. 51 E., toward center of sec. 1, same township.

**Sagamore Siltstone Member** (of Bedford Shale)

Sagamore Sandstone Lentil (in Bedford Shale)[1]

Mississippian: Northeastern Ohio.

Original reference: C. S. Prosser, 1912, Ohio Geol. Survey, 4th ser., Bull. 15, p. 26, 86, 88.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1354–1356. Here termed Sagamore siltstone member; unit is of unknown areal extent and is made up predominantly of quartzose siltstone containing a small amount of very fine sand; contains thin to massively bedded gray siltstones from 4 to 20 inches thick. Maximum thickness 20 feet. Occurs 30 feet above base of Bedford; underlain by silty gray shale containing many ripple-marked siltstones; stratigraphically above Euclid siltstone member.

Named for Sagamore Creek, Bedford Township, Cuyahoga County. Crops out along Cuyahoga River valley south of Bedford.

**Saganaga Granite**[1]

Precambrian: Northeastern Minnesota.

Original reference: A Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1033. Townline Lake granodiorite (new) which cuts Ely greenstone, may be offshoot of Saganaga granite.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 2), 1590, 1613, pl. 1. In Knife Lake area, contacts of granite with overlying Knife Lake sediments dips to west at angles of 60° to 70° in many places at western edge of batholith. Crooked Lake granite pebble conglomerates (new) were deposited on arkosites and graywacke which rest directly on Saganaga granite.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1041. Underlies Animikie rocks (Gunflint formation) in hills east of Gunflint Trail (road) between Gunflint and Saganaga Lake, secs. 22 and 23, T. 65 N., R. 4 W. Intrudes Ely greenstone.

First described on shores and islands of Saganaga Lake, Cook County.

Saganaga Syenite[1]

Precambrian (Keewatin): Northeastern Minnesota.

Original reference: A. Winchell, 1891, Am. Jour. Sci., 3d, v. 41, p. 386.

**Sagavanirktok Formation**

Paleocene to Oligocene(?): Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 167, fig. 2. Mainly of red-bed-type poorly consolidated siltstone, sandstone, conglomerate, and lignite. Structurally conformable with underlying Colville group and no large erosional break indicated. Unconformably underlies Gubik formation. Contains early Tertiary flora.

T. G. Payne, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–84. Nonmarine. Contains bentonite, tuff. Maximum thickness 2,000 feet. Tertiary Paleocene(?).

Type locality: In Franklin Bluffs along lower part of Sagavanirktok River. Also well exposed in White Hills area.

**Sagavanirktok River Glaciation**

Pleistocene: Central northern Alaska.

R. L. Detterman, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 11, 13 (table 1). Four Quaternary glacial advances recognized in Sagavanirktok-Anaktuvuk district. Sagavanirktok, the oldest well-defined advance, succeeded Anaktuvuk glaciation (new); preceded Itkillik glaciation (new). Morainal remnants cover area of 230 square miles. Piedmont lobe probably was formed with maximum extension 30 miles north of mountains.

Renamed Sagavanirktok River Glaciation in order to retain name Sagavanirktok for formation.

Morainal remnants along Sagavanirktok River, 60 miles east of Anaktuvuk.

Sage Limestone (in Gallatin Group)

Sage Limestone Member (of Gallatin Formation)

Sage Limestone Member (of Red Lion Formation)

Sage Pebble-Conglomerate Member (of Snowy Range Formation)

Upper Cambrian: Central, southern, and southwestern Montana and northwestern Wyoming.

Christina Lochman, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2212. Proposed for upper member of Snowy Range formation. Intercalated shales and limestone pebble conglomerates with dense columnar limestone near base. Thickness 150 to 175 feet in southern Montana where entire member is preserved. Overlies Dry Creek shale member. Upper Sage members is lithic unit called "Pebbly limestone" by Peale (1893, U.S. Geol. Survey Bull. 110).

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 18. In southwestern Montana, considered member of Red Lion formation.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. Lochman (1950) revised and redescribed the Dry Creek shale and named what in Wyoming is called "upper Gallatin limestone" the Sage pebble conglomerates. This name seems applicable in Wyoming, but because of lithic changes, term Sage limestone is preferred. Dry Creek shale is thin and rarely mappable and most commonly should be regarded as member of Sage limestone. Gallatin formation is herein raised to rank of group and includes Sage limestone.

C. R. DeLand, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12. pt. 2, p. 1374. Sage limestone considered upper member of Gallatin formation in Wind River Mountains, Wyo.

Type locality: On south slope of Castle Rock, at junction of the East Fork with Mill Creek, N¼SE¼ sec. 13, T. 6 S., R. 9 E., Livingston quadrangle, Montana. Name derived from Lower Sage Creek which enters East Fork of Mill Creek 1½ miles up stream from type locality.

**Sage Breaks Shale Member** (of Carlile Shale)

Sage Breaks Shale Member (of Niobrara Formation)[1]

Upper Cretaceous: Northeastern Wyoming, southeastern Montana, and western South Dakota.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

H. D. Thomas, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 9, p. 1190 (table 1), 1194 (fig. 1), 1195. Term Sage Breaks member of Niobrara extended into Laramie basin, southeastern Wyoming. Replaces term "Carlile" as used in this area.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2187. Reallocated to member status in Carlile formation.

W. A. Cobban and J. B. Reeside, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 10, p. 1948–1949. South-southeast of Rapid City, S. Dak., 70 feet thick; at Belle Fourche, S. Dak., 200 feet; and in Carter County, Mont., 300 feet. In all these areas, the Sage Breaks is conformable with Turner sandy member of Carlile and disconformable with Niobrara. Member is absent over much of central Great Plains. Reasons for reallocation discussed.

Named for exposures in the Sage Breaks, in T. 56 N., R. 63 W., Weston County, Wyo.

Sage Creek Basalts

Eocene: Southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 373, pl. 1. Named for several small basalt flows that occur at base of Sage Creek formation in T. 12 S., R. 8 W., north of Sage Creek. Similar flows crop out 2 miles to northwest and on southwest side of Blacktail Range, secs. 2 and 11, T. 10 S., R. 9 W., where they are overlain by Cook Ranch formation (new). Rocks are all badly weathered.

Described in T. 12 S., R. 8 W., Beaverhead County.

Sage Creek Formation[1]

Eocene, upper, and Oligocene: Southwestern Montana.

Original reference: E. Douglass, 1903, Carnegie Mus. Annals, v. 2, p. 145–146.

Jean Hough, 1955, Jour. Paleontology, v. 29, no. 1, p. 22–36. Sage Creek problem discussed. Formation redefined to include 200 feet of higher breccias and tuffs at its type locality and in adjoining areas. As redefined includes Cook Ranch formation of Wood (1933).

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 373, pl. 1. Basalt flows occurring at base and top of formation are here named Sage Creek basalts.

Named for occurrences north of Sage Creek, about 7 miles northeast of Lima, Beaverhead County.

Sage Hen Limestone Member (of Colorado Shale)[1]

Upper Cretaceous: Central northern Montana.

Original reference: C. T. Lupton and Wallace Lee, 1921, Am. Assoc. Petroleum Geologists Bull., v. 5, p. 264, 266.

Named for exposures in Sage Hen Creek, Little Rocky Mountains region.

Sage Valley Limestone Member (of Goldens Ranch Formation)

Eocene, middle or upper: Central Utah.

Siegfried Muessig, 1951, Science, v. 114, no. 2957, p. 234. Relatively pure limestone with abundant plant remains. Occurs 820 feet above base of formation. Age considered middle or upper Eocene on basis of plant fossils.

Occurs in Long Ridge area, southwest of Levan, Juab County. Derivation of name not stated.

**Saginaw Formation[1]**

Saginaw Group

Pennsylvanian: Southern Michigan.

Original reference: A. C. Lane, 1901, Michigan Miner, v. 3, no. 1, p. 9.

W. A. Kelly, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 158 (table 1), 159, 165–205. Saginaw group is composed of material of fresh water, brackish water, and marine origin, and consists of sandstones, shales, coal, and limestones. Comprises many cyclical formations, one which, herein named Verne, contains a persistent shaly marine limestone member that makes it convenient to divide the group into pre- and post-Verne cyclical formations. Thickness 400 feet. Group directly overlies Parma sandstone wherever that formation is present; in some areas, directly overlies Bayport formation, as in area immediately north of Jackson; in several localities, may rest directly on Napolean sandstone. Underlies Grand River group herein proposed to include all strata younger than Saginaw. Type section given.

G. V. Cohee, Carol Mach, and Margery Holk, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–41, sheet 5. Recommended that Eaton and Ionia be considered members of Saginaw formation and that Woodville be restricted to a sandstone member in lower part of Saginaw.

Michigan Geol. Soc., 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 28. Includes Verne limestone member. Seven cyclothems, of which Grand Ledge is typical, are recognized in vicinity of Grand Ledge, Eaton County.

Type section: Near Grand Ledge, Eaton County. Name derived from Saginaw Valley and Saginaw County.

**Sailor Canyon Formation**[1]

Lower and Middle Jurassic: Northern California.

Original reference: H. W. Turner, 1894, Am. Geologist, v. 13, p. 232.

N. L. Taliaferro, 1942, Geol. Soc. America Bull., v. 52, no. 1, p. 99–100. Near northern end of Sierras, Triassic and Jurassic sediments and volcanics have been named Milton and Sailor Canyon formations, but there is little doubt that they are equivalent. Since name Milton has priority, it is used here to include all Triassic and Jurassic rocks of higher parts of Sierra Nevada, south of Taylorsville.

E. D. McKee and others, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–300. Correlation chart (table 1) shows lowermost part of Sailor Canyon formation in Upper Triassic.

Named for exposures in Sailor Canyon, which drains into American River about 6 miles south-east of Cisco, Placer County.

**St. Albans Slate**[1]

St. Albans Slate (in Woods Corners Group)

Middle Cambrian: Northwestern Vermont.

Original reference: J. Marcou, 1862, Boston Soc. Nat. History Proc., v. 8, p. 239–253.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1021, 1039–1041. Type locality cited.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1 (column 70). Listed as St. Albans shale.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 532 (fig. 5), 536–537, pl. 1. St. Albans slate is commonly black, gray-black, or tan and is micaceous. At type locality, top of formation is soft tan to golden brown micaceous slate, highly cleaved and contorted. Locally contains thick conglomerate of large blocks of arenaceous dolomite. Near Swantown Junction, a mass of limestone conglomerate is tentatively assigned to the St. Albans. Estimated thickness about 200 feet ± 50 percent. Belt of outcrop widens northward from type locality, but structure exposed in bed of Stevens Brook suggests that beds have flattened out and that formation has not thickened in that direction. Elsewhere than at type locality, formation is commonly less than 100 feet thick. Overlies Rugg Brook dolomite underlies Mill River conglomerate and Skeels Corners slate. Basal formation of Woods Corners group (new). Middle Cambrian.

Type locality: Adams pasture, at western edge of St. Albans, north of road from St. Albans to St. Albans Bay, Franklin County.

St. Charles Intraglacial Substage

Pleistocene (Wisconsin): North-central United States.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 549, 550. Name applied to Tazewell-Cary intraglacial substage. Represented by cutting of Fox River valley.

Named for St. Charles, the locality where Minooka moraine of Cary substage descends into the valley. Later West Chicago moraine of Cary substage also descends into this valley near town of Cary.

**St. Charles Limestone**[1]

Upper Cambrian: Southeastern Idaho and northeastern Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 6.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1108–1109, 1117 (fig. 4), 1123–1124. Walcott gave thickness of St. Charles as 1,227 feet in Blacksmith Fork section, Utah. Section is herein emended to exclude upper 777 feet which were found to contain Ordovician fossils. As emended, formation is about 400 feet thick; consists of basal dolomite zone about 148 feet thick and an upper limestone zone about 258 feet thick. Worm Creek quartzite member only questionably present here. Overlies Nounan dolomite.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 13, 14, pl. 1. Described in Randolph quadrangle, Utah, where it crops out on both limbs of Fish Haven syncline, on flanks of Bear River Range west of Garden City. Consists of basal Worm Creek quartzite and overlying limestone. Thickness approximately 400 feet. Overlies Nounan limestone. Restricted to lower 400 feet (approximately) of formation as defined by Walcott; upper 900 feet (approximately) now considered Lower Ordovician and assigned to Garden City limestone.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1134–1135, pl. 1. Described in Logan quadrangle, Utah. Overlies Nounan formation; underlies Garden City limestone. Consists of basal quartzite member (Worm Creek), middle member of thin-bedded limestone, and upper member of massive dark-gray dolomites. Deiss (1938) erred in redefinition of St. Charles in Blacksmith Fork section, because he failed to locate the Worm Creek which is distinctly present here. The 258 feet of limestone and intercalated intraformational conglomerates which he included at top of formation are basal Garden City.

H. W. Coulter, 1956, Idaho Bur. Mines and Geology Pamph. 107, p. 17–19, geol. map. Thickness east of Willow Flat, Idaho, 771 feet; Worm Creek 170 feet. Overlies Nounan formation; underlies Garden City formation.

Type locality: West of St. Charles, Bear Lake County, Idaho.

St. Clair facies (of Murfreesboro Limestone)

Middle Ordovician: Southwestern Virginia.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 126, 132, 133. Name given to a purely limestone facies in the Murfreesboro. Thickness varies from 271 feet in Lee County to as much as 1,142 feet near Bluefield, Tazewell County. The St. Clair is confined to the northwest belt of the Murfreesboro and the Blackford facies (new) to the southeast side.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 88–89. Limestone referred to by Butts (1940) as Murfreesboro is now known not to be Murfreesboro, and the limestones have been placed in other formations.

Well exposed just south of St. Clair Railroad station, 2½ miles west of Bluefield, Tazewell County.

**St. Clair Limestone**[1]

St. Clair Formation (in Bainbridge Group)

Silurian: Northern Arkansas, southern Illinois, and central eastern Oklahoma.

Original reference: R. A. F. Penrose, Jr., 1891, Arkansas Geol. Survey Ann. Rept. 1890, v. 1, p. 102–103, 112–114, 124–128, 166–174.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 12, 13. Lower formation of Bainbridge group. Name is here applied regionally to the pink crinoidal limestone of early Niagaran age throughout its distribution in midwestern States except where local names are applicable to separate tongues in marginal areas, as the Lego and Laurel tongues in Tennessee and a tongue in base of Joliet formation in Illinois and Wisconsin. Underlies Moccasin Springs formation (new). Thickens progressively east and northeast from 20 to 25 feet in outcrop area along Ozark border to about 80 feet near Illinois-Indiana boundary; maximum Illinois thickness 80 to 150 feet over area beneath and just beyond wedge edge of overlying Moccasin Springs formation; locally reaches thickness of 200 feet; thins nortnwestward from area of greatest development by interfingering and gradation of upper beds into rocks typical of Chicago area with only basal member maintaining its identity. Formation occupies belt about 100 miles wide, lying on east and southsides of Ozark highland, and extending discontinuously from western Oklahoma and west-central Texas through Arkansas, western Tennessee, western Kentucky, Illinois, and Indiana to central part of Michigan basin. [Discussion of Niagaran reefs in Illinois and their relation to oil accumulation; much data relative to thickness and distribution of unit are based on subsurface studies].

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as St. Clair limestone.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 29–33, pl. 4. Described as St. Clair formation in northeastern Oklahoma on south and west flanks of Ozark uplift, where it is best exposed in Marble City area on southern and eastern sides of Quarry Mountain. Characteristically white to pink medium to coarsely crystalline massive-bedded limestone; locally has bluish tint. Because of lack of impurities and coarse texture has been called "marble" by quarry industry. Thickness 95 to 165 feet; maximum thickness not determined as base and top are not exposed near areas of greatest development. Near Qualls unconformably overlies lower beds of the Sylvan; succeeded unconformably by Frisco limestone, Sallisaw sandstone, or Sylamore member of Chattanooga formation.

Named for St. Clair Springs, 8 miles northeast of Batesville, Independence County, Ark.

†St. Claire Shale[1]

Upper Devonian: Michigan.

Original reference: A. C. Lane, as reported by M. E. Wadsworth, 1893, Michigan Geol. Survey Rept. 1891 and 1892, p. 66.

Named for exposures along St. Clair River, St. Clair County.

St. Cloud Granite[1]

Precambrian: Wisconsin.

Original reference: C. C. Wang, 1932, Geol. Soc. China Bull., v. 11, no. 4, p. 426–428.

St. Cloud Gray Grandodiorite

Precambrian (late Algoman): Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, 1002, 1009, 1012–1013, pl. 1. Massive but not homogeneous; exposures are dotted with small dark inclusions and schlieren, cut by numerous dikes and veins, and irregularly altered to a lighter pinker rock; this pink facies appears to be grandodiorite that was granitized by St. Cloud red granite, dikes and apophyses of which twist and branch irregularly and in some places form a network in the St. Cloud gray granodiorite. One of five major intrusives in late Algoman; these cannot be shown to be members of a single magma series; age relations of the named intrusives, St. Cloud gray granodiorite, Freedhem tonalite, Hillman tonalite, and Warman quartz monzonite, are indeterminate because no contacts are exposed.

Named for the fact that it occurs in vicinity of St. Cloud, Stearns County.

St. Cloud Red Granite (in Stearns Magma Series)

Precambrian (middle Keweenawan): Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60. no. 6, p. 1002, 1005–1006, pl. 1. Pink to red augite-hornblende granite. Cuts and contains inclusions of St. Cloud gray granodiorite, Freedhem tonalite, Hillman tonalite, and Thomson formation; cuts the quartz latite porphyry of the Stearns magma series and grades into the Rockville facies and porphyritic granite facies.

Crops out near St. Cloud, Stearns County; also in Benton, Mille Lacs, and Morrison Counties. Quarried extensively near St. Cloud.

St. Cloud Sandstone (in Greene Formation)[1]

Permian: Northern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 171.

Named for St. Cloud post office, Monongalia County.

†St. Croix Formation[1], Sandstone[1], Series[1], or Shales[1]

St. Croixan Formation

Upper Cambrian: Eastern Minnesota and western Wisconsin.

Original references: N. H. Winchell, 1873, Minnesota Geol. and Nat. History Survey 1st Ann. Rept. for 1872; 1874, Minnesota Geol. Nat. History Survey 2d Ann. Rept.; 1886, Minnesota Geol. Nat. History Survey 14th Ann. Rept., p. 334–337; C. W. Hall, 1889, Minnesota Acad. Nat. Sci. Bull., v. 3, p. 125–136; N. H. Winchell, 1900, Geol. map of Minnesota.

S. G. Bergquist, 1937, Michigan Acad Sci., Arts and Letters, Papers, v. 22, p. 421-435. Discussion of part of Alger County in which St. Croixan series of the Cambrian system come in contact with younger Hermansville calcareous formation, which, in Delta County, Ulrich and Hussey have tentatively assigned to Ozarkian system. Ulrich (personal commun.) gives evidence to support view that St. Croixan formation of Wisconsin area extends into Superior region of Alger County. The so-called Lake Superior sandstone would thus be included as a member of that formation. The Pictured Rocks, which rise out of Lake Superior as range of cliffs 100 to 150 feet high, are sculptured in St. Croixan formation.

Named for occurrence in St. Croix Valley, Minn.

**St. Croixan Series**[1]

St. Croixan Epoch[1]

Upper Cambrian: North America.

Original reference: C. D. Walcott, 1912, Smithsonian Misc. Colln., v. 57, no. 10, p. 306–307.

G. O. Raasch, 1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf., p. 302–315. St. Croixan series crops out in more or less crescentric belt having its base in central southern Wisconsin and its extremities in east-central Minnesota and in northern peninsula of Michigan. Belt includes northwest corner of Iowa and isolated inlier in northern Illinois. In area of outcrop, series is considerably less than 1,000 feet thick, but in subsurface reaches maximum of more than 2,000 feet. Supposed thickening takes place at base of series. Series embraces all beds from base of Mount Simon member of Dresbach to top of Madison formation. Excludes Bayfield sandstone of the Keweenawan and all older rocks; and Oneota formation of Ordovician and all younger deposits. Both lower and upper boundary coincident with major unconformities. Comprises (ascending) Dresbach formation with Mount Simon, Eau Claire, and Galesville members; Franconia formation with Ironton, Goodenough, Hudson, and Bad Axe members; Trempealeau formation with St. Lawrence, Lodi, and Jordan members; and Madison formation.

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935, Geol. Soc. America Bull., v. 46, no. 11, p. 1687–1744. Croixian series, Upper Cambrian of Upper Mississippi Valley, comprises (ascending) Dresbach formation with Mount Simon, Eau Claire, and Galesville members; Franconia formation with Ironton, Goodenough, Hudson, and Bad Axe members; and Trempealeau formation with basal greensand and conglomerate member, and St. Lawrence, Lodi, Jordan, and Madison members.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1227-1244. St. Croixian series in Minnesota comprises (ascending) Dresbach formation with Mount Simon, Eau Claire, and Galesville members; Franconia formation with Ironton, Taylors Falls, Hudson, and Bad Axe members; St. Lawrence formation with Nicollet Creek (new) and Lodi members; Jordan formation with Norwalk and Van Oser members. Minnesota classification differs from Wisconsin classification (Twenhofel, Raash, and Thwaites, 1935) or Conference classification (Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L) in that their Trempealeau is equivalent to the two topmost formations of Minnesota classification. Hinckley sandstone not included in St. Croixian series by Minnesota Geological Survey.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9 (geol. column), 24–49. As shown on geologic column, St. Croixian series occurs above Lake Superior series with Hinckley sandstone at top and below Beekmantownian series with Kasota sandstone at base.

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 165–184. In Upper Mississippi Valley, Croixan strata above Franconia formation consist of dolomite and dolomitic siltstone and sandstone overlain by massive nondolomitic sandstone. Previous classifications of this successions have employed both faunal and lithologic criteria for discrimination of formations and members. Strata can be divided on lithologic characters alone. Terms St. Lawrence and Jordan formations are applied to the dolomitic strata and massive sandstone respectively. Strata with which present report is concerned have in past been called St. Lawrence, Mendota, Trempealeau, Black Earth, Nicollet Creek, and Lodi. Trempealeau should be abandoned as formational term and its usage restricted to Trempealeauan stage.

W. C. Bell, R. R. Berg, and C. A. Nelson, 1956, Internat. Geol. Cong., 20th, Mexico City, Cambrian Symposium, pt. 2, p. 415–446. Discussion of Croixan type area, Upper Mississippi Valley. By usual definition, the Croixan is said to constitute those rocks that originated during Late Cambrian epoch of geologic time, but in practice the Croixan is defined by those faunal assemblages that by common agreement among paleontologists are assigned to the Croixan. In North America, lowest Ordovician faunas are characterized by trilobites *Symphysurina*, *Bellefontia*, and *Hystrictus*, among others, and lowest and highest Croixan faunas are characterized, respectively, by *Cedaria* and *Plethopeltis*. Only in central Texas have trilobite faunas on both sides of this commonly accepted systemic boundary received critical attention, and this study has not been published; the boundary lies within conformable strata of San Saba member of Wilberns formation. A similar situation is reported in Montana (Lochman and Duncan, 1944, Geol. Soc. America Spec. Paper 54). Neither lowest or highest strata of type Croixan series have received critical lithostratigraphic and biostratigraphic attention, nor have Raasch's biostratigraphic studies been properly documented. Apparently there has been unanimous agreement among previous workers that Croixan series consists of several formations—variously named—and that highest formation is topped by unconformity at Cambrian-Ordovician boundary. This connection is so deeply rooted that Kasota sandstone is defined as reworked Jordan sand continuing Ordovician fauna and overlying Jordan unconformably. It is herein contended that the commonly accepted Cambrian-Ordovician faunal change occurred at Kasota and St. Peter during deposition of sand that today is part of lithogenetic unit that bears formational name Jordan sandstone. In other words, to Croixan series are assigned fossiliferous strata (and their presumed unfossiliferous temporal equivalents) that contain fossil faunas that by consensus are called Croixan and to rock units such as Jordan sandstone are assigned strata on basis of petrologic criteria. In type area, Croixan series consists of two transgressive-regressive sedimentary cycles of marine deposition. Lower cycle, comprising Dresbach formation, is underlain and overlain by unconformities. Upper cycle comprising Franconia, St. Lawrence, and Jordan formations reached maximum transgressive extension during deposition of Black Earth wedge and has unconformity at its top by implication but not thus far by demonstration. Series includes Dresbachian, Franconian, and Trempealeauan stages.

Type area: Upper Mississippi Valley. Name derived from St. Croix River, Minn.

St. David cyclothem (in Carbondale Formation)

St. David cyclothem (in Carbondale Group)[1]

Pennsylvanian: Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 102-107, 197 (geol. section 21). Includes (ascending) Springfield (No. 5) coal, St. David limestone, and Canton shale. Thickness 18 to 55 feet in localities where upper part is not truncated by Cuba sandstone. Appears to be conformable on Summum cyclothem; contact with overlying Brereton cyclothem is an erosional unconformity along which more than 50 feet of St. David strata are locally eroded. Name St. David was originally applied to the limestone by Savage (1927) and subsequently extended to entire cyclothem. Type locality and derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Carbondale formation (redefined). Above Summum cyclothem and below Brereton cyclothem in northern, western, and eastern areas and below Briar Hill cyclothem (new) in southwestern and southeastern areas. Presentation of new rock-stratigraphic classification of Pennsylvanian in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Ravine sloping southeast to Big Creek, SE¼SE¼ sec. 17, NE¼NE¼ sec. 20, and NW¼NW¼ sec. 21, T. 6 N., R. 4 E., 1 mile west of St. David, Havana quadrangle, Fulton County.

St. David Limestone Member (of Carbondale Formation)

St. David Limestone (in Carbondale Group)

St. David Shale and Limestone (in Carbondale Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 207–316.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 105–106, 197. St. David limestone included in St. David cyclothem, Carbondale group. Limestone is most typically developed in north half of Havana quadrangle where it is a single bed 10 inches to 2 feet thick, light blue gray, dense, and fossiliferous; weathers to buff or light yellow brown. Overlies and underlies unnamed shale intervals. Stratigraphically below Canton shale.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 47 (table 1), pl. 1. Rank reduced to member status in Carbondale formation (redefined). In southern area, occurs above Harrisburg (No. 5) coal member and below Briar Hill (No. 5A) coal member. In western and northern area, occurs above Springfield (No. 5) coal member and below Canton shale member. Replaces Absher limestone. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: SE¼SE¼ sec. 17, T. 6 N., R. 4 E., Fulton County. Named for exposures near St. David.

St. Edwards Tuff (in Burditt Marl)

Upper Cretaceous: South-central Texas.

C. O. Durham, Jr., 1955, Corpus Christi Geol. Soc. [Guidebook] Ann. Field Trip, March 11–12 [p. 59], pl. 16. Occurs within basal Burditt marl. Younger than Pilot Knob tuff (new).

Exposed near St. Edwards University, south of State Capitol, Austin, Travis County.

St. Elias Schist[1]

Age(?): Southeastern Alaska.

Original reference: I. C. Russell, 1891, Nat. Geog. Mag., v. 3, p. 167–175.

St. Elias Range in St. Elias region.

†St. Elizabeth Formation[1]

Lower Ordovician (Beekmantown) : Central Missouri.

Original reference: S. H. Ball and A. F. Smith, 1903, Missouri Bur. Geology and Mines, v. 1, 2d ser., p. 50.

Named for St. Elizabeth, Miller County.

St. Francis Series or Group

Silurian(?) and Devonian: Quebec, Canada, and Massachusetts and Vermont.

T. H. Clark, 1937, Canada Geol. Survey Mem. 211, p. 37–42. Series made up of two members, a group of lavas and a formation consisting mainly of impure quartzite and graywacke. Thickness of lavas may be in excess of 8,000 feet. Thickness of series may be as much as 10,000 feet. Northern boundary is line drawn from Lac Rocheux in Adstock Township to Elgin Lake in Stratford. Series underlies all of Disraeli map area southeast of this line, except parts underlain by Winslow granite and Lake Aylmer series.

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 7. Group extends from Quebec to Massachusetts. In Vermont, includes Waits River formation and Gile Mountain formation. Tentatively assigned to Devonian.

J. H. Eric and J. G. Dennis, 1958, Vermont Geol. Survey Bull. 11, p. 18, pl. 1. Group includes Northfield slate, Waits River formation, Gile Mountain formation, and Meetinghouse slate. Devonian and Silurian(?).

St. Francis Lake and St. Francis River are in Quebec.

†St. Francois Limestone[1]

Upper Cambrian: Eastern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 346, 349–354.

Named for St. Francois County.

†Ste. Genevieve Group[1]

Mississippian: Missouri, Illinois, and western Kentucky.

Original reference: C. R. Eastman, 1903, Harvard Coll. Mus. Comp. Zoology Bull., v. 39, no. 7, p. 195.

†Ste. Genevieve Group[1]

Mississippian: Missouri, Illinois, and Iowa.

Original reference: H. S. Williams, 1922, Pan-Am. Geologist, v. 37, no. 1, p. 39–40.

Probably named for Ste. Genevieve County, Mo.

**Ste. Genevieve Limestone**

Ste. Genevieve Limestone (in Blue River Group)

Ste. Genevieve Limestone (in Meramec Group)[1]

Upper Mississippian (Meramec Series): Eastern Missouri, northern Alabama, Georgia, southern Illinois, Indiana, Iowa, Kentucky, and Tennessee.

Original reference: B. F. Shumard, 1860, St. Louis Acad. Sci. Trans., v. 1, p. 406.

Stuart Weller and F. F. Krey, 1939, Illinois Geol. Survey Rept. Inv. 60, p. 7–8. Ste. Genevieve limestone, Iowa series, described in Dongola, Vienna, and Brownfield quadrangles where it is as much as 300 feet thick, overlies St. Louis limestone and underlies Renault limestone of Chester series. Fredonia, Rosiclare, and Levias members recognized in Dongola quadrangle but are poorly exposed and cannot be mapped separately. In addition to these members, a variable succession of clastic beds including some limestone overlies the Levias in Union County, and for these name Hoffner member is proposed.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 133–134. Ste. Genevieve limestone classified as uppermost formation in Meramec group, Valmeyer series. Overlies St. Louis limestone; underlies Aux Vases sandstone of New Design group (new) Chester series. In southeastern Illinois, consists of three members (ascending): Fredonia limestone, Rosiclare sandstone, and Levias limestone.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 366–378. Ste. Genevieve limestone occurs in Virginia in two different facies: pure oolitic limestone along Cumberland escarpment and in northwestern margin of Appalachian Valley next to the coal fields and predominant shale with subordinate limestone beds along middle belt of Greendale syncline from Saltville, Smyth County, to Tennessee. Overlies St. Louis limestone; underlies Gasper limestone. Thickness 85 to 1,500 feet.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 815–817. Classified as uppermost formation in Meramec group, Iowa series. This classification follows that of Illinois Geological Survey.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 160–164. In this report [Burkes Garden quadrangle], term Ste. Genevieve is used in tentative sense for beds which possible, though not certainly, are same age as Ste. Genevieve of type region. Thickness 300 to 525 feet. Overlies Hillsdale limestone which name is used to replace St. Louis limestone as used by Butts (1940); underlies "Gasper" limestone of Chester series. Ste. Genevieve of this report may correspond to the lower, or Fredonia member, of the Ste. Genevieve of Ohio Valley. In West Virginia, the same beds are classified with the Sinks Grove and Patton limestones. The "Ste. Genevieve" corresponds to lower part of Newman and Greenbrier limestones of older reports. Meramec series.

F. E. Tippie, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 11, p. 1654–1667. Formation is overlain by Renault formation in Hardin and Pope Counties, Ill. In southwestern Illinois, the Aux Vases sandstone intervenes between the Ste. Genevieve and Renault, but it is not present east of western Johnson County. Ste. Genevieve consists of (descending) Levias limestone, Rosiclare sandstone, and Fredonia limestone members. Unconformity at top of the Fredonia is more important than the one at top of the Levias limestone. If this condition should be true for all of Illinois basin, it may develop that the base of the Rosiclare sandstone, rather than base of Aux Vases sandstone as now recognized, should be considered base of Chester series.

C. A. Malott, 1946, Jour. Geology, v. 54, no. 5, p. 322–326. Entire Ste. Genevieve is exposed at double falls of Mill Creek near Cataract, Owen

County, Ind. Thickness 75½ feet. Overlies St. Louis limestone; underlies thin representative of Aux Vases sandstone. Comprises (ascending) Fredonia, Rosiclare, and Levias members. Unit referred to as "Cataract Falls sandstone" (Malott, 1945) is correlated with Rosiclare sandstone of southern Illinois.

D. H. Swann and Elwood Atherton, 1948, Jour. Geology, v. 56, no. 4, p. 269–287. Comparison of logs of closely spaced wells and their assembly into cross sections appear to demonstrate a number of inconsistencies in nomenclature that is currently applied to lower part of Chester series and to Ste. Genevieve formation in different parts of Eastern Interior Basin. Evidence indicates that the oil-producing "Aux Vases" sand of central basin area is equivalent to outcropping Rosiclare sandstone member of Ste. Genevieve; the Levias limestone and part of Shetlerville (Renault) together form a continuous limestone sequence which overlies both "Aux Vases" of the basin and Rosiclare sandstone of outcrop area in southeastern Illinois.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 46, geol. map. Geographically extended into northwestern Georgia where it is about 90 feet thick. Overlies St. Louis limestone; underlies Gasper limestone.

A. H. Sutton, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 7, p. 1661–1668. Discussion of Ste. Genevieve-Renault contact and article by Tippie (1945). Evidence presented to show that unconformity between the Levias and Renault is of greater magnitude and much more significant than the one between the Fredonia and Rosiclare and that Renault limestone and shale or Aux Vases sandstone were it is present, and not Rosiclare sandstone, is basal unit of Chester series.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 18–22, 30–36, pl. 1. Ste. Genevieve limestone (late Meramec) and Chester formations (late Mississippian) crop out in northward-narrowing wedge from Ohio River to west-central Putnam County, in central Indiana. Ste. Genevieve comprises (ascending) Fredonia, Rosiclare, and Levias members. The Fredonia contains Lost River chert, and the Levias contains the Bryantsville breccia. Thickness 70 to 170 feet. Underlies Aux Vases formation; base not exposed in many areas. Field separation of Levias member from younger Paoli limestone is dependent upon recognition of Aux Vases formation if it is present or upon Bryantsville breccia. Where Bryantsville breccia is present and exposed, it is best stratigraphic marker and easiest means of locating the boundary, as currently defined, between Meramec and Chester series.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Alsobrook member of Pride Mountain formation (new) of Colbert County, Ala., and Tishomingo County, Miss., and the *Platycrinites*-bearing beds of the eastern counties are the strata that Butts (1926, Alabama Geol. Survey Spec. Rept. 14) referred to Ste. Genevieve limestone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 50–51, pl. 1. Included in Blue River group (new). Overlies St. Louis limestone; underlies Paoli limestone. Oldest formation exposed in Huron area [this report]. Only upper 35 feet exposed.

Named for outcrops in Mississippi River bluffs 1 or 2 miles below Ste. Genevieve, St. Genevieve County, Mo.

†Ste. Genevieve Marble[1]

Mississippian: Central eastern Missouri.

Original reference: G. C. Swallow, 1855, Missouri Geol. Survey 2d Ann. Rept., pt. 1, p. 96.

Quarried at St. Genevieve, St. Genevieve County.

†Ste. Genevieve Sandstone (in Chester Group)[1]

Mississippian: Central eastern Missouri.

Original reference: J. A. Gallagher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 37.

Named for exposures at Ste. Genevieve, Ste. Genevieve County.

**St. George Formation**[1]

Pliocene: Northwestern California.

Original reference: J. H. Maxson, 1933, California Jour. Mines and Geology, v. 29, nos. 1–2, p. 135, map.

William Back, 1957, U.S. Geol. Survey Water-Supply Paper 1254, p. 17 (table), 20–23, pl. 5. Principally massive poorly bedded siltstone and shale containing discontinuous irregular lenses and beds of sand and scattered pebbles and carbonized wood fragments. Exposed thickness about 75 feet near Point St. George; maximum thickness estimated about 400 feet. Underlies Battery formation; overlies Jurassic rocks. Pliocene.

Named for exposures in sea cliff at Point St. George, Del Norte County. Crops out for about 1½ miles south from Point St. George along Pebble Beach and for a short distance to north of Point St. George.

**St. Helena Rhyolite Member** (of Sonoma Volcanics)

St. Helena Rhyolite[1]

Pliocene: Northern California.

Original reference: V. C. Osmont, 1904, California Univ. Pub., Dept. Geology Bull., v. 4, p. 59–87.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 110 (table 24), 122, 123, 128–130, pls. 6, 7, 10. Described and mapped as St. Helena member of Sonoma volcanics. Consists of lava flows, tuffs, and breccias with lentils of sandstone and conglomerate; ranges in thickness from 50 to over 500 feet; in most areas, rests on upper tuffaceous and andesitic units of the Sonoma volcanics. In Mayacmas Mountains, rhyolites appear to transgress the andesites and rest on shales of the Knoxville. Most typical development of the flows and tuffs occurs in higher parts of Howell Mountains east of Napa.

Apparently named for occurrence on Mount St. Helena, Sonoma County.

**St. Ignace Formation**

St. Ignace Dolomite (in Salina Group)

St. Ignace Formation (in Bass Islands Group)

Upper Silurian (Cayugan): Northern Michigan.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv. Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 34, 35 (table 1), 53–73. Proposed for youngest known Upper Silurian in Northern Peninsula. Occupies position between Upper Silurian Pointe aux Chenes formation (new) and Lower Devonian Garden Island formation (new). In some areas, underlies Bois Blanc formation (new); as result of collapse of rocks in region, large segments of St. Ignace are present in Mackinac breccia. Lower part of formation consists of even-bedded very light gray, cream-colored, and light-buff dolomites; upper part consists of thick-bedded buff dolomites overlying thick-bedded light-gray dolomites. Thickness of exposed sections varies from 10 to 76 feet; however, probable order of superposition of the strata exposed in many blocks of the Mackinac breccia indicates that thickness may not be less than 250 feet and not more than 300 feet. Bass Island[s] group.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 24. Most of strata are dolomite; hence, unit is termed St. Ignace dolomite. Assigned to Salina group.

Named for exposures within the Mackinac breccia in St. Ignace area. Also occurs on Mackinac Island. Underlies Round Island, northern part of Bois Blanc Island, and northern part of Garden Island.

St. James Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9. Dolomite with weak green shale partings. Thickness about 18 feet. Shown on columnar section as underlying Beecher member (new) and overlying Buckhorn member (new).

In copy of this guidebook used by compiler name Buckhorn had been crossed out and name Red Oak written in with pen. The compiler had no way to determine whether or not this change had been made in all copies of the guidebook.

Occurs in Dixon-Oregon area.

†St. Joe Limestone (in Shawnee Formation)[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 52–53.

Named for exposures near St. Joseph, Buchanan County.

**St. Joe Limestone Member** (of Boone Formation)[1]

St. Joe **Group**

St. Joe Limestone or **Formation**

Lower Mississippian: Northern Arkansas, eastern Oklahoma, and southwestern Missouri.

Original reference: T. C. Hopkins, 1893, Arkansas Geol. Survey Ann. Rept. 1890, v. 4, p. 10, 212, 253–349, pl. 10.

L. M. Cline, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 9, p. 1137–1141. Rank raised to formation.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 204–207. Limestone comprises Compton, Northview, and Pierson members.

C. P. Kaiser, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2157–2161. Formation typically consists of light-gray crinoidal limestone with a red to green silty and shaly zone near middle. Thickness 0 to 75 feet. Rests unconformably on Sedalia, Northview, Sylamore, and Chattanooga formations from north to south and at a few places on Ordovician. Conformably overlain by Reeds Spring limestone. Present only in southern part of area of this report [southwestern Missouri]. Recommended that term Pierson be dropped as a synonym for St. Joe.

T. R. Beveridge and E. L. Clark, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 75. Rank raised to group. Comprises (ascending) Compton, Northview, and Pierson formations. Kinderhook-Osage boundary is considered to be at contact of Northview with Pierson. Hence, St. Joe group straddles series line. In some parts of southwestern Missouri, the Northview, although persistent, is too thin to map. In such cases, the St. Joe group may be mapped as an undifferentiated unit. Overlies Chattanooga; underlies Reeds Spring.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 41–43, pls. 1–5. Group described on south and west flanks of Ozark uplift. Three-fold lithic development present. Basal part consists of about 10 feet of gray nodular-weathering limestone which is thin bedded in upper parts; middle part composed of 3 to 5 feet of olive-green soft limy shale; upper part consists of maximum of 25 feet of gray, thick-bedded finely crystalline limestone. Maximum thickness 40 feet. Thins southward by loss of units and by unconformity at top. Unconformably overlies Chattanooga shale; unconformably underlies Reeds Spring formation. Kinderhookian-Osagean.

Named for exposures at St. Joe, Searcy County, Ark.

†St. Joseph Formation[1]

Mississippian: Southeastern Indiana.

Original reference: P. B. Stockdale, 1929, Ohio Jour. Sci., v. 29, no. 4, p. 170.

Probably named for St. Joseph, Clark County.

†St. Joseph Limestone[1]

Upper Cambrian: Eastern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 347.

Named for mines of St. Joseph Lead Co. near Fredericktown, Madison County.

St. Landry Marble[1]

Cretaceous(?) : Southwestern Louisiana.

Original reference: E. W. Hilgard, Suppl. and Final Rept. Geol. Reconn. Louisiana, 1869, p. 12.

St. Landry and Evangeline Parishes.

**St. Laurent Limestone[1]**

St. Laurent Formation

Middle Devonian: Eastern Missouri and southern Illinois.

Original reference: C. L. Dake, 1918, Missouri Bur. Geology and Mines, v. 15, 2d ser., p. 88, 175.

J. M. Weller *in* J. M. Weller and G. E. Ekblaw, 1940, Illinois Geol. Survey Rept. Inv. 70, p. 16; J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 26. Strata intervening between Grand Tower limestone (or Dutch Creek sandstone where Grand Tower is absent) and the black Mountain Glen shale (or the Springville shale where Mountain Glen is absent) have been referred by Savage (1920) to the Misenheimer shale and Lingle and Alto limestones. Restudy of area suggests that recognition of these three formations may be neither stratigraphically logical nor practically feasible. It might be advisable to apply to them name St. Laurent formation which is used for the Devonian overlying Grand Tower limestone in southeastern Missouri.

G. A. Cooper and others, 1942, Geol. Soc. America Bull. v. 53, no. 12, pt. 1, p. 1778–1779, chart 4. Occurs in two areas not yet satisfactorily correlated: one is in Union and Jackson Counties, Ill., and an adjacent series of outcrops on west side of Mississippi in Altenburg quadrangle, Missouri; other is in Little Saline Valley south of Ste. Genevieve, Mo. St. Laurent limestone is herein regarded as lower Hamilton (Cazenovia stage) and below Lingle limestone. Present position of St. Laurent is tentative but it seems unlikely that formation can be placed above Lingle because no post-Centerfield (Tioughnioga) formations are now known in Midwest.

Named for exposures along St. Laurent Creek, Perry County, 3 miles south of St. Mary's, Ste. Genevieve County, Mo.

**St. Lawrence Formation**[1]

**St. Lawrence Member** (of Trempealeau Formation)

Upper Cambrian: Southern Minnesota, Illinois, Iowa, and southern Wisconsin.

Original reference: N. H. Winchell, 1874, Minnesota Geol. Nat. History Survey 2d Ann. Rept., p. 86, 132, 138–157.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 236 (table 2). Chart shows St. Lawrence formation comprises (ascending) unnamed shale, Mendota, and Lodi members. Underlies Jordan sandstone.

C. R. Stauffer, G. M. Schwartz, and G. M. Thiel, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1902. In suggested revised Cambrian classification for Minnesota, St. Lawrence formation includes Judson (new) and Lodi members.

C. R. Stauffer, G. M. Schwartz, and G. A. Theil, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1237–1239. Discussion of St. Croixian classification of Minnesota. St. Lawrence formation comprises (ascending) Nicollet Creek (new) and Lodi members. Overlies Franconia formation; underlies Jordan formation.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9, 30, 42–46, measured sections. Formation discussed in detail. St. Croixian series.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart as member of Trempealeau formation.

G. O. Raasch, 1951, Illinois Acad. Sci. Trans., v. 44, p. 147. Member of Trempealeau. Overlies Arcadia member (new); underlies Lodi member.

R. R. Berg, 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 860–861. Above Franconia is a nonglauconitic unit of dolomite, dolomitic siltstone, and very fine- grained sandstone, first named St. Lawrence in Minnesota and later named Trempealeau in Wisconsin. St. Lawrence is used in this report [southern Minnesota and west-central Wisconsin] because of priority.

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 167–171, 173–177, measured sections. Discussion of upper Croixan stratigraphy in upper Mississippi Valley. Terminology adopted represents return to early lithologic classification in which St. Lawrence and Jordan formations are recognized as the dolomitic strata and the massive sandstone, respectively. St. Lawrence of present study consists of dolomitic sediments between Franconia below and Jordan above. Subdivided into Black Earth member below and Lodi member above. Term Nicollet Creek member abandoned. Thickness 63 feet in typical basinward exposure at Lake City; 15 feet in shoreward areas at Ridgeland and Kingston. Suggests that term Trempealeau, previously used as a formation name to include above strata and also as a stage name, be restricted to Trempealeauan stage.

Named for exposures at St. Lawrence, Scott County, Minn.

†St. Lawrence Limestone or Dolomite Member[1] (of Trempealeau Formation)

Upper Cambrian: Southern Minnesota and southern Wisconsin.

Original reference: F. T. Thwaites, 1923, Jour. Geology, v. 31, p. 547.

Exposed at St. Lawrence, Scott County, Minn.

†St. Louis Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

**St. Louis Conglomerate**[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, p. 2, p. 79, 83.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

Occurs on St. Louis property, Houghton County.

†St. Louis Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

†St. Louis Group[1]

Mississippian: Missouri, Tennessee, Illinois, Iowa, and western Kentucky.

Original reference: A. H. Worthen, 1866, Illinois Geol. Survey, v. 1, p. 41–43, 83–89.

Named for St. Louis, Mo.

**St. Louis Limestone**

St. Louis Limestone (in Blue River Group)

St. Louis Limestone (in Meramec Group)[1]

Upper Mississippian (Meramec Series): Missouri, Alabama, Georgia, Illinois, Indiana, Iowa, Kentucky, Tennessee, and southwestern Virginia.

Original reference: G. Engelmann, 1847, Am. Jour. Sci., 2d, v. 3, p. 119–120.

Charles Butts, 1922, Kentucky Geol. Survey, 6th ser. v. 7, p. 120–136. In northern central Tennessee and southeastern Kentucky, the St. Louis overlies Garrett Mill sandstone member (new) of Warsaw formation. Underlies Ste. Genevieve limestone.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 133. Classified as formation in Meramec group, Valmeyer series. Overlies Salem (Spergen) limestone; underlies Ste. Genevieve limestone.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 813–815. Middle formation in Meramec group, Iowa series. Overlies Salem limestone; underlies Ste. Genevieve. This classification follows Illinois Geological Survey. In southeastern Iowa, the St. Louis comprises (ascending) Croton and Verdi members; overlies older Mississippian strata unconformably and overlaps formations as low as the Kinderhook. In western Illinois and northeastern Missouri, the St. Louis has not been separated from overlying beds that may be Ste. Genevieve in age. In Indiana, the St. Louis constitutes lower part of Mitchell limestone up to and including Lost River chert member.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 359–366. In Virginia, the St. Louis rests upon Fort Payne chert or upon Price formation, as in Cumberland-Big Stone Gap area, and southeast of South Clinchfield, Russell County; upon the Maccrady or possibly upon the Warsaw, as at Bluefield, in the Narrows of New River, 1 mile southeast of Richlands, and 2 miles southeast of Bandy, Tazewell County. Succeeded by Ste. Genevieve limestone everywhere from Ste. Genevieve, Mo., to Appalachian Valley.

Paul Averitt, 1941, Virginia Geol. Survey Bull. 56, p. 14–15, 17. In Scott and Washington Counties, consists of 265 feet of very dark colored thick-bedded crystalline limestone overlain by 50 feet of shale and underlain by 16 feet of argillaceous limestone. Underlies limestones of Gasper and Ste. Genevieve ages; overlies Little Valley limestone (new).

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 158. In this report [Burkes Garden quadrangle], term Hillsdale is used to replace St. Louis, name used by Butts (1940) for same succession in southwestern Virginia. There are several objections to continued use of name St. Louis in southwestern Virginia. Beds so named are not areally continuout with the St. Louis of Mississippi Valley. Not definitely established that the so-called St. Louis limestone of southwestern Virginia does not contain correlatives of Salem limestone.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 45–46, geol. map. Geographically extended into northwestern Georgia where it is about 100 feet thick. Underlies Ste. Genevieve limestone; contact with Fort Payne not exposed.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 47–49. Youngest Mississippian formation in Beardstown-Glasford-Havana-Vermont area. Maximum thickness about 30 feet in outcrop. Overlies Salem formation; separated from overlying Pennsylvanian strata by erosional unconformity. Meramec group, Valmeyer series.

Charles Collinson and D. H. Swann, 1958, Geol. Soc. America Guidebook St. Louis Mtg., Field Trip 3, p. 4 (fig. 3), 8, 9, 10–17. St. Louis-Ste. Genevieve boundary is in doubt in Alton, Ill., area as it is at many places in midwestern United States. Boundary has been placed at as many as four different positions at Alton Bluff outcrop, Madison County, as high as top of main white bed and as low as base of cycle h of cyclic beds. At other localities in area, boundary has been placed even higher, and possibly even lower. It is not possible to correlate individual beds from this area to Ste. Genevieve, some 80 miles south. Hence, a transition zone containing Ste. Genevieve-like oolites and fragmental limestone as well as St. Louis-like fine-grained light-colored pure limestones is placed in St. Louis limestone. Valmeyer series.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 48, 52. Included in Blue River group (new). Underlies Ste. Genevieve limestone. Not exposed in Huron area [this report].

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 2–4, pl. 1. Overlies Rocher member (new) of Salem limestone in southwestern Illinois.

Named for exposures in St. Louis, Mo.

†St. Louis Marls[1]

Mississippian: Iowa.

Original reference: H. Hinds, 1909, Iowa Geol. Survey, v. 19, p. 339.

Des Moines County.

†St. Louis Slate[1]

Precambrian: Northeastern Minnesota.

Original reference: R. D. Irving, 1888, U.S. Geol. Survey 7th Ann. Rept., p. 440–441.

†St. Louis River Gabbro[1]

Precambrian (Keweenawan): Northeastern Minnesota.

Original references: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept. p. 143–146, pl. 14; 1883, U.S. Geol. Survey Mon. 5.

Exposed along north of St. Louis River to Duluth, St. Louis County.

†St. Louis River Slate[1]

Precambrian (upper Huronian): Northeastern Minnesota.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 384.

Named for exposures on St. Louis River, St. Louis and Carlton Counties.

St. Luke Limestone Member (of Edinburg Formation)

Middle Ordovician: Western Virginia.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 81, 82. Proposed for the beds which form the topmost division of the Edinburg in Shenandoah Valley. Consists of rather pure, dove-gray limestone above the *Nidulites-Lambeophyllum* zone and below the *Reuschella "edsoni"* beds that characterize the basal Oranda formation (new). Thickness at type locality 90 feet.

Type locality: One mile S. 60° E. of St. Luke, Shenandoah County. Exposed west of U.S. Route 11, between Forestville and Saumsville.

St. Marks facies (of Tampa Stage)

Miocene, lower: Florida.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 16 (table 1), 20–21. Name St. Marks limestone (type locality, Wakulla County) was originally used by Finch (1823, Am. Jour. Sci., v. 7, p. 31–43) in describing the occurrence of large oysters. Name St. Marks revived to include calcareous downdip facies of Tampa stage. Near Tampa, facies consists of basal light-gray to yellow limestone of which "Silex bed" is a part. Upper part consists of greenish clay with calcareous nodules. Estimated thickness in subsurface 65 feet. Updip facies named Chattahoochee facies. [Finch, 1823 [1824], described a limestone at St. Marks, Fla., but did not use term St. Marks limestone.]

Ste. Marie Sandstone[1]

Upper Cambrian: Northern Michigan.

Original reference: W. E. Logan, 1863, Canada Geol. Survey Rept. Prog. to 1863, p. 196.

Sault Ste. Marie region.

**St. Mary River Formation**[1]

Upper Cretaceous: Southwestern Alberta, Canada, and northwestern Montana.

Original reference: G. M. Dawson, 1883, Canada Geol. Survey Rept. 1880–1882, p. 3B–6B.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 108 (fig. 1), 118. Overlies Horsethief sandstone and underlies Willow Creek formation on northwest flank of Sweetgrass arch, Montana. Thickness about 980 feet.

G. W. Viele, 1960, Dissert. Abs., v. 21, no. 4, p. 853. Overlies Hogan formation (new) in Flat Creek area, Lewis and Clark County, Mont.

Named for exposures on banks of St. Mary River, Alberta, a few miles north of Blackfeet Indian Reservation.

†St. Marys Epidote[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 25.

In St. Mary's mine, sec. 18, T. 55, R. 33, Houghton County.

**St. Marys Formation**[1] (in Chesapeake Group)

Miocene, middle and upper: Eastern Maryland, Delaware, and eastern Virginia.

Original reference: G. B. Shattuck, 1902, Science, new ser., v. 15, p. 906.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Age shown on correlation chart as middle and upper Miocene.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 78. Present in Delaware. Middle Miocene.

L. W. Stephenson and F. S. MacNeil, 1954, Geol. Soc. America Bull., v. 65, no. 8, p. 733–738. Underlies Yorktown formation in both Maryland and Virginia.

Named for development in St. Marys County and on St. Marys River, Md.

St. Marys Sandstone[1]

Upper Cambrian: Michigan and northeastern Wisconsin.

Original reference: C. Rominger, R. Pumpelly, and T. B. Brooks, 1873, Michigan Geol. Survey Atlas, map of Upper Peninsula.

Named for exposures on St. Mary's River, east end of Upper Peninsula of Michigan.

St. Marysan Substage

Miocene, middle: Maryland, New Jersey, and Virginia.

D. S. Malkin, 1953, Jour. Paleontology, v. 27, no. 6, p. 767, 768. Substage based on microfaunal assemblages; includes all sediments deposited in central Atlantic Coastal Plain province during time of accumulation of St. Marys formation, type exposure of which is considered exemplary of the substage. In sequence the St. Marysan succeeds Choptankian substage and is followed by Yorktownian substage.

†St. Maurice Formation[1]

Eocene, middle: Northwestern Louisiana.

Original references: W. C. Spooner, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, no. 1, p. 7; no. 3, p. 234–237.

†St. Maurice Formation (in Claiborne Group)[1]

Eocene, middle: Northwestern Louisiana and southwestern Arkansas.

Original reference: G. D. Harris, 1910, Science, new ser., v. 31, p. 502.

Named for exposures at St. Maurice, Winn Parish, La.

**St. Paul Group**

Middle Ordovician: Maryland, Pennsylvania, Virginia, and West Virginia.

R. B. Neuman, 1951, Geol. Soc. America Bull., v. 62, no. 3, p. 267–324, pls. 1, 2. Proposed as a substitute for "Stones River" group as mapped through West Virginia, Maryland, and the Mercersburg-Chambersburg quadrangles in Pennsylvania. Need for such substitution has been apparent since Cooper and Prouty (1943, Geol. Soc. America Bull., v. 54, no. 6) demonstrated that central Tennessee Stones River was definitely younger than Appalachian "Stones River." As proposed, the group is bounded above by Chambersburg limestone, or by Lincolnshire where it is present, and is underlain by Beekmantown group. Type section. 485 feet thick, contains two formations, a lower Row Park (new) and overlying New Market limestone. South of Bessemer, W. Va., group contains only New Market limestone.

F. M. Swartz and R. B. Thompson, 1958, Pennsylvania State Univ. Mineral Industries Exp. Sta. Bull. 71, p. 1–14. Row Park and New Market limestones of Middle Ordovician St. Paul group occur in Franklin County, Pa., as lower and upper parts respectively of rock mapped by Stose (1909, U.S. Geol. Survey Geol. Atlas, Folio 170) under name Stones River limestone in report on Mercersburg and Chambersburg quadrangles. Thickness 800 to 1,300 feet. Underlies Chambersburg limestone; overlies Beekmantown dolomite.

Carlyle Gray and others, 1960, Geologic map of Pennsylvanian (1:250,000): Pennsylvania Geol. Survey, 4th ser. As mapped, includes Annville formation.

Type section: On Boward Farm, south of U.S. Highway 40, about 500 yards southwest of St. Paul's church and junction of Maryland Highway 57 with U.S. Highway 40, 9 miles south of center of Hagerstown, Washington County, Md.

†St. Peter Group[1]

Lower Ordovician: Missouri.

Original reference: C. L. Dake, 1921, Missouri Univ. School Mines and Metallurgy, v. 6, no. 1.

**St. Peter Sandstone[1]**

Middle Ordovician: Minnesota, Arkansas, Illinois, Indiana, Iowa, Kansas, Kentucky, Michigan, Missouri, Ohio, Oklahoma, and Wisconsin.

Original reference: D. D. Owen, 1847, Prelim, rept. of the Geological Survey of Wisconsin and Iowa: U.S. Gen. Land Office Rept. 1847 (U.S. 30th Cong., 1st sess. S. Ex. Doc. 2), p. 169. 170.

H. S. McQueen, 1937, Missouri Geol. Survey and Water Resources 59th Bienn. Rept., app. 1, p. 10–11, 12, 22–23. In southeastern Missouri, the St. Peter overlies Everton formation and underlies Dutchtown formation (new); where Dutchtown is absent, the St. Peter underlies the Joachim formation.

C. R. Stauffer and G. A. Thiel, 1941, Minnesotota Geol. Survey Bull. 29, p. 66–69. Thickness at type section 155 feet. Overlies Shakopee dolomite; underlies Platteville formation. Chazyan series.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. [11], fig. 3, [22], fig. 12. In Dixon-Oregon area, St. Peter sandstone underlies Kingdom formation (new) of Glenwood subgroup of Ancell group (new).

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 255 (fig. 32), 273–274, 275. St. Peter sandstone, in lead-zinc district, is about 40 feet thick, overlies Prairie du Chien group [undifferentiated] and underlies Glenwood shale member of Platteville formation. Middle Ordovician.

Type section: At Fort Snelling, Hennepin County. Named for exposures on St. Peter River, now called Minnesota River, southern Minnesota.

**St. Regis Formation** (in Ravalli Group)[1]

Precambrian (Belt Series): Northeastern Idaho and northwestern Montana.

Original reference: F. L. Ransome, 1905, U.S. Geol. Survey Bull. 260, p. 277–285.

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 62, p. 37–39, pl. 11. Indurated shales and more or less flaggy sandstones; colors mostly green and purple; characterized by shallow-water features. Thickness about 1,000 feet. Overlies Revett quartzite; underlies Wallace formation.

F. C. Calkins, 1909, U.S. Geol. Survey Bull. 384, p. 38. Top formation of Ravalli group.

R. E. Wallace and J. W. Hosterman, 1956, U.S. Geol. Survey Bull. 1027–M, p. 582–584, pl. 48. Underlies Wallace formation; overlies Revett quartzite. In Idaho, typically gray to purplish-gray argillite, about 1,200 to 1,400 feet thick, and has an upper member of thinly laminated greenish argillite, 150 to 450 feet thick. In Mineral County, Mont., exhibits marked facies changes and thicknesses of as much as 3,000 to 5,000 feet.

Named for exposures in vicinity of St. Regis Pass, southeastern part of Coeur d'Alene district, Idaho.

St. Regis Granite

Precambrian: Northern New York.

A. F. Buddington, 1937, New York State Mus. Bull. 309, p. 8, 34–35, 38, 45–46; 1939, Geol. Soc. America Mem. 7, p. 136, 137. Pink hornblende granite; commonly contains narrow bands or small shreds of black amphibolite. In some areas, intrusive into Santa Clara complex (new) and in others adjacent to it.

Named for town of St. Regis Falls, Nicholville quadrangle, Franklin County.

†St. Stephens division,[1] Formation,[1], Group,[1] or Limestone[1]

Eocene, upper, and Oligocene: Southern Alabama.

Original reference: T. A. Conrad, 1856, Philadelphia Acad. Nat. Sci. Proc., v. 7, p. 257–258.

Named for exposures in bluff at St. Stephens, Washington County.

†St. Thomas Sandstone[1]

Lower Ordovician: Central Missouri.

Original reference: J. A. Gallaher, 1900, Missouri Geol. Survey, v. 13, p. 124.

Named for St. Thomas, Cole County.

St. Wendells Formation

St. Wendell Sandstone[1]

Pennsylvanian: Southwestern Indiana and southeastern Illinois.

Original reference: M. M. Fidlar, 1933, Indiana Acad. Sci. Proc., v. 42, p. 137.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 103. St. Wendells formation, a division of post-Allegheniau, between Friendsville above and Parker formation. Exposures noted.

F. D. Spencer, 1953, U.S. Geol. Survey Circ. 266, p. 14 (fig. 4). Chart shows St. Wendells sandstone underlying New Haven formation and overlying Parkers formation.

Fidlar appears to have applied this name to the same unit Culbertson (1932) called Claypole Hills Sandstone. Culbertson's St. Wendells Limestone appears to have been included in the Parker Formation by Fidlar.

Exposed near St. Wendells, Robinson Township, Posey County, Ind.

St. Wendells Limestone (in McLeansboro Formation)

Pennsylvanian: Southwestern Indiana.

J. A. Culbertson, 1932, The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 3, 7. Fossiliferous limestone; maximum thickness 4 feet. Separated from underlying Inglefield sandstone by Parker coal and black shale; underlies Claypole Hills sandstone (new).

This does not appear to be same as St. Wendell Sandstone of Fidlar (1933). It was apparently included in Fidlar's Parker Formation; Fidlar's St. Wendell Sandstone may be same as Culbertson's Claypole Hills Sandstone.

Type locality and derivation of name not given.

Sais Quartzite

Precambrian: Central New Mexico.

J. T. Stark and E. C. Dapples, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1936. Referred to as Sais quartzite. Older than Blue Springs muscovite schist (new); intruded by Los Pinos granite (new).

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1, p. 1127–1129, pl. 1. Rocks of Sais quartzite vary from light to dark gray, with greenish and nearly white facies in a few outcrops. Grain size rarely more than 1 mm. in diameter, and in most outcrops grains cannot be distinguished megascopically. Massive quartzose beds 3 to 5 feet thick alternate with thinner bedded zones, commonly sericitic. Intruded by Priest granite (new) at northernmost outcrop. Greatest thickness about 600 feet, measured at Abo Pass.

Named for Santa Fe Railway Station of Sais near Abo Pass. Excellent exposures in quarries of Atchison, Topeka, and Santa Fe Railroad near pass. Exposed on up-thrown side of thrust fault in belt extending along east flank of Los Pinos Range from Abo Pass southward for about 5 miles. Width of outcrop less than 500 feet in central part; averages 1,000 feet north of pass.

†Sakonnet Sandstone[1]

Pennsylvanian: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 357–365, pl. 31, map.

Forms upper part of Aquidneck series on east side of Sakonnet River and also across Portsmouth and Middletown Townships on west side of Sakonnet River, Newport County.

**Salado Formation**

Salado Halite

Permian (Ochoa Series): Western Texas and southeastern New Mexico.

Original reference: W. B. Lang, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 2, p. 262–270.

W. B. Lang, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 10, p. 1569–1572. Base of Salado formation redefined to include anhydrite formerly considered part of Castile formation. As redefined, base of Salado is placed at depth of approximately 3,300 feet in Means well (center of Loving County, Tex.) instead of at 2,350 feet as arbitrarily selected when unit was originally defined.

S. C. Giesey and F. F. Fulk, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 4, p. 598 (fig. 3), 601–604. In North Cowden Field, Ector County, Tex., the Salado underlies Rustler formation and overlies Tansill formation. Includes Cowden anhydrite member (new) in lower part.

W. B. Lang, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 1, p. 63–79. Discussion of basal beds of Salado in Fletcher potash core test, near Carlsbad, N. Mex. Sequence described extends from above Cowden member of Salado into underlying Carlsbad limestone. Two members of Salado are defined, La Huerta siltstone and Fletcher anhydrite (at base).

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 610–612. Salado formation, which overlies Castile formation, is poorly exposed in Gypsum Plain east of Delaware Mountains, but it may come to surface here and there near west edge of Rustler Hills. However, most of it is cut out in this region by unconformity at base of Rustler and it reaches its full thickness only east of the outcrop. As indicated by wells east of outcrops, maximum thickness of formation in Delaware basin is somewhat more than 2,000 feet, but decreases to 1,000 feet or less in shelf area beyond margins of the basin.

J. E. Adams, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 11, p. 1608–1612. Includes Vaca Triste member (new) in upper part.

Western Texas and southeastern New Mexico.

**Salamanca Conglomerate Member** (of Conewango Formation)[1]

**Salamanca Conglomerate** or **Sandstone Member** (of Cattaraugus Formation)[1]

Salamanca Member (of Venango Formation)

Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: J. F. Carll, 1880, Pennsylvania 2d Geol. Survey Rept. $I_3$.

R. M. Leggette. 1936, Pennsylvania Geol. Survey. 4th ser.. Bull. W–3, p. 204. Conewango formation, in Warren County, has thickness of about 550 feet and is divided about in half by Salamanca conglomerate. The Salamanca is persistent throughout county and ranges in thickness from about 10 to 20 feet.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Listed as member of Venango formation; underlies Saegerstown member; overlies Panama conglomerate.

S. W. Lohman, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. W–6, p. 40. Member of Cattaraugus. Where exposed in quarry near Lewis Run, McKean County, it is greenish-gray sandstone.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Upper Devonian. In column, Salamanca occurs above the Amity and below the Saegerstown. Term Conewango group is elevated to rank of stage.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 63. Conglomerate member of Cattaraugus formation described in Wellsville quadrangle. Overlies Wolf Creek conglomerate member; underlies Oswayo formation.

Named for Salamanca "rock city," New York.

Salamanca formational suite[1]

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71. p. 85–86.

Typically developed in Olean-Salamanca region, Cattaraugus County, N.Y.

†Salem Breccia[1]

Lower Ordovician (early Chazy): Northern central Alabama.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. Cahaba coal field, p. 152.

Named for exposures in Salem Hills, southwest of Bessemer, Jefferson County.

**Salem Gabbro-Diorite[1]**

Lower Paleozoic(?): Eastern Massachusetts.

Original reference: C. H. Clapp, 1910, Igneous rocks of Essex County, Massachusetts, p. 5, 7, 8, 11.

N. E. Chute, 1940, Massachusetts Dept. Public Works Bull. 1, p. 4, 9–10, pls. 2–A, 2–B. Ordovician(?) or Silurian(?).

N. E. Chute, 1950, Bedrock geology of the Brockton quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–5]. Extensively intruded by Dedham granodiorite in Brockton quadrangle. Lower Paleozoic(?).

Named for occurrence at Salem, Essex County.

Salem Lavas

Salem Hills Basalt

Miocene, middle: Northwestern Oregon.

R. E. Corcoran and F. W. Libbey, 1956, Oregon Dept. Geology and Mineral Industries Bull. 46, p. 7–8, 12. In Salem Hills area, Eugene formation is overlain unconformably by series of basalts called Salem lavas in Salem quadrangle by Mundorff (1939, unpub. thesis) and Stayton lavas in that general region by Thayer (1939). On west side of Salem Hills, the lavas are at least 410 feet thick and dip northeast approximately 2° to 3°. According to Mundorff, the Salem lavas are typically medium to dark gray, fine grained, and dense, rarely porphyritic. Salem-Stayton lavas are correlated with Columbia River basalt. Also referred to as Salem Hills basalt.

Named for occurrence in Salem quadrangle.

**Salem Limestone**[1]

Salem Formation

Upper Mississippian (Meramec Series): Southern Indiana, southern Illinois, southeastern Iowa, western and central Kentucky, and eastern Missouri.

Original references: E. R. Cumings, 1901, Jour. Geology, v. 9, p. 233; Am. Geologist, v. 27, p. 147.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 224, 227, pls. 6, 25, 26. Salem limestone (Spergen of some authors) was traced across Kentucky as far as Cumberland River, southern Pulaski County. Somerset shale member of Warsaw formation (Butts, 1922) has been traced from southern Indiana to type locality at Somerset, Pulaski County, Ky., and is here interpreted as being a basal argillaceous phase of Salem limestone.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 811–813. Names Salem and Spergen, both taken from localities in Washington County, Ind., have been applied to limestone from which the Bedford, Ind., building stone is obtained. Name Salem, which was proposed first and has been used consistently by Indiana Geological Survey is preferable to name Spergen. In standard Mississippian section, the Salem underlies St. Louis limestone and overlies Warsaw limestone. In Indiana, overlies Harrodsburg limestone. In its typical development in Indiana, the Salem is lenticular; attains thickness of 50 to 60 feet near Bedford but locally pinches out; layers of buff to nearly black bituminous calcareous shale are associated with massive limestone, particularly at top and bottom, and, including these beds, formation has maximum thickness of 90 to 100 feet. In Ste. Genevieve County, Mo., 160 feet of gray to white, more or less oolitic limestone have been referred to the Salem, but paleontologic evidence suggests that upper part of these beds is of St. Louis age; central 100 feet is exceptionally pure oolite; northward the Salem becomes progressively less pure and beyond Alton, Ill., consists mainly of earthy limestone with minor shaly beds. At Warsaw, Ill., beds referred to Salem consist of 4 to 8 feet of more or less crossbedded yellowish limestone that grades laterally into calcareous sandstone, which has been termed Sonora sandstone (Keyes, 1895). Apparently equivalent beds in southeastern Iowa attain maximum thickness of nearly 30 feet; name Belfast (Van Tuyl, 1925) has been proposed for Salem formation in Iowa. South of Warsaw, Ill., boundary between Salem and Warsaw is drawn at horizon that separates a lower dominantly shale zone from an upper zone of hard massive- to thin-bedded granular to fine-grained more or less earthy, impure and dolomitic limestone beds separated by layers or partings of shale that are commonly calcareous. This report places the Salem in Meramec group, Iowa series.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5. Shown on correlation chart in Meramecian series.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 28 (fig. 9), 47. In Illinois, Salem formation is included in Meramec group, Valmeyer series.

J. W. Baxter, 1959, Dissert, Abs., v. 19, p. 2910, 2911. In southwestern Illinois, Salem limestone is subdivided into four members [sequence not indicated]: Kidd, Fults, Chalfin, and Rocher.

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 1–32. Salem limestone, in southwestern Illinois, subdivided into (ascending) Kidd, Fults, Chalfin, and Rocher members. Thickness about 200 feet. Overlies Warsaw formation; underlies St. Louis limestone. Valmeyer series.

Named for Salem, Washington County, Ind.

Salem Limestone (in Allegheny Formation)[1]

Pennsylvanian: Northeastern Ohio.

Original reference: Wilber Stout and R. E. Lamborn, 1924, Ohio Geol. Survey, 4th ser., Bull. 28, p. 146–150.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 27. Light-bluish- to brownish-gray dense-textured limestone. Thickness about 8 inches. Allegheny series.

Named for exposures at Salem, Columbiana County. Not positively identified outside county.

†Salem Syenite[1]

Carboniferous: Massachusetts.

Original reference: E. Cornelius, 1821, Am. Jour. Sci., v. 3, p. 232.

Named for occurrence in town of Salem, Essex County.

Salem Church Granite[1]

Precambrian: Northwestern Georgia.

Original reference: W. S. Bayley, 1928, Georgia Geol. Survey Bull. 43, p. 103–108, map.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 276–277. Stose and Stose (1944, Am. Jour. Sci., v. 242, p. 411) accepted conclusion of Bayley (1929) that the Salem Church granite intrudes the Hiwassee slate of Ocoee series and the statement of Crickmay (1936, Geol. Soc. America Bull., v. 47, no. 9) that the Corbin granite is intrusive into the Talladega series which the writers [Stose and Stose] include in the Ocoee series. Salem Church granite, exposed in an oval area in western part of Tate quadrangle and adjacent Cartersville quadrangle, is surrounded by a band of Hiwassee slate and several small areas of slate lie within the granite. Relation of the granite to the slate is confused because the granite in places is sheared to mylonite on cross fractures, which also offset the slate. The Salem Church may be part of an injection complex which is older than the Ocoee series. Hiwassee slate as mapped around the granite underlies Great Smoky quartzite and is interpreted as basal formation of Ocoee series equivalent to Hurricane graywacke (new). The Corbin granite is exposed southwest of Salem Church granite and just east of Cartersville overthrust. The Salem Church resembles phases of the Corbin granite and because of this similarity has been called Corbin granite by Furcron and Teague (1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 2 p. 1195). Precambrian.

Well exposed at Salem Church, Tate quadrangle, and west and southwest of church.

**Salem Point Shale Member**[1] (of Grenola Limestone)

Permian: Southeastern Nebraska, eastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1.

N. G. Lane, 1958, Kansas Geol. Survey Bull. 130, pt. 3, p. 134–137, 160. In type area of Grenola limestone, the Salem Point is shale, generally unfossiliferous, interbedded with thin earthy limestone layers. Thickness about 9½ feet. Lower boundary is marked by upper massive osagite bed of Burr limestone member; upper boundary is base of first fusulinid limestone, which is lowest bed of Neva limestone member. Lower Permian, Wolfcamp series.

Type locality: Roadcuts at Salem Point, 1½ miles northwest of Salem, Richardson County, Nebr.

**Salem School Limestone Member** (of Graham Formation)[1]

Salem School Limestone Member (of Gonzales Formation)

Upper Pennsylvanian: Central northern Texas.

Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 12, 16–18. First marine member of Graham formation. Highly fossiliferous yellowish earthy limestone. Thickness 8 inches to nearly 2 feet. Overlies both the channel deposits (Kisinger channel) at base of the Graham and the older Home Creek limestone member of Caddo Creek formation of Canyon group. Underlies unnamed shale and sandstone unit which in turn underlies Gonzales limestone member.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in the Gonzales here raised to formational status in Graham group. Overlies Kisinger channel and underlies an "upper limestone."

E. L. Thackery, 1951, West Texas Geol. Soc. Guidebook, June 1–2, p. 14–15, chart. Chart shows Salem School limestone near base of Graham group. Occurs below Gonzales limestone in Brazos River section and below North Leon limestone in Colorado River section.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook May 25–26, fig. 4. Generalized columnar section shows Salem School limestone at base of Graham group, stratigraphically below Bunger limestone and above Home Creek limestone in Caddo Creek group.

Well exposed one-half mile southeast of Salem School, in southeastern part of Young County, Brazos River area.

Salesville Formation (in Whitt Group)

Salesville Shale Member (of Mineral Wells Formation)[1]

Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 25, 31; Texas Univ. Bull. 2132, p. 77, charts.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Whitt group (new). Expanded below to include Lake Pinto sandstone member. Underlies Keechi Creek formation; overlies East Mountain shale in Lone Camp group. Name Mineral Wells dropped in this report.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 23–24, fig. 3, pl. 1. In this report [Parker County] Salesville is considered a formation although author does not wholly agree with Cheney's redefinition and believes it confusing to expand meaning of a rock name vertically to include a previously named rock body. As defined here, formation includes Lake Pinto sandstone at base and an unnamed shale member above which includes Dog Bend limestone bed in lower parts. Whitt group not used in this report.

Named for small town in Palo Pinto County, north of Mineral Wells.

Salida Schists[1]

Precambrian: Central Colorado.

Original reference: W. Cross, 1893, On a series of peculiar schists near Salida, Colorado: Colorado Sci. Soc. Proc., v. 4.

Chaffee County.

**Salina Formation**[1] or **Group**

Upper Silurian: New York, Michigan, and northern Ohio.

Original reference: J. D. Dana, 1863, Manual of geology, 1st ed., p. 246–251.

T. G. Payne, 1938, Rochester Mus. Arts and Sci Guide Bull. 5, p. 69. In Genesee country, group comprises (ascending) Vernon shale, 300 feet, Camillus shales, 550 feet, Bertie waterlime, 85 feet, and Akron dolomite, 6 feet.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. As shown on correlation chart, Salina group comprises (ascending) Pittsford shale, Vernon shale, Syracuse salt, Camillus shale, and Bertie waterlime. Occurs above Guelph group and below Cobleskill (Akron) dolomite.

L. V. Rickard, 1955, New York Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Upper Cayugan series (revised) contains two formations, Salina and Bertie. Salina consists of two facies, Vernon red shales near base, and Camillus gray calcareous shales and dolomites with salt and gypsum beds.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Shown on correlation chart as Salina group. Includes Camillus shale, Vernon shale, and Syracuse dolomite (salt). Name Pittsford shale discontinued. Overlies Lockport group; underlies Bertie group. In Canastotan stage (new). Cayugan series. Upper Silurian. Note on type locality.

W. P. Leutze, 1960, Dissert. Abs., v. 20, no. 12, p. 4633–4634. In central New York, group attains maximum thickness of about 1,000 feet at outcrop. Divisible into (ascending) Vernon shale, Syracuse formation, Camillus shale, and Bertie formation. In eastern New York, Camillus and Bertie cannot be separated and combined unit is called Brayman shale.

Precise type locality unknown but numerous exposures of Vernon, Syracuse, and Camillus rocks exist in northern part of Onondaga County (Syracuse quadrangle), N.Y. Supplies salt wells at Salina, N.Y.

†Salinas Shale[1]

Eocene, middle: Southern California.

Original reference: W. A. English, 1918, U.S. Geol. Survey Bull. 691, p. 219–250.

Well developed on west side of Salinas Valley.

**Saline Formation** (in Wilcox Group)

Eocene: Central Arkansas.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 11 (fig. 4), 46–55, plates. Proposed for section of dark-chocolate-brown laminated clay and silt and interbedded white, tan, orange, and red sand that overlies Berger formation (new) and underlies Detonti sand (new). Thickness 350 feet at type locality; thickness recorded in drill holes 165 to 495 feet. Rests with local unconformity upon the Berger and, in places, unconformably on Wills Point and Kincaid formations and nepheline syenite masses and their included small pendants of metamorphic rocks of Paleozoic age.

Type locality: Roadcut immediately north of Benton pumping station, several hundred feet east of northwest corner SW¼SE¼ sec. 25, T. 2 S., R. 15 W., Saline County. Named for Saline River. Crops out in irregular band as much as 9 miles wide that extends in a northeasterly direction across bauxite region and surrounds or covers a part of every nepheline syenite hill. Mapped from east bank of Saline River in Saline County to west bank of Fourche Bayou near Sweet Home in Pulaski County where formation wedges out beneath Quaternary alluvium of Arkansas River flood plain.

Saline Bayou Member (in Claiborne Group)[1]

Saline Bayou Member (of Cook Mountain Formation)

Eocene: Northwestern Louisiana and eastern Texas.

Original reference: A. C. Ellisor, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 1339–1346.

J. Huner, Jr., 1939, Louisiana Dept. Conserv. Geol. Bull. 15, p. 87, 96–101, pls. 3, 8 (fig. 1). Described in Winn Parish, La., as member of Cook Mountain formation. Thickness 20 to 35 feet. Overlies Milams member (restricted); underlies Little Natches member (new).

Type locality: Saline Bayou at St. Maurice, Winn Parish, La.

Saline Creek (cave) Conglomerate[1]

Pennsylvanian: Central Missouri.

Original reference: S. H. Ball and A. F. Smith, 1903, Missouri Bur. Geology and Mines, v. 1, 2d ser., p. 92–95.

Named for exposures on Saline Creek, Miller County.

Salineno Sandstone Member or Tongue (of Fayette Formation)[1]

Eocene, upper: Southern Texas, and northern Mexico.

Original reference: W. G. Kane and G. B. Gierhart, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 9, p. 1375, 1383, 1387.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 267. Basal member or tongue of Fayette. As sandstone enters Starr County from Mexico, it is about 40 feet thick; northward it becomes extinct in a section of red and green bentonitic shales. Contains oyster and other shells; distinguished in Roma area by abundance of calcareous sandy concretions which are highly fossiliferous; borings of *Halymenites* abundant. Underlies Resendez member (new).

Named from town of Salineno on east bank of Rio Grande, southern part of Falcon quadrangle, Starr County.

Salisbury Granite

Age not stated: Western North Carolina.

Felix Chayes, 1952, Am. Jour. Sci., v. 250, no. 4, p. 282–284. Coarse moderately gneissic granite in which quartz is always either magnificently undulant or entirely granulated.

Salisbury is in Rowan County.

†Salisbury Schist[1]

Pre-Triassic: Northwestern Connecticut.

Original references: J. D. Dana, 1874, Am. Assoc. Adv. Sci. Proc., v. 22, p. 25–27; W. M. Agar, 1932, Am. Jour. Sci., 5th ser., v. 23, p. 31–48.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Pre-Triassic.

Occurs in Salisbury-Canaan region, Litchfield County.

**Salitral Shale Tongue** (of Chinle Formation)

Salitral Shale Member (of Moenkopi Formation)

Upper Triassic: Northwestern New Mexico.

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. Tongue of Chinle formation in and around Nacimiento Mountains and San Pedro Mountains. Consists of variegated shale with limestone concretions. Underlies Poleo sandstone lentil; overlies Agua Zarca sandstone member (new). Cannot be differentiated from main body of Chinle formation south of latitude of Los Pinos Arroyo. Upper Triassic.

J. A. Momper, 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 91, 92. Considered member of Moenkopi in San Juan Basin. Thickens westward into main body of Moenkopi at expense of underlying Agua Zarca member.

J. A. Momper and W. W. Tyrrell, Jr., 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 23. Thickness in San Juan Basin 30 to 100 feet. Type locality indicated.

Type locality: Salitral Creek, T. 22 N., Rs. 2 and 3 W., Rio Arriba County.

†Salkehatchie Marl[1] or phase[1]

Miocene: Southern South Carolina.

Original reference: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 18, 19.

Named for exposures along Salkehatchie River, Colleton County.

**Sallisaw Formation**

Sallisaw Sandstone[1]

Lower or Middle Devonian: Northeastern Oklahoma.

Original reference: I. H. Cram, 1930, Oklahoma Geol. Survey Bull. 40–QQ, p. 24, map.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 35–40, pl. 4. On southwestern flank of Ozark uplift Sallisaw formation is composed of several distinct lithologies; most common is light- to dark-gray fine-grained medium-bedded calcareous sandstone which weathers gray to brown and grades laterally into sandy limestone;

white to light-gray chert is interbedded with the calcareous sandstone or sandy limestone; locally contains large amounts of dark ferromagnesian minerals and some phosphatic material; where Sallisaw fills solution cavities in underlying St. Clair, it is typically a gray dense fine-grained limestone containing fine sand. Reaches maximum thickness of 11 feet in sec. 15, T. 13 N., R. 23 E., thins rapidly northward and is essentially absent north of T. 13 N. Unconformably overlies Frisco or St. Clair; unconformably underlies Chattanooga shale or its basal member, the Sylamore sandstone.

Well exposed along Sallisaw Creek near Marble City, Sequoyah County.

Sallisaw Marble[1]

Silurian: Central eastern Oklahoma.

Original reference: C. Schuchert, 1922, Geol. Soc. America Bull., v. 33, p. 670.

Near Marble City, Sequoyah County.

**Sallyards Limestone Member**[1] (of Grenola Limestone)

Permian: Eastern Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1.

R. C. Moore, and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Shaly to massive limestone with thin shale breaks. Thickness ½ to 3½ feet. Underlies Legion shale member; overlies Roca shale. Wolfcamp series.

Type locality: South bank of ravine 1 mile northeast of Sallyards, Greenwood County, Kans.

**Salmon Hornblende Schist**[1]

Pre-Silurian: Northern California:

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 225–245.

F. G. Wells and F. W. Cater, Jr., 1950, California Div. Mines Bull. 134, pt. 1, p. 81. Within Applegate group is a massif of Precambrian(?) Salmon and Abrams schist that lies between Seiad and Beaver Creeks and extends southward across Kalamath River, Siskiyou County.

Seymour Mack, 1958, U.S. Geol. Survey Water-Supply Paper 1462, p. 15 (table 4), 16–18, pl. 1. In northern and western parts of Scott Valley, Siskiyou County, Abrams and Salmon schists are overlain unconformably by several thousand feet of greenstone and greenstone schist possibly correlative with Devonian(?) Copley greenstone. In southern part of Klamath Mountains, the Chanchelulla(?) formation of Hinds (1931), a series of moderately metamorphosed sedimentary rocks probably of Silurian age, lies unconformably on Abrams and Salmon schists. Thus, evidence indicates only that the Abrams and Salmon schists can be adjudged with certainty to be of pre-Silurian age. Any assignment of these rocks to Precambrian or lower Paleozoic would be extremely tenuous.

W. P. Irwin, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B315–B316; 1960, California Div. Mines Bull. 179, p. 19–20. Mapping in Weaverville quadrangle indicates that (1) structure of metamorphic rocks included in that quadrangle is synclinorial, with Abrams mica schist overlying Salmon hornblende schist, (2) the Abrams is probably younger rather than older than the Salmon, and (3) the marble lenses are of stratigraphic significance in that they are chiefly in lower part of Abrams.

Abrams occupies trough of synclinorium, and thus structurally overlies the Salmon. Early workers believed that the Salmon overlay the Abrams, but this view, based chiefly on reconnaissance, now seems to be erroneous, and so does the view, tentatively advanced by Diller and Ferguson (unpub. data) that the Salmon represents an intrusive body.

Named for exposures along Salmon River, Trinity and Shasta Counties.

**Salmon Lake Glaciation**

Pleistocene: West-central Alaska.

D. M. Hopkins, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 10–11, 13 (table 1). Four Quaternary glaciations recognized on Seward Peninsula. Salmon Lake succeeded Nome River glaciation (new); preceded Mount Osborn glaciation (new). Salmon Lake ice extended into upland valleys south of Kigluaik Mountains, and in upper parts of valleys in Bendeleben, Darby, and York Mountains. End moraines consist of arcuate zones of slightly modified knob and kettle topography. Lateral moraines on valley walls breached by gullies and ravines.

D. M. Hopkins, F. S. MacNeil, and E. B. Leopold, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 4, p. 46–57. Outwash and gravel of Salmon Lake glaciation described in report on coastal plain at Nome. Believed to be Wisconsin.

Salmon Lake, large lake a few miles southwest of Iron Creek, dammed by moraine marking most advanced position of Salmon Lake glaciation, Seward Peninsula.

†Salmon River Sandstone[1]

Upper Ordovician: Northern New York.

Original reference: T. A. Conrad, 1839, New York Geol. Survey 3d Rept., p. 58, 62–63.

Forms falls of Salmon River in town of Orwell and above Redfield village, Lewis County.

†Salmon River Sandstones and Shales[1]

Upper Ordovician: New York.

Original reference: T. A. Conrad, 1840, New York Geol. Survey 4th Rept., p. 201.

**Salmon Springs Drift, Glaciation**

Pleistocene, middle(?) to upper(?): Northwestern Washington.

D. R. Crandell, D. R. Mullineaux, and H. H. Waldron, 1958, Am. Jour. Sci. v. 256, no. 6, p. 385, 394. Pre-Vashon till and pebble and boulder gravel that overlies Puyallup formation. In most areas, these sediments appear to represent a single glacial drift unit; in exposures near Sumner, presence of nonglacial sediments between post-Puyallup glacial gravels indicate that two glaciations or two advances of a single major glaciation are represented; the Salmon Springs drift is defined as including both of these post-Puyallup-pre-Vashon glacial deposits. At Salmon Springs, the drift is separated into upper and lower drift sheets by 4 feet of peat and volcanic ash. Salmon Springs glaciation is the third in a sequence of four glaciations in Puget Sound lowland. Preceded by Stuck glaciation and followed by Vashon glaciation.

Typically exposed in east valley wall of Stuck River in gully 150 feet east and another gully 400 feet north of SE cor. SW¼ sec. 18, T. 20 N., R. 5 E., in vicinity of Salmon Springs, city water supply about 1 mile northeast of Sumner, Pierce County.

**Salmontrout Limestone**[1]

Middle Devonian: Northeastern Alaska.

Original reference: E. M. Kindle, 1908, Geol. Soc. America Bull., v. 19, p. 262, 325–327.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown as Lower or Middle Devonian on correlation chart.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Outcrops on both banks of Porcupine River immediately above Salmontrout River.

Salona Formation[1]

Middle Ordovician (Trentonian): Central and south-central Pennsylvania, northwestern Virginia, and eastern West Virginia.

Original reference: R. M. Field, 1919, Am. Jour. Sci., 4th ser., v. 48, p. 404, 420.

R. R. Rosenkrans, 1934, Am. Jour. Sci., 5th ser., v. 27, no. 158, p. 113–134. Six bentonite beds recognized near base of Salona. These are designated in ascending order Nos. 0–5. Overlies Rodman formation.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 2, p. 109–114. Includes about 175 feet of dark argillaceous limestone and calcareous shale in type section. Contains eight metabentonite beds. Overlies Rodman member of Nealmont formation with essential conformity; base of Salona lies 2 feet below metabentonite 0. Underlies Coburn limestone. Geographically extended to West Virginia. Trenton group. Mohawkian.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 742–745. In south-central Pennsylvania, the Martinsburg shale overlies Oranda formation. Lower part of Martinsburg is equivalent in Blacklog Valley to the part of the Salona succeeding metabentonites 1 and 2 and including metabentonite 6.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 89–91, 95. Subdivided in West Virginia and Virginia to include Onego member (new), which is believed to correspond approximately to lowermost Salona of Pennsylvania, though it probably extends a little lower. Underlies "Martinsburg" formation in West Virginia and Virginia sections. Trentonian series.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 89. In Virginia overlies Oranda formation. In Pennsylvania, overlies Rodman member of Nealmont formation.

Named for occurrence at Salona, Clinton County, Pa.

Saltash Formation

Precambrian(?): East-central Vermont.

W. F. Brace. 1953, Vermont Geol. Survey Bull. 6, p. 44–45, tables 2, 3. Consists of grits, phyllite, and quartzite, clearly divisible into three members. Lowest, member A, includes green or white grits, schist and sericite quartzite, and a few conglomerate beds. Member B is a graphitic black phyllite with thin dolomite and limestone beds; it is separated from lower grits by pyritic white sericite schist, quartzite, and dolomitic sandstone. Member C consists of vitreous quartzites; a few beds of dolomite and thin-bedded graphitic quartzite separate it from member B. Total thickness varies from about 1,700 to 2,000 feet. Underlies Tyson formation; overlies Mount Holly complex, both unconformably.

Well exposed in all east-flowing brooks of the Ottauquechee and Black River valleys from Saltash Mountain to West Bridgewater in the Rutland area.

Salt Creek Conglomerate

Upper Cretaceous: Northern California.

N. L. Taliaferro, 1954, *in* Northern California Geol. Soc. [Guidebook] Spring Field Trip, [p. 6, 7, 8], correlation chart, structure sections A, B, and C. Shown on correlation chart and structure sections as underlying Antelope shale (new) and overlying Horsetown group or Lower Cretaceous strata. Beds vertical to overturned. Thickness 1,250 to 2,200 feet. The Salt Creek is stratigraphic marker which indicates a possible disconformity or minor unconformity. Conjectural base of Upper Cretaceous.

Occurs in Rumsey Hills-Capay Valley-Wilbur Springs area on west side of Sacramento Valley.

Salt Creek Fanglomerate[1]

Pleistocene: Eastern Utah.

Original reference: A. J. Eardley, 1933, Michigan Acad. Sci., Arts, and Letters, v. 18, p. 310, 336.

K. D. Johnson, 1959, Brigham Young Univ. Research Studies, Geology Ser., v. 6, no. 6, p. 26, 27–28, pl. 8. Described in Mount Nebo-Salt Creek area where, at mouth of Foote's Canyon, it forms red cap on ridges of Arapien shale and at Left Fork of Foote's Canyon overlies vertical beds of Nugget and Ankareh formations. Pleistocene.

First described in Salt Creek Canyon, southern Wasatch Mountains.

†Salt Creek Gravel Beds[1]

Pleistocene: North-central Kansas.

Original reference: W. N. Logan, 1897, Kansas Univ. Geol. Survey, v. 2, p. 218.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 110. Used by Logan (1897) for beds which are now, at least in part, the Sanborn formation.

Named for Salt Creek, Russell County.

Salt Creek Marble (in Blaine Formation)[1]

Permian: Northwestern Oklahoma.

Original reference: G. G. Suffel, 1930, Oklahoma Geol. Survey Bull. 49, p. 69.

In vicinity of Salt and Bitter Creeks, Blaine County.

Salt Creek Member (of Moenkopi Formation)[1]

Lower Triassic: Northeastern Arizona.

Original reference: D. Hager, 1921, Oil possibilities of Holbrook area, northeastern Arizona, private publication.

E. D. McKee, 1954, Geol. Soc. America Mem. 61, p. 19. Lower and middle subdivisions of Moenkopi, in Little Colorado Valley, referred to as the Salt Creek by Hager (1922, Mining and Oil Bull., v. 8, no. 2, p. 73), here called, respectively, Wupatki member and Moqui member.

Occurs at mouth of Salt Creek, mouth of Clear Creek, southeast corner of Winslow, and just south of Holbrook.

**Salt Creek Bend Shale Member** (of Pueblo Formation)

Salt Creek Bend Shale (in Cisco Group)[1]

Permian (Wolfcamp): Central Texas.

Original reference: F. M. Bullard and R. H. Cuyler, 1935, Texas Univ. Bull. 3501, p. 245, 249.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as shale member of Pueblo formation. Underlies Camp Colorado limestone member; overlies Stockwether limestone member. Average thickness 45 feet. Upper part of member consists mostly of dark-red to maroon clay; near Colorado River, a sandstone 5 to 15 feet thick is persistent subdivision; in eastern Coleman County, three limestone beds, 1 to 5 feet thick, occur in upper part, and the middle of these limestones is sandy and locally grades to sandstone.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 269. Geographically extended into Brazos River valley where it is 40 to 100 feet thick and consists of variegated shale with minor amounts of sandstone and siltstone. Underlies Camp Colorado limestone member; overlies Stockwether limestone member.

Type locality: A sharp bend on Colorado River, 0.1 mile east of mouth of Salt Creek, McCulloch County

Salt Fork Group (in Cimarron Series)

Salt Fork division (of Cimarron Group)[1]

Permian: Central southern Kansas and western Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 18.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 25–26. Referred to as group in Cimarron series. Data in this report is from subsurface records.

Named for Salt Fork, Comanche and Barber Counties, Kans.

Salt Grass Shale Member (of Pierre Shale)[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 22. As currently defined, consists of gray clayey shale that contains numerous thin bentonite beds, limestone concretions, and concretionary limonite zones. Thickness 60 feet. Overlies Lake Creek shale member; underlies an unnamed shale 500 to 600 feet thick that in turn underlies Beecher Island shale member.

Named for Salt Grass Canyon, the southern tributary of Goose Creek in secs. 1 and 12, T. 12 S., R. 42 W., Wallace County.

†Saltillo Limestone[1]

Middle Ordovician: Western Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 33–35, 44.

Named for Saltillo, Hardin County.

Salt Lake Conglomerate[1]

Quaternary(?): Western Wyoming.

Original reference: A. C. Peale, 1879, U.S. Geog. and Geol. Survey Terr. 11th Ann. Rept., p. 552, 612, 641.

Occurs at various points in lower valley of Salt River, Lincoln County.

**Salt Lake Formation[1]**

Salt Lake Group

Pliocene: Northern Utah, southeastern Idaho, and northern Nevada.

Original reference: F. V. Hayden, 1869, U.S. Geol. and Geog. Survey Terr. Rept. on Colorado and New Mexico, 3d Ann. Rept., p. 92.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 845–846. Norwood tuff (new) is recognized as division under Hayden's Salt Lake group. When intermontane valleys west of the Wasatch become better known stratigraphically, Salt Lake group may be found to include several formations, perhaps separated in age by considerable parts of the Tertiary.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1130 (table), 1147, pl. 1. Group comprises light-colored tuffs, tuffaceous sandstones, and conglomerates that underlie foothill benches about margins of Cache Valley and extend in irregular patches through passes that connect valley with adjacent valleys to south, east, and north. Thickest section, exposed in Junction Hills horst in sec. 15, T. 13 N., R. 2 W., is 1,140 feet. Unconformable above Paleozoic rocks. Oligocene(?) to Pleistocene(?).

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 44–46, pl. 1. Formation described in Ammon and Paradise quadrangles, Idaho. As mapped, consists of conglomerate, calcareous grit, sandstone, shale, and marl; includes some bedded volcanic ash and tuff and windblown dust of Pleistocene age. Thickness varies from 0 to as much as 800 feet. Unconformably overlies rocks of all earlier formations represented. Pliocene(?).

Neal Smith, 1953, Intermountain Assoc. Petroleum Geologists Guidebook 4th Ann. Field Conf., p. 73–76. Williams (unpub. thesis) subdivided Salt Lake group in Cache Valley into basal Collingston conglomerate, West Spring formation, and Cache Valley formation (all new). Figure 2, this report, shows Norwood tuff as basal unit of group. Group is unconformable above Knight formation of Wasatch group. Oligocene through Pliocene.

C. B. Hunt, H. D. Varnes, and H. E. Thomas, 1953, U.S. Geol. Survey Prof. Paper 257–A, p. 13–14, pl. 1. Formation described and mapped in northern Utah Valley where thickness may exceed 1,000 feet. Unconformable below pre-Lake Bonneville deposits. Pliocene(?).

L. W. Slentz, 1955, Utah Geol. Soc. Guidebook 10, p. 23–36. Group, as described in lower Jordan Valley, Utah, comprises (ascending) Traverse volcanics, Jordan Narrows unit, Camp Williams unit, Harkers fanglomerate, and travertine unit (all new). Maximum aggregate thickness 3,700 feet. Oligocene through Pliocene.

R. D. Adamson, C. T. Hardy, and J. S. Williams, 1955, Utah Geol. Soc. Guidebook 10, p. 1 (table 2), 2 (table 1), 4–22. Group in Cache Valley redefined to include (ascending) Colliston conglomerate, Cache Valley formation (redefined) and Mink Creek conglomerate (new). Underlies pre-Lake Bonneville group. Overlaps unit referred to as "Wasatch" conglomerate and in places overlaps Paleozoic rocks. Miocene-Pliocene.

W. J. Mapel and W. J. Hail, Jr., 1956, Utah Geol. Soc. Guidebook 11, p. 2 (table 1), 4 (fig. 3), 9–16, fig. 2. Formation described and mapped in Goose Creek district, Idaho, Utah, and Nevada. Comprises lower unit, 1,550 feet, mainly white volcanic ash containing a few beds of shale, sandstone, and conglomerate; beds of black to reddish-brown welded tuff in upper half; lenticular beds of carbonaceous shale and lignite in lower half; upper unit, about 700 feet, interbedded white and grayish-orange volcanic ash, with a few lenticular beds of conglomerate; a thick persistent bed of welded tuff at base. Overlies unit referred to as Payette(?).

Named for extensive developments in Weber and Salt Lake Valleys, Utah.

**Salt Lake Tuff**[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 64.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 130–131. Subaerial gray to brown tuff, partly palagonitized, containing bombs of peridotite and fragments of coral limestone. Maximum thickness about 300 feet. Overlies Aliamanu tuff and eroded gravel terraces graded to plus 95-foot (Keana) stand of sea.

Named for Salt Lake (Aliapaakai) which lies in crater of tuff cone that marks the vent. Together with Makalapa tuff covers about 6 square miles just east of Pearl Harbor, on southwest side of Koolau Range 18 miles west of Makapuu Head.

Saltlick Beds[1]

Salt Lick Limestone (in Breathitt Formation)

Pennsylvanian: Eastern Kentucky.

Original reference: W. C. Morse, 1931, Kentucky Geol. Survey, ser. 6, v. 36, p. 296, 303.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 100. Thin marine limestone in Breathitt formation between Haddix coal (above) and Magoffin marine horizon.

Well exposed at head of Salt Lick Creek, Knott County, Ky.

**Salt Mountain Limestone**

Salt Mountain Limestone (in Midway Group)

Salt Mountain Limestone (in Wilcox Group)[1]

Paleocene: Southwestern Alabama.

Original references: D. W. Langdon, 1891, Geol. Soc. America Bull., v. 2,

p. 589–605; 1894, Alabama Geol. Survey Rept. Coastal Plain, p. 107–122.

L. D. Toulmin, 1941, Jour. Paleontology, v. 15, no. 6, p. 567–611. Foraminifera indicate that Salt Mountain limestone, at least upper part, is younger than Midway and probably is Wilcox in age.

A. R. Loeblich, Jr., and Helen Tappan, 1957, Jour. Paleontology, v. 31, no. 6, p. 1113 (fig. 2); 1957, U.S. Natl. Mus. Bull. 215, p. 174, 177 (fig. 28). Age discussion. Chart shows Salt Mountain limestone above Naheola formation and below Nanafalia formation in Midway group. Paleocene.

C. W. Cooke, 1959, U.S. Geol. Survey Prof. Paper 321, p. 2 (table 1). Chart shows age of Salt Mountain limestone as Paleocene.

Named for exposures at Salt Mountain, Clarke County.

Saltos Shale Member (of Monterey Shale)

Miocene, lower and middle: Southern California.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2977 (fig. 3), 2989–2990. Lower member of Monterey in Caliente Range. Where best exposed on southwest slope, consists of (1) an upper 1,100 feet of thin-bedded brown clay shale, with minor siliceous shale beds and near its base a 75-foot basalt sill, and (2) a lower 1,000 feet of gray-brown, less well-bedded claystone and siltstone; on northeast flank of range, grades eastward into sandstone of the lower part of Branch Canyon formation (new); can be traced northwestward into a clay shale which occurs on northeast side of La Panza Range and where it was mapped as Sandholdt shale by Bramlette and Daviess (1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 24); the Saltos, therefore, is in part equivalent to Sandholt shale of Salinas Valley as defined by Thorup (1953, California Div. Mines Bull. 118). In western Cuyama Valley in vicinity of Taylor Canyon, consists of a basal 150 to 300 feet of siliceous shale overlain by about 500 feet of clay shale; this basal siliceous shale was mapped as Whiterock Bluff member of Santa Margarita formation by English (1916) and included in the Vaqueros by Eaton and others (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2). Conformably underlies Whiterock Bluff shale herein designated as member of Monterey; conformably overlies Painted Rock sandstone. Age, based on foraminiferal content, ranges from Saucesian through most of Relizian stage. The basalt sill marks boundary between Relizian and Saucesian stages in type section of the Saltos. The Saltos was mapped by English (1916) as Maricopa shale and by Eaton and others (1941) as upper part of the "Temblor."

Type locality: The steeply dipping section exposed in an unnamed canyon in sec. 20, and offset along strike in secs. 18 and 19, T. 11 N., R. 27 W. Caliente Mountain quadrangle.

Salt Plain Formation or Siltstone (in Nippewalla Group)

Salt Plain Shale (in Cimarron Group)[1]

Permian (Leonard Series): Central southern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 20–24.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1762–1763 (fig. 2), 1764–1765 (fig. 3), 1786–1789. Included in Nippewalla group (new). Overlies Harper sandstone (restricted); underlies Cedar Hills sandstone. Cimarron series, Salt Fork division.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 39. Formation consists chiefly of red, flaky, silty shale and some siltstone. Includes two prominent coarse siltstone beds, the upper, about 25 feet thick, occurring about 42 feet below top of formation and the lower, Crisfield, about 29 feet thick, occurring about 115 feet below top of formation. Thickness 265 feet. Overlies Harper sandstone; underlies Cedar Hills sandstone. In Kingman County, overlapped by Cenozoic deposits. Leonardian. In Nippewalla group (new).

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Chart shows Salt Plain siltstone with Crisfield sandstone member in upper part.

Named for Great Salt Plain of Cimarron River, Kan.

Saltsburg Formation (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: G. H. Ashley, 1926, Pennsylvania Geol. Survey Topog. and Geol. Atlas 65, p. 23–24, pl. 4.

Punxsutawney quadrangle.

Saltsburg Member (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

Pittsburgh quadrangle.

**Saltsburg Sandstone Member** (of Conemaugh Formation)[1]

Saltsburg Sandstone (in Conemaugh Group)

Upper Pennsylvanian: Western Pennsylvania, Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1878, Pennsylvania 2d Geol. Survey Rept. K₃, p. 22.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 49, 50, geol. map. In this report [Morgan County] the Conemaugh is classified as a series and the included units referred to as members. Cyclothemic classification not used in this report. From Condit's (1912, Ohio Geol. Survey, 4th ser., Bull. 17) description, it seems that Saltsburg sandstone and Round Knob shale are contemporaneous units, or the names are applied to different facies of same unit. In Morgan County, interval between Barton and Harlem coals, both of which are discontinuous, is 15 to 20 feet. The Saltsburg is represented in some parts of county by sandstones or sandy shales, which change facies rapidly, and which may comprise entire interval or may be present only in lower half of interval. Term Round Knob is applied to shaly phase and term Saltsburg to sandy phase. In some areas, the Round Knob overlies the Saltsburg. Two spellings of the name, Saltsburg and Saltzberg, have appeared in literature.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 130. In this report [Athens Conuty], Saltsburg shale and sandstone is classified as lowermost member of Harlem cyclothem, Conemaugh series. Thickness about 10 feet. Underlies Round Knob redbed member of cyclothem.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 69 (fig. 4). In this report [western Pennsylvania], the Conemaugh is classified as a group. On columnar section, Saltsburg sandstone occurs above Upper Bakerstown coal and below Pittsburgh redbed.

Named for exposures along Conemaugh and Loyalhanna Rivers near Saltsburg, Indiana County, Pa.

Saltville Chert (in Helderberg Group)[1]

Lower or Middle Devonian: Southwestern Virginia.

Original reference: F. M. Swartz, 1929, Pennsylvania Acad. Sci. Proc., v. 3, p. 80.

G. A. Cooper, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

Name applied from Tumbling Creek, near Saltville, Smyth County, to Gala, Botetourt County.

**Salt Wash Sandstone Member** (of Morrison Formation)[1]

Upper Jurassic: Eastern Utah, northeastern Arizona, southwestern Colorado and northwestern New Mexico.

Original reference: C. T. Lupton, 1914, U.S. Geol. Survey Bull. 541, p. 127.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 963. Correlates with lower part of Recapture shale member proposed by Gregory (1938).

L. C. Craig and others, 1955, U.S. Geol. Survey Bull. 1009–E, p. 135–137, 138 (fig. 21). Salt Wash member constitutes lower part of Morrison in eastern Utah, parts of western Colorado, northeastern Arizona, and northwestern New Mexico. It was formed as a large alluvial fan by streams diverging to north and east from an apex in south-central Utah. Blunt apex of fan lies along a northwest-southeast-trending line in south-central Utah and north-central Arizona; this line is limit of preservation; southwest of it, Salt Wash has been removed by erosion. South side of fan is limit of deposition; south of Monticello, Utah, upper part of Salt Wash intertongues with and grades into Recapture member; in northeasternmost Arizona, lower parts of Salt Wash intertongue with Recapture, and farther south a basal tongue of Salt Wash reaches limit of deposition. Western edge of fan is poorly defined limit of deposition trending almost north-south along zero isopach in south-central Utah. Rounded margin of fan is irregular line extending from northwestern to south-central Colorado, beyond which Salt Wash cannot be distinguished from upper part of Morrison. Member arbitrarily divided into four facies: conglomeratic sandstone; sandstone and mudstone; claystone and lenticular sandstone; and claystone and limestone. From maximum thickness of more than 600 feet in south-central Utah, member in general thins radially to north and east. Near Vernal, Utah, 285 feet thick; this thickening is poorly understood but may represent accumulation of sediment from source unrelated to main source of member. In southeastern Utah, a thin area of Salt Wash is related to the thickness of underlying Bluff sandstone because, in general, as Bluff thickens, Salt Wash in this area thins. Extension of Salt Wash as recognizable unit through southeastern Utah and into northeastern Arizona and northwestern New Mexico constitutes restriction of Gregory's original definition of Recapture member.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 52, strat. sections. Stokes (1944) correlates Salt Wash member with parts of Gregory's (1938) Recapture in San Juan County, and this correlation is used in this paper on Navajo country. Present only in northern part of area; to the south, intertongues with and grades into overlying Recapture member; in vicinity of Marsh Pass, there is indication that Salt Wash intertongues with Cow Springs sandstone; at Red Mesa, Ariz., intertongues with upper part of Bluff sandstone. Thicknesses: 616 feet on Navajo Point, Utah, and 125 feet near near Rough Rock, Ariz.

T. E. Mullens and V. L. Freeman, 1957, Geol. Soc. America Bull., v. 68, no. 4, p. 505–526. Detailed discussion of lithofacies of Salt Wash member.

Named for Salt Wash, 30 miles southeast of Green River, Grand County, Utah.

†Salt Wells Group[1]

Upper Cretaceous: Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 49, 154.

Occurs at and around Salt Wells Station, Sweetwater County, Wyo.

**Saluda Limestone** (in Richmond Group)[1]

Saluda Formation (in Richmond Group)

Saluda Limestone Member (of Whitewater Formation)

Upper Ordovician: Southeastern Indiana, north-central Kentucky, and southwestern Ohio.

Original reference: A. F. Foerste, 1902, Am. Geologist, v. 30, p. 369.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 110, 114, chart facing p. 108. In Ohio, listed as member of Whitewater formation. Sequence shown on p. 110 (ascending): Weisburg, Saluda, and Oxford; stratigraphic chart and p. 114 shows sequence (ascending): Lower Whitewater, Saluda, and Upper Whitewater.

James Conkin, 1952, Kansas Acad. Sci. Trans., v. 55, p. 126–130. Liberty formation and Saluda member of Whitewater formation in this part of Kentucky [Oldham County] are separated by 14 feet of Whitewater facies. The Saluda wedges into Whitewater formation of Ohio. Upper Richmond beds thus coincide in their stratigraphic succession with Upper Richmond of Ohio. Heretofore, Kentucky section was given as Liberty, Saluda, and Whitewater (Hitz). Recognition of Whitewater beds permits division of Kentucky Upper Richmond, which is similar to that of Ohio into Liberty formation, Lower Whitewater, Saluda, and Upper Whitewater members of the Whitewater formation of Ohio.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Shown on stratigraphic chart of Indiana as Saluda formation in Richmond group. Consists of limestone, drab-gray, granular, massive to thin-bedded, impure, dolomitic; weathers to banded buff and salmon surface; coral masses at base. Thickness 40 to 65 feet. Underlies Whitewater; overlies Liberty.

Named for Saluda Creek, 6 miles south of Hanover, Jefferson County, Ind.

Saluda zone[1]

Precambrian: Northwestern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 6, 8, 12.

Named for exposures in Saluda Mountain Range.

Salvisa Formation

Salvisa Limestone Member (of Perryville Formation)[1]

Middle Ordovician: North-central Kentucky.

Original reference: A. M. Miller, 1913, Kentucky Geol. Survey, 4th ser., v. 1, pt. 1, p. 329.

A. C. McFarlan, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 992. An exposure in northern Jessamine County seems to indicate that the Faulconer and Salvisa are not entirely distinct stratigraphic units but are lithologic facies, in part contemporary.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1640. Term Perryville is a synonym of Benson; name Devils Hollow division of the Lexington is proposed for the post-Woodburn "Perryville" of the Frankfort-Versailles area. At its type section, the Devils Hollow includes 15 feet of the "Faulconer" rock and 10 feet of the "Salvisa."

J. A. Stokley and F. H. Walker, 1953, Kentucky Geol. Survey, ser. 9, Rept. Inv. 8, p. 44, 45. At Harrodsburg, Mercer County, Salvisa formation is 10 feet thick; underlies Cornishville formation; overlies Faulconer formation.

Named for Salvisa, Mercer County.

Samaniego Granite

Precambrian: Southeastern Arizona.

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 113. In composition, rock ranges from granodiorite to quartz monzonite and contains large microcline crystals associated with quartz, plagioclase, and hornblende. In fault contact with late Cenozoic sediments on west and with Pinal schist on east. Name credited to R. M. Wallace (unpub. thesis).

Crops out along western side of northern Santa Catalina Mountains, Pima and Pinal Counties.

**Sam Creek Limestone Member** (of Savanna Sandstone)[1]

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

M. C. Oakes and M M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 51–52, pl. 3. Overlies Spaniard limestone member. In Haskell County, underlies a 20-foot massive sandstone referred to as "Spiro" sandstone member.

Named from exposure in center of W½E½ sec. 15, T. 14 N., R. 18 E., along south bank of Sam Creek, Muskogee County.

Samelias Formation

Precambrian: Western South Dakota.

J. R. Berg, 1946, South Dakota Geol. Survey Rept. Inv. 52, p. 7. Similar to and of apparently same stratigraphic horizons as Roubaix group (new). In Keystone district, overlies rocks tentatively correlated with Lead system. Name credited to R. G. Hamilton (unpub. thesis).

First described in Keystone district, southern Black Hills. Also present in Galena-Roubaix district.

**Sample Sandstone**

Sample Formation (in West Baden Group)

Sample Sandstone Member (of Gasper Oolite)[1]

Upper Mississippian: Western Kentucky and southwestern Indiana.

Original reference: C. Butts, 1917, Mississippian formations of western Kentucky: Kentucky Geol. Survey, p. 67, 70.

R. E. Stouder, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 3, p. 270 (fig. 2), 273–275. In Meade, Hardin, and Breckinridge Counties, Ky., Sample sandstone occurs below Reelsville limestone and above Beaver Bend limestone.

D. J. McGregor, T. G. Perry, and W. J. Wayne, 1957, Indiana Geol. Survey Field Conf. Guidebook 9, p. 6, pl. 2. Sample formation in Indiana is 24 to 42 feet thick. Consists of thin-bedded fine-grained sandstone and siltstone and olive-gray and red-brown mudstones and shale; locally includes lenses of crossbedded sandstone. Underlies Reelsville limestone; overlies Beaver Bend limestone.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 46, pl. 1. Included in West Baden group (redefined). Thickness 22 to 36 feet. Underlies Reelsville limestone; overlies Beaver Bend limestone.

Typically exposed 1 mile east of Sample, Breckinridge County, Ky.

Sampson Rock Sandstone (in Pottsville Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 571.

Well exposed at Sampson Rock, west of Frostburg, Allegany County.

Sams Creek Metabasalt

Precambrian: Western Maryland.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12] Carroll and Frederick Counties, p. 58, 63–65. Grayish-green schistose to massive rock spotted with light-green, white, or pinkish knots, which are amygdules filled with quartz, calcite, or green epidote. All gradations occur from a massive amygdular rock with inconspicuous schistosity through a schistose variety in which the amygdules are drawn out into elliptical form, to fissile slate without recognizable volcanic characteristics in which amygdules are represented by flattened blebs or stringers. Crops out in a linear belt which extends southwestward from Maryland-Pennsylvania State line, in vicinity of Lineboro, to a point 1 mile northeast of Taylorsville; belt lies 1 mile north of Manchester and passes through Westminster. In this belt, the metabasalt overlies Wakefield marble and underlies albite-chlorite schist of Wissahickon formation. West and southwest of linear belt, the Sams Creek has a curvilinear strike which is common to the Wakefield, is repeated several times across the strike and is overlain by Ijamsville phyllite; in vicinity of Union Bridge, Unionville, Linganore, and Dollyhyde Creek, it is interbedded with Libertytown metarhyolite (new); from New London southward to New Market and Monrovia, it is overlain by Urbana phyllite; west of Parrsville, it is exposed in several narrow upfolds in Marburg schist. The unit was mapped as metabasalt in Glenarm series on geologic map of Frederick County [Maryland Geol. Survey, 1938] and age given as Precambrian(?).

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 43 (table 7), 65. Volcanic series in eastern part of Piedmont province includes Sams Creek metabasalt. Libertytown metarhyolite, Ijamsville phyllite, and Urbana phyllite. Quartzites occur in all of the members; some of the quartzites pass directly from the Ijamsville into the Urbana and into the Libertytown, and from the Urbana into the Sams Creek, indicating relative contemporaneity of these formations, all of which are apparenty equivalent to Harpers formation. Late Precambrian.

Named from village of Sams Creek on Carroll-Frederick County line.

Sams Spring Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3). Discussion of Paleozoic continental margin in central Nevada. Clipper Canyon sequence comprises (ascending) Charcoal Canyon, Petes Summit, Sams Spring, and Joes Canyon formations (all new). Clipper Canyon sequence is isolated by surrounding Tertiary volcanic rocks.

Clipper Canyon, Toquima Range, Nye and Lander Counties.

**San Andres Limestone**

San Andres Formation (in Manzano Group)

San Andres Group

San Andres Limestone Member (of Chupadera Formation)[1]

Lower and Upper Permian (Leonard and Guadalupe Series): Central and southeastern New Mexico.

Original reference: W. T. Lee, 1909, U.S. Geol. Survey Bull. 389.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 42–44. Report gives geologic section from Fisher County through Andrews County, Tex., to Eddy County, N. Mex. The "Blaine of Texas" is herein called the San Andres because it is believed that unconformity at top of Dog Creek shale on east side of basin can be tied into top of San Andres on west side of basin by means of well logs. San Andres on east side can be divided into (descending) Dog Creek shale, Blaine gypsum, and Flowerpot shale, a division known in Oklahome for some time. Top of Dog Creek shale is there called top of El Reno group. Term San Andres as used on west side of basin at present time includes beds between base of Whitehorse group and top of Yeso. In Guadalupes, San Andres is about 1,250 feet thick, and in wells in basin is about 1,460 feet. It has been assumed that this entire thickness is San Andres in age. At type locality in San Andres Mountains, formation is 500 feet thick and contains fossils which suggest its correlation with the Leonard of Glass Mountains of Texas. At type locality, base of formation is exposed, but top passes under alluvium of the Jornado del Muerto. There is evidence that the increased thickness of the so-called San Andres in the Guadalupes and in subsurface is due to the fact that additional section is younger than San Andres of type locality. This implies a division within the so-called San Andres dividing that part of section which is Leonard in age and which corresponds to San Andres as originally defined from younger beds which are probably middle Delaware Mountain in age.

F. E. Lewis, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 73–103. San Andres problem discussed. San Andres group believed to be time equivalent of Word formation, lower two divisions of Delaware Mountain group, and El Reno group, each of which is separable into an upper and lower division over wide area in south Permian basin. Evidence indicates San Andres group should be placed in Guadalupe series.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 542, 687–694, 701–703, pl. 2. Rank raised to formation; term Chupadera abandoned. In northern shelf area, upper part mostly limestone in outcrop; anhydrite and red beds interbedded to northeast; in lower part, sandstone beds replace limestone forming Glorieta sandstone member of northern New Mexico, Hondo sandstone member in Sacramento Mountains. Occurs above Yeso formation. In San Andres and other ranges of central New Mexico, formation is overlain unconformably by Mesozoic rocks, no higher Permian beds exposed; in Pecos Valley, overlain by Chalk Bluff formation. Included in Manzano group. Leonard series.

J. M. Hills *in* R. L. Bates, 1942, New Mexico Bur. Mines Mineral Resources Bull. 18, p. 269–271. In subsurface includes Lovington sandstone member (new).

C. E. Needham and R. L. Bates, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1662, 1663 (fig. 2), 1664–1666. Lee (1909) gave no detailed section. At new type section, herein designated, consists mainly of gray limestone with minor amounts of sandstone. Thicknesses 593½ feet at type section; 110 feet, Bluewater Canyon in Zuni Mountains; 15 feet, Glorieta Mesa. Overlies Glorieta sandstone herein given formational status; underlies Permian and other beds.

C. B. Read and D. A. Andrews, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 8. In upper Pecos River and Rio Galisteo region, formation consists of (ascending) Glorieta sandstone member (100 to 250 feet); light-gray thick-bedded cavernous-weathering limestone member (1 to 20 feet); and upper member (0 to 80 feet) of light-terra-cotta to orange gypsiferous siltstone and fine-grained sandstone. Overlies Yeso formation; underlies Dockum formation.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. In northwest Mora County, restricted to exclude upper clastic member which is here named Bernal formation. Includes Glorieta sandstone member at base. Middle limestone member, recognized in other areas, not present in mapped area of this report. Overlies Yeso formation or Sangre de Cristo formation.

W. F. Tanner, 1956, Jour. Sed. Petrology, v. 26, no. 4, p. 307–308. Group, between Las Vegas and Santa Fe includes (ascending) Glorieta sandstone, Lagunita formation (new), and Bernal formation.

C. H. Dane and G. O. Bachman, 1957, U.S. Geol. Survey Misc. Geol. Inv. Map I–224. As used on this map, Glorieta sandstone is considered separate formation.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 690 (fig. 1). Mapped as limestone [limestone seems more appropriate designation since Glorieta sandstone has been removed from formation].

P. T. Hayes and R. L. Koogle, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–112. Formation described in Carlsbad Caverns West quadrangle where it is more than 300 feet thick and consists of dolomite and limestone in even to irregular beds. Underlies Grayburg formation; basal contact not exposed. Upper part grades eastward into sandstone tongue of Cherry Canyon formation.

E. D. McKee and others, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–300, p. 2. Age of formation in Zuni uplift is not certain. To southeast, in southeasternmost New Mexico and adjoining parts of Texas, the San Andres is considered, on stratigraphic grounds, to be of Guadalupe age. To west, in Arizona, Kaibab limestone with which it apparently is continuous, is considered, from faunal evidence, to be of Leonard age. Assuming that both ages are correct, the San Andres of northwestern New Mexico must either transgress time planes across the State toward its type locality or represent a lithologic unit distinct from that of type San Andres. An indication that formation transgresses time planes is found north of Guadalupe Mountains where it is reported to include rocks of both Leonard and Guadalupe age.

Type section: South wall of Rhodes Canyon 2 miles west of road fork at top of Rhodes Pass and 14.6 miles by road east of Continental Airlines beacon near Engle. Canyon extends from near middle of north line sec. 29, T. 12 S., R. 2 E. Inquiry established that canyon referred to by Lee is one now known as Rhodes Canyon, San Andres Mountains, Socorro County.

**San Angelo Sandstone**[1] (in Pease River Group)

San Angelo Sandstone or Formation (in El Reno or San Andres Group)

Permian: Central northern Texas.

Original reference: W. F. Cummins and O. Lerch, 1891, Am. Geologist, v. 7, p. 73–77, 321–325.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 97. Included in El Reno group. Underlies Flower Pot shale; overlies Choza formation of Clear Fork group. On east side of Permian basin, name El Reno group appears to have priority and to be more appropriate on facies basis than term San Andres group which has been suggested for beds of Leonard age.

F. E. Lewis, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 73–103. San Angelo is basal formation in San Andres group as defined in this report.

Robert Roth, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1412, 1413. Basal formation in Pease River group.

E. C. Olson, 1952, Jour. Geology, v. 60, no. 3, p. 286–288; E. C. Olson and J. R. Beerbower, 1953, Jour. Geology, v. 61, no. 5, p. 389–423. Vertebrate fauna discussed. Evidence indicates post-Leonard age.

Well exposed a few miles west of San Angelo, Tom Green County.

**San Antonio Formation**[1]

Pleistocene: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

P. D. Trask and J. W. Rolston, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1083. Thickness 15 to 120 feet. Overlies Alameda formation; underlies Posey formation (new).

Named for development in San Antonio Township, Alameda County.

San Antonio Canyon Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 295–296, geol. map. Gneisses, migmatized metamorphics, and marble. Rocks have been intruded by a fine-grained quartz monzonite which is most probably an equivalent of Stoddard Canyon quartz monzonite (new). Similar to Rainbow Flat group (new), and future work may prove that the two were a continuous unit before they were separated by the strike-slip(?) East San Antonio fault.

Exposed on west side of San Antonio Canyon and west of East San Antonio fault, Cucamonga quadrangle, Los Angeles County.

San Ardo Group

Pliocene: West-central California.

T. A. Baldwin, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1988. Term suggested for three partly equivalent Pliocene units (ascending) Pancho Rico, Etchegoin, and Paso Robles facies.

Well exposed on slopes of Pancho Rico Canyon and the nearby gulches which drain westward to the Salina River at the town of San Ardo, Monterey County.

Sanastee Sandstone Member (of Mancos Shale)

Cretaceous: Northern New Mexico.

W. B. Hoover, 1951, *in* C. T. Smith and others, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 13 (chart), 46, 47, 79. Member of Mancos shale; about 450 feet above Dakota sandstone.

Dan Bozanic, 1955, Four Corners Geol. Soc. Guidebook [1st] Field Conf., p. 91. Term Sanastee was apparently applied to unit which had earlier been named Juana Lopez by Rankin (1944).

Named for prominent development around Sanastee Trading Post in vicinity of Grants, Valencia County.

Sanatoga Member (of Brunswick Formation)[1]

Upper Triassic: Southeastern Pennsylvania.

Original reference: D. G. McLaughlin, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 179.

Named for excellent exposures in a large quarry and in the railroad cut at Sanatoga Station on Schuylkill River, Montgomery County.

Sanatorium Limestone Lentil (in Geuda Springs Shale member of Wellington Formation)

Permian: Central Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 14. Name applied to limestone in Geuda Springs that caps the hills below the Geuda Springs sanatorium.

Occurs at type locality of Geuda Springs member, sec. 7, T. 34 S., T. 3 E. [Cowley County].

San Augustine Group (in Claiborne Group)[1]

Eocene: Eastern Texas.

Original reference: E. T. Dumble, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, no. 4, p. 428.

Probably named for San Augustine, San Augustine County.

San Benito Gravels[1]

Pliocene to Pleistocene: Wsetern California.

Original reference: A. C. Lawson, 1893, California Univ. Pub. Dept. Geol. Bull., v. 1, p. 151–153.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, p. 225 (fig. 4), 246–249, 257, pl. 3. In San Benito quadrangle, consists of gravels, sands, and clays, in part consolidated into conglomerate, sandstone, and clay shale. About 1,500 feet thick. Overlies Etchegoin group; overlaps Los Muertos Creek formation (new) and Tres Pinos sandstone.

In San Benito quadrangle, main belt of gravels, lying between San Benito fault zone and Tres Pinos Creek, is folded into a broad, gentle syncline, plunging toward the northwest.

**Sanborn Group**

Sanborn Formation[1]

Pleistocene and Recent: Western Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7, p. 163.

A. B. Leonard and J. C. Frye, 1943, Am. Jour. Sci., v. 241, no. 7, p. 453–462. Stratigraphic position of these deposits [Sanborn formation] unconformably above middle Pliocene Ogallala beds, and the snails which they contain conclusively demonstrate a Pleistocene age.

C. W. Hibbard, J. C. Frye, and A. B. Leonard, 1944, Kansas Geol. Survey Bull. 52, p. 3–26. Elias' term Sanborn is used in this paper to refer to essentially the entire Pleistocene section exposed in north-central and northwestern Kansas, although some distinct terrace beds of local extent have not been included within it. Term is used despite the fact that in some localities beds have been studied that are probably stratigraphic equivalents of the Peorian and Loveland as described by Lugn in southern Nebraska. Beds herein assigned to Sanborn formation have been observed from western Jewell County westward for more than 200 miles to Yuma County, Colo. Formation mantles upland of much of north-central part of state. Consists of an upper gray silt bed which is persistent over entire area, and an underlying soil zone that occurs only in north-central Kansas, and pre-soil zone deposits consisting of a wide variety of lithologic types.

J. C. Frye and O. S. Fent, 1947, Kansas Geol. Survey Bull. 70, p. 40–41. Proposed that late Pleistocene loesses, associated deposits, and lateral facies generally occurring in northern and central Kansas, be classed as Sanborn formation and the Loveland silt, Peoria silt, and Bignell silt and their lateral coarse-textured facies be assigned rank as members. Type section designated.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 106–110. Sanborn formation, unlike other stratigraphic units of formational rank in Kansas Pleistocene, includes deposits of two stages (Illinoian and Wisconsinan) and the several substages of the Wisconsinan. Includes two unconformities, defined by the Sangamon and Brady buried soils, and represents three distinct cycles of deposiiton. As classified by Kansas Geological Survey, includes (ascending) Crete sand and gravel member; Loveland silt member, commonly containing Sangamon buried soil at top; unnamed early Wisconsinan alluvial deposits; Peoria silt member, commonly containing Brady buried soil; unnamed Wisconsinan alluvial deposits; and Bignell silt member. Thickness 130 feet at type locality. Among units that consist in part or entirely of deposits known to be of Illinoian or younger age and which are properly classed at least in part as Sanborn are Kingsdown marl or formation, Odee formation, and Vanhem formation.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Rank raised to group. In southwestern Kansas, includes Kingsdown formation below and Vanhem formation above. For other parts of Kansas, includes (ascending) Crete formation, Loveland formation, early Wisconsin terrace deposits, Peoria formation, terrace deposits, and Bignell formation. Overlies Meade group. Classification used in this report is in accord with agreement at Pleistocene conference at Lawrence, Kans., June 28–29, 1956.

Type section: In canyons in NW¼ sec. 20, T. 1 S., R. 41 W., Cheyenne County, Kans. Name derived from Sanborn, Nebr., which is nearest town to a locality of the formation in Cheyenne County.

San Bruno Sandstone (in Franciscan Group)[1]

Jurassic(?): Western California.

Original reference: R. Crandell, 1907, Am. Philos. Soc. Proc., v. 46, p. 3–58.

Named for fact that it forms San Bruno Mountains.

**San Carlos Formation**[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: T. W. Vaughan, 1900, U.S. Geol. Survey Bull. 164, p. 81–82.

Named for San Carlos, Presidio County.

San Carlos Formation[1]

Pleistocene(?): Panamá.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 259.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 345. Poorly defined name for surficial deposits. Pleistocene(?).

Present on San Carlos Plain, Panamá Province.

Sanchez Sandstone Member or Tongue (of Fayette Formation)

Eocene, upper: Southwestern Texas and northern Mexico.

Original reference: W. G. Kane and G. B. Gierhart, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 9, p. 1387.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 269. Sanchez member (or tongue) overlies Gorgora shale member (new) and underlies Agua Verde shale member (new). Thickness in Starr County about 100 feet; thins and dies out half way across Zapata County.

Lies 280 feet below top of Fayette in section measured on both sides of Rio Grande between Roma and Rio Grande City, Starr County. Derivation of name not stated.

Sand Bay Agglomerate (in Sand Bay Volcanics)

Tertiary: Southwestern Alaska.

F. S. Simons and D. E. Mathewson, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 4, p. 61, 63, pls. 4, 5. At Sand Bay, composed of subangular to rounded boulders as much as 3 feet across in tuff matrix. Sorting very poor but bedding fairly well defined. Boulders mainly of two rock types: black glassy highly vesicular lava and reddish vesicular porphyry. At south end of Akuyah Cliffs, on west side of island, 1,000 to 1,500 feet thick and unconformably overlies coarse well-bedded tuffs [Finger Bay volcanics]. Numerous dikes exposed in cliffs. Similar agglomerate forms lower slopes of southern half of island. Further inland, toward the cone, agglomerate contains interbedded thin lava flows and is cut by dikes. Constitutes lower part of Sand Bay volcanics (new); underlies Sand Bay lava flows (new) and Great Sitkin volcanics (new).

F. S. Simons and D. E. Mathewson, 1955, U.S. Geol. Survey Bull. 1028–B, p. 28–29, pl. 5. Unit included in Sand Bay volcanics. Term Sand Bay agglomerate not used in this report.

Sand Bay agglomerate and lava flows combined form most of southern half of Great Sitkin Island, in central part of Aleutian Islands.

Sand Bay Lava Flows (in Sand Bay Volcanics)

Tertiary: Southwestern Alaska.

F. S. Simons and D. E. Mathewson, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 4, p. 61, 63, pls. 4, 5. Lava flows, which are porphyritic, include andesite, olivine andesite, and andesite flow-breccia, and basalt. Colors range from black through purplish gray and reddish gray to light gray. Most flows are medium grained but few are very fine grained. Platy lavas rare, and most rocks show little or no flow structure. Columnar jointing common. Vesicular flows rare. Lavas dip gently south or southeast and thicken toward center of island. Flows cap main ridges in southern part of island and reach aggregate thickness of 400 feet on Triple Divide Peak at head of Middle Yoke Valley. Constitute upper part of Sand Bay volcanics (new). Overlie Sand Bay agglomerate (new); underlies Great Sitkin volcanics (new).

F. S. Simons and D. E. Mathewson, 1947, U.S. Geol. Survey Bull. 1028–B, p. 29, pl. 5. Unit included in Sand Bay volcanics. Term Sand Bay lava flows not used in this report.

Sand Bay lava flows and agglomerate combined form most of southern half of Great Sitkin Island, in central part of Aleutian Islands.

**Sand Bay Volcanics**

Tertiary: Southwestern Alaska.

F. S. Simons and D. E. Mathewson, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 4, p. 61-63, pls. 4, 5. Comprise a lower pyroclastic sequence containing a few thin lava flows, designated the Sand Bay agglomerate, and an upper sequence of andesite and basalt flows, designated the Sand Bay lava flows. Overlie Finger Bay volcanics unconformably; older than Great Sitkin volcanics (new). Presumed to be of late Tertiary age.

F. S. Simons and D. E. Mathewson, 1955, U.S. Geol. Survey Bull. 1028-B, p. 28-29, pl. 5. Volcanics comprise a lower pyroclastic sequence consisting of agglomerate and a few thin flows, and an upper sequence composed of andesitic and basaltic lavas. Age not certain. Older than Great Sitkin volcanics, which have been glaciated, and of which at least part are probably of Pleistocene age.

Form most of southern half of Great Sitkin Island in central part of Aleutian Islands. Well exposed in vicinity of Sand Bay.

Sand Beach terrace deposit

Recent: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg, p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703 (fig. 8), 1710, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Sand Beach is proposed for the terrace deposits that is younger than and lies about 20 feet below the Riverview (new); a second bench, designated Sand Beach No. 2, lies about 5 feet lower, or about 10 to 15 feet above water level in Colorado River at Austin. Largely sand and silt.

Named for Sand Beach Reserve along north side of Colorado River at Austin, Travis County.

Sand Branch Member (of Caney Shale)

Mississippian (Chesterian): South-central Oklahoma.

M. K. Elias, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 65-69, 70 (table 2). Composed of dark-gray to black, finely laminated to flaky, noncalcareous bituminous shale, commonly shattered, with abundant crystals of gypsum; phosphatic concretions locally abundant; gray to dark-gray limestone concretions present along some bedding planes; locally concretions are closely spaced and produce concretionary lentils 10 or more feet thick. Consists of an upper and lower part, but in no area have the two parts been observed together; only lower part exposed at type locality. Higher shale of the Caney, with an upper concretionary lentil, is exposed in banks of Sandy Creek south of Wapanucka (SW¼SW¼ sec. 36, T. 2 S., R. 8 E.); if it should be found desirable to segregate the highest Caney shale in the Arbuckle Mountains as still another member, name Sand Branch would be retained for part exposed northwest of Frisco. Thickness about 130 feet. Overlies Delaware Creek member (new); unconformably underlies Pennsylvanian Rhoda Creek formation (new) at type locality of Rhoda Creek.

M. K. Elias and C. C. Branson, 1959, Oklahoma Geol. Survey Circ. 52, p. 7, 15-16. Type section redesignated. Thickness 172½ feet.

Type section: Beds 4 to 37, measured section B, sec. 14, T. 2 S., R. 7 E., Johnston County. Named derived from Sand Branch, a tributary of Clear Boggy Creek.

Sand Canyon Formation

Pleistocene, upper: Eastern New Mexico.

Sheldon Judson, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 263; 1953, Smithsonian Misc. Colln., v. 121, no. 1, p. 21–22, 24 (fig. 9), 30 (table 2). Reddish to reddish-brown alluvium; alternating beds of sand and clayey-humic material. Thickness 0 to 50 feet. Disconformably underlies Wheatland formation (new); disconformably overlies San Jon formation (new).

Type exposure: Sand Canyon, a dissected depression containing the San Jon site, which is approximately 10 miles south of town of San Jon, Quay County. Occurs in broad channels cut into underlying formations 40 to 50 feet above grade of modern arroyos.

Sand Canyon Member (of Sheep Creek Formation)

Miocene (Hemingford): Northwestern Nebraska.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 128, 129–131. Name applied to middle member of formation. The whole exposed section (type) which is about 145 feet, is made up largely of fine-grained sand, grayish in lower half and greenish in upper half; about 30 feet above base is a 3- to 4-foot bed of dark-gray volcanic ash. The fine sand below the ash bed has several zones of concretionary type of cementation and contains bones of mammals (this is zone of remains of *Merychippus* and *Pronomotherium*). Basal 10 feet is somewhat stratified by development of interbedded streaks of white fine sandy silt and contains a bed of white marl. The fine sand above the bed of the dark-gray volcanic ash is partially cemented into harder ledges, which approach in appearance the "mortar beds" of the Ogallala. Overlies Spottedtail member (new); underlies Box Butte member.

Type locality: Sand Canyon, 13 miles south and 5 miles west of Hay Springs. Type section is on southwest side of canyon at and around junction of secs. 11, 13, and 14, T. 29 N., R. 47 W., Dawes County.

†Sand Coulee Beds[1]

Eocene, lower: Western Wyoming.

Original reference: W. Granger, 1914, Am. Mus. Nat. History Bull., v. 33, p. 202–205.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 30, pl. 1. Not clearly separable as member of either Gray Bull or "Bighorn Wasatch." Shown on correlation chart as local fauna, Wasatchian.

Exposed in vicinity of Big Sand Coulee in Clark Fork Basin, Bighorn basin.

Sand Creek Flows

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 89–90. Sand Creek flows were results of glowing avalanches of pumic and scoria that descended southern slope of Mount Mazama through Kerr Notch. Flows emptied into Williamson River near present site of village of Kirk.

Glowing avalanches of pumice were part of final activity of Mount Mazama and followed what is termed main pumice fall.

Sand Creek flows southeastward from Crater Lake.

†Sand Creek Formation[1]

Pennsylvanian: Central northern Oklahoma.

Original reference: C. N. Gould, 1925, Oklahoma Geol. Survey Bull. 35, p. 79.

R. C. Moore, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 105. Essentially synonymous with Admire group.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey.

Named for Sand Creek in north part of Osage County.

†Sand Draw Sandstone Lentil (in White River Formation)

Eocene, upper, or Oligocene, lower: Southwestern Wyoming.

F. B. Van Houten, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM-140. Name applied to deposit in stream channel. Most of channel deposit is soft, pale greenish-gray to yellowish-gray tuffaceous sandstone. In upper part of lentil conglomerate lenses a foot thick contain pebbles as much as an inch in diameter. Across width of channel sediments grade upward into facies of Beaver Divide conglomerate member. At margins of channel cross section the upper part of channel fill interfingers with and is conformably overlain by volcanic facies of Beaver Divide conglomerate member. Thickness about 75 feet. Mammalian fossils suggest either Duchesnean or earliest Chadronian (latest Eocene or earliest Oligocene) age.

Name derived from Sand Draw drainage in Long Creek-Beaver Divide area, Fremont County.

Sandel Formation

Oligocene, lower: Western Louisiana.

H. V. Andersen, 1960, Louisiana Dept. Conserv.. Geol. Bull. 34. p. 102, 103–106. Delaney (1958, unpub. ms.) proposed name Sandel for greenish-yellow or tan fine-grained well-sorted. sometimes crossbedded. silty quartz sand which overlies Mosley Hill formation (restricted) and underlies the Rosefield. Thickness about 15 feet at type locality. As interpreted in this report [Sabine Parish], the Oligocene series consists of basal sand, the Sandel formation. and an upper silty clay, the Nash Creek formation (new). Sandel overlies Mosley Hill, as restricted by Delaney. Roadcuts along U.S. Highway 171, in vicinity of Hodges Gardens have been leveled and sodded in recent highway development program. Delaney's type locality of Sandel including macrofossil bed, and Murray's comparative outcrop for Mosley Hill formation (Nash Creek of this report) have been destroyed. Alternate reference localities for both formations are herein designated.

H. V. Andersen. ed., 1960. Type localities project unit 1: Baton Rouge. La.. Soc. Econ. Paleontologists and Mineralogists, Gulf Coast Sec., p. [46–48]. Age given as lower Oligocene.

Type section (Delaney): Series of roadcuts and ditches on east and west sides of U.S. Highway 171 on north inface slope of Catahoula cuesta, 1.1 miles southeast of Sandel, Sabine Parish, in SW¼NE¼ sec. 31, T. 5 N.,

R. 10 W., just north of main gate of A. J. Hodges experimental gardens. Alternate type locality (Andersen): In gully which heads on west side of U.S. Highway 171, 0.3 mile south of entrance to Hodges Gardens (NW¼SE¼ sec. 31, T. 5 N., R. 10 W.).

**Sanders Basalt**

(?)Tertiary, upper, or Pleistocene(?): West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 178, p. 1, 27–28, pl. 3. Grayish-black basalt that contains conspicuous laths of plagioclase separated by microscopic crystals of olivine and augite. Individual flows of lava are thin, ranging from 5 to 50 feet in thickness. Thickness 200 feet. Along southern mesas rests directly on rhyolite tuff beds of Gila (?) conglomerate, but to north overlies Wilder formation (new) or Gila(?) conglomerate. Along eastern margin of Bozarth Mesa, flows of Sanders basalt interfinger with lava flows of Wilder formation.

Covers all the mesas and receives its name from Sanders Mesa in south-central part of Bagdad area, Yavapai County. A crescent-shaped belt extends from Nelson Mesa on east to Black Mesa on west. Caps the extensive mesas far to the west, north, and northeast beyond the mapped area.

Sanders Bridge Limestone (in Palo Pinto Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: G. Scott and J. M. Armstong, 1932, Texas Univ. Bull. 3224, p. 24.

Type locality: On Boone Creek, 3¼ miles northwest of Booneville, Wise County. Well exposed at Sanders Bridge over Boone Creek, on Booneville-Willowpoint Road.

Sanderson Formation (in New Albany Shale)

Sanderson Member (of New Albany Shale)

Lower Mississippian (Kinderhookian): Southern Indiana, northern Kentucky, and Ohio.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 840 (fig. 3), 847–849, 857, 870. Proposed for division of the New Albany shale between the Blackiston and Underwood or Henryville formations (all new). Thickness 10 feet. Contains two beds, each with layers of phosphatic nodules at top; shale is less hard, less brittle, and less black than the upper Blackiston shale but is so similar that under varying conditions of weathering the two cannot be distinguished on lithology; fossiliferous. Includes Falling Run member (new) at top. Uniform in character from Indiana into Kentucky and from Lake Erie to Tennessee. Southwest of Irvine, Ky., Falling Run member is present and is overlain by the New Providence; from Irvine north through Ohio, the Falling Run is absent and the Sanderson is overlain by Bedford shale.

H. H. Murray and others, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 43, pl. 1. Mississippian part of New Albany has been divided into (ascending) Sanderson, Underwood, and Henryville "formation." Indiana Geological Survey uses these terms with rank of member.

Type section: In northwest angle of intersection of Klerner and Mount Tabor Roads, 1 mile northwest of Sanderson, 2 miles north of New Albany, Floyd County.

**Sandersville Limestone Member** (of Barnwell Formation)

Eocene, upper: Eastern Georgia.

C. W. Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 62, 63, 65. Limestone referred by Veatch and Stephenson (1911) to McBean formation and by Cooke and Shearer (1918, U.S. Geol. Survey Prof. Paper 120–C) to upper part of Barnwell is herein named Sandersville limestone member. Thickness probably not more than 40 feet; at type locality 19 feet.

P. E. LaMoreaux, 1946, Georgia Geol. Survey Bull. 50, pt. 1, p. 18. Sandersville limestone member is believed to be equivalent in part to the Irwinton sand member (new) but may represent in part a still younger bed of Jackson age.

Type locality: At a sink west of the Tenmile Road, 0.8 mile south of courthouse at Sandersville, Washington County.

**Sandfall Member** (of Pride Mountain Formation)

Upper Mississippian: Northern Alabama and northeastern Mississippi.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Consists mainly of noncalcareous to slightly calcareous olive-gray shale, grading upward to calcareous shale and partly oolitic limestone in upper 30 feet; strata becomes increasingly calcareous eastward, grading completely into limestone in Madison County, Ala. Thickness ranges from 86 feet at type locality to about 65 feet on Cane Creek, Colbert County, Ala. Underlies Mynot sandstone member (new); overlies Wagnon member (new).

Named for exposures in cuts along the road up Sandfall Mountain, a northern spur of Pride Mountain, in SE¼ SE¼ sec. 15, T. 4 S., R. 12 W., Colbert County, Ala.

Sand Gap Sandstone (in Slatestone Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology, [folio], p. 6, 19, pls. 2, 3, 4. Includes both massive and thin facies. Thickness near Sand Gap about 100 feet; in Cross Mountain section about 5 feet. Underlies a shale interval 40 to 120 feet thick that in turn underlies Newcomb sandstone (new); overlies a shale interval 40 to 170 feet thick that in turn overlies the Petros sandstone (new).

Named for exposures in Sand Gap, a short distance north of Elk Valley, Pioneer quadrangle, Campbell County.

**Sandgrass Andesite**[1]

Tertiary: Central Nevada.

Original reference: J. E. Spurr, 1915, Econ. Geology, v. 10, p. 729.

Exposed in Sandgrass mine, Tonopah Extension mine, and other mines in Tonopah district.

**Sand Hills Formation**[1]

Pleistocene and Recent: Western Nebraska, eastern Colorado, and southern South Dakota.

Original reference: A. L. Lugn, 1934, Nebraska State Mus., v. 1, Bull. 41, p. 321, 322, 326, 331, 350.

D. R. Hill and J. M. Tompkin, 1953, U.S. Geol. Survey Bull. 1001, p. 32–33, pl. 1. Geographically extended into Wray area, Colorado, where it makes up northwestward-trending ridges north of the Republican River. Consists of well-sorted pale-yellowish-brown unconsolidated sand; unfossiliferous. Estimated maximum thickness 100 feet. Overlies Grand Island formation and in some areas covers Pleistocene and Recent sandy silt. Considered late Pleistocene and Recent. Formation probably in part contemporaneous with the valley fill and the Pleistocene and Recent sandy silt and clay.

S. G. Collins, 1959, Geology of the Martin quadrangle (1:62,500): South Dakota Geol. Survey. Geographically extended into southern South Dakota. Covers most of southern third of Martin area. Consists of fine sands derived from underlying Valentine formation, reworked by Pleistocene and Recent wind action into a succession of consolidated dunes. Individual dunes rise as much as 160 feet above their base, and most are 80 to 120 feet in height. Total maximum thickness of material affected by eolian reworking estimated to be about 200 feet.

The Sand Hills occupy about 20,000 square miles of central and northern Nebraska.

Sand Hills[1] (series)

Cretaceous: New Jersey.

Original reference: W. B. Clark and G. B. Shattuck, 1897, Johns Hopkins Univ. Circ. 128, p. 13–16.

**Sandholdt Shale Member** (of Monterey Shale)

Sandholdt Shale

Miocene, lower, middle, and upper: West-central California.

R. R. Thorup, 1941, Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1958. Listed as a formation underlying Monterey shale and overlying Vaqueros formation (restricted). Subdivided into three unnamed members. Thickness about 800 feet.

R. R. Thorup, 1943, California Div. Mines Bull, 118, pt. 3, p. 465 (fig. 192), 466. Clay shale with minor amount of interbedded sandstone in lower part. Thickness about 950 feet. Occurs stratigraphically between sandy Vaqueros and overlying porcellaneous and cherty Monterey.

M. N. Bramlette and S. N. Daviess, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim, Map. 24. Described as a shale. Thickness as much as 2,100 feet in Horse Canyon, near Arroyo Seco, Salinas Valley.

U.S. Geological Survey currently classifies the Sandholdt as a member of the Monterey Shale on the basis of a study now in progress.

Type locality: N½ and SE¼ sec. 14, NE¼ sec. 15, T. 20 S., R. 6 E., Junipero Serra quadrangle, Monterey County.

Sandia Clay[1]

Quaternary: Central northern New Mexico.

Original reference: E. D. Cope, 1875, Ann. Rept. Chief Engineer, USA, Rept. Secretary War to 44th Cong., v. 2, pt. 2, p. 997.

In Sandia Mountains.

**Sandia Formation** (in Magdalena Group)[1]

Lower Pennsylvanian: Central northern New Mexico and southern Colorado.

Original references: C. L. Herrick, 1900, Jour. Geology, v. 8, p. 112–126; Am. Geologist, v. 25, p. 234–237; New Mexico Univ. Bull., v. 2, pt. 3, p. 1–14.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 49–50. In Sandia Mountains, formation, as herein interpreted, corresponds in age to lower part of type section of Armendaris group (new). Fauna in uppermost arenaceous beds corresponds in age almost exactly with fauna in lower part of type section of Elephant Butte formation (new). Thickness about 127 feet.

C. B. Read and D. A. Andrews, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 8; C. B. Read and G. H. Wood, 1947, Jour. Geology, v. 55, no. 3, pt. 3, p. 224 (fig. 1), 228 (fig. 2), 229, 230 (fig. 4), 231 (fig. 5), 233 (fig. 6). Includes lower limestone member and upper clastic member. Underlies Madera formation; overlies Precambrian.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 815. Clastic member of Sandia traced from New Mexico as far north as Huerfano Park, Colo. Thickness about 300 feet in Pecos, Gallinas River, Coyote Creek, and Whiskey Creek Pass sections and probably as much as 700 feet in western Huerfano Park.

A. K. Armstrong, 1955, New Mexico Bur. Mines Mineral Resources Circ. 39, p. 3, 13, 23, 28. In some areas, overlies Arroyo Penasco formation (new) and, in some areas, overlies Log Springs formation (new).

E. H. Baltz, Jr., and G. O. Bachman, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 98 (fig. 2), 99. Lower limestone member considered Devonian(?) and Mississippian; remainder of formation Early Pennsylvanian (Morrow).

D. W. Bolyard, 1956, Rocky Mountain Assoc. Geologists Guidebook to geology of the Raton Basin, Colorado, p. 52–53; 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1904–1910. Name Deer Creek formation proposed for beds called Clastic member of Sandia by Brill (1952).

E. H. Baltz and C. B. Read, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1754 (fig. 5), 1755 (figs. 6, 7), 1756 (fig. 8), 1765, 1766 (fig. 12), 1767, 1769. In much of Sangre de Cristo region, unconformably overlies Cowles member of Tererro formation (both new). Lower Pennsylvanian.

First described in Sandia, Manzano, and San Andres Mountains, N. Mex.

Sandia quartzites[1]

Middle Carboniferous: New Mexico.

Original reference: C. R. Keyes, 1903, Ores and Metals, v. 12, p. 48.

Sandia Mountains.

†Sandia series[1]

Carboniferous: New Mexico.

Original reference: C. R. Keyes, 1903, Rept. of the Governor of New Mexico to the Secretary of the Interior.

San Diego Formation[1]

Upper Cretaceous: Eastern Puerto Rico.

Original reference: H. A. Meyerhoff, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 289; 1933, Geology of Puerto Rico, p. 44.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2). Thickness about 600 feet. Occurs above Fajardo shale. Upper Cretaceous.

Present in Fajardo district.

**San Diego Formation**[1]

Pliocene: Southern California.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 337.

L. G. Hertlein and U.S. Grant 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 63 (fig. 4), 68–71. Described in San Diego quadrangle as soft yellowish and gray sands, occasionally micaceous or marly, fossiliferous; minor amounts of conglomerate. Thickness 1,250 feet. Rests with angular unconformity upon Rose Canyon shale member of the La Jolla, or on Poway formation, or overlaps them and rests with marked unconformity upon Black Mountain volcanics; unconformably underlies Sweitzer formation.

G. B. Cleveland, 1960, California Div. Mines Spec. Rept. 64, p. 7–9, pl. 1. Middle or late Pliocene.

Well developed in immediate environs of city of San Diego.

San Dimas Formation[1]

Pleistocene, upper: Southern California.

Original reference: R. Eckis, 1928, Jour. Geology, v. 36, p. 228, 235–236.

J. S. Shelton, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 77, pl. 1. Extensively exposed as remnants of Pleistocene fan deposits along base of San Gabriel Mountains. Unconformably overlies Duarte conglomerate.

Type locality: San Dimas, 5 miles west of Claremont, Los Angeles County.

†Sand Mountain Conglomerate[1]

Pennsylvanian: Northern central Alabama.

Original reference: J. L. Campbell and W. H. Ruffner, 1883, Phys. survey from Atlantic Ga., across Alabama and Mississippi, p. 54–57.

Jefferson and Blount Counties.

Sandoval granite[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des moines, Robert Henderson, State Printer, p. 4, 11.

Magdalena and Sandia Mountains. Derivation of name not given.

Sandpoint Conglomerate[1]

Late Carboniferous(?): Northern Idaho.

Original reference: A. L. Anderson, 1930, Idaho Bur. Mines and Geology Bull. 12.

Occurs in Purcell trench, north of Sandpoint, Bonner County.

†Sand Pond Gneiss[1]

Precambrian: Northern New Jersey.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 439.

**Sand Springs Basalt**[1] (in Snake River Group)

Pleistocene, upper: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 80–82, pl. 5. Thickness about 500 feet. Older than Minidoka basalt.

Exposed along borders of Snake River for distance of 32 miles upstream from Sand Springs Creek. Fills a former deep canyon of Snake River from Paul to Sand Springs, Gooding and Jerome Counties.

**Sandstorm Rhyolite**[1]

Tertiary: Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 43.

In Sandstorm mine and hills lying west of road from the mine to Columbia, Esmeralda County.

**Sandsuck Formation** (in Walden Creek Group)

Sandsuck Shale[1] (in Chilhowee Group)

Precambrian (Ocoee Series): Eastern Tennessee and western North Carolina.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16.

G. W. Stose and A. J. Stose, 1947, Am. Jour. Sci., v. 245, no. 10, p. 626 (table), 629. In Hot Springs Window area, North Carolina, Sandsuck shale is 800 to 1,000 feet thick. Underlies Cochran quartzite; overlies Vann quartzite (new). Chilhowee group. Lower Cambrian. Name substituted for Hiwassee slate of Keith.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 300. In Hot Springs Window, lowest beds exposed in Chilhowee group are soft fine-grained arkose and shale (Sandsuck formation, which has no known counterpart in the Unicoi). Late Precambrian and Lower Cambrian.

P. B. King, 1949, Am. Jour. Sci., v. 247, no. 9, p. 627, 629 (fig. 8), 630 (fig. 9), 631 (table 4), 639. Discussion of base of Cambrian in southern Appalachians. Proposed sequence in northeast part of Great Smoky Mountains shows Sandsuck shale, about 4,000 feet thick, at top of Precambrian Ocoee series. Consists of argillaceous shale, with interbedded layers and lenses of limestone and of conglomerate (latter is Citico conglomerate of Keith's early reports). Underlies Cochran conglomerate; overlies Pigeon siltstone.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 23–25. Sandsuck formation is used in this report [Hot Springs Window area] for rocks between Unicoi above and Snowbird below. Keith's use of Hiwassee in Hot Springs area considered inappropriate.

John Rogers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 24–30; pt. 1, pls. As mapped Sandsuck shale is uppermost unit of Ocoee series. Southwest of Pigeon River (especially Sevier County) overlies Pigeon siltstone; northeast of Pigeon River overlies Snowbird formation. Sandsuck as mapped northeast of river corresponds roughly to what Keith (1904) mapped as Hiwassee slate in same area. In present usage, Wilhite slate (Keith, 1895), is considered synonym of Sandsuck shale, but Citico conglomerate (Keith, 1895) may be used as member name for conglomerate beds and lenses within Sandsuck shale, especially south of Miller Cove fault. Hayes (1895) named Starr conglomerate lentil in Sandsuck shale. Because of poor base map on which he had to work, he made error in tracing units from Hiwassee River to Ocoee

River; hence, Starr conglomerate is now considered synonym of Cochran conglomerate and should be abandoned.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 962–963. Formation included in Walden Creek group (new). Lies beneath sandstone and conglomerate which Keith (1895) considered to be basal Cochran, but intertongues widely with these coarser rocks. Base of Cochran redefined at higher level, at base of persistent beds of arkose and quartzite, in part maroon; shale, sandstone, and conglomerate beneath is redefined as Sandsuck formation. Best section is not along Sandsuck Branch but on opposite northwest slope of Chilhowee Mountain; there 2,500 feet is exposed, but base is cut off by Great Smoky fault. Formation is lowest unit of sequence on Chilhowee Mountain and occurs in same position on English Mountain farther east; in both places its base is cut off by faults, and it is overlain by Cochran formation of Chilhowee group. These two occurrences are in fault blocks along front of Great Smoky thrust sheet and are not in sequence with main body of Walden Creek group. In section south of English Mountain, about 4,000 feet of beds identified as Sandsuck overlie Wilhite formation; top not preserved.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 37; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Sandsuck shale (formation) mapped in Madison and Yancey Counties. Thickness about 700 feet in Hot Springs area. Ocoee series.

Named for exposures on Sandsuck Branch of Walden Creek, Sevier County, Tenn.

**Sandtrap Conglomerate**

(?)Pliocene, upper: West-central Arizona.

S. G. Lasky and B. N. Webber, 1949, U.S. Geol. Survey Bull. 961, p. 14 (table 2), 35–38, pls. 1, 2. Largely light-red to dark-red poorly sorted conglomerate with discontinuous bedding. Includes prominent basalt member in northwest part of area (along Sandtrap Wash west of Maggie Canyon). Basalt is dense and partly vesicular. Thickness estimated to range from 300 to possibly 2,000 feet in main part of valley southwest of Artillery Mountains. Rests unconformably upon Cobwebb basalt (new), or, where basalt is absent, upon Chapin Wash formation (new), and extends well beyond limits of both to rest with angular unconformity upon Artillery formation (new) and Precambrian rocks. Referred to upper Pliocene because it is youngest of the three supposedly Pliocene formations in the basin and is separated from other two (Cobwebb and Chapin Wash) by erosional unconformity. Shown on plate 1 as Pliocene(?) and on plate 2 as late Pliocene(?).

Named from Sandtrap Wash, along which it is typically and extensively exposed. Occupies mainly the central part of valley between Artillery and Rawhide Mountains.

Sandusky Limestone[1]

Middle Devonian: Northern and central Ohio.

Original reference: J. S. Newberry, 1873, Ohio Geol. Survey, v. 1, p. 143–144, table opposite p. 89.

Occurs at Sandusky, Erie County, and Delaware, Delaware County.

Sandy Creek Beds[1]

Upper Ordovician: Northern New York.

Original reference: R. Ruedemann, 1925, New York State Mus. Bull. 258, p. 85, 137, 141, 149, 154.

Exposed along upper Sandy Creek, Jefferson County.

Sandy Hook Member (of Redbank Formation)

Upper Cretaceous: Eastern New Jersey.

R. K. Olsson, 1959, Dissert. Abs., v. 19, no. 8, p. 2063. Redbank formation is divided into Shrewsbury and Sandy Hook members.

R. K. Olsson, 1960, Jour. Paleontology, v. 34, no. 1, p. 2, 4 (fig. 2). Consists of clayey micaceous slightly glauconitic quartz sand. Underlies Shewsbury member; overlies Navesink formation.

Occurs in New Jersey Coastal Plain.

Sandy Huff Shale (in New River Group)

Sandy Huff Shale (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 193.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 226–227. Dark-gray and somewhat sandy; as much as 25 feet thick. Compensates for varying thickness of overlying Harvey sandstone and is locally cut out by it. Separated from underlying Guyandot sandstone by Castle coal. Included in New River group, Pottsville series.

Named for exposure at mouth of Sandy Huff Branch, McDowell County.

San Emedio Series[1]

Precambrian(?): Southern California.

Original reference: O. H. Hershey, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, pl. 1, map.

Probably named for San Emigdio Mountain in Kern County.

†San Emigdio Formation[1]

Eocene, upper and Oligocene: Southern California.

Original reference: G. C. Gester, 1917, California Acad. Sci. Proc., 4th ser., v. 7, pl. opp. p. 220.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 160, fig. 14. Included in Refugian stage (Oligocene).

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Age shown as upper Eocene and lower Oligocene.

Exposed on east side of San Emigdio Creek, southwestern part of Kern County.

**Sanford Formation** (in Newark Group)[1]

Upper Triassic: Central North Carolina.

Original reference: M. R. Campbell and K. K. Kimball, 1923, North Carolina Geol. and Econ. Survey Bull. 33, p. 20, 43-45.

J. A. Reinemund, 1955, U.S. Geol. Survey Paper 246, p. 35–39, pl. 1. Formation includes youngest Triassic rocks in Deep River basin. Conformably overlies Cumnock formation in Sanford and Durham basins, but appears to lie unconformably on Pekin formation in Colon cross structure. Thickness 4,000 feet in northeastern part of Sanford basin, southeast of Deep River fault, entire formation is exposed; about 3,000 feet thick northwest of fault. Largely sandstones, claystones, and siltstones; strata are lenticular or laterally gradational; no outcrop gives section that is typical outside a small area.

Named for development around town of Sanford, Lee County. Borders southeast edge of Deep River basin throughout mapped area in a belt that attains a breadth of 10½ miles in eastern part of Sanford basin, narrows to little more than one-half mile in Colon cross structure, and broadens again to a width of 3 or 4 miles in southern part of Durham basin.

Sanford Quartzite

Triassic(?): Eastern California.

G. A. Schroter, 1938, Eng. Mining Jour., v. 139, p. 44. Pure white to cream-colored translucent sugary grained quartzite, locally grading into hornfels. Occurs in Sebrina complex.

Area is on east flank of Sierra Nevada Mountains, southwest of Bishop, Inyo County.

San Francisco Alluvium

Quaternary: Southwestern Utah.

P. J. Barosh, 1960, Utah Geol. and Mineralog. Survey Bull. 68, p. 28, 29. Name applied to alluvium on east-sloping flank of San Francisco Mountains.

Area of report is Beaver County.

†San Francisco Group[1]

Franciscan (Jurassic?) and Tertiary, upper: Western California.

Original reference: J. S. Newberry, 1857, Pacific Railroad Repts., v. 6, pt. 2, p. 10–12.

Forms slopes of the axis lying between San Francisco and the ocean.

†San Francisco Sandstone[1]

Jurassic(?) and Tertiary, upper: Western California.

Original reference: W. P. Blake, 1856, Expl. and Survey for railroad route Mississippi River to Pacific Ocean, v. 5, 33d Cong., 2d sess., S. Ex. Doc. 78, p. 145–156.

Forms greater part of hills and mountains around the San Francisco Bay and, also, a considerable part of mass of Coast Mountains.

San Gabriel Formation[1] or Complex

Precambrian: Southern California.

Original reference: W. J. Miller, 1934, Univ. California at Los Angeles Pub. in Math. and Phys. Sci., v. 1, no. 1, p. 12, 25–65, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 465–469, table 4. Referred to as San Gabriel complex. Older Precambrian.

Named for extensive development in San Gabriel Mountains.

**Sangamon Interglaciation**

Sangamon Interglacial Stage

Sangamon (Sangamonian) Stage, Age

Sangamon stage of deglaciation[1]

Pleistocene: Mississippi Valley.

Original reference: F. Leverett, 1898, Jour. Geology, v. 6, p. 171–181.

Leland Horberg, 1950, Illinois Geol. Survey Bull. 75, p. 29. Sangamon interglacial stage includes Early Sangamon soil and Late Sangamon loess. Footnote states that deposits herein referred to as Late Sangamon loess have been named Farmdale loess by Leighton who regards the Farmdale loess as pro-Wisconsin (pre-Iowan) rather than Late Sangamon age.

J. C. Frye and A. B. Leonard, 1955, Am. Jour. Sci., v. 253, no. 6, p. 358–364. Provincial classification of post-Sangamonian time into Scandian, Bradyan, and Almenan subages, proposed for use in Midcontinent region.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 3–4, 11. Revision of time-stratigraphic classification of the Wisconsinan. Names Wisconsin, Sangamon, and Yarmouth stages of previous usage are here changed to adjectival endings Wisconsinan, Sangamonian, and Yarmouthian to make them consistent with form long used for Nebraskan, Aftonian, Kansan, and Illinoian stages. In terms of stratigraphic sequence, Wisconsinan stage includes all deposits above Sangamon soil and below Recent alluvium. Sangamonian stage is followed by Altonian substage (new) of Wisconsinan stage.

Name amended to Sangamon Interglaciation to comply with Stratigraphic Code adopted 1961.

Named for exposures of the soil in Sangamon County, Ill.

San Germán Limestone[1] or Formation

Upper Cretaceous: Puerto Rico.

Original reference: G. J. Mitchell, 1922, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 3, p. 253.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 44, 47, 60 (table 7). In Ponce district, overlies Río Yauco shale and underlies Peñuelas shale. Thickness 1,000 feet.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1 p. 196. In Mayagüez area, San Germán formation includes Cotui limestone member (new) near top. Occurs above Mayagüez group (new); underlies Paleocene limestone and tuffs.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, no. 1, p. 200. In Yauco district, a complex, 9,000 meters thick, of volcanic flows with interbedded marine limestone, mudstones, tuffs, and sedimentary rocks derived from volcanic rocks, is divided into eight formations [sequence not indicated]: Sabana Grande, El Rayo, Ensenada, Río Yauco, Río Loco, Río Blanca, San Germán, and Jicara (new). San Germán and Jicara formations are separated from underlying Ensenada and Río Yauco, at least locally, by unconformities. Age of complex is Senonian to late Paleocene, possibly Eocene.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 340–344, pl. 1. Mitchell (1922) used term San Germán to describe massive limestone herein called Cotui limestone. Slodowski (1956, unpub. thesis [1958, Dissert. Abs., v. 18, no. 1]) used name to refer to massive limestone and associated volcanic rocks and conglomerates. Present report [Mayagüez area] slightly expands the latter usage. The San Germán is a thick sequence of andesitic volcanic rock with interbedded conglomerate and lenses of massive limestone. One flow near base is differentiated as Cabo Rojo agglomerate; massive Cotui limestone member occurs commonly near top of volcanic sequence; locally andesitic volcanic rock, shale, and conglomerate overlies the Cotui. Maximum thickness 600 meters. Overlies Mayagüez group, probably unconformably; conformably underlies Jicara formation. Upper Cretaceous.

Type locality: In hills southwest of San Germán, Ponce district.

San Gorgonio Igneous-Metamorphic Complex

Mesozoic and older: Southern California.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 318–322, pl. 1. Consists of migmatitic gneiss, flaser gneiss, piedmontite-bearing gneiss, and green schist. Complex crops out over most of map area and constitutes a metamorphic terrane of intermediate to basic composition that has been intruded and partially reconstituted by Mesozoic(?) quartz monzonite (the Cactus?).

Occurs in San Gorgonio Pass area, Riverside County.

**Sangre de Cristo Formation**[1]

Pennsylvanian and Permian: Southern Colorado and northern New Mexico.

Original reference: R. C. Hills, 1899, U.S. Geol. Survey Geol. Atlas, Folio 58, p. 1.

C. B. Read and G. H. Wood, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 223. For continental arkoses and red beds that rest conformably, disconformably, or unconformably on Magdalena group over large areas in New Mexico, several terms have been used. Throughout most of the State, Abo formation is accepted. In Rowe-Mora basin, where indivisible arkose and red shale range in age from Upper Pennsylvanian to Permian, Sangre de Cristo formation is used. Arkosic member of Madera formation grades laterally and vertically into Sangre de Cristo.

K. G. Brill, 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 821–822. In southern Colorado, contact with underlying Madera is obscure; in this region, term Sangre de Cristo is redefined to include the Permo-Pennsylvanian strata that overlie Whiskey Creek Pass limestone member (new) of Madera limestone or its equivalent. Piedmont cyclothems characterize formation; each cyclothem consists of arkosic conglomerate grading upward into finer-grained clastic strata, and, in some, nodular limestone is present at top. Includes Crestone conglomerate near center of Sangre de Cristo Range. Thicknesses: about 500 feet near Pecos; about 2,400 feet east of Mora; about 9,500 feet east of Whiskey Pass; more than 5,500 feet east of Crestone; and about 8,800 feet in Arkansas River valley. Equivalent to Maroon formation, division between the two units placed arbitrarily at Fremont-Park County line. Assumed that formation is mainly Wolfcampian, although it may be late Pennsylvanian.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. In northwestern Mora County, N. Mex., intertongues with Madera and interfingers with Yeso formation; where Yeso is absent, directly underlies Glorieta sandstone member of San Andres formation.

E. H. Baltz, Jr., and G. O. Bachman, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 98 (fig. 2), 100–101. Summary article on occurrence of formation in southeastern Sangre de Cristo Mountains, N. Mex. Lower contact generally placed at top of highest marine limestone of underlying Magdalena group (Madera limestone). Underlies Yeso formation. Ranges in age from Middle or Late Pennsylvanian to Early Permian.

D. W. Bolyard, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1903 (fig. 5), 1904 (fig. 6), 1922–1927. Described in Sangre de Cristo Mountains between La Veta Pass and Westcliffe, Colo. Comprises up to 8,000 feet or more of predominantly fluvial strata; differentiated from underlying units by its redbeds. Two members recognized in northern part of area: lower, characterized by piedmont cyclothems and Crestone conglomerate. In fault contact with Pass Creek sandstone (new); overlies Madera formation and in some areas Minturn formation. Upper Pennsylvanian(?) and Permian (probably Wolfcamp). Type locality designated.

R. B. Johnson and E. H. Baltz, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1895–1902. Sedimentary rocks of Triassic age generally have been thought to be missing from outcrops in Sangre de Cristo formation of Pennsylvanian and Permian age. Two units of probable Triassic age have been separated from top of the Sangre de Cristo formation; one is herein named Johnson Gap formation. The other correlated with Lykins formation and in this report referred to as Lykins(?) formation.

Type locality: Area east of Crestone townsite, on west flank of central anticline between Crestone Needle on south and Eureka Mountain on north, Saguache County, Colo. Here, both members are well developed and structure is least complex. Continuous type section not designated for entire formation because faulting, topography, and inaccessibility make it difficult to measure such a section.

Sangre de Cristo Granite[1]

Precambrian: Colorado.

Original reference: R. D. George, 1913, Colorado Geol. Survey geol. map of Colorado.

Sangre de Cristo Range.

San Gregorio Sandstone Member (of Purisima Formation)

Pliocene: Northern California.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1325–1326. Composed of 150 to 350 feet of lithic arenites. Overlies Pomponio member (new); underlies Lobitos mudstone member (new).

Area of report is in Santa Cruz Mountains, 30 to 40 miles south of San Francisco.

San Jacinto Granodiorite

Jurassic or Cretaceous: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 60–61, pl. 1. Varies from quartz diorite to granite. Constitutes main part of San Jacinto batholith. Massive granitic dikes, presumably of San Jacinto granodiorite cut Bradley granodiorite and Palm Canyon complex (both new). Unit was described (but not named) by Fraser (1931, California Div. Mines Rept. 27).

Occurs west and southwest of Palm Springs, Riverside County.

San Jacinto Series[1]

Pliocene and Pleistocene: Southern California.

Original reference: P. H. Dudley, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 223.

Probably named for San Jacinto, Riverside County.

**San Joaquin Formation**[1]

Pliocene, upper: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 181.

W. F. Barbat and John Galloway, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 4, p. 476–499. San Joaquin clay described at type section herein designated. Thickness 1,860 feet. Unconformably underlies Tulare formation; overlies Etchegoin sand.

W. P. Woodring, Ralph Stewart, and R. W. Richards, 1940, U.S. Geol. Survey Prof. Paper 195, p. 27–53, pl. 3. Name San Joaquin formation adopted for greater part of apparently nonmarine and marine strata underlying nonmarine Tulare formation; overlies Etchegoin formation. This usage restricts name Etchegoin as used by Arnold and Anderson (1910, U.S. Geol. Survey Bull. 398). Predominantly fine-grained silty sandstone, silt, and clay. Thickness 1,200 to 1,800 feet. Includes Cascajo conglomerate member (new) at base. Faunal zone mapped.

Type section: Sec. 23, T. 22 S., R. 18 E., north dome of Kettleman Hills, Fresno and Kings Counties, San Joaquin Valley.

San Jon Formation

Pleistocene, upper: Eastern New Mexico.

Sheldon Judson, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 263; 1953, Smithsonian Misc. Colln., v. 121, no. 1, p. 18–20, 24 (fig. 9), 30 (table 2). Consists chiefly of dark-blue-gray clay grading laterally into greenish clay and into reddish compact sandy alluvium toward borders of basin. Thickness 0 to 50 feet. Disconformably underlies Sand Canyon formation (new). Rests on nearly horizontal but slightly irregular top of unit referred to as basal sand that unconformably overlies Purgatoire formation. Bones of extinct bison and artifacts found in top of blue clay.

Type exposure: San Jon site, approximately 10 miles south of San Jon, Quay County.

San Jose Formation

Eocene, lower: Northern New Mexico and southern Colorado.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 257–282; no. 6, p. 363–385. Name proposed for the "Wasatch" of authors in San Juan Basin. In this region the San Jose is preceded by hiatus representing late Paleocene time. There was gentle regional uplift and probably stronger folding outside present basin between deposition of Nacimiento and that of San Jose, but strong uplift that now defines eastern margin of basin is post-San Jose. In southern Colorado there was nearly continuous deposition through the later Paleocene into the Eocene. As a "specific locality at which the unit is typically developed" the badlands exposures along and near continental divide about 1 mile northwest of Regina in sec. 29, T. 22 N., R. 1 W., are designated. These exposures include only one of several distinguishable facies within formation and do not include either highest or lowest beds assigned to it. Characteristically lithology of formation is highly variable, both vertically and horizontally. There is not any one continuous sequence of exposures where full thickness of all major facies of formation are displayed. It is preferable to speak of type region rather than type locality. Type region herein designated. This enlarged type locality includes good development of lithologic facies considered typical of formation and also includes localities where have been found most of early Eocene mammals which constitute typical, but not only, faunas of formation. In type region, and more generally over much of area of formation, three major facies recognized. These intergrade almost imperceptibly in places but are markedly dissimilar in their typical development. In type region are two distinguishable clay facies, corresponding with Granger's (1914) Almagre and Largo beds. These facies contain mammalian faunas also recognizably different in facies. These faunas are all Wasatchian and probably extend over early and middle parts of that age, rather than middle and later parts as commonly supposed. Total thickness as preserved in type region 1,200 to 1,300 feet. Tiffany fauna of southern Colorado, well known to be of late Paleocene age, is in beds not now separated from the San Jose but probably separable and only tentatively assigned to that formation. Discussion of previous nomenclature, especially term Canyon Largo as used by early workers (Newberry, Holmes, and Keyes) and proposed reinstatement of Canyon Largo by Wood and others (1941, Geol. Soc. America Bull., v. 52, no. 1).

Type region: Exposures extending along eastern edge of basin from Yegua Canyon southward about 25 miles to exposed base of formation northwest of Cuba and westward from this front 10 or 15 miles approximately to meridian of settlement of Lindrith. Name derived from San Jose Valley, northwestern Sandoval County, N. Mex. Valley is followed by San Jose Creek, or Arroyo, an intermittent stream rising mainly on west flank of San Pedro Mountain, above settlement of Regina, in T. 23 N., R. 1 W., and running southward from Regina near western border of T. 22 N., R. 1 W., to junction with the Rito de los Pinos and Rio Puerco near town of Cuba in T. 21 N., R. 1 W. Formation extends into southwestern Colorado.

**San Juan Breccia** or **Formation**

San Juan Tuff[1]

Middle and late Tertiary: Southwestern Colorado.

Original reference: W. Cross, 1896, Colorado Sci. Proc., v. 5, p. 225–228.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 14, 69–75, pl. 1. Composed almost entirely of fragments of dark rocks. Thickness varies because both upper and lower surfaces are irregular surfaces of erosion. Maximum thickness about 3,000 feet, in southern part of Ouray quadrangle. Overlies Telluride conglomerate without apparent unconformity in Telluride quadrangle, but to the east only remnants of Telluride remain and San Juan directly overlies older pre-Tertiary rocks ranging from Precambrian to Cretaceous in age;

in Uncompahgre quadrangle, overlies Lake Fork quartz latite. Underlies flows and tuffs of Silverton volcanic series. Equivalent to West Elk breccia in Anthracite and Crested Butte areas.

F. B. Van Houten, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 383–385. Gunnison (tillite) volcanic conglomerate believed to be a volcanic-rich mudflow and stream deposit that is seemingly a basal part of San Juan tuff.

Confined to northwestern part of San Juan Mountains, chiefly to area of about 50 miles across. Extends west of Telluride quadrangle, is widely distributed in Telluride, Silverton, and Montrose quadrangles. Extends to north of Montrose and Uncompahgre quadrangles into West Elk Mountains.

San Juan Formation[1]

Pleistocene: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 10, 11.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 62–64. In strictest sense, San Juan formation refers to consolidated resistant crossbedded calcarenites of aeolian origin, generally forming ridges of calcareous sandstone elongated parallel to coastline and showing distinctly disconformable relations to the Tertiary. Composed mostly of somewhat rounded grains of shell and coral fragments, along with quartz, bonded together with calcite cement. Formation may be Pliocene, but until further studies are made it is probably best to retain Pleistocene age.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 323 (fig. 2), 348. Pleistocene dune-sand deposit. Caps Ponce formation on Cabo Rojo, in Mayagüez area.

Well developed on site of city of San Juan.

†San Juan Glacial Epoch[1]

Pleistocene: Southwestern Colorado.

Original references: W. W. Atwood and K. F. Mather, 1912, Science, new ser., v. 35, p. 315; 1912, Jour. Geology, v. 20, p. 388; 1912, Geol. Soc. America Bull., v. 23, p. 732.

San Juan Mountains.

San Juan Series[1] or Group

Devonian and Carboniferous: Northwestern Washington.

Original reference: R. D. McLellan, 1924, Am. Jour. Sci., 5th, v. 8, p. 217.

F. T. Etherington, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 191. San Juan group listed on table of formations of western Washington. Argillite, graywacke, schist, and limestone, all metamorphosed by batholithic intrusives. Underlies Nanaimo formation. Jurassic and older.

Named for exposures on San Juan Islands.

San Juan Bautista Formation[1] (in San Lorenzo Group)

Oligocene: Southern California.

Original reference: P. F. Kerr and H. G. Schenck, 1925, Geol. Soc. America Bull., v. 36, p. 470, 471, 472, 493, map.

J. E. Allen, 1946, California Div. Mines Bull. 133, p. 18 (fig. 2), 27, pls. 1, 2, 3. Described in San Juan Bautista quadrangle. Basal formation of San Lorenzo group. Thickness 1,500 to 1,800 feet. Underlies Pinecate formation; overlies granite.

Named for exposures in vicinity of San Juan Bautista, San Benito County.

**Sankakuyama Formation**

Sankakuyama Liparite

Eocene(?): Mariana Islands (Saipan).

Risaburo Tayama, 1938, Geomorphology, geology, and coral reefs of Saipan Island: Tropical Industry Inst., Palau, South Sea Islands, Bull. 1 [English translation in library of U.S. Geol. Survey, p. 50, 51]. Liparite is chocolate colored on fresh surfaces and grayish white on weathered surfaces. Feldspar is plagioclase. Lower part is lava, which is almost vertical and forms summit of Sankakuyama; middle part is tuff, extensively exposed on shore opposite Tsukimishima Island. Older than Hagman anesite; relationship not clear because contact of the units not observed.

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 39–46, pl 2. chart 2. Formation consists of dacite flows and pyroclastic rocks of several textural varieties. Includes four principal facies of varied relations and known to be repeated in the general succession: Massive dacite flow rocks; vitrophyric and perlitic dacite breccias; dacite tuffs; mixed dacite pyroclastics. Maximum thickness not known, but incomplete section, estimated to be 1,800 feet, is exposed at Mount Achugau; actual thickness probably of order of few thousand feet. Dacite rocks are oldest outcropping rocks on Saipan; disconformably overlain by andesitic tuffs and flows of Hagman formation, by beds of Densinyama formation, and by Matansa limestone, all of which contain Foraminifera and are late Eocene age. Type section designated.

Type section: Succession that begins in cliffs that form northern flank of Mount Achugau, and continues through its south flank. Complete section nowhere exposed. Named for exposures at Sankakuyama (Mount Achugau) north of Densinyama.

Sankaty Beds[1] or Group[1]

Pleistocene: Southeastern Massachusetts.

Original reference: J. B. Woodworth, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 975–988.

Occurs on Gardners Island, Marthas Vineyard, and Block Island. Named for Sankaty Head, on Nantucket Island.

**Sankaty Sand[1]**

Pleistocene: Southeastern Massachusetts, southeastern New York, and southern Rhode Island.

Original reference: J. B. Woodworth, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 975–988.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1715, chart 12. Pleistocene (Sangamon). Area given as New England Islands and Cape Cod, Mass.

Named for Sankaty Head on Nantucket Island, Mass.

†Sankaty Head Beds[1]

Pleistocene: Massachusetts.

Original references: J. H. Wilson, 1905, Jour. Geology, v. 13, p. 713–734; 1906, Glacial history of Nantucket and Cape Cod, p. 13–30.

Probably named for Sankaty Head on Nantucket Island, Mass.

Sankoty Sand

Pleistocene (pre-Kansan or Nebraskan): Northeastern Illinois (subsurface).

Leland Horberg, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1204. An extensive fill of sand and gravel up to 300 feet thick within the ancient Mississippi (middle Illinois) bedrock valley.

Leland Horberg, 1950, Illinois Geol. Survey Bull. 75, pt. 1, p. 29, 30 (fig. 5), 34–36; 1953, Illinois Geol. Survey Rept. Inv. 165, p. 12–18. Defined as lowermost sand and gravel deposit which underlies glacial till or related outwash and overlies bedrock along ancient Mississippi Valley. Typically sand is 70 to 90 percent quartz grains, about 25 percent of which are pink, rounded, and polished. Thickness varies owing to topography on which it was deposited; along axis of bedrock valley thickness may be almost 300 feet; average about 100 feet. Underlies Kansan and possibly Nebraskan drift; rests directly on Paleozoic formations.

Named for Sankoty water field, north of Peoria, where numerous wells penetrate the deposit.

**San Lorenzo Formation[1]**

San Lorenzo Group

Oligocene: Southern California.

Original reference: R. Arnold, 1906, U.S. Geol. Survey Prof. Paper 47, p. 16.

J. E. Allen, 1946, California Div. Mines Bull. 133, p. 18 (fig. 2), 27. Referred to as San Lorenzo group in San Juan Bautista quadrangle. Includes San Juan Bautista and Pinecate formations. Thickness about 1,500 feet. Overlies Santa Lucia quartz diorite; underlies Vaqueros group.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1325. Formation, in La Honda and San Gregorio quadrangles, San Mateo County, includes 1,900 to 3,000 feet of mudstones and sandstones of late Eocene and Oligocene (Refugian and Zemorrian) age. Diabase sills as much as 600 feet thick intrude the lower San Lorenzo and are related to igneous activity which supplied volcanic material in overlying Mindego formation (new).

E. E. Brabb, 1960, Dissert, Abs., v. 21, no. 5, p. 1163. San Lorenzo formation of Eocene and Oligocene age is divided into two members herein named Twobar shale and Rices mudstone. Latter unit is type Oligocene of California, although it probably does not correspond to Oligocene series of Europe. Fossils indicate Twobar is Narizian and Rices is Refugian and Zemorrian. Underlies Butano sandstone of late Eocene (Narizian) age.

Typically exposed along bed of San Lorenzo River about 2 miles above Boulder Creek, Santa Cruz County.

San Lorenzo Quartz Diorite[1]

Age(?): Puerto Rico.

Original reference: C. R. Fettke, 1924, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 2, p. 153.

†San Lorenzo Series[1]

Oligocene: Southern California.

Original reference: B. L. Clark, 1918, California Univ. Pub., Dept. Geol. Bull., v. 11, p. 54–111.

†San Luis Formation[1]

Jurassic(?): Southern California.

Original reference: H. W. Fairbanks, 1904, U.S. Geol. Survey Geol. Atlas, Folio 101.

Named for development in San Luis Valley, San Luis Obispo County.

**San Marcos Gabbro**

San Marcos Mountain Gabbro

Cretaceous: Southern California.

F. S. Miller, 1935, *in* C. S. Hurlburt, Jr., Am. Mineralogist, v. 20, no. 9, p. 609–611. Named San Marcos Mountain gabbro. Medium-grained dark-gray plutonic rock composed essentially of plagioclase feldspar and pyroxene. In the intrusive sequence, San Marcos Mountain gabbro is followed by Bonsall tonalite (new).

F. S. Miller, 1937, Geol. Soc. America Bull., v. 48, no. 10, p. 1398–1408. Described as San Marcos gabbro. Rocks included cover a wide range of composition and texture within the gabbro family. Most abundant rock type is medium-grained dark-gray norite. Derivation of name given.

Richard Merriam, 1946, Geol. Soc. America Bull., v. 57, no. 3, p. 224–225, 227, pl. 1. Gabbro and related rocks were described from eastern edge of Ramona quadrangle by Hudson (1922) under name Cuyamaca basic intrusive. Miller (1937) described similar rocks in San Luis Rey quadrangle, where he called them San Marcos gabbro. Mapping in Ramona area, which lies between the two above-mentioned areas, has shown that the two formations are probably the same. The gabbro is here referred to as the San Marcos. Occurs as numerous small bodies scattered among younger and larger tonalite and granodiorite masses and as irregular patches cutting schist and Stonewall rocks [Stonewall formation]. Middle Cretaceous(?).

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 485, table 4. Suggested Late Mesozoic plutonic sequence: San Marcos gabbro (and Cuyamaca basic intrusive), Green Valley tonalite, Bonsall tonalite, Lakeview tonalite, Stonewall granodiorite, La Posta quartz diorite, and Rattlesnake granite.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 41–53, pl. 1. Intrudes Bedford Canyon formation (new) and rocks of overlying Santiago Peak volcanics. Older than Green Valley tonalite and Lakeview Mountain tonalite; appears to be oldest rock in Cretaceous(?) batholith. Cretaceous.

Occurs in San Luis Rey, Elsinore, Corona, Ramona, and Santa Ysabel quadrangles. The norite-type gabbro makes up greater part of San Marcos Mountains, San Luis Rey quadrangle, from which name San Marcos gabbro is derived.

San Martine Limestone Member (of Boracho Limestone)

Cretaceous (Comanche Series): Southwestern Texas.

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 374 (fig. 2), 383–384. Name proposed for upper member of Boracho limestone. Basal 30 to 40 feet of member consists of nodular to thick-bedded slightly argillaceous, aphanic limestone. Thickness 260 feet. Overlies Levinson limestone member (new); unconformably underlies Buda limestone.

Type section: On northwest face of a hill 1 mile south of San Martine Station on Texas and Pacific Railroad, and 1,500 feet south of the railroad, San Martine quadrangle [Reeves County].

San Mateo Formation[1]

Pliocene(?): Southern California.

Original reference: A. O. Woodford, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 7, p. 169, 217–219.

Named for occurrence along San Mateo Creek, in northwest corner of San Diego County.

†San Miguel Cherts[1]

Jurassic(?): Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416.

Type locality: Rocks of San Miguel Hill, San Francisco County.

†San Miguel Conglomerate[1]

Eocene: Southwestern Colorado.

Original reference: W. Cross, 1896, Colorado Sci. Soc. Proc., v. 5, p. 235–241.

Typically exposed on north side of San Miguel River, from Marshall Creek westward for several miles.

**San Miguel Formation[1]**

Upper Cretaceous (Gulf Series): Southern Texas.

Original reference: E. T. Dumble, 1892, Geol. Soc. America Bull.. v. 3, p. 224–230.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 9. Shown on correlation chart above Upson clay and below Olmos formation. Upper Cretaceous.

Named from abandoned village of San Miguel, near Eagle Pass, Maverick County.

**San Onofre Breccia[1]**

Miocene, middle: Southern California.

Original reference: A. J. Ellis, 1919, U.S. Geol. Survey Water-Supply Paper 446.

L. E. Redwine and others, 1952, Cenozoic correlation section paralleling north and south margins, western Ventura basin, from Point Conception to Ventura and Channel Island, California: Am. Assoc. Petroleum Geologists, Pacific Section. Shown on stratigraphic column of Santa Cruz Island as about 2,000 feet thick. Underlies Monterey formation; overlies Cozy Dell. However, this breccia may better be designated as a member of Rincon formation.

A. O. Woodford and others, 1954, California Div. Mines Bull. 170, chap. 2, p. 68 (fig. 2), 71, 75 (fig. 5), pl. 1a. Described in Los Angeles Basin. Composed almost exclusively of fragments of glaucophane schist and related rocks of Western bedrock complex (Catalina schist), with numerous blocks 3 to 10 feet in diameter. Interbedded with Monterey shale that contains middle or late Miocene fish scales; overlain by Monterey shale with middle Miocene Foraminifera. Separated from underlying main part of Topanga formation by notable unconformity.

Probably named from fact it forms San Onofre Hills, in San Diego County.

San Pablo Formation

San Pablo phase (of Barbacoas Formation)

Oligocene(?): Panamá.

R. T. Hill, 1898, Harvard Coll. Zoology Bull., v. 28, no. 5, p. 184–185, 206, 236 (table). Brownish rock with fragments of decomposed light-blue eruptive material imbedded in it. Grades upward into Barbacoas formation and is termed San Pablo phase of Barbacoas, Term Panamá formation used to include analogous deposits of Barbacoas, San Pablo, and Miraflores.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 345–346. Listed as formation. Considered informal name. Oligocene(?):

Described near village of San Pablo, west of Barbacoas. Now submerged locality in Canal Zone.

**San Pablo Group[1] or Formation[1]**

Miocene, upper: Western California.

Original reference: J. C. Merriam, 1898, California Univ. Pub., Dept. Geol. Bull., v. 2, p. 109–118.

B. L. Clark and A. S. Campbell, 1942, Geol. Soc. America Spec. Paper 39, p. 5. In Mount Diablo region, formation rests directly on Kellogg shale (new).

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 16 (fig. 2), pls. In Tesla quadrangle, group comprises (ascending) Cierbo and Neroly formations. Thickness as much as 2,700 feet. Overlies Panoche rocks, angular unconformity; underlies Livermore gravels.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 75–85, pls. San Pablo group, in San Francisco Bay region, comprises (ascending) Briones, Cierbo, and Neroly sandstones.

F. F. Davis and D. W. Carlson, 1952, California Jour. Mines and Geology, v. 48, no. 3, p. 212. Formation, in Merced County, overlies Kreyenhagen formation and underlies Ora Loma formation (new).

C. K. Ham, 1952, California Div. Mines Spec. Rept. 22, p. 6 (fig. 3). In Las Trampas Ridge area, San Pablo group overlies Monterey group and underlies Contra Costa group (new).

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 12 (fig. 2), 44–46, pl. 2. Described in Ortigalita Peak quadrangle an San Pablo formation consisting of about 400 feet of bentonitic gravel, sand, and clay. Underlies Oro Loma formation; overlies Kreyenhagen formation.

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–88. Described in Hayward quadrangle as formation consisting of two units:

an upper sequence of poorly consolidated biotitic glauconitic sandstone, clay shale, and pebble conglomerate, and a lower overlapping sequence of biotitic arkosic sandstone with ferruginous nodules. Thickness ranges from 200 feet to as much as 1,700 feet. Overlies Briones sandstone; underlies Orinda formation; contact gradational. For purpose of this report, the Briones sandstone is separated from San Pablo group.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 20–21. In Pleasanton and several others areas of San Francisco Bay region, confusion might be avoided if term San Pablo formation was redefined and used in place of Cierbo and Neroly formations. Need for restudy of San Pablo formation and group arises from fact that in some localities formational boundaries are difficult to recognize because formations have similar lithology. Formational contacts have been drawn chiefly on faunal evidence and with overemphasis on topographic expression of formations of the group. Terms San Pablo group, Cierbo, and Neroly are used with reluctance in this report.

Named for occurrence on San Pablo Bay, Contra Costa County, near town of Rodeo.

San Pedran Epoch[1]

Pleistocene: Southern California.

Original reference: O. H. Hershey, 1902, California Univ. Pub. Dept. Geol. Bull., v. 3, p. 1–29.

San Pedro Group

San Pedro Series

Pliocene: Southeastern Arizona.

G. G. Simpson, 1933, Am. Mus. Nat. History Bull., v. 67, art. 3, p. 109, fig. 2. A Pliocene series between Benson and Tombstone.

A. A. Stoyanow, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 297 (table). Fossiliferous unit of tuffaceous clays in arkosic gravels and conglomerates.

Between Benson and Tombstone, Cochise County.

**San Pedro Sand**[1] or **Formation**

Pleistocene, lower: Southern California.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, 1898—first published in 1897 as House Doc. 5, 55th Cong., 2d sess., p. 335.

T. L. Bailey, 1943, Geol. Soc. America Bull., v. 54, no. 10, p. 1557. Described in Santa Barbara County. San Pedro formation, as defined here, is synonymous with Pressler's (1929) Las Posas except that his so-called Kalorama member (near Ventura) which contains a typical Santa Barbara fauna, is retained in the Santa Barbara; it is also approximately equivalent to the combined Hall Canyon and Saugus formations of Eaton (1928). Saugus, Las Posas, and Hall Canyon are abandoned.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 42–53, pls. 1, 13, 14. Described in Palos Verdes Hills area as San Pedro sand. Rests directly on the Miocene or Pliocene or overlies the Lomita marl or Timms Point silt. Maximum exposed thickness about 170 feet. Lower Pleistocene. Type region designated.

California State Water Resources Board, 1953 (revised 1956), California State Water Resources Bull. 12, v. 2, p. B–103–B–104, pls. B–1C, B–2. In Ventura County, includes basal Fox Canyon member (new) and Epworth gravel member (new) near top.

T. L. Bailey, 1954, *in* Pacific Petroleum Geologist, v. 8, no. 9, p. 1. South of South Mountain, lower 200 to 500 feet of San Pedro formation is Fox Canyon member. San Pedro conformably overlies Santa Barbara formation and is between 1,000 to 3,500 feet thick.

J. F. Poland and others, 1956, U.S. Geol. Survey Water-Supply Paper 1109, p. 38 (table), 60–86, pl. 3. Described in Long Beach-Santa Ana area as a formation. Expanded to include Timms Point silt and Lomita marl as basal members. Full stratigraphic sequence underlies unnamed upper Pleistocene deposits and overlies the Pico formation. Thickness as much as 1,350 feet.

J. F. Poland, A. A. Garrett, and Allen Sinnott, 1959, U.S. Geol. Survey Water-Supply Paper 1461, p. 39–57, pls. In this report [Torrance-Santa Monica area], the San Pedro is considered to be essentially correlative with (but much thicker and more heterogeneous) the type San Pedro sand, Timms Point silt, and Lomita marl as defined by Woodring and others (1946). However, it doubtless includes some younger strata and may include some which are older than any exposed in type section. Nonlithologic designation San Pedro formation is preferred to term San Pedro sand. Timms Point silt and Lomita marl are treated as basal members of the formation. As here defined, formation embraces all strata of early Pleistocene age. In most of area, formation occurs between unnamed upper Pleistocene deposits above and Pico formation below. Thickness as much as 1,000 feet.

Type region: Localities along San Pedro waterfront, Los Angeles County.

San Pedro Schist Breccia and Sandstone[1]

Miocene or Pliocene: Southern California.

Original reference: A. O. Woodford, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 7, p. 210–221.

Probably named for San Pedro, Los Angeles County.

†San Pedro Shales[1]

Eocene(?): Western California.

Original reference: R. Crandall, 1907, Am. Philos. Soc. Proc., v. 46, p. 3–58.

Exposed in cliffs north and south of San Pedro Point, San Francisco region.

San Pedro Valley Formation

Pliocene (Blancan) to Pleistocene: Arizona.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 31, pl. 1. Replaces San Pedro as used by Simpson (1933, Am. Mus. Nat. History Bull. 67, p. 109). Term San Pedro preoccupied.

Cochise County.

**Sanpete Formation** (in Indianola Group)

Upper Cretaceous: Central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 127, 133 (fig. 17). Distinct unit of sandstone and conglomerate, with minor amounts of shale, containing fossils of lower Colorado age. Overlies Morrison(?) and underlies Allen Valley shale (new). Where clearly differentiable, it is set apart as Sanpete formation. Consists of brown, ochre, buff, and gray sandstone, gray to ochre shale, mainly sandy, and gray conglomerate. Thickness in Salina Canyon about 1,350 feet. The lower 335 feet of the formation, as here specified, may belong to the Morrison(?).

Named from Sanpete Valley, on east side of which, south of Manti, the rocks of formation are exposed in hogbacks and low ridges. In Salina Canyon, about 4 miles east of Salina, is a complete and well-exposed section. Also exposed in canyon of Lake Fork about 1½ miles southeast of Thistle.

**Sanpoil Volcanics**

Sanpoil volcanic rocks

Eocene or Oligocene: Northwestern Washington.

Hunting Geophysical Services, Inc., 1960 *in* Washington Div. Mines and Geology Rept. Inv. 20, p. 6. Correspond in part to Umpleby's (1910, Washington Geol. Survey Bull. 1) andesite flows; however, with his flows he included rocks which are here assigned to Klondike Mountain formation (new). Consists of flows and flow breccias ranging in composition from quartz latite to dacite; locally tuffaceous interbeds. Intruded by bodies of Scatter Creek rhyodacite (new). Republic quadrangle and part of Aeneas quadrangle were mapped by Muessig and Quinlan (1959, U.S. Geol. Survey open-file map); Curlew quadrangle mapped by Calkins, Parker, and Disbrow (1959, U.S. Geol. Survey open-file map).

Report discusses parts of Okanogan and Ferry Counties.

**San Rafael Group**[1]

Middle and Upper Jurassic: Eastern Utah, Arizona, western Colorado, and New Mexico.

Original reference: A. A. Baker and others, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, p. 787.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1664–1668. Includes Wanakah formation geographically extended into New Mexico and adjacent parts of northeastern Arizona to include Todilto sandstone as member.

C. T. Snyder, 1952, Utah Geol. Soc. Guidebook 7, p. 12. In section from Cedar City, Utah, to Las Vegas, Nev., group includes (ascending) Carmel, Entrada, Curtis, and Winsor formations.

C. T. Smith, 1954, New Mexico Bur. Mines Mineral Resources Bull. 31, p. 12–14. In Thoreau quadrangle, McKinley and Valencia Counties, San Rafael group comprises (ascending) Entrada sandstone, Todilto limestone, and Thoreau formation (new). Underlies Morrison formation; overlies Glen Canyon group.

F. W. Cater, Jr., 1955, U.S. Geol. Survey Geol. Quad. Map GQ–71. In Davis Mesa quadrangle, Colorado, comprises (ascending) Carmel, Entrada, and Summerville. Overlies Navajo sandstone, Glen Canyon group; underlies Salt Wash sandstone member of Morrison formation. Group crops out in narrow band along canyon walls and on sides of Paradox Valley.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 32–48. At type locality, includes (ascending) Carmel formation, Entrada sandstone, Curtis formation, and Summerville formation. In area of this report [Navajo country], includes (ascending) Carmel, Entrada, Todilto limestone, Summerville, and Bluff sandstone. Unconformably overlies units of Glen Canyon group; in some areas, Navajo sandstone; and in others, Wingate sandstone (Lukachukai member). In some areas, underlies Morrison formation (Salt Wash or Recapture member); in other areas, underlies Cow Springs sandstone. Middle and Upper Jurassic.

E. B. Ekren and F. N. Houser, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-221. In Moqui SE quadrangle, Colorado, group comprises (ascending) Entrada sandstone, Summerville formation, and Junction Creek sandstone. Overlies Navajo sandstone; underlies Morrison formation.

Named for exposures in San Rafael Swell, southeastern Utah.

**San Ramon Sandstone**[1]

Oligocene, upper, or Miocene, lower: Western California.

Original reference: B. L. Clark, 1918, California Univ. Pub., Dept. Geol. Bull., v. 11, p. 54–111.

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Upper Oligocene.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 64–65, pl. 7. Described in Coast Ranges north of San Francisco Bay, where it occurs southeast of Martinez in Carquinez quadrangle and on east side of Carneros Valley in Sonoma quadrangle. In Martinez area, approximately 140 feet thick; disconformably overlies Domengine sandstone and is slightly unconformably beneath Sobrante sandstone. Near Carneros Creek, approximately 300 feet thick; lies in fault contact with the Knoxville and disconformably underlies undifferentiated Monterey shale. Type section is 525 feet thick. Refers to Clark (1918) for derivation of name and type section.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 56–59, pls. Formation in Martinez area is exposed in east and west limbs of Pacheco syncline where it is 130 to 190 feet thick. Overlies Pereira shale member of Alhambra formation (both new); underlies Sobrante sandstone.

U.S. Geological Survey currently designates the age of the San Ramon Sandstone as late Oligocene and early Miocene on the basis of a recent study of marine mollusks.

Type section: Southwest of Walnut Creek, Contra Costa County. Named from San Ramon Creek in Concord quadrangle on west side of Mount Diablo, where it lies in two nearly parallel bands in San Ramon syncline.

**San Saba Limestone Member** (of Wilberns Formation)

Upper Cambrian: Central Texas.

Frederick Romberg and V. E. Barnes, 1944, Geophysics, v. 9, no. 1, p. 88, fig. 7. San Saba member of Wilberns underlies Pedernales member (new) and overlies Point Peak shale member (new). Name credited to Josiah Bridge and V. E. Barnes.

Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 117–121, pls. 1, 2. Name San Saba was originally used as a series by Comstock (1890) who applied it either to these beds or some part of them. Dake and Bridge (1932, Geol. Soc. America Bull., v. 43, p. 729–732) called these beds "Post Wilberns," correlated them with the Fort Sill and Signal Mountain formations, and suggested that Comstock's name San Saba might be revived for a part of them. The name is now applied to entire series of more or less glauconitic limestone overlying Point Peak shale member of Wilberns and underlying Threadgill member of Tanyard formation. Replaced eastward by Pedernales dolomite member. Grades downward into Point Peak shale, boundary being drawn on lithic grounds and not at definite stratigraphic horizon. In areas where stromatolitic bioherms do not occur, San Saba-Point Peak boundary is top of highest significant shale; where bioherms occur, selection of boundary commonly depends on lateral tracing and consensus of varied factors. In type section, the zone of stromatolitic bioherms formerly included in San Saba are now considered to be in Point Peak. Top boundary is Cambrian-Ordovician contact in western part of Llano uplift and contact with Pedernales dolomite member elsewhere. Thickness at type section about 280 feet.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 145, 156, 188, 193, 226, 255, pls. [1946]. Type section and local stratigraphy described in detail.

Type section: Along both sides of Mason-Brady Highway, beginning at bridge across San Saba River and extending northward for 0.7 mile, McCulloch County. Here it is in collapse contact with Threadgill member of Tanyard.

San Saba Series[1]

Upper Cambrian(?) and Lower Ordovician: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxii, 301–306, pl. 3.

Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v: 58, no. 1, p. 117. Name San Saba was originally used as series term by Comstock who applied it either to beds here termed San Saba limestone member of Wilberns formation or to some part of them.

Named for San Saba County and San Saba River valley.

**San Sebastián Formation** (in Río Guatemala Group)

San Sebastián Shale[1]

Oligocene: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 10, 17.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85. San Sebastián formation, Lares limestone, and Cibao marl (sequence ascending) are facies equivalents that show rapid lateral transition; term Río Guatemala group is introduced for this sedimentary complex. Names are retained to designate predominantly clastic facies, predominantly reef-type limestone, and predominantly marl and chalky limestone respectively. Formation changes upward from predominantly gravel in lower part to predominantly shale, locally interbedded and interfingered with marl and limestone at top. Maximum thickness about 300 meters in vicinity of the Río Guatemala northwest of San Sebastián. About 4 kilometers east of San Sebastián, outcrops of approximately 200 meters of basal part of formation end against a salient of Cretaceous rocks; the upper 80 to 110 meters of the sequence overlap salient and continue in outcrop eastward, finally disappearing against another promontory of Cretaceous rock a short distance east of the Rio Tanama. Farther east, thickness of sediments referred to San Sebastián increases steadily into eastern clastic basin; this increase in thickness is largely at expense of Lares limestone.

K. N. Sachs, Jr., 1959, Bulls. Am. Paleontology, v. 39, no. 183, p. 399–416. Upper Oligocene; age determination made on basis of foraminifera.

Principal outcrop area extends from the Quebrada Collazo (4 kilometers east of San Sebastián), northwestward to within 4 kilometers of Aguadilla, where outcrops disappear under alluvium of Río Culebrinas Valley.

San Simon limestone[1]

Mississippian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52.

Derivation of name not stated.

Santa Ana[1] [metamorphic rocks]

*See* Santa Ana Formation (California).

Santa Ana Formation

Santa Ana Limestone[1]

Upper(?) Triassic: Southern California.

Original reference: J. P. Smith, 1898, Jour. Geology, v. 6, p. 779, 780.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 19. Replaced by Bedford Canyon formation.

Rene Engel, 1959, California Div. Mines Bull. 146, p. 16–25, pl. 1. In Elsinore quadrangle, metamorphic rocks consist of rocks of undoubted sedimentary origin, correlative with Santa Ana formation of Upper(?) Triassic age, including Bedford Canyon formation (Larsen, 1948), and rocks of igneous origin, extrusive and hypabyssal, including Santiago Peak volcanics (Larsen, 1948). Rocks to which name Santa Ana formation is applied form a band, 2 to 3 miles wide, that traverses northern part of area from Railroad Canyon westward to Clevelin Hills, northwest of Elsinore. Band disappears under alluvium at end of Lake Elsinore but is exposed without interruption from point near Leach Canyon westward toward Los Pinos Peak and Trabuco Canyon. Same band extends westward for about 3 miles into Corona quadrangle where it joins main mass of Triassic rocks in Santa Ana Mountains. North of this band, formation is exposed in a few scattered areas. To the south, a few isolated masses of the formation are enclosed by granodiorite; to the southeast in Santa Rosa region, a few patches of older sedimentary rocks are associated with undifferentiated metamorphic rocks. To the southwest, a band of these sedimentary metamorphic rocks extends northwest from Tenaja Canyon to San Juan Canyon. In the quadrangle, these rocks occupy an area of about 64 square miles. The Triassic rocks were intruded by diorite, andesite, dacite porphyry, or quartz latite porphyry, in the northern part of area, and by quartz diorite and granodiorite. Greatest thickness of undisturbed Triassic sediments measured northeast of Lake Elsinore, between North Elsinore fault and north end of Railroad Canyon where unfaulted beds that dip 50° NE. exceed 28,000 feet in thickness; about 6,000 feet of this extends beyond mapped area; entire Triassic section could not be measured because it extends beneath alluvium of San Jacinto River flood plain. Thickness of formation on west limb of Los Pinos syncline, 19,000 feet or more; on east limb of syncline, 8,600 feet. Smith (1898) used name Santa Ana limestone for the hard black siliceous limestone exposed on west slope of Santa Ana Mountain. Merrill (1915 [1914? or 1916?] California Mining Bur. Rept. 14) used term in broader sense to designate metamorphic rocks of Santa Ana Mountains, including the limestone. Moore (1930, unpub. thesis) used name "Silverado formation" to designate most Triassic rocks of southwest slope of Santa Ana Mountains. These rocks have been correlated with the metamorphosed sediments exposed in Elsinore quadrangle, and name "Silverado formation" conflicts with older name Santa Ana formation. Name "Elsinore formation" proposed by Dudley (1935) for metamorphic rocks in Railroad Canyon is not considered applicable in area of this report. Hence, it is proposed to continue earlier name Santa Ana formation to designate the Upper(?) Triassic metasedimentary rocks.

Named for occurrences on west slope of Santa Ana Mountains, Orange County.

Santa Ana Formation

Upper Cretaceous (Santonian): Puerto Rico.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayaguez, Puerto Rico, 1959, Trans., p. 83. Consists of 30,000 feet (maximum) of volcanic conglomerates, thin-bedded tuffaceous siltstones, thin-bedded argillaceous limestones, and massive argillaceous limestones. Underlies and interfingers with Toa Vaca formation (new). Footnote states that name Santa Ana no longer used; unit currently called Idlefonso [Ildefoñso].

In Ponce-Coamo area.

Santa Ana Lens (in Ildefonso Formation)

Upper Cretaceous: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 34. Massive limestone lens in lower or middle part of formation.

Named for Cerro Santa Ana located 0.5 kilometer north of Río Cuyon and 3 kilometers northeast of Coamo.

Santa Ana Sandstone[1]

Probably Pliocene, upper, or Quaternary, lower: Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 378–379, map.

Named for Santa Ana River, San Bernardino County, along which it is exposed.

**Santa Anna Shale Member** (of Moran Formation)[1]

Permian (Wolfcamp Series): Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 419.

R. C. Moore, 1948, *in* M. G. Cheney, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, sheets, 3, 4; R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Underlies Sedwick limestone member; overlies Gouldbusk limestone member (new).

Named for exposures in buttes at Santa Anna, Coleman County, and at various points north of town.

**Santa Anna Branch Shale Member** (of Putnam Formation)[1]

Santa Anna Branch Formation (in Putnam Group)

Permian (Wolfcamp Series): Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 420.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Putnam group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as shale member of Putnam formation where it is about 120 feet thick and consists chiefly of variegated red and gray or light-brown shale; includes fairly prominent, persistent sandstone in upper part and a thin limestone near middle. Underlies Coleman Junction limestone member; overlies Sedwick limestone member of Moran formation.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 271, pls. 11, 12. Geographically extended into Brazos River valley where it is basal member of Putnam formation. Thickness 75 to 205 feet. Underlies Coleman Junction limestone member.

Probably named for exposures along Santa Anna Branch, Coleman County.

**Santa Barbara Formation**

Santa Barbara Beds or Marls[1]

Pleistocene, lower: Southern California.

Original reference: J. P. Smith, 1912, California Acad. Sci. Proc., 4th ser., v. 3, p. 161–182.

W. P. Woodring, Ralph Stewart, and R. W. Richards, 1940, U.S. Geol. Survey Prof. Paper 195, p. 110–111. Name Santa Barbara formation applied to the marine formation exposed in the southwestern part of Santa Barbara and near Rincon Point. At Rincon Point, lies unconformably on vertical beds of Miocene shale. Lower Pleistocene.

J. E. Upson, 1951, U.S. Geol. Survey Water-Supply Paper 1108, p. 18–21, pl. 2. As used in this report, comprises marine sand, silt, and clay; total maximum thickness about 2,000 feet. Underlies alluvium and terrace deposits; unconformably overlies older rocks that range from Monterey shale at least down through the Sespe. In Carpenteria basin, underlies Casitas formation (new).

Type locality: On Santa Barbara "mesa" at Rincon Point near Santa Barbara-Ventura County line.

Santa Catalina Formation[1]

Middle Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 476, 477, 480, 482.

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 110. Consists of mudstone near base, calcareous mudstone in middle, and sandstone near top. Thickness 300 feet. Overlies Troy quartzite; underlies Southern Belle quartzite.

Type locality: Peppersauce Canyon on north side of Santa Catalina Mountains.

Santa Catalina Gneiss[1]

Precambrian: Southern and central Arizona.

Original reference: W. P. Blake, 1908, Science, new ser., v. 28, p. 379–380.

Well developed on south side of Santa Catalina Mountains near Tucson.

Santa Clara Basalt

Quaternary: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103. Named as seventh (and youngest) in a series of Quaternary formations in area. Santa Clara basalt and Bandelier rhyolite (new) tuff locally overlie Puye formation (new).

Occurs in Abiquiu quadrangle, Rio Arriba County.

Santa Clara Complex

Precambrian: Northern New York.

A. F. Buddington, 1937, New York State Mus. Bull. 309, p. 8, 9, 29–34, 37–38, 42–45; 1939, Geol. Soc. America Mem. 7, p. 111–116. Proposed for a group of igneous rocks which crop out over much of Santa Clara quadrangle and which appear to be genetically related; comprises: medium-grained pyroxene-hornblende quartz syenite interpreted as border chill facies; pyroxene quartzose syenite with coarse lenticular structure; hornblende and biotite granite with coarse lenticular stucture; latter two members form core of complex. Along the northwest border, the pyroxene-hornblende quartz syenite is intrusive into gabbro; here, St. Regis granite (new) appears to cut at a slight angle across banding of the quartz syenite and in Nicholville quadrangle is directly adjacent to the hornblende granite; granite pegmatite veins thought to be related to St. Regis granite occur in the quartz syenite.

Complex extends northwest from Santa Clara quadrangle into Loon Lake quadrangle and southwest across Nicholville area.

**Santa Clara Formation[1]**

Pliocene and Pleistocene: Western California.

Original reference: J. G. Cooper, 1894, California Acad. Sci. Proc., 2d ser., v. 4, p. 171.

C. F. Tolman, and J. F. Poland, 1940, Am. Geophys. Union Trans., no. 21, pt. 1, p. 25, 26–27. Further described in Santa Clara County. Consists of silt-cemented conglomerate, fine silt-cemented sandstone, siltstone, and claystone; evenly and well bedded near base. Near Murphy Dam site on Stevens Creek where formation is folded, exposed thickness is about 2,000 feet. Overlies Purisima formation; underlies alluvium. Crops out in foothills west of the valley from Palo Alto on north to Los Gatos on south.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 22 (fig. 4), 43–44, pls. 1–2. Described in San Jose-Mount Hamilton area as unconsolidated clay, siltstone, and pebbly sandstone; poorly sorted; obscurely bedded. No diagnostic evidence of age found in area. Considered younger than Packwood gravels (new).

H. C. Langerfeldt and L. W. Vigrass, 1959, *in* U.S. Congress, Joint Committee on Atomic Energy, Subcommittee on Research and Development, and Subcommittee on Legislation, Stanford Linear Electron Accelerator, Hearings: U.S. 86th Cong., 1st sess., App. D, p. 621. In Santa Clara and San Mateo Counties, Santa Clara formation overlaps Searsville and Los Trancos formations (both new).

Appears to have been named for its extensive development in Santa Clara County.

Santa Claran Epoch[1]

Pleistocene: California.

Original reference: O. H. Hershey, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, p. 1–29.

Area of Santa Clara River valley of the South.

Santa Cruz Group

Upper Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1937 (abs.) Geol. Soc. America Proc. 1936, p. 297 (table). Named on table. Thin-bedded shaly limestone. Older than Sonoita group (new); younger than Patagonia group (new).

Santa Cruz Island Formation[1]

Pleistocene: Southern California.

Original reference: R. W. Chaney and H. L. Mason, 1934, Carnegie Inst. Washington Pub. 415, p. 4–6, 48 [preprint 1930].

P. C. Orr, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1118. Locally Santa Rosa formation (new) because of its location on lowest terrace, its lithology, and its fauna, is probably equivalent, in part at least, to Santa Cruz Island formation (Chaney and Mason, 1934).

Occurs on Santa Cruz Island.

Santa Emigdeo Formation

Probably lapsus for San Emigdio Formation.

**Santa Fe Formation[1] or Group**

Miocene, middle(?) to Pleistocene(?): Northern New Mexico and central southern Colorado.

Original reference: F. V. Hayden, 1869, U.S. Geol. and Geog. Survey Terr. 3d Ann. Rept., p. 66, 90.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103. Formation overlies Abiquiu tuff (new).

H. T. U. Smith, 1938, Jour. Geology, v. 46, no. 7, p. 952–957. Formation described in Abiquiu quadrangle, New Mexico. Thickest and most typical exposures are in western slopes of Black Mesa. Here thickness is 990 feet. Base of exposed section lies undetermined distance (probably several hundred feet) above base of formation, and an unknown thickness has been eroded from top of section. Formation consists of alluvial deposits with some interbedded basalt flows. Where formation overlies Abiquiu tuff, there is a gradational transition extending over vertical range of from 100 to 300 feet.

C. S. Denny, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1877. Note on type area.

C. S. Denny, 1940, Jour. Geology, v. 48, no. 1, p. 78–79 (fig. 1), 82 (fig. 3), 84–99. Formation in San Acacia area, New Mexico, overlies Popotosa formation (new). Total thickness undetermined; structure section (fig. 3) assumes thickness of about 6.000 feet just east of Loma Pelada fault. Fossils suggest middle to upper Pliocene.

C. E. Stearns, 1943, Jour. Geology, v. 51, no. 5, p. 304 (fig. 2), 316–317. Formation unconformably overlies Espinaso volcanics (new). Along base of Sangre de Cristo Mountains, Sante Fe formation unconformably overlies Precambrian granite gneiss. At north end of Sandia Mountains, formation overlies the Mesaverde with angular unconformity. Map legend shows Santa Fe formation below Cuerbio basalt (new).

E. H. Baltz and others, 1952, New Mexico Geol. Soc. Guidebook 3d Field Conf., p. 12. Surface of Santa Fe Plateau is underlain by strata of late Tertiary or Quaternary age which have been called upper beds of Santa Fe formation, or more recently, the "Ancha formation" by Baldwin, Kottlowski, and Spiegel.

F. E. Kottlowski, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 144. Proposed that Santa Fe formation be raised to group status.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 10, 11–13, 17 (table 1), 36, 37, pl. 1. Santa Fe fanglomerates in Dwyer quadrangle are postvolcanic except for minor interbedded basalts. Name Gila formation may be as applicable to rocks of Dwyer quadrangle as name Santa Fe. Term Santa Fe is used in this report to include all consolidated valley-fill sediments younger than units grouped under informal term of Upper Volcanic series. In northern part of the quadrangle, formation is confined to eastern side of Mimbres fault, but, east and southeast of mouth of Tom Brown Canyon, it covers Mimbres fault zone and all other major structures. Thickness of fanglomerates may be as much as 1,000 feet. Overlies Swartz rhyolite (new) with angular unconformity. Stratigraphically above Pollack rhyolite (new).

A. E. Disbrow and W. C. Stoll, 1957, New Mexico Bur. Mines Mineral Resources Bull. 48, p. 5 (table 1), 26–29, pl. 1. Referred to as Santa Fe group in Cerrillos area. Near city of Santa Fe, strata originally placed in Santa Fe formation have been subdivided into three map units which comprise Santa Fe group. They are (ascending) Tesuque formation (with Bishops Lodge member) and Ancha formation. Terminology has been modified in Cerrillos area, where only strata similar to basal and upper units of group are found. Tuffaceous strata similar to Bishops Lodge member are placed in Abiquiu(?) formation. Name Ancha is used in both areas. Table 1 shows Santa Fe group younger than Cieneguilla limburgite and older than Cuerbio basalt. Age of group middle Miocene(?) to early Pleistocene(?).

D. B. Givens, 1958, New Mexico Bur. Mines Mineral Resources Bull. 58, p. 18–20. Discussion of geology of Dog Springs quadrangle. Santa Fe formation consists of gravels and basalts. Summits of D Cross, Tres Hermanos, Table Mountain, and Blue Mesas are capped with basalt which is considered to be part of Santa Fe formation. The basalt truncates Mesaverde group, Baca formation, and Spears Ranch member of Datil formation. Old channels filled with Santa Fe gravel are present under basalt on Tres Hermanos Mesa and on Table Mountain Mesa. Lens of Santa Fe gravel present within basalt of Tres Hermanos Mesa. Age of formation and basalt not definitely known. Believed to be Pliocene-Pleistocene. Santa Fe beds in other parts of State may or may not be age equivalents of Santa Fe beds in area of this report.

W. J. Powell, 1958, U.S. Geol. Survey Water-Supply Paper 1379, p. 18–19. Discussion of ground-water resources of San Luis Valley, Colo. Several outcrops of formation occur in valley, but they are small and do not fully reveal character of formation. Most reliable data are logs of artesian wells and deep oil tests. Thickness may be more than 5,000 feet. Underlies Alamosa formation. In this report, formation is considered to be largely of Pliocene age but in part of Miocene age.

A. J. Budding, C. W. Pitrat, and C. T. Smith, 1960, New Mexico Geol. Soc. Guidebook 11th Field Conf., p. 83, 84. In Chama basin, formation includes Abiquiu tuff member.

Type area (Denny): Region north of Santa Fe, N. Mex., between Sangre de Cristo and Jamez Mountains.

Santa Fe Granite[1]

Precambrian(?): Central northern Colorado.

Original reference: H. B. Patton, 1909, Colorado Geol. Survey 1st Rept., p. 126–128, map.

Forms highest point of Santa Fe Peak in Clear Creek, Summit, and Park Counties.

Santa Isabel Series[1]

Recent: Puerto Rico.

Original reference: E. T. Hodge, 1920, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 2, p. 166.

J. D. Weaver *in* R. Hoffstetter and others, 1956, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 344. Name given to recent alluvial deposits in south-central Puerto Rico. Term not employed since, and does not appear to have any stratigraphical value.

Santa Lucia Granite[1] or Quartz Diorite[1]

Santa Lucia Granodiorite

Pre-Cretaceous or Upper Cretaceous: Southern California.

Original reference: A. C. Lawson, 1893, California Univ. Pub. Dept. Geol. Bull., v. 1, p. 6, 9–18, pl. 1.

Philip Andrews, 1936, California Univ. Pubs. Dept. Geol. Sci. Bull., v. 24, no. 1, p. 7–9, geol. map. Term Santa Lucia is applied to granitic rocks of Gavilan [Gabilan] Range, since they are considered to be generally related to the granites of Santa Lucia Range. Pre-Franciscan.

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 118. Several names have been given to the ancient crystalline complex in San Francisco Bay Counties. Originally it was called Santa Lucia series, a name applied to the crystalline complex as a whole. Later, name Sur schists was given to the metamorphosed sedimentary and volcanic rocks, and name Santa Lucia was retained for the plutonic rocks. It has become customary to call all schist the Sur series, all crystalline limestones, marbles, and dolomites, Gabilan limestone, and all plutonic rocks the Santa Lucia granodiorite. These names are essentially petrographic and not formational in usual sense since rocks of very different ages might be included under any one of the names.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 9. Potassium-argon age determinations on some granitic rocks given. Sample of Santa Lucia granodiorite gave age 81.6 million years. Dated specimen was collected by Lawson from quarry at Carmel Cove on Carmel Bay.

Forms main ridge of Santa Lucia Range.

Santa Lucia Series[1]

Pre-Franciscan (possibly Precambrian): Southern California.

Original reference: B. Willis, 1900, Sicence, new ser., v. 11, p. 221.

Occurs in Santa Lucia Range, Monterey and San Luis Obispo Counties, and Fremont's Peak of Gavilan Range, San Benito County.

Santa Margarita Granodiorite

[Cretaceous]: Southern California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 10. Discussed in report dealing with potassium-argon age determinations. Age given as 84.1 million years.

Dated specimen collected from outcrop in bottom of creek one-fourth mile north of McKittrick 3.6 miles east of Santa Margarita, sec. 10, T. 29 S., R. 13 E., MD. Approximately 100 square miles of intrusive rocks are exposed east of Santa Margarita. Oldest unmetamorphosed sedimentary rocks lying nonconformably on the mass are Upper Cretaceous in age.

**Santa Margarita Sandstone[1] or Formation**

Miocene, upper: Southern California.

Original reference: H. W. Fairbanks, 1904, U.S. Geol. Survey Geol. Atlas, Folio 101.

R. R. Simonson and M. L. Krueger, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1611 (fig. 2), 1617–1620. Term Santa Margarita, as used in this report [Crocker Flat landslide area], applies (1) to the punky diatomaceous shales and conglomerates above Antelope shale member of Monterey formation and below Etchegoin (Pliocene) formation, on northeast side of Temblor Range, and (2) to the extremely coarse clastics, conglomerates, sands, and shales containing upper Miocene macrofossils, in summit area and on southwest flank of the range. Term is used with reluctance in this area because uppermost Miocene beds are only in part similar lithologically to type Santa Margarita; also, it is believed that upper part of interval is younger than type section. Thickness about 2,700 feet on northeast side of Temblor Range; about 4,000 feet on southwest side of Range. In Recruit Pass area, unconformably underlies Tulare formation. Upper Miocene.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 222–240. Formation, in San Benito quadrangle, consists chiefly of fossiliferous grayish calcareous sandstone, containing "reef" beds and pebbly conglomeratic layers, and occasional interbedded clay-shales. Maximum thickness more than 2,000 feet. Exposed only in narrow belt along southwest flank of San Benito River in southern part of quadrangle. This belt dips uniformly to west below Etchegoin group; on the east side, the Santa Margarita is in fault contact with Etchegoin along Pine Rock fault, and base is nowhere exposed. To the southeast in Priest Valley quadrangle, Santa Margarita rests unconformably on the Franciscan. Upper Miocene.

M. N. Bramlette and S. N. Daviess, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 24. In southeast part of Salinas Valley, including type area, Santa Margarita sandstone is of upper Miocene age and extends down to about top of middle Miocene. Base of formation is of progressively later age northwestward, so that west of San Ardo and San Lucas it appears to be of lower Pliocene age.

J. E. Kilkenny, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 12, p. 2259–2260. In Salinas Valley, unconformably overlies Monterey shales;

underlies McLure formation in Northeast fault block; underlies Poncho Rico formation in Central block. Maximum thickness 2,500 feet, east of Salinas River, in Cholame Hills; some of this may be sandy phase of Monterey shales. Upper Miocene (Neroly stage of Clark; Delmontian and part of Mohnian stage of Kleinpell). King City formation is included in uppermost part of Santa Margarita.

W. E. Ver Planck, 1952, California Div. Mines Bull. 163, p. 35–37, pl. 3. In Quatal Canyon, Ventura County, includes Quatal red clay (new) member.

T. W. Dibblee, Jr., 1951, Soc. Econ. Paleontologists and Mineralogists [Guidebook] Pacific Sec., Stop 2, p. 1–2. In Salisbury Canyon, overlies Bitter Creek formation (new).

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2874 (fig. 1), 2978 (fig. 3), 2995–2996. Discussion of Cuyama Valley-Caliente Range area. In Morales Canyon (T. 11 N., R. 8 W.), Santa Margarita sandstone is about 1,000 feet thick and consists of fine- to coarse-grained locally pebbly, granitic white sandstone in gradational contact with underlying Monterey formation. Unconformably overlain by Morales formation. Accordant contact with underlying Branch Canyon sandstone (new). Upper part of sandstone contains at least two calcareous reefs of *Ostrea titan*. This littoral Santa Margarita sandstone unit was mapped as *Ostrea titan* zone of Monterey by Eaton and others (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2). Northwestward from Morales Canyon, the Santa Margarita extends along northeast flank of La Panza Range and is traceable into Santa Margarita formation as mapped by Bramlette and Daviess. On northeast flank of Caliente Range, the equivalent of the Santa Margarita is Quatal formation. On southside of Cuyama Valley, formation is exposed from Bitter Creek eastward to Salisbury Canyon. At Branch Canyon (sec. 1, T. 9 N., R. 27 W.), it was mapped as Neroly by Eaton and others. Assigned to upper Miocene (Mohnian and (or) Delmontian).

Named for exposures at Santa Margarita, San Luis Obispo County.

†Santa Maria Formation[1]

Pliocene and Pleistocene: Southern California.

Original reference: C. M. Carson, 1925, Pan-Am. Geologist, v. 43, p. 265–270.

In Santa Maria district, Santa Barbara County.

**Santa Monica Slate**[1]

Triassic(?) and Jurassic: Southern California.

Original reference: H. W. Hoots, 1931, U.S. Geol. Survey Prof. Paper 165–C, p. 88–89.

Cordell Durrell, 1954, California Div. Mines Bull. 170, map sheet 8. Consists of metamorphosed black shale and graywacke of unknown thickness. Crops out only in eastern part of Santa Monica Mountains. Triassic(?).

U.S. Geological Survey currently designates the age of the Santa Monica Slate as Triassic(?) and Jurassic on the basis of a study now in progress.

Named for occurrence in Santa Monica Mountains, Los Angeles County.

Santa Paula Formation[1]

Miocene(?) and Pliocene, lower: Southern California.

Original references: J. E. Eaton, 1926, Oil and Gas Jour., p. 72; 1926, Oil Age, p. 16.

Well exposed on great monocline, northwest of Santa Paula, Ventura County.

Santa Rita Granodiorite Porphyry

Upper Cretaceous or later: Southwestern New Mexico.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 288–289, 302, fig. 3, pl. 1. A single intrusive mass of biotite granodiorite porphyry. Groundmass of equigranular, interlocking grains of quartz and slightly sericitized orthoclase. Lustrous, striated green-gray feldspar phenocrysts common; occasional phenocrysts of hornblende and quartz.

Rounded body about 1 mile across best exposed in copper pits of Santa Rita copper mine, in southeastern corner of Santa Rita quadrangle, about 12 miles east of Silver City, Grant County.

Santa Rita Limestone[1]

Silurian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1908, Am. Inst. Mining Engrs. Bi-Monthly Bull. 19, p. 7–21.

Type locality: Santa Rita, Grant County.

Santa Rita Limestone[1]

Middle(?) Devonian: Southeastern Arizona.

Original reference: C. R. Stauffer, 1927, Geol. Soc. America Bull., v. 38, p. 133.

In Santa Rita Mountains region.

Santa Ritan series[1]

Silurian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1908, Am. Inst. Mining Engrs. Bi-Monthly Bull. 19, p. 7–21.

Probably named from Santa Rita, Grant County.

Santa Rosa Basalt

Pliocene(?): Southern California.

J. F. Mann, Jr., 1955, California Div. Mines Spec. Rept. 43, p. 9–10, pl. 1. Name applied to olivine basalt flows that rest on a nearly horizontal surface that consists partly of Paleocene(?) sediments and partly of basement rocks. Thickness varies; in Temecula region, usually only a few tens of feet; may be as much as 100 feet.

Occurs on Hogback, Vail Mountain, and Mesa de Burro, Temecula region, Riverside County.

Santa Rosa Beds

Eocene(?): Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 47, table 4 [English translation in library of U.S. Geol. Survey, p. 57]; S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 56–57. Consist of alternate strata of tuff, shale, and marl, with 1 or 2 layers of limestone; characteristically green. Strata dip at high angles. Discordantly (unconformably) overlie Umatac andesite.

Typically exposed on Mount Santa Rosa, Mount Chachao, and Mount Tenjo, Guam.

**Santa Rosa Sandstone** (in Dockum Group)[1]

Upper Triassic: Northeastern New Mexico.

Original reference: D. Hager and A. E. Robitaille, 1919, Geol. Rept. on oil possibilities in eastern New Mexico, corr. table.

W. B. Lang, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1674. In Pecos Valley, Santa Rosa sandstone grades into Pierce Canyon redbeds; the two units are in part contemporaneous. Upper(?) Triassic.

G. E. Hendrickson and R. S. Jones, 1952, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 3, p. 23–24. In Eddy County, overlies Pierce Canyon redbeds and redbeds that possibly represent Chinle formation. Thickness 200 to 300 feet.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. Described in northwestern Mora County where it is 425 feet thick and consists mainly of brownish-red shale and sandstone. Underlies Chinle formation; overlies Bernal formation (new). Upper Triassic.

Well exposed at Santa Rosa and Puerto de Luna, Guadalupe County, and along canyon of Pecos for many miles.

Santa Rosa Island Formation

Pleistocene, upper: Santa Rosa Island, California.

P. C. Orr, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1113–1119. Proposed for the formation that covers lower terrace on island. Includes three members (ascending): Garanon, Fox, and Tecolote. Each member has two or more facies. Unconformably overlies Rincon shale on northwest coast of island. Lower terrace is less than 300 yards in width and is underlain by three wave-cut platforms.

Type locality: Extends about 4,000 yards along sea cliffs on northwest coast. Also exposed at mouth of Soledad Canyon, Ranch House Canyon, and from San Augustine to Wreck Canyons and between China Camp and Bee Rock on south coast of island.

Santa Susana Formation[1] or Shale

Paleocene-Eocene, lower: Southern California.

Original reference: B. L. Clark, 1924, Pan-Pacific Sci. Cong. Proc. Australia, 1923, p. 874–879.

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Chart shows age Paleocene through lower Eocene.

T. E. Gay, Jr., and S. R. Hoffman, 1954, California Jour. Mines and Geology, v. 50, nos. 3 and 4, pl. 4. Formation mapped in Los Angeles County with marine deposits Tejon, Llajas, and Domengine formations. Eocene.

Named for occurrence in vicinity of Santa Susana, Ventura County.

†Santee Beds[1]

Eocene (Jackson and Claiborne): Eastern and central South Carolina.

Original reference: M. Tuomey, 1848, Geology of South Carolina, p. 156, 190, 211.

Well exposed on the Santee River.

**Santee Limestone[1]**

Eocene, middle: Eastern and central South Carolina and North Carolina.

Original reference: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 17.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 20 (fig. 2), 21, 24–25. Santee limestone, long supposed to be of early

Jackson age, represents the *Ostrea sellaeformis* zone of Claiborne group, equivalent to the restricted McBean formation, of which it is an offshore facies. This determination was made on basis of field profiles and restudy of the molluscan fauna. Older than Castle Hayne limestone. Chart shows occurrence in North Carolina.

Commonly accepted type exposure is at Eutaw Springs, Orangeburg County, S.C., 3½ miles east-northeast of Eutawville. Back water from Lake Marion has partly inundated the old exposure, but some limestone still stands above level of reservoir (Cooke and MacNeil).

Santee River Beds[1]

Eocene: South Carolina.

Original reference: F. S. Holmes, 1870, Phosphate rock of South Carolina, pl. 1.

Exposed along Santee River.

†Santiago Chert[1]

Santiago Formation

Upper Devonian: Southwestern Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bull. 44, p. 41.

W. B. N. Berry and H. M. Nielsen, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2254–2259. Because King's (1937) lower two members of Caballos novaculite form one genetic unit, and King's upper three members of Caballos form another genetic unit, it is proposed to revive original terminology of Udden, Baker, and Böse and recognize two distinct formations. Name Caballos novaculite should be restricted to lower formation and name Santiago formation applied to middle chert member, upper novaculite member, and upper chert members of King. Thickness about 225 feet. Upper Devonian. Type exposure noted.

Type exposures are at east base of Santiago Range near Santiago Peak. Brewster County.

**Santiago Formation**

Eocene: Southern California.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Name proposed for Eocene deposits of northwestern Santa Ana Mountains. These deposits had been called Tejon by Dickerson (1914, California Univ. Dept. Geol. Bull., v. 8, no. 11) and English (1926, U.S. Geol. Bull. 768). An unnamed basal member 40 to 220 feet thick consists of massive coarse-grained poorly sorted arkosic buff or brownish-gray sandstone and conglomerate, sandstone generally predominating. In some areas, basal member is overlain by soft medium-grained moderately well-sorted arkosic gray or brownish-gray "salt and pepper" sandstone. Uppermost part of formation consists of coarse-grained arkosic gray sandstone and grit. Thickness 650 to 725 feet. Overlies Silverado formation (new) without discordance.

Type locality: North of Santiago Creek, near Irvine Park, Santa Ana Mountains, Orange County.

Santiago Formation[1]

Oligocene, upper: Panamá.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 241.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, Geol. Sci., p. 234 (chart), 241–242. Beds of sandstones and shales. Chart shows Santiago above Tonosi limestones. Upper Oligocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 346. Oligocene.

At Santiago and adjoining areas, Veraguas Province.

**Santiago Peak Volcanics**

Upper Jurassic(?) to Lower Cretaceous(?): Southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 22–32, pl. 1. Name proposed to replace preoccupied name Black Mountain volcanics. Group of mildly metamorphosed volcanics, mostly agglomerates, that include some sediments; older than quartz diorite of southern California batholith. Thickness undetermined, probably many thousands of feet. Unconformably overlie Bedford Canyon formation (new).

Rene Engel, 1959, California Div. Mines Bull. 146, p. 17. Santa Ana formation includes Santiago Peak volcanics and Bedford Canyon formation of Larsen (1948).

U.S. Geologicl Survey currently designates the age of the Santiago Peak Volcanics as Upper Jurassic(?) to Lower Cretaceous(?) on the basis of a study now in progress.

Outcrops form a strip from south of La Jolla quadrangle, across San Luis Rey quadrangle, northward in Santa Ana Mountains nearly to Santa Ana River; exposed width about 10 miles.

Santiam Basalts or Lavas

Pleistocene: Northwestern Oregon.

T. P. Thayer, 1936, Jour. Geology, v. 44, no. 6, p. 705, 706, 709 (fig. 2), 713 (fig. 3); 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1616 (fig. 2), 1617, 1619, 1625, 1626, 1627; 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 18–19, fig. 2 (geol. map). High Cascade lavas are divided into four groups; in chronological order these are: Outerson basalts, Minto basalts, Santiam basalts, and Olallie lavas. Santiam basalts and Olallie lavas are not in contact hence relative ages unknown, similar degrees of erosion suggest they may have been nearly contemporaneous. Fills North Santiam River valley to known depth of 1,800 feet; valley was cut in Minto and Outerson lavas. Pre-Wisconsin but undoubtedly Pleistocene.

Named for occurrence in North Santiam River valley.

San Timoteo Beds[1] or Formation

Pliocene: Southern California.

Original reference: C. Frick, 1921, California Univ. Pub., Dept. Geol. Bull., v. 12, p. 283–288.

D. I. Axelrod, 1938, Carnegie Inst. Washington Pub. 476, p. 129. Characterized by coarse yellowish sands and cobble beds which are crossbedded and exhibit rapid lateral variation and channeling; interbeds of finer gray-brown sands and clays present throughout formation. Unconformably overlie Mount Eden formation.

Occur in San Timoteo Canyon, San Jacinto quadrangle, Riverside County. Form badlands west of Beaumont.

Santo Limestone (in Millsap Lake Formation)[1]

Santo Limestone Member (of Grindstone Creek Formation)

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1929, Geologic map of Palo Pinto County: Texas Bur. Econ Geology.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in Grindstone Creek formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 19, fig. 3. Correlation of Parker exposures with outcrops in Palo Pinto County is made on basis of similarity of lithology and stratigraphic position. Limestone is gray to brownish gray and fairly pure; bedding irregular to massive. Thickness 2 to 4 feet. Occurs about middle of formation. Report follows classification of Cheney (1940) [also refers to this unit as a limestone bed].

Typically exposed along creek 0.4 mile south of railroad crossing in Santo, Palo Pinto County. Outcrop of limestone is interrupted by Littlefield Bend of Brazos River.

Santos Shale[1] Member (of Temblor Formation)

Miocene, lower: Central California.

Original reference: G. C. Gester and J. Galloway, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 10, p. 1169.

H. H. Heikkila and G. M. McLeod, 1951, California Div. Mines Spec. Rept. 6, p. 4 (table 1), 5 (table 2), 7–9, pl. 1. Temblor formation, in Bitter Creek area, Kern County, is divided into (ascending) Agua sandstone, Upper Santos shale, Carneros sandstone, Media shale, and "Button bed" sandstone members. Upper Santos consists of tan platy siliceous and calcareous silty to sandy shale with discontinuous thin limestone and sandstone beds. Thickness of Upper Santos 0 to 1,500 feet. Lower Santos not exposed in area of present report.

L. B. McMichael, chm., 1959, San Joaquin Geol. Soc. Guidebook May 9, p. 5–6, 13. Topographic profile of Chico Martinez Creek area shows Santos shale below Carneros sands and separated from underlying Salt Creek shale by *Phacoides* reef. Columnar section shows Lower Santos shale about 200 feet and Upper Santos shale about 100 feet, separated by "Agua sand" interval about 70 feet thick. All in Temblor formation.

First mentioned in McKittrick-Midway-San Emigdio region, San Joaquin Valley. Type area presumed to be at Santos Creek, Kern County.

**Santurce Sand**

Miocene, lower, to Recent: Puerto Rico.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (chart), 36–37, pl. 2. Proposed for the widespread deposit of quartz sand and interbedded somewhat clayey quartz sand that forms the surficial deposit of much of the coastal plain. Characteristically white, locally bright red. Foundation borings have penetrated 80 to 100 feet of the deposit; maximum thickness not known. Pliocene(?) and Pleistocene.

U.S. Geological Survey currently designates the age of the Santurce Sand as lower Miocene to Recent on the basis of a study now in progress.

Named for town of Santurce, because deposits are particularly thick under low lying areas near there. Occurs widely as discontinuous surface deposits for a distance of 50 miles west of San Juan both on coastal plain and on broader bottom lands between the haystack hills of middle Tertiary limestone.

Sanup Plateau Member (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 90–92. At Meriwitica section, member consists of thick-bedded dark-gray aphanitic limestone with prominent bands of siltstone that weather red brown. Farther west, at Quartermaster Canyon, Rampart Cave, and elsewhere, the same type of lithology prevails, but eastward and southward algal limestone dominates the facies. Thickness moderately uniform across area but becomes progressively thinner near its eastern and southern margins. Average thickness about 25 or 30 feet. Older than Spencer Canyon member (new); younger than Rampart Cave member (new).

Designation, Sanup Plateau, comes from large promontory of that name in western Grand Canyon. Lower of two thin but persistent cliff-forming units that extend through the western two-thirds of Grand Canyon between slope-forming tongues of shale and other weak sediments.

San Xavier Conglomerate Beds

Tertiary: Southeastern Arizona.

L. A. Heindl, 1959, Arizona Geol. Soc. Guidebook 2, p. 154, 155, fig. 29. Light-pinkish-brown alluvial conglomerate made up of fragments of Cretaceous(?) arkose, siltstone, and mudstone, and Tertiary rhyolite and andesite, which are commonly of pebble size but may be as large as small boulders. Individual beds lenticular and contain scour-and-fill structures. Base nowhere exposed, but unit appears to overlie older volcanic rocks on east side of Tucson Mountains and may overlie speckled rhyolite at Black Mountain. Maximum exposed thickness about 450 feet. Underlies unnamed andesite porphyry.

Crops out in discontinuous patches on north side of Black Mountain and on southeast slopes of Tucson Mountains, San Xavier Indian Reservation, central Pima County.

**San Ysidro Member** (of Yeso Formation)

Permian: Northwestern New Mexico.

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. Thin- to medium-bedded light orange-red to dark-red sandstone and siltstone with a few thin limestone beds. Conformably overlies Meseta Blanca sandstone member (new). In area from San Miguel Canyon north to Senorito Canyon, the San Ysidro member tongues with the underlying Meseta Blanca sandstone member. Underlies Glorieta sandstone member of San Andres formation.

Type sections: Near Canon, in sec. 3, T. 16 N., R. 2 E., Sandoval County, and the area immediately to the north of this section in the Canon de San Diego Grant.

Sapello quartzite[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 11.

In Solitario Peak region, northwest of Las Vegas, San Miguel County. Derivation of name not given.

**Sappa Formation**

Sappa Member (of Meade Formation)

Pleistocene: Eastern Nebraska, western Iowa, southwestern Kansas, and southeastern South Dakota.

J. C. Frye, Ada Swineford, and A. B. Leonard, 1948, Jour. Geology, v. 56, no. 6, p. 504–505, 520 (fig. 1), 522. Referred to as Sappa member of Meade formation in Kansas and Sappa formation in Nebraska. Name Sappa is used to designate deposits formerly called Upland. In Nebraska, overlies Grand Island formation; in Kansas, overlies Grand Island member of Meade formation. At type locality of Meade formation, Sappa member contains Pearlette volcanic ash of the type area.

G. E. Condra and E. C. Reed, 1950, Nebraska Geol. Survey Bull. 15–A, p. 22, 25. Formation is a gray to greenish silty clay deposit of aqueous-eolian origin. Thickness 2 to 30 feet or more; average 15 feet. Overlies Grand Island sand; underlies Crete sand and gravel (new). Occurs in old valleys of till region in eastern Nebraska, western Iowa, and southeastern South Dakota where it occasionally includes lenticular beds of volcanic ash and is locally overlain by Crete sands and underlain by sand and gravel which Nebraska Geological Survey correlates as Grand Island. However, this sand and gravel and horizons represented by the Upland, Pearllette ash, Crete sand and Loveland formation in exposures northeast of Little Sioux, Iowa, have been correlated by Iowa Geological Survey as Yarmouth age.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 87. Derivation of name given.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Chart of revised classification of Kansas Pleistocene shows Sappa as member of unnamed formation in Meade group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown as formation in Kansas. Overlies Grand Island formation; underlies Pearlette ash. Yarmouthian.

E. C. Reed (1948, Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1346) stated that a new name had been substituted for name Upland (Lugn, 1930). The formation was described and type locality designated in Sappa Township, but no name was applied to unit.

Named from exposures in abandoned volcanic ash mine of Cudahay Packing Co. near Orleans in Sappa Township, Harlan County, Nebr.

**Sappington Sandstone Member** (of Three Forks Shale)

Sappington Sandstone or Formation

Upper Devonian and Lower Mississippian: Southwestern Montana.

G. W. Berry, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 14–16. Sappington sandstone proposed for 60 feet of yellow sandstone lying above *Cyrtospirifer* zone of Three Forks shale. Contains lower Carboniferous *Syringothyris* fauna (Kinderhook). Underlies Madison formation. Formerly included in Three Forks shale.

L. L. Sloss and W. M. Laird, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 8, p. 1411. Rank reduced to member status in Three Forks formation.

F. D. Holland, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1706–1709. Thickness of Sappington sandstone at type locality is 100 feet. This is much more than thickness (60 feet) measured by Berry. Unconformably underlies Lodgepole limestone of Madison group at Sappington type section. Appears to be Kinderhookian.

M. M. Knechtel, J. E. Smedley, and R. J. Ross, Jr., 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 11, p. 2398 (fig. 2c), 2399. Referred to as sandstone member of Three Forks; underlies Little Chief Canyon member (new) of Lodgepole limestone.

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, p. 1389 (table 1), 1397–1399. In vicinity of Sacajawea Peak, Mont., formation comprises (ascending) black fissile conodont-bearing shale, 8 to 16 feet; pale-brown to yellow-brown thin- to medium-bedded fine-grained calcareous siltstone and sandstone noticeably more sandy in upper part, 62 feet; dark-brown to black silty shale or siltstone, 2 to 3 feet. Cooper and Sloss (1943, Jour. Paleontology, v. 17) call the upper part basal Lodgepole black shale. Devonian(?).

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2322. Considered member of Three Forks formation. Assigned Late Devonian and Early Mississippian age.

C. W. Achauer, 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 41–49. Detailed discussion on stratigraphy and microfossils of formation. Mississippian age for Sappington could be questioned on grounds that there is intermingling of Devonian forms with characteristic Mississippian fossils in Sappington middle member. Until more investigation is conducted, precise age of formation will remain in doubt.

Type locality: NW¼ sec. 36, T. 2 N., R. 1 W., near village of Sappington, Gallatin County, Mont.

†Sapulpa Group[1]

Pennsylvanian: Central northern and central Oklahoma.

Original reference: C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910, Oklahoma State Univ. Research Bull. 3, p. 6, 11.

Named for Sapulpa, Creek County.

Sarac Ridge Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 283–292, geol. map. Predominantly dark-gray biotite-hornblende-quartz-plagioclase mylonites; small amounts of amphibolite also present. Rocks are present in an east-northeast-trending belt north of East Ridge belt and south of the El Dorado Ridge-Stoddard Canyon plutons. Alf (1948, Geol. Soc. America Bull., v. 59, no. 11) referred to these rocks as the "Black Belt mylonite." In order to follow practice of adopting geographical names in nomenclature, Alf's term is discarded, and term Sarac Ridge group introduced.

Occurs in Cucamonga quadrangle, San Bernardino County.

Saragossa Quartzite[1]

Probably Carboniferous or pre-Carboniferous(?): Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 13, no. 9, p. 344, 352–363, map.

R. B. Guillou, 1953, California Div. Mines Spec. Rept. 31, p. 5, 7, pl. 1. Redefined and restricted to exclude gneisses and granitic intrusions (here named Baldwin gneiss) and quartzites (here named Chicopee formation) that lie beneath a thrust plate that overrides Baldwin gneiss and parts of Chicopee formation. Term Saragossa quartzite is used for the quartzite of the thrust plate. Thickness of Saragossa may be over 1,000 feet if section is not duplicated by faulting. Considered younger than Baldwin gneiss and older than Chicopee formation. Age given as pre-Carboniferous(?).

Well developed near and named for Saragossa Spring, San Bernardino County. [Considered type locality by Guillou (1953).]

Saranac Formation[1]

Saranac Quartz Syenite Complex

Precambrian: Northeastern New York.

Original reference: H. P. Cushing, 1905, New York State Mus. Bull. 95.

David Gallagher, 1937, New York State Mus. Bull. 311, p. 15. Although it is not specifically mentioned, there is no doubt that Cushing intended to include the country rock around Lyon Mountain under this term. [Saranac formation].

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 116–123. Saranac complex forms a band in Saranac Lake quadrangle, extending west across St. Regis quadrangle on northwest and trending toward Lake Placid quadrangle on east. Its relationships to Santa Clara complex (new) and to syenites of Lake Placid quadrangle as yet to be determined. Most of discussion is of Tupper-Saranac complex.

A. F. Buddington, 1953, New York State Mus. Bull. 346, p. 15 (table 1), 67–71. Saranac quartz syenitic complex described in Saranac quadrangle. Geologic column lists Saranac complex above Loon Lake complex.

Well exposed along Saranac River, Clinton County.

**Saratoga Chalk**[1]

Upper Cretaceous: Southwestern Arkansas.

Original reference: J. C. Brenner, 1898, Am. Inst. Min. Engrs. Trans., v. 27, p. 52–59.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Shown on correlation chart as unconformable below the Nacatoch sand and above the Marlbrook marl.

R. G. Drouant, 1960, Dissert, Abs., v. 20, no. 11, p. 4367–4368. Saratoga formation of this paper includes a lower chalk member and an upper argillaceous-arenaceous unit which has previously been considered a part of Nacatoch formation. Base of the Saratoga marks first appearance of abundant sand sized clastics following a long period of deposition of nonarenaceous marls which constitute Marlbrook formation.

Named for typical outcrops just north and also east of Saratoga, Hempstead County.

Saratoga Sand[1]

Pleistocene: Eastern New York.

Original reference: A. Fitch, 1850, Hist., Topog., and Agr. survey of county of Washington, N.Y., pt. 3, p. 878.

Occurs in Kingsbury and Fort Edward, Washington County; also in Saratoga and counties south of it.

Sardine Series

Oligocene or Miocene: Northwestern Oregon.

T. P. Thayer, 1936, Jour. Geology, v. 44, no. 6, p. 703–704, 709 (fig. 2), 713 (fig. 3); 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1616 (fig. 2), 1623–1624. West of Mill City, andesitic lavas are so abundant in Mehama and Fern Ridge formations that formational identity is lost. and unconformity between Mehama volcanics and Stayton lavas is not traceable. Mehama, Stayton, and Fern Ridge formations are grouped in the Sardine series, which at type locality consists of about 6,000 feet of basaltic to dacitic lavas. Grades downward into Breitenbush series (new). Mineralized by Halls diorite (new).

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 8–9, fig. 1. Entire series may be Miocene, or lower part may be Oligocene; not intended that any Eocene formations be included.

Type locality: In Sardine Mountains, northwest of Detroit, Marion County.

Sarpy Formation (in Kansas City Group)

Pennsylvanian (Missouri Series): Eastern Nebraska.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37–38. Underlies Quivira formation; overlies Fontana formation. Thickness about 15 feet. Classed on a cyclothemal basis, formation includes (descending) Westerville limestone, Wea shale, and Block limestone.

Type locality: Platte Valley bluffs at the PWA quarry, 2½ miles south of Richfield. Named for Sarpy County.

**Sarten Sandstone**[1]

Lower Cretaceous: Southwestern New Mexico.

Original reference: N. H. Darton, 1916, U.S. Geol. Survey Bull. 618, p. 19, 43.

H. L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 26, 34 (fig. 3). In Lake Valley quadrangle, consists of 300 feet of light-gray massive sandstone, mostly quartzitic or very hard. Underlies Colorado shale; overlies Lobo formation.

C. H. Dane and G. O. Bachman, 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 98. Sarten is now regarded as of Kiamichi age. Contains fauna originally said to be of Washita age.

Type locality: Sarten Ridge, east of Cooks post office, Deming quadrangle.

Sasakwa Limestone Member (of Holdenville Shale)[1]

Pennsylvanian (Des Moines Series): Central southern Oklahoma.

Original references: G. D. Morgan, 1923, Oklahoma Geol. Survey Circ. 12, p. 9, 10; 1924, Bur. Geology [Oklahoma] Bull. 2, p. 103–105.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 45–48, pls. 1, 2. Occurs 30 feet or more below top of formation. Thickness a few inches to about 15 feet. Des Moines series.

Named for exposures in Saskawa, Seminole County.

†Sassafras River Greensand[1]

Upper Cretaceous: Northeastern Maryland.

Original reference: W. J. McGee, 1888, U.S. Geol. Survey 7th Ann. Rept., p. 612.

Occurs only along Sassafras River for short distance above its mouth to Back Creek Neck and on Maudens Mountain and a few neighboring eminences.

**Satan Tongue** (of Mancos Shale)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1934, U. S. Geol. Survey Bull. 860–A.

C. B. Hunt, 1936, U.S. Geol. Survey Bull. 860–B, p. 45. Wedges into Hosta sandstone member of Mesaverde and separates it into an upper and lower part. Thickness 300 feet in northern part of Mount Taylor coal field. Stratigraphically above Mulatto tongue of Mancos.

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 94. In parts of Fort Defiance-Tohatchi quadrangles, intertongues with Point Lookout sandstone.

Named for exposures in Satan Pass, Gallup region.

**Satanka Shale**[1]

Permian: Southeastern Wyoming and northeastern Colorado.

Original reference: N. H. Darton, 1908, Geol. Soc. America Bull., v. 19, p. 430.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2. Discussion of correlation of formations of Laramie Range, Hartville uplift, Black Hills, and western Nebraska. Terms Satanka, Lykins, and probably Embar should be abandoned.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 34. North of Ingleside, Colo., conformably overlies Ingleside formation. Thickness about 181 feet just south of Wyoming line at Soldier Canyon.

R. S. Agatston, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 547–548. On west side of Laramie Mountains, directly overlies Casper sandstone and underlies Forelle limestone.

Named for railroad station a few miles south of Laramie, Albany County, Wyo.

†Satilla Formation (of Columbia Group)[1]

Pleistocene: Eastern Georgia.

Original reference: J. O. Veatch and L. W. Stephenson, 1911, Georgia Geol. Survey Bull. 26, p. 60, 424, 434–445.

Named for development along both sides of Satilla River, in Camden and Charlton Counties.

**Satsop Formation**[1]

Pleistocene: Western Washington.

Original references: J. H. Bretz, 1914, Geol. Soc. America Cordilleran section abstract of meeting in May 1914; 1915, Geol. Soc. America Bull., v. 26, p. 131.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 7, 9. Name Troutdale was introduced by Hodge (1933) for gravels and sands deposited by ancestral Columbia River, which are well displayed near Troutdale, Oreg. Williams (1916, Oregon Bur. Mines and Geology Min. Resources, v. 2, no. 3) had referred these gravels to Satsop formation.

Type section: Satsop Valley, a tributary of Chehalis Valley.

**Saturday Mountain Formation**[1]

Upper Ordovician: Southern central Idaho.

Original reference: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth.

C. P. Ross, 1937, U.S. Geol. Survey Bull. 877, p. 18–22, pl. 1. Type area designated.

C. P. Ross, 1947, Geol. Soc. America, v. 58, no. 12, pt. 1, p. 1104–1105, pl. 1. Described in Borah Peak quadrangle where its distribution is similar to that of Kinnikinic quartzite which immediately underlies it. Thickness 500 to 700 feet. Underlies Laketown dolomite. Upper Ordovician.

R. J. Ross, Jr., 1959, U.S. Geol. Survey Prof. Paper 294–L, p. 441–459. Brachiopod fauna described. Most of the fauna shows affinities with Late Ordovician species, but Middle Ordovician elements are present.

Named for Saturday Mountain Ridge, which lies west of lower Squaw Creek, near middle of the western boundary of Bayhorse quadrangle. The formation crops out on both sides of lower Squaw Creek from a point above Red Bird mine to mouth of the creek.

Sauceda Volcanics

Cretaceous: Southwestern Arizona.

E. D. Wilson, R. T. Moore, and R. T. O'Haire, 1960, Geologic map of Pima and Santa Cruz Counties, Arizona (1:375,000): Arizona Bur. Mines. Named on map legend. Includes rhyolite, latite, and andesite; locally contains volcanic glass.

Mapped in Pima County. Type locality and derivation of name not stated.

Saucesian Stage[1]

Miocene, lower: California.

Original reference: R. M. Kleinpell, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 3, p. 376–378.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 113–117, figs. 4, 14 (correlation chart). Superjacent to Zemorrian stage and subjacent to Relizian stage. Comprises three zones: *Siphogenerina transversa* and *Plectofrondicularia miocenica* in lower part and *Uvigerinella obesa* in upper part. Systematic catalogue.

Type locality: Los Sauces Creek, Ventura County.

†Saugerties Limy Shale

Saugerties lithofacies (of Leeds facies of Schoharie Formation)

Lower(?) Devonian: Eastern New York.

G. H. Chadwick, 1940, New York State Geol. Assoc. 16th Ann. Mtg. Field Guide Leaflets, p. 2, 3. Limy shale 80 feet thick. Overlies Esopus and underlies Onondaga. Fossils listed.

Winifred Goldring and R. H. Flower, 1942, Am. Jour. Sci., v. 240, no. 10, p. 686. Name Saugerties formation, suggested by Chadwick as possible name for new formation, is considered inadvisable. This unit is considered to be Leeds facies (new) of Schoharie formation. Chadwick's type section for Saugerties stated.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 233 [1946]. Saugerties shaly limestone abandoned in favor of Leeds facies of Schoharie formation.

J. H. Johnson, 1957, Dissert. Abs., v. 17, no. 10, p. 2247. Referred to as lithofacies in upper part of Leeds facies of Schoharie formation. Occurs above Aquetuck lithofacies (new).

Type section: Cut three-eighths mile west of railroad underpass, on western edge of Saugerties, Ulster County.

**Saugus Formation**

Saugus Formation (in Fernando Group)[1]

Pliocene and Pleistocene: Southern California.

Original reference: O. H. Hershey, 1902, Am. Geologist, v. 29, p. 349–372.

R. H. Jahns, 1940, Carnegie Inst. Washington Pub. 514, p. 166. Unconformably overlies Mint Canyon strata and brownish sandstones and shale tentatively correlated with the Modelo.

G. B. Oakeshott, 1950, California Jour. Mines and Geology, v. 46, no. 1, p. 50 (fig. 3), 61–62, pls. 14, 16. Overlies upper Pliocene continental Sunshine Ranch member of Pico formation; overlaps Sunshine Ranch eastward onto Repetto siltstone; underlies (with angular unconformity) oldest terrace deposits.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 22 (fig. 2), 23 (fig. 3), 83–85, pls. 1–3. Restricted to terrestrial deposits of probable lower Pleistocene age lying with slight unconformity on members of upper Pliocene Pico formation and with great angular discordance below middle(?) and upper Pleistocene Pacoima formation and terrace deposits. Sunshine Ranch member of Pico formation is roughly equivalent of "lower Saugus" of earlier workers. Saugus occupies several square miles of San Fernando quadrangle [this report], both north and south of San Gabriel fault. Maximum thickness 6,400 feet as measured on east side of Lopez Canyon; thins in short distance eastward to 2,000 feet, 2 miles east of Little Tujunga Canyon and disappears by further thinning and minor faulting at Big Tujunga Canyon.

E. L. Winterer and D. L. Durham, 1958, U.S. Geol. Survey Oil and Gas Inv. Map OM–196. Includes Sunshine Ranch member. Thickness as much as 7,000 feet. Overlies Pico formation. Includes beds of both late Pliocene and Pleistocene age.

Named for exposures in Soledad Canyon, near Saugus, Los Angeles County.

†Saugus Granodiorite[1] or Quartz Diorite[1]

Lower Paleozoic: Northeastern Massachusetts.

Original reference: C. H. Clapp, 1910, Igneous rocks of Essex County, Mass.

In Essex County.

Sauk sequence

Precambrian (upper Proterozoic) to Upper Cambrian: Central and western United States.

L. L. Sloss, W. C. Krumbein, and E. C. Dapples *in* C. R. Longwell, chm., 1949, Geol. Soc. America Mem. 39, p. 111–115, 116–119. An "operational unit" for use in interregional facies analysis. Name is derived from Sauk County in the Driftless Area of southern Wisconsin. Within the county all the rocks of the sequence are exposed with both bounding horizons, one at the base of the Dresbach sandstones, where they unconformably overlie the Precambrian Baraboo quartzites, and the other at the contact between the St. Peter sandstone and the Oneota dolomite. Formational limits in Illinois, Shakopee dolomite-Mt. Simon sandstone; in Kansas, Arbuckle dolomite-Reagan sandstone; in Wyoming, Grove Creek formation-Flathead sandstone.

Sault St. Mary Sandstones[1]

Upper Cambrian: Northern Michigan, and Ontario, Canada.

Original reference: A. R. C. Selwyn, 1883, Science, v. 1, p. 11.

Sault Ste. Marie region, Michigan-Ontario.

**Saunders Formation**[1] (in Chocolay Group)

Precambrian (Animikie Series): Northern Michigan.

Original reference: R. C. Allen, 1910, Michigan Geol. and Biol. Survey Pub. 3, p. 33, 36.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Included in newly defined Chocolay group. Considered a partial equivalent of the Randville dolomite.

Named for [exposures east of] village of Saunders, Iron County.

Sauquoit Beds,[1] Shale, or Formation (in Clinton Group)

Middle Silurian: East-central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 333, 341.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 13 (fig. 2), 72–79. Shale is dominant lithology; hence, unit is referred to as Sauquoit shale. Overlies Oneida conglomerate and in some areas Wolcott Furnace iron ore; underlies Willowvale shale; at Lakeport, underlies Williamson shale. Middle part of Clinton group. Thickness about 90 feet at Verona Station; pinches out to west.

W. L. Grossman, 1953, *in* Marshall Kay, New York State Mus. Bull. 347, p. 68–69. Formation described in Utica quadrangle. Consists of sandstone and shale. Thickness about 200 feet. Overlies Oneida sandstone and conglomerate; underlies Willowvale shale. Clinton group.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Clinton group, Ontarian stage. Middle Silurian.

Type section: On Swift Creek, north of Sauquoit village, Oneida County.

**Sausalito Chert Member** (of Franciscan Formation)

Sausalito Chert (in Franciscan Group)[1]

Jurassic and Cretaceous: Western California.

Original reference: A. C. Lawson, 1902, Science, new ser., v. 15, p. 416 (table).

U.S. Geological Survey currently classifies the Sausalito Chert as a member of the Franciscan Formation on the basis of a study now in progress.

Named for exposures west of town of Sausalito, on Marin Peninsula, Marin County.

†Savage Formation[1]

Pennsylvanian: Western Maryland and northeastern West Virginia.

Original reference: N. H. Darton and J. A. Taff, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

Savage River region.

**Savanna Sandstone**[1] or **Formation** (in Krebs Group)

Pennsylvanian (Des Moines Series): Eastern and southern Oklahoma and western Arkansas.

Original reference: J. A. Taff, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 437.

S. W. Lowman, 1933, Tulsa Geol. Soc. Digest, p. 31. Includes Spaniard limestone member (new).

C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 508–510. In southern Muskogee County, Okla., includes (ascending) Tamaha sandstone, Keota sandstone, Spiro sandstone (all new), and Bluejacket sandstone members. In northern part of county, includes (ascending) Tamaha sandstone, Keota sandstone, Spaniard limestone (new), and Sam Creek limestone (new) members. Overlies McAlester shale; underlies Boggy shale. Thickness 205 to 332 feet.

C. H. Dane and T. H. Hendricks, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 3, p. 312–314. Restricted to exclude Bluejacket sandstone which is herein allocated to member status in Boggy shale.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 44–54. Restricted to exclude Tamaha sandstone and Keota sandstone members which are herein allocated to member status in McAlester formation. Thickness 450 to 1,400 feet thick on south side of Haskell County and 100 to 200 feet on north side. Overlies McAlester formation; underlies Boggy formation.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1523–1526. Included in Krebs group (new).

C. C. Branson, 1954, Oklahoma Acad. Sci. Proc., v. 33, p. 192, 193 (table 1). In Craig County includes Doneley limestone member (new).

Named for Savanna, Pittsburg County, Okla.

**Saverton Shale**[1]

Saverton Formation (in Champ Clark Group)

Saverton Shale (in Fabius Group)

Lower Mississippian: Northeastern Missouri, western Illinois, and southeastern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 149, 151, 153–156.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 101, chart 5; J. M. Weller, 1948, (abs.) Am. Jour. Sci., v. 246, no. 3, p. 150. Included in Fabius group (new). Overlies Grassy Creek shale; underlies Louisiana limestone. Mississippian or Devonian.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 16–18. Reallocated to Champ Clark group (new), proposed to replace Fabius group of Weller and others (1948). Overlies Grassy Creek shale; underlies Louisiana limestone in Macoupin and Montgomery Counties; elsewhere conformably overlain by either the Glen Park or Maple Mill. Thickness 0 to 75 feet.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 85–87. Keyes (1913. Am. Jour. Sci., 4th, v. 36) used name Saverton for upper part of the "black and green" shales beneath the Louisiana limestone at Louisiana. He stated that immediately beneath the Louisiana limestone at the original locality are 2 feet of blue shales; this apparently insignificant layer is usually included in the Grassy Creek black shales below. Keyes' proposal has been generally accepted and characteristic features and distribution of Saverton were discussed in detail by Moore (1928). Branson and Mehl (1933, Missouri Univ. Studies, v. 8, no. 3) concluded that the blue shales of the "Saverton" represent the upper weathered part of the Grassy Creek and suggested that name Grassy Creek be used as originally defined by Keyes. Weller (1935) saw no reason to separate the blue and black shales and proposed that together they be known as the Saverton. Neither of these proposals has gained general acceptance and current practice in assembling stratigraphic data generally follows Keyes' proposal of separation. Regardless of fact that Keyes named these shales "Saverton," the original locality described by him (1897, [1898], Iowa Acad. Sci. Proc., v. 5), is as follows: "Immediately beneath the well-defined Louisiana limestone, in the vicinity of Louisiana, there are about 6 feet of black and green shales carrying a characteristically Devonian fish fauna." Therefore, type locality is herein specifically designated. Outcrops of Saverton are essentially coextensive with those of underlying Grassy Creek; in Missouri, confined to northeastern part of State north of Lincoln arch. In Pike County, average thickness probably a little more than 2 feet and somewhat less in vicinity of type locality. Saverton seems to thicken toward northwest; Moore (1928) reported 100 feet in river bluff near Saverton, Ralls County; it is likely that Saverton, as herein defined, is much less. Branson and Mehl (1933) measured 15 to 20 feet of shale between the Louisiana and Mineola (Callaway) on Sees Creek, west of Hannibal, Marion County; this shale, which they designated as Grassy Creek, is now believed to be Saverton. Overlies Grassy Creek shale; underlies Louisiana limestone or where Louisiana is missing, the Hannibal shale. Late Devonian.

Type locality (Mehl, 1960): Missouri River bluff several hundred feet above Champ Clark Bridge, the same as the type locality for the Grassy Creek (SW¼NW¼SE¼ sec. 18, T. 54 N., R. 1 W.), Pike County, Mo.

**Savoy Schist**[1]

Ordovician: Northwestern Massachusetts and southeastern Vermont.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 156–163, 220–221, pl. 34.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Shown on correlation in east Vermont above Ottauqueechee formation and below Hawley formation.

Named for development in eastern part of Savoy Township, Berkshire County, Mass.

**Sawatch Quartzite**[1]

Upper Cambrian: Western and central Colorado.

Original reference: G. H. Eldridge, 1894, U.S. Geol. Survey Geol. Atlas, Folio 9.

Q. D. Singewald, 1947, Preliminary geologic map and section of the upper Blue River area, Summit County, Colorado (1:31,250): U.S. Geol. Survey Prelim. Map; 1951, U.S. Geol. Survey Bull. 970, p. 9 (table). Thickness 100 to 140 feet. Underlies Peerless formation; unconformably overlies Precambrian.

H. F. Donner, 1949, Geol. Soc. America Bull., v. 60, no. 9, p. 1218–1221. Described in McCoy area where it is 270 feet thick, overlies Precambrian granite, gneiss, and schist and underlies Leadville limestone.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 158–161. Described in Pando area where it consists of fine-grained thick-bedded to massive white quartzite; pink near base and at top. Thickness 140 to 185 feet. Underlies Peerless formation; unconformably overlies Precambrian.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 39. Described along Front Range where it is about 50 feet thick, underlies Ute Pass dolomite (new) ; overlies Precambrian granite.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 892 (fig. 2), 894, 896, 897. In White River Plateau, underlies Glenwood Canyon member (new) of Dotsero formation (redefined).

C. H. Behre, Jr., 1953, U.S. Geol. Survey Prof. Paper 235, p. 25–27. On west slope of Mosquito Range, Sawatch is limited to the quartzite, generally white and averaging 105 feet in thickness. Underlies Peerless formation; overlies Precambrian.

M. G. Ding and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 10–11. In Garfield quadrangle, consists of a lower quartzite member, a middle glauconitic sandstone member, and an upper quartzite member. Thickness 100 feet. Underlies Manitou dolomite; overlies Precambrian gneiss.

R. R. Berg and R. J. Ross, Jr., 1959, Jour. Paleontology, v. 33, no. 1, p. 107 (fig. 1), 108, 110. On basis of faunal correlations, unit called Ute Pass at Williams Canyon by Maher (1950) is restored to lower part of Manitou formation. On bases of lithology and stratigraphic position, the Ute Pass of Missouri Gulch is correlated with Peerless formation; term Ute Pass is abandoned. Hence, in some areas the Sawatch underlies the Manitou and in others the Peerless.

Named for persistent occurrence around flanks of Sawatch Range.

Sawatch Schist[1]

Precambrian: Central Colorado.

Original reference: J. T. Stark and F. F. Barnes, 1935, Colorado Sci. Soc. Proc., v. 13, no. 8, p. 466–479, map.

Probably named for Sawatch Range.

†Sawatchan series[1]

Upper Cambrian: Colorado.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 281, 286.

Encircle Sawatch uplift in Sawatch Range.

Saw Mill Conglomerate (in Almy Conglomerate)

Paleocene: Northern Utah.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1), 842, pl. 1. Lower 400 feet, massive red cliff-making conglomerates; middle 500 feet, light-tan and gray conglomerates, grits, sandstones, and shales; upper 300 feet, brownish-tan conglomerates. Overlies Pulpit conglomerate division (new) ; underlies Fowkes formation.

B. E. Lofgren, 1955, Utah Geol. Soc. Guidebook 10, p. 75. Since Eardley's original mapping, he and students have remapped area and now regard Saw Mill conglomerate as Knight conglomerate.

Named from Saw Mill Canyon, 4½ miles up Echo Canyon from the Weber, Morgan County.

Sawmill Stage

Pleistocene: Southwestern Montana.

W. B. Hall, 1960, Billings Geol. Soc. [Guidebook] 11th Ann. Field Conf., p. 192–195. Discussion of multiple glaciation in Madison and Gallatin Ranges. Three stages recognized: Marble Point (oldest), intermediate, and Sawmill. Prominent feature of Sawmill stage is Sawmill moraine which rests at elevation of 7,000 feet up valley floor of Taylor Fork of Gallatin River.

Named for former establishment of Sawmill, built along the moraine in Taylor Fork valley, in Madison Range.

Sawmill Creek Member (of Cashaqua Formation)

Upper Devonian: Western New York.

R. G. Sutton, 1960, New York State Mus. Sci. Service Bull. 380, p. 14–17, 54, 55–56, figs. 2, 5. Proposed for gray and black shales that underlie Rock Stream member and overlie Middlesex black shale. Thickness 19 to 236 feet; thickens eastward. After submission of this paper for publication, Colton and de Witt (1958) proposed name Pulteney for unit herein named Sawmill Creek; former name thus has priority.

Type section: Sawmill Creek, on east side of Seneca Lake, 8 miles north of Watkins, Schuyler County.

**Sawtooth Formation** (in Ellis Group)

Middle Jurassic: North-central and western Montana.

W. A. Cobban, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 9, p. 1264 (fig. 1), 1270–1277, strat. sections. Consists of basal fine-grained sandstone, a medial dark-gray shale containing a few thin dark limestone layers, and an upper highly calcareous siltstone. Thickness at type section 136 feet; at Swift Reservoir section 198 feet; formation is thickest along Rocky Mountain front and in trough extending slightly south of west from Sweetgrass Hills to Rocky Mountain front; thins over Kevin-Sunburst dome; absent over most of South arch. Basal formation of group; underlies Rierdon formation (new); where Rierdon is absent, underlies Swift formation (new); in Sun River section, overlies Hannan limestone. Bathonian age indicated by fossils. Subsurface data.

R. W. Imlay and others, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 32. Detailed description in discussion of marine Jurassic formations of Montana. In south-central Montana grades eastward into Piper formation (new).

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 968–969, chart 8C (column 56). Middle Jurassic age of Sawtooth is based on presence of *Defonticeras* near its base and of *Arctocephalities* and *Procerites* in its upper silty beds and on its stratigraphic position beneath beds containing varied ammonite faunas that allow correlation with lower Callovian ammonite zones of northwest Europe. Formation pinches out by overlap on South arch of Sweetgrass uplift and on Big Belt uplift east of Helena but grades eastward into Piper formation in northern and southern Montana.

T. P. Storey, 1958, Alberta Geol. Soc. Petroleum Geologists Jour., v. 6, no. 4, p. 90–104. Discussion of Jurassic of Williston Basin and adjacent areas. On basis of faunal, environmental, and tectonic evidence units are grouped into four major depositional sequences or stagelike intervals which Imlay refers to as Gypsum Spring (or Piper), Sawtooth, Rierdon, and Swift formations. Miscorrelation of type sections of these formation are result of variations in stratigraphic succession caused by sub-Swift and sub-Rierdon unconformities which correspond respectively to Arkell's (1956, Jurassic geology of the World: New York, Hafner Publishing Co.) Lower Callovian and uppermost Callovian to Lower Oxfordian marine transgressions. Recognition of regional extent and significance of these unconformities suggests that these are the following stratigraphic variations from those generally accepted: (1) the Lower Swift (Stockade Beaver-Hulett of Lower Sundance) is older than type Swift and younger than type Rierdon; and (2) Sawtooth is discrete stratigraphic unit which is younger than Piper or Gypsum Spring.

Type section: Rierdon Gulch, W½ sec. 23, T. 24 N., R. 9 W., Teton County. Named for exposures in Sawtooth Range.

**Sawyer Limestone Member** (of Waxahatchee Slate)[1]

Precambrian or Paleozoic: Eastern Alabama.

Original reference: C. Butts, 1926, Alabama Geol. Survey Special Rept. 14, p. 51, map.

Charles Butts, 1940, U.S. Geol. Survey Geol. Atlas, Folio 226, p. 3. Described as member of Waxahatchee slate. Separated from overlying Brewer phyllite by an interval of clay rock of brownish, greenish, or pinkish tint banded with thin yellowish, pinkish, or grayish laminae: Derivation of name given.

Name derived from Sawyer Cove, Shelby County, Columbiana quadrangle.

Sawyer Quartz Syenite[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1904–1905, pl. 1. Pink medium-grained equigranular quartz syenite. Megascopically visible quartz invariably present; hornblende and biotite also visible. Contains xenoliths of schist and angular blocks of Belknap syenite. Patches of a shonkinitic type of syenite surrounded by quartz syenite occur locally. Older than Albany quartz syenite and Conway granite; younger than Gilmanton monzodiorite and Belknap syenite. Assigned to White Mountain magma series.

Named from farm at west base of Gunstock Mountain in Belknap Mountains. Extends northward from the mountain for more than 2 miles.

Saxe Brook Dolomite (in Woods Corners Group)

Saxe Brook Formation

Middle Cambrian: Northwestern Vermont, and Quebec, Canada.

B. F. Howell, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1964. Sandy dolomite, in part a dolomitic sandstone. Underlies

Hungerford formation; overlies Skeels Corners formation (new) disconformably.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 543–546, pl. 1. Dolomites south of Missisquoi River that were originally included in formation are now placed in amended Skeels Corners slate and Saxe Brook dolomite limited to beds that form Carter Hill, a mile west of Highgate Center, and the ridge to north on east side of Saxe Brook valley. Extends into Canada only in much reduced thickness. Regarded as northern equivalent of Rockledge conglomerate, but separate names retained because of lithologic differences between the two units. Contains three main rock types. Most common is highly arenaceous gray dolomite, next is sandstone with dolomitic cement, least common is nonarenaceous dolomite. These types are arbitrary divisions of a continuous, gradational lithic sequence. Thickness 600 to 700 feet; about 350 feet at international boundary. Overlies Skeels Corners slate with slight angular unconformity; contact with Hungerford slate not exposed. Included in Woods Corners group (new). Middle Cambrian.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, p. 572, pl. 3 (correlation chart). Presumably mappable unit north of boundary into Quebec.

Best exposed on Carter Hill, on eastern side of valley of Saxe Brook, northwest of Highgate Falls, Franklin County. Extends several miles northeastward and southwestward of Highgate.

Saxian Series[1]

Upper Cretaceous: Northwestern Iowa.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 43, p. 300.

Occurs a short distance east of Missouri River.

**Saxton Conglomerate Member** (of Chemung Formation)[1]

Upper Devonian: Central Pennsylvania.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 523, 535.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Member of Chemung formation. Consists of conglomeratic sandstones and greenish-gray and chocolate-brown shales. Thickness 102 feet.

Exposed in and about Saxton, Huntingdon County.

Saxton Shale (in Catskill Formation)[1]

Upper Devonian: Central southern Pennsylvania and eastern West Virginia.

Original reference: D. B. Reger, 1927, Geol. Soc. America Bull., v. 38, p. 157, 397–410.

Well exposed on north side of deep cut at Riddlesburg, Bedford County, Pa.

Saypo Limestone (in Hannan Limestone)

Saypo Limestone Member[1] (of Madison Limestone)

Mississippian (Kinderhookian): Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 46.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 2 (column 38). Shown on correlation chart as the lowermost unit in Hannan limestone. Underlies Dean Lake chert. Kinderhookian.

J. M. Andrichuk, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 85. Assignment of group status to the Madison of northwestern Montana precludes any need for term Hannan.

Type locality: On south side of upper part of Pentagon Mountain, SW¼ sec. 14, T. 25 N., R. 12 W. [Flathead County]. Named for Saypo quadrangle, over much of which it is well exposed.

**Sayreville Sand Member** (of Raritan Formation)

Upper Cretaceous: East-central New Jersey.

H. C. Barksdale and others, 1953, The ground-water supplies of Middlesex County, New Jersey: New Jersey State Water Policy Comm. [Spec. Rept. 8], p. 101–103. Bed of variable composition composed dominantly of fine- to medium-grained, white, micaceous sand (No. 2 sand of previous reports). Separated from overlying Old Bridge sand member (new) by South Amboy fire clay, and from underlying Farrington sand member (new) by Woodbridge clay. North of Raritan River consists of fine white micaceous sand, crossbedded fine- to coarse-grained white sand, with or without layers of white clay, and beds of arkosic sand; here thickness is 35 to 40 feet. Near Sayreville thickness is 6 to 7 feet. In this report, Woodbridge and South Amboy clays are considered informal economic names.

Named for exposures at several localities in northern part of Borough of Sayreville, Middlesex County.

Scajaquada Limy Shale[1]

Scajaquada Shale or Waterlime (in Bertie Group)

Upper Silurian: Western New York.

Original reference: G. H. Chadwick, 1917, Geol. Soc. America Bull., v. 28, p. 173–174.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 9. Mentioned in discussion of Bertie formation in east-central New York.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Scajaquada shale or waterlime included in Bertie group. Overlies Falkirk dolomite; underlies Williamsville waterlime. Fieldwork has not demonstrated lateral continuity of Scajaquada and Forge Hollow shale as shown on present chart. Thick glacial deposits conceal units in area where they may merge. Therefore, distinct names are used in western and central New York.

Derivation of name not stated.

**Scales Creek Flow** (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Persistent lava flow noteworthy for its thickness in Portage Lake lava series. Older than Old Colony sandstone; younger than Copper City flow (new).

Geologic map indicates that Scales Creek transects the strike of the flow in southeastern part of Ahmeek quadrangle.

Scammon Formation (in Cabannis Group)

Scammon Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas, southwestern Missouri, and northeastern Oklahoma.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 196. Cherokee group is divided into 15 cyclic formational units. The Scammon, eighth in the sequence (ascending), overlies the Pilot and underlies the Mineral. Average thickness 33 feet. Includes a thin coal here designated Scammon. [For complete sequence see Cherokee group.]

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Scammon formation in Cabaniss group. Underlies Mineral formation; overlies Tebo formation.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as a coal cycle in Senora formation in Oklahoma. Includes Tiawah black shale, Tiawah limestone, shale, and Chelsea sandstone. Overlies Tebo coal cycle; underlies Mineral coal cycle. Cabaniss group.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 22 (fig. 11). Thickness of formation about 4 feet in Vernon County, Mo. Includes Tiawah limestone and Chelsea sandstone. Overlies Tebo formation. Cabaniss group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 52–60. Formation in Cabaniss subgroup of Cherokee group. Includes beds above Tebo coal and extends to top of Scammon coal. Complete succession included in formation is exposed at only one Kansas locality (strip-pit highwall in SE¼NE¼ sec. 24, T. 28 S., R. 25 E., Crawford County). Following divisions recognized in Kansas: dark-gray to black fissile shale at base, including single limestone bed (Tiawah); fine-grained sandstone and siltstone; medium- to dark-gray shale; sandstone (Chelsea); underclay; Scammon coal bed. In some areas in Kansas and Missouri, the Chelsea sandstone rests on an erosion surface extending down through the lower beds and locally through the Tiawah limestone and underlying Tebo coal. Thickness of formation 28 to 32 feet in eastern Crawford County; 35 to 45 feet in central and southern Crawford County and northern Cherokee County.

Type locality of Scammon coal is along Cherry Creek, northwest of Scammon, Cherokee County, Kans.

Scandian Sub-Age

Pleistocene: Midcontinent region.

J. C. Frye and A. B. Leonard, 1955, Am. Jour. Sci., v. 253, no. 6, p. 359 (fig. 1), 362. Provincial time-stratigraphic and time term used to designate the interval from the end of Sangamonian to the beginning of Bradyan.

Type locality is the section (NW¼ sec. 5, T. 3 S., R. 4 W.) of fossiliferous silt, 40 feet thick, resting on Sangamon soil developed in thin Loveland silt that overlies the Greenhorn limestone, in the bluff of the Republican River valley north of the town of Scandia, Republic County, Kans.

**Scanlan Conglomerate Bed** (in Pioneer Formation)

Scanlan Conglomerate (in Apache Group)[1]

Precambrian: Central and southeastern Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. Thickness 1 to 6 feet in Globe quadrangle. Composed of angular and subrounded fragments of vein quartz, small chips of schist, and a few fragments of the more resistant granitic rocks in a matrix that differs from underlying rock. Where it lies on schist [Pinal], matrix is dark gray to black and is composed of fine grains of schist, mica, and quartz. Where it overlies granite [Ruin], matrix is an arkose composed mainly of orthoclase and quartz. Underlies Pioneer formation.

U.S. Geological Survey currently classifies the Scanlan Conglomerate as a bed in Pioneer Formation on the basis of a study now in progress.

Named for Scanlan Pass, Globe quadrangle, through which the trail passes just east of Barnes Peak.

**Scappoose Formation**

Oligocene, upper, and Miocene, lower: Northwestern Oregon.

W. C. Warren and Hans Norbisrath, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 220 (table 1), 231–233. Gray yellowish-weathering firm fossiliferous sandy tuffaceous shale and shaly sandstone, commonly spotted with pumiceous material; loosely consolidated medium-grained sandstone; in some areas, strata show pebble band, crossbedding, and interbedded carbonaceous material. Thickness and distribution erratic; measured thickness in Buxton-Manning area approximately 1,500 feet. Capped by Columbia River basalt; disconformably overlies Pittsburg Bluff formation, and locally, separated from it by a conglomerate of variable thickness.

Typical exposures occur in valley of South Fork, of Scappoose Creek and along Rocky Point Road a few miles east and southeast of Scappoose on Columbia River Highway, Columbia County.

**Scarboro Phyllite** (in Casco Bay Group)[1]

Pennsylvanian(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7 p. 198.

Named for exposures in Scarboro, Cumberland County.

**Scatter Creek Rhyodacite** or **Formation**

Eocene or Oligocene: Northeastern Washington.

Hunting Geophysical Services, Inc., 1960, *in* Washington Div. Mines and Geology Rept. Inv. 20, p. 5, 6. Consists of variety of fine- to medium-grained porphyritic rocks ranging in composition from quartz monzonite to quartz diorite; local facies of syenite, diorite, and hornblendite; also quartz monzonite and quartz diorite dikes and irregular intrusive bodies that occur in White Mountain area west of Bacon Creek fault. In Curlew quadrangle, has largely engulfed Permian-Triassic and O'Brien Creek rocks (new) and parts of Sanpoil volcanic rocks (new). Intrudes Covada group. Republic quadrangle and part of Aeneas quadrangle mapped by Muessig and Quinlan (1959, U.S. Geol. Survey open-file map); Curlew quadrangle mapped by Calkins, Parker, and Disbrow (1959, U.S. Geol. Survey open-file map).

Widespread in Republic and Curlew quadrangles. Occurs as dikes, sills, and irregular intrusive bodies that occupy considerable part of Republic graben.

Scenic Member (of Brule Formation)

Oligocene: Southwestern South Dakota.

J. D. Bump, 1956, Am. Jour. Sci., v. 254, no. 7, p. 430–431. Unit formerly known as *Oredon* beds (Wortman, 1893, Am. Mus. Nat. History Bull., v. 5), minus the upper *Oredon* bed, is here designated Scenic member. At standard section, consists of upper nodular zone of light-cream-colored clays and gray clays 123 feet thick and a lower nodular zone of pink-gray clays 36 feet thick. Underlies Poleslide member (new); overlies Chadron formation.

Standard section: SW¼ sec. 23, T. 3 S., R. 13 E., 2.2 miles south of Scenic, Pennington County.

Scenic Point Member (of Appekunny Formation)

Precambrian (Belt Series): Western Montana, and southern Alberta, Canada.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1886–1887, fig. 2. Argillites, sandstones, and gravelly conglomerates; green, purplish, buff, brown, and dull brownish red at type locality. Northward and westward from type locality, member grades into thickly bedded, coarsely mud-cracked argillites, which give way to thick quartzites and subordinate gray and iron-stained argillites. Mud breccias, mud cracks, and ripple marks abundant. Thickness 200 to 700 feet. Overlies Appistoki member of Appekunny formation and underlies Rising Wolf member of Grinnell formation.

Type locality: Scenic Point, overlooking Two Medicine Valley, Glacier National Park, Mont.

**Schaefferstown Formation** (in Conococheague Group)

Schaefferstown Member (of Conococheague Formation)

Upper Cambrian: Southeastern Pennsylvania.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Geologic map of the Richland quadrangle, Pennsylvania (1:24,000): Pennsylvania Geol. Survey, 4th ser., Atlas 167–D. Limestone sequence that stratigraphically overlies Snitz Creek member (new); top is drawn at base of first bed of white to pinkish-gray crystalline limestone of overlying Millbach member (new). Consists of medium-light- to medium-gray limestone with distinct shaly bands and laminae; rock is thick bedded in fresh exposures, but weathered rock appears rare; some pinkish-gray limestone beds near base; shaly bands and laminae are carbonaceous and make member particularly susceptible to flowage. Thickness probably 200 to 300 feet; partial section (type) 68 feet with neither top nor base exposed.

Carlyle Gray and D. M. Lapham, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 148–150. Upper Cambrian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Conococheague group.

Type section: Partial section measured in small quarry on west side of Schaefferstown just south of Route 897, Lebanon County. No satisfactory type section available in Lebanon County but best partial section has been measured and used as type section.

**Schaghticoke Shale**[1]

Upper Cambrian or Lower Ordovician: Eastern New York and western Vermont.

Original reference: E. Ruedemann, 1903, New York State Mus. Bull. 69, p. 934–966.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Correlation chart for Vermont shows Schaghticoke shale in Taconic sequence below Deepkill shale. Stratigraphically above Zion Hill quartzite. Lower Ordovician.

Typically exposed along Hoosic River at and in vicinity of Schaghticoke, Rensselaer County, N.Y.

Schell shale[1]

Lower Ordovician: Eastern Nevada.

Original references: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53; 1924, Pan-Am. Geologist, v. 41, p. 78.

Named for outcrops in full thickness in a fault block near middle of Schell Creek Range, east of Ely, White Pine County.

**Schenectady Formation**[1]

Middle Ordovician: East-central New York.

Original reference: R. Ruedemann, 1912, New York State Mus. Bull. 162.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 273. Discussed under heading of formations of Sherman age, Trenton group. Composed of interbedded blue-gray calcareous sandstones with intercalated dark-gray arenaceous shale. Underlies Indian Ladder beds; overlies Snake Hill formation.

J. M. Berdan, 1950, New York Water Power and Control Comm. Bull. GW–22, p. 10 (table 2), 14. Formation, in Schoharie County, underlies Brayman shale. Thickness estimated at 2,000 feet but entire thickness not exposed in county. No record of wells that have passed completely through formation. Middle Ordovician.

Type exposures: Dettbarn quarries, at Schenectady, and at Aqueduct and Rexford Flats at Schenectady, Schenectady County.

Schenley Red Beds (in Conemaugh Formation)[1]

Pennsylvanian: Southwest Pennsylvania.

Original reference: M. E. Johnson, 1925, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 37, p. 54, 121.

Occurs just north of Blackburn on Turtle Creek branch of Pennsylvania Railroad. Named because of their execllent exposure in Schenley district, Pittsburgh, Allegheny County.

**Scherrer Formation** (in Naco Group)

Scherrer Formation (in Snyder Hill Group)

Permian: Southeastern Arizona and southwestern New Mexico.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 1, 27–29. Comprises (ascending) about 65 feet of bright-red siltstone at base; about 30 feet of fine-grained gray limestone; 270 feet of sandstone containing a few beds of limestone in lower part;

165 feet of fine-grained, relatively thin bedded, and in part somewhat dolomitic, gray limestone; and 150 feet of sandstone. Sandstone nearly white on fresh fracture but generally weathers rusty brown. Thickness of type section 687 feet. Overlies Colina limestone (new) with sharp contact; underlies Concha limestone (new) at some localities and disconformably underlies Glance conglomerate at others. In Naco group.

D. L. Bryant, 1955, Dissert. Abs., v. 15, no. 7, p. 1224. Excluded from Naco group because it is not present in type area of original Naco. Reassigned to Snyder Hill group (new). Overlies Andrada formation (new) in western part of southern Arizona.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 39–41, tables 1, 2, pl. 1. In Peloncillo Mountains, N. Mex., about 50 feet of thick-bedded well-cemented dusty-red siltstone forms crest of ridge north from Cienega Peak. Overlies Colina limestone; underlies Chiricahua limstone. Formation thins in easterly direction—687 feet thick in central Cochise County, 150 feet in Chiricahua Mountains, and 30 to 50 feet in western part of Peloncillo Mountains. In Naco group.

Type section: On Scherrer Ridge (from which formation takes its name) and Concha Ridge, Gunnison Hills, central Cochise County, Ariz. Top of section measured along crest of Concha Ridge (SW¼NW¼ sec. 28, T. 15 S., R. 23 E.).

**Schieffelin Granodiorite**

Upper Cretaceous or Tertiary: Southeastern Arizona.

B. S. Butler, E. D. Wilson, and C. A. Rasor, 1938, Arizona Bur. Mines Bull. 143, Geol. Ser. 10, p. 25–26, pls. 3, 4. Has general appearance of a rather fine-grained light-gray granite and locally is referred to by that name. Slightly reddish tint in places and passes into various porphyritic modifications along its contact with the sedimentary rocks into which it is intrusive, including the Naco limestone and beds of the Bisbee group.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 102–104, pl. 5. Intrusive contacts found with all members of Naco group and with Bisbee formation, Bronco volcanics, and Uncle Sam porphyry. Occupies area of about 3 square miles in Tombstone district and forms Bronco Hill in central Cochise County.

Named from its typical occurrence in vicinity of Schieffelin's monument, about 1 mile northwest of Tombstone, western Cochise County.

**Schodack Formation**[1]

Lower Cambrian: Eastern New York and southwestern Vermont.

Original reference. R. Ruedemann, 1914, New York State Mus. Bull. 169, p. 67–70, map.

C. E. Resser and B. F. Howell, 1938, Geol. Soc. America Bull., v. 49, no. 2, p. 204. Bomoseen grit grades upward into calcareous beds to which Ruedemann (1914) assigned name Schodack and which Dale called "Cambric black shales." It is possible that Ruedemann's Mattawee [Mettawee] slate (Dale's "Cambric roofing slate") which crops out about Greenwich, N.Y., and in a belt extending from Pawlet to Fairhaven, Vt., is also Schodack.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland, 1942, New York State Mus. Bull. 331, p. 64–65. In Catskill quadrangle the following units distinguished (descending): Zion Hill quartzite, Schodack shale and limestone, Burden conglomerate, Bomoseen grit, Burden iron ore, and

Nassau beds. Zion Hill quartzite, Schodack shale and limestone, Burden conglomerate, and Bomoseen grit are intimately connected and interfolded. In conference with Resser, it was found to be more practicable to extend term Schodack formation so as to include as members the beds associated or interbedded with it such as Zion Hill quartzite, Burden conglomerate, and also Troy shale and limestone. Resser would unite Ruedemann's Mettawee slate, Schodack shale and limestone, and Eagle Bridge quartzite (Zion Hill quartzite) into Schodack formation.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 64–84. Schodack formation is used here [Coxsackie quadrangle] as extended by Ruedemann to include all members associated or interbedded with it from Bomossen grit through Zion Hill quartzite. In Troy and Cohoes quadrangles, it includes (ascending) Bomoseen grit, Diamond Rock quartzite, Troy shale and limestone, Schodack shale and limestone; in Washington County and Vermont, Bomoseen grit, Mettawee slate, Eddy Hill grit, Schodack shale and limestone, and Zion Hill quartzite; in Catskill quadrangle, Bomoseen grit, Schodack shale and limestone, and Zion Hill quartzite. Zion Hill quartzite not present in area of this report. Bomoseen grit overlies Nassau beds. Underlies Deepkill shale.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart above Bomoseen formation.

E. P. Kaiser, 1945, Geol. Soc. America Bull., v. 56, no. 12, pt. 1, p. 1084 (table 1), 1087–1089, 1091, pl. 1. In northern Taconic area, Schodack slate underlies Wallace Ledge slate (new) and overlies Eddy Hill grit. Units called Beebe limestone and Hooker slate by Keith (1932) are herein considered part of Schodack formation.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 50–53, pl. 2. Described in Castleton area. Crops out in several narrow north-trending bands in slate belt west of Taconic Range and south of Castleton River. North of Castleton River Kaiser (1945) mapped outcrops of Schodack both in and west of Taconic Range in townships of Castleton, Hubbardton, and Ira. Some of Schodack mapped by Kaiser on eastern flank of Taconic Range in Pittsford is here called Hortonville slate, which lies beneath Taconic overthrust. Maximum thickness about 200 feet. Underlies Zion Hill quartzite; overlies Mettawee slate; in some areas, Eddy Hill grit lies between the Schodack and Mettawee. There are two current usages of name Schodack formation: one includes the Bomoseen grit, the other does not. This report follows Cushing and Ruedemann's (1914) usage. Also Resser and Howell's (1938) interpretation of Schodack and Mettawee formations is rejected.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 329, 341–342. Ruedemann (1914) applied name Schodack to "Cambrian black shales" of Dale (1898, U.S. Geol. Survey 19th Ann. Rept., pt. 3B). This is regrettable because it cannot be conclusively demonstrated that fossiliferous limestone exposed near Schodack Landing in Columbia County, where Ford (1885, Am. Jour. Sci., 3d, v. 28) discovered Lower Cambrian fossils, is same lithogenetic unit that Dale had reference to in Washington County. Name Schodack has been used to delimit differing intervals of rock, and this has caused confusion toward understanding relationships of early Cambrian strata in New York. Much of what has been called Schodack in past, both in Columbia and Washington Counties, has proved to be Ordovician Schaghticoke and Deepkill shales, by virtue of discovery of graptolites. Some of Dale's

"Cambrian black shales" (Ruedemann's Schodack) have been found to contain *Dictyonema flabelliforme*, a Schaghticoke graptolite and faunal zone considered as base of Ordovician in North America.

Named for exposures 2 miles south of Schodack Landing, N.Y.

**Schoharie Grit**[1]

Schoharie Formation

Lower and Middle Devonian: Eastern New York, New Jersey, and northern Pennsylvania.

Original reference: L. Vanuxem, 1840, New York Geol. Survey 4th Rept., p. 378.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1779, chart 4. Lower or Middle Devonian. Onesquenthaw stage (new).

Winifred Goldring and R. H. Flower, 1942, Am. Jour. Sci., v. 240, no. 10, p. 673–694. Schoharie and Esopus formations restudied. Formations were traced from Schoharie west to Springfield Center, then east to Helderbergs and then south of Pennsylvania border. Esopus formation restricted, and beds formerly classed as upper Esopus are separated into the new Sharon Springs formation, which may be locally separated from overlying [Schoharie] and underlying beds by glauconite bands. Instead of disappearing to south, Schoharie grit changes rapidly to a shaly and cherty facies, here termed Leeds facies, and thickens as it approaches Pennsylvania border. Contacts with overlying Onondaga are transitional.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland, 1942, New York State Mus. Bull. 331, p. 130, 183, geol. map [1946]. Schoharie grit is local development of sandy facies of lower Onondaga limestone.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 42, 212–225, geol. map. Schoharie grit and limestone exposed in many areas in Coxsackie quadrangle where it has maximum estimated thickness of between 60 and 70 feet. Overlies Esopus shale; underlies Onondaga limestone. Schoharie formation here is dissimilar to beds outcropping in type area and Helderberg region. Possible that this formation does not properly belong to Schoharie. On geological map, Sharon Springs formation, with thickness in northern part of area of about 35 feet, and in Leeds Gorge of about 75 feet, is largely included in Schoharie formation.

Winifred Goldring and R. H. Flower, 1944, Am. Jour. Sci., v. 242, no. 6, p. 340. Preoccupied name Sharon Springs replaced by new name Carlisle Center.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW—20, p. 8 (table 1), 11 (fig. 3), 14, pl. 2. Schoharie grit in Albany County is impure siliceous dark-bluish-gray limestone. In places, merges with underlying Esopus shale and overlying Onondaga limestone. Maximum thickness 20 feet. Lower or Middle Devonian.

J. H. Johnsen, 1957, Dissert. Abs., v. 17, no. 10, p. 2247. Schoharie formation is complex of lithologic facies and faunal zones extending from Herkimer County, N.Y., at least to Monroe County, Pa. Thickens south of Port Jervis, N.Y., and thins again in New Jersey and Pennsylvania. Overlies Esopus formation; underlies Onondaga. Includes Carlisle Center, Rickard (new), and Leeds facies.

Named for exposures at Schoharie, Schoharie County, N.Y.

†Schoharie Stage[1]

Lower Devonian: New York.

Original reference: A. W. Grabau, 1898, Buffalo Soc. Nat. History, v. 6, p. xviii.

School Canyon Granite

Jurassic(?): Southern California.

J. C. Crowell, 1952, California Div. Mines Spec. Rept. 24, p. 8, pls. 1, 2. Buff and orange coarse-grained granite. Resembles Tejon Lookout granite (new) to which it may be closely related, although the relationship has not been established.

Exposed in northwestern corner of Lebec quadrangle, Kern County, within the Pastoria fault zone. Large jagged outcrops and cockscombs occur north of School Canyon, after which the granite is named.

Schoolcraft Dolomite or Formation (in Manistique Group)

Schoolcraft Member[1] (of Manistique Formation)

Middle Silurian: Northern Michigan and eastern Wisconsin, and Ontario, Canada.

Original reference: R. B. Newcombe, 1933, Michigan Geol. Survey Pub. 38, p. 23, 37.

C. K. Swartz, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 536, chart 3. Schoolcraft dolomite and Cordell dolomite replace term Waukesha in eastern Wisconsin.

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (chart), 19, 20–21. Rank raised to formation in Manistique group. Predominantly thin even-bedded finely crystalline gray dolomite. Thickness 40 to 60 feet. Underlies Cordell dolomite; overlies Hendricks dolomite of Burnt Bluff group, probably disconformably.

Exposed in abandoned quarry of White Marble Lime Company on eastern side of Manistique, Schoolcraft County, Mich. Traced from northeastern Wisconsin to region of Owen Sound, Ontario.

Schoolhouse Group

Cretaceous(?) or younger: Southwestern New Mexico.

J. G. Wargo, 1958, abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1748. Volcanic rocks ranging in composition from basalt to rhyolite. Basal units of two andesite flows which rest on Cretaceous(?) shale. Middle unit of thick sequence of pyroclastics, welded tuffs, and flows largely of rhyolitic composition. Five formations can be distinguished locally. Uppermost unit of thin basalt flows interbedded with consolidated gravels of Gila(?) age. Maximum thickness about 9,000 feet.

In Schoolhouse Mountain area, northern Grant County, approximately 20 miles west of Silver City.

Schoolhouse Sand

Schoolhouse Tongue (of Weber Sandstone)

Middle Permian: Western Colorado.

W. O. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 1, p. 72. The so-called Weber sand of Rangely oil fields thins eastward gradually and disappears among red sediments on west slope of Gore

Range, about 10 miles east of Eagle. This sandstone is referred to as Schoolhouse sand. Middle Permian (Leonardian).

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 823. Renamed tongue of Weber sandstone. On west side of McCoy area, 59 feet thick and lies between McCoy and State Bridge formation. Thickness 79 feet at South Canyon, near Glenwood Springs; 46 feet, 4 miles north of Eagle; 27 feet, 10 miles east of Eagle.

Named for typical outcrop near schoolhouse east of Meeker, Rio Blanco County.

School Mine Ledge Bed (in Rich Fountain Formation)

Lower Ordovician: Central Missouri.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 15–16, pls. 2, 3. Massive medium to coarsely crystalline dolomite that forms a prominent ledge in lower part of formation.

Well exposed at experimental mine of Missouri School of Mines and Metallurgy on east line of SW¼SW¼SE¼ sec. 10, T. 37 N., R. 8 W., Rolla quadrangle, Phelps County.

Schooner Head Series[1]

Precambrian or Cambrian(?): Southeastern Maine.

Original reference: N. S. Shaler, 1889, U.S. Geol. Survey 8th Ann. Rept., pt. 2, p. 1037, 1041, 1060, map.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1797. Abandoned; synonymous with Frenchmans Bay series (new) of Silurian age.

Named for exposures at Schooner Head, east coast of Mount Desert Island, Hancock County.

Schooner Hill facies[1] (of Locust Point Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 137–143.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. In north and south direction, Locust Point formation comprises Belmont, Nelson, Hill, Schooner Hill, and Spickert Knob facies.

Name derived from Schooner Hill in Brown County, NE¼ sec. 3 and NW¼NW¼ sec. 2, T. 8 N., R. 2 E., 3½ miles southwest of Nashville.

**Schrader Bluff Formation** (in Colville Group)

Upper Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160 (table 1), 162, 164, 166, fig. 2. Largely marine sandstone to south and shale to north. Contains considerable bentonite and tuff which increases upward through formation. Comprises three members (ascending): Seabee (new), Tuluga (new), and Sentinel Hill (new). Members exposed in over 3,000 feet of continuous outcrop at Schrader Bluff. Thickness at Fish Creek test well No. 1 is 2,600 feet. Overlies Umiat formation (new) in Umiat area and to the south; also overlies Chandler formation (new) to the south. Intertongues with nonmarine Prince Creek formation (new). Underlies Sagavanirktok formation (new).

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 212 (fig. 2), 249–251. Restricted to predominantly marine rocks lying above and interfingering with Tuluvak and Kogosukruk tongues of Prince Creek formation. Type locality redefined by restricting it to steeply south-dipping marine rocks in Schrader Bluff from top of Tuluvak tongue (800 feet above base) to top of exposure (2,700 feet above base). Divided into three members in outcrop area (ascending): Rogers Creek member (new), Barrow Trail member (new), and Sentinel Hill member. In general, formation represents marine deposits of one great transgression and regression of the sea. Thickness about 2,200 feet along Colville River northeast of Umiat, at least 1,900 feet at Schrader Bluff.

Type locality: In north (northeast) bank of Anaktuvuk River about 5 miles above mouth of Tuluga River. Named for exposures at Schrader Bluff on Anaktuvuk River just south of junction with Tuluga River, identified also in well cores from Umiat, Fish Creek, Sentinel Hill, and Cape Simpson areas.

Schreyfogels Limestone[1]

Mississippian: Northeastern Pennsylvania.

Original reference: F. Platt, 1880, Pennsylvania 2d Geol. Survey Rept. $G_2$, p. 187, 199.

Exposed on hillside south of Schreyfogel's Hotel and 170 feet above level of Loyalsock Creek, Sullivan County.

Schroeppel Shale[1] (in Clinton Formation)

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Charles Butts, 1939, *in* Rudolf Ruedemann and Robert Balk, eds., Berlin gebrüder Borntraeger, Geologie der Erde, North America: v. 1, p. 368. Section from Lakeport, Madison County, to Wolcott, Wayne County, shows Schroeppel shale in Clinton formation below Irondequoit limestone and above Brewerton shale.

D. W. Fisher, 1959, New York State Mus. Sci. Service Map and Chart Ser. No. 1. Gillette (1947) in his detailed study of Clinton group ignored Chadwick's (1918) Phoenix and Schroeppel shales, probably because they were so loosely defined. Instead he introduced name Willowvale for the green fossiliferous shale beneath the Herkimer and above the Kirkland. Gillette's view is followed in present report.

Type locality: Phoenix, on Oswego River, Oswego County. Phoenix is in Schroeppel Township.

**Schroyer Limestone Member** (of Wreford Limestone)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference:; G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 33.

D. E. Hattin, 1957, Kansas Geol. Survey Bull. 124, p. 43–49, pls. 1–3. Three units invariably present in Schroyer (ascending): basal cherty limestone, which locally contains some shale in northern Kansas; a shaly unit, which commonly contains a cherty limestone bed; and algal limestone. No exposure examined during this study includes more than 13 feet of what can be called Schroyer. On basis of lithology, much of what has been called Schroyer at type locality should be included in underlying Havensville shale. At several places in Marshall and Pottawatomie Counties, the Havensville includes a molluscan-limestone phase; at first appearance, this molluscan limestone seems to belong to the Schroyer; however, placement of this unit in the Havensville is harmonious with respect both to cycles of sedimentation and to observed thicknesses of shaly exposures of the Havensville. Therefore only 5 feet of cherty limestone at type section should be classified as Schroyer, and at present only 1.6 feet of Schroyer is actually exposed. In this report, boundary between Schroyer limestone and Havensville shale is placed at the contact of chert-bearing limestone on shale or noncherty limestone, the strata above and below the contact thus being lithologically and stratigraphically compatible units. Placed in Wolfcamp series.

Type locality: East side of Big Blue Valley, about 1¼ miles below Schroyer, Marshall County, Kans.

Schubert Creek Limestone[1]

Pennsylvanian: Eastern Kansas and northwestern Missouri.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 90, 97.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 41. Name introduced by Moore for lower member of Hertha. Later it was found that this limestone is the one called Hertha at Kansas City. Kansas Geological Survey now uses names Sniabar limestone, Mound City shale, and Critzer limestone as members of the Hertha.

Type locality: On Schubert Creek between Bronson and Uniontown, Kans., on U.S. Highway 54.

**Schuler Formation** (in Cotton Valley Group)

Upper Jurassic: Subsurface in Arkansas, Louisiana, and Texas.

H. K. Shearer, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 6, p. 724–725. Schuler formation or Schuler facies of Cotton Valley formation applied to formation underlying basal gravel of Travis Peak and overlying Buckner formation (new) or older beds where Buckner is absent in south Arkansas. Includes Morgan sands zone near top and Jones sand at base in Schuler oil field, where thickness is about 2,250 feet. Named by Shreveport Geological Socity.

F. M. Swain, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 594–609. Redefined as formation to include nearshore or nonmarine pastel and red-green shales, sandstones, and basal conglomerates and offshore equivalents of these rocks which are dark-gray fossiliferous shales, limestones, sandstones, and basal conglomerates lying stratigraphically between base of Hosston formation and top of Bossier formation (new). Subdivided into (ascending) Dorcheat and Shongaloo members. In Cotton Valley group. Type section stated.

Type locality: Schuler oil field, Union County, Ark. Type section (near shore facies): Lion Oil Refining Co., and Phillips Petroleum Co.'s Edna Morgan No. 1, C., NE¼SW¼ sec. 18, T. 18 S., R. 17 W., Union County.

**Schultze Granite**[1]

Tertiary(?): Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

M. N. Short and others, 1950, Arizona Bur. Mines Bull. 151, Geol. Ser. 16, p. 50. Tertiary.

In Globe mining district.

Schulz Member (of Williams Formation)

*See* **Schulz Ranch Sandstone Member** (of Williams Formation).

**Schulz Ranch Sandstone Member** (of Williams Formation)

Schulz Member (of Williams Formation)

Upper Cretaceous: Southern California.

W. P. Popenoe, 1937, Jour. Paleontology, v. 11, no. 5, p. 380. Named Schulz member of Williams formation (new). Light-colored coarse arkosic sandstones with numerous beds of well-rounded boulders; unfossiliferous. Average thickness 200 feet. Underlies Pleasants member (new) of Williams formation; overlies Holz member of Ladd formation (both new).

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166, 168 (fig. 2), 173–174. Type locality designated.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Renamed Schulz Ranch sandstone member. North of Silverado Canyon, underlies Silverado formation (new).

Type locality: Approximately a quarter of a mile upstream from mouth of Williams Canyon, near west boundary of Schulz Ranch, northern Santa Ana Mountains, Orange County.

Schumann Formation[1]

Pliocene(?) and Pleistocene: Southern California.

Original reference: R. D. Reed, 1933, Geology of California, p. 232.

G. F. Worts, Jr., 1951, U.S. Geol. Survey Water-Supply Paper 1000, p. 28 (footnote). Term sometimes applied to Paso Robles formation; Paso Robles used in this report.

Exposed near north end of Schumann cut, where railroad enters Casmalia Hills south of Guadalupe, Guadalupe quadrangle.

Schuyler Soapstone[1]

Precambrian: Central Virginia.

Original reference: A. I. Jonas, 1928, Virginia Geol. Survey prelim. ed. of geol. map of Virginia.

Mapped at and around Schuyler, Nelson County.

**Schuylkill Member** (of Pottsville Formation)

Schuylkill Formation (in Pottsville Group)

Lower Pennsylvanian: Eastern Pennsylvania.

G. H. Wood, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2674 (fig. 3), 2675–2676, 2679–2680; 1957, U.S. Geol. Survey Coal Inv. Map C–43, sheet 1. Consists of several beds of fine to coarse pebble conglomerate and quartzose sandstone intercalated with thinner beds of shale and coal. Thickness about 300 feet at type section. Conformably overlies Tumbling Run member (new) with contact sharp where observed in anthracite region; studies in southern and western middle anthracite field indicate that Schuylkill member intertongues on a regional scale with Tumbling Run member; underlies Sharp Mountain member (new).

Carlyle Gray and others, 1960, Geologic map of Pennsylvanian (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Pottsville group in anthracite region.

Type section: Included in Pottsville formation reference section which is in roadcut on east side of U.S. Highway 122, about 150 feet farther east than original type section of the Pottsville which is on eastern side of Pennsylvania Railroad cut through water gap south of Pottsville, Schuylkill County.

Scio Beds or Formation

Oligocene, upper, or Miocene, lower: Western Oregon.

E. I. Sanborn, 1947, Oregon State Coll. Studies in Geology Mon. 4, p. 1–2, 11–12. Beds consist of a series of sandstones and water-lain tuffs and breccias which dip about 12° N. and 40° E. Character of beds varies from very fine grained white tuffaceous shale through quartz-mica sandstone containing as much as 96 percent quartz; on Franklin Butte, formation is more tuffaceous and about 75 feet of it is a well-defined white sandy shale containing fossil leaves. Beds apparently overlie marine Oligocene (Eugene) formation, but exact relationship is questionable because no contacts were observed; unconformably underlie a series of basic lava flows that are presumably middle Miocene in age. Name credited to W. M. Felts (unpub. thesis).

I. S. Allison and W. M. Felts, 1956, Geology of the Lebanon quadrangle, Oregon (1:62,500): Oregon Dept. Geology and Mineral Industries. Tentative names Scio beds and Berlin volcanics used by Felts (1936, unpub. thesis) are abandonded. Name Mehama volcanics used in area.

Well exposed in eastern part of Lebanon quadrangle, Linn County. Named for town of Scio, 9 miles southeast of Jefferson, on U.S. Highway 99.

Scioto Freestone (in Allegheny Formation)[1]

Pennsylvanian: Central southern Ohio.

Original reference: D. D. Owen, 1859, Rept. Geol. Reconn. State of Indiana in 1838, pt. 2, p. 50.

Probably named for Scioto Valley.

†Scioto Slates and Shales[1]

Upper Devonian: Southern Ohio.

Original reference: D. D. Owen, 1859, Rept. geol. reconn. State of Indiana, in 1838, pt. 2, p. 59.

Probably named for Scioto Valley.

Scioto Valley shale facies[1] (of Cuyahoga Formation)

Scioto Valley shale facies (of Logan Formation)

Mississippian: Southern Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 657, 757–758.

F. T. Holden, 1941 Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942 Jour. Geology, v. 50, no. 1, p. 54 (fig. 3), 60–62. Here considered a facies of Logan formation. Includes Portsmouth shale, Buena Vista sandstone, and Vinton sandstone members. Lies between Pretty Run shale facies (new) to the east and Vanceburg siltstone facies to the west.

Crops out to the east along the Scioto River valley.

Sciotoville clay member

Sciotoville Fire Clay (in Pottsville Formation)[1]

Pennsylvanian (Pottsville Series): Southern Ohio.

Original reference: E. B. Andrews, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 166, pl. opp. p. 242.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 21, 22, table 1. Included in Anthony cyclothem in Perry County. Thickness 1½ to 6 feet. Underlies Anthony coal; overlies basal sandstone or shale member of cyclothem. Throughout most of county, the clay and coal lie only a few feet above Mississippian-Pennsylvanian boundary; locally clay lies directly on Mississippian Vinton sandstone.

R. E. Lamborn, 1954, Ohio Geol. Survey Bull. 53, p. 39–41, geol. map. Position of Sciotoville clay member (Pottsville series) is on an average about 30 feet below Sharon or No. 1 coal, and about 28 feet below Quakertown or No. 2 coal. Widely distributed but lacks continuity developed in localized basins or depressions flanked by uplands composed of strata of Mississippian age.

First described at Sciotoville, Scioto County.

**Scituate Granite Gneiss**

Mississippian(?) or older: Rhode Island.

A. W. Quinn, 1951, Bedrock geology of the North Scituate quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad. Map [GQ–13]. Light-gray, gray, or pink medium- to coarse-grained granite gneiss. Almost massive in places. Formerly included in Sterling granite gneiss. Intrusive into Blackstone series; intruded by Esmond granite.

G. M. Richmond, 1951, *in* G. M. Richmond and W. B. Allen, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 4, p. 14. Thickness of one mass in Georgiaville quadrangle is 2,000 to 4,000 feet. Cuts Woonasquatucket formation.

G. E. Moore, Jr., 1958, U.S. Geol. Survey Geol. Quad. Map GQ–105. Described in Hope Valley quadrangle. Younger than Blackstone series; grades into Hope Valley alaskite gneiss (new); cut by dike of Ten Rod granite gneiss (new). Devonian(?) or older.

U.S. Geological Survey currently designates the age of the Scituate Granite Gneiss as Mississippian(?) or older on the basis of a study now in progress.

Named for extensive exposures in Scituate Township, Providence County. Good exposures at east wall of spillway at west abutment of the Kent Dam of the Scituate Reservoir and in small quarry one-half mile west of Snake Den.

Scossa Slates[1]

Jurassic: Northwestern Nevada.

Original reference: J. C. Jones, A. M. Smith, C. Stoddard, 1931, Nevada Univ. Bull., v. 25, no. 4, p. 6, 7, 8.

Scossa district, Pershing County.

Scotia Bluffs Sandstone (in Wildcat Group)

Pliocene, upper: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 33–55, 111–113, pls. 1, 2. Massive fine-grained sandstone with mudstone members in lower part. Thickness 1,000 to 2,000 feet. Underlies Carlotta formation (new), contact gradational; overlies Rio Dell formation (new). In Wildcat Ridge section, upper part of Carlotta formation is not exposed, and lower part is noticeably more sandy than lower Carlotta in Eel River area. Term Ferndale (MacGinitie, 1943) has been used for the sandstone and conglomerate in section along Wildcat Ridge. The two are mappable units, and name Scotia Bluffs sandstone is proposed for the lithologic unit immediately overlying the Rio Dell formation and underlying Carlotta formation.

Type section: Along Scotia Bluffs on east side of Eel River.

**Scotland Schist**[1]

Scotland schist phase (of Hebron Gneiss)

Pre-Pennsylvanian: Eastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 114, 132, 141, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 76, 77, pl. 1. Abandoned in favor of Brimfield schist; two units are identical.

John Rodgers and others, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Rank reduced to a phase. Occurs in the southern and east-central parts of the Hebron outcrop area. Pre-Triassic.

Crops out in town of Scotland, Windham County.

Scott Member (of Day Point Formation)

Middle Ordovician (Chazyan): Northwestern Vermont and northeastern New York.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 821–827, 845, geol. sections. Defined as 44 feet of light- to medium-gray coarse-grained coquinal calcarenite in medium to thick beds, commonly cross laminated,, overlying Head member (new) at Scott Point, Isle La Motte; underlies Wait member (new). Base exposed in cove south of Scott Point is calcarenitic quartz conglomerate, succeeded in lower 24 feet by strongly cross-laminated quartz-sandy calcarenite; upper 6 feet has pinkish cystid fragments and small biostromal swellings, more or less dolomitized and with bryozoans; in contact with Wait member in cove north of point. Thins eastward to 32 feet on Wait Bay; on Wool Point 17 feet; near Chazy, N.Y., minimal thicknesses are 76 and 58 feet and beds are partly dolomitized; thickens from 6 feet on South Hero to about 40 feet on southern Valcour Island where it is poorly defined . Presumably overlapped southward.

Type locality: Scott Point. Isle La Motte, Vt.

**Scott Shale**

Scott Shale (in Pottsville Group)[1]

Middle Pennsylvanian: Eastern Tennessee.

Original reference: A. Keith, 1896, U.S. Geol. Survey Geol. Atlas, Folio 33.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 89–93, 150. Scott formation (of shale) occurs between Anderson sandstone above and Jellico formation (called Wartburg by Keith) below.

C. W. Wilson, Jr. J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [Folio], pl. 1.

As a result of recent fieldwork, names Briceville, Jellico, Scott, and Anderson formations are discontinued and a complete new classification presented.

Named for occurrence in Scott County.

**Scott Canyon Formation**

Lower or Middle Cambrian(?): North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler Peak quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–10]. Chert, argillite, slate, limestone, and intercalated greenstone (altered andesitic lava) predominate. Chert is dark, thin bedded, and lenticular with argillite partings. Thickness estimated to be more than 2,000 feet and may exceed 5,000 feet. Mississippian(?).

H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–15]. Type locality designated.

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2829–2830. Exposed in Antler Peak quadrangle. Consists of about 5,000 feet of dark thin-bedded chert, shale, and greenstone with a little limestone and quartzite. Overthrust by Harmony formation. Relations to younger formation, such as Valmy, not known.

Type locality: Scott Canyon, a tributary of Galena Canyon, southeast flank of Antler Peak. Well exposed in Galena, Little Cottonwood, and Scott Canyons in southeastern part of Antler Peak quadrangle.

†Scotts Bluff Formation[1]

Miocene: Southwestern Nebraska.

Original reference: H. Engelmann, 1876, Eng. Dept. U.S. Army, J. H. Simpson's Expl. of Great Basin of Terr. of Utah, p. 247, 282–284.

On North Fork of Platte River.

Scotts Creek Flint[1]

Mississippian: Eastern Ohio.

Original reference: E. Orton, 1880, Review of stratigraphy of Ohio, p. 22.

Occurs on all tributaries of Scott's Creek.

Scottville cyclothem (in McLeansboro Group)

Pennsylvanian: Southwestern Illinois.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 21, 31–32. Proposed for the cyclothem which includes the Scottville limestone and is well exposed in vicinity of Scottville. At type outcrop, includes basal sandstone and shale, underclay, coal, fossiliferous shale, and Scottville limestone. In sequence occurs above Gimlet cyclothem and below Trivoli cyclothem.

Type outcrop near west limits of Scottville, Macoupin County.

Scottville Limestone Member (of Modesto Formation)

Scottville Limestone (in McLeansboro Group)

Pennsylvanian: Southern Illinois.

J. N. Payne, 1943, Illinois Geol. Survey Circ. 88, p. 4, pls. 1, 2, 3. Gray to dark gray, fossiliferous, fine grained, massive. Lies below Carlinville limestone; separated from underlying Piasa limestone by Scottville coal.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 32. Thickness 1 to 6½ feet; average about 2½ feet. Included in Scottville cyclothem (new).

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. In McLeansboro group. Type locality stated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1), 69, 70, pl. 1. Rank reduced to member status in Modesto formation (new). Name Rock Branch coal member is applied to coal formerly included in Scottville so that latter name may be restricted to the limestone. Name Athensville coal member is introduced for coal formerly called Upper Scottville. Occurs below Trivoli sandstone member and above Athensville coal member (new). Thickness 6½ feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: W½SW¼ sec. 16, T. 12 N., R. 9 W., Macoupin County. Well exposed along Apple Creek and its tributaries in southern Morgan and northwestern Macoupin Counties in vicinity of village of Scottville.

**Scotty Wash Quartzite**[1]

Upper Mississippian: Eastern Nevada.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171, p. 7, 21, map.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). On correlation chart of recommended revision of stratigraphic units of Great Basin, Scotty Wash quartzite is replaced by Diamond Peak formation in Pioche district.

Walter Sadlick, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 81–90. Discussion of aspects of Chainman stratigraphy. Chainman is recognized as a valid stratigraphic unit. Diamond Peak and Scotty Wash are not recognized as distinct units but are referred to as facies within the Chainman.

Named for Scotty Wash which passes through formation east of Silverhorn, Pioche district.

Scrag Granite[1] (in New Hampshire Magma Series)

Upper Devonian or Carboniferous: Northwestern New Hampshire.

Original reference: C. R. Williams, 1934, Appalachia, v. 20, no. 4, p. 69–78.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 510, pls. 1, 12. In New Hampshire magma series. Cuts Bethlehem gneiss. Magma series is younger than Lower Devonian, either late Devonian or late Carboniferous.

Named for occurrence on Scrag Hill, Franconia quadrangle.

Scranton Sandstone (in Pottsville Formation)[1]

Pennsylvanian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $G_5$, p. 45, 46, 48.

Well exposed along railroad, about one-half mile south of depot, and at many other places around Scranton, Lackawanna County.

**Scranton Shale** (in Wabaunsee Group)

Scranton Shale (in Shawnee Group)[1]

Scranton Shale Member (of Shawnee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original references: Erasmus Haworth and John Bennett, 1908, Kansas Acad. Sci. Trans., v. 21, pt. 1, p. 82; 1908, Kansas Univ. Geol. Survey, v. 9, p. 57–160.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 49 (fig. 11), 211–214. Term Scranton discarded. Named subdivision treated as formations in Wabaunsee group.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2277. Scranton shale reintroduced as a formation with same stratigraphic span assigned originally to it by Haworth and Bennett. Consists predominantly of shale but contains some thin limestones and shaly sandstones. Comprises upper half of Sac-Fox subgroup of Wabaunsee group; includes strata between Bern limestone (new) above and Howard limestone below. Thickness about 125 feet. Includes (ascending) White Cloud shale, Happy Hollow limestone, Cedar Vale shale, Rulo limestone, and Silver Lake shale members. Reference section proposed.

Reference section: Exposures along an eastward-flowing stream extending through middle part of sec. 34, T. 12 S., R. 15 E., Shawnee County, Kans.

Scrubgrass cyclothem

Pennsylvanian (Allegheny Series): Southeastern Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 44–46, table 1, geol. map. Includes (ascending) Scrubgrass sandstone, 9 feet; Scrubgrass coal; Vanport flint or chert, 1 foot; and Ferriferous ironstone. Occurs below Lower Kittanning cyclothem and above Clarion cyclothem. In area of this report, Allegheny series is described on a cyclothemic basis; nine cyclothems, are named. [For sequence see Brookville cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 59–60. Cyclothem includes (ascending) Scrubgrass shale and (or) sandstone, Scrubgrass underclay and coal, Vanport flint, limestone or shale members. Occurs above Clarion cyclothem and below Lawrence cyclothem. In this report, Allegheny series is described on a cyclothemic basis; 13 cyclothems are named. [For complete sequence see Brookville cyclothem.]

Type area for Scrubgrass coal is along Scrubgrass Creek in Venango County, Pa.

Scrubgrass Fire Clay (in Allegheny Formation)[1]

Scrubgrass underclay member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. P. Lesley, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 59. Scrubgrass underclay is member of Scrubgrass cyclothem, although it is not present in area of this report [Athens County].

Named for association with Scrubgrass coal, type locality of which is along Scrubgrass Creek in Venango County, Pa.

Scrubgrass shale and (or) sandstone member

Pennsylvanian: Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 59. Member of Scrubgrass cyclothem in report on Athens County. Average thickness about 10 feet.

**Seabee Formation** (in Colville Group)

Seabee Member (of Schrader Bluff Formation)

Upper Cretaceous: Northern Alaska (subsurface and surface).

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 166, figs. 2, 3. Formation, of which Seabee is lowest member, consists largely of marine sandstone to south and shale to north, with bentonite and tuff increasing upward through the formation. Top part of member marked by distinctive 150-foot unit of fossiliferous paper shale, which is low-grade oil shale. Thickness at type locality 450 feet. Overlies Niakogon tongue (new) of Chandler formation (new) in outcrop area; overlies Topagoruk member (new) of Umiat formation (new) to the north; underlies Tuluga member (new) of Schrader Bluff formation (new) and Tuluvak tongue (new) of Prince Creek formation (new).

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 246–248, figs. 2, 4, 5. Redefined as formation to include all dominantly marine rocks of Colville group below Tuluvak tongue of Prince Creek formation. Includes, in many areas, strata previously assigned to lower part of Tuluga member of Schrader Bluff formation as well as strata assigned to Seabee member. Thickness in vicinity of Umiat about 1,500 feet. Unconformably overlies Ninuluk formation at Umiat, and in other areas generally overlies that formation or Niakogon tongue of Chandler formation. South of Umiat area, upper part of formation contains lithologically and faunally distinct unit, the Ayiyak member, but at Umiat and farther north this unit not certainly identified. Ayiyak formerly included in Tuluga member of Schrader Bluff formation. New type locality designated for formation. Although parts of formation are exposed at localities in vicinity of Umiat, only complete section in Umiat area is in Umiat test well No. 11.

Type locality of member: Along Seabee Creek, a tributary of Colville River, for which named. Also well exposed along Maybe Creek, a tributary of Ikpikpuk River.

Type locality of formation: In Umiat test well No. 11, 2½ miles west-northwest of Umiat Mountain, between 545 and 2,040 feet. Named from area of fair to poor exposures in vicinity of Seabee Creek 6½–8½ miles west of Umiat Mountain.

Seahorne cyclothem (in Spoon Formation)

Seahorne cyclothem[1] (in Tradewater Group)

Pennsylvanian: Western and southwestern Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 76–79, 200. Includes Seahorne limestone and Seahorne sandstone. Thickness 3 to 12 feet. Underlies Wiley cyclothem; overlies DeLong cyclothem. Derivation of name and type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Spoon formation (new). Above Delong cyclothem and below Wiley cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type outcrop: Seahorne Branch, SE¼SE¼ sec. 5, T. 3 N., R. 3 E., Havana quadrangle, Fulton County.

Seahorne Limestone Member (of Spoon Formation)

Seahorne Limestone (in Cherokee Group)

Seahorne Limestone[1] (in Tradewater Group)

Pennsylvanian: Southwestern and western Illinois and eastern Iowa.

Original references: H. R. Wanless, 1931, Geol. Soc. America Bull., v. 42, p. 801–812; 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 31). Correlation chart shows Seahorne limestone in Cherokee group in Iowa.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 78–79, geol. sections 5–7, 23, 28–32, 34, 36, 37, 39, 40, 42. Grades from scattered limonite-stained nodules in clay about 4 inches thick to a solid ledge more than 6 feet thick. Included in Seahorne cyclothem, Tradewater group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), pl. 1. Rank reduced to member status in Spoon formation (new). In southwestern area, occurs above Vergennes sandstone member and below Davis coal member; western area, occurs above DeLong coal member and below Wiley coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: S½SE¼ sec. 5, T. 3 N., R. 3 E., Fulton County, Ill.

Seahorne Sandstone (in Tradewater Group)

Pennsylvanian: Western and southern Illinois and southern Ohio.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 77, 200. Sandstone in Seahorne cyclothem, Tradewater group. Thickness 6 inches to 6 feet. Where sandstone is more than 3 feet thick, it generally consists of two units separated by about 1 foot of light-gray sandy shale; this threefold division is found at numerous localities in western Illinois.

Type locality not stated; sandstone crops out at type outcrop of Seahorne cyclothem which is on Seahorne Branch, S½SE¼ sec. 5, T. 3 N., R. 3 E., Havana quadrangle, Fulton County, Ill. Sandstone recognized at many places in western Illinois and southern Ohio.

†Sea Island Sands[1] or loams[1]

Pleistocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; 1907, Summary of mineral resources of South Carolina, p. 2 (table); 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 485.

Named for development on islands off coast of Charleston and Beaufort Counties.

Seaman Ranch Shale (in Brad Group)

Seaman Ranch Shale Member (of Brad Formation)[1]

Pennsylvanian (Canyon Series): North-central Texas.

Original references: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31; 1922, Texas Univ. Bull. 2132, p. 111.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Shown on chart as formation in Brad group. Brad is here raised to group status.

Named for Seaman Ranch in west part of Palo Pinto County, where it is typically exposed along Caddo Creek.

Searsville Formation

Eocene: Northern California.

H. C. Langerfeldt and L. W. Vigrass, 1959, *in* U.S. Congress, Joint Committee on Atomic Energy, Subcommittee on Research and Development, and Subcommittee on Legislation, Stanford Linear Electron Accelerator, Hearings: U.S. 86th Cong., 1st sess., app. D, p. 621. Consists of interbedded sandstones, mudstones, and shales. Ratio of sandstone to mudstone is about 4:3. Sandstones are generally feldspathic, thick bedded to massive, and medium to coarse grained with kaolin matrix. Argillaceous rocks are commonly yellowish-buff massive mudstone, but some grade to grayish and brownish fissile shales. Thickness of interlayers of sand and argillaceous rocks varies from several tens of feet to less than 1 foot. Underlies Miocene Los Trancos formation (new), angular discordance; overlapped by Santa Clara formation and Recent alluvium. Name credited to R. G. Thomas (unpub. map).

Type locality and derivation of name not given. Area described is in Santa Clara and San Mateo Counties. Board on Geographic Names states that Searsville was once a town, now abandoned and flooded by Searsville Lake about 3½ miles southwest of Stanford University campus.

Seattle Formation[1]

Oligocene, upper: Northwestern Washington.

Original reference: R. Arnold and H. Hannibal, 1913, Am. Phil. Soc. Proc., v. 52, p. 579, 582, 604.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 104, 117–118. Upper Oligocene. Suggests name is no longer useful as strata included in the Seattle as originally defined had previously been included in the Lincoln and Blakeley formations.

Probably named for occurrences in vicinity of Seattle.

Seawall Metafelsite

Age not stated: Southeastern Maine.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 176. Described as pink "sugar granite." Along margins grades into Cranberry Island volcanic facies.

Occurs in central part of southwest lobe of Mount Desert Island, Hancock County.

†Sebastian Stage[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Probably named for Sebastian County, Ark.

744–954—vol. 3—66——40

**Seboomook Formation**

Seboomook Slate[1]

Lower Devonian: West-central Maine, and Quebec, Canada.

Original reference: E. H. Perkins, 1925, Am. Jour. Sci., 5th ser., v. 10, p. 374–375.

R. A. Marleau, 1958, Quebec Dept. Mines, Geol. Survey Br., Prelim. Rept. 362, p. 2 (table), 3–4. Formation geographically extended into East Megantic area, Quebec, where it occurs as a northeasterly trending band, consists chiefly of slates with minor metasandstones. Stratigraphically equivalent to Compton formation. Underlies Frontenac formation.

A. J. Boucot, Charles Harper, and Keith Rhea, 1959, Maine Geol. Survey Spec. Geol. Studies Ser. 1, p. 6, 7–9, map. In Beck Pond area, formation consists of main body of gray slate, Bear Pond limestone member (new), and a granite talus member. Top of unit eroded; thickness not measured. Nonconformable on granitic basement complex of pre-Silurian age; locally, unconformably overlies Beck Pond limestone (new). Basal part of formation is of New Scotland (low Lower Devonian), but middle and upper parts to southeast of Beck Pond area are Oriskany (high Lower Devonian).

Best exposure at Seboomook Dam on West Branch of Penobscot River in extreme eastern part of Somerset County, Maine.

Sebree Sandstone Member (of Carbondale Formation)[1]

Pennsylvanian: Western Kentucky.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 27.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 101. Cliff-forming sandstone. Basal member of Carbondale formation, between No. 8a above and Dekoven coals.

Named for development between Sebree and Steamport Ferry, Webster County.

Sebrina Complex

Triassic(?): Eastern California.

G. A. Schroter, 1938, Eng. Mining Jour., v. 139, no. 4, p. 43–44. Intercalated arkosic sandstones, fine sandy shales, and thin-bedded dolomitic limestones metamorphosed into quartzites, schists, gneisses, and hornfels. Thickness 50 to 1,500 feet. Includes Sanford quartzite (new).

Occurs on east flank of Sierra Nevada Mountains, southwest of Bishop, Inyo County.

Seco Formation[1]

Eocene: Central Texas.

Original reference: R. A. Liddle, 1921, Texas Univ. Bull. 1860, p. 85, map, columnar sections.

Exposed in Seco Creek, 3 miles south of west of Yancey, Medina County.

Second Mountain Member (of Pocono Formation)

Lower Mississippian: Central Pennsylvania.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, ser. 4, Bull. G–8, p. 18. Name proposed for massive gray sandstone and pebble beds composing lowest member of formation. Conformably underlies Peters Mountain member (new) ; overlies Catskill red beds. Lithologically similar to Cove Mountain member (new) at top of Pocono, but lacks coal beds of that member. Has been referred to as "Berea" but there seems little ground for correlation with Berea of northwestern Pennsylvania.

Named for excellent exposure at Second Mountain on the railroad north of Heckton, Dauphin County.

Second Value Formation (in Montoya Group)

Second Value Member (of Montoya Dolomite)

Upper Ordovician: Southwestern New Mexico.

L. P. Entwistle, 1944, New Mexico Bur. Mines Mineral Resources Bull. 19, p. 17, 18. Member consists of deep-purplish-gray sandy dolomite. Sand grains grouped in wormlike aggregates. In a few places, sand is thinly bedded and crossbedded, and red or black chert fragments are visible. Locally lenticular. Maximum thickness at type locality 90 feet. Underlies Par Value member (new) ; overlies El Paso dolomite.

R. H. Flower, 1958, Roswell Geol. Soc. Guidebook 11th Field Conf., p. 70, 72. Formation comprises the Cable Canyon and the Upham members.

Type locality: On Second Value claim, Boston Hill mining district, Grant County.

†Secretan series[1]

Middle Cambrian: Nevada.

Original references: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53; 1924, Pan-Am. Geologist, v. 41, p. 78.

**Secret Canyon Shale**[1]

Middle Cambrian: Eastern Nevada.

Original reference: Arnold Hague, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 255–259.

H. E. Wheeler and D. M. Lemmon, 1939, Nevada Univ. Bull., Geology and Mining Ser., no. 31, p. 23–25, 30, fig. 3. Overlies Geddes limestone (new) ; underlies Hamburg dolomite. Thickness 1,035 feet.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 12–16. Subdivided to include Clarks Spring member in upper part. Overlies Geddes limestone; underlies Hamburg dolomite.

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 9–14. Described in White Pine district where it comprises four lithologic members, the lower two of which correspond generally to section at Eureka. Thickness at least 1,500 feet, possibly 2,500. Overlies Geddes limestone(?) ; disconformably underlies Dunderberg shale; Hamburg dolomite, normally present between the Secret Canyon and Dunderberg, missing in this area. Middle Cambrian. [Editor's note on p. 114 includes the following statements: Re-examination of Humphrey's collections from the "Secret Canyon" and re-collection of trilobites from top of member 2 in 1949, show that all known trilobites of "Secret Canyon" in Hamilton district are Upper Cambrian forms. Earlier identifications of *Elrathis*, *Kochaspis*, and *Glyphasis* by Lochman are in error. Trilobites from top of member 2 and also in some of Humphrey's collections represent species of *Aphelaspis* and *Olenaspella*. Member 2 is lithically like the Swarbrick Limestone at Tybo, Nev., and have an *Aphelaspis* in their upper beds. Revision of age of "Secret Canyon" removes need for an unconformity between it and the Dunderberg. As far as can be determined, Cambrian section on west face of Mount Hamilton is without significant stratigraphic breaks.]

Named for exposures in Secret Canyon, Eureka district.

**Sedalia Limestone**

Sedalia Formation (in Chouteau Group)

Sedalia Limestone (in Easley Group)

Sedalia Limestone (in Osage Group)[1]

Lower Mississippian: Central, southwestern, and northeastern Missouri and western Illinois.

Original reference: R. C. Moore, 1928, Missouri Bur. Geology and Mines, v. 21, 2d ser., p. 61, 78, 84, 86, 90, 91, 144, 146, 149–154, 166, 254.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 100, 150–155, chart 5. In standard Mississippian section, Sedalia limestone is included in Easley group (new) of Kinderhookian series; overlies Chouteau limestone; underlies Gilmore City limestone.

C. P. Kaiser, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2143–2154. In much of the area of this report [southwestern Missouri], Sedalia dolomite lies conformably on Chouteau limestone. Where Chouteau is absent, the Sedalia rests either on Sylamore sandstone or on rocks of Ordovocian age. In southern area, upper noncherty zone of Sedalia conformably overlaps Northview formation. Unconformably overlain by Osagian rocks, ranging in age from St. Joe to Burlington. Thickness 0 to 70 feet; gradual thickening from east to west. Kinderhookian.

T. B. Beveridge and E. L. Clark, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 71, 72 (fig. 1), 74. [Reprinted from Kansas Geol. Soc. Guidebook 16th Regional Field Conf.] Chouteau redefined as group to comprise (ascending) Compton, Sedalia, and Northview formations. Kinderhookian. Note on Moore's type section.

Charles Collinson and D. H. Swann, 1958, Geol. Soc. America Guidebook St. Louis Mtg., p. 24 (fig. 3), 46 (fig. 8), 49, 50 (fig. 9), 51. Described in western Illinois where it is light-buff massive calcareous dolomite or dolomitic limestone. Maximum thickness 20 feet. Conodont faunas show Illinois Sedalia to be Valmeyer in age and type Sedalia to be Kinderhook. On basis of stratigraphic position and lithologically, the Illinois Sedalia correlates with basal Osage Pierson formation of Missouri. Overlies Chouteau formation; underlies Fern Glen formation.

Type section: At M. K. and T. Sweeney quarry in SW¼SW¼SE¼ sec. 4, T. 46 N., R. 19 W., Cooper County. Named for exposures in vicinity of Sedalia, Pettis County, Mo.

Sedley Formation

Pleistocene: Eastern Virginia.

W. E. Moore, 1956, Virginia Acad. Sci., Geology Sec., Field Trip Guidebook, no pagination. Consists of sands, silts, and clays. Younger than Miocene Yorktown but older than either Sunderland or Wicomico terraces. Underlies Kilby formation (new). New formation names are necessary because names Sunderland formation and Wicomico formation are meaningless. Both of these terraces are underlain by the same formation, not two formations as was previously believed. Terrace as used here refers to land form only and does not refer to or imply existence of any deposits genetically related to them.

Area discussed is south of James River.

**Sedwick Limestone Member** (of Moran Formation)[1]

Sedwick Formation (in Moran Group)

Permian (Wolfcamp): Central and central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 40.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Moran group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Described in Colorado River valley as succession of dense hard brown-weathering limestone beds, each 1 to 2 feet thick, separated by brownish clay shale, 3 to 10 feet thick; persistent thin dark chert containing gastropods at top of member. About 25 feet thick. Overlies Santa Anna shale member; underlies Santa Anna Branch shale member of Putnam formation.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 270–271. Geographically extended into Brazos River valley where it is 40 to 55 feet thick and consists principally of alternating thin limestone and thick shale beds. South of Clear Fork of Brazos River, basal limestone grades laterally into calcareous sandstone in part of Shackelford County. Uppermost member of Moran formation, three underlying members of formation not differentiated in area. Underlies Santa Anna Branch shale member of Putnam formation.

Named for outcrops west of Sedwick, Shackelford County.

Seeber Flats Sandstone (in Indian Bluff Group)

Pennsylvanian (Pottsville series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Thickness as much as 60 feet; average 25. Underlies a shale interval 40 to 120 feet thick which in turn underlies the Stockstill sandstone (new); overlies a shale interval 40 to 120 feet thick at base of group.

Named from exposures in the Briceville-Norman School section, Lake City quadrangle, Anderson County. At an elevation of 1,670 feet, a side road leads southward to Seeber Flats, formed on this sandstone.

Seekonk Beds[1]

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 173–176.

Named for occurrence in Seekonk Township, Bristol County, Mass.

Seekonk Conglomerate[1]

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 174, 176.

Named for occurrence in Seekonk, Bristol County, Mass.

Seekonk Sandstone[1]

Pennsylvanian: Southeastern Massachusetts.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134.

**Seeley Slate**[1]

Precambrian (middle? Huronian): Southern Wisconsin.

Original reference: S. Weidman, 1904, Wisconsin Geol. Nat. History Survey Bull. 13, p. 46.

Named for occurrences near Seeley Creek, Sauk County.

Seeleyville Coal Member (of Spoon Formation)

Pennsylvanian: Western Indiana and eastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), pl. 1. Assigned member status in Spoon formation (new). Only named member of formation in area. Has been referred to as Coal III in Indiana. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Mines in vicinity of Seeleyville, Ind., T. 12 N., Rs. 7 and 8 W., Vigo County, Ind.

**Sego Sandstone** (in Mesaverde Group)

Sego Sandstone Member (of Price River Formation)[1]

Upper Cretaceous: Central eastern Utah and central western Colorado.

Original references: C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851, p. 23, 35–36, 38–40, pl. 6; D. J. Fisher, 1936, U.S. Geol. Survey Bull. 852.

C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851, p. 23 (table), 32, 34–40. Lowest mappable division of Mesaverde group in Colorado is Sego sandstone, this name having been applied to these beds in Utah by Fisher (in preparation), who treats them as a member of Price River formation. Coal-bearing rocks and associated strata above the Sego sandstone are herein named Mount Garfield formation. Boundary between Mancos shale and overlying Sego sandstone marks transition from marine shale to deposits of littoral zone. The sandstone in part rests conformably on the shale and in part intertongues with it. At type locality, the Sego consists of single unit of sandstone, but in Book Cliffs of Colorado it is split by Anchor Mine tongue of Mancos shale.

J. D. Fisher, 1936, U.S. Geol. Survey Bull. 852, p. 9 (table), 14, 15–16. Price River formation thickens eastward and beyond Price River is divisible into four members (ascending): Castlegate sandstone, Sego sandstone, Neslen coal-bearing member, and Farrer non-coal-bearing member. In area of this report [Book Cliffs, Utah], Castlegate and Sego sandstones are separated by Buck tongue of Mancos shale. Thickness 140 to 210 feet.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 188, 189–190, figs. 2, 3, pl. 3. Neslen facies of Price River formation includes (ascending) Castlegate, Sego, Corcoran (new), Cozzette (new) and Cameo (new) members. Term Sego member is used to replace name Sego sandstone member as applied by Fisher (1936) to a series of interbedded sandstone and shales at town of Sego. It includes rocks formerly called Sego sandstone as well as the overlying and closely related coal-bearing rocks. Base is drawn at gradational contact of lowermost littoral marine sandstone tongue with underlying marine shale. Upper boundary placed at slight disconformity between the coal-bearing rocks and overlying marine shale tongue beneath Corcoran member. Average thickness 200 feet. Littoral-marine part consists of several thin sandstone tongues; the first appears near Woodside, Utah. Three are more persistent than the rest and can be traced eastward into Colorado. In most localities, each main sandstone tongue is overlain by fresh- or brackish-water deposits of sandstone, sandy shale, or shale. Thin westward-pointing tongues of Mancos grade upward into overlying littoral-marine sandstone tongue and rest disconformably on the brackish- or fresh-water deposits. Littoral-marine sandstones vary from massive-bedded medium-grained buff sandstones to thin-bedded fine-grained silty gray sandstones with shale partings; maximum thickness of sandstones about 50 feet. Above upper sandstone tongue are 60 feet of coal-bearing rocks which include the main coal bed (Anchor coal) of the Sego member. Montana age.

J. D. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 10–11, 13, 15–16, pls. 5b, 6b, 10–12. Rank raised to formation in Mesaverde group. In eastern Book Cliffs (western Colorado), the Sego is basal unit of Mesaverde and contains Anchor Mine tongue of Mancos shale; underlies Mount Garfield formation. In central Book Cliffs (Utah, east of Green River), the Sego underlies Neslen formation.

Named for settlement of Sego in T. 20 S., R. 20 E., Utah. In Book Cliffs.

Seguin Formation (in Wilcox Group)[1]

Eocene, lower (Midway-Wilcox): Eastern Texas.

F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 558, 574, 634. Proposed for all marine strata between the compact silty clays of Midway group and base of nonmarine Rockdale formation of Wilcox group. In most places, base is marked by contact of thinly laminated carbonaceous and fossiliferous sands with silty clays; top is limited by a thin concretionary layer made up largely of shells of *Ostrea multilira* Conrad. Consists of about 50 percent fine sand, 30 percent silt, 19 percent clay, and 1 percent carbonaceous matter. Thickness throughout central Texas 50 to 75 feet; Rio Grande Valley probably 190 feet; in wells south of outcrop 100 to 160 feet. Comprises two members: Caldwell Knob oyster bed above and Solomon Creek clays and sands. Conformably overlies Kerens member of Wills Point formation in northeastern Texas; disconformable on middle Wills Point in south-central Texas; disconformable on Kincaid in southwestern Texas.

M. W. Beckman and F. E. Turner, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 608–621. As originally defined, straddles Midway-Wilcox boundary. Solomon Creek clays and Caldwell Knob sands are redefined so that base of Wilcox is placed at a disconformity marking top of Solomon Creek and base of Caldwell Knob clays. where it is possible to recognize these divisions as redefined, Solomon Creek member should be regarded as member of Wills Point formation and Caldwell Knob as basal member of Rockdale formation. Where these divisions cannot be differentiated, it may be necessary to continue use of Seguin formation, recognizing that it contains the break between the Midway and Wilcox.

Type locality: Along banks of Moss Branch 10 miles northwest of Bastrop, in northwestern part of Bastrop County.

Seigas Conglomerate or Sandstone

Upper Silurian: Northern Maine, and New Brunswick, Canada.

O. O. Nylander, 1940, Geological formations of the St. John River valley, northern Maine and New Brunswick: Caribou, Maine, p. 7–8. Limestone conglomerate made up of rounded blue limestone slabs and small boulders in a sand matrix; in center of outcrop is a coarse sandstone, about 3½ feet thick, made up of quartz pebbles.

Named for exposures 2.3 miles east of St. Ann's Church and 1½ miles west of Seigas River, northern Maine.

Seignelay glaciation

Seignelay till[1]

Pleistocene (pre-Nebraskan): Illinois and Iowa.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203, 217.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 68, no. 2, p. 129. Referred to as glaciation.

Seine Series[1]

Precambrian: Ontario, Canada, and northern Minnesota.

Original reference: A. C. Lawson, 1912, Canada Geol. Survey Mem. 28, p. 10.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1031. Sediments of Seine series are equivalent to Knife Lake group; latter name has priority.

Selah Formation

Selah Tuff Member (of Ellensburg Formation)

Miocene and Pliocene: South-central Washington.

J. H. Mackin, 1947, (abs.) Northwest Sci., v. 21, no. 1, p. 33. Defined as tuff member of Ellensburg formation. Contains distinctive beds of pummicite and quartzitic gravel. Overlies Yakima basalt; underlies Wenas basalt member of Ellensburg.

W. N. Laval, 1956, Dissert, Abs., v. 16, no. 5, p. 945. Rank raised to formation. Consists essentially of fluviatile and aeolian clastics of volcanic origin. Miocene-Pliocene formations are (ascending) Yakima basalt, Selah, Wenas basalt, and Ellensburg. This sequence comprises a part of two mutually interfingered lithosomes—one of sedimentary rocks and other of flood lavas.

Type locality: South flank of Selah Ridge, Yakima-Ellensburg area.

Selah Butte Flow

Miocene and Pliocene: South-central Washington.

A. C. Waters, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 673, pl. 1. Wenas basalt between Selah Butte and Selah Springs is surmounted by several small buttes eroded from overlying Ellensburg formation. Four of these buttes are capped by remnants of a basalt flow. This flow, here called Selah Butte flow, is basalt tongue in Ellensburg about 150 feet above top of Wenas basalt. Flow could not have extended far to south or west because Ellensburg sequence is well exposed on either side of Yakima Ridge and in lower Wenas Creek, but Selah Butte flow is missing at these localities. Stratigraphically below Elephant Mountain flow (new). Map bracket shows Ellensburg and associated basalt flows as Miocene and Pliocene. Text states that much or all of Ellensburg and its associated intercalated basalt flows is regarded as Pliocene.

Caps four small buttes between Selah Butte and Selah Springs, Yakima East quadrangle.

**Selatna Glaciation**

Pleistocene: Central-southern Alaska.

A. T. Fernald, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 6, 13 (table 1); A. T. Fernald. 1960, U.S. Geol. Survey Bull. 1071–G, p. 222–225, 232–233. Two major glaciations of western part of Alaska Range recognized in upper Kuskokwim region. The older Selatna preceded the Farewell glaciation (new). Represented along West Fork of Kuskokwim River by high lateral moraines within mountainous area and by broad end moraine on piedmont; along Middle Fork by irregularly shaped, tundra-covered area of greatly subdued morainal topography on the piedmont, 10 to 12 miles north of range; along South Fork by scattered remnants of a lone arcuate moraine which extends to maximum distance of 25 miles from range.

Named from a tributary of Selatna River which originates in the end moraine. In upper Kuskokwim region.

Selby Member (of Rockland Formation)

Middle Ordovician: Southern Ontario, Canada, and northern New York.

G. M. Kay, 1937, Geol. Soc. America Bull., 48, no. 2, p. 252–255, pl. 2. Name proposed for lower member of formation. Includes limestone characterized by *Doleroides ottawanus* Wilson succeeding Black River group. In type section where only upper 4 feet is exposed, unit consists of dark-gray to black medium- to fine-textured petroliferous limestone in thin buff-weathering beds with a jointed splintery fracture. In northwestern New York and Ontario, lithology is variable but similar to that at type locality. Represented by rather heavy-bedded black chert-bearing limestone southeastward. Maximum thickness about 15 feet. Underlies Napanee member (new); overlies Chaumont formation of Black River group. In exposure showing contact of Selby or Watertown limestone, east of Dexter, Jefferson County, N.Y., Black River and Trenton beds are separated by undulating bedding plane. In earlier description of this section (Kay, 1931, Jour. Geology, v. 39, no. 4), the thin metabentonite that is 3 feet from base of Selby was mistakenly believed to separate Leray and Watertown members of Chaumont formation and to be same as persistent clay at that horizon in Glenburnie shale of Ontario. Type Hounsfield metabentonite is of Selby (lower Rockland) age. At Dexter section, the Selby is about 8 feet thick. Probable Selby exposures in Herkimer County, N.Y., previously called Black River. Trenton group. Mohawkian series.

Named for exposure 1 mile north of Napanee Station along Selby Creek in Lot 22, Conc. III, Richmond Township, Lennox and Addington County, Ontario.

Selden Basalt Tongue

Tertiary: Southwestern New Mexico.

F. E. Kottlowski, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 32 (map), 33, 146. Olivine basalt, interbedded with basal beds of the Santa Fe group.

Near south end of Selden Canyon, Rio Grande Valley.

Seligman limestone (in Tusayan series)[1]

Permian: Northwestern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, no. 3, p. 251, 338.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (table). Underlies Yampai shales; overlies Pierce shales. In Tusayan series (new) of Carbonic age.

Exposed best perhaps in Aubrey Cliffs near Seligman. In Grand Canyon region.

†Selinsgrove (upper) Limestone[1]

Middle Devonian: Central Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_7$, p. 78–81.

Occurs below Selinsgrove, Snyder County.

Selinsgrove Limestone (in Onondaga Group)

†Selinsgrove (lower) Limestone[1]

Middle Devonian: Central Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_7$, p. 78–81.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 144, 146–149. White applied Selinsgrove to five members of Middle Devonian. Here proposed to drop name for all but his "Selinsgrove lower limestone" with adjective lower now omitted. Thickness varies—65 feet at Selinsgrove Junction (probably maximum); 7 feet in Lebanon County; 20 feet in Carbon County; farther east, appears to merge with Buttermilk Falls limestone. Overlies Needmore shale (new) with contact gradational; underlies Marcellus black shales. Needmore shale was Selinsgrove shale of White (1883).

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 313. Lower Selinsgrove (Onondaga) limestone and Lower Selinsgrove shale of White are represented in Greenbrier County but limestone merges into typical Marcellus shale and cannot always be recognized.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., 53, no. 12, pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

Named from exposures near Selinsgrove Junction on east bank of Susquehanna, below Sunbury, Northumberland County.

†Selinsgrove (lower) Sandstone[1]

Middle Devonian: Central Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_3$, p. 78–81.

Occurs below Selinsgrove, Snyder County.

†Selinsgrove (upper) Sandstone[1]

Middle Devonian: Central Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_7$, p. 78–81.

Well exposed in railroad cuts just opposite town of Selinsgrove, Snyder County and 1 mile below Selinsgrove Junction, Northumberland County.

†Selinsgrove Shale[1]

Lower Devonian: Central Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_7$, p. 78–81. 363.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 144. Unit termed Needmore shale.

Exposed about one-fourth mile below Selinsgrove Junction, Northumberland County.

Sellers Limestone Member (of Caseyville Formation)

Sellers Limestone (in Caseyville Group)

Pennsylvanian: Southeastern Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 36, 101. Ferruginous dense fossiliferous limestone about 2 feet thick. Between Battery Rock coal above and Lick Creek sandstone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Inf. Circ. 217, p. 9, pl. 1. Correlated chart shows Sellers limestone in Caseyville group below Battery Rock coal and above Battery Rock sandstone. Included in Battery Rock cyclothem. Gives type locality.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 29, 44 (table 1), pl. 1. Rank reduced to member status in Caseyville formation (redefined). Occurs above Battery Rock sandstone member and below Gentry coal member (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: SE¼ sec. 21, T. 11 S., R. 10 E., near Sellers Landing, Hardin County.

**Sellersburg Limestone**[1]

Middle Devonian: Southern Indiana and north-central Kentucky.

Original reference: E. M. Kindle, 1899, Bulls. Am. Paleontology, v. 3, no. 12, p. 8, 20, 110.

G. G. Sutton and A. H. Sutton, 1937, Jour. Geology, v. 45, no. 3, p. 326, 328. Subdivided to include Speeds limestone member (new) which underlies Silver Creek limestone member.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1066–1067. Close relationship of the Silver Creek and Beechwood [herein given formational rank] implied by their treatment as members of the Sellersburg does not exist. Their fossils represent separate time division in standard Hamilton scale and Beechwood species are distinct from those of all other Indiana Hamilton formations. Swanville formation (new) was deposited after the Silver Creek, and the Beechwood is separated from the Silver Creek and apparently from the Swanville by an erosional disconformity. Terms Sellersburg and Sellersburg beds, as they have been used practically, are each equivalent to term Hamilton group (as used in this report) which includes all formations between the Jeffersonville and New Albany. To include the Speeds, Deputy (new), and Swanville in Sellersburg would indicate a relationship of all the formations that is contradicted by the different faunal associations and by the affinities of these faunal associations to those in other areas.

J. B. Patton and T. A. Dawson *in* H. H. Murray, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 41, 42, pl. 1. Term North Vernon limestone includes entire Hamilton sequence. Sellersburg in its original sense was nearly in synonymy with North Vernon, although its author failed to account for lowest rocks of Hamilton age. Sellersburg, as defined by Kindle (1899) and modified by later workers, is present in Clark County and southern Scott County—that is, throughout the area where Hamilton rocks are readily divisible into Beechwood, Silver Creek, and Speed lithologies; it is not applicable in Bartholomew and Jennings Counties or in most of Jefferson County where Hamilton rocks are not readily divisible on lithologic criteria, and a name other than Sellersburg is useful when reference is made to undifferentiated Hamilton limestones of this area. Name North Vernon as set forth by Borden (1876) is meaningful when applied to the relatively homogeneous Hamilton limestone of Bartholemew, Jennings, and Jefferson Counties. If only one name is to be retained, it should be North Vernon on grounds of priority and inclusiveness. At present, Indiana Geological Survey uses both terms North Vernon and Sellersburg as formation names that include all of the limestones of Hamilton age of southeastern Indiana outcrop. Term Beechwood is used for member at top of Hamilton sequence; names Silver Creek and Speed are applied to lithofacies of the Hamilton rocks; these lithofacies may be used as members in southern part of outcrop belt; Deputy and Swanville "formations" might better be called "zones" or "faunal facies" of the Sellersburg (North Vernon) limestone.

Named for Sellersburg, Clark County, Ind.

†Selma division (of Selma Chalk)[1]

Upper Cretaceous: Alabama.

Original reference: E. A. Smith, 1903, 58th Cong., 1st sess., S. Ex. Doc. 19, p. 12–20, map.

Exposed in bluffs along Alabama River from Kings Landing to Selma and beyond. Named for exposures at Selma, Dallas County.

**Selma Group**

Selma Chalk[1]

Upper Cretaceous: Alabama, Mississippi, and Tennessee.

Original reference: E. A. Smith, L. C. Johnson, and D. W. Langdon, 1894, Alabama Geol. Survey Rept. Geol. Coastal Plain of Alabama, p. 15, 22, 27, 255, 276–286.

L. W. Stephenson and W. H. Monroe, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1639–1657. Chalk overlies Eutaw formation unconformably. Consists of nearly 900 feet of chalk in west-central Alabama, but is broken by minor unconformity or diastem about 300 feet above its base, a few feet above a thin but persistent zone of hard pure limestone layers interbedded with chalk, the Arcola limestone member (new). Northwestward into Mississippi, lower third of Selma passes by merging and intertonguing into Coffee sand; upper third merges into Ripley formation; middle third continues into Tennessee as an impure chalk unit. In eastern part of Alabama, the part of chalk below Arcola limestone member merges by intertonguing into Blufftown formation, middle part merges into and intertongues with Cusseta sand, and upper part merges into Ripley formation. Selma and Ripley are separated from overlying Prairie Bluff chalk by important unconformity.

W. S. Cole, 1938, Florida Geol. Survey Bull. 16, p. 25–26. Referred to as formation in report on stratigraphy and micropaleontology of the two deep wells in Florida.

W. H. Monroe, 1941, Alabama Geol. Survey Bull. 48, p. 48–72. Selma chalk divided into three distinct lithologic members: unnamed lower member that includes typical chalky marl exposed at Selma, Arcola limestone member, and upper member of purer chalk designated Demopolis member. Chalky sand that underlies Prairie Bluff chalk in Sumter County and that merges eastward into Ripley formation has been called part of Selma chalk. In this report, it is treated as chalky facies of Ripley formation, restricting name Selma to purer underlying chalk; thus, Selma is restricted to marl and chalk that intervene between Eutaw formation below and Ripley formation above.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Rank raised to group. Includes Mooreville chalk, Coffee sand, Demopolis chalk, Ripley formation, Prairie Bluff chalk, and Owl Creek formation.

H. L. Reade, Jr., and J. C. Scott, [1958] Profile showing geology along U.S. Highway 331, Montgomery County, Alabama (1:16,000): Alabama Geol. Survey. Map legend shows that Selma group includes (ascending) Eutaw formation, Mooreville chalk, Demopolis chalk, Ripley formation, Prairie Bluff chalk, and Providence sand.

Named for Selma, Dallas County, Ala.

**Seminoe Formation**[1]

Precambrian: Southern Wyoming.

Original reference: T. S. Lovering, 1930, U.S. Geol. Survey Bull. 811–D, p. 221–222.

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consist of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

A typical section is on east bank of Deweese Creek, one-fourth mile south of Pyler's Ranch in SW¼ sec. 19, T. 26 N., R. 85 W., South Park, Carbon County.

**Seminole Formation** (in Skiatook Group)

Seminole Conglomerate[1]

Pennsylvanian (Missouri Series): Northeastern, central, and central southern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

R. C. Moore and others, 1937, Kansas Geol. Soc. 11th Ann. Field Conf. Guide Book, p. 40 (table). Included in Skiatook group.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 23–26. Use of name Seminole formation extended into northeast Oklahoma and applied to shale and sandstone unit lying above unconformity at base of Missouri subseries and below base of Checkerboard limestone. North of Talala, uppermost Des Moines bed is Lenapah limestone; in vicinity of Oologah, it is Nowata shale; and near Tulsa, it is the Memorial shale. Type locality stated.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 47–52. In type area, lies above Holdenville formation and below Francis formation. Morgan (1924, Oklahoma Geol. Survey Bull. 2) found that in Pontotoc County the Seminole is overlapped by the Ada formation which normally occurs about 800 feet higher in the section. In Okfuskee and Tulsa Counties and northward, the Seminole lies above the Holdenville and below the Checkerboard.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 54–62. Further described in Seminole County.

Type locality: Southeast part of Seminole Nation, now Seminole County (probably T. 6 N., Rs. 7 and 8 E.).

†Seneca Chert (in Boone Limestone?)[1]

Mississippian: Southwestern Missouri.

Original reference: W. P. Jenney, 1894, Am. Inst. Mining Engrs. Trans., v. 22, p. 178.

At Seneca, Newton County.

Seneca Flow or Tongue (of Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 112, 133, 134, 143 (fig. 20). East of type locality Clayton basalt consists of many long tongues. For purposes of this report these tongues have been named, from south to north, Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that gave rise to these basalts are unknown.

Forms south rim of Seneca Creek valley, eastern Union County.

Seneca Group

Senecan Group[1]

Senecan Series

Senecan Stage

Upper Devonian: North America.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. As shown on correlation chart, Devonian comprises (ascending) Ulsterian, Erian, Senecan, Chautauquan, and Bradfordian (in part) series. Senecan comprises Finger Lakes stage (new) below and Chemung stage. Upper Devonian.

I. H. Tesmer, 1954, Dissert, Abs., v. 14, no. 12, p. 2317. In study of Cherry Creek quadrangle, New York, Chautauquan series is reduced to Chautauqua group and incorporated in upper part of Senecan series.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 8. Seneca group, Chautauquan series, comprises (ascending) Genesee, Naples, and Chemung formations. Occurs below Arkwright group and above Hamilton group of Erian series.

Charles Schuchert (1910, Geol. Soc. America Bull., v. 20, p. 514) used term Senecan Series for interval between Erian Series (below) and Chautauquan Series above.

Named for exposures in Seneca County and along shores of Seneca Lake.

**Seneca Member** (of Onondaga Limestone)

Seneca Limestone[1]

Middle Devonian: New York.

Original reference: L. Vanuxem, 1939, New York Geol. Survey 3d Rept., p. 275–278.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1774–1775, chart 4. In central New York, a third division of the Onondaga, the Seneca limestone, is a dark shaly rock underlying the Marcellus and containing an abundance of *Chonetes lineatus*, *Dalmanites selenurus*, and large coiled cephalopods. Name Seneca has fallen into disuse, but, because interval it defines is a well-marked unit, it is here revived. Onesquethaw stage (new). Lower or Middle Devonian.

W. A. Oliver, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 7, p. 629–635, 637–641. Uppermost member of Onondaga in central and western New York. Underlies Moorehouse member (new). Base of member is defined by "Tioga bentonite," a prominent marker bed and an important paleontologic break. Seneca passes to east into Union Springs black shale of overlying Marcellus formation. Thickness near Union Springs (Auburn quadrangle) about 25 feet. Cooper and others (1942) included much more in "Seneca" than did early workers who defined it.

W. A. Oliver, Jr., 1960, U.S. Geol. Survey Prof. Paper 400–B, p. 173–174. Middle Devonian.

Named for occurrence in Seneca County.

Seneca Quartz Porphyry[1]

Precambrian (pre-Huronian?): Central southern Wisconsin.

Original reference: R. D. Irving, 1877, Geology Wisconsin, v. 2, p. 520.

Occurs in sec. 2, T. 17, R. 11 E., Green Lake County.

**Senora Formation**[1] (in Cabaniss Group)

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1525. Included in Cabaniss group (new).

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 26. In northeastern Oklahoma includes (ascending) Tiawah, Chelsea, Verdigris, and Breezy Hill members. Conformably overlies Stuart shale and underlies Calvin sandstone.

Named for old post village of Senora, which was located in southern part of Okmulgee County.

†Senorito Sandstone Lentil (in Chinle? Formation)[1]

Upper Triassic: Central northern New Mexico.

Original reference: B. C. Renick, 1931, U.S. Geol. Survey Water-Supply Paper 620.

Well exposed in Senorito Canyon, western Sandoval County.

Sensori Agglomerate and Limestone[1]

*See* Sinosri Formation, correct spelling.

Sentinel Dolomite[1] (in Telescope Group)

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 311, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Dept. Geol. Sci., v. 30, no. 5, p. 355, 372, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible the correlation of formations defined by Murphy (1930, 1932 [1933]) in Telescope Peak quadrangle with formations now commonly used in Death Valley region. Murphy tentatively assigned all rocks above the Panamint metamorphic complex to Lower Paleozoic. Sentinel dolomite, Radcliff formation, and Redlands dolomitic limestone are correlated with Noonday dolomite here assigned to Precambrian as defined in this report.

Occurs on Sentinel Peak, southern part of Panamint Range, Inyo County.

**Sentinel Granodiorite**[1] (in Tuolumne Intrusive Series)

Cretaceous: East-central California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 125, map.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2121, 2122, 2123 (fig. 1). Discussed in paper dealing with potassium-argon dating of igneous rocks. Age given as 88.4 millions of years. Younger than El Capitan granite and older than Half Dome quartz monzonite.

Named for fact it composes Sentinel Rock, Yosemite National Park.

**Sentinel Butte Member** (of Fort Union Formation)

Sentinel Butte Member (of Tongue River Formation)

Sentinel Butte Shale Member (of Fort Union? Formation)[1]

Paleocene: Southwestern North Dakota and northeastern Montana.

Original reference: A. G. Leonard, 1908, North Dakota Geol. Survey 5th Bienn. Rept.

W. E. Benson and W. M. Laird, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1167. Golden Valley formation (new) overlies Sentinel Butte shale member of Fort Union formation now considered to be of Paleocene age.

R. W. Brown, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 7, p. 1265–1274. New stratigraphic and paleontologic evidence indicates that Sentinel Butte shale, lately considered by some geologists to be of Wasatch (Eocene) age, is, as originally described and assigned, a dark sequence of strata in upper part of Fort Union formation (Paleocene). Correlations discussed.

E. P. Beroni and H. L. Bauer, Jr., 1952, U.S. Atomic Energy Comm. TEI Rept. 124, p. 6, 14–16. In Golden Valley County, N. Dak., shale member contains a 15-foot uraniferous lignite bed herein referred to as Bullion Butte bed. In southwestern North Dakota, member is 300 to 500 feet thick and is conformable with both underlying Tongue River member and overlying rocks tentatively identified as Golden Valley(?) formation.

S. P. Fisher, 1953, North Dakota Geol. Survey Rept. Inv. 11. Referred to as Sentinel Butte facies of Tongue River formation in area of this report [central McKenzie County].

P. R. May, 1954, U.S. Geol. Survey Bull. 995–G, p. 267, 268. About 200 feet of Sentinel Butte shale, uppermost member of Fort Union, is exposed at top of Blue Mountain in northern Wibaux area, Montana and North Dakota. Composed of gray and brown sandstone and shale and contains thin lignite beds. Overlies Tongue River member. Paleocene.

B. M. Hanson, 1955, North Dakota Geol. Survey Rept. Inv. 18. Reallocated to member status in Tongue River formation. Only lower 250 feet present in area [Elkhorn Ranch area, Billings and Golden Valley Counties]. Contact of Sentinel Butte member and underlying part of Tongue River formation is locally picked at base of most persistent and prominent clinker bed or on basis of characteristic lithologies—Tongue River light-tan to gray sand and clay and Sentinel Butte brown sands and clays. Paleocene.

Typically developed at Sentinel Butte, Billings County, N. Dak.

**Sentinel Hill Member** (of Schrader Bluff Formation)

Upper Cretaceous: Northern Alaska (subsurface and surface)

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1941, Washington Acad. Sci. Jour., v. 41, no. 5, p. 166, figs. 2, 3. Marine unit characterized by volcanic glass shards, abundant bentonite, and tuff. In outcrop beds are less consolidated than the underlying members. A little over 1,100 feet of marine beds of this member and nonmarine beds of Kogosukruk member [tongue] penetrated in Sentinel Hill core test well No. 1. In outcrop belt along Colville River, equivalent intertonguing marine and nonmarine beds total 2,340 feet. Overlies Tuluga member (new); underlies Sagavanirktok formation (new). Intertongues with Kogosukruk tongue (new) of nonmarine Prince Creek formation (new).

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 251–252, figs. 3, 4, 5. Surface type locality designated. Type section includes 1,040 feet of strata, of which 335 feet near middle of section are nonmarine beds assigned to Kogosukruk tongue.

Type locality: Bluffs along northwest side of Colville River from 5 to 15 miles northeast of Umiat Mountain. Named from section in Sentinel Hill core test well No. 1.

Sentinell Limestone

Cambrian(?): Northwestern Utah.

V. E. Peterson, 1942, Econ. Geology, v. 37, no. 6, p. 471 (table 1). Described as light-gray medium-grained crystalline thin-bedded limestone, usually broken and containing numerous calcite stringers. Thickness 50 to 100 feet. Underlies newly named Vipont limestone; overlies newly named Sentinell quartzite.

In Ashbrook mining district on west side of Goose Creek Range.

Sentinell Quartzite

Cambrian(?): Northwestern Utah.

V. E. Peterson, 1942, Econ. Geology, v. 37, no. 6, p. 471 (table 1). Described as white to tan sucrose quartzite. Thickness 100 feet or more. Underlies newly named Sentinell limestone; overlies Harrison series.

In Ashbrook mining district on west side of Goose Creek Range.

**Sentinel Mountain Dolomite Member** (of Nevada Formation)

Middle Devonian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 41, 43–44, pl. 2. Entirely composed of dolomite and typically exhibits an alternation of light- and dark-colored beds. The light-gray beds are thick bedded and are commonly coarse grained and more saccharoidal in texture than the darker dolomites interbedded with them. Mottling and a faint lamination are characteristic of the darker dolomites. Thicknesses assigned to the member are rather variable, ranging from 410 to 590 feet. The contacts between the Sentinel Mountain member and the underlying Oxyoke Canyon sandstone member (new) and the overlying Woodpecker limestone member (new) are gradational ones.

The member takes its name from Sentinel Mountain at the head of Oxyoke Canyon in the vicinity of Eureka, on the lower southeast slope of which it is well exposed.

Sentinel Rock Flow, Lava

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 47. Andesite flow from vent on Sentinel Rock. Thickness 300 to 400 feet in central part. Probably coeval with Watchman flow (andesite). [Diller and Patton, 1902, U.S. Geol. Survey Prof. Paper 3, described a Sentinel Rock andesite area].

Sentinel Rock is on southeastern rim of Crater Lake.

**Sequatchie Formation**[1]

Upper Ordovician: Eastern Tennessee, northeastern Alabama, northwestern Georgia, and southwestern Virginia.

Original reference: E. O. Ulrich, 1912, 12th Internat. Geol. Cong., Canada, p. 614, 646, 647, 648, 649, 651, 665, pl.

R. L. Bates, 1939, Virginia Geol. Survey Bull. 51–B, p. 42 (table 1), 55–56, pl. 6. Formation, in Powell Valley, Lee County, is top of Ordovician section. Unconformably overlies Reedsville formation; underlies Clinch formation. Thickness 135 feet along State Highway 64, south of Lee-Wise County line. Richmond age.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Prelim. Map 76, 2 sheets. Formation, in Rose Hill oil field, Lee County, Va., underlies Hagan member (new) of Clinch formation. Overlies Reedsville shale. Thickness 274 feet. Upper Ordovician.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 33–35, geol. map. Formation known to be present wherever its horizon crops out as far east as northwest slope of White Oak Mountain and its southward continuation, Taylor Ridge. Not observed in ridges carrying Red Mountain formation east and south of Tunnel Hill to and including Lavender Mountain. Thickness about 250 feet. Map legend shows Sequatchie above the Maysville and below the Red Mountain. Silurian or Ordovician.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 209, 211, 219–229. Term Sequatchie used for the calcareous shale, mudstone, argillaceous limestone in Sumner, Macon, Trousdale, Clay, and Pickett Counties and in Sequatchie Valley that occur between Leipers formation and Brassfield limestone, or Chattanooga shale where Brassfield is absent. Fernvale limestone can be recognized in parts of Sumner and Marion Counties, and the underlying argillaceous beds are referred to Sequatchie formation. Thickness as much as 160 feet. Believed to contain beds equivalent to Mannie shale and Fernvale limestone. Western tongue of Sequatchie underlies Fernvale limestone and overlies the Arnheim or Leipers formation. Richmond group.

L. D. Harris and R. L. Miller, 1958, U. S. Geol. Survey Geol. Quad. Map GQ–111. Name Sequatchie has been applied to sequence of marine rocks between top of Reedsville shale and base of Clinch sandstone on Powell Mountain (Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1). Purported nonmarine equivalent of the Sequatchie at Clinch Mountain in Duffield quadrangle has been called Juniata formation by Butts (1940). This sequence of rocks on Clinch Mountain is calcareous throughout, and marine fossils have been collected from lower part of formation. Proposed herein to abandon name Juniata in Clinch Mountain area of Duffield quadrangle and to extend use of term Sequatchie for these rocks. Thickness 260 feet at Powell Mountain; about 325 feet at Clinch Mountain.

Named for exposures in Sequatchie Valley, Tenn.

**Sequoyah Formation** (in Pottsville Group)[1]

Lower Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44.

Type locality not stated.

Serbin Sand Lentil (in Mount Tabor Member of Yegua Formation)

Eocene (Claiborne): Eastern Texas.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3945, pt. 2, p. 859 [1940]. Name applied to hard glauconitic sand lentil at top of Mount Tabor member of Yegua.

Type locality: About 1¾ miles northwest of Serbin, Lee County. Forms prominent cuesta.

Sergeant shale[1]

Upper Cretaceous: Northwestern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 148, 150.

Named for Sergeant Bluff, Woodbury County.

Serna schist[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 11.

In section near Picuris, north of Santa Fe, on west flank of Rocky Mountains, in Santa Fe region.

Serpiente Sandstone

Upper Cretaceous: Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 20–24, pls. 1, 2. Consists of about 85 percent arkosic sandstone and 15 percent shale. Divided into three members: Huevo—massive conglomeratic, concretionary sandstone with *Glycimcris veatchi* bed—occurs locally at top of formation; Torcido—light-brown finely laminated, fine-grained arkose with hassock structures; conglomerate at top contains *Baculites chicoensis*, *Submortoniceras chicoensis*, *Trigonia* sp.; Avila member (new). Thickness 4,160 feet at type locality. Conformably overlies Aguila sandstone (new) northeast of Johnson Peak and for distance of 2.3 miles northeast of Avila Canyon; at all other places in area an undetermined thickness of basal part of formation is missing where it has been thrust upon other units. In Sawtooth Ridge and Devil's Den synclines, is overlain conformably by Moonlight formation; elsewhere upper contact is fault separating it from Red Man sandstone (new). Huevo is Spanish word for egg and refers to rounded concretions in the unit; Torcido is Spanish word for contorted and refers to contorted bed in the unit. [Hence, Huevo and Torcido are descriptive terms, not formal names.]

Type locality: Serpiente Ridge and vicinity, Pyramid Hills quadrangle, Orchard Peak area which lies principally in northwestern Kern County.

**Serrano Clay Bed** (in Silverado Formation)

Paleocene: Southern California.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Name applied to a white clay that lies 275 feet above the Claymont clay bed (new). It is generally a quartzose sandstone with a light-gray clay matrix. Thickness variable, not more than 1⅓ feet.

Type locality: Serrano clay pits about half a mile southeast of divide between Santiago Creek and Aliso Creek, northeastern Santa Ana Mountains, Orange County.

Servilleta Formation

Pliocene, upper, or Pleistocene, lower: Central northern New Mexico.

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 53, 83, pl. 1. Consists of alluvial beds with prominent interlayered basalt flows. Alluvial beds composed of gravel, sand, and clay. Gravels distinguished by abundant layers of micaceous sand and much limonite. Flows of basalt are typically about 50 feet thick. Thickness at least 1,500 feet in area north of Picuris Range along the Rio Grande and near Embudo. Unconformably overlies both Picuris and Santa Fe beds along northeasterly and north-central borders of Picuris Range. Name credited to Butler (unpub. thesis).

Exposed along northeasterly and north-central borders of Picuris Range, Taos County.

**Sespe Formation**

Eocene, upper, and Oligocene: Southern California.

Original reference: W. L. Watts, 1897, California State Mining Bur. Bull. 11, p. 22–38.

W. C. Putnam, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 697 (fig. 3). Shown on generalized columnar section of Ventura region as overlying Coldwater sandstone member of Tejon formation and underlying Vaqueros formation. Thickness about 4,000 feet. Oligocene; lower part Eocene.

T. L. Bailey, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1913–1935. Name applied to nonmarine red-bed facies of group of sedimentary rocks up to 7,500 feet thick that range in age from upper Eocene to lower Miocene in southern and eastern parts of Ventura basin but that are probably restricted to the Oligocene in most of northern and western part of basin. Variation in age of Sespe is from east to west. North of Santa Clara River, between Fillmore and Point Conception, overlies Coldwater sandstone.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 31, 38 (fig. 2), pls. 1, 2. Formation, in western Santa Ynez Mountains, is series of continental sandstones, clays, and conglomerate lying above the Gaviota or older formations and below Vaqueros sandstone. Thickness 2,200 feet. Between Refugio and Gaviota Canyons progressively lower beds of formation grade laterally westward into marine Alegria formation (new). Oligocene.

Type locality: On Sespe Creek about 6 miles north of Fillmore, in northwestern part of Camulos quadrangle.

Seth Limestone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southwestern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 168.

H. R. Wanless, 1939, Geol. Soc. America Special Paper 17, p. 60, 101, pl. 9. Blue-gray fossiliferous limestone that occurs a few feet above the Cedar Grove coal. Kanawha group.

Type locality: Near Seth, Sherman district, Boone County.

**Setters Formation[1]**

Setters Quartzite

Lower Paleozoic(?) (Glenarm Series): Maryland, Pennsylvania, and Virgina.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Rept., v. 1, p. 130–132.

E. B. Bailey and J. H. Mackin, 1937, Am. Jour. Sci., v. 33, no. 195, p. 187. Baltimore gneiss, which forms basement complex, is Precambrian; the succeeding Setters quartzite, Cockeysville marble, and Wissahickon schist are Lower Paleozoic.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12], Carroll and Frederick Counties, p. 53–55, 81. Formation directly overlies Baltimore gneiss; structural discordance is observable in many places, but in many places the contact is obscured. Comprises three lithologic types: mica schist, vitreous quartzite, and mica gneiss; base of formation in Maryland is a feldspathic mica schist. Underlies Cockeysville marble. Maximum thickness, measured on north side of Glenarm-Towson anticline in Baltimore County, 1,100 feet; estimated thickness on borders of Woodstock anticline, 250 feet. May be Lower Cambrian.

P. W. Choquette, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1029 (table 1). At base of Glenarm series. Underlies Cockeysville formation; overlies Basement complex. Pre-Silurian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Probably Lower Paleozoic.

Most characteristic occurrence is in Setters Ridge, which forms the north front of the Chattolanee anticline, Baltimore County, Md.

Setters Ridge Quartzite[1].

Precambrian (Glenarm Series): Maryland, southeastern Pennsylvania, and Virginia.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Rept., v. 1, p. 130–132.

**Seven Devils Volcanics**[1]

Permian and Upper Triassic: Central Idaho.

Original reference: Waldemar Lindgren, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 193–198, pl. 8.

E. F. Cook, 1954, Idaho Bur. Mines and Geology Pamph. 97, p. 3. Age changed to Permian and Upper Triassic. Described as thick series of clastic and volcanic rocks, including andesitic flows and tuffs metamorphosed to greenstones, rhyolitic flows, waterlaid volcanic grits and conglomerates, quartzites, lenses of impure limestone, and small intrusive bodies. Because metamorphosed andesitic rocks predominate, the most common rock colors are dark green to black; some tuffs are reddish purple, quartzitic rocks are pale green or gray, and rhyolites are gray to almost white. Thickness probably exceeds 10,000 feet in Seven Devils region.

Mapped over large area at and around Seven Devils Mountains.

Seven-Mile Tuff and Sand Member (of Tuscan Formation)

[Pliocene]: Northern California.

R. C. Treasher, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1257. Tuscan formation is subdivided into five members. Seven-Mile tuff and sand is third in sequence (ascending). Underlies Iron Canyon agglomerate member; overlies Bald Hill agglomerate member.

Occurs at Iron Canyon dam site near Red Bluff, Tehama County.

**Seven Rivers Formation** (in Artesia Group or Whitehorse Group)

Seven Rivers Formation (in Carlsbad Group)

Seven Rivers Gypsiferous Member (of Chalk Bluff Formation)[1]

Permian (Guadalupe Series): Southeastern New Mexico and western Texas.

Original reference: O. E. Meinzer, B. C. Renick, and Kirk Bryan, 1926, U.S. Geol. Survey Water-Supply Paper 580–A, p. 6–7, 13–15, map.

R. K. DeFord and E. R. Lloyd, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 9. Whitehorse group of West Texas and New Mexico is divided into (ascending) Grayburg, Queen, Seven Rivers, Yates, and Tansill formations.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 67–68, 101 (fig. 12). Term Seven Rivers gypsiferous member of Chalk Bluff used for outcrop area of this report [southern Guadalupe Mountains]; correlation chart shows Seven Rivers formation in Whitehorse group in subsurface in Midland Basin.

N. D. Newell, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 46. Carlsbad group comprises (ascending) Seven Rivers, Yates, and Tansill formations; in each of these are several laterally equivalent interfingering lithologic facies arranged in belts parallel to Capitan reef. Within a few miles of equivalent part of reef, the Seven Rivers consists of thin-bedded fine-grained white dolomite about 500 feet thick. In some areas, thin sandstones, which wedge out toward reef, are interbedded with the dolomites. Entire formation passes shelfward from dolomite to gypsum within a few miles. Tongue of fine-grained thin-bedded dolomite (Azotea) in upper part of formation extends several miles shelfward into red facies.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Seven Rivers limestone described in Wylie Mountains region, Texas, where it is youngest Paleozoic formation. Maximum thickness 160 feet. Overlies Victorio Peak formation; unconformable below Cretaceous Cox sandstone.

P. T. Hayes, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–98. Formation described in Carlsbad Cavern East quadrangle, New Mexico, where it is lowermost formation in Carlsbad group. Underlies Yates formation; grades laterally into Capitan limestone.

P. T. Hayes and R. L. Koogle, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–112. Described in Carlsbad West quadrangle, New Mexico-Texas. Basal formation of Carlsbad group. Formation present at surface in broad outcrop band, in numerous nearby outliers, and in one inlier in northwest part of quadrangle. Conformably overlain by Yates formation. Seven Rivers grades laterally into lower part of Capitan limestone of Delaware Basin margin area. In stratigraphically higher beds this facies change takes place progressively to southeast. Individual beds thicken considerably and change from dolomite to limestone within horizontal distance of several hundred feet. A little northwest of gradation between Capitan and Seven Rivers, another lateral gradation from predominant dolomite to predominant gypsum occurs within Seven Rivers. This takes place in and near Johnson Canyon. Within limits of this report gypsiferous facies contains high percentage of dolomite, but percentage of dolomite decreases in northwesterly direction. Thickness 460 feet in Bear Canyon.

Terms Carlsbad Group and Chalk Bluff Formation abandoned; replaced by Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4).

Named from exposures in bluffs south of Seven Rivers, notably bluff that lies in secs. 17 and 18, T. 20 S., R. 26 E., Eddy County, N. Mex.

†Seven Sisters Sandstone[1]

Pennsylvanian: Eastern Kentucky.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 119.

Exposed at Seven Sisters on Cumberland River.

Seven Springs Formation (in McCutcheon Volcanic Series)

Tertiary: Southwestern Texas.

G. K. Eifler, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 4, p. 345–346, pl. 1. Name applied to the lavas, tuffs, and interbedded sediments between Star Mountain rhyolite (new) and top of McCutcheon volcanic series. Formation is divided into four lava members and four tuff members that alternate with one another. Composite section near type locality is 682 feet thick.

Named for Seven Springs near Willis McCutcheon ranchhouse 7 miles south of Toyahvale, Reeves County. Exposed in syncline north of Star Mountain.

†Severn Formation[1]

Upper Cretaceous and Eocene: Eastern Maryland.

Original reference: N. H. Darton, 1891, Geol. Soc. America Bull., v. 2, p. 431, 438.

N. D. Darton, 1951, Geol. Soc. America Bull., v. 62, no. 7, p. 748. Incidental mention in discussion of Magothy formation. Overlies Magothy.

Named for exposures in cliffs at Round Bay, Severn River.

**Severy Shale** (in Wabaunsee Group)

Severy Shale (in Shawnee Group)[1]

Severy Shale Member (of Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northeastern Missouri, southeastern Nebraska, and northern Oklahoma.

Original reference: E. Haworth, 1908, Kansas Univ. Geol. Survey, v. 3, p. 66.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 20. Thickness in Iowa and southeastern Nebraska 9 to 20 feet.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 63. Underlies Bachelor Creek limestone member of Howard limestone; overlies Coal Creek limestone member of Topeka limestone. Thickness commonly 70 to 80 feet.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 45 (fig. 18), 47–48. Moore (1936, Kansas Geol. Survey Bull. 22) redefined Severy as basal formation of Wabaunsee group, including section between top limestone of Topeka formation and bottom limestone of Howard formation. Moore (1932) introduced name Aarde for shale section between lower and middle limestone members (Bachelor Creek and Church limestones, respectively) of Howard formation and suggested (1936) that where basal limestone is missing, the resulting shale section should be called Severy-Aarde shale. Lowest stratigraphic unit of Wabaunsee group in Pawnee County is shale-sandstone section between Turkey Run and Bird Creek limestones. Branson (1956, Oklahoma Geology Notes, v. 16, no. 11) applied name Severy shale to this unit in north-central Oklahoma. Inasmuch as Bird Creek is equivalent to Church limestone member of Howard, it is evident that Severy shale of Pawnee County is equivalent to Severy-Aarde shale of Kansas. Severy can be traced southward from Kansas into Creek and Lincoln Counties, Okla., where one or both of the limiting limestones pinch out. Thickness 27 to 40 feet in Pawnee County. Overlies Turkey Run limestone member of Pawhuska; underlies Bird Creek limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 14, fig. 5. Forms base of Wabaunsee group. In places, underclay is present beneath Nodaway coal. Black slaty shale or gray fossiliferous shale overlies coal, and gray shale with some limestone nodules forms base of formation. Average thickness about 7 feet. Underlies Howard limestone; overlies Topeka limestone.

Named for Severy, Greenwood County, Kans.

**Sevier Shale or Formation**

Sevier Shale (in Blount Group)[1]

Middle Ordovician: Eastern Tennessee, northern Georgia, western North Carolina, and southwestern Virginia.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 4.

C. H. Gordon, 1924, Tennessee Dept. Ed. Div. Geol. Bull. 28, p. 39–40, 63–65, map. Near Friendsville, Tenn. includes Meadow marble member (new).

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1182–1183. Discussion of lower Middle Ordovician of southwestern Virginia and northeastern Tennessee and suggests recommendations for revision of nomenclature. The Sevier and "Ottosee" are essentially equivalent formations, the latter being named by Ulrich to obviate use of term Sevier, which had been erroneously applied to the younger Martinsburg formation in much of earlier mapping in Virginia and Tennessee. In this respect, Ottosee formation offers no improvement over Sevier since it too has been applied erroneously in northeast Tennessee and southwest Virginia. Gratton limestone is absent in Knoxville region. Benbolt and Wardell equivalents are not readily differentiated lithologically. Therefore, terms Benbolt and Wardell are not applicable in that area; either Sevier should be redefined or a new formational name applied to these beds. According to type description, the Sevier occurs between Tellico and "Bays" sandstones. The type Bays is same as the Moccasin. The latter is in better usage in Tennessee and Virginia and should have precedence over "Bays." Base of Moccasin as generally mapped was not included in type Moccasin by Campbell and was assigned name Bowen (Cooper and Prouty, 1943). The Bowen forms base of the "Bays" and would therefore mark top of Sevier formation. The Sevier might be redefined as bluish-gray buffish-weathering shaly limestone occurring between the Tellico sandstone and Bowen formation. In absence of the latter, the Sevier would underlie Witten limestone and, in absence of this, would underlie Moccasin proper. Section southeast of Lenoir City, Tenn., may serve as a standard for the Sevier. Inasmuch as the Sevier contains equivalents of the Benbolt, Gratton(?), and Wardell, it might be considered a group. However, it is useful as a mapping unit in Tennessee and is herein maintained under formational status.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 29. In belt north of Dalton, Holston marble is overlain by yellowish fossiliferous shale about 100 feet thick. This answers character of much of Sevier or Ottosee shale in Tennessee and is tentatively referred to Ottosee. If it is Sevier, Athens shale and Tellico sandstone which normally intervene between the Holston and Sevier are absent from section in this narrow belt. No Ottosee or Sevier was recognized elsewhere in Georgia.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 76–81, pls. Keith (1895) named Sevier shale for the wide belt of shale in Sevier

County immediately northwest of Chilhowee Mountain. First published maps on which formation is shown are plate 57 in 13th Annual Report of the U.S. Geological Survey in 1893 and Estillville folio (Campbell, 1894); on these maps, name Sevier was applied to whole mass of shale between the thin limestone below (called Chickamauga by Campbell and Keith) and Bays formation above (Campbell also applied it to the younger Martinsburg shale north of Clinch Mountain, but this erroneous usage may be ignored). Later Keith attempted to subdivide the shale in Bays Mountain area into Athens shale below and Sevier shale above and that in Sevier County area into three units—Athens shale, Tellico sandstone, and Sevier shale, but as result he actually mapped very little of type belt as Sevier. Except southwest of Sevier County, Keith's subdivisions have not proved usable, partly because of complex structure; the mass of shale forms a single mappable unit, though locally it may be possible to map members in it. It is proposed here to return to original meaning of term Sevier and apply it to whole mass of shale where undivided. As thus defined, includes equivalents of typical Athens and Ottosee shale and also of typical Lenoir and Holston formations.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145 (table), 160–164, pl. 28. Discussion of Middle Ordovician rocks of Tellico-Sevier belt, eastern Tennessee; it includes type area of Sevier shale of Keith. Term Sevier formation is applied to sequence of calcareous shale, calcareous sandstone, and calcarenite about 1,800 feet thick. At top is distinctive unit, 40 to 165 feet thick, characterized by slump-bedding structures, here named Bacon Bend member. Main body of Sevier is similar to Tellico formation, having beds and lenses of sandstone and calcarenite interbedded with shale. Keith (1895) applied term Sevier to interbedded sandstone, shaly limestone, and shale northwest of Chilhowee Mountain. He divided formation into three parts: two shale divisions separated by sandstone lentil. In present report, the shale division below the lentil is assigned to Tellico formation, the sandstone lentil is termed Chota formation, and the Sevier is restricted to shales and sandstones that lie between the Chota and Bays formations.

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–76. Keith (1895) mapped as Sevier shale the rocks in Shooks quadrangle herein called Ottosee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 90. Name is applied to thick series of sandy shales and fine-grained sandstones with intercalated beds of calcarenite, bryozoan "reefs" and thin lenses of sandy limestone. Best developed in belts south of Knoxville and along Great Smoky Mountain front into northern Georgia. In vicinity of Friendsville, overlies Red Knobs formation (new) and contains fossils that suggest a Benbolt age. In belt along Great Smoky Mountain Front, the Sevier is very extensive. In northern Georgia, near village of Cisco, Sevier-type lithology succeeds Tellico sandstone and extends to base of Bays red beds. The Sevier appears to be a facies rather than a definite formation.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 57. Term Blount group discarded.

Named for exposures in Sevier County, Tenn.

**Sevier River Formation**

Pliocene, upper, or Pleistocene, lower: Central Utah.

Eugene Callaghan, 1937, (abs.) Washington Acad. Sci. Jour., v. 27, p. 359; 1938, U.S. Geol. Survey Bull. 886–D, p. 100–101. Series of partly consolidated sediments of fanglomerate, conglomerate sand, and silt; fanglomerate and conglomerate grade eastward into pinkish sand and silt, which in turn grade into white diatomite beds. Overlies Tertiary volcanic rocks; underlies Quaternary alluvium.

P. E. Dennis, G. B. Maxey, and H. E. Thomas, 1946, Utah State Engineer Tech. Pub. 3, p. 28 (table). Shown on table of rocks exposed in vicinity of Pavant Valley. Thickness about 800 feet. Occurs below Pavant flow.

P. F. Kerr and others, 1957, Geol. Soc. America Spec. Paper 64, p. 36–37. Only widespread younger sedimentary unit in Marysvale region. Importance of this sediment is its indirect structural implication. Believed to represent accumulation from torrential runoff. It is plastered on steep walls of Mount Belknap rhyolite along Beaver Creek Canyon. Probably deposited after, partly as a result of, main period of Pleistocene graben faulting. Thickness commonly less than a few hundred feet and related to underlying topography.

R. R. Kennedy, 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 4, p. 26, 28, 29, geol. map. Thickness in Tushar Range 300 feet. Unconformable above Tushar conglomerate (new).

Well exposed north of Junction of Clear Creek and Sevier River, Sevier County.

Seville cyclothem (in Abbott-Spoon Formation)

Seville cyclothem[1] (in Tradewater Group)

Pennsylvanian: Western and central Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 189, 192.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 63, 70–73. Thickness in outcrop 3 to 26 feet. Includes (ascending) Bernadotte sandstone, Rock Island (No. 1) coal, and Seville limestone. Underlies DeLong cyclothem; commonly rests unconformably on Pope Creek shale or coal. Type locality and derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Abbott-Spoon formations (both new). Above Pope Creek cyclothem and below Hermon cyclothem (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: In bluff of Spoon River, in SW¼SW¼ sec. 23, T. 6 N., R. 1 E., about 1 mile southwest of Seville, Vermont quadrangle, Fulton County.

Seville Limestone Member (of Spoon Formation)

Seville Formation (in Cherokee Group or Krebs Group)

Seville Limestone (in Pottsville Formation)[1]

Seville Limestone (in Tradewater Group)

Pennsylvanian: Central Illinois, Iowa, southeastern Kansas, and western Missouri.

Original reference: H. R. Wanless, 1931, Geol. Soc. America Bull., v. 42, no. 3, p. 805.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748, (fig. 1). Shown on composite stratigraphic column of Desmoinesian rocks in northern midcontinent as Seville formation in Krebs group. Underlies Weir formation; overlies Bluejacket formation.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 4), 41. Seville formation, as defined in southeastern Kansas and southwestern Missouri, includes only Seville limestone (Wanless, 1931). Present in Barton and Vernon Counties, Mo., and in southeastern Kansas near Pittsburg, Crawford County. At this place, identification is tentative being based mainly on stratigraphic position because limestone is very impure, has little resemblance to Seville of western Missouri, and, although fossiliferous, does not contain fauna characteristic of Seville. In Kansas, bed tentatively identified as Seville is argillaceous and weathers to thin, irregular slabs; thickness about 6 inches. Seville lies above Bluejacket coal and below underclay of Weir-Pittsburg coal bed where complete succession is present. Forms uppermost unit of Krebs subgroup of Cherokee group. Also present in Iowa.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 72–73, 201 (geol. section 33). Seville limestone included in Seville cyclothem, Tradewater group. At type exposure of cyclothem, the limestone is about 4 feet thick and is argillaceous, blue gray, unevenly bedded, fossiliferous (brachiopods, bryozoa, crinoid stems). Was designated Parks Creek sandstone by Savage (1927)—apparently a typographical error for Barker Creek near Seville.

R. M. Kosanke and others, 1961, Illinois Geol. Survey Rept. Inv. 214, p. 33, 45 (table 1), 63, pl. 1. Assigned to member status in Spoon Formation (new). Occurs above Rock Island (No. 1) coal member and below Hermon coal member (new). Thickness 3¼ feet at type section of Spoon formation. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Southwest bank of Spoon River, SW¼SW¼ sec. 23, T. 6 N., R. 1 E., Vermont quadrangle, Fulton County, Ill.

Sevilleta Metarhyolite

Sevilleta Rhyolite or Formation

Precambrian: Central New Mexico.

J. T. Stark and E. C. Dapples, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1936. Rhyolite younger than White Ridge quartzite (new); intruded by Los Pinos granite (new).

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1, p. 1134–1135, pl. 1. Two distinct facies of rhyolite recognized—light-buff to reddish-brown sericitic schistose rock at base and upper flows of dense dark-red to black less metamorphosed rhyolite. Base of formation contains about 500 feet of sericitic rhyolite which grades downward into White Ridge quartzite; its groundmass extremely fine grained and compact and exhibits silky luster due to abundance of sericite. Thickness measured north of Los Pinos Arroyo 4,500 feet but undoubtedly greater than exposed in this section. Derivation of name given.

J. T. Stark, 1956, New Mexico Bur. Mines Mineral Resources Bull. 34, p. 11–13, pl. 1. Mapped and described as metarhyolite in South Manzano Mountains. Easily recognized rock types are banded rhyolite, sericite schist, garnet schist, chloritoid schist, and hornblende-rich rhyolite. Name spelled Sevillita in text.

Named after old Sevilleta Grant within the bounds of which the rhyolites occur; Los Pinos Mountains.

Sevillita Metarhyolite

*See* Sevilleta Metarhyolite.

**Sevy Dolomite**[1]

Lower(?) and Middle Devonian: Western Utah and east-central Nevada.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

J. C. Osmond, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1911–1931. Geographically extended into east-central Nevada. Overlies Laketown dolomite; underlies Simonson dolomite. Lower part probably late Silurian. Tentatively correlated with Lone Mountain formation. Detailed discussion of unit.

J. K. Rigby, 1958, Utah, Geol. Soc. Guidebook 13, p. 34–35. Described in Stansbury Mountains where it is as much as 80 feet thick; gradationally overlies Laketown and underlies Simonson(?) dolomite.

M. H. Staatz and F. W. Osterwald, 1959, U.S. Geol. Survey Bull. 1069, p. 8, 29–31, pl. 1. Described in Juab County, Utah, where it is 1,122 feet thick; overlies Thursday dolomite (new) and underlies Simonson dolomite and Guilmette formations undifferentiated.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 143–145. Described in Fivemile Pass-North Boulter Mountain area where it is 128 feet thick; disconformably overlies Laketown dolomite and underlies Simonson dolomite. Dora dolomite (in part at least) should be termed Sevy.

U.S. Geological Survey currently designates the age of the Sevy Dolomite as Lower(?) and Middle Devonian on the basis of a study now in progress.

Named for exposures in Sevy Canyon, on western side of Deep Creek Range, Gold Hill region, Utah.

**Sewanee Conglomerate** (in Lee Group)[1]

**Sewanee Conglomerate Member** (of Lookout Sandstone)

**Sewanee Member** (of Crab Orchard Mountains Formation)

Sewanee Conglomerate (in Crab Orchard Mountains Group)

Sewanee Conglomerate Member (of Lee Formation)

Lower Pennsylvanian: Eastern Tennessee and northern Georgia.

Original reference: J. M. Safford, 1893, Tennessee State Bd. of Health Bull., v. 8, no. 6, p. 89–98.

H. R. Wanless, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1941. Listed as member of Lee formation.

V. H. Johnson, 1946, Coal deposits of Sand and Lookout Mountains, Dade and Walker Counties, Georgia: U.S. Geol. Survey Prelim. Map. Geographically extended into northern Georgia where it is reduced to member status in Lookout sandstone. Overlies Gizzard member; underlies Whitwell shale.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio],

p. 4, 19, pls. 2, 3, 4, 12–C. Basal unit of Crab Orchard Mountains group (new). Medium- to coarse-grained crossbedded massive extremely conglomeratic sandstone in most areas. Thickness as much as 160 feet; average about 80 feet. In northwestern part of the plateau, merges into Fentress formation. The sandstone that has been called "Bon Air" at Bon Air, White County, is equivalent to the Sewanee conglomerate; Sewanee has priority, and name Bon Air is discontinued. Pottsville series. Type locality stated.

Type locality: In area around town of Sewanee, Franklin County, Tenn.

Seward Formation

Pliocene: Southeastern Nebraska.

G. E. Condra and E. C. Reed, 1947, Nebraska Geol. Survey Bull. 15, p. 15–16, fig. 8. Consists principally of medium- to light-gray, in part brownish-gray, very calcareous silts and siltstones with some interbeded marly zones; locally includes basal gravel member composed principally of pebbles of reworked Cretaceous bedrock. Thickness varies from knife edge to about 200 feet. Unconformably overlies Cretaceous or older bedrock; unconformably underlies Holdrege sands and gravels or younger Pleistocene formations. Can be traced westward through late Tertiary channels into typical Ogallala sediments.

Profile section shows Seward present from Lancaster County westward into Buffalo County.

†Sewell Formation (in Rancocas Group)[1]

Eocene: New Jersey.

Original reference: W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897, Geol. Soc. America Bull., v. 8, p. 316–338.

Named for Sewell, Gloucester County.

**Sewell Member** (of New River Formation)

Sewell Formation (in Pottsville Group)[1]

Lower Pennsylvanian; Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487, 494.

U.S. Geological Survey currently classifies the Sewell as a member of the New River Formation on the basis of a study now in progress.

Occurs along New and Kanawha Rivers, W. Va. Named for Sewell, Fayette County.

**Sewemup Member** (of Moenkopi Formation)

Lower and Middle(?) Triassic: Southwestern Colorado and southeastern Utah.

E. M. Shoemaker and W. L. Newman, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1839–1840, 1842, 1846–1847. Chiefly chocolate-brown fissile siltstone or shale with subordinate interbedded light-brown fine-grained sandstone; gypsum present throughout member, mainly as interstitial cement or crosscutting veinlets near base and in discrete thin nodular beds near top; some beds of light maroon coarse-grained sandstone; locally sandstone is conglomeratic. Thickness 0 to about 450 feet. Cut out toward Uncompahgre Plateau, and locally over salt anticlines and small folds peripheral to Fisher Valley by angular unconformity at base of overlying Chinle formation; in Sinbad Valley, overlapped by Pariott member (new) toward axis of anticline. Conformably overlies and intertongues with Ali Baba member (new). Underlies Pariott member (new).

Type section: East side Sinbad Valley, sec. 15, T. 49 N., R. 19 W., Mesa County, Colo. Named for Sewemup Mesa which forms east wall of Sinbad Valley.

Sewickley cyclothem

Pennsylvanian (Monongahela Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 173–176. Embraces interval between Lower Sewickley cyclothem (new) below and Benwood cyclothem (new) above. Normal sequence includes six members (ascending): unnamed shale and sandstone, Sewickley redbed, Sewickley limestone, Sewickley underclay, Sewickley (Meigs Creek) (No. 9) coal, and Sewickley roof shale. Thickness ranges from 11 to 64 feet and averages 33. This variation is accounted for in part by where basal boundary is drawn. Usually base of cyclothem is placed at top of Fishpot coal bed and roof shale; however, if Lower Sewickley cyclothem is present, base is drawn at top of Lower Sewickley coal bed, which results in average thickness of 17 feet for Sewickley cyclothem. Wherever Lower Sewickley cyclothem is present, base of Sewickley cyclothem is placed at top of Lower Sewickley coal zone, and an unnamed shale and sandstone of local occurrence becomes basal member of Sewickley cyclothem. Laterally, this sandstone grades into redbed or is lost in a thick deposit of Lower Sewickley sandstone and cannot be identified. Wherever this unnamed sandstone and underlying Lower Sewickley coal zone cannot be carried laterally Lower Swickley cyclothem is lost and base of Sewickley cyclothem is then drawn at top of Fishpot coal bed and roof shale. Name Lower Sewickley shale and sandstone is used for lowest unit of Sewickley cyclothem when its lower boundary rests on Fishpot cyclothem because it is proper term for this lithology in usual Fishpot to Sewickley coal bed interval, and is continuous with Lower Sewickley shale and sandstone of Lower Sewickley cyclothem. Also, Lower Sewickley redbed member may be represented laterally as either a redbed or sandstone facies of Sewickley cyclothem when base of that cyclothem is considered to be a top of Fishpot coal and roof shale. Under this condition, name Sewickley redbed is more appropriate than Lower Sewickley redbed and is adopted for this facies where Lower Sewickley cyclothem is absent. In area of this report Monongahela series is discussed on a cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Present in Athens County.

†Sewickley Limestone (in Monongahela Formation)[1]

Sewickley limestone member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: F. Platt and G. W. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$, p. 55–104, 286.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 175. Name Sewickley limestone was first used by Platt and Platt (1877) to designate the fresh-water limestone underlying Sewickley coal bed in Somerset County, Pa. White (1891, U.S. Geol. Survey Bull. 65) continued to use this term but applied it to all limestone strata between the Redstone and Sewickley coal beds, and it was not until after Clark and Martin (1905, Maryland Geol. Survey, v. 5) named and described Fishpot coal bed that name Sewickley limestone was restricted to interval between Fishpot and Sewickley coal beds. In present report [Athens County], Sewickley limestone is referred to as a member of Sewickley cyclothem. Occurs between Sewickley redbed member and Sewickley underclay member. Limestone member is thin or wanting in Athens County but prominent in parts of West Virginia and Pennsylvania.

Named for association with Sewickley coal in Somerset County, Pa.

Sewickley Member (of Monongahela Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

Pittsburgh quadrangle.

Sewickley redbed member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 175. Member of Sewickley cyclothem in Athens County. Present above an unnamed shale and sandstone member and below Sewickley limestone member. Thickness 2 to 26 feet.

Sewickley roof shale member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon, 1958, Ohio Geol. Survey Bull. 57, p. 176. Member of Sewickley cyclothem in Athens County. Persistent clay shale 3 or 4 inches to 5½ feet thick. Overlies Sewickley coal bed.

**Sewickley Sandstone Member** (of Monogahela Formation)[1]

Sewickley Sandstone (in Monongahela Group)

Upper Pennsylvanian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 60.

R. V. Hennen, 1912, West Virginia Geol. Survey [Rept.] Doddridge and Harrison Counties, p. 199–200. Sewickley sandstone (White, 1891) is herein renamed Upper Sewickley sandstone in contradistinction to Lower Sewickley ledge belonging immediately under Sewickley coal. Thickness 40 to 60 feet.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 100, 121, 124 (fig. 29). In Fayette County, Sewickley sandstone lies 120 to 150 feet above Pittsburgh coal which is base of Monongahela group. Thickness as much as 35 feet; average 20 feet. Separated from underlying Fishpot limestone by lower Sewickley coal and from overlying Benwood limestone by upper Sewickley coal.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 19 (table 3). Shown on summary of stratigraphic sections of Monongahela formation in Harrison County as Lower and Upper Sewickley sandstone. Units are separated by (ascending) unnamed sandy shale, Sewickley coal and (or) slate, and unnamed brown shale. Underlies unnamed shale below Benwood limestone; overlies Sewickley limestone and (or) shale.

*See* Lower Sewickley Sandstone and Upper Sewickley Sandstone.

Probably named for its association with Sewickley coal which was named for exposures along Sewickley Creek, Westmoreland County, Pa.

Sewickley shale and sandstone member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958 Ohio Geol. Survey Bull. 57, p. 177. Shale and sandstone member of Benwood cyclothem in Athens County. Sewickley sandstone was named by White (1891, U.S. Geol. Survey Bull. 65) in his study of Pennsylvanian coal fields of Ohio, West Virginia, and Pennsylvania. In much of its area of occurrence, this member varies radically from thin flaggy sandstone to a massive one from 20 to 60 feet thick or gives way entirely to limestone or redbeds. In Athens County, member is represented by all gradations of sandy shale to massive sandstone. Average thickness 27 feet. Locally member gives way laterally almost in its entirety to redbed facies; more commonly, it is upper part of the member that grades laterally into redbeds and is interbedded with them. Below Tyler redbed member.

Sewickley underclay member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 175. Referred to as member of Sewickley cyclothem in Athens County. Usually occurs in association with Sewickley coal bed. Discontinuous in its lateral extent.

Sexton Creek Limestone[1]

Lower Silurian (Alexandrian Series): Southwestern Illinois and eastern Missouri.

Original reference: T. E. Savage, 1909, Am. Jour. Sci., 4th v. 28, p. 518.

J. M. Weller *in* J. M. Weller and G. E. Ekblaw, 1940, Illinois Geol. Survey Rept. Inv. 70, p. 10; J. M. Weller. 1940, Illinois Geol. Survey Rept. Inv. 71. p. 20. In southern Illinois, overlies both Edgewood and Girardeau limestones and may overlap locally on Orchard Creek shale; in Missouri, overlaps upon strata as old as Kimmswick. Underlies Bainbridge limestone. Consists principally of more or less cherty limestone; lower part of formation is gray, more or less crystalline limestone with thin tabular masses or continuous beds of chert; higher strata are more massive, crystalline, generally darker colored, slightly glauconitic, and less cherty. Locally as much as 40 feet thick.

Named for exposures on Sexton Creek, Alexander County, Ill .

**Seymour Formation[1]**

Pleistocene: Central northern Texas.

Original reference: W. F. Cummins, 1893, Texas Geol. Survey, 4th Ann. Rept., pt. 1, p. 181–190.

G. W. Willis and D. B. Knowles. 1953. Texas Board Water Engineers Bull. 5301, p. 9. In Odell Sand Hills, Wilbarger County, composed of discontinuous layers of sandy clay, sandy caliche, medium- to very coarse-grained sand, and pebbles that range in diameter from about an eighth of an inch to slightly more than an inch; the beds of pebbles and coarse-grained sand range in thickness from about 1 foot to 85 feet and are, in general, near base of formation. Unconformably overlies Permian rocks. Type locality stated.

Type locality: Between Brazos and Wichita Rivers in Baylor and Knox Counties. Named for town of Seymour, Baylor County.

Shadehill facies

*See* **Ludlow Member** (of Fort Union Formation)

**Shades Sandstone Member** (of Pottsville Formation)[1]

Lower Pennsylvanian: Central Alabama.

Original reference: Charles Butts, 1910, U.S. Geol. Survey Geol. Atlas, Folio 175, p. 10, 11.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 27. Mentioned in report on Alabama shales and fire clays. Base of Pottsville is placed at base of Brock coal seam which underlies Shades sandstone in Cahaba coal field.

Named for occurrence on Shades Mountain, Jefferson County.

Shadow Mountain Basalt Flow

Quaternary: Northwestern Arizona.

D. N. Hinckley, 1955, U.S. Atomic Energy Comm. [Pub.] RME-81 (rev.), p. 8. The Quaternary period was marked by igneous activity in the region. The Tappan lava flow and the Shadow Mountain cinder cone and basalt flow are the nearest volcanics.

In Cameron region, Coconino County.

Shadrick Mill Sandstone (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept. pt. 1, p. 374, 376.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 76. Sandstone, commonly massive but with some flaggy beds and thin conglomerate. Thickness 150 feet. Overlies Elliott Creek bed; underlies bed no. 8. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315-D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Shadrick Mill, Lampasas County.

**Shady Dolomite**[1] or **Formation**

Lower Cambrian: Eastern Tennessee, northern Alabama, northwestern Georgia, western North Carolina, and southwestern Virginia.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51-A, p. 1-30. Shady dolomite of Great Valley of Virginia is Lower Cambrian and rests on Erwin quartzite and is overlain by Rome formation. Shady dolomite is equivalent to Tomstown dolomite. On lithologic grounds, they may be divided in most places into a lower blue argillaceous banded dolomite and an upper gray to white purer granular dolomite. In southwestern Virginia, Butts (1933) divided Shady into a lower ribboned limestone member (Patterson) and an upper saccharoidal dolomite member. Currier (1935, Virginia Geol. Survey Bull. 43) locally included at top of saccharoidal dolomite member a pure limestone which he named Ivanhoe member. In present report, the Ivanhoe is included in base of Rome formation. Partial section of typical Shady south of Fosters Falls Mountain is about 620 feet thick. The equivalent of the Lower Cambrian dolomite in small area on southeastern edge of Great Valley, southeast of Austinville contains group of fossiliferous beds whose fauna, lithology, and stratigraphic position are comparable with Kinzers formation of the York and Lancaster valleys of Pennsylvania. This fossil-bearing series of beds, although equivalent to Shady dolomite of Great Valley, is different sedimentary facies deposited to southeast of main Applachian geosyncline and has been carried northwestward by thrust faulting to rest on typical Shady dolomite. Proposed to extend Pennsylvania names Vintage dolomite, Kinzers formation, and Ledger dolomite to the lower dolomite, middle fossil-bearing beds, and upper dolomite, respectively, of the Shady equivalents of this area.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 40-56. Name Shady has been used south of Roanoke and name Tomstown north of Roanoke. Term Shady has priority and is used throughout this report. Predominantly dolomite, but in some areas includes limestone in both upper and lower parts. In New River district, three members recognized: Patterson limestone in lower part; saccharoidal dolomite in middle herein named Austinville; and Ivanhoe limestone at top. Thickness 1,400 feet at Jackson Ferry; 5,040 feet near Austinville. Overlies Erwin quartzite-Antietam sandstone; underlies Rome formation.

T. L. Kesler, 1950, U.S. Geol. Survey Prof. Paper 224, p. 10–12, pl. 1. In Cartersville district, Georgia, the Shady dolomite consists of variably siliceous specular hematite interbeded with dolomite. Age of rocks is established by fossils, which occur in great numbers in some parts of hematite beds and in residual silicified parts of the dolomite. Thickness about 30 feet. Conformably overlies Weisner formation but is lenticular and not everywhere present. Overlain in most places by dolomite, which has been regarded previously as Shady dolomite. However, name Shady should be restricted to stratigraphic zone containing interbedded hematite and dolomite. The dolomite beds are here included in the carbonate rocks of Rome formation.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 9–12, pl. 1. Shady dolomite, within Hot Springs window, exhibits the several distinct rock types noted in Shady in Tennessee—basal ribboned member, lower blue member, ribboned member, middle blue member, upper white member, and upper blue member. Thickness about 1,975 feet. Overlies Helenmode member of Erwin formation; underlies maroon shales of Rome formation.

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–76. Shady dolomite, oldest exposed unit in Shooks Gap quadrangle, Tennessee, is at base of overriding block of Dumplin Valley fault southwestward from Bean Ridge. Keith (1895, U.S. Geol. Survey Geol. Atlas, Folio 16) mapped these beds with considerable thickness of overlying beds as Apison shale. Underlies Rome formation; faulted against Knox dolomite.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 45–52, pl. 1. Shady dolomite is lowest carbonate unit of Paleozoic section of Appalachians. The Shady is widely distributed and underlies wide areas of lowlands of Shady Valley, Stony Creek valley, Johnson

County cove, and Doe River cove; north of area of this report, north of Damascus, Va., it crops out in Appalachian Valley. Few outcrops occur at type locality. Much better section is exposed in Stony Creek valley but whole sequence not exposed at single locality. Here Shady is 1,150 feet thick and consists of six members: lower white member (dolomite), about 35 feet; lower blue member (dolomite), 90 feet; ribboned member (dolomite and limestone), 250 feet; middle blue member (dolomite), 250 feet; upper white member (dolomite), 125 feet; and upper blue member (dolomite), 400 feet. Regionally the members probably form interfingering wedges because same members cannot recognized everywhere. In Shady Valley, type locality, the dolomite underlies upper basin and basin below Crandull, the two areas being separated by Helenmode member of Erwin formation of Chilhowee group. Here whole formation is probably present because red shale of Rome formation is exposed along U.S. Highway 421. Inferred that same members are present as in Stony Creek valley and that thickness is about the same.

Typically exposed in Stony Creek valley, Carter County, Tenn. Named for Shady, Johnson County, Tenn.

Shaffer Shale[1]

Middle Devonian: West-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 22, table.

Ontario County.

**Shafter Limestone** (in Trinity Group)[1]

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: J. A. Udden, 1904, Texas Univ. Min. Survey Bull. 8, p. 10, 11, 25, 30–39.

C. P. Ross, 1943, U.S. Geol. Survey Bull. 928–B, p. 78–83, pl. 7. Rocks herein designated Shafter limestone are exposed in and around town of Shafter and on banks of Cibolo Creek south of Shafter and form part of prominent range of hills about 3.2 miles southeast of Shafter and the valley north of the range. They appear to rest unconformably on Presidio formation. Shafter is defined by Udden contains rocks of both Trinity and Fredericksburg age. Because the Walnut(?) and other younger rocks are susceptible of being mapped separately and are not present close to Shafter, it is here proposed to restrict name Shafter to beds of upper Trinity. Thickness as restricted 1,085 feet. Shafter (restricted) is lithologically similar to Glen Rose limestone and contains similar faunal assemblage.

Exposed in and around town of Shafter, Presidio County.

**Shaggy Peak Rhyolite**[1]

Eocene(?): Central northern Utah.

Original reference: J. Gilluly, 1932, U.S. Geol. Survey Prof. Paper 173, p. 59–60.

In Shaggy Peak, Fairfield quadrangle.

**Shakopee Dolomite** (in Prairie du Chien Group)[1]

Shakopee Dolomite Member (of Prairie du Chien Formation)

Lower Ordovician: Southern Minnesota, northern Illinois, Iowa, and southern Wisconsin.

Original reference: N. H. Winchell, 1874, Minnesota Geol. Nat. History Survey 2d Ann. Rept., p. 138–147.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 62, 63–66. Overlies and interbedded with Root Valley sandstone (new). Underlies St. Peter sandstone. Thickness 35 feet in Winona County.

R. L. Heller, 1956, Geol. Soc. America Guidebook Minneapolis Mtg. Field Trip 2, p. 38–39. Prairie du Chien group reduced to formation and Oneota dolomite, New Richmond sandstone, and Shakopee dolomite reduced to member status. Name Root Valley shale suppressed. Typical Shakopee is fine- to medium-grained light-brownish-gray to buff thin- to thick-bedded dolomite. Chert not common but where present can be of use in differentiating upper and lower dolomites of the Prairie du Chien. Thickness 37 to 56 feet.

Named for outcrops at Shakopee, Scott County, Minn.

†Shakopee Group[1]

Ordovician: Minnesota.

Original reference: F. W. Sardeson, 1924, Pan-Am. Geologist, v. 41, p. 107–122.

**Shaktolik Group[1]**

Lower Cretaceous: Central western and central Alaska.

Original reference: P. S. Smith and H. M. Eakin, 1911, U.S. Geol. Survey Bull. 449, p. 57.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, pl. 1 (facing p. 246). Age given as Lower Cretaceous on correlation chart.

T. G. Payne, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–84. Mostly marine. Group divided into (descending) Kaltag formation (nonmarine), Nulato, and Melozi formations (marine) in Koyukuk geosyncline and Hogatza uplift areas.

J. M. Hoare and W. L. Coonrad, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–292. Group, in Russian Mission quadrangle, comprises part of rocks mapped and described by Harrington (1918, U.S. Geol. Survey Bull. 683) north of the Yukon as Upper Cretaceous. Rocks described by Harrington that are included in group are interbedded sandstone, shale, "argillite," grit, and conglomerate. They are mapped on basis of Harrington's field notes and on basis of photogeologic interpretation. Tuffaceous, "argillaceous," and siliceous rocks as well as "associated grit and conglomerate" mapped by Harrington as Upper Cretaceous are probably of Early Cretaceous (Neocomian) age or older and do not belong to Shaktolik group. Fossils indicate Shaktolik is late Early Cretaceous (Albian) age. Not subdivided in this area. Correlative with lower part of Kuskokwim group.

Named after Shaktolik River which affords good section of the beds. In Lower Yukon River, Norton Bay-Nulato, and Koyukuk River regions.

Shamokin Black Shale Member[1] (of Marcellus Formation)

Middle Devonian: Central Pennsylvania.

Original reference: Bradford Willard, 1935, Geol. Soc. America Bull., v. 46, Proc. Paleont. Soc. Feb. 28, p. 202–203.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 173. Includes a dark coquinite. Usually lithologically indistinguishable from Mahanoy black shale member above unless intervening sandy members are present.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 4, 27. In Juniata, Mifflin, and Perry Counties, the Marcellus is subdivided into (ascending) Shamokin shale, Turkey Ridge sandstone, and Mahanoy shale members. Thickness 82 feet at East Waterford section.

Named for Shamokin Creek in western part of Northumberland County.

Shandon Formation

†Shandon Quartzite[1]

Upper Cambrian: Southwestern New Mexico.

Original reference: C. H. Gordon, 1907, Jour. Geology, v. 15, p. 91–92.

R. H. Flower, 1958, Roswell Geol. Soc. Guidebook 11th Field Conf., p. 65–66. Discussion of Cambrian-Mississippian beds of southern New Mexico. Here are included basal sandy beds of the Paleozoic which lies between the Precambrian and the El Paso. They are conspicuous dark-weathering beds, appearing black between the tan El Paso and the Precambrian which is pink and granitic. These beds were formerly known as Shandon quartzite in New Mexico, but this name was suppressed in favor of older name Bliss sandstone because they were believed to be identical. Bliss has long been considered Cambrian. Discovery of Canadian fossils in the Bliss in Van Horn region has raised question as to whether whole of formation might be Ordovician. In Caballo Mountains, Mud Springs Mountain, and Tonuco Mountain, the so-called Bliss consists of two parts. Lower unit is of very late Franconian age. Above is 70 feet of dominantly very thin bedded sands and glauconites, somewhat calcereous, and with a narrow but thin conspicuous zone of green silt near top which yields *Dictyoncma flabelliforme* var. angelicum. Term Shandon formation is applied to this unit. The Shandon here contains a hiatus, embracing Trempealeauan time, upper Upper Cambrian and Canadian deposition begins with a conspicuous coarse crossbedded sandstone.

Named for Shandon, eastern part of Sierra County.

**Shannon Sandstone Member** (of Cody Shale)

Shannon Member (of Eagle Formation)

Shannon Sandstone Member (of Steele Shale)[1]

Upper Cretaceous: Central Wyoming.

Original reference: C. H. Wegemann, 1911, U.S. Geol. Survey Bull. 452, p. 43, 47.

C. J. Hares and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 51. Stratigraphic section [southeastern part of Wind River Basin and adjacent areas in central Wyoming] shows Shannon sandstone member of Cody shale. Occurs in upper part of formation. Term Cody shale replaces terms Carlile shale, Niobrara shale, and Steele shale as used in this area by Hares (1916, U.S. Geol. Survey Bull. 641–I).

J. M. Parker, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 90–102. Reallocated to member status in Eagle formation in Powder River Basin. Subsurface cross section shows that the Shannon extends into Montana. Stratigraphic unit terms Lewis, Mesaverde, Steele, Cody, Ferguson, and Ash Creek should not be used in Powder River Basin.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 49, pls. Described in Buffalo-Lake De Smet area, Johnson and Sheridan Counties, Wyo., where it is member of Cody shale. Consists mainly of nonresistant fine-grained light-gray sandstone with thin partings of dark-gray shale. Thickness 215 feet near Elgin Creek. Separated from underlying Niobrara shale member by unnamed shale and sandstone member; underlies unnamed upper shale member.

Shannondale Limestone Member (of Benbolt Formation)

Middle Ordovician: Southwestern Virginia.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 833, 834–835, 868–869, 870, 871, 884 (fig. 3). In Tazewell County the strata embraced by the Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Shannondale limestone member is applied to zones 11 and 12. These comprise the second coarse-grained limestone below and the *Opikina* beds, which in type locality are 19 and 60 feet thick respectively. Maximum thickness 125 feet. Underlies Burkes Garden member (new); overlies Peery limestone member (new).

Type section: About three-fourths mile south of Shannondale, Tazewell County.

Shannon Run Limestone (in Washington Formation)[1]

Permian: Northern West Virginia.

Original reference: E. L. Core, 1929, West Virginia Acad. Sci. Proc., v. 3, p. 205.

Named from its exposure on Shannon Run, 2 miles west of Mount Morris, Monongalia County.

**Shark River Marl**[1]

Eocene, middle: Northeastern New Jersey.

Original reference: T. A. Conrad, 1865, Acad. Nat. Sci. Philadelphia Proc., v. 17, p. 70–73.

H. G. Richards, 1945, Geol. Soc. America Bull., v. 56, no. 4, p. 402. There is no evidence, faunal or stratigraphic, for an unconformity between the Manasquan and Shark River formations (Eocene). It is more probable that these two formations represent a single unit.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 8 (fig. 4), 59–61. Originally described as separate formations, Manasquan and Shark River marls are now thought to be equivalent. Manasquan-Shark River formation is reported to overlie conformably the Vincentown and dips on average about 15 feet per mile southeast. No good exposures of the formation occurs in which both upper and lower limits are exposed; hence, thickness is not known but is probably 25 to 30 feet. Chart shows Shark River-Manasquan stratigraphically below Kirkwood formation.

Typically developed in valley of Shark River, Monmouth County.

Sharon Clay[1]

*See* Sharon cyclothem.

**Sharon Conglomerate Member** (of Pottsville Formation)[1]

Sharon Conglomerate (in Pottsville Group)

Pennsylvanian: Western Pennsylvania, Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. P. Lesley, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$, p. 319–333.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 141. Conglomerate is at base of Pottsville formation in Ohio. Varies from medium-grained sandstone to coarse pebbly conglomerate, very loosely cemented. Deposits occupy broad, deep depressions, resembling erosion valleys, cut in Mississippian floor; erratic in distribution; vary from 10 to 250 feet in thickness.

J. O. Fuller, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 159–176. Basal Pennsylvanian Sharon conglomerate of Ohio lies disconformably on even-bedded marine Mississippian shale and sandstone, in relationship similar to its correlatives, the Olean of New York and the Mansfield of Indiana. Crops out in three separate areas: A, B, and C. A covers about 150 square miles in Ohio and is continuation from type area in Mercer County, Pa.; B covers about 2,400 square miles and is separated from area A by the 12-mile-broad Grand River valley; C. covers about 450 square miles in south-central Ohio and is separated from areas A and B by an area about 100 miles along the strike in which the Sharon is lacking and basal Pennsylvanian is a younger formation than the Sharon. This paper deals chiefly with area B in which mapping has been most detailed. In this area, the Sharon is dominantly an orthoquartzite; long narrow belts of conglomerate with a southerly trend lie in the orthoquartzite. It is difficult to separate Sharon orthoquartzite phase from Massillon sandstone (orthoquartzite) when Sharon shale is absent; hence, many sections of sandstone have been classed as Sharon when actually both Sharon and Massillon are present; also lack of recognition that Sharon is dominantly orthoquartzite instead of conglomerate has caused much of orthoquartzite away from conglomerate belts to be classed as Massillon rather than Sharon. This latter fact supported idea of a formation confined to long narrow depressions. Detailed mapping has established the Sharon as a sheetlike deposit with fairly flat top and an irregular base, caused by filling of irregular topography of Mississippian surface. Thickness of sheet of orthoquartzite in area B, 0 to 170 feet. Source of conglomerate and environment of deposition discussed.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 68. In extreme western and northwestern Pennsylvania, and also in southwestern Pennsylvania, the Sharon conglomerate [conglomerate sandstone] forms basal Pottsville but is thought to be absent in other areas.

Type area: Sharon, Mercer County, Pa.

Sharon cyclothem

Pennsylvanian (Pottsville Series): Eastern Ohio.

N. K. Flint, 1951, Ohio Geol. Survey Bull. 48, p. 21. Consists of (ascending) Sharon sandstone, shale, and conglomerate, Sharon clay, Sharon (No. 1) coal, unnamed shale, Sharon ironstone, marine. None of named units definitely identified in Perry County [this report].

Name derived from Sharon, Mercer County, Pa.

Sharon Group[1] or Series[1]

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 474–477, 489.

Named for Sharon, Mercer County, Pa.

Sharon Sandstone[1]

*See* **Sharon Conglomerate Member** (of Pottsville Formation).

†Sharon Shale Member (of Pottsville Formation)[1]

Lower Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology of Pennsylvania, v. 2, pt. 1, p. 474–477, 489.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 67–70. In this report, term Sharon (Pottsville series) is used to include the rock strata in interval between top of Sharon No. 1 coal and base of Sciotoville clay. Thickness about 25 feet.

Named for Sharon, Mercer County, Pa.

**Sharon Syenite**[1]

Devonian(?): Southeastern Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 182–184, map.

Well developed in town of Sharon, Norfolk County.

Sharon Mountain Quartz Diorite[1]

Precambrian(?): Northwestern Connecticut.

Original reference: W. M. Agar, 1929, Am. Jour. Sci., 5th, v. 17, p. 202–238.

Occurs only in range of hills between Sharon, Litchfield County, and Housatonic River.

†Sharon Springs Formation

Middle Devonian: East-central New York.

Winifred Goldring and R. H. Flower, 1942, Am. Jour. Sci., v. 240, no. 10, p. 677–678, 679, 689–690, 694. Name applied to 20 feet of siliceous shale in vicinity of Sharon Springs, set off from Esopus below and Schoharie above by comparatively thick beds of glauconite. Beds were formerly included in Esopus shale. Both at top and base, contact may be gradational, and exact position of its boundaries is a matter of opinion for many sections in the Helderbergs and in Hudson Valley. In Port Jervis region, has estimated thickness of 200 to 225 feet.

Winifred Goldring and R. H. Flower, 1944, Am. Jour. Sci., v. 242, no. 6, p. 340. Preoccupied name Sharon Springs replaced by term Carlisle Center.

Named for exposures near Sharon Springs, Schoharie County.

**Sharon Springs Member** (of Pierre Shale)[1]

Upper Cretaceous: Northwestern Kansas, eastern Colorado, western and northwestern Nebraska, and southeastern South Dakota.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7.

W. V. Searight, 1938, Iowa Acad. Sci. Proc., v. 45, p. 137. Geographically extended into South Dakota where it underlies Gregory zone [marl] of Sully formation. Overlies Niobrara. Considered contemporaneous with beds described by Searight (1937) as lower Gregory.

A. L. Moxon, O. E. Olson, and W. V. Searight, 1939, South Dakota State Coll. Agriculture and Mech. Arts Tech. Bull. 2, p. 20–22. In South Dakota, all beds above the Niobrara and below Gregory marl are included in Sharon Springs. Member as here identified consists of beds of dark bituminous shale in lower part, and dark-rusty-weathering beds above. Thicknesses: 7 feet at Yankton; 155 feet at mouth of White River and eastward; possibly 200 to 250 feet north of Belle Fourche.

J. P. Gries and E. P. Rothrock, 1941, South Dakota Geol. Survey Rept. Inv. 38, p. 8 (fig. 2), 9–11, 31–32; J. P. Gries, 1942, South Dakota Geol. Survey Rept. Inv. 42, p. 6 (fig. 2), 7–9. Beds comprising "upper" member (Moxon and others, 1939) actually lie above Gregory marl and are characterized by absence of fish remains. The Sharon Springs of Moxon and others and the "upper beds" are included in redefined Gregory member. Sharon Springs of this report underlies Gregory member (redefined) and overlies Niobrara formation. Divisible into a lower zone, characterized by fish remains and an upper zone in which fish remains are absent. Thickness 35 feet at Rosebud Bridge, Gregory County.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2346. Restricted to the fish-bearing bituminous shale that underlies Gregory member and overlies Niobrara formation.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Columnar section shows Sharon Springs shale member underlying Weskan member and overlying Smoky Hill chalk.

H. E. Simpson, 1960, U.S. Geol. Survey Prof. Paper 328, p. 31–34. Described in Yankton area, South Dakota and Nebraska, where it is 5½ to 11 feet thick and consists of a lower bituminous unit and an upper nonbituminous unit. Underlies Gregory member; overlies Smoky Hill chalk member of Niobrara formation.

First described and mapped at and around Sharon Springs, Wallace County, Kans.

**Sharp Mountain Member** (of Pottsville Formation)

Sharp Mountain Formation (in Pottsville Group)

Lower and Middle Pennsylvanian: Eastern Pennsylvania.

G. H. Wood, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2674 (fig. 3), 2676–2678, 2679; 1957, U.S. Geol. Survey Coal Inv. Map C–43, sheet 1. Consists chiefly of cobble and coarse pebble conglomerate and fine to coarse sandstone and siltstone, shale, and coal; basal conglomerate beds are coarser and topographically more conspicuous than the other beds in member and are followed by several sequences of conglomeratic sandstone, sandstone, siltstone, shale, and coal intercalated with sequence of finer pebble conglomerate. Comprises upper 280 feet of formation at type section. Conformably overlies Schuylkill member (new). In many localities in the southern anthracite field, basal beds are 30 feet more or less above the Lykens Valley No. 1 coal bed; at type section, they are 40 to 70 feet above the Lykens Valley No. 1 coal; such variations in stratigraphic interval may be due either to local intertonguing of the fine conglomerate and sandstone and shale facies of the Schuylkill member with coarser conglomerate and sandstone facies of the Sharp Mountain. Upper contact of Sharp Mountain with post-Pottsville rocks is at base of carbonaceous shale beneath the Buck Mountain coal bed which rests conformably on the conglomerate; contact is sharp and even.

Carlyle Gray, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Pottsville group in anthracite region.

Type section: Included in Pottsville reference section which is in roadcut on east side of U.S. Highway 122, about 150 feet farther east than original type section of Pottsville which is on eastern side of Pennsylvania Railroad cut through water gap south of Pottsville, Schuylkill County.

Sharps Formation (in White River Group or Arikaree Group)

Miocene: Southwestern South Dakota.

J. C. Harksen, 1960, Geology of the Sharps Corner quadrangle, South Dakota (1:62,500): South Dakota Geol. Survey. Composed of massive poorly consolidated compact pinkish-tan silt with gray calcareous potato-ball concretions; some lenses of impure limestone; clastic and chalcedonic dikes present throughout formation but not as common as in underlying Brule; channel sands and gravels present at several levels. Thickness approximately 340 feet. Includes Rockyford ash member (new) at base. Underlies Monroe Creek formation of Arikaree group. White River group.

S. G. Collins, 1960, Geology of the Patricia quadrangle, South Dakota (1:62,500): South Dakota Geol. Survey. Lowermost formation in Arikaree group. Thickness at least 153 feet. Underlies Monroe Creek formation. Contact with Monroe Creek only approximately located; practicality of separating the two units in future mapping farther east questionable.

Named for exposures 8 miles north and 5 miles west of Sharps corner.

Sharpsdale Formation

Pennsylvanian: Southwestern Colorado.

D. R. Williamson and Lorraine Burgin, 1950, Colorado School Mines Mineral Industries Bull., v. 3, no. 1, p. 11 (chart), 12. About 400 feet of red-gray siltstone, sandstone, and conglomerate that contains several fossiliferous marine limestones. Transitional into overlying Madera formation; overlies Kerber formation.

May extend as far north as Hayden Pass and as far south as New Mexico border. Type locality and derivation of name not stated.

Sharpsville formational suite[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 131, table facing p. 131.

**Sharpsville Sandstone** (in Cuyahoga Group)

Sharpsville Sandstone Member (of Cuyahoga Formation)[1]

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

Original reference: I. C. White, 1880, Pennsylvania 2d Geol. Survey Rept. $Q_3$, p. 61–62.

H. P. Cushing, Frank Leverett, and F. R. Van Horn, 1951, U.S. Geol. Survey Bull. 818, p. 50–52. Cuyahoga, in its typical area, is elevated to group rank and its subdivisions (ascending) Orangeville shale, Sharpsville sandstone, and Meadville shale are treated as formations. Thickness 25 to 50 feet in Cleveland, Ohio, district. Contacts with Orangeville and Meadville transitional.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 41. Included in Tinkers Creek shale facies (new) of Cuyahoga formation.

Wallace de Witt, Jr., 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 21. Sharpsville is composed of varying amounts of flaggy sandstone and interbedded sandy shales. Base is drawn at first massive sandstone in shale section above Berea sandstone or Corry sandstone. Locally, near Warren, Ohio, and Meadville, Pa., lower part of Sharpsville is composed almost completely of massive sandstone and can be used for local correlation. Elsewhere the Sharpsville is composed of thin flaggy sandstones, and boundaries can not be drawn definitely. Base of Sharpsville is irregular. In some areas, flags of the Sharpsville are almost in contact with the Berea, but in some areas a thick shale separates the two units. In vicinity of Titusville, Pa., the Sharpsville merges with underlying Orangeville shale.

J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 45. In Ohio, base of Sharpsville is generally placed at base of first massive bed of siltstone in shale sequence above the Berea except in those areas where the Aurora or Chardon member is present near base of Orangeville shale. In northwestern Pennsylvania, the Sharpsville is first massive siltstone above Bartholomew siltstone member of Orangeville shale, except in local area in Crawford County where the Bartholomew is absent and its place is occupied by Hungry Run sandstone member.

E. J. Szmuc, 1958, Dissert. Abs., v. 18, no. 6, p. 2109. In northern Ohio, eight members recognized in Cuyahoga formation. They are (ascending) Orangeville, Sharpsville, Strongville (new), Meadville, Rittman, Armstrong, Wooster (new), and Black Hand.

Named from village of Sharpsville on Shenango River, in Mercer County, Pa.

Shasta Lavas

Pliocene: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

**Shasta Series**[1]

Shasta Group

Lower Cretaceous: California and Oregon.

Original reference: W. M. Gabb, 1869, California Geol. Survey Pal., v. 2, p. vii, xvi, 129, 133.

F. M. Anderson, 1938, Geol. Soc. America Spec. Paper 16, p. 37–86, pl. 84. Series in Great Valley sections in California has been divided into two major groups, primarily upon paleontological grounds, but division is supported by other important criteria, found in their distribution and lack of coincidence, and in the thick beds of conglomerate usually lying between them, and in some places by direct evidence of disconformity and transgression. Later, and somewhat thicker, part of series constitutes Horsetown group and lower part is Paskenta group. In its more complete sections, Shasta series is set off from underlying Knoxville and overlying Chico series by well-marked unconformities.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 129, 130 [preprint 1941]. Referred to as Shasta group. The divisions of Shasta, the Paskenta and Horsetown, classed as groups by some authors, are here considered to be stages. Mid-Cretaceous disturbance separates Shasta group from Upper Cretaceous Pacheco group (new). Group in northern Coast Ranges has maximum thickness of over 20,000 feet; maximum thickness in central Coast Ranges not known, but in some localities group is more than 5,000 feet thick.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 183, 184 (fig. 68) [preprint 1941]; 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 914–937. Paskenta group of Shasta series overlies Newville group (new) of Knoxville series. Where Shasta is in contact with Knoxville, it is generally unconformable, but in places it overlaps the Knoxville and rests directly upon pre-Knoxville. Lower Cretaceous.

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 287–2891. Shasta series, in Sacramento Valley south of Willows, Glenn County, underlies Venado formation (new) of Chico series. Evidence of mid-Cretaceous disturbance of Santa Lucian orogeny, postulated by Taliaferro as separating Chico and Shasta series and as basis for his Pacheco and Asuncion groups respectively, is meager in this area.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 31–39, pls. 6, 7, 11, 12. Shasta series as used in this report [Coast Ranges immediately north of San Francisco Bay region] includes Knoxville and Horsetown(?) formations. Rocks of series are mainly thinly laminated siltstones with interbedded medium-grained brownish-gray sandstones, lenses of conglomerates, and occasional thin layers of limestone. These are entirely marine and nearly 19,000 feet thick. No definite depositional base of Knoxville observed in area, but formation is in contact with Franciscan group at many places such as south of St. John Mountain, west of Oakville, and in area west and north of Capell Valley. The contacts are along thrust or normal faults, Underlies Chico formation, erosional unconformity. Jurassic and Lower Cretaceous.

W. P. Irwin, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2284–2297. Discussion of Franciscan group in Coast Ranges and its equivalents in Sacramento Valley. Shasta series has been divided into a lower and upper part, Paskenta and Horsetown formations, respectively. Contact between Shasta and Knoxville is marked by a fairly abrupt and complete change in fauna, and at many places by beds of conglomerate. The concept of a "basal conglomerate" has much influenced the subdivision of the Sacramento Valley section. However, along much of Sacramento Valley, the transition from one unit to the other is one of nearly continuous deposition and, judged from broad structural conformity, was accomplished with little disturbance. Strata referred to Shasta series have higher ratio of sandstone to shale than has Knoxville formation. Average total thickness of the Shasta is about 10,000 feet, and is divided about equally between lower and upper faunal divisions, the Paskenta and Horsetown. Term Shasta series has generally been considered as including only Lower Cretaceous strata, but along much of west side of Sacramento Valley there has been little agreement as to contact between Shasta series and Upper Cretaceous strata. This lack of agreement casts doubt as to validity of a hiatus many earlier workers have postulated between the Lower and Upper Cretaceous. Some geologists have placed contacts at base of Venado sandstone (Kirby, 1943). Others have placed it lower in the section, at base of a conglomerate. The conglomerate and Venado are separated by thickness of several thousand feet of shale referred to by Kupper (1956) as Antelope shale of Taliaferro. If Shasta series is to be restricted to Early Cretaceous, the base of the conglomerate below the so-called Antelope shale fo Taliaferro appears to be a better choice for its upper limit, and is so considered in this paper. Evidence indicates that Franciscan group has been deposited contemporaneously with the Knoxville, Paskenta, Horsetown, and lower Upper Cretaceous strata.

Named for development of the rocks in Shasta County, Calif.

Shasta Bally Quartz Diorite

[Jurassic]: Northern California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 5–6. Name applied to quartz diorite in Shasta Bally pluton. Potassium-argon dating gives age of 134 million years.

Batholith is southernmost of granitic masses exposed in Klamath Mountains, northern California. Specimens collected 1 mile north of Ono, Shasta County.

†Shastan System[1]

†Shastian System[1]

Lower Cretaceous: Western North America.

Original reference: T. C. Chamberlin and R. D. Salisbury, 1906, Geology, v. 3, p. 107–137.

Shattuck Member (of Queen Formation)

Permian (Guadalupian): New Mexico and Texas.

N. D. Newell and others, 1953, Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 15 (fig. 6), 43 (fig. 26), 44 (fig. 27), 45–46. Name applied to persistent sandstone in upper part of Queen formation. Thins rapidly from 100 feet at Wind River Gap to a series of small lenses and pockets of sandstone at top of Goat Seep reef, about 1 mile down North McKittrick Canyon. Underlies Seven Rivers formation. Mapped by King (1948, U.S. Geol. Survey Prof. Paper 215) as basal sandstone of Carlsbad group.

Named from outcrops along Shattuck Valley escarpment in vicinity of Devils Den, El Paso quadrangle, New Mexico.

**Shawangunk Conglomerate[1]**

Shawangunk Formation

Silurian: Southeastern New York, northern New Jersey, and Pennsylvania.

Original reference: W. W. Mather, 1840, New York Geol. Survey 4th Rept., p. 246–250.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Albion and Niagaran series.

K. L. Glenby, 1942, Geological Review, v. 2, no. 2, p. 11, 12, 13. Conglomerate overlies Ordovician Hudson River shales in Shawangunk Mountains.

Bradford Willard, 1943, Geol. Soc. America Bull., v. 54, no. 8, p. 1089. Shawangunk formation unconformably overlies Martinsburg group in northern New Jersey and at Otisville, N.Y. Contact not exposed at Delaware Water Gap.

P. K. Sims and P. E. Hotz, 1951, U.S. Geol. Survey Bull. 978–D, p. 104–105. Thickness 250 to 300 feet at Shawangunk mine, Sullivan County, N.Y., section does not include approximately 475 feet of lower part of the Shawangunk. Underlies High Falls shale; unconformably overlies Ordovician slates, shales, and sandstone.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation, as mapped, consists of light-gray to tan thick-bedded impure quartzitic sandstone and conglomerate with thin shale interbed. In eastern Pennsylvania only.

Named for occurrence on Shawangunk Mountain, Ulster County, N.Y.

**Shaw Mountain Formation**

Lower or Middle Silurian: Central Vermont.

L. W. Currier and R. H. Jahns, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1492, 1496–1501. Thin group of beds with three lithologic varieties; at base is massively bedded quartz conglomerate which grades upward into papery to platy soda rhyolite tuff; near top is white to slightly bluish crinoidal limestone occurring as thin beds and lenses usually interbedded with the tuff. Thickness difficult to determine, maximum total probably about 900 feet. Underlies Northfield slate unconformably; overlies Cram Hill formation (new) unconformably. Ordovician(?).

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Middle Ordovician.

W. H. Bucher, 1953, Geol. Soc. America Bull., v. 64, no. 3, p. 283. Devonian.

W. M. Cady, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–79. In Montpelier quadrangle, underlies Northfield slate; overlies Moretown formation. Silurian.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, pl. 3. Lower and Middle Silurian.

Named for good exposure near base of north slope of Shaw Mountain, 2 miles south-southwest of Northfield, Barre quadrangle. Also occurs in Randolph and Montpelier quadrangles, and is traced northward by reconnaissance to Quebec border.

**Shammut Amygdaloid[1]**

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Shawmut mine, Houghton County.

**Shawmut Conglomerate**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane, 1911, Michigan Geol. and Biol. Survey Pub. 6, geol. ser. 4, p. 527, 536, 546, 554, pls. 11, 12, fig. 50.

Named for occurrence at Shawmut mine, Houghton County.

**Shawmut Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burkank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Shawmut mine, Houghton County.

Shawmut Group[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. O. Crosby, 1877, Geol. map of eastern Mass.

Occurs near Boston, on Marblehead Neck and neighboring islands, and in basin of Parker River, Boston Basin region.

**Shawnee Group**[1]

Shawnee Formation[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 93–94.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 48 (fig. 10), 159–199. Redefined group comprises (ascending) Oread limestone, Kanwaka shale, Lecompton limestone, Tecumseh shale, Deer Creek limestone, Calhoun shale, and Topeka limestone. Overlies Douglas group; underlies Wabaunsee group.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, p. 28–29, pl. 5. Group in Missouri comprises (ascending) Kanwaka shale, Lecompton limestone, Tecumseh shale, Deer Creek limestone, Calhoun shale, Topeka limestone, Severy shale, Howard limestone, White Cloud shale, Happy Hollow limestone, Cedar Vale shale, Rulo limestone, Silver Lake-Auburn shale interval, Reading limestone, Harveyville shale, Elmont ("Emporia") or Preston limestone, and Willard shale. Succession of beds shown on plate 5 from base of Kanwaka to top of Howard limestone is fairly accurate and beds are regular with the limits indicated. Above Howard limestone, outcrops are so restricted and so widely scattered, that some errors may be present. There are no complete exposures of the White Cloud. Between top of White Cloud shale and Reading limestone there is discrepancy in nomenclature, thickness and lithology in section in plate 5 and sections published by Kansas and Nebraska Geological Surveys. Overlies Douglas group; underlies Wabaunsee group.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2034–2036. Interstate agreement recognized Shawnee group as comprising interval from base of Oread formation to top of Topeka. Agreed that where stratigraphic variation calls for omission or combination of stratigraphic terms, appropriate adjustment of nomenclature is to be employed.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii (fig. 3), 16–18. Shawnee group redefined for Missouri to accord with interstate agreement. Expanded at base to include Oread limestone and restricted above to exclude beds above the Topeka.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 15–23, fig. 5. Group in Iowa includes interval from base of Oread limestone to top of Topeka. Formations are persistent although members are not everywhere recognized.

Type locality: Shawnee County, Kans.

†Shawnee Limestone (in Allegheny Formation)[1]

Shawnee limestone member

Pennsylvanian: Southeastern Ohio.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, p. 888, 895, pls.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 84, 86–87. Member of Bolivar cyclothem in report on Athens County. Proposed that name Shawnee be reinstated to good standing and be used for the fresh-water limestone associated with Bolivar underclay and that name Upper Freeport, as applied to limestone, be restricted to limestone associated closely with Upper Freeport underclay. Shawnee limestone is stratigraphically below Upper Freeport shale and sandstone, and the Upper Freeport limestone is above the same shale and sandstone.

Named for Shawnee, Perry County.

Shawnee Sandstone[1]

Pennsylvanian: Oklahoma.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 108. Abandoned by Oklahoma Geological Survey. Named by Taff (1899, U.S. Geol. Survey 19th Ann. Rept., pl. 6). A Pennsylvanian limestone in Ohio was given name Shawnee in 1878. Haworth named Shawnee formation in Kansas in 1898 and this unit has since been raised to group status. Shawnee sandstone of Taff was named Thurman sandstone in text of his [Taff's] 1899 report (p. 439).

Shawneetown Coal Member (of Carbondale Formation)

Pennsylvanian: Eastern and southern Illinois (subsurface).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), pl. 1. Proposed for coal believed to be lower of two coals formerly called No. 2 A (Harrison, 1951, Illinois Geol. Survey Rept. Inv. 153). Not recognized in outcrops but encountered at depth of 543 feet 10 inches in drill hole. In southern Illinois, stratigraphically above Colchester (No. 2) coal member and below Roodhouse coal member (new). In eastern Illinois, occurs above Colchester (No. 2) coal member and below Summum coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Union Colliery Co. drill hole 28, sec. 23, T. 9 S., R. 9 E., Gallatin County.

Shaw Point cyclothem

Pennsylvanian: Southwestern Illinois.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 12, 13. In Macoupin County, four cyclothems are recognized of which the Shaw Point is fourth in series (ascending). Occurs above the Macoupin. Name credited to J. R. Ball in manuscript report.

Type locality and derivation of name not given.

Shaws sandstone member[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 132, table opposite p. 61.

Well exposed in ravine behind Shaws brick schoolhouse on Meadville-Franklin Highway, Meadville quadrangle.

**Shea Basalt** (in Ash Creek Group)

Shea Diabase

Precambrian (Yavapai Series): Central Arizona.

L. E. Reber, Jr., 1938, Arizona Bur. Mines Bull. 145, Geol. Ser. 12, p. 58, 61, pl. 8. Diabase is a dark moderately fine-grained dioritic rock.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 12–13, pl. 1. Term Shea diabase modified to Shea basalt. Included in Ash Creek group (new). Composed mostly of lava flows and intercalated tuffaceous beds, and in Black Canyon, many coarse fragmental deposits contain vesicular fragments as much as 6 inches in diameter. Basalt is a dark-green to black rock. Flows commonly contain quartz and chlorite amygdules and, in a few places, pillow lavas. Interbedded tuffaceous sedimentary rocks commonly thin, from 2 to 4 feet thick. In northern exposures, tuffaceous rocks range from 20 to 40 feet in thickness. These sedimentary rocks are dark green to greenish gray. Massive lava from thick flows has diabasic texture. Overall thickness on north side of Black Canyon about 2,000 feet. Underlies Deception rhyolite; overlies Buzzard rhyolite (new).

In vicinity of Shea mine, Jerome district, Yavapai County. Crops out southeast and east of Mingus Mountain. Southeastern exposures appear north and south of Black Canyon and in the canyon west of the Verde fault. Eastern exposures form continuous belt northward from Oak Wash to Mescal Gulch.

**Shedhorn Sandstone**

Permian: Southwestern Montana and northwestern Wyoming.

E. R. Cressman and R. W. Swanson *in* V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2852–2854; 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 31–33, pl. 3. Medium- to very fine-grained quartz sandstone that contains small amounts of black chert and phosphate grains and amber to white phosphatic shell and bone fragments; some sandstone slightly glauconitic. At type locality, consists of lower member 17 feet thick and upper member 78 feet thick, separated by tongues of Retort and Tosi members (both new) of Phosphoria formation; at this locality, sandstone is underlain by Quadrant quartzite and overlain by Dinwoody formation. In Madison Range and adjacent areas, Shedhorn is medium to brownish gray in contrast to the light gray of quartz sandstone in underlying Quadrant quartzite.

Type section: In cliffs on north side of Indian Creek in SW¼ sec. 20, T. 8 S., R. 2 E., Madison County, Mont., about one-fourth mile west of mouth of Shedhorn Creek. In Montana, Shedhorn extends east to Yellowstone River, north to Three Forks, northwest to Garrison in Garnet Range, and west to Dalys Spur; thin tongues extend southeast in Wyoming to Wyoming and Salt River Ranges.

**Shedroof Conglomerate**

Precambrian: Northeastern Washington and western Idaho.

C. F. Park, Jr., and R. S. Cannon, Jr., 1943, U.S. Geol. Survey Prof. Paper 202, p. 6 (table), 7–9, pl. 1. Name applied to a coarse poorly sorted gray-brown conglomerate. Thickness 3,000 to 11,000 feet. Unconformably overlies Priest River group(?); underlies and is gradational into Leola volcanics (new).

Named for exposures on Shedroof Mountain, Pend Oreille County, Wash.

**Sheep Bay Granite**[1]

Paleozoic(?): Southeastern Alaska.

Original reference: U.S. Grant and D. F. Higgins, 1910, U.S. Geol. Survey Bull. 443, p. 43, 46.

Occupies northeastern third of point of land separating Port Gravina from Sheep Bay, Prince William Sound region.

Sheep Canyon Basalt (in Buck Hill Volcanic Series)

Sheep Canyon Basalt (in Pruett Formation or Tuff)

Oligocene and younger(?): Western Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Lava flows intercalated with Pruett tuff (new) are (ascending) Crossen trachyte, Sheep Canyon basalts, and Potato Hill andesite (all new).

S. S. Goldich and C. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Fall Field Trip, Oct. 29–31, p. 14 (table 1), 17 (fig. 3), 19–20; 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1153–1155. In Sheep Canyon (type area), the Sheep Canyon basalt consists of four flows separated by beds of tuff and tuffaceous limestone. Thickness of flows together with intervening tuff and tuffaceous limestone, 234 feet. Flows rest on both Crossen trachyte and on Pruett fresh-water limestone underlying the trachyte. Thick flows assigned to Sheep Canyon basalt occur on Pruett tuff in Elephant Mountain where there are three flows totaling 380 feet. Underlies Potato Hill andesite. Eocene(?).

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 547–549, pl. 1. Described in Cathedral Mountain quadrangle. Rank raised to formation in Buck Hill volcanic series. Term Pruett restricted to the tuff, sandstone, conglomerate, and limestone below Crossen trachyte which underlies Sheep Canyon basalt. Underlies Potato Hill andesite. Thickness 0 to 454 feet. Oligocene and younger(?).

Named for Sheep Canyon, a reentrant of Calamity Creek valley in Alpine quadrangle, Brewster County.

Sheep Canyon Granite

Precambrian: Southeastern Arizona.

F. F. Sabins, 1957, Geol. Soc. America Bull., v. 68, no. 10, p. 1321–1322, pl. 1. Gneissose granite. Very pale orange on fresh surfaces and weathers light brown. Bounded on the west by a Tertiary stock of quartz monzonite, and on south by Pinal schist. Overlapped by alluvium on the north and east. Oldest of the Precambrian igneous rocks in area.

Crops out over area of about 4 square miles in northwest corner of Cochise Head quadrangle, Cochise County. Exposure cut by steep-sided gorge of Sheep Canyon.

Sheep Creek Conglomerate[1]

Upper Paleozoic or Mesozoic: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 91, map.

Exposed on east side of Sheep Creek, Stevens County, at international boundary.

**Sheep Creek Formation**

Sheep Creek Beds[1] or Group

Sheep Creek Formation (in Hemingford Group)

Miocene: Western Nebraska and eastern Wyoming.

Original reference: W. D. Matthew and H. J. Cook, 1909, Am. Mus. Nat. History Bull., v. 26, art. 27, p. 362–363.

A. L. Lugn, 1938, Am. Jour. Sci., v. 36, 5th ser., no. 213, p. 226, 227. Upper formation in Hemingford group (new). Thickness 140 feet. Contains *Stipidium* and *Berriochloa* fossil seeds. Unconformable above Marsland formation (new). Underlies Valentine formation of Ogallala group.

A. L. Lugn, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1254–1258, 1266 (table 2). Discussion of confusion in use of terms Snake Creek and Sheep Creek formation, both of which were named by Matthew and Cook and both of which have their type localities in south-central Sioux County, Nebr. The Sheep Creek beds were said to lie unconformably on lower Miocene, equivalent to the *Daemonelix* beds of Niobrara valley [Harrison formation]. Matthew and Cook considered the Snake Creek beds to be the remains of a formation which they regarded as an outlier of the Ogallala. The Snake Creek was said to lie on the eroded surface of the Sheep Creek beds. Later, confusion resulted especially because of the "mixed" faunal lists which have resulted from mixed collections from the Sheep Creek-Snake Creek locality. The typical "Snake Creek" formation, or at least the so-called "upper Snake Creek," is correlative with some part of upper Ogallala group. However "Snake Creek" has been incorrectly(?) applied to beds, mainly channel fills, as late as Pleistocene and to other beds as old as Miocene. Much of the Miocene "Snake Creek" or perhaps the so-called "lower Snake Creek" seems to be in part not Snake Creek at all but Sheep Creek channel beds in place and in proper stratigraphic sequence. Also, some of the Miocene and "Sheep Creek" vertebrate fossils collected from "Snake Creek" channel deposits have come from large blocks of Sheep Creek formation, which were broken away from banks of Snake Creek streams. These large blocks have dimensions of 10 to 20 feet or more and were never broken up or distintegrated by Snake Creek rivers. They lie buried in younger silt and sand, the true Snake Creek sediments, which are always channel-fill material. Sheep Creek formation consists of channel gravels and sands; fine silty sands, silt and clay, and harder caliche beds of widely ranging textural characteristics, all of which fill for the most part narrow valleys or ravines to depths ranging from 30 or 40 feet to 140 feet or more. These deposits, many of which are isolated and unconnected, are widespread in northwestern Nebraska. In central part of south half of Sioux County, the Sheep Creek extends continuously as a basin deposit of channel, flood-plain, and slack-water sediments over about 25 square miles. Total thickness of Sheep Creek exposed above unconformable contact on Harrison formation in type locality is more than 200 feet. Overlapping exposures in Dawes County indicate that fundamental formational entity includes about 70 feet of additional beds which are stratigraphically higher than uppermost Sheep Creek exposures in type locality. This does not include a still higher "member" to be described later. It is mainly this upper part of the Sheep Creek that has been called by some workers "lower Snake Creek beds." The distribution of this heretofore unrecognized member of the Sheep Creek seems to have been nearly the same as that of Marsland formation, and at present it overlies and extends beyond limit of most of the Sheep Creek valley fills more or less throughout areal extent of Hemingford group and in some areas rests on Harrison formation. Original definition of Snake Creek and Sheep Creek formations may be essentially valid and it is proposed to continue use of these names to correctly differentiated formations.

R. C. Cady, 1940, Am. Jour. Sci., v. 238, no. 9, p. 663–667. Includes Box Butte member (new) in uppermost part. Formation, exclusive of Box Butte member, fills narrow channels in Marsland formation.

M. K. Elias, 1941, Geol. Soc. America Spec. Paper 41, p. 126–132. As used by Nebraska Geological Survey, the Sheep Creek includes all higher rocks of Hemingford group between Marsland formation below and Ogallala group above. Comprises three members (ascending) Spottedtail (new), Sand Canyon (new), and Box Butte.

H. J. Cook, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 204. Sheep Creek group, as shown on generalized geologic section in type localities of late Tertiary deposits of northwestern Nebraska and eastern Wyoming, overlies Runningwater formation (new) of "Marsland" group and underlies Snake Creek beds of Ogallala group.

Named for Sheep Creek, Sioux County, Nebr.

Sheepeaters Basalt

Tertiary: Northwestern Wyoming.

R. E. Wilcox, 1944, Geol. Soc. America Bull., v. 55, no. 9, p. 1053–1054, 1059–1060, pls. 1, 2. Younger of two basalt flows not included in Gardiner River rhyolite-basalt complex (new)—that is, younger than Elkhorn basalt (new) and also younger than Cataract basalt (new) of Gardiner River rhyolite-basalt complex. Even-grained texture and columnar structure.

Typically exposed along Sheepeaters Cliffs on north side of Gardiner River, Yellowstone Park. Blankets entire northwest part of mapped area and crops out consistently at elevations near 7,300 feet at top of cliffs; forms walls of "The Amphitheater," an extinct waterfall of glacial tributary of the Gardiner just below Sevenmile Bridge. Outcrop continues along left bank of river almost without interruption to First Cataract where it apparently overlaps part of complex.

Sheep Mountain Quartzite[1] (in Missoula Group)

Precambrian (Belt Series): Western Montana.

Original reference: C. H. Clapp and C. F. Deiss, 1931, Geol. Soc. America Bull., v. 42, p. 683, fig. 2, 3.

D. A. Andrews, G. S. Lambert, and G. W. Stose, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 25. Missoula group comprises (ascending) Miller Peak, Hellgate, McNamara, and Garnet Range formations, and Sheep Mountain quartzite.

On upper slopes of Sheep Mountain, sec. 24, T. 15 N., R. 18 W., and sec. 30, T. 14 N., R. 17 W. In Missoula to Helena region.

**Sheep Mountain Quartz Latite** (in Potosi Volcanic Group)

Sheep Mountain Andesite (in Potosi Volcanic Series)[1]

Tertiary, middle or upper: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13, 93 (table 18), 124–132. Name Sheep Mountain quartz latite is applied to unit of dark quartz latites belonging to Potosi volcanic series and normally lying between Treasure Mountain rhyolite below and Alboroto rhyolite above. Lower contact regular; upper contact irregular. Erupted from at least four centers: San Cristobal quadrangle, Summitville quadrangle, Saguache quadrangle, and Del Norte quadrangle.

U. S. Geological Survey currently designates the age of the Sheep Mountain Quartz Latite as middle or late Tertiary. This designation is made on the basis of an age change of Potosi Volcanic Group.

Named for development under Sheep Mountain, northwestern part of Summitville quadrangle.

**Sheep Pass Formation**

Eocene: East-central Nevada.

W. M. Winfrey, Jr., 1958, Am. Assoc. Petroleum Geologists Rocky Mountain Sec., Geol. Rec., p. 77–82. Divided into six members (ascending): A, conglomerate breccia, 630 feet; B, interbedded fossiliferous limestones, shales and mudstones, 983 feet; C, clastic sequence of sandstones, siltstones, shales, and gritty conglomerates, 642 feet; D, homogeneous interval of white, siliceous, extremely fine-grained siltstones, in part calcareous, 731 feet; E, tan lithographic thickly bedded limestone, 90 feet; and F, siltstone-claystone beds, 147 feet. At type locality unconformably overlies Ely limestone (Pennsylvanian) and Chainman shale (Mississippian); unconformably underlies Oligocene(?) Garrett Ranch volcanic group (new).

Type section: Sheep Pass Canyon, sec. 12, T. 10 N., R. 62 E. and sec. 7, T. 10 N., R. 63 E., White Pine County. Exposed continuously along western flank of Egan Range for distance of 10 miles southwesterly from sec. 21, T. 11 N., R. 63 E.

Sheep Pen Sandstone[1] (in Dockum Group)

Upper Triassic: Northeastern New Mexico.

Original references (Sheep Pen Canyon): B. H. Parker, 1930, Kansas Geol. Soc. [Guidebook] 4th Ann. Field Conf., p. 19; 1933, Jour. Geology, v. 41, no. 1, p. 40–43.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 35 (table 2), 40–42. Uppermost formation in Dockum group. Consists of thin-bedded light-brown sandstone. As much as 107 feet thick. Overlies Sloan Canyon formation; underlies Exeter sandstone.

Type locality: E½NW¼ sec. 35, T. 32 N., R. 35 E., Union County. Named for Sheep Pen Canyon, which joins Cimarron Valley about one-half mile northwest of type locality.

Sheep Pen Canyon Formation

*See* Sheep Pen Sandstone (in Dockum Group).

†Sheep Rock Conglomerate[1]

Age(?) : Virginia.

Original reference: J. P. Lesley, 1873, Am. Philos. Soc. Proc., v. 12, p. 492–496.

Forms Sheep Rock between Big Tom's Creek and Little Tom's Creek, east of Gladeville (now called Wise), Wise County.

Sheeprock Group or Series

Precambrian: West-central Utah.

DeVerle Harris, 1958, Bringham Young Univ. Research Studies, Geology Ser., v. 5, no. 1, p. 6–8, pl. 1. Consists of phyllites, phyllitic quartzites, quartzites, graywackes, graywacke conglomerates, graywacke conglomerate semischists, and tillites(?). Includes Auts Canyon formation (new) below and Ekker formation (new) above. Total measured thickness of two formations is 9,718 feet. Base of group marked by plane of Sheeprock thrust in Dutch Peak area. Underlies Quaternary alluvium.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 17–19, 24, 128–138, pl. 1. Sheeprock series, in Sheeprock Mountains, is a 9,000- to 10,000-foot sequence of metasediments composed of slate, tillite, phyllite, quartzite, and conglomerate. Subdivided into—lower Sheeprock series, Dutch Peak tillite (new), and upper Sheeprock series. Oldest rocks exposed in Sheeprock Mountains; underlies Mutual(?) formation.

In Dutch Peak area, Sheeprock Range, Tooele County.

Sheepskull Gap Tuffs

*See* Keechelus Andesitic Series.

Sheffield Formation[1]

Upper Devonian: Central northern Iowa.

Original reference: C. L. Fenton, 1919, Am. Jour. Sci., 4th, v. 48, p. 355–376.

Walter Youngquist and R. F. Peterson, 1947, Jour. Paleontology, v. 21, no. 3, p. 242–253. Conodont fauna from type area of Sheffield indicates Upper Devonian age. Specimens in this report procured from clay pit of Sheffield Brick and Tile Co., near center sec. 9, T. 93 N., R. 20 W., Franklin County.

M. A. Stainbrook, 1950, Jour. Paleontology, v. 24, no. 3, p. 365–366. Stratigraphically restricted above to exclude a series of dolomitic beds here named Aplington formation.

Named for exposures in vicinity of Sheffield, Franklin County.

Sheffield Shale (in McLeansboro Formation)

Sheffield Shale (in Carbondale Group)

Pennsylvanian: West-central Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 102. In McLeansboro formation between Copperas Creek sandstone (above) and Brereton limestone.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 112–113. Light gray, with brownish, olive, or bluish cast. Maximum thickness 22 feet: average 8 or 10; 4 feet in Beardstown quadrangle; variations in thickness due to trucation by overlying Copperas Creek sandstone. Included in Brereton cyclothem, Carbondale group. Savage [1927] used name Copperas Creek to include Sheffield shale and the overlying sandstone, but name Copperas Creek has been restricted to the sandstone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35. Replaced by Lawson shale member of Carbondale formation (redefined).

Named for exposures near Sheffield, near center sec. 24, T. 16 N., R. 6 E., Bureau County.

**Shelburn Formation**[1]

Upper Pennsylvanian: Southwestern Indiana.

Original reference: E. R. Cumings, 1922, Indiana Dept. Conserv., Pub. 21, pt. 4, p. 408, 525, 529, chart.

C. E. Wier, 1950, U.S. Geol. Survey Coal Inv. Map. C–1. Unconformably overlies Dugger formation (new).

C. E. Wier, 1951, U.S. Geol. Survey Coal Inv. Map C–9. As proposed by Cumings, included rocks in the interval from top of Coal VII to base of Merom sandstone, thus including in upper part beds that had previously been included in West Franklin and Ditney formations. Upper part of Cuming's Shelburn formation has been separated from it by Schrock and Malott (1929) who restored name West Franklin formation to include two limestone members and the shale and coal between them and by Malott (1948) who restored name Ditney for formation overlying West Frankfort and underlying Merom sandstone. Shelburn is here restricted to those rocks above the unconformity that overlies Coal VII or locally cuts out Coal VII and below base of West Franklin formation. Contains 250 feet of sandstone, shale, limestone, and thin lenticular coal beds, of which only basal part, approximately 30 feet, of Busseron sandstone member is exposed in Linton quadrangle.

F. E. Kottlowski, 1954, U.S. Geol. Survey Coal Inv. Map C–11. In Dugger quadrangle, includes (ascending) Busseron sandstone member and Maria Creek limestone member (new).

Courtney Waddell, 1954, U.S. Geol. Survey Coal Inv. Map C–17. In Shelburn quadrangle, formation includes Vigo sandstone member (new).

J. D. McGregor, 1958, Indiana Geol. Survey Bull. 15, p. 46 (table 8). Table shows Shelburn formation, 210 to 300 feet, comprises (ascending) Busseron sandstone, Maria Creek limestone, Vigo limestone, and Murphys Bluff sandstone members.

Named for Shelburn, Sullivan County.

†Shelburne Gneiss[1]

Age(?): Massachusetts.

Original reference: W. O. Crosby, 1876, Rept. on geol. map of Massachusetts, Massachusetts Comm. to Centennial Exposition, Boston, p. 1–42.

At Shelburne Falls.

**Shelburne Marble**[1] or **Formation** (in Stockbridge Group)

Shelburne Formation

Lower Ordovician: West-central Vermont and northwestern Massachusetts.

Original reference: Arthur Keith, 1923, Am. Jour. Sci., 5th ser., v. 5, p. 115.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524, 539–541, pl. 10. Shelburne marble mapped in west-central Vermont. Occurs between Clarendon Springs dolomite below and Cutting dolomite (new) above. Lower Ordovician.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Shelburne marble included in Stockbridge group in Cheshire quadrangle, Massachusetts. Overlies Clarendon Springs dolomite; underlies Bascom formation. Lower Ordovician.

J. B. Thompson, Jr., 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 75. Formation described in Clarendon-Dorset area where it consists of Sutherland Falls marble member, 50 to 100 feet; intermediate dolomite member, 150 to 200 feet; and Columbian marble member, 200 to 250 feet. Underlies Bascom formation; overlies Clarendon Springs formation. Lower Ordovician.

Main belt of outcrop in town of Shelburne, Burlington quadrangle, Vermont.

Shelby cyclothem

Pennsylvanian: South-central Illinois.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 13. Studies by S. E. Ekblaw led to tentative recognition of six cyclothems of which the Shelby is fifth in sequence (ascending). Succeeds Omega cyclothem and is followed by Shumway cyclothem. Subsequent attempts to set up a single standard section based on assumption that Omega and Greenup limestones are equivalent resulted in a series of 13 cyclothems in which the term Shelby was omitted. If the Greenup and Omega are not equivalent, the section includes 14 cyclothems with the Shelby below the Shumway or Newton and above the Omega. If this sequence is correct, or nearly so, it is probably incomplete, and other cyclothems may occur both above and below the Omega. Another difficulty in this arrangement is that the Shelbyville coal, which according to Ekblaw is a part of the Shelby cyclothem, was assigned to the Newton cyclothem by Newton (1941, Illinois Geol. Survey Rept. Inv. 76) who believed that it occurred beneath the Omega in Shelby County.

Type locality and derivation of name not given.

†Shelby Dolomite[1]

Silurian: Western New York.

Original reference: J. M. Clarke and R. Ruedemann, 1903, New York State Mus. Mem. 5, p. 9–13.

B. F. Howell and J. T. Sanford, 1947, Wagner Free Inst. Sci. Bull., v. 22, no. 4, p. 33–34. Preoccupied name Shelby replaced by Oak Orchard Creek member (new) of Lockport formation.

Named for exposures along Oak Orchard Creek, south of village of Shelby, in Shelby, the southwest township of Orleans County.

†Shelby Limestone[1]

Middle Devonian: Central Indiana.

Original reference: A. F. Foerste, 1898, Indiana Dept. Geology and Nat. Resources 22d Ann. Rept., p. 234–235.

Type locality not stated but probably named for Shelby County.

Shelbyville Coal Member (of Mattoon Formation)

Pennsylvanian: Central and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 51 (table 1), pl. 1. Assigned member status in Mattoon formation (new). Occurs above McClearys Bluff coal member and below Trowbridge coal member. Coal named by Broadhead (1875, *in* Geology and Paleontology, v. 4, Illinois Geol. Survey). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Outcrops and mines in vicinity of Shelbyville, T. 11 N., Rs. 3 and 4 E., Shelby County.

Shelbyville Drift or Till

Pleistocene (Wisconsin): Central Illinois.

H. B. Willman and others, 1942, Illinois Geol. Survey Bull. 66, p. 145 (fig. 85), 146 (fig. 86), 155–158. Consists of (1) till, (2) outwash, and (3) laminated clays, silts, and sand deposited in Lake Kickapoo. Maximum thickness at least 40 feet. Overlies Illinoian till and Sangamon interglacial deposits and underlies widespread pink till of Bloomington age; at some places, lake beds are overlain by gravel and sand outwash thought to be of Bloomington age. Six drifts listed in the Tazewell (ascending): Shelbyville, Bloomington, Cropsey, Farm Ridge, Chatsworth, and Marseilles.

Leland Horberg, 1950, Illinois Geol. Survey Bull. 75, pt. 1, p. 29. In Peoria area, Shelbyville drift is listed as older than Leroy drift.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 8, 11. Shelbyville till, 40 feet thick, occurs above Morton loess (new) and below Richland loess (new). Woodfordian substage.

Named for Shelbyville, Shelby County. Deposits occur principally in preglacial Ticona Valley and crop out at many places along Fox Valley and its tributaries above Dayton, along Illinois Valley east of Marseilles, and a few localities along Vermilion River.

**Sheldon Limestone Member** (of Topeka Limestone)

Sheldon Limestone (in Calhoun Shale)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, 2d ser., p. 47.

G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 26, 30, 45, 46, 48–49. Reallocated to member status in Topeka limestone. Underlies Turner Creek shale member; overlies Jones Point shale member. Thickness varies from maximum of 3 feet or more in northern outcrops to 2 feet or less in northeastern Kansas and northwestern Missouri. Occurrences in Iowa noted. Derivation of name given.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035. Member of Topeka formation. Overlies Jones Point shale member; underlies Turner Creek shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 16, fig. 5. Light-gray fossiliferous generally fine-grained complex of two or three beds depending upon presence of shale separations. Usually at least one of beds is massive unit containing brachiopods and pelecypods. Thickness 3. 2 feet north of Thurman, Fremont County; 2.1 feet west of Macedonia, Pottawattomie County; 5 feet near Howe, Adair County. Underlies Turner Creek shale member; overlies Jones Point shale members.

Named for exposures at Vilas Sheldon quarry, east of Nehawka, Cass County, Nebr.

**Shelikof Formation**[1]

Upper Jurassic: Southwestern Alaska.

Original reference: S. R. Capps, 1923, U.S. Geol. Survey Bull. 739, p. 91, 97, map.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1). Comprises (ascending) interbedded sandy shale and fine- to medium-grained silty sandstone, about 100 feet thick; well-stratified gray shale interbedded with thin lenticular layers of limestone and thin beds of soft gray sandstone, 950 feet; Chinitna shale member, 400 to 1,300 feet; gray sandy shale, 200 to 1,200 feet; massive brown to gray sandstone, 4,000 to 4,700 feet; and massive black shale, 700 to 1,000 feet.

R. W. Imlay, 1953, U.S. Geol. Survey Prof. Paper 249–B, p. 48–49, table 5 facing p. 60. In Wide Bay and Puale Bay areas, consists of three lithologic members. Lower siltstone member, 800 to 1,800 feet thick, mainly of gray siltstone and sandy siltstone which contains many sandy interbeds from few inches to 200 feet thick in Wide Bay area and represented by about 800 feet of brown-weathering siltstone that includes many concretions at Puale Bay; middle sandstone member, 1,000 to 3,500 feet, dominantly of massive gray sandstone with interbeds of siltstone and lenses of conglomerate; and upper siltstone member, 900 to 1,500 feet, mostly of hard dark-gray gray-weathering siltstone. Formation shown on table as lateral correlative of Chinitna formation.

Prevailing rock formation on northwest shore of Shelikof Strait, from Katmai Bay at least as far southwest as Kialagvik Bay and in Wide Bay and Puale Bay (formerly Cold Bay) areas.

†Shell Bluff Marl[1] or Group[1] (in Barnwell Formation)[1]

Eocene, upper: Eastern Georgia and South Carolina.

Original reference: T. A. Conrad, 1866, Am. Jour. Sci., 2d, v. 41, p. 96.

Named for Shell Bluff, on Savannah River in Burke County, Ga.

Shell Creek Shale

Lower Cretaceous: Central northern Wyoming.

R. A. Paull, 1957, Dissert. Abs., v. 17, no. 10, p. 2249. Name proposed for the shale sequence above the Muddy and below the Mowry shale. Formerly included in upper part of Thermopolis shale.

**This may or may not be same unit as Shell Creek Shale of Eicher (1960). In Bighorn Basin.**

Shell Creek Shale

Lower Cretaceous: Central northern Wyoming.

D. L. Eicher, 1960, Yale Univ., Peabody Mus. Nat. History Bull. 16, p. 17–18, 34–36, 39, 52, 80. Proposed for soft black shale sequence that underlies Mowry shale and that was included in the upper part of Thermopolis shale of Lupton. Includes a few ironstone beds and concretions and a few prominent white bentonite beds. Thickness at type locality 252 feet; thins southward and pinches out in southern Wyoming. Overlies Muddy sandstone; contact becomes increasingly gradational southward.

Type section: Measured 6 miles northwest of Greybull in N½ sec. 14, T. 53 N., R. 94 W., Big Horn County. Named for exposures along Shell Creek, which flows within 6 miles of type locality; also mappable to north and northeast of Bighorn Basin.

**Shellhammer Hollow Formation**

Mississippian: Northwestern Pennsylvania.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1347, 1351, 1362. Name proposed for thin sequence of intercalated siltstones, silty mudstones, and shales. Composed of about equal parts of each rock-type in thickest parts; composed almost completely of shale in thinnest parts. Thickness 4 inches to 5 feet. Underlies Bartholomew siltstone member (new) of Orangeville shale; overlies Cussewago sandstone. Grades laterally into easternmost recognizable Bedford shale and Berea sandstone near Meadville. Grades laterally eastward into Corry sandstone. Lower Mississippian.

J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 18 (fig. 9), 41. Further described. More exact location of type section stated.

Type locality: Two miles north of Meadville, Crawford County, where Meadville-Saegerstown Road on east side of French Creek crosses Shellhammer Hollow. Exposed on road on each side of hollow about 20 feet above stream.

Shell Rock Formation

Shell Rock Limestone[1]

Upper Devonian: Central northern Iowa.

Original reference: A. O. Thomas, 1924, Iowa Geol. Survey, v. 29, p. 411–412.

A. H. McNair, 1942, Jour. Paleontology, v. 16, no. 3, p. 349, 350. Fossil collections made from Mason City dolomite member of Shell Rock (Shellrock) formation.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 661. Formation includes (ascending) Mason City, Rock Grove, and Nora members.

Named for development along Shell Rock River between Rockford and Nora Springs and northward, Floyd County.

**Shelter Formation**

Lower Cretaceous(?): Southeastern Alaska.

Fred Barker, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–100. Conglomerate with interlayered pebbly graywacke, graywacke, and greenstone. Conglomerate ranges from rock with 40 percent pebbles (by volume) through pebbly graywacke to graywacke. Massive very fined grained chlorite-albite-epidote greenstone with aggregates of opaque white clay overlies the conglomerate. Parent rocks probably were flows and sills of basalt or andesite. Conglomerate and graywacke about 500 to 1.000 feet thick: overlying greenstone at least several hundred feet thick. Formation may grade by facies change into Symonds formation (new).

Extends the length of Shelter Island, and crops out at north end of Portland Island, Juneau (B–3) quadrangle.

Shelton Granite Gneiss[1]

Precambrian: Northern North Carolina and central southern Virginia.

Original reference: A. I. Jonas, 1928, Virginia Geol. Survey prelim. ed. geol. map of Virginia.

C. B. Brown, 1937, Virginia Geol. Survey Bull, 48, p. 14. Exposed in small area northwest of Tabscott, Goochland County. A mylonitized or crushed facies of Columbia granite.

Quarried near Shelton, Caswell County, N.C.

Shelton Cliff Sandstone[1]

Pennsylvanian: Southwestern Indiana.

Original reference: W. N. Logan, 1924, Indiana Dept. Conserv. Pub. 42, p. 16.

Shely Group

Oligocene(?): Southwestern Texas.

D. L. Amsbury, 1957, Dissert. Abs., v. 17, no. 9, p. 1981. Named in a stratigraphic sequence as younger than Vieja formation and older than Moonstone rhyolite (new).

D. L. Amsbury, 1958, Texas Univ. Bur. Econ. Geology Quad. Map 22. Group consists of trachyte tuff, trachyte, rhyolite and rhyolite ignimbrite, and conglomerate. Near Loma Plata mine, overlies Buckshot ignimbrite; from Loma Plata mine to Pinto Creek, overlies progressively older Comanche strata and along the Shely rim rests on Pinto Canyon formation. Underlies Brite rhyolite.

Type locality: In canyon west of Cleveland triangulation station, Pinto Canyon area, Presidio County. Named for Terry Shely Ranch.

**Shenandoah Limestone**[1]

Shenandoah Group

Lower Cambrian to Middle Ordovician: Eastern West Virginia and western Virginia.

Original reference: H. R. Geiger and A. Keith, 1891, Geol. Soc. America Bull., v. 2, p. 157–163, pl. 4.

C. E. Resser, 1938. Geol. Soc. America Spec. Paper 15, p. 3, 4. Shenandoah limestone listed among abandoned names. It was common practice of earlier workers to group the calcareous strata of Appalachian Valley under one term; thus the Shenandoah limestone was used for the calcareous rocks above the clastics; consequently Shenandoah group of older usage includes all formation from Lower Cambrian Shady or Middle Cambrian Elbrook to Ordovician.

A. A. Pegau, 1958, Virginia Div. Mineral Resources Circ. 7, p. 9. In northern valley of Virginia, Shenandoah group includes Stones River limestone below and Chambersburg limestone. Ordovician. Undifferentiated Shenandoah is classed as Cambro-Ordovician.

Shenandoah River valley, West Virginia, is characterized by this limestone.

Shenandoah Mountain Granite[1]

Precambrian: Southeastern New York.

Original reference: C. E. Gordon, 1911, New York State Mus. Bull. 148, p. 11, 17–18.

Occurs on Shenandoah Mountain, at summit of steep northwest slope, along road from East Hook to Hortontown, Poughkeepsie quadrangle.

Shenandoan Series[1]

Lower Ordovician: Southern Appalachians and Mississippi regions.

Original reference: A. W. Grabau, 1936, Pan-Am. Geologist, v. 66, no. 1, p. 27.

A. W. Grabau, 1937, Paleozoic formations in the light of the pulsation theory, v. 3, Cambrovician pulsation, pt. 2, Appalachian, Palaeocordilleran, Pre-Andean, Himalayan, and Cathaysian geosynclines: Peiping, China, Univ. Press, Natl. Univ. Peking, p. 11–12, 13 (table), 15, 282 (table). Proposed to revive name Shenandoan group or Shenandoan by restricting it to cover the post-Ozarkian part of the Cambrovician as here defined—that is—southern equivalent of the Beekmantown or Canadian. Term is used for Lower Ordovician of southern Appalachians and Mississippian region in place of Beekmantownian or Canadian, but excluding from it the Stonehenge division and its equivalents elsewhere in this southern region.

Shenango Formation (in Pocono Group)

†Shenango Group[1]

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $Q_4$, p. 66, 77–81.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. As mapped, Pocono group includes, in Appalachian Plateau, Burgoon, Shenango, Cuyahoga, Cussewago, Corry, and Knapp formations.

Named for exposures on Shenango River, Mercer County, Pa.

Shenango monothem[1]

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 138–139.

Shenango Sandstone[1]

Lower Mississippian: Northwestern Pennsylvania and eastern Ohio.

Original reference: J. P. Lesley and I. C. White, 1879, Pennsylvania 2d Geol. Survey geol. map of Mercer County.

E. J. Szmuc, 1958, Dissert. Abs., v. 18, no. 6, p. 2109. Shenango sandstone wedges out a short distance west of Ohio-Pennsylvania State line. Evidence indicates that sandstone and overlying Hempfield shale are stratigraphic equivalents of upper part of Meadville member of Cuyahoga; previous correlations with Logan formation are erroneous.

Exposed along Shenango River, Mercer County, Pa.

†Shenango Series[1]

†Shenango River Series[1]

Mississippian and Pennsylvanian: Western Pennsylvania.

Original reference: F. Platt, 1875, Pennsylvania 2d Geol. Survey Rept. H., p. 1–9.

Named for Shenango River, Mercer County.

Shenango Shale[1]

Mississippian: Northwestern Pennsylvania.

Original reference: I. C. White, 1880, Pennsylvania 2d Geol. Survey Rept. $Q_3$, p. 59–60.

R. M. Leggette, 1936, Pennsylvania Geol. Survey, 4th ser., Bull. W-3, p. 114. Top 75 feet of sandstone and shale of the Pocono group in this area (Crawford County) has been correlated with the Burgoon sandstone and is now called by that name. These beds are the Shenango shale and Shenango sandstone of White. The shale which occurs between the Sharon conglomerate [above] and the sandstone is as much as 60 feet thick.

Named for exposures on Shenango River, Mercer County.

Shenango Stage[1]

Mississippian: Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 138–139.

Hugo Greiner, 1957, Yale Univ., Peabody Mus. Nat. History Bull. 11, p. 9 (table). Discussion of evolution and paleoecology of "*Spirifer disjunctus*" in Catskill delta. Stratigraphic chart lists Shenango stage at top of Kinderhookian series. Follows Meadville stage.

Named derived from Shenango River, Mercer County.

**Shepard Formation**[1] (in Missoula Group)

Shepard Dolomite (in Siyeh or Wallace Group)

Shepard Formation (in Piegan Group)

Precambrian (Belt Series): Northwestern Montana, and southern British Columbia, Canada.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 324.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1899–1900. Shepard formation consists of argillaceous and siliceous dolomites and magnesian limestones in thin strata but thick beds; dark gray, green gray, or brown. Interbeds of greenish-white magnesian quartzites basally. Ripple marks, mud cracks, channel fillings, and edgewise mud breccias characteristic. Represents final stage of Piegan sedimentation. Thickness 585 to 1,500 feet. Younger than Spokane formation, older than Miller Peak formation. Type locality given.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 112, 113. Reallocated to Missoula group. This classification follows Clapp and Deiss (1931, Geol. Soc. America Bull., v. 42, chart and p. 691).

S. D. Theodosis, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 62, chart facing p. 62. Considered to be the upper member of Upper Siyeh limestone and part of Siyeh or Wallace group.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 19 (table), 52–53, pls. 1, 2. Shepard [originally spelled Sheppard] formation in Glacier National Park is coextensive with underlying Purcell basalt. Thickness about 400 feet. Missoula group.

Type locality: Cliffs of Lewis Range near Shepard [Sheppard] Glacier, Glacier National Park, Mont. Well exposed on Mount Carthew, Boulder, and Swiftcurrent Peaks, mountains near Logan Pass, and in valley of Middle Fork of Flathead River.

Shepherdstown Gravel[1]

Pliocene(?): Northern West Virginia and southern Pennsylvania.

Original reference: M. R. Campbell, 1933, Geol. Soc. America Bull., v. 44, no. 3, p. 558–573.

Well developed at Shepherdstown, W. Va.

Sheppard Formation

*See* **Shepard Formation.**

**Sheppard Granite**[1]

Tertiary: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Rept. Mines Mem. 38, p. 354–356, map 8.

Forms small stock at head of Sheppard Creek, British Columbia.

Sherburne Conglomerate[1]

Cambrian or Ordovician: Southern Vermont.

Original reference: C. H. Richardson, 1929, Vermont State Geologist 16th Rept., p. 208–246, table opposite p. 288.

H. E. Hawkes, Jr., 1941, Geol. Soc. America Bull., v. 52, no. 5, p. 654, 655, 657. Included in upper part of Plymouth Union series (new) north of Sherburne.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 46–47, pl. 1. Included in Cambro-Ordovician Tyson formation as unnamed coarse conglomerate near base.

Good exposures about 2 miles southeast of North Sherburne, Rutland County, at head of narrow valley leading down to Sherburne.

**Sherburne Flagstone Member** (of Genesee Formation)

Sherburne Flagstone Member (of Portage Formation)[1]

Sherburne Formation

Upper Devonian: Eastern and central New York.

Original reference: L. Vanuxem, 1840, New York Geol. Survey 4th Ann. Rept., p. 381.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 45, 47 (fig. 2), 66–70. Name Sherburne includes rocks between top Penn Yan tongue (new) of West River and base of Middlesex remnant. According to original definition (Vanuxem, 1840), the Sherburne at type locality is a sparsely fossiliferous shale and sandstone series overlying Geneseo and terminating at first appearance in abundance of Ithaca fossils. Cooper and Williams (1935) indicate that the Sherburne east of type locality, as indicated by workers after Vanuxem, includes beds as low as the Tully, which in this area is same facies as the Sherburne. Sherburne as used in this report includes 310 feet of interbedded shales and flags (siltstones and very fine sandstones) between Penn Yan tongue (new) of the West River and the attenuated remnant of Middlesex black shale in Cayuga Lake valley. Starkey tongue (new) penetrates westward into West River shale, between Penn Yan tongue and Milo tongue (new) of West River in central New York.

R. G. Sutton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 231 (table 1), 236 (fig. 4), 237. Discussion of use of flute casts in stratigraphic correlation. West River shale is equivalent to Sherburne sandstone and Ithaca formation.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2814 (fig. 3), 2815, 2821, 2824. Sherburne flagstone member is excluded from Portage formation of Williams (1906, Science, new ser., v. 24: Williams and others, 1909, U.S. Geol. Survey Geol. Atlas, Folio 169) and assigned to Genesee formation. Flagstone member, as here defined, lies above Penn Yan shale member and below Renwick shale member. Name Sherburne was originally applied to a sequence of silty and sandy rocks above a black shale that overlies the Tully limestone in vicinity of Sherburne. Member in vicinity of Cayuga Lake is western part of wedge of sandy rocks that was originally named Sherburne by Vanuxem. At reference section, herein designated, member is 110 feet thick. Member is composed largely of very silty shale, very silty mudrock, and cross-laminated siltstone in beds 1 inch to 3 feet thick. Near Ithaca, the first *Reticularia laevis* zone of Williams and others (1909) is upper 35 feet of the member. Upper boundary of the Sherburne member is at base of lowest bed of brownish black shale of Renwick member. Traced westward from vicinity of Ithaca to exposures near south end of Seneca Lake where it is about 40 feet thick. Grades laterally into gray shale and mudrock in lower part of Penn Yan shale member in area north and west of Fir Tree Point, on west side of Seneca Lake, 6 miles north of Watkins Glen, and is not present in exposures at Keuka Lake.

Reference section: Glenwood Creek, in Cayuga Lake area. Named for occurrence near Sherburne, Chenango County.

†Sherburne Group[1]

Devonian: New York.

Original reference: T. A. Conrad, 1841, New York Geol. Survey 5th Ann. Rept., p. 31.

Occurs near Apulia, Onondaga County.

†Sherburne Shale[1]

Middle Devonian: Central southern New York.

Original reference: W. W. Mather, 1843, Geology New York, v. 1

†Sheridan Beds[1]

Pleistocene: South Dakota to panhandle of Texas.

Original reference: W. B. Scott, 1897, Introduction to geology, p. 532–533.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 110. Used by Scott (1897) for beds that are now, at least in part, the Sanborn formation.

Named for exposures in Sheridan County, Nebr.

Sheridan Formation[1]

Middle Ordovician: Northwestern Michigan.

Original reference: R. C. Allen, 1910, Michigan Geol. and Biol. Survey Pub. 3, geol. ser. 2, p. 113.

On Sheridan Hill, Iron River district.

†Sheridan Quartzite[1]

Precambrian: Northwestern Wyoming.

Original reference: W. H. Weed, 1896, U.S. Geol. Survey Geol. Atlas, Folio 30.

J. D. Love and others, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC-43. Term abandoned. Lower 40 feet of the "rusty beds" of Morrison(?)—Cloverly sequence is a quartzite that forms cliffs. This is part of quartzite sequence that Weed (1896) named Sheridan quartzite and that he considered to be of Precambrian age. Weed's type area of the Sheridan was restudied; in several places, a normal stratigraphic section is exposed in which the lower quartzite overlies variegated beds of the Cloverly and is overlain by black Thermopolis shale. This shale is, in turn, overlain by an upper quartzite that is in the stratigraphic position of Muddy sandstone member of the Thermopolis. Weed did not explain why he considered the quartzite Precambrian.

Well exposed on slopes of Mount Sheridan, Yellowstone National Park.

Sheridan Sandstone[1]

Silurian: Northeastern Maine.

Original reference: H. S. Williams, 1900, U.S. Geol. Survey Bull. 165, p. 21, 45, 47–49, 51.

W. H. Twenhofel, 1941, Jour. Paleontology, v. 15, no. 2, p. 172–173, 174. Stratigraphic revision. Unit now considered younger than shales and limestones of the Ashland formation.

R. L. Miller, 1947, Maine Geol. Survey Bull. 4, p. 8, 9. Name not used; preoccupied by a Precambrian unit in Yellowstone National Park.

Named for exposures on Sheridan plantation, south of Aroostook River, in Aroostook County.

**Sherman Diorite[1]**

Miocene: Yellowstone National Park, Wyoming.

Original reference: A. Hague and others, 1904, U.S. Geol. Survey Mon. 32, Atlas.

Exposed on Sulphur Creek in vicinity of Hot Springs, Canyon quadrangle. Derivation of name not stated.

**Sherman Granite[1]**

Precambrian: Southeastern Wyoming and northern Colorado.

Original reference: E. Blackwelder, 1908, Science, new ser., v. 27, p. 778–788.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 28. Older than Silver Plume granite and probably correlated with Pikes Peak granite.

Exposed in large batholith extending from northern part of Front Range, Colo., well into Wyoming. Mapped over large area at and around Sherman, Albany County, Wyo.

Sherman Marble[1]

Lower Cambrian(?): Southeastern Vermont.

Original reference: G. D. Hubbard, 1924, Vermont State Geologist 14th Rept., p. 269–276, map.

Well exposed in and named for town of Sherman, on Hoosac Tunnel and Wilmington Railroad, Whitingham Township, Windham County.

Sherman Fall Formation (in Trenton Group)[1]

Middle Ordovician: Northwestern New York, and Ontario, Canada.

Original reference: G. M. Kay, 1929, Jour. Geology, v. 37, no. 7, p. 664–671.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 263–268, 271. Overlies Hull formation and underlies Cobourg limestone in northwestern New York and Ontario. Type section lacks exposure of about 30 feet of base of formation, but total thickness in vicinity is about 200 feet. Comprises Shoreham and Denmark members (both new). In Oneida County, includes Dolgeville facies. Trenton group.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p. 525–535. In this report, Shoreham and Denmark members are raised to formational rank.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 42. Sherman Fall was originally defined as "the 'Prasopora beds' or 'Trenton (restricted)' of Raymond, Johnston and others." It was originally supposed to include beds now classified as the whole of the Russia and lower half of Rust limestone at Trenton Falls, 105 feet of beds above Sherman Fall; subsequent study shows that the "Prasopora beds" correspond to the Shoreham and Denmark formations of this report [Utica quadrangle].

Named for Sherman Fall, in Trenton Falls Gorge of West Canada Creek, Oneida County, N.Y.

Shermanian (Sherman Fall) Stage

Middle Ordovician (Trentonian): Eastern North America.

G. M. Kay, 1937, Geol. Soc. America Proc. 1936, p. 82. Stage in middle Trenton.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 263–277, 293, 298. Discussion of stratigraphy of Trenton group and list of formations of Sherman Fall age. Medial Trenton marked a time of distinct alteration of preceding conditions [Rockland and Hull stages]. Maximum of lower Trenton submergence seems to have been reached in earliest part of Sherman Fall stage—the Shoreham. In middle Trenton Sherman Fall stage, the Vermontian disturbance produced a geanticline east of the region that became an important synchronous elevation of Adirondack arch.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Cophenhagen, pt. 7, p. 30. Suggested that term Shermanian stage be applied to Shorehamian and Denmarkian substages. Shermanian stage follows Nealmontian stage and is followed by Pictonian stage.

Name derived from Sherman Fall, Trenton Falls gorge, New York, for which Sherman Fall limestone was named.

Sherman Ridge Formation (in Hamilton Group)

Upper Devonian: East-central Pennsylvania.

H. H. Arndt and others. 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3–4. Overlies Montebello formation and consists of Mahantango-type shales. Includes as much as 550 feet of section. Name credited to Miller (unpub. ms.).

Type locality and derivation of name not stated.

**Sherwin Glaciation**

Sherwin glacial stage[1]

Sherwin Till

Pleistocene: East-central California.

Original references: E. Blackwelder, 1930, Geol. Soc. America Bull., v. 41, p. 91–92; 1931, Geol. Soc. America Bull., v. 42, p. 865–922.

W. C. Putnam, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1281, 1290. At least four ice advances occurred in Pleistocene: earliest, here named Aeolian Buttes, was followed by Sherwin, Tahoe, and Tioga, previously named by Blackwelder. Constructional forms have been destroyed on the two older tills but preserved on the later ones. Rhyolitic ash and pumice, now Bishop welded tuff, were erupted in interval between Aeolian Buttes and Sherwin glacial stages.

W. C. Putnam, 1960, California Univ. Pubs., Geol. Sci., v. 34, no. 5, p. 233–235, map 1. Sherwin till is pre- rather than post-Bishop tuff. Name Aeolian Buttes considered invalid as representing an earlier Pleistocene. pre-Sherman glacial stage. Sherwin is second in sequence of four major glacial tills on eastern slope of the Sierra Nevada; it was preceded by McGee stage. Part of till rests unconformably on pre-Tertiary crystalline rocks, another part on late Tertiary (?) basalt.

Name amended to glaciation in compliance with 1961 Code of Stratigraphic Nomenclature.

Well developed in area north of Sherwin Hill, northwest of Bishop, in Mount Morrison quadrangle. Putnam states type locality of till at Sherwin Hill in Mount Goddard quadrangle. Greatest expanse of till is in lobe east of Whiskey Canyon; along both sides of Rock Creek gorge, thickness of about 450 feet of glacial detritus is exposed.

†Sherwood Limestone[1]

Lower Cambrian: Central western Virginia.

Original reference: H. D. Campbell, 1905, Am. Jour. Sci., 4th, v. 20, p. 445–447.

Named for exposures in James River at Sherwood, Rockbridge County.

Sherwood Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 24, figs. 3, 12. Dolomite, argillaceous and very cherty in upper part. Thickness about 10 feet. Shown on columnar section as underlying Wall member (new) and overlying Rivoli member (new).

Occurs in Dixon-Oregon area.

Shetlerville Formation[1]

Shetlerville Member (of Renault Formation)

Mississippian (Chester Series): Southeastern Illinois and northern Kentucky.

Original references: S. Weller, 1920, Jour. Geology, v. 28, no. 4, p. 281–290 and no. 5, p. 395–416; 1920, Illinois Geol. Survey Bull. 41.

Elwood Atherton, 1947, Illinois Acad. Sci. Trans., v. 40, p. 129, 130 (fig. 7), 131 (fig. 8). Frank Tippee (unpub. ms.) correlated upper part of Renault with basal Paint Creek of western Illinois and proposed name Downeys Bluff for this member of the Paint Creek; remainder of the Renault is referred to as the Shetlerville member. Overlies Levias member of Ste. Genevieve.

J. M. Weller and others, 1952, Illinois Geol. Survey Bull. 76. p. 62–63. In fluorspar district, discussed as member of Renault; consists of alternating beds of limestone and shale in about equal proportions. Thickness about 60 feet. Underlies Downeys Bluff member; at most places, separation of the two is difficult, especially where shale is not abundant in the Shetlerville; at Downeys Bluff, contact is unconformable; overlies Levias limestone unconformably, and at some places zone of rounded limestone pebbles marks this boundary.

Named for Shetlerville, Hardin County, Ill. Well exposed just east of Shetlerville between Rich and Melcher Hills.

**Shields Formation** (in Walden Creek Group)

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 962. Most prominent rocks are sandstone and conglomerate which form units a few feet to more than 1,000 feet thick that project in ledges and ridges; sandstones are coarse grained, feldspathic, and not graded; conglomerates are interbedded with the sandstones as seams, lenses, and thick beds; associated with sandstone and conglomerate is argillaceous shale, which contains thin lenses of gritty sandstone. In type area, shales dominate upper half of formation but intertongue at their base with sandstones and conglomerates of the lower half. Overlies Licklog formation (new); underlies Sandsuck formation.

Named for Shields Mountain, [Sevier County], a high ridge along the northwest edge of the foothills west of the Little River, which is made up of a southeastward-dipping sequence of the formation 2,000 to 2,500 feet thick.

**Shiloh Marl Member** (of Kirkwood Formation)[1]

Miocene, middle: Southern New Jersey.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 40–44.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 31, pl. 1. Probably late Hemingfordian.

D. S. Malkin, 1953, Jour. Paleontology, v. 27, no. 6, p. 763. Incidentally mentioned in discussion of ostracods from middle Miocene formations.

Unit from which samples were taken might be more accurately described as a fine-grained argillaceous fossiliferous sand.

First described at Shiloh, Cumberland County.

**Shimer Gypsum Member** (of Blaine Formation)[1]

Permian: Central southern Kansas and western Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 27, 28, 31.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1794, 1797. Overlies Nescatunga gypsum (new). Thickness at type locality 24 feet.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 39. Underlies Haskew gypsum member; overlies Nescatunga gypsum member. Leonard series.

Type locality: Shimer Township, Comanche County, Kans. Well exposed at confluence of Nescatunga Creek with Salt Fork Creek, where it caps an outlier of the Blaine.

Shinarump Clay[1]

[Upper Triassic]: Southern Utah.

Original reference: A. C. Lawson, 1913, Econ. Geology, v. 8, p. 435.

†Shinarump Group[1]

Triassic: Utah, Arizona, and northwestern New Mexico.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 53, 54, 68, 150, 152.

Named for Shinarump Cliffs, south of Vermilion Cliffs, Kane County, southern Utah.

**Shinarump Member** (of Chinle Formation)

Shinarump Conglomerate[1]

Upper Triassic: Southern and northeastern Utah, northern Arizona, southeastern Nevada, and northwestern New Mexico.

Original reference: G. K. Gilbert, 1875, U.S. Geol. and Geog. Survey W. 100th M., v. 3, p. 1–187.

A. A. Baker, 1936, U.S. Geol. Survey Bull. 865, p. 44–47, pl. 1. Shinarump conglomerate, in Monument Valley-Navajo Mountain region, San Juan County, Utah, has maximum thickness of 210 feet. Unconformably overlies Moenkopi formation; underlies Chinle formation.

Parry Reiche, 1937, Am. Jour. Sci., 5th, v. 34, no. 200, p. 130. In Cameron area, Arizona, Shinarump sandstones underlie Tolchaco gravels (new).

H. E. Gregory, 1938, U.S. Geol. Survey Prof. Paper 188, p. 48–49. Shinarump conglomerate, in San Juan country is 0 to 120 feet thick. Unconformably overlies Moenkopi; underlies Chinle.

E. T. McKnight, 1940, U.S. Geol. Survey Bull. 908, p. 63–66, pls. Shinarump conglomerate, in area between Green and Colorado Rivers, Grand and San Juan Counties, Utah, is 0 to 50 feet thick. Unconformably overlies Moenkopi formation; underlies Chinle formation.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1392. Shinarump conglomerate in Gore area, Eagle and Summit Counties, Colo., unconformably overlies State Bridge formation.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 477–478. Shinarump conglomerate, in eastern Uinta Mountains, underlies Chinle shale and unconformably overlies Red Wash formation (new).

A. A. Baker, 1946, U.S. Geol. Survey Bull. 951, p. 58–60, pls. 1, 3. Shinarump conglomerate, in Green River Desert-Cataract Canyon area, Emery, Wayne, and Garfield Counties, Utah, is 0 to 135 feet thick. Overlies Moenkopi formation; underlies Chinle formation.

C. L. Camp and others, 1947. Plateau, v. 20, no. 1, p. 1, 8 (chart). Shinarump believed to be basal conglomerate of Chinle.

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 594, 595. In Strawberry Valley quadrangle, Utah, disconformably overlies Ankareh shale and underlies Chinle formation. Thickness 35 feet.

E. D. McKee, 1952, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 87 (fig. 1). In Little Colorado River area overlies Holbrook member of Moenkopi.

D. M. Kinney, 1955, U.S. Geol. Survey Bull. 1007, p. 63–67, pls. 3, 6. Shinarump conglomerate, in Uinta River-Brush Creek area, Duchesne and Uintah Counties, Utah, is 0 to 90 feet thick and consists of light-gray medium- to coarse-grained in part conglomeratic sandstone. Unconformably overlies Moenkopi formation; underlies Chinle formation.

J. H. Stewart, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 442–444, 448 (fig. 4), 449–452. Strata formerly called Shinarump conglomerate in southeastern Utah consist, in places, of a lower sandstone and conglomerate unit, a middle claystone unit, and an upper sandstone and conglomerate unit. The lower and upper units are Shinarump-type deposits whereas middle unit is Chinle-type deposit. Deposits of Shinarump-type and Chinle-type are interstratified and intertonguing. Proposed that the two types be grouped together in Chinle formation and that Shinarump conglomerate be redefined as Shinarump member of Chinle. Lower unit is correlative with strata in southwestern Utah, that are designated as type Shinarump conglomerate, and it is proposed that term Shinarump member be restricted in southeastern Utah to this lower unit. The middle and upper units, although formerly included in the Shinarump conglomerate, are considered separate members of the Chinle; middle unit has been defined as Monitor Butte member of Chinle, and name Moss Back is proposed for upper unit. In southeastern Utah, Shinarump conglomerate included, in places, all of the Shinarump, Monitor Butte and Moss Back Members. In other places, Shinarump conglomerate consisted only of Moss Back member, and in still other parts of southeastern Utah, Shinarump conglomerate consisted of only the Shinarump member. Locally, in San Rafael Swell area, unit now called Temple Mountain member, was included in Shinarump conglomerate. Although this report deals mainly with southeastern Utah, it is believed that term Shinarump member of Chinle should replace term Shinarump conglomerate everywhere. Name Shinarump member should be restricted to strata that can be correlated with reasonable certainty with type Shinarump; where correlations are less certain or where units can be shown to be distinct from Shinarump, other names should be applied. Member has same type area as unit formerly called Shinarump conglomerate. Member ranges in thickness from wedge-edge to 225 feet; commonly not more than 50 feet. Unconformably overlies Moenkopi formation except in few places where it overlies strata possibly correlative with Temple Mountain member; conformably underlies Monitor Butte member. Shinarump member is recognized in many areas outside southeastern Utah. It extends through much of northern and southern Utah and may be present in Nevada and New Mexico. Longwell (1928, U.S. Geol. Survey Bull. 798), Glock (1929, Am. Jour. Sci., 5th, v. 17), and Hewitt (1931, U.S. Geol. Survey Prof. Paper 162) have recognized Shinarump conglomerate (Shinarump member of present report) in southeastern Nevada, but present author considers this a tentative correlation. Unit mapped by Darton (1928, U.S. Geol. Survey Bull. 794) as Shinarump conglomerate on north and west sides of Zuni uplift, west-central New Mexico, lies 400 feet above base of Chinle and was incorrectly called Shinarump. Unit called Shinarump in northeastern Utah by Kinney (1955) and in northwestern Colorado by Thomas, McCann, and Raman (1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 16) is correlated with strata higher stratigraphically than type Shinarump, and author does not believe that term Shinarump is justified in these areas. Strata, called Shinarump in publications prior to 1952, in southeastern Utah were composed of most of units now called Temple Mountain, Shinarump, Monitor Butte, and Moss Back members of Chinle. Unit called Shinarump conglomerate by Baker (1936), Miser (1924, U.S. Geol. Survey Water-Supply Paper 538; 1924, U.S. Geol. Survey Bull. 751–D), Gregory and Moore (1931, U.S. Geol. Survey Prof. Paper 164), Hunt (1953, U.S. Geol. Survey Prof. Paper 228), and Gregory and Anderson (1939, Geol. Soc. America Bull., v. 50, no. 12, pt. 1) in Monument Valley, Circle Cliffs, and Capital Reef areas is essentially same as Shinarump member of present report. In part of White Canyon and Elk Ridge areas, Shinarump conglomerate of Gregory (1938) is Moss Back member. In these places, Gregory included the Monitor Butte member and Shinarump member, where present, in the Moenkopi. In other places in White Canyon and Elk Ridge areas, the Shinarump conglomerate of Gregory is apparently the Shinarump member, and he included the Monitor Butte and Moss Back members in the Chinle. In area near junction of Green and Colorado Rivers, the Shinarump and Monitor Butte members are absent, and unit mapped as Shinarump conglomerate by Baker (1933, U.S. Geol. Survey Bull. 84; 1946) and McKnight (1940) is the Moss Back. McKnight's Shinarump does not extend as far up the Green River as Moss Back of present report. In San Rafael Swell, Shinarump conglomerate of Gilluly (1929, U.S. Geol. Survey Bull. 806–C), Baker (1946), and Hunt (1953) consists mostly of Moss Back and Monitor Butte members or of Moss Back where Monitor Butte is absent. In San Rafael Swell, these authors included Temple Mountain member in Shinarump in some places; in other places, they included it partly in the Shinarump and partly in the Moenkopi; in still other places, they included it entirely in the Moenkopi. In Moab area, unit called Shinarump conglomerate by Baker (1933) and McKnight (1940) is not considered by present author to be correlative with either Shinarump or Moss Back, but is a stratigraphically higher conglomeratic sandstone at base of Chinle and is arbitrarily assigned to Church Rock member.

Type locality: Shinarump Cliffs, south of Vermilion Cliffs, southern part of Kane County, Utah.

Shinersville Conglomerate (in Pottsville Formation)[1]

Pennsylvanian: Northeastern Pennsylvania.

Original reference: F. Platt, 1880, Pennsylvania 2d Geol. Survey Rept. $G_2$, p. 186–199.

Exposed near Shinersville school house, Sullivan County.

Shingle Hills Formation (in Trinity Group)

Lower Cretaceous: Central Texas.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 1, 7 (fig. 2), 8. Proposed to include Glen Rose limestone member (above) and Hensell sand member. Upper formation of group; overlies Travis Peak formation (restricted).

Named for Shingle Hills in western Travis County where entire sequence of Hensell sand and Glen Rose limestone is traversed by road between Hamilton Pool and Shingle Hills.

Shingle Pass Tuff

Tertiary: Eastern Nevada.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 140 (fig. 4). Highly welded, dark red vitric-crystal ignimbrite. Thickness 80 to 130 feet. Occurs above Needles Range formation.

Present in Grant Range.

**Shinumo Quartzite** (in Unkar Group)[1]

Precambrian (Grand Canyon Series): Northern Arizona.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

J. H. Maxon, 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1963. Thickness 1,500 feet in Bright Angel quadrangle. Overlies Hakatai shale. Grand Canyon series.

Named for exposures in Canyon of Shinumo Creek, Shinumo quadrangle, Grand Canyon region.

Ship Mountain Granite

Jurassic: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

Shippensburg Formation

Middle Ordovician (Bolarian): South-central Pennsylvania and western Maryland.
