L. C. Craig, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1963–1964. Name given to beds formerly included in basal part of Chambersburg limestone. Consists of dark-gray limestone, cobbly below and even bedded above. Thickness 500 feet. Underlies Mercersburg formation (new); overlies "Lowville." Shippensburg thins westward from Marion to extinction along Cove and North Mountains. In western belts of outcrop in Cumberland Valley, the Mercersberg and Greencastle converge, the former being separated from the Shippensburg by Hatter limestone and Snyder member of Benner limestone.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 715 (fig. 1), 717–718. Redefined and subdivided. Stratigraphically restricted by assignment of beds at top of formation to Mercersburg formation. Includes five distinct limestone types: dark gray, fine-grained, and cobbly; dark gray, fine grained, and evenly bedded; medium to coarse calcarenite; interbedded dark-gray medium-grained limestone and calcilutite pellet conglomerate; and dove-colored calcilutite. Seven metabentonites recognized in eastern belts of outcrop; not all present in one section. In western belts, includes (ascending) Pinesburg, Fannettsburg and Doylesburg members (all new). In eastern belts, where thickest only Pinesburg and Fannettsburg members are recognized. Thickness 416 feet at type locality; thins to northeast, south, and west. Unconformably overlies "Stones River" limestone; unconformably underlies Mercersburg formation. Upper contact marked by lithologic change and a prominent irregular partially silicified bedding surface; lower contact poorly exposed and marked only by contrasting lithologic character at type section. Geographically extended to Maryland. Type locality further described. Derivation of name given.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped in lower part of Chambersburg formation.

Type section: Along Cumberland Valley 2.1 miles southwest of Marion, Franklin County, Pa. Named for exposure at Middle Spring 2.5 miles northwest of Shippensburg, Franklin County.

Shipps Creek Shale Member (of Wautubbee Formation)

Eocene (Claiborne): West-central Mississippi.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 62–65, pl. 2. Carbonaceous shales complexly interbedded and interlensed with silts and sands. Thickness 43 feet at type section. Underlies Cockfield formation, contact varies from sharply defined to transitional; overlies undifferentiated Wautubbee with contact conformable and highly transitional and arbitrarily drawn at base of section in which carbonaceous shales are predominant facies in southwestern Carroll and northwestern Holmes Counties.

Type section: Along county road south of bridge across Shipps Creek, SE¼NE¼ sec. 28, T. 15 N., R. 3 E., about 4 miles northeast of Lexington, Holmes County.

†Shirley Stage[1]

Upper Jurassic: Southeastern Wyoming.

Original reference: W. C. Knight, 1900, Geol. Soc. America Bull., v. 11, p. 377–388.

Named for Shirley Mountains.

Shiwits shale[1] or sandstones (in Tusayan Series)

Permian: Northwestern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, no. 3, p. 251, 338.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (table). In Tusayan series (new) of Carbonic age. Overlies Yampai shales; unconformably underlies Hermit shales.

In Grand Canyon region.

**Shnabkaib Member** or **Shale Member** (of Moenkopi Formation)[1]

Lower Triassic: Southwestern Utah and northwestern Arizona.

Original reference: H. Bassler and J. B. Reeside, Jr., 1921, U.S. Geol. Survey Bull. 726–C, p. 90, 92.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 60, 61. Described in Zion Park region where it is 216 to 476 feet thick; underlies an unnamed upper red member and overlies an unnamed middle red member. Cream-white, pink, and green-white gypsum in regular beds one-eighth to 3 inches thick and deep-red soft arenaceous gypsiferous mud shales; a few thin layers and oolitic aggregates of marine fossiliferous limestone.

Named for Shnabkaib Mesa, 2 miles southeast of town of Washington, on northwestern flank of Washington dome, Washington County, Utah.

**Shoal Gneiss**

Precambrian: Southwestern Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 41–43, pl. 1. Fine-grained banded gneiss containing quartz and feldspar porphyroclasts. Sericite schist interlayered with the porphyroclastic gneiss. On uplands schists weather to micaceous clay soil containing sericitic fragments. In places along Beaverdam and Brush Creeks, near Penitentiary Hill and northward, and in Privett Knob, unit is dark-colored biotite mylonite schist. Predominant rock type between New River and U.S. Route 58 and west of Saddle Creek is greenish-gray schist with blue quartz grains and coarse flesh-colored microcline. Schist and augen gneiss facies in region south of Bridle Creek. Mapped as younger than Grayson granodiorite gneiss, older than the associated mylonite.

In extreme southwestern part of Gossan Lead district, Grayson County. Extends from Beaverdam Creek, south of Independence, southwestward to south of New River. Area lies largely south of U.S. Route 58.

Shoal Creek Breccia

Tertiary: Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 41, 43 (map 2). Dark massive to rudely bedded deposits of hypersthene-augite-hornblende andesite(?) with maximum thickness of at least several hundred feet. Overlies Rencher formation; underlies Maple Ridge porphyry (new). Name credited to H. R. Blank (unpub. thesis).

Well exposed along Shoal Creek, west of Enterprise, Washington County.

Shoal Creek cyclothem[1] (in McLeansboro Group)

Shoal Creek cyclothem (in Modesto-Bond Formations)

Pennsylvanian: Southern and southeastern Illinois.

Original reference: H. R. Wanless, 1931, Geol. Soc. America Bull., v. 42, p. 801–812.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 10–11. In southeastern Illinois, Shoal Creek occurs in the sequence below the Flannigan cyclothem (new) and above the Collinsville cyclothem (new).

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 7, 11, pl. 1. Underlies Sorento cyclothem. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Modesto-Bond formations (both new). Above Macoupin cyclothem and below Sorento cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Sec. 34, T. 4 N., R. 3 W., Clinton County. Named from exposures along Shoal Creek.

†Shoal Creek Limestone[1]

Lower Cretaceous (Comanche Series): Central Texas.

Original references: R. T. Hill, 1889, Am. Geologist, v. 3, p. 289; 1889, Am. Jour. Sci., 3d, v. 38, p. 470; 1889, Texas Geol. Survey Bull. 4, p. xiv, xxii.

Named for Shoal Creek at Austin, Travis County.

**Shoal Creek Limestone** (in McLeansboro Group)

Shoal Creek Limestone Member (of Bond Formation)

Shoal Creek Limestone Member (of McLeansboro Formation)[1]

Middle and Upper Pennsylvanian: Central western and southwestern Illinois.

Original reference: H. Engelmann, 1868, Illinois Geol. Survey, v. 3, p. 148, 159–164, 175, 220.

J. M. Weller and W. A. Newton, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 11. Included in Shoal Creek cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, pl. 1. Rank raised to formation in McLeansboro group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), 67, 73, pl. 1. Rank reduced to member status in Bond formation (new). Basal member of formation. In central and southwestern area, occurs below McWain sandstone member; in southeastern and eastern area, occurs below Mount Carmel sandstone. Thickness 6 to 13 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: Along Shoal Creek and vicinity T. 3 N., R. 4 W., Clinton County.

**Shoal River Formation** (in Alum Bluff Group)[1]

Shoal River facies (of Alum Bluff Stage)

Miocene, middle: Northwestern Florida.

Original reference: Julia Gardner, 1926, U.S. Geol. Survey Prof. Paper 142, p. 1–3.

H. R. Smith, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 270 (fig. 2), 271 (table 1), 275. Includes Whites Creek beds (new).

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 167–180. Includes Oak Grove member and two faunal zones, *Yoldia waltonensis* and *Arca rubisiniana,* formerly included in Choctawatchee formation. Overlies Chipola formation; underlies Duplin marl.

Julia Gardner, 1947, U.S. Geol. Survey Prof. Paper 142–H, p. 493. Type locality stated.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 24–26. Considered facies of Alum Bluff stage. Includes Oak Grove facies in basal part.

Type locality: Shell Bluff, north bank of Shoal River, E½ sec. 4, T. 3 N., R. 21 W., 3½ miles (airline) northwest of Mossyhead and ¾ mile east of Godwin Bridge. Base of shell bed, 42 feet above river and about 135 feet above sea level.

†Shoal River Marl Member[1] (of Alum Buff Formation)

Miocene, middle: Northwestern Florida.

Original reference: G. C. Matson and F. G. Clapp, 1909, Florida Geol. Survey 2d Ann. Rept., p. 91, 104–106, table opposite p. 50.

Named for exposures on Shoal River, Walton County.

Shochary Sandstone (in Martinsburg Group)

Shochary Sandstone Member (of Martinsburg Formation)

Upper Ordovician (lower Maysville): South-central and east-central Pennsylvania and northwestern New Jersey.

Bradford Willard and A. B. Cleaves, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1183–1184, 1196. Name proposed for massive sandstone member in upper part of formation. Disconformably underlies Tuscarora sandstone. Lithologically, stratigraphically, and faunally, appears to be correlate of Bassler's Fairview sandstone in south-central sections but it is not traceable through. Carries Pulaski fauna.

Bradford Willard, 1943. Geol. Soc. America Bull., v. 54, no. 8, p. 1069, 1070, 1071–1074, 1118. Further described as unit in Martinsburg group. Upper part, unlike lower, essentially noncalcareous. Throughout, sandstone is medium to fine grained, well sorted, even bedded, and arkosic; conglomeratic beds rare. Dark-gray to gray-brown sandstone occurs in beds up to 4 feet thick. Interbedded with limestone, quartz-pebble, and limestone and shale-chip conglomerates. Thickness 750 feet at type locality. Overlies Dauphin shale (new) of Martinsburg group. No sharp line of separation between unit and underlying shaly or slaty beds of Martinsburg.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 20). Geographically extended to New Jersey.

Named for Shochary Ridge in northeastern Berks County and northwestern Lehigh County, Pa.

**Shoemaker Gravel**

Pleistocene: Southern California.

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Gravel, sand, and silt; some local beds of caliche a few inches thick near base. More consolidated than older alluvium and dips more steeply. Nature of contact with underlying Harold formation uncertain.

Type locality: Shoemaker Canyon, Valyermo quadrangle. Present only north of San Andreas fault but two small patches occur south of fault 2 miles west of quadrangle.

Shoemaker Limestone[1] Member (of Cass Formation)

Pennsylvanian (Virgil Series): Southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 33, 35, 173.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 29–30. Redefined and reallocated to Cass formation. Shoemaker as here redefined is the lower member of "Shoemaker" limestone defined by Condra (1927); that is, the name is now applied to the lower member of the Cass. Member consists of two dense bluish limestones separated by a shale seam. Thickness about 1½ feet. Underlies Little Pawnee shale member (new); overlies Plattford formation.

Type locality: West of Shoemaker Bridge along-side Shoemaker Farm, about 2½ miles northwest of Nehawka, Cass County.

Shohola Formation[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: B. Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 571, 585–587.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Generalized sequence for the (largely) nonmarine Upper Devonian or northeastern Pennsylvania shows Shohola formation above Delaware River flags and below Damascus red shale. Comprises Barryville member below and Paupack sandstone member above. Included in Catskill facies group.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7). Diagram shows facieological nomenclature of Chemung stage and shows Shohola facies group composed of Barryville and Paupack parvafacies.

Named from Shohola, on Delaware River near mouth of Lackawaxen Creek, Pike County.

Shongalo Greensand (in Claiborne Group)[1]

Eocene, middle: Northwestern Mississippi.

Original reference: E. W. Hilgard, 1860, Mississippi Geol. and Agr. Rept., p. 164–165.

Occurs in railroad cut at Vaiden Station, Shongalo, Carroll County.

**Shongaloo Member** (of Schuler Formation)

Upper Jurassic: Subsurface in northern Louisiana, southern Arkansas, and eastern Texas.

F. M. Swain, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 600–602. Lower member of formation. Includes nearshore facies of red and red-green shales, red and white sandstones and basal conglomerates, and the basinward offshore equivalents of these rocks, which are dark-gray fossiliferous shales, shelly limestones and sandstones, and basal conglomerates, lying beneath the Dorcheat member. In most wells, overlies Bossier formation; in southern Arkansas unconformably overlies Buckner or Smackover formation. In type well, occurs between depths of 8,455 and 9,450 feet. Thickness ranges from featheredge at northern limit to more than 1,000 feet in southern Arkansas and in Morehouse Parish, La. Thins southward in Louisiana to about 500 feet; in east Texas averages about 600 feet.

Type well: Magnolia Petroleum Co.'s Sexton Unit No. 1, SW¼NW¼SE¼ sec. 32, T. 23 N., R. 9 W., Webster Parish, La.; Shongaloo Field.

**Shoo Fly Formation**

Shoofly Formation[1]

Silurian(?): Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 132, chart 5, column 14. Fusulinids reported from the Shoofly indicate that [it] is as young as Pennsylvanian. Shown on chart as Pennsylvanian(?).

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California Westwood Sheet (1:250,000): California Div. Mines. Dark phyllite, slate, quartzite, and graywacke. Pre-Permian. Spelled Shoo Fly.

Named for exposures in road between Shoo Fly Bridge and Spanish Creek, Taylorsville region.

Shoreham Member (of Sherman Fall Formation)

Shoreham Limestone or Formation (in Trenton Group)

Shoreham Limestone Member (of Glens Falls Limestone)

Middle Ordovician: New York and Vermont, and Ontario, Canada.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 264–267. Member of Sherman Fall formation. Constitutes zone of *Cryptolithus tesselatus* Green, the limestones of lowest Sherman Fall age. In type region, beds comprise upper Glens Falls limestone, overlie lower Glens Falls Larrabee member of Hull age, and underlie Canajoharie shale of later Sherman Fall age. Beds consistently contain *Cryptolithus tesselatus*, which is limited to the member, and *Prasopora orientalis* Ulrich and *Trematis terminalis* (Emmons). This zone persists in the Sherman Fall northwestward to Lennox and Addington County, Ont., in the equivalent beds of northern Lake Champlain, and northeastward to city of Quebec. In type section, lower 36 feet of member is exposed. Along Mohawk Valley, member is composed of 15 to 25 feet of dark-gray calcareous claystones and shales that contrast with subjacent Larrabee member, and are succeeded abruptly by Canajoharie shale. Member has exposed thickness of 30 feet north of McBrides Bay, South Hero Township, Grande Isle County, Vt., with a metabentonite 11 feet from base. Overlying beds are Cumberland Head shaly limestone and Stony Point shale, both of later Sherman Fall age. In New York, underlies Denmark member (new).

G. M. Kay, 1942, Geol. Soc. America Bull., v. 53, no. 11, p. 1611–1612. Referred to as Shoreham limestone. Overlies Hull formation.

G. M. Kay 1943, Am. Jour. Sci., v. 241, p. 597–606. Rank raised to formation. Disconformably underlies Rathbun limestone member (new) of Denmark formation. Overlies Kirkfield limestone. (Term Kirkfield is preferred to term Hull). Thickness 45 feet.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 31, 34. Blue marble that may be Shoreham member of Glens Falls is called Whipple marble (new) in this report [Castleton area]. It cannot be traced northward around Taconic Range into the Glen Falls outcrop in Sudbury, Vt.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p. 525–527. Term Shoreham formation extended to include all *Prasopora orientalis* beds from top of coarse-bedded calcarenites of Kirkfield formation to base of *Trocholites* subzone and base of Camp member (new) of Denmark formation. Rathbun member of Denmark is herein removed from the Denmark and placed in Shoreham formation. Maximum thickness 52 feet, Lewis County, N.Y.; minimum thickness 15 feet in Mohawk Valley where it spans Adirondack arch.

R. B. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 30, 31–32, 81–82, 89–90, pl. 1. Upper member of Glens Falls formation. Thickness about 45 feet on Isle La Motte. Overlies Larabee limestone member. Underlies Head formation.

Named for exposures in Shoreham Township, Addison County, Vt.

Shorehamian Stage or Substage

Middle Ordovician (Trentonian): Eastern North America.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1414. Middle Trentonian includes rocks equivalent to Shoreham and Denmark limestone of New York or undivided Sherman Fall limestone. The Shorehamian marked by first appearance of *Cryptolithus tesselatus* Green in New York and Ontario has been recognized in lower part of Salona limestone of central Pennsylvania and eastern West Virginia and in Oranda limestone of Cumberland and Shenandoah Valleys, the "*Christiania*" beds of "Chambersburg limestone." There is a possibility that uppermost Eggleston and Collierstown beds are of this age. Lower "Hermitage" limestone of southwestern Virginia and Logana limestone of Kentucky have been included in stage. Shorehamian is of limestone throughout its extent, being generally more argillaceous than subjacent Kirkfieldian, particularly east of Adirondack line.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30. Suggested that term Shermian stage be applied to the Shorehamian and Denmarkian.

Name derived from Shoreham Township, Addison County, Vt., for which Shoreham member of Sherman Fall formation was named.

**Short Creek Oolite Member** (of Boone Formation)[1]

Short Creek Oolite Member (of Keokuk Limestone)

Upper Mississippian: Southeastern Kansas, southwestern Missouri, and northeastern Oklahoma.

Original reference: W. S. T. Smith and C. E. Siebenthal, 1907, U.S. Geol. Survey Geol. Atlas, Folio 148.

R. C. Moore, G. M. Fowler, and J. P. Lyden, 1939, Geol. Soc. America Spec. Paper 24, p. 3, 10, pl. 1. Named subdivisions of Keokuk are Short Creek oolite near top and Grand Falls chert near base. Short Creek is light-gray massive oolitic limestone which commonly appears as single bed 4 to 5 feet thick. Appears to be continuous throughout southwestern Missouri and in adjoining States wherever proper stratigraphic horizon is present.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 236. Included in Keokuk in this report with reservation that evidence for including it in Warsaw is equally strong. Occurs either at top of Keokuk or base of Warsaw. Until fauna is thoroughly studied solution of problem of its age cannot be reached.

E. L. Clark and T. R. Beveridge, 1952, Kansas Geol. Soc. Guidebook 16th Field Conf., p. 13 (fig. 1), 46 (fig. 19), 47 (fig. 20); (reprinted as Missouri Geol. Survey and Water Resources Rept. Inv. 13). Shown as member of Keokuk. Osagean.

G. G. Huffman, 1953, Oklahoma Geol. Survey Guidebook 1, p. 7. In northeastern Oklahoma, Boone formation is divided into (ascending) St. Joe, Reeds Spring, and Keokuk members. In Ottawa and northern Delaware Counties, a bed of white oolite, 2 to 10 feet thick, known as the Short Creek is present in upper Keokuk.

C. H. Behre, Jr., and A. V. Heyl, Jr., 1959, Deutsche Geol. Gesell. Zeitschr., v. 110, pt. 3, p. 517 (fig. 2). Chart shows Short Creek member of Boone formation in upper part of formation. Thickness 1 to 3 feet thick. Disconformably underlies Cherokee shale.

Named for exposures along Short Creek, a stream flowing westward between Galena and Empire in Cherokee County, Kans.

Short Mountain facies (of Fort Payne Formation)

Lower Mississippian: Central and southern Tennessee.

H. J. Klepser, 1937, Ohio State Univ. Abs. Doctors' Dissert, 24, p. 182. Named as southern facies of formation in Eastern Highlands Rim area.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 53–54. Silty siliceous limestones. Facies is everywhere underlain by Maury formation, contact conformable and district. At places where top of Fort Payne formation grades into impure, cherty limestone of the Warsaw, exact stratigraphic boundary is uncertain. Derivation of name given.

Named from Short Mountain, eastern Cannon County. Extends from central Jackson and Overton Counties to southern limit of the State.

Shorts Ranch Andesite

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 734–735, fig. 2, pl. 1. One of the most massive of the series of volcanics in the area and when fresh is light purplish gray. Weathers to reddish purple or, less commonly, brown. Has marked flow structure in southern part of range. Thickness at least 400 feet and probably much thicker. West of Tucson and in area north of Ajo Road it overlies Safford tuff (new).

J. E. Kinnison, 1959, Arizona Geol. Soc. Guidebook 2, p. 149 (fig. 2). Underlies Water Tank conglomerate (new); overlies Ivy May andesite (new).

Type locality: On Shorts Ranch, 10,000 feet northeast of Cat Mountain, Tucson Mountains, Pima County.

Shoshone[1]

Upper Triassic: Western Wyoming.

Original reference: W. C. Knight, 1901, Engr. Mining Jour., v. 72, p. 359.

Wind River Mountains.

Shoshone Group[1]

Upper Cretaceous and Eocene: Montana to New Mexico.

Original reference: W. Cross, 1909, Washington Acad. Sci. Proc., v. 11, p. 27–45.

Map published by Bureau of Ethnology shows district once occupied by Shoshone and Ute Indians.

†Shoshone Falls Andesite[1]

Miocene, upper: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 32 (table), 37–38, pl. 5. Exposed thickness about 200 feet; total thickness unknown. Underlies Pillar Falls mud flow, erosional unconformity.

H. T. Stearns, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 463. Suggested that the typical block-lava top of the andesite is represented by the overlying Pillar Falls mud flow.

Type section: Forms Shoshone Falls and Pillar Falls, in Twin Falls and Jerome Counties. Exposed along Snake River from foot of Twin Falls down as far as Perrine Ranch, a distance of 6 miles.

Shoshoni Limestone[1]

Cambrian: Western Wyoming.

Original reference: E. B. Branson, 1917, Geol. Soc. America Bull., v. 28, p. 347–350.

In Wind River Mountains.

†Shot Pouch Sandstone[1]

Mississippian: Western Kentucky.

Original references: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, p. 174, pl; 1857, Kentucky Geol. Survey, v. 2, p. 85–88.

Forms cliff at the Tar Spring, Breckinridge County.

Shrewsbury Member (of Redbank Formation)

Upper Cretaceous: Eastern New Jersey.

R. K. Olsson, 1959, Dissert. Abs., v. 19, no. 8, p. 2063. Redbank formation is divided into Shrewsbury and Sandy Hook members.

R. K. Olsson, 1960, Jour. Paleontology, v. 34, no. 1, p. 2, 4 (fig. 2). Consists of slightly glauconitic quartz sand. Overlies Sandy Hook member; underlies Tinton formation.

Occurs in New Jersey Coastal Plain.

**Shriver Chert** (in Oriskany Group)[1]

Shriver Chert Member (of Oriskany Formation)

Lower Devonian: Western Maryland, central Pennsylvania, central western Virginia, and eastern West Virginia.

Original reference: C. K. Swartz and others, 1913, Maryland Geol. Survey Lower Devonian volume, p. 91, table opposite p. 30.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull., G–19, p. 67. In some areas, overlies Mandata shale and chert.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 15 (table), 97, 107, 110. In West Virginia, replaced by Port Ewen and Port Jervis formation.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 86. In Maryland, Oriskany formation is subdivided into two members: Shriver chert below and Ridgeley sandstone above. Thickness of Shriver about 100 feet; may be absent in Washington County.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 4, 13, 26. Referred to as member of Oriskany formation; underlies Ridgeley member. Overlies Mandata member of Hamilton formation.

Named for Shriver Ridge at Cumberland, Md.

**Shublik Formation**[1]

Lower(?), Middle, and Upper Triassic: Northern Alaska.

Original reference: E. D. Leffingwell, 1919, U.S. Geol. Survey Prof. Paper 109, p. 103, 115, map.

W. W. Patton, Jr., and J. J. Matzko, 1959, U.S. Geol. Survey Prof. Paper 302–A, p. 3, 7–8, figs. 1–3. Composed principally of highly carbonaceous grayish-black shale, chert, and limestone. Comprises three members in Tiglukpuk Creek and upper Kiruktagiak River areas: lower member of black, gray, and greenish-gray shale with minor intercalated dark limestone, about 100 feet thick in upper Kiruktagiak River area but more than 500 feet thick in Tiglukpuk Creek area, with fauna dated as early Middle Triassic; middle member of dark siliceous limestone, black paper shale, and dark calcareous shale; and upper member of dark fossiliferous limestone capped by dark shale. Middle and upper members about same thickness in two areas—130 to 150 feet and 60 to 80 feet respectively—and have a Late Triassic fossil assemblage. Formation mapped and correlated over most of northern Alaska.

U.S. Geological Survey currently designates the age of the Shublik Formation as Lower(?) Middle, and Upper Triassic on the basis of a study now in progress.

Type locality: Shublik Island, on Channing River, at southwestern corner of Shublik Mountains.

**Shubuta Member** (of Yazoo Clay)

Eocene, upper: Eastern Mississippi and western Alabama.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1838 (fig. 6), 1839 (footnote). Shubuta (clay) member of Yazoo clay (or formation) proposed for 20 to 250 feet of clays and clayey marls, underlain by the Pachuta (marl) member (new) and overlain by the Forest Hill or Red Bluff clay of the Oligocene.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 122, 126, pl. 3. In Choctaw County, Ala., consists of light-greenish-gray and white highly calcareous clay which weathers to light greenish yellow to white; contains small irregular white lime concretions; in many places it is a white chalky calcareous clay or clayey limestone. Thickness 25 to 35 feet.

G. E. Murray, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 702 (fig. 1), 703. Underlies Mosley Hill formation.

Type locality: East side of Chickasawhay River, just north of U.S. Highway 45 bridge east of Shubuta, SW¼ sec. 3, T. 10 N., R. 16 E., Clarke County, Miss.

Shubuta Hill Clay

Eocene (Jackson): Central Alabama.

R. H. Smith and others, 1944, *in* Southeastern Geol. Soc. [Guidebook] 1st Field Trip, [Geol. section of] Little Stave Creek, Clarke County, Ala. Shown on geologic cross sections and stratigraphic column as a fossiliferous, glauconitic marl with phosphate nodules near top. Stratigraphically above Yazoo clay and below Red Bluff [clay].

O. L. Bandy, 1949, Bulls. Am. Paleontology, v. 32, no. 1, p. 13. Mentioned as a fossil locality in discussion of Little Stave Creek Foraminifera.

Shuksan Formation

Upper Jurassic: North-central Washington.

C. E. Weaver, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 10, p. 1391, 1392 (table 3). Mentioned as Shuksan formation consisting of marine sediments partly metamorphosed. Upper Jurassic. On table, occurs above Triassic Cultus and below Cretaceous Pasayten. (Plutonics are omitted from table).

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 977, chart 8C (column 99). Shuksan formation includes sandstone, shales, conglomerates, and cherty beds. Outcrop area noted.

Crops out in valley of North Fork of Shuksan River north of Mount Baker.

Shullsburg Member (of Quimbys Mill Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9. Thin-bedded dolomite. Thickness as much as 8 feet. Shown on columnar section as underlying Strawbridge member (new) and overlying Hazel Green member (new).

Occurs in Dixon-Oregon area.

Shultz Limestone Member (of Talpa Formation)[1]

Permian: Central Texas.

Original reference: W. Kramer, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1579, 1582.

Named from ranchhouse of Mrs. Winifred Shultz which is on the ledge formed by the outcrop in NE¼ T. & N. O. Railroad Co. Survey 127, 8 miles southeast of Paint Rock, Concho County.

Shumla Sandstone[1] (in Canadaway Group)

Shumla Siltstone Member (of Canadaway Formation)

Upper Devonian: Western New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 25 and chart.

I. H. Tesmer, 1955, New York State Mus. and Sci. Service Circ. 42, p. 10 (fig. 1), 18. Termed siltstone member of Canadaway formation. Underlies Northeast shale member; overlies Westfield shale member. Thickness at type locality about 30 feet.

Exposed at Shumla, Chautauqua County.

Shumway cyclothem (in McLeansboro Group)

Shumway cyclothem( in Mattoon Formation)

Pennsylvanian: Central Illinois.

J. M. Weller and W. A. Newton, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 329. Upper part of McLeansboro formation is divided into (ascending) Merom, Shumway, Woodbury, Gila, Greenup, Newton, Bogota (upper and lower), Cohn, La Salle, Macoupin, Flannigan, and Shoal Creek cyclothems.

J. M. Weller and A. H. Bell, 1941, Illinois Geol. Survey Rept. Inv. 76, p. 7. Youngest complete cyclothem known in Illinois. Includes Shumway limestone.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 13. Studies by Ekblaw in south-central Illinois resulted in tentative recognition of six cyclothems of which the Shumway is sixth in sequence (ascending); occurs above Shelby (new). Subsequent attempts to set up a single standard section based on assumption that Omega and Greenup limestones are equivalent resulted in a series of 13 cyclothems of which the Shumway is the 13th and occurs above the Woodbury. If the Greenup and Omega are not equivalent, section includes 14 cyclothems in which the Shumway and Newton are equivalent and occur below the Greenup and above the Shelby.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Included in McLeansboro group. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Mattoon formation (new). Plate 1 shows Shumway above Omega cyclothem and below Bogota cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: SE¼SE¼ sec. 26, T. 9 N., R. 5 E., Effingham County.

Shumway Limestone Member (of Mattoon Formation)

Shumway Limestone (in McLeansboro Group)

Pennsylvanian: South-central Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, Illinois Geol. Survey Bull. 67, p. 19 (fig. 4), 28 [1943]. Shumway "middle" limestone is lower of the two marine limestones of Shumway cyclothem. A lenticular discontinuous dark-bluish-gray argillaceous hard massive bed. Maximum thickness 1½ feet. Overlies a thin coal horizon; underlies a persistent black sheety shale and "upper" limestone, 1 to 3 feet thick. Stratigraphically above Omega limestone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Type locality stated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 51 (table 1), 81, pl. 1. Rank reduced to member status in Mattoon formation (new). Occurs above Omega limestone member and below Effingham limestone member. Thickness about 2 feet at type outcrop. Presentation of new rock-stratigraphic classification of Pennsylvanian strata of Illinois. Cyclical classification is retained but is independent of rock-stratigraphic classification.

Type locality: SE¼SE¼SW¼ sec. 26, T. 9 N., R. 5 E., Effingham County.

Shunganunga Shale[1]

Pennsylvanian: Northeastern Kansas.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 29.

Named for Shunganunga Creek, Shawnee County.

**Shurtz Sandstone Tongue** (of Navajo Sandstone)

Triassic(?) and Jurassic: Southwestern Utah.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2520, 2521. At type locality, 110 feet thick and consists of fine- to medium-grained moderate reddish-orange sandstone in beds ranging from 2 to 5 feet in thickness. Lies between 410 and 720 feet below of Navajo as mapped by Thomas and Taylor (1946, U.S. Geol. Survey Water-Supply Paper 993) and as accepted in this report. In section along Coal Creek (measured by Thomas and Taylor), the Shurtz tongue is designated as units 26 and 27 of Chinle formation; in section republished by Gregory (1950, Utah Geol. and Mineralog. Survey Bull. 37), tongue appears as units 21 and 22. Although Thomas and Taylor's section shows Shurtz sandstone as separate unit below base of Navajo, Gregory mapped base of Shurtz tongue as base of Navajo, but did not note change on republished section. Interpretation that Shurtz sandstone is more appropriately regarded as tongue of Navajo is based on observations of pronounced thinning of Shurtz from 345 feet in Coal Creek to 110 feet in Shurtz Creek, and to 62 feet in Muries Creek; this abrupt thinning takes place in a distance of 8 miles. Underlies Cedar City tongue (new) of Kayenta formation. Lamb Point tongue (new) of Navajo at Kanab thins abruptly westward as Shurtz tongue at Cedar City thins southward; the possibility exists that the two tongues join somewhere between the two localities.

Type locality: Shurtz Canyon, about 6 airline miles south of Cedar City. Makes up prominent ledge that forms crest of Red Hill east of Cedar City.

†Shutesbury Serpentine[1]

Lower Cambrian: Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 55.

Named for exposure 1 mile south of village of Shutesbury, Franklin County.

Shutler Formation[1]

Tertiary, late, and Pleistocene: Central northern Oregon.

Original reference: E. T. Hodge, 1932, Oregon Univ. Pub. Suppl. to Geol. Ser., v. 1, no. 5, p. 6.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, pl. 2. Chart shows age as lower and middle Pliocene:

Well developed near Shutler post office, T. 2 N., R. 21 E., Gilliam County.

**Shuttle Meadow Formation** (in Newark Group)

Upper Triassic: Central Connecticut.

E. P. Lehmann, 1959, Connecticut Geol. and Nat. History Survey Quad. Rept. 8, p. 7, 8 (table 1), 11–12, pl. 1. Proposed for sedimentary rocks overlying Talcott basalt and underlying Holyoke basalt. Unit had been termed lower sedimentary division of Meriden formation by Krynine (1950). Predominant rock type is grayish-red to dark-reddish-brown shale with occasional mudstone of similar color; pale-orange, grayish-orange, grayish-red, and dark-reddish-brown coarse to very fine arkose also present; minor amounts of yellowish-gray and pale-brown coarse- to fine-grained feldspathic sandstone. Shrinkage (mud) cracks, current ripple marks, and crossbedding common; some shales and sandstones very finely laminated; some mudstones massive. Of total calculated thickness of about 310 feet, only about 50 feet are exposed. Contact with underlying Talcott basalt basically conformable, but evidence suggests minor erosion.

R. W. Schnabel, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–134. Described in Avon quadrangle, Connecticut, where it consists of moderate reddish-brown to grayish-red arkosic siltstone and shale with subordinate lenses of fine- to medium-grained arkose. Lies between Talcott below and Holyoke basalts; forms bench between basalt cliffs along west face of Talcott Mountain. Thickness 50 to 100 feet, thinnest at northern end of quadrangle.

Type sections: Shuttle Meadow Reservoir sections as described by Krynine (1950)—that is, southern shore of Shuttle Meadow Reservoir between Meriden and New Britain, Middletown quadrangle. Exposed in narrow belt along southern half of west margin of quadrangle; outcrops few and small in lateral extent.

**Siamo Slate**[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 554.

W. T. Stuart, E. A. Brown, and E. C. Rhodehamel, 1954, Michigan Dept. Conserv., Geol. Survey Div. Tech. Rept. 3, p. 11 (table 3). Thickness about 650 feet in Marquette district. Overlies Ajibik quartzite; underlies Negaunee iron-formation. Middle Huronian.

Named for exposures on Siamo Hill, just south of western part of Teal Lake, Marquette district.

Sias Quartzite

*See* Sais Quartzite.

Siberia Limestone (in Chester Group)[1]

Mississippian: Southern Indiana and northern Kentucky.

Original references: C. A. Malott, 1920, Science, new ser., v. 51, p. 521–522; 1925, Indiana Acad. Sci. Proc., v. 34, p. 109–132.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7. Replaced by Menard limestone. Local Indiana names of upper Chester are dropped, and formations given names of standard Chester column.

Named for exposures in vicinity of Siberia, Perry County, Ind.

Sicily Island Formation or terrace

Recent: Southwestern Louisiana.

J. A. Doering, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1822 (table 1), 1829–1830, 1831 (table 2), 1837 (table 3), 1840. In description of physiography of southwest Louisiana the following new formation names are introduced (descending): Sicily Island, Holloway Prairie, Eunice, and Oberlin. However, text discusses Sicily Island as as terrace; hence, it is not clear which use is intended.

Town of Sicily Island is in Tensas Parish on south end of low ridge of the A series, or oldest Sicily Island sediments. Topographic feature averages about 6 miles in width and extends about 80 miles northward up valley, through Winnsboro and Delhi to a point beyond Oak Grove. Elevations rise from 75 feet at Sicily Island to 115 and 120 feet at Oak Grove.

Sidewinder Volcanic Series

Triassic(?): Southern California.

O. E. Bowen, Jr., *in* L. A. Wright and others, 1953, California Jour. Mines and Geology, v. 49, no. 1, pl. 2. Shown on columnar section as rhyolite and dacite flows and pyroclastics about 3,000 feet thick; overlies Fairview Valley formation (new).

O. E. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 16 (fig. 2), 42–53, pls. 1, 2, 3, 8. Replaces name Sidewinder Valley metavolcanics as used by Miller (1944). Name Sidewinder Valley does not appear on existing maps, and Miller's map does not show its location. Miller's Sidewinder Valley metavolcanics, as mapped, included rocks of several ages; Miller believed series to be interbedded with Oro Grande series and to be Paleozoic in age. As redefined, Sidewinder volcanic series is prodominantly a pyroclastic assemblage subaerially laid onto very irregular topography. Over most of Barstow quadrangle series consists of overlapping interfingering irregularly shaped masses of dacite, quartz latite, latite-andesite, and rhyolite. Unconformably overlies Permian Fairview Valley formation, intruded by Jura-Cretaceous granitic rocks.

Type locality: Sidewinder Mountain, Barstow quadrangle, San Bernardino County. Greatest thicknesses are in Silver Mountain group of hills, Sidewinder Mountain, Stoddard Mountain, and Raven Ridge.

Sidewinder Valley Metavolcanics

Upper Paleozoic: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 73–74, 100–102, pl. 5. Include both original lavas and tuffs which have been highly altered and usually strongly foliated. In type area, consist entirely of schistose metavolcanics with a little interbedded quartz schist and quartzite. In some places, interbedded with late Paleozoic Oro Grande metasediments.

E. O. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 42. Replaced by Sidewinder volcanic series.

Type area: Eastern half of small mountain just north and west of Victorville-Barstow road. Named for typical occurrences in hills overlooking northeastern end (or head) of Sidewinder Valley, 3½ to 5 miles northeast of Sidewinder Well, Victorville area of Barstow quadrangle, San Bernardino County.

Sidney Gravel or Formation (in Ogallala Group)

Sidney Gravel and Silt Member (of Kimball Formation)

Pliocene, middle to upper: Southwestern Nebraska, northeastern Colorado, and western Kansas.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, no. 213, p. 224, 227; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1261–1263, 1266 (table 2). At type exposure, consists of crystalline sand and gravel ranging in texture from fine and medium river sand to pebbles and cobbles as much as 4 to 6 inches in diameter. Thickness 15 to 50 feet; at type locality 20 feet. Overlies caliche at top of Ash Hollow formation; underlies Kimball formation (new). Middle to late Pliocene.

C. B. Schultz and T. M. Stout, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 555–556. Referred to as gravel and silt member at base of Kimball formation; locally unconformable on older beds, but generally affording a transition from latest Ash Hollow sand and gravel channels.

Type exposure: Bluff at north side of town of Sidney, Cheyenne County, Nebr. Widespread in Nebraska, Colorado, and Kansas.

Sidney Shale Member (of Markley Formation)

Eocene, upper: Northern California.

B. L. Clark and A. S. Campbell, 1942, Geol. Soc. America Spec. Paper 39, p. 9–10. Radiolarian-bearing shale occurring a little more than 2,000 feet above base of the Markley. Toward the base, the Sidney is a gray shale which grades downward into the Markley. Thickness about 700 feet; thins rapidly to northwest and wedges out into sands; cut out to southeast as a result of San Pablo (upper Miocene) overlap. Near Kirker Creek, underlies about 500 feet of micaceous gray to yellow-brown sandstone, with intercalated shale included in Markley formation by Clark (1918).

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Unit described and assigned to member rank in Kreyenhagen formation. However, term Sidney is used in quotational sense because name Sidney is preoccupied.

C. V. Fulmer, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1341. Referred to as Sidney Flat shale member.

Type section: A long narrow outcrop beginning a little west of Kirker Creek, Mount Diablo quadrangle.

Sidney Flat Shale Member (of Markley Formation)

*See* Sidney Shale Member (of Markley Formation)

†Siebert Formation[1] or Lake Beds

Miocene, upper: Southern and central Nevada and southeastern California.

Original reference: S. H. Ball, 1907, U.S. Geol. Survey Bull. 308, p. 27, 32–34, map.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines. Siebert Lake beds mapped in Inyo County. Pliocene.

Probably named for occurrence in vicinity of Siebert Mountain, Tonapah region, Nevada.

**Siebert Tuff**[1]

Miocene, upper: Central Nevada.

Original reference: J. E. Spurr, 1905, U.S. Geol. Survey Prof. Paper 42, p. 51–55, maps.

Exposed on east slope of Siebert Mountain, Tonopah region.

Sierra limestone[1]

Mississippian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1908, Am. Inst. Mining Engineers Bi-Monthly Bull. 19, p. 7–21.

Sierra County. Derivation of name not given.

Sierra Blanca Limestone[1]

Eocene, middle: Southern California.

Original reference: R. N. Nelson, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 10, p. 350, 352–354, pl. 46, map.

B. M. Page, J. G. Marks, and G. W. Walker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1745–1749. Described northeast of Santa Barbara. Unconformably overlies undifferentiated Cretaceous shale. In some localities, grades upward into sandstone of Juncal formation (new). Thickness 20 to 50 feet. Lower middle Eocene. At type locality, disconformably overlies Upper Cretaceous Mono shale and grades upward into sandstone and shale of Eocene age. Thickness at type locality 225 feet.

Type locality: On Indian Creek, 10 miles northwest of Pendola Guard Station, Santa Barbara County.

Sierra Blanca Series[1]

Sierra Blanca coal measures[1]

Upper Cretaceous (Benton): Southern central New Mexico.

Original reference: D. R. Semmes, 1920, Am. Jour. Sci., 4th, v. 50, p. 415–420.

Probably named for Sierra Blanca, Lincoln and Otero Counties.

Sierra de Cayey Series

Cretaceous: Puerto Rico.

E. T. Hodge, 1920, New York Acad. Sci. Scientific Survey of Puerto Rico and the Virgin Islands, v. 1, pt. 2, p. 137–142. Series of conglomerates and tuffs. Thickness between 3,000 and 4,000 feet. Overlies Barranquitas-Cayey series; contact sharp; underlies Guayama series.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 24. Ildefonso formation (new) includes part of the Río Jueyes, Guayama, and Sierra de Cayey series of Hodge (1920) which could not be recognized in area of present study.

Named for exposures along crest of Sierra de Cayey Mountains, Coamo-Guayama district.

Sierra de Cayey Tuffs[1]

Cretaceous: Puerto Rico.

*See* Cayey Tuffs.

Sierra Grande Andesite or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 122–124, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined but stratigraphic position of Sierra Grande, Purvine Mesa, Dunchee Hill, and Gaylord Mountain is not known. Sierra Grande andesite resembles Red Mountain dacite of Collins (1949) and if it is a correlative it is earlier than Clayton basalt of Collins (1949) but in this report it is grouped with Clayton basalts.

Sierra Grande is in Union County.

Sierran[1] (period)

Pliocene and Quaternary: California.

Original reference: J. Le Conte, 1899, Jour. Geology, v. 7, no. 6, p. 525–544.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 23. Incidental mention in discussion of Mio-Pliocene floras from west-central Nevada.

Named for Sierra Nevada region.

Sierra Negra Basalt

Pliocene: Northwestern New Mexico.

A. J. Budding, C. W. Pitrat, and C. T. Smith, 1960, New Mexico Geol. Soc. Guidebook 11th Field Conf., p. 83 (table 1), 85. Name applied to dikes and flows of basaltic composition. Dikes cut El Rito and Abiquiu and Cutler formations. Basalt flow 90 feet thick caps Sierra Negra and overlies Abiquiu tuff.

Present in southern part of Canjilon Southeast quadrangle.

Sierrita Granite

Precambrian: Southeastern Arizona.

W. C. Lacy, 1959, Arizona Geol. Soc. Guidebook 2, p. 186, fig. 44. Coarse-grained oligoclase granite. Forms basement rock and much of core of Sierrita Mountains. Unconformably underlies Bolsa quartzite.

Exposed in long strip in western part of east Sierrita area (eastern side of Sierrita Mountains), Pima County, about 25 miles south of Tucson.

Sierrite Limestone or Formation (in El Paso Group)

Lower Ordovician: Southwestern New Mexico.

V. C. Kelley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2201 (table). On table only. Thickness from fraction of a foot to 250 feet. Underlies Bat Cave limestone (new) ; overlies Bliss sandstone.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 42–45, fig. 4. Thin- to medium-bedded, the thin beds and laminations result in a distinctive banded appearance. Laminations commonly consist of alternating layers of limestone and chert with latter generally the thinner. Chert laminations are brown weathering, whereas limestone generally weathers medium gray. On fresh surfaces, Sierrite limestone is medium gray to dark gray with slight brownish cast. Most beds are microgranular, but fine- to medium-grained textures are common. Limestone entirely calcite at type locality. Chert is light gray to white on fresh surfaces. Except for chert laminations, formation is almost exclusively limestone. At Molinas Canyon section in southern end of the range, a few thin lentils of brick-red shale present about 35 feet above base of formation. Thickness 167 feet at type locality. Conformable with confining formations. Lower formation of El Paso group. Type section and areal distribution indicated.

Type locality: Exposures on north side of Cable Canyon, Caballo Mountains. Named from Sierrite iron mine on south side of the canyon. Crops out all along west face of Caballo Mountains, in west face of Mud Springs Mountains, and in west face of south Red Hills, at south end of Nakaye Mountain, and in west face of Red House Mountain.

**Siesta Formation**[1] (in Berkeley Group)

Siesta Formation (in Contra Costa Group)

Pliocene: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pub., Dept. Geol. Bull., v. 2, p. 384–390, map.

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 143. Described as consisting of marsh and lake clays, ostracodal clays and impure ostracodal limestone, banded impure cherts, silts, sandstones, gravels, thin lignitic beds, and beds of volcanic ash. Thickness 700 feet in south part of area; thins to less than 50 feet north of Grizzly Peak. Succeeded by and interbedded with Bald Peak lavas; interbedded with underlying Moraga volcanics. Lower Pliocene.

D. E. Savage, B. A. Ogle, and R. S. Creely, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1511. Included in sequence of formations in west-central Contra Costa County for which a new group name is proposed (name not given). Sequence (ascending) is Orinda, Moraga, Siesta, Bald Peak, and unnamed formation. Unnamed unit is exposed east of Moraga fault system in fault contact with Siesta and Moraga formations.

C. K. Ham, 1952, California Div. Mines Spec. Rept. 22, p. 15. Lists sequence of Contra Costa group (new) as Orinda, Grizzly Peak, Siesta, Bald Peak, and Mulholland (new) formations.

Named for development in Siesta Valley, Berkeley Hills, San Francisco region.

Signal Hill Beds

Pleistocene, lower: Southern California.

J. E. Eaton, 1943, California Div. Mines Bull. 118, pt. 2, p. 204 (fig. 86) [preprint 1941]. Referred to as coarse, highly deformed, and deeply degraded beds apparently younger than the San Pedro, but their relation to this substage is unknown.

Occurs in Los Angeles Basin.

**Signal Mountain Formation**[1] (in Arbuckle Group)

Upper Cambrian: Southeastern Oklahoma.

Original reference: E. O. Ulrich, 1932, Geol. Soc. America Bull., v. 43, p. 742–747.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 21–22, measured sections. Thickness 114 to 478 feet in Arbuckles. On McKenzie Hill, rests with apparent conformity on Fort Sill limestone, but hiatus probably occurs at this locality, because Royer formation lies between it [Signal Mountain] and Fort Sill in northwestern part of Wichitas and in all of its exposures in Arbuckle Mountains. In latter region, it is overlain by Butterly formation (new) and occupies position between two dolomites, Royer below and Butterly above.

Named for exposures in sec. 8, T. 2 N., R. 12 W., about 1 mile south of Signal Mountain, a prominent peak at eastern end of Wichita Range.

**Signal Point Shale** (in Gizzard Formation)

Signal Point Shale (in Gizzard Group)

Lower Pennsylvanian: Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4, 19, pls. 2, 3, 4. Overlies Warren Point sandstone; underlies Sewanee conglomerate of Crab Orchard Mountains group (new). Thickness at type section 52 feet; thins westward to 10 feet at type section of Gizzard group; along eastern edge of Walden Ridge averages about 60 feet; along Western Escarpment commonly very thin and locally completely truncated by Sewanee conglomerate. Pottsville series.

Type locality: On State Highway 8 east of Signal Point and just south of town of Signal Mountain, Chattanooga quadrangle, Hamilton County.

**Siksikpuk Formation**

Lower(?) Permian: Northern Alaska.

W. W. Patton, Jr., 1957, U.S. Geol. Survey Prof. Paper 303–B, p. 41–43. Chiefly of variegated green, gray, and dark red shale and siltstone that locally are notably calcareous, cherty, or ferruginous. Variegated nature and bright yellow and orange weathering of ferruginous beds are distinctive. Thickness of composite section measured in type area totals 354 feet. Everywhere it appears to rest disconformably upon rocks of Lisburne group; disconformably underlies Shublik formation.

Type section is composite of two separate outcrops, approximately 2 miles apart along narrow belt of exposures immediately adjacent to north front of Brooks Range. Basal 62 feet measured in cutbank on east side of Skimo Creek at about lat 68°17′ N. and long 151°53′ W. Remainder of section measured in cutbank on east side of small tributary to Tiglukpuk Creek at about lat 68°17′ N. and long 151°48′ W. Named from Siksikpuk River, to which Tiglukpuk Creek is a major tributary.

**Siletz River Volcanic Series**

Eocene, lower: Northwestern Oregon.

P. D. Snavely, Jr., and E. M. Baldwin, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 5, p. 806–812. Name proposed for a series of basaltic flows, pillow lavas, flow breccias, and pyroclastic rocks that includes small amounts of water-laid tuffaceous sedimentary rocks that contain a fauna correlative with the Capay shale of California. Base of series not exposed; minimum thickness of 3,000 to 5,000 feet computed for section between Valsetz and forks of Siletz River. Overlain with apparent conformity, except where faulting has produced local angular relationships, by rhythmically bedded micaceous arkosic sandstone of middle(?) Eocene age; in northwestern part of area upper Eocene siltstones unconformably overlap the middle(?) Eocene sandstones and rest directly on the volcanics. Structurally the volcanics are folded into broad anticlinal arches with minor flexures; one arch trends northward along western half of mass, plunging northeast; the other trends north of east and plunges beneath the Willamette Valley near Dallas. Correlated with Umpqua formation and with lower part of Tillamook volcanic series.

P. D. Snavely, Jr., and H. E. Vokes, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 97. Described in coastal area between Cape Foulweather and Cape Kiwanda where it conformably underlies Burpee formation.

H. E. Vokes, D. A. Myers, and Linn Hoover, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–150. In west-central border area of Williamette Valley, includes Kings Valley siltstone member (new) in upper part. Volcanics extend in broad north-east trending belt from northwest corner of Monroe quadrangle into Albany quadrangle where they are well exposed in quarries near Coffin Butte.

Type section: Along Siletz River from Valsetz milldam, sec. 28, T. 8 S., R. 8 W., to the Lower Gorge, sec. 16, T. 9 S., R. 9 W., Lincoln County. Well exposed along Siletz River and its tributaries in Euchre Mountain and Valsetz quadrangles.

Silica Shale, or Formation

Silica Shale (in Traverse Formation)[1]

Middle Devonian: Northwestern Ohio.

Original reference: G. A. Stewart, 1927, Ohio Geol. Survey, 4th ser., Bull. 32, p. 5–9.

G. A. Stewart, 1936, Jour. Paleontology, v. 10, no. 8, p. 739–740. As originally defined, was considered to comprise a single shale unit about 10 feet thick. Herein stratigraphically expanded above and below to include a sequence, approximately 45 feet thick, of blue shales, blue argillaceous limestones, and blue shaly limestones. Of total thickness only basal 16 feet are exposed in quarry at Silica.

G. A. Stewart, 1938, Geol. Soc. America Spec. Paper 8, p. 6, 7. Underlies Tenmile Creek dolomite (new). Separated from underlying Columbus limestone by an 8-foot unit termed Blue limestone. Considered best to discontinue use of term Traverse for upper Middle Devonian units of northwestern Ohio between Columbus limestone and Ohio shale.

G. M. Ehlers, E. C. Stumm, and R. V. Kesling, 1951, Devonian rocks of southeastern Michigan and northwestern Ohio: Ann Arbor, Mich., Edward Brothers, Inc., p. 18–20. Stratigraphically expanded below to include 8-foot unit termed Blue limestone by Stewart (1938). Overlies Dundee limestone ("Columbus limestone" of Ohio geologists). Well records in southeastern Michigan show a northward continuation of several units of the Silica and indicate that formation is thicker than in Ohio.

K. V. Hoover, 1960, Ohio Geol. Survey Inf. Circ. 27, p. 8–16. Stratigraphic position and correlation of Olentangy shale discussed in detail. It is here suggested that the Olentangy, Plum Brook shale, Prout limestone, Silica shale, and Ten Mile Creek dolomite are stratigraphically correlatable, with the reservation that Olentangy is probably Upper Devonian. Olentangy interval is represented by Silica shale and Ten Mile Creek dolomite in northwestern Ohio. Silica formation is series of alternating shales and limestones that are highly fossiliferous and are thin to thick bedded. Basal beds are bluish gray and have been called "Blue" limestone. Field relationships between limestone beds of Silica formation and Ten Mile Creek dolomite are similar. Regional information regarding Silica formation-Ten Mile Creek dolomite has not been worked out. Combined thickness of 93 feet for the two units has been reported in Lucas County exposures.

Named for exposures in quarry of Sandusky Cement Company [now operated by Medusa Portland Cement Company] one-half mile north of Silica, Lucas County.

†Silo Sandstone[1]

Upper Cretaceous: Southeastern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79, p. 6.

Named for Silo, Bryan County.

Silver Shales[1]

Silver Shale Member (of Percha Shale)

Upper Devonian or Lower Mississippian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1898, Am. Inst. Mining Engineers Bi-Monthly Bull. 19, p. 7, 9.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228 (table). Assigned to Linnian series.

M. A. Stainbrook, 1947, Jour. Paleontology, v. 21, no. 4, p. 298. Considered lower member of Percha shale. Lower part of Percha also termed Ready Pay member by Stevenson (1944). There is little doubt that the Silver and Ready Pay were proposed for identical division of Percha, and there is little reason to replace earlier name. Percha of early Mississippian age.

Named for Silver City.

**Silverado Formation**

Paleocene: Southern California.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Name proposed for Paleocene strata of northwestern Santa Ana Mountains. In type area and nearby, formation consists of a lower nonmarine member and an upper marine member; marine member is thinner than nonmarine and thins and disappears southeastward through gradation into nonmarine deposits. Formation includes Claymont clay bed about 65 to 140 feet above base and Serrano clay bed about 275 feet above the Claymont. Thickness of formation ranges from about 700 feet to 1,475 feet. Underlies Santiago formation; rests disconcordantly on different parts of Upper Cretaceous sequence; on ridge forming divide between Sierra Canyon and Gypsum Creek and Coal Creek, formation rests successively on Pleasants sandstone, Schulz Ranch sandstone, and Holz shale.

R. F. Yerkes, 1957, U.S. Geol. Survey Prof. Paper 274–L, p. 324–325. Formation in El Modeno area, Orange County, consists of five lithologic units (ascending): conglomerate bed, 20 to 40 feet; lower arkosic sandstone about 100 feet; Claymont clay bed, about 2 feet; arkosic sandstone unit as much as 700 feet; and marine sandstone bed, about 300 feet. Underlies Santiago formation; unconformably overlies Cretaceous sedimentary rocks.

Rene Engel, T. E. Gay, Jr., and B. L. Rogers, 1959, California Div. Mines Bull. 146, p. 24, 77, 80, 81, 93, 95, 97, pls. 5, 7. Name "Silverado formation" was used by B. N. Moore (1930, unpub. thesis) to designate most of Triassic rocks on southwest slope of Santa Ana Mountains. These rocks have been correlated with metamorphosed sediments in Elsinore quadrangle [this report], and name "Silverado formation" conflicts with older name "Santa Ana formation." Footnote (p. 77) states that, in the discussion which follows, the rock units referred to as Bedford Canyon formation and Santiago Peak volcanics correspond in general to units referred to as Santa Ana formation and the Jurassic(?) volcanic and hypabyssal rocks respectively in preceding pages of bulletin. Term Silverado formation is used in place of Martinez formation to designate the Tertiary clay-bearing sedimentary rocks. Martinez formation mapped on plate 1. Silverado formation, Paleocene, is mapped on plates 5 and 7.

Type region: Area northeast of Irvine Park, northwestern Santa Ana Mountains, Orange County.

Silver Bell Formation

Tertiary: Southeastern Arizona.

J. H. Courtright, 1958, Arizona Geol. Soc. Digest, p. 7, 8. Composed mainly of angular to subrounded fragments of dark-gray to purplish-hued andesite porphyry enclosed in matrix of gritty andesitic mudstone. Fragments commonly 1 to 6 inches in diameter, but large blocks several feet in diameter occasionally present. Evidence of stratification extremely rare. Thickness from a few feet to possibly 200 feet. Appears to lie unconformably on Cretaceous and older sediments, although actual contacts not observed. Underlies volcanics that closely resemble Cat Mountain rhyolite of Tucson Mountains. Formation regarded as separate from underlying Cretaceous sediments.

Kenyon Richard and J. H. Courtright, 1960, Arizona Geol. Soc. Digest, v. 3, p. 1, 7. Unconformably overlies Claflin Ranch formation (new).

At Silver Bell mine [35 miles northwest of Tucson, in Silver Bell Mountains], Pima County. A formation of considerable extent.

Silver City Granite[1]

Age(?): Southwestern Idaho.

Original reference: A. M. Piper and F. B. Laney, 1926, Idaho Bur. Mines and Geology Bull. 11, p. 15.

Silver City, Owyhee County.

Silver City Monzonite

Eocene, middle or upper: Northern Utah.

D. R. Cook, 1957, Utah Geol. Soc. Guidebook 12, p. 65 (fig. 6). As shown on chart overlies Swansea quartz monzonite.

Area of report is Main Tintic mining district.

Silver Coulee Beds (in Polecat Bench Formation)

Paleocene: Northwestern Wyoming.

G. L. Jepsen *in* W. B. Scott, 1937, A history of land mammals in the Western Hemisphere: New York, Macmillan Co., p. 99; 1940, Am. Philos. Soc. Proc., v. 83, p. 236–237, 238 (table). Proposed for beds, 1,200 to 3,000 feet thick, that occur approximately 2,400 feet above base of formation. Matrix is fine-grained green sandstone. Faunally beds may be called the *Microcosmodon-Phenacodaptes-Litolestes* zone. Stratigraphically above Rock Bench quarry beds (new); and below Clark Fork beds.

Named for Silver Coulee, a tributary of Big Sand Coulee, in Sand Coulee Basin, Park County. Fossil quarry is in sec. 21, T. 57 N., R. 100 W.

Silver Creek Glacial Substage

Silver Creek Till

Pleistocene (Wisconsin): North-central Colorado.

D. F. Eschman, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1380. Time of third of four glacial advances in the area. Marked by terminal and recessional moraines. Followed Gould advance (new), preceded American Lakes advance (new).

D. F. Eschman, 1955, Jour. Geology, v. 63, no. 3, p. 205–206, fig. 2, table 1. Deposits of substage mapped as Silver Creek till. Substage represented by the most extensive and complete morainic system on Michigan River. Till is loose, sandy, and light brown; contains many subrounded cobbles and pebbles; reddish-brown clayey streaks rare; depth of oxidation in till about 20 inches.

Named from Silver Creek, a tributary of South Fork of Michigan River, the valley of which is choked at its lower end with a great amount of drift, Michigan River basin, North Park.

**Silver Creek Limestone Member** (of Sellersburg Limestone)[1]

Silver Creek Formation (in Hamilton Group)

Middle Devonian: Southern Indiana and central northern Kentucky.

Original reference: C. E. Siebenthal, 1901, Indiana Dept. Geology and Nat. Resources 25th Ann. Rept., p. 345.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1057, 1061–1063, 1067. Rank raised to formation in Hamilton group. Underlies Swanville formation (new); overlies Deputy formation (new). Close relationship of Silver Creek and Beechwood implied by their treatment as members of the Sellersburg does not exist. Their fossils represent separate time divisions in standard Hamilton scale. Beechwood is separated from Silver Creek by erosional disconformity. The two facies of upper beds of Silver Creek more or less merge in central Clark County and contain layers of bedded chert and chert nodules. New Chapel chert bed proposed by Whitlatch and Huddle (1931) is only local and perhaps of secondary origin; it does not identify bed as whole or at all localities; therefore, term seems unnecessary.

J. B. Patton and T. A. Dawson *in* H. H. Murray, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 42, pl. 1. Indiana Geological Survey considers Silver Creek and Speed as lithofacies of Hamilton rocks. These lithofacies may be used as members in southern part of outcrop belt.

Named for Silver Creek, Clark County, Ind.

†Silver Creek Shale[1]

Upper Devonian: Western New York.

Original reference: D. D. Luther, 1903, New York State Mus. Bull. 69, p. 1019–1029.

Well exposed in Walnut and Silver Creek Ravines, Chautauqua County.

Silver Dyke Breccia[1]

Tertiary: Central Montana.

Original reference: P. A. Schafer, 1935, Montana Bur. Mines and Geology Mem. 13, map.

Occurs west of Silver Dyke mine, Little Belt Mountains.

†Silverheels Porphyry or Porphyrite[1]

Eocene: Northeastern Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1886, U.S. Geol. Survey Mon. 12, p. 83, 104–107.

Named from the fact that it forms important intrusive sheets on Mount Silverheels, northeast of Alma, Park County.

**Silver Hill Formation**[1]

Middle Cambrian: Central western Montana.

Original reference: F. C. Calkins and W. H. Emmons, 1913, U.S. Geol. Survey Prof. Paper 78.

W. T. Holser, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1058–1059 (table 1). Underlies Hasmark dolomite; overlies Flathead quartzite. Limestone and shale 210 to 350 feet thick.

Named for exposures on steep east face of Silver Hill, south of Silver Lake, Philipsburg region.

Silver Hills facies[1] (of New Providence Formation)

Lower Mississippian: Southern Indiana and northern Kentucky.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 96–100.

J. E. Conkin, 1957, Bulls. Am. Paleontology, v. 38, no. 168, p. 110–111, 114–116. Silver Hills facies divided into three members in Jefferson and Bullitt Counties, Ky.: Kenwood sandstone, Button Mold Knob (new), and Coral Ridge (new) members.

Name derived from Silver Hills at southwest side of New Albany, Floyd County, Ind.

**Silverhorn Dolomite**[1]

Middle Devonian: Eastern Nevada.

Original references: L. G. Westgate and A. Knopf, 1927, Am. Inst. Min. and Met. Eng. Trans., no. 1647, p. 7; 1932, U.S. Geol. Survey Prof. Paper 171.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1781, chart 4. Age shown on correlation chart as Middle and Upper Devonian.

Named for exposures south of old Silverhorn mining camp, 4 miles northwest of Bristol Pass, Pioche district.

Silveria Formation[1]

Pleistocene: Northwestern Illinois.

Original reference: O. H. Hershey, 1896, Am. Jour. Sci., 4th, v. 2, p. 324–330.

Named for extinct Lake Silveria, in Pecatonica Basin, Stephenson County.

Silver King Dolomite Member[1] (of Bonanza King Formation)

Middle Cambrian: Southeastern California and southern Nevada.

Original reference: J. C. Hazzard and J. F. Mason, 1936, Geol. Soc. America Bull., v. 47, no. 2, p. 236–237.

J. C. Hazzard and J. F. Mason, 1953, Am. Jour. Sci., v. 251, no. 9, p. 651–652. Geographically extended into Goodsprings area, Nevada, where it lies within the Goodsprings dolomite of Hewett (1931). Described as a very dark smoky gray dolomite with inconspicuous bands 6 inches to 10 feet thick; upper part is a transition zone 20 to 25 feet thick in which light-gray beds, averaging 1 foot thick, alternate with darker beds 2 to 3 feet thick. Thickness about 190 feet.

Named for Silver King mine, on east side of Providence Mountains, San Bernardino County, Calif.

Silver King Quartz Monzonite Porphyry

Age not stated: South-central Arizona.

M. N. Short and others, 1943, Arizona Bur. Mines Bull. 151, Geol. Ser. 16, p. 42–43. In the least altered area, the rock is medium-dark-gray quartz diorite porphyry. In vicinity of mineralized area, the porphyry is light brown and highly weathered into spheroidal forms of variable size, mostly more than 1 foot in diameter. A specimen from inside a large spheroidal boulder is medium gray with faintly greenish tint. Rock is fine grained and holocrystalline.

Crops out as a roughly elliptical mass approximately 2,500 feet long from east to west by 1,200 feet wide. Represents the rock in which was developed the Silver King ore body, Superior mining area, northeastern Pinal County.

Silver Lake Group[1]

Pliocene: Central southern Oregon.

Original reference: T. Condon, 1902, The two Islands.

**Silver Lake Shale Member** (of Scranton Shale)[1]

Silver Lake Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 30.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 49 (fig. 11), 214. Rank raised to formation in Wabaunsee group. Term Scranton abandoned. Overlies Rulo limestone; underlies Burlingame limestone. Average thickness about 25 feet.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 3090 (fig. 14). Graphic section of Pennsylvanian in western Adams County shows Silver Lake shale underlying Burlingame and overlying Elmo coal which in turn overlies Cedar Vale (Cedarvale) shale.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Scranton shale here reintroduced as a formation with stratigraphic span as assigned to it by Haworth and Bennett (1908). Overlies Rulo limestone member; underlies Burlingame limestone member of Bern limestone (new).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 13, fig. 5. Bright-gray shale, well-bedded, with some limonitic bands at base. Thickness about 11 feet. Underlies Burlingame limestone; overlies Cedar Vale shale. Rulo limestone which underlies Silver Lake in some areas, not identified in Iowa. Wabaunsee group.

Type locality: Northeast of Silver Lake, Shawnee County, Kans.

Silver Mine Granite

Precambrian: Southeastern Missouri.

H. B. Graves, 1938, Acad. Sci. St. Louis Trans., v. 29, no. 5, p. 119. Medium-grained red granite distinguished from other granites of area [St. Francois Mountains] by its heavy-mineral assemblage. Cut by a number of dikes.

Occurs along southern border of main mass granite in Iron Mountain and Mine La Motte quadrangles.

Silver Mountain Monzonite Porphyry[1]

Eocene(?): Southeastern Colorado.

Original reference: R. C. Hills, 1900, U.S. Geol. Survey Geol. Atlas, Folio 68.

Well exposed in Huerfano Park quadrangle, adjoining Walsenburg quadrangle on west in Huerfano County.

Silver Pass Volcanics

Paleocene or Eocene: Central Washington.

R. J. Foster, 1957, Dissert. Abs., v. 17, no. 9, p. 1982; 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 105–107, pl. 1. Proposed for unit composed mainly of andesite and more felsic volcanic rocks, including flows, tuff, and breccia. Smith and Calkins (1906) included these rocks in their Kachess rhyolite, although they commented on the differences. Silver Pass volcanic rocks include "type area" of Smith's and Calkins' Kachess. In mapped area of this report, rocks called Kachess by Smith and Calkins can be separated into two groups, presumably of different ages: Silver Pass volcanic rocks of post-Swauk and pre-Teanaway age, and rhyolite within Naches formation. At Silver Pass, the volcanic rocks unconformably overlie Easton schist; to the southwest on ridge of French Cabin Mountain, they overlie Swauk formation; near Silver Pass, they are intruded by basaltic dikes presumably of Teanaway dike swarm; farther south, on ridge between Kachess Lake and Silver Creek, they apparently unconformably underlie Teanaway basalt. Unfossiliferous. May be Paleocene or Eocene, but discovery of fossils may alter this interpretation.

Type area: Silver Pass, between Silver Creek and French Cabin Creek, both of which drain region between Kachess and Cle Elum Lakes, central Cascades Mountains.

Silver Peak Andesites

Late Tertiary: Central eastern California.

H. D. Wilshire, 1957, California Univ. Dept. Geol. Sci. Bull., v. 32, no. 4, fig. 1. Named on map legend of Ebbetts Pass region. Younger than Raymond Peak andesites (new).

Ebbetts Pass region is in Alpine County.

†Silver Peak Group[1]

Lower Cambrian: Southwestern Nevada and eastern California.

Original reference: H. W. Turner, 1902, Am. Geologist, v. 29, p. 261–272.

C. R. Longwell, 1952, Washington Acad. Sci. Jour., v. 42, no. 7, p. 210, 211. Discussion of lower limit of Cambrian in Cordilleran region. Silver Peak series is of particular interest because fossils in relative abundance range through large part of its thickness. Beds overlie Campito sandstone. Correlates with Wood Canyon formation. Thickness about 7,000 feet.

Named for exposures in Silver Peak Range, Esmeralda County, Nev.

**Silver Plume Granite**[1]

Precambrian: Central northern Colorado.

Original reference: S. H. Ball, 1906, Am. Jour. Sci., 4th, v. 21, p. 389.

J. M. Bray, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 768 (fig. 1), 770. Younger than rocks of Pikes Peak group—Boulder Creek granite and Overland Mountain granite (new).

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 28, 29, 74, pl. 1. Younger than Pikes Peak and Sherman granites. As used in this report, Cripple Creek granite, Longs Peak granite, and Mount Olympus granites are included in the Silver Plume.

Forms south wall of Clear Creek Canyon at mining town of Silver Plume.

†Silver Reef Sandstone[1]

Upper Triassic: Southwestern Utah.

Original reference: J. B. Reeside, Jr., and Harvey Bassler, 1922, U.S. Geol. Survey Prof. Paper 129–D, p. 62, 73.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 23–25. Reeside and Bassler noted Silver Reef sandstone in section measured on Smiths Mesa, 3 miles north of Virgin City, Utah, and 12 miles east of Silver Reef. According to these authors, Silver Reef sandstone is 260 feet above base of Chinle, yet in Silver Reef area the correlative sandstone is 620 feet above base of Chinle. Reeside and Bassler's "arkosic sandstone" or supposed Silver Reef sandstone, lies about same distance above base of Chinle as that measured in present report [Silver Reef area, Washington County] for arkosic bed in Hartley shales and sandstones (new). Silver Reef sandstone in Silver Reef area is about same horizon as "mauve crossbedded, ripple-marked sandstone" of Reeside and Bassler.

Section measured on Smiths Mesa, 3 miles north of Virginia [Virgin] City, and 12 miles east of Silver Reef, Washington County.

Silver Reef Sandstone Member (of Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1950, Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1495. Includes lenselike bentonitic shales.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 23–25, pl. 2. Subdivided into the Leeds sandstone (new) which includes mainly white to buff fine- to medium-grained sandstone beds with interbedded shales; and an overlying lavender, fine- to medium-grained sandstone called Tecumseh sandstone (new). Member is 620 feet above base of formation. Contained all known commercial quantities of silver which were mined in the past in Harrisburg (Silver Reef) mining district. Underlies Duffin sandstone and shale (new) with local unconformities; overlies Trail Hill sandstone (new). The Silver Reef sandstone (of Reeside and Bassler) may be the same zone as the arkosic bed in the Hartley shale and sandstone (new) rather than the lateral equivalent of the Silver Reef sandstone member.

Described from Silver Reef (Harrisburg) mining district, Washington County.

**Silver Run Limestone**

Lower Paleozoic(?) (Glenarm Series): Western Maryland and southeastern Pennsylvania.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 346; A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties [Rept. 12], p. 62–63. Blue thin-bedded argillaceous banded finely crystalline limestone in which the argillaceous material forms slaty or muscovite partings. Occurs largely northwest of Wakefield marble (new) and in places seems to grade into the marble and may be equivalent to it; infolded with and underlies Marburg schist and Ijamsville phyllite (both new).

U.S. Geological Survey currently considers the age of the Glenarm Series to be Lower Paleozoic(?).

Named from valley of Silver Run, Carroll County, Md. Also present in Frederick, Md., and York County, Pa.

**Silver Star Granodiorite**

Tertiary: Southwestern Washington.

W. M. Felts, 1939, Ohio Jour. Sci., v. 39, no. 6, p. 297, 302–303, 306–307, 315 (fig. 4). Contains subordinate amounts of augite diorite and quartz diorite near borders. Intrudes Eagle Creek formation and lower parts of Skamania andesites (new). Miocene. J. E. Allen (unpub. thesis) described the granitic rock near Silver Star Mountain as Silver Star Formation.

†Silver Terrace Sandstone[1]

Jurassic(?): Western California.

Original reference: R. Crandall, 1907, Am. Philos. Soc. Proc., v. 46, p. 3–58.

Forms Silver Terrace Hills, in eastern part of San Francisco.

Silvertip Conglomerate Member[1] (of Madison Limestone)

Upper Devonian or Mississippian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 46.

L. L. Sloss and W. M. Laird, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 15. On correlation chart, included in DA unit of Devonian age which underlies Madison limestone.

Named for Silvertip syncline, because it is thickest on Lone Butte, which lies nearly in center of syncline. Known to occur in only three areas—Lone Butte, Spotted Bear Mountain, and Pentagon Mountain [Flathead County].

**Silverton Volcanic Group**

Silverton Volcanic Series[1]

Tertiary, middle and upper: Southwestern Colorado.

Original reference: W. Cross, 1901, U.S. Geol. Survey Bull. 182, p. 29–39.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13–14, 75–81, pl. 1. Complex of lavas, tuffs, and agglomerates. Maximum thickness about 3,000 feet. Includes (ascending) Picayune quartz latite, Eureka rhyolite, Burns quartz latite, pyroxene-quartz latite flows, and Henson tuff. Overlies San Juan tuff; older than Potosi volcanic series.

U.S. Geological Survey currently classifies the Silverton as a group and designates the age as middle and late Tertiary on the basis of a study now in progress.

Named after Silverton quadrangle where units have their greatest development. Present extent is about 40 miles east and west and 25 miles north and south.

Silverwood cyclothem (in Tradewater Group)

Pennsylvanian: Western Indiana.

J. W. Alexander, 1943, Illinois Acad. Sci. Trans., v. 36, no. 2, p. 142 (fig. 1), 143. Name applied to cyclothem in which Indiana coal II is developed. Unit is a dark shale 6 feet thick where it attains its maximum thickness. Near base are two limestones, the upper 2 inches thick, and the lower 4 inches thick. Stratigraphically below Middle Delong cyclothem and above Minshall limestone.

Well exposed on Coal Creek just north of route 234 in NE¼SW¼ sec. 36, T. 18 N., R. 8 W., in vicinity of Silverwood, Fountain County.

Silvey Gap Sandstone (in Redoak Mountain Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, 19, pls. 2, 3, 4. Maximum thickness 60 feet, at type locality. Separated from underlying Fodderstack sandstone (new) by shale interval that ranges from 45 to 110 feet in thickness; separated from basal shale of Vowell Mountain group (new) by a shale interval and the Pewee coal.

Named from exposures in Silvey Gap, above Windrock, Windrock quadrangle, Anderson County.

Silvies River Beds[1]

Lower Jurassic: Southeastern Oregon.

Original reference: W. D. Smith and E. L. Packard, 1919, Oregon Univ. Bull., v. 16, no. 7, p. 105.

Probably named for Silvies River, Harney County.

Simi Conglomerate[1]

Eocene, lower: Southern California.

Original reference: R. N. Nelson, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 11, p. 400–401, map.

Named for occurrence on flanks of Simi Hills, Ventura County.

†Similkameen Formation[1]

Lower Cretaceous: Central northern Washington.

Original reference: I. C. Russell, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 2, p. 100–137, map.

Exposed throughout a large part of elevated region drained by headwaters of Similkameen River.

Similkameen Granite[1]

Similkameen Granodiorite

Mesozoic: North-central Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

A. C. Waters and Konrad Krauskopf, 1941. Geol. Soc. America Bull., v. 52, no. 9, pl. 1. Mapped as granodiorite.

Exposures in eastern part of Chopaka quadrangle, Okanogan County, Wash., and British Columbia.

Simmler Formation

Oligocene(?) and Miocene, lower(?) : Southern California.

T. W. Dibblee, Jr., 1952, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Guidebook, Joint Ann. Mtg., p. 82, 86. Dark-red sandstone and basal conglomerate 3,000 feet thick. Underlies Miocene Soda Lake formation (new); overlies Eocene(?) marine sandstone and shale. Outcrops noted in road log.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2978 (fig. 3), 2981, 2982–2983. At designated type locality, consists of continuous series of hard pink to dark-grayish-red fine- to medium-grained massive sandstone beds with numerous interbeds of dark maroon and greenish siltstone. Sandstones are biotitic, well laminated, and commonly crossbedded; basal part consists of about 30 feet of conglomerate in dark maroon matrix. Thickness about 3,000 feet. Overlies Pattiway formation (new), with slight angular unconformity; conformably underlies Soda Lake sandstone member (new) of Vaqueros formation. In vicinity of Soda Lake, conformably underlies Soda Lake shale member (new) of Vaqueros formation. In western Cuyama Valley and La Panza Range, consists of maroon-red conglomerate and sandstone resting unconformably on Cretaceous sediments or granitic basement and attains maximum thickness of 3,000 feet. Oligocene(?) and perhaps lowermost Miocene. This formation was mapped as Redrock Canyon sandstone member of Santa Margarita by English (1916, U.S. Geol. Survey Bull. 621–M) and nonmarine Vaqueros by Eaton and others (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2).

Type locality: Southeastern Caliente Range, T. 10 N., R. 25 W., east of Cuyama Ranch quadrangle. Range is an anticlinal uplift developed in a thick series of Tertiary sediments and is partially overturned and thrustfaulted southwestward toward Cuyama Valley.

†Simmons Bluff Beds[1]

Pleistocene: Southern South Carolina.

Original reference: W. H. Dall, 1897, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 336, published in 1897 as House Doc. 5, 55th Cong., 2d sess.

Exposed at Simmons Bluff, about 12 miles below Rantowles, Charleston County.

Simon Limestone[1] (in Mississippian Series)

Carbonic: Southeastern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 243, 251, 338.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart). In Mississippian series. Underlies Truxton limestones. Of Carbonic age.

Exposed in face of Chiricahua Mountains and overlooking San Simon bolson, in northeast corner of Cochise County.

**Simon Quartz Keratophyre**[1]

Middle Triassic: Central Nevada.

Original reference: A. Knopf, 1921, U.S. Geol. Survey Bull. 725–H.

Named for Simon mine in Cedar Mountains.

Simons Syenite[1]

Precambrian: New York.

Original reference: H. P. Cushing, 1907, New York State Mus. 60th Ann. Rept., pt. 2, map.

Exposed on shores of Simons Pond, Franklin County.

**Simonson Dolomite**[1]

Middle Devonian: Western Utah and east-central Nevada.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

J. C. Osmond, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1931–1953. Geographically extended into east-central Nevada. Overlies Sevy dolomite. Detailed discussion of unit.

R. W. Rush, 1956, Utah Geol. and Mineralog. Survey Bull. 53, p. 12 (fig. 3), 23 (fig. 2). Described in western Millard County where it is about 460 feet thick, consists of medium-light-gray to medium-gray dolomite, overlies Kings Canyon dolomite (new), and underlies Guilmette limestone.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 84–86, pls. 1, 21. Described in Sheeprock Mountains where it is 450 to 563 feet thick, conformably overlies Sevy dolomite and conformably underlies Victoria-Pinon [Pinyon] Peak formations undifferentiated.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 145–150. Described in Fivemile Pass and North Boulter Mountains quadrangles where it is 563 feet thick, disconformably underlies Victoria formation and overlies Sevy dolomite. Noah dolomite of Bluebell formation is considered equivalent to Simonson dolomite; suggested that name Simonson be used in central Utah in preference to Bluebell.

Named for exposures in Simonson Canyon, on west side of Deep Creek Range, Gold Hill region, Utah.

**Simpson Group**[1]

Middle Ordovician: Central and southern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55, 56–57. Group comprises (ascending) Joins, Oil Creek, McLish, Tulip Creek, and Bromide formations. Overlies Arbuckle group; underlies Viola group, which includes (ascending) Viola proper and Fernvale. Chazy.

C. E. Decker, 1942, Oklahoma Acad. Sci. Proc., v. 22, p. 154 (table 1). Underlies Patterson Ranch group (new).

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, 333p, pls. Group comprises (ascending) Joins, Oil Creek, McLish, Tulip Creek, Bromide, and Corbin Ranch (new) formations. Comprehensive review of Simpson investigation and extensive bibliography of Simpson stratigraphy ; part 2 describes Simpson Ostracoda.

Named for former village of Simpson, just north of Pontotoc, Johnston County.

Simpsonian Series

Ordovician: Central and eastern North America.

A. W. Grabau, 1937, Paleozoic formations in the light of the pulsation theory, v. 3, Cambrovician pulsation, pt. 2, Appalachian, Palaeocordilleran, Pre-Andean, Himalayan, and Cathaysian geosynclines: Peiping, China, Univ. Press. Natl. Univ. Peking, p. 20, 282. Term applied to rocks of Simpson, or Stones River age.

Simsboro Formation (in Wilcox Group)

Simsboro Sands Member (of Rockdale Formation)[1]

Eocene, upper: Central and southern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 586, etc.

H. B. Stenzel, 1953, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Econ. Geologists Guidebook, Joint Ann. Mtg., Houston, p. 53 (geol. map). Shown on geologic map as a formation underlying Calvert Bluff formation and unconformably overlying Hooper formation.

Typically exposed at town of Simsboro, Freestone County.

**Sinbad Limestone Member** (of Moenkopi Formation)[1]

Lower Triassic: Central eastern Utah.

Original reference: J. B. Reeside, Jr., and others, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, no. 5, p. 797.

C. B. Hunt and R. L. Miller, 1946, Utah Geol. Soc. Guidebook 1, p. 10. Generalized section of exposed sedimentary rocks in Henry Mountains structural basin shows Moenkopi formation 250 to 685 feet, including Sinbad limestone member.

Type area: San Rafael Swell.

Singas Formation

Upper Triassic: North-central Nevada.

R. R. Compton, 1960, Geol. Soc. America Bull., v. 71, no. 9, p. 1387–1388, pl. 1. Sequence of phyllites with minor quartzite beds and clastic limestone lenses. Thickness 4,000 to 7,000 feet. Overlies O'Neill formation (new), contact drawn at top of highest O'Neill quartzite bed. Underlies Andorno formation (new).

Name derived from Singas Creek, Santa Rosa Mountains, Winnemucca region. Well exposed on ridge between Wash O'Neill Creek and Provo Canyon. Composes most all of Bloody Run Hills.

Singleshot Member (of Appekunny Argillite[1] or Formation)

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1885–1886. Lowermost member of Appekunny formation. Thickness 300 to 400 feet. Underlies Appistoki member; overlies Carthew member (new) of Altyn formation. Type locality designated.

Type locality: Singleshot Mountain near St. Mary Lake, Glacier National Park.

Sing Sing Marble[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey and J. R. Healy, 1912, Columbia Univ. Contr., v. 20, p. 1907–1912.

In Westchester County.

Sinks Grove Limestone (in Greenbrier Limestone[1] or Series)

Middle Mississippian (Meramecian): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 451, 484.

Dana Wells, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 5, p. 903. Denmar formation (new) includes Sinks Grove and Patton limestones of Reger (1926). Age of Denmar, Middle Mississippian (Meramecian series).

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 50, no. 9, p. 1910–1912. Patton and Sinks Grove do not represent a single stratigraphic unit; in Monroe County, where they were named, they are separated by 10 to 20 feet of plant bearing shale [Patton shale]. Use of term Denmar for these two units is without merit. Middle Mississippian.

Type locality: Along Sinks Grove-Knobs Road, in vicinity of Sinks Grove, Monroe County, W. Va.

Sinosri Formation

Oligocene: Panamá and Costa Rica.

Original reference: D. F. MacDonald and others, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 364.

Karl Sapper, 1937, Mittelamerika Handbuch der regionalen Geologie: Heidelberg, vol. 8, sec. 4a, no. 29, p. 131, 132, 134 (chart), pl. 9. Chart shows middle Oligocene Senosri limestone below upper Oligocene Uscari formation.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 346. Undefined name for deposit of Oligocene age. Sinosri is correct spelling.

Bocas del Toro Province.

Sinsinawa Member (of Wise Lake Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 12. Thick-bedded dolomite, pure, brown, coarsely crystalline. Thickness 13 feet. Shown on columnar section as underlying Stewartville member (new) of Wise Lake formation and overlying Wyota member (new) of Dunleith formation.

Occurs in Dixon-Oregon area.

Siouan series[1]

Precambrian: Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 147–151.

**Sioux Quartzite**[1]

Precambrian: Northwestern Iowa, southwestern Minnesota, northeastern Nebraska, and southeastern South Dakota.

Original reference: C. A. White, 1870, Iowa Geol. Survey, v. 1, p. 26, 167–171.

Brewster Baldwin, 1949, South Dakota Geol. Survey Rept. Inv. 63, p. 1–25. Consists predominantly of pink-coated fine grains of quartz sand cemented to a nonporous quartzite of silica. Seams and beds of coarse-grained quartzite present locally; also contains some shale and pipestone. Known exposures in South Dakota are in Minnehaha, Lincoln, Turner, McCook, and Hanson Counties. Covers belt some 70 miles long in eastwest direction and about 30 miles in north-south direction. On indirect evidence formation is probably Precambrian. On basis of lithology, absence of fossils, and structures, formation has been correlated with Baraboo quartzite in Wisconsin, which is overlain directly by Upper Cambrian sediments.

Named for exposures in banks of Big Sioux River, Iowa.

Sipe Springs Formation (in Big Saline Group)

Pennsylvanian (Lampasas Series): North-central Texas (subsurface).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 84 (fig. 5), 85. Sequence of limestone and shale. Lies at depth of 3,760 to 3,870 feet in type well. Underlies Eastland Lake formation (new); overlies De Leon formation (new.

Type well: Roxana Petroleum Co. Seaman No. 1, northwest Palo Pinto County. Name derived from town in northern Comanche County.

Sisar Black Shale

Eocene, middle: California.

T. L. Bailey, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1920 (fig. 3), 1931. Shown on structure section as underlying Topatopa sandstone and overlying Wheeler sandstone.

Exposed in the Santa-Ynez-Topatopa Mountains north of the Santa Clara Valley, [Ventura County].

Siscowit Granite

Age not stated: Southeastern New York and southwestern Connecticut.

D. M. Scotford, 1956, Geol. Soc. America Bull., v. 67, no. 9, p. 1177, pl. 1. Name proposed for medium- to fine-grained massive light-reddish-gray granite weathering dark-reddish-gray to dark-gray. Foliation not pronounced. Formerly considered part of Thomaston granite. Not continuous with type Thomaston and bears little resemblance to it.

Named for reservoir in outcrop area [in Westchester County, N.Y.] Also mapped in Fairfield County, Conn.

Siskiyou Granodiorite[1]

Jurassic: Northwestern California.

Original reference: J. H. Maxson, 1933, California Jour. Mines and Geology, v. 29, nos. 1, 2, p. 131, map.

Del Norte and Siskiyou Counties.

Siskiyou terrane[1]

Pre-Silurian: Northwestern California.

Original reference: N. E. A. Hinds, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 20, no. 11, p. 375–410.

N. E. A. Hinds, 1940, 6th Pacific Sci. Cong. for 1939, v. 1, p. 277–278. Pre-Silurian.

Well exposed in Siskiyou Mountains, [Siskiyou County].

**Sisquoc Formation**[1]

Miocene, upper, and Pliocene, middle: Southern California.

Original reference: W. W. Porter, II, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 2, p. 135–143.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1340 (table 1), 1347–1352. Described as including two principal facies: a fine-grained basin facies made up dominantly of diatomaceous strata and a sandstone marginal facies represented at eastern margin of basin. When formation was named, the marginal sandstone facies was emphasized. According to current usage, term Sisquoc formation when unqualified refers to the basin facies, which is more extensive in both outcrop and subsurface sections. Marginal facies is designated Tinaquaic sandstone member; Todos Santos claystone member is applied to porcelaneous claystone forming about the lower half of basin facies in Casmalia Hills. In Purisima Hills, basin facies has exposed maximum thickness of 3,000 feet; in Casmalia Hills, formation is 2,000 to 3,000 feet thick, Todos Santos claystone constitutes about 1,500 feet of lower part. Overlies Monterey shale; underlies Foxen mudstone.

W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 26–36, pl. 1. Late Miocene and middle Pliocene.

Named for section on Sisquoc Ranch, on south side of Sisquoc River, in Sisquoc grant, Santa Barbara County. Woodring and others regard the western Purisima Hills as type region of basin facies.

Sites Formation

Upper Cretaceous (Chico Series): Northern California.

J. M. Kirby, 1942, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 899. Listed as underlying Funks formation and overlying Mills formation (both new).

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 282, 284–285, 291, 293. Described as consisting mostly of massive- to well-bedded or rhythmically banded, concretionary, greenish-gray or light-drab sandstone. Thickness 2,095 to 3,965 feet. Conformably underlies Funks formation; conformably overlies Yolo formation (new name for preoccupied Mills). Derivation of name given.

Named for exposures both north and south of Stone Corral Creek, particularly in E¼ sec. 33 and E½ sec. 28, T. 17 N., R. 4 W., Colusa County.

**Sitgreaves Tuff**[1]

Tertiary, middle or upper: Northwestern Arizona.

Original references: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743; Carl Lausen, 1931, Arizona Bur. Mines Bull. 131, Geol. Ser. 6, p. 39, map.

Named for Sitgreaves Pass, Oatman district.

**Sitkin Point Formation**

Early Quaternary: Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 175, 177, pl. 23. Waterlaid pyroclastic material; tuffaceous graywacke, dacite-boulder tuff-breccia, andestitic tuff, and pumiceous tuff. On tip of Sitkin Point, formation is of semiconsolidated volcanic wacke or graywacke in beds 2 to 20 feet thick and averaging 4 feet thick. Exposed deposits more than 450 feet thick. Underlies Double Point dacite (new) and overlies Williwaw Cove formation (new) with unconformable contacts. Probably early Quaternary.

Named for deposits exposed at Sitkin Point, Little Sitkin Island, in Rat Islands group of Aleutian Islands.

Sixmile Granite[1]

Precambrian: Central Texas.

Original reference: H. B. Stenzel, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 144.

Virgil Barnes, Frederick Romberg, and W. A. Anderson, 1954, Internat. Geol. Cong., 19th Algiers 1952, Comptes rendus, sec. 9, pt. 9, p. 153. Town Mountain granite invaded the already deformed metasediments [Valley Spring gneiss and Packsaddle schist] and was followed by the Oatman Creek granite, Sixmile granite, and Llanite, the latter being the youngest.

Quarried near Sixmile, near Llano, Mason County.

Sixmile Schist

Age not stated: Central Virginia

W. R. Brown, 1951, (abs.) Virginia Jour. Sci., new ser., v. 2, no. 4, p. 347. Incidental mention.

Lynchburg quadrangle.

Six Mile Shale (in Ithaca Shale)

Six Mile Shale Member[1] (of Middlesex Shale)

Upper Devonian: South-central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 202.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4. Shale reallocated to lower part of Ithaca shale. Underlies Cascadilla shale; overlies Renwick shale.

Occurs in Ithaca region.

**Sixmile Canyon Formation** (in Indianola Group)

Upper Cretaceous: Central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 128. Succession of coarse-grained gray sandstone and conglomerate containing coal-bearing member of finer grain. In Sixmile Canyon, three members recognizable (ascending): prominent gray conglomeratic sandstone about 2,000 feet thick; coal-bearing member containing gray to cream-colored and white mainly fine-grained sandstone, gray to white shale, carbonaceous shale, and coal, about 300 feet thick; conglomerate and conglomeratic sandstone of which 425 feet are exposed. Uppermost formation in group; overlies Funk Valley formation (new); unconformably underlies Price River formation.

Named for exposures in Sixmile Canyon, south of Manti, Sanpete County.

**Six-Mile Lake Amphibolite** (in Dickinson Group)

Precambrian: Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 32. Uppermost formation in group. A massive dark fine- to medium-grained aggregate of hornblende and plagioclase, with strong preferred planar and linear orientation of minerals; amphibolite is basaltic in composition and represents a metamorphosed sequence of flows and possible tuffs; amphibolite grades to the south (across the strike) into a mile-wide zone of banded gray gneiss that is the product of reaction between the amphibolite and post-Dickinson gneissic granite. Thickness about 3,000 feet. Overlies Solberg schist (new).

Named for Six-Mile Lake in sec. 22, T. 42 N., R. 29 W., Dickinson County. Well exposed in low knobs and ridges immediately south of the lake and for several miles to the east and west.

Sixshooter Group

Cretaceous (Comanche Series): Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology, Geol. Quad. Map 21; J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 378–385. Name applied to sequence of limestone lying between Cox sandstone below and the Boquillas flags in Kent quadrangle. Name credited to J. P. Brand and R. K. DeFord (in press). In area of this report (Wylie Mountains and vicinity), group comprises 330 to 350 feet of limestone of a neritic facies; divided into three formations (ascending): Finlay, Boracho (new), and Buda limestones.

Well exposed in southern part of Kent quadrangle along U.S. Highway 80.

Sixth Street terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703 (fig. 8), 1708–1709, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Sixth Street is applied to a terrace deposit composed of 5 to 10 feet of dark-gray to reddish silt overlying limestone gravel. Younger than Capitol terrace deposit and lies about 70 feet below surface of Capitol terrace. Downstream along Colorado, the terrace appears to join surface of the Beaumont. Seems desirable to retain name Sixth Street for deposits at Austin since relation of younger terrace deposits, First Street and Riverview, at Austin, to formations near coast has not been completely determined.

Named for occurrence along Sixth Street east of Congress Avenue, Austin, Travis County.

**Siyeh Limestone**[1] (in Piegan Group)

Siyeh Formation (in Piegan Group)

Siyeh Group

Precambrian (Belt Series): Northwestern Montana, and southwestern Alberta and southeastern British Columbia, Canada.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 323.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1892–1894. Includes argillites, quartzites, and extensive mud breccias, as well as thick algal deposits. Dominantly dark gray to black; all dolomites weather buff or fawn. Second dominantly calcareo-magnesian formation in Glacier Park facies. Thickness 2,900 to 4,000 feet in Lewis Range; 5,400 feet in Blackfoot Canyon facies. Consists of (ascending) *Collenia symmetrica* zone, Goathaunt member, *Collenia frequens* zone, and Granite Park member in Glacier National Park. Underlies Spokane formation; overlies Grinnell formation. Type locality given.

D. A. Andrews, G. S. Lambert, and G. W. Stose, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 25, sheet 1. Mapped as Siyeh group. Includes Helena limestone, Spokane formation, Newland limestone, Marsh shale, and Wallace formation in Montana.

C. E. Erdmann, 1944, U.S. Geol. Survey Water-Supply Paper 866–B, p. 48. Consists of two thick, massive bodies of impure limestone or dolomite, separated by thinner westward-lensing body of reddish argillite. Upper member known in various localities as Upper Siyeh, Blackfoot, Helena, or Wallace limestones. Middle member called red band in Siyeh or, where more fully developed, Spokane formation. Lower member called Lower Siyeh or Newland limestone.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Limestone mapped in Piegan group.

Richard Rezak, 1957, U.S. Geol. Survey Prof. Paper 294–D, p. 137–139. Siyeh limestone contains three stromatolite zones: *Collenia symmetrica* zone (includes Goathaunt member of Fenton and Fenton); *Conophyton* zone; *Collenia multiflabella* zone (includes Granite Park member of Fenton and Fenton).

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 19 (table), 33–43, pls. 1, 2. Siyeh limestone (redefined) is main unit of Piegan group (redefined). Argillaceous beds that have been included by some workers at base and top of the Siyeh have been separated from it in present report. Unit termed "greenish calcareous argillite" (up to several hundred feet thick), formerly included in the Siyeh, is herein considered basal part of overlying Missoula group and separates Siyeh limestone from Purcell basalt. Believed that when later detailed mapping is done the Siyeh will be divided into several units of formational rank and name "Siyeh" will be restricted in its application or abandoned. The Siyeh underlies broad areas in median parts of Flathead and Swan Ranges. These areas extend almost entire length of parts of both ranges that are within Flathead region and in Flathead Range persists to foot of Lake McDonald. According to Clapp's map (1932, Montana Bur. Mines and Geology Mem. 4) and Deiss's unpublished geologic map of Ovando quadrangle, the Siyeh is continuously exposed as far south as T. 18 N., R. 15 W., and at intervals beyond this. In Glacier National Park, the Siyeh forms core of mountain mass. It extends from near intersection of long 113°30′ with lat 48°30′ northwestward past Canadian border, widening northward. Thickness 1,800 to 5,000 feet. Overlies Grinnell argillite of

Ravalli group. Rezak's stromatolite zones and their importance discussed.

Type locality: Mount Siyeh, Glacier National Park, Mont.

Skagit Gneiss or Gneisses

Skagit Volcanic Formation[1]

Mesozoic: Southwestern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 15.

Peter Misch, 1952, The Mountaineer, v. 45, no. 13, p. 4 (geol. map), 12–14. Discussion of geology of northern Cascades of Washington. Skagit gneisses originated during time of Mesozoic folding. At least most of the gneisses are probably earlier than Lower Cretaceous sediments. Older than Chilliwack granodiorite (which formed from it); on eastern border of the Skagit is Black Peak granodiorite (new) which apparently formed from the Skagit. Marblemount quartz diorite (new) was earlier than Mesozoic folding.

Extends from first summit west of Skagit River to summit of Custer Ridge, Whatcom County, Wash., the main divide of Skagit Range.

**Skajit Limestone**[1]

Middle(?) and Upper Devonian: Northern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 238.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,-000): U.S. Geol. Survey. Appears on map legend.

W. P. Brosgé, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B351–B352. Skajit limestone has been referred to the Silurian. In type area on John River, it seems related to limestone that is locally interbedded in the basal part of overlying black slate and phyllite unit that contains fossils of Middle(?) Devonian age. Also fossils of Middle or Late Devonian age have been collected in Western Brooks Range from limestone which had been mapped as Skajit by Smith and Mertie (1930, U.S. Geol. Survey Bull. 815).

Named for Skajit Mountains, Endicott Range.

Skamania Andesites or Andesitic Series

Miocene to Pliocene: Southwestern Washington.

W. M. Felts, 1939, Ohio Jour. Sci., v. 39, no. 6, p. 301–302, 304–306, 315 (fig. 4). Proposed for a thick series of andesites with minor amounts of breccia and other pyroclastics; divisible into two units, an upper and a lower; lower has undergone more folding and metamorphism than upper. Thickness more than 800 feet. Overlie Eagle Creek formation; contact not exposed in mapped area, but to the east in Washougal basin, contact is disconformable. Lower part intruded by Silver Star granodiorite (new). Miocene to Pliocene.

Well exposed near Star Mountain and over wide areas in adjacent parts of Skamania County.

**Skaneateles Shale** (in Hamilton Group)[1]

Middle Devonian: Central and western New York.

Original reference: L. Vanuxem, 1840, New York Geol. Survey 4th Rept., p. 380.

G. A. Cooper, 1930, Am. Jour. Sci., 5th ser., v. 19, p. 214–219. In Chenango and Unadilla Valleys, subdivided into (ascending) Mottville, Delphi, Pompey, Berwyn, and Colgate. West of Cayuga Lake includes Stafford and Levanna members. Overlies Marcellus; underlies Lowville.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 180–181. Delphi Station (new), Chenango sandstone (new), and Butternut shale (new) replace Delphi shale (Cooper, 1930), Colgate sandstone (Cooper, 1930), and Berwyn (Cooper, 1930), respectively.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1772, chart 4. Mottville-Stafford members transferred to the Marcellus.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 358–361, pl. 1. Formation crops out from east-central New York to extreme western limits of the State. Thickness about 215 feet in Batavia quadrangle where it is represented by Stafford and Levanna members. Overlies Oatka Creek shale member of Marcellus; underlies Centerfield limestone member of Ludlowville formation.

[G. A. Cooper], 1955, New York State Geol. Assoc. 27th Ann. Mtg., p. [10], 11. Formation comprises (ascending) Delphi Station, Pompey, Butternut, and Chenango members. Thickness 434 feet. Overlies Marcellus, underlies Ludlowville.

Name derived from Skaneateles Lake, Onondaga County.

Skate Creek Laharic Breccia or deposits

Eocene-Oligocene: Northwestern Washington.

R. V. Fisher, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 127–132. An andesitic volcanic breccia that unconformably overlies dark-gray pebbly volcanic sandstone layer as much as 2 feet thick. Fragments of breccia are porphyritic to dense andesite and angular to subangular (some well rounded) and average about one-half inch in longest dimension. Some scattered water-worn vesicular bomb-shaped fragments present. Scattered nonoriented carbonaceous fragments and one well-preserved spruce cone (*Picea* sp.) observed. These characteristics indicate deposition either by lahars or pyroclastic flows but preclude deposition from air.

Occurs at junction of Skate and Johnson Creeks, eastern Lewis County.

Skeels Corners Formation

Skeels Corners Slate (in Woods Corners Group)

Middle Cambrian: Northwestern Vermont.

B. F. Howell, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1964. Name proposed for dark-gray shale formerly lower part of Hungerford formation. Underlies Saxe Brook formation (new) disconformably. Middle or Upper Cambrian.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1 (column 70). Overlies Mill River formation.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Upper Cambrian.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1136, 1153. Thickness unknown. Middle Cambrian. More exact location of type section given.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 539–542, pl. 1. Skeels Corners slate includes some beds formerly called Georgia slates by Walcott (1886, U.S. Geol. Survey Bull. 30) and a large part of those referred to Hungerford and Highgate slates by Keith (1932, Washington Acad. Sci. Jour., v. 22), Schuchert (1937), and Raymond (1937, Geol. Soc. America Bull., v. 48, no. 8, p. 1079). Name originally proposed by Howell (1939) to refer to the *Bovicornellum* beds alone, but it is here extended to include all strata above Mill River conglomerate or, in its absence, St. Albans slate, and below Rockledge conglomerate. Typically black slate, with local developments of dolomite, sandstone, dolomite conglomerate, limestone bioherms, limestone, and calcareous shale in minor quantities. Accurate measurement of thickness not possible. Thickness at type locality about 400 feet, estimated 1,200 feet in adjoining Milton quadrangle. Included in Woods Corners group (new). Middle Cambrian.

Typically exposed west of Skeels Corners, 7¼ miles north of St. Albans, Franklin County. Extends northward to point northwest of Highgate Center and southward to vicinity of West Georgia.

Skeene Member (of Whitehall Formation)

*See* Skene Dolomite Member (of Whitehall Formation).

Skelley Limestone (in Conemaugh Formation)[1]

Skelley limestone member

Pennsylvanian (Conemaugh Series): Eastern Ohio.

Original reference: D. D. Condit, 1912, Ohio Geol. Survey, 4th ser., Bull. 17, p. 27.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 56–57, geol. map. In Morgan County, Skelley limestone member of Conemaugh series is a nonpersistent bed of gray to brownish-gray fine- to medium-crystalline limestone, commonly nodular to conglomeratic and locally sandy or shaly. Thickness averages 7 to 8 inches. Stratigraphically below Duquesne shale member [not present in Morgan County]; occurs 7 to 12 feet above Gaysport limestone member and from 25 to 33 feet above Ames limestone member.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 146–147. Member of Duquesne cyclothem in report on Athens County. There is a possibility that type Gaysport limestone correlates with type Skelley and that limestone under consideration here is actually without a name. At present, best choice seems to be to use both names until their correlation is shown to be in error. That mistaken field identity of Gaysport and Skelley limestones has been made is indicated by statements by Mark (1912, Ohio Geol. Survey, 4th ser., Bull. 17) and Lamborn (1951, Ohio Geol. Survey, 4th ser., Bull. 49) that Skelley occurs 15 to 35 feet above Ames limestone. In sequence of beds, the Gaysport is almost everywhere overlain by Lower Grafton shale and sandstone, but the Skelley is succeeded upward at numerous places by Birmingham redbed. Thickness commonly less than 12 inches. Overlies Skelley shale and sandstone member; underlies Birmingham redbed member of Elk Lick cyclothem. Conemaugh series.

Named for Skelly Station, on Pennsylvanian Railroad, Jefferson County.

Skelley shale and sandstone member

Pennsylvanian (Conemaugh Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 146. Member of Duquesne cyclothem in report on Athens County. Overlies Duquesne coal member and underlies Skelley limestone member. Similar to underlying Lower Grafton. Skelley and Lower Grafton members may replace Duquesne coal, underclay, limestone, and redbed forming continuous sequence of shale and sandstone between Gaysport and Skelley limestone. Average thickness of Skelley shale and sandstone member is 12¾ feet.

Named for association with Skelley limestone.

Skelt Shale (in New River Group)

Skelt Shale (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: D. B. Reger, 1920, West Virginia Geol. Survey Rept. Webster County, p. 198.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 227. Black shale about 6½ feet thick below Guyandot sandstone and above Sewell "B" coal. Included in New River group, Pottsville series.

Named for occurrence on north side of Sugar Creek, one-half mile east of village of Skelt, Webster County.

Skene Dolomite Member (of Whitehall Formation)

Upper Cambrian: Northeastern New York.

R. R. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939; 1942, Am. Jour. Sci., v. 240, no. 7, p. 518–524. Barren light-gray slightly cherty thin-bedded dolomite grading upward into crossbedded worm-riddled sandstone. Thickness about 120 feet. Overlies Hoyt limestone member; underlies Norton limestone member (new) of Tribes Hill formation. Discussion of revisions in Champlain, Hudson, Mohawk, and St. Lawrence Valleys involving definitions and succession of previously accepted Cambro-Ordovician formations (Potsdam, Theresa, Hoyt, and Little Falls of Upper Cambrian age and the Whitehall, Tribes Hill, and Beekmantown of Lower Ordovician age). Each revised unit is tied in with Divisions A through E of original "Calciferous" formation (Brainerd and Seely, 1890, Am. Mus. Nat. History Bull., v. 3). The Skene is the sandy base of C plus upper part of B.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 795–814. Term Skene dolomite not applicable in Saratoga Springs region because it was defined as Upper Cambrian. Replaced by Gailor dolomite (new). Wheeler (1942) classified Hoyt limestone as basal member of Whitehall formation and Skene as upper member, the latter being a very late Upper Cambrian offlapping unit. It is evident that Wheeler mistook the Ordovician Gailor dolomite for the older Little Falls dolomite, because the Hoyt of his supposed "Little Falls" is in fault contact in his "unfaulted" area, 4 miles west of Saratoga Springs.

Occurs in Skene Mountain section.

**Skiatook Group**

Skiatook Shale[1]

Pennsylvanian (Missouri Series): Northeastern and central Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 34.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 39–40. Ohern introduced term Skiatook to apply to beds between Lenapah and Dewey limestones; term was used only in southern part of area mapped by him, and, as shown by his mapping, he mistook Checkerboard limestone for Lenapah. Consequently, original application of Skiatook was really to strata between Checkerboard and Dewey. Term is herein restored to formal nomenclature and rank raised to group. Lower boundary coincides with disconformity that marks base of Missouri subseries; upper boundary is placed at top of Drum limestone, or where Drum is absent, at base of sandstone in lowermost Chanute shale of Ochelata group. Includes (ascending) Seminole sandstone, Checkerboard limestone, Coffeyville shale, Dennis limestone, Cherryvale shale, and Drum limestone.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 20–23; 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 718 (fig. 2), 720 (table 1), 721–725. Includes (ascending) Seminole formation, Checkerboard limestone, Coffeyville formation, Hogshooter limestone, Nellie Bly formation, and Dewey limestone.

Name derived from Skiatook, Tulsa County.

Skinners Eddy limestone (in Catskill Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_7$, p. 117, 118, pl. X.

Occurs about one-third mile below Skinner's Eddy, on Tuscarora Creek, Braintree Township, Wyoming County.

Skolai Volcanics[1]

Triassic: Eastern Alaska.

Original reference: O. Rohn, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 429–430, pl. 52, map.

Skolai Range.

Skookum Formation (in Newport Group)

Precambrian: Northeastern Washington.

M. C. Schroeder, 1952, Washington Div. Mines and Geology Bull. 40, p. 7 (table), 13–20, pl. 1. Predominantly argillaceous sandstone and quartzite with carbonate rocks and red and dark-gray argillites. Thickness about 13,000 feet. Contains Moon Hill quartzite member (new) near top. Gradationally overlies No Name argillite (new) with transition zone about 400 feet thick; top not exposed. Cut by Marshall diorite (new).

Named after Skookum Peak, Pend Oreille County.

**Skookumchuck Formation**

Eocene, upper: Southwestern Washington.

P. D. Snavely, Jr., and others, 1951, U.S. Geol. Survey Coal Inv. Map C-8, sheet 1. Predominantly massive crossbedded sandstone and thin-bedded siltstone with intercalated beds of coal, bone, and carbonaceous siltstone and shale. Maximum thickness about 2,700 feet. Unconformably underlies Oligocene(?) basaltic sandstone; overlies Northcraft formation (new) with angular unconformity.

P. D. Snavely, Jr., and others, 1958, U.S. Geol. Survey Bull. 1053, p. 26-35, pl. 1. Formation, in Centralia-Chehalis district, consists generally of a lower sandstone unit which is separated from an upper sandstone unit by a westward-thickening wedge that is predominantly siltstone; possibility exists that siltstone unit is older than type Skookumchuck. Formation has maximum thickness of about 3,500 feet and crops out in a broad irregular belt that extends across mapped area from southeast to northwest. Unconformably overlies Northcraft formation; unconformity may be local in extent. Conformably underlies Lincoln formation. Strata referred to Skookumchuck were included in Puget series by Culver (1919, Washington Geol. Survey Bull. 19). Skookumchuck of this report is equivalent to part of Cowlitz formation of Weaver (1937).

Well exposed along banks of Skookumchuck River west of Willamette meridan, particularly near the Wabash Railroad junction on Northern Pacific Railway, 2 miles north of Centralia, Lewis County.

Skooner Gulch Basalt or Formation

Tertiary: Northern California.

C. E. Weaver, 1943, California Div. Mines Bull. 118, p. 629-630. Massive dense fine-grained basalt with alternating flows of vesicular and amygdaloidal rock and intercalated lenslike masses of tuffaceous sandstone; pillow structure. About 900 feet thick. Underlies Gallaway beds; unconformably overlies shales and sandstones of Gualala series.

C. E. Weaver, 1944, Washington [State] Univ. Pubs. in Geology, v. 6, no. 1, p. 4, 20-21, pl. 2. Redescribed as a formation consisting of massive- to medium-grained gritty sandstone with thin interstratified layers of sandy and clayey shales 350 feet thick. Underlies Gallaway formation; overlies Iversen basalt (new).

Exposed in sea cliffs and in the beach at low tide in a belt about 400 feet wide for a distance of 3,000 feet south of Skooner Gulch, Point Arena-Fort Ross area, Mendocino County.

Skrainka diabase[1]

Precambrian: Southeastern Missouri.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 253.

Named for old post office at Skrainka, southwest of Mine LaMotte Station, Madison County.

**Skull Creek Shale**

**Skull Creek Shale Member** (of Colorado Shale)

Skull Creek Group

Skull Creek Member (of Omadi Formation)

Skull Creek Shale Member (of Graneros Shale)[1]

Lower Cretaceous: Northeastern Wyoming, Montana, and South Dakota.

Original reference: A. J. Collier, 1922, U.S. Geol. Survey Bull. 736, p. 79, table.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7). Shown on columnar section as member of Omadi sandstone (new). Overlies Fall River member; underlies Newcastle member.

B. C. Petsch, 1949, South Dakota Geol. Survey Rept. Inv. 65, p. 15; R. E. Stevenson, 1952, South Dakota Geol. Survey Rept. Inv. 69, p. 4. Basal member of Graneros.

C. E. Dobbin and G. H. Horn, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 103. Lower Cretaceous. Thickness 160 to 200 feet in Weston County, Wyo. Overlies Fall River sandstone of Inyan Kara group; underlies Newcastle sandstone of Colorado group.

A. J. Crowley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 1, p. 83–90. Table shows Skull Creek shale at base of Skull Creek group. Newcastle sandstone is at top of Skull Creek group. Skull Creek group overlies Inyan Kara group and underlies Graneros shale. Lower Cretaceous.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 57–58. Skull Creek shale, in Johnson County, Wyo., is 165 feet thick at exposure on Muddy Creek. Overlies Cloverly formation, contact placed at top of first resistant siltstone ledge above the 15- to 45-foot basal sandstone of the Cloverly. Underlies Newcastle sandstone. Correlates with that part of Thermopolis shale which underlies Muddy sandstone member in central Wyoming.

Herbert Skolnick, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 791–793. Includes Newcastle sandstone member. Basal formation in Colorado group. Underlies Mowry shale; overlies Fall River sandstone of Inyan Kara group. Lower Cretaceous. Correlated by Foraminifera with rocks in Kansas, Oklahoma, and Texas. Faunal and mineralogical evidence indicates that physically and spatially the Skull Creek shale, Newcastle sandstone, and lower Mowry shale are sufficiently related to be considered one unit.

W. A. Pettyjohn, 1960, (abs.) South Dakota Acad. Sci. Proc., v. 38, p. 34–38. Dakota controversy discussed. Suggested that term Dakota group be used to include Lakota, Fuson, Fall River, Skull Creek, and Newcastle formations.

Well exposed along Skull Creek southeast of Osage oil field, Weston County, Wyo.

**Skunk Creek Member** (of Solberg Schist)

Precambrian: Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 32. Iron-rich unit about 100 feet thick occurring about 1,000 feet below top of formation. Exposed only in a small outcrop, but the magnetic anomaly caused by the rock has been traced for more than 20 miles and the bed has been drilled in several places. Drill cores show rock to consist of three interlayered types: biotite-hornblende schist with magnetite layers; thin-bedded rock consisting of alternating layers of metachert and magnetite; and various mixtures of hornblende, biotite, grunerite, garnet, and epidote.

Named for Skunk Creek, a tributary of the East Branch of the Sturgeon River, which crosses the member near the SE cor. se. 17, T. 42 N., R. 28 W., Dickinson County.

Skunk Point Sandstone Member (of Frontier Formation)

*See* **Frontier Formation.**

**Skunk Ranch Conglomerate** (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 534, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 25–26, pl. 1. Consists largely of coarse conglomerate composed of red boulders and pebble in a matrix of red sandstone and shale. Boulders and slabs as much as 20 inches across comparatively common, and average diameter about 4 inches. Lateral gradations from the red bouldery conglomerate to gray and finer grained limestone conglomerate and to coarse-grained sandstone exposed locally. Layers of yellow clay-shale and soft sandstone present at several horizons. Large part of upper half of formation consists of alternating beds of red clay-shale and massive red conglomerate in members 5 to 60 feet in thickness. A 200-foot layer of augite basalt exposed at one place. Maximum exposed thickness 3,400 feet. Topmost part formation covered by Miocene(?) volcanic rocks; overlies Corbett sandstone (new). Trinity age.

Crops out only west and south of Skunk Ranch in Eureka section of Little Hatchet Mountains.

Skunk Springs limestone band

*See* **Chainman Shale.**

**Skunnemunk Conglomerate**[1]

Upper Devonian: Southeastern New York and northern New Jersey.

Original reference: N. H. Darton, 1894, Geol. Soc. America Bull., v. 5, p. 367–394.

Ely Mencher, 1939, Geol. Soc. America Bull., v. 50, no. 11, p. 1786. Skunnemunk conglomerate is an outlier of Middle and Upper Devonian age.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1781, chart 4. Consists of conglomerates alternating with red sandstones. Thickness 200 to 2,500 feet. Skunnemunk Mountain, an outlier, believed to be continuation of sequence west of Catskill and represents about same facies as found in that area. From Albany and Catskill, the Hamilton outcrop belt extends seaward rather than parallel to old shore. This is shown by the fact that along Catskill Front the marine facies of Hamilton comes more and more to dominate the section, until entire sequence is marine at Port Jervis. Shoreward continuation of Catskill sequence is believed to be the Skunnemunk outlier and its continuation into New Jersey. Occurs above Bellvale sandstone. Middle Devonian.

Caps Bellvale and Skunnemunk Mountains, Orange County, N.Y.

**Skwentna Group**[1]

Jurassic(?) : Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 149–152, 180.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 981. Listed as Skwentna group. Has been assigned to Lower Jurassic because of stratigraphic position below Tordrillo formation and because it is lithologically similar to Talkeetna formation.

First seen on Skwentna River 10 or 15 miles above junction with Yentna River, then on right bank of the Skwentna some miles below mouth of Haynes River, Cook Inlet region.

Sky Blue Quarry Limestone[1]

Paleozoic(?) or Upper Paleozoic(?) : Southern California.

Original reference: J. W. Daly, 1935, Am. Mineralogist, v. 20, no. 9, p. 638–647, map.

A. O. Woodford, R. A. Crippen, and K. B. Garner, 1941, Am. Mineralogist, v. 26, no. 6, p. 351. Probably Upper Paleozoic.

Named for quarry at Crestmore, Riverside County.

Slagle Trachyte

Quaternary: Northeastern New Mexico.

Helen Stobbe, 1948, (abs.) Geol. Soc. America Bull., v. 59, no. 12, pt. 2, p. 1355. Associated with tinguaites and analcime microfoyaites and usually intrusives.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1021 (table 2), 1022, 1033–1034, pl. 1; H. R. Stobbe, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1071–1073. Light-tan fine-grained porphyritic rocks with phenocrysts of chalky feldspar and abundant hornblende needles. Weathering produces reddish to brown surface. Flow structure evident. Restricted area of outcrop characteristic of sills and dikes. Age, derivation of name, and geographic distribution given.

Named from exposures in Slagle Canyon, sec. 4, T. 26 N., R. 25 E., Colfax County. Found in only four localities grouped in a 10-mile radius—Slagle Canyon, Red Hill, Joe Cabin Arroyo, and Turkey Mountain, Colfax County.

Slate Creek Limestone Member (of Wellington Formation)

Permian: Central Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 4, 8–10. Two prominent chalky claystones separated by green and red clays. Thickness 12 feet. Underlies Afton limestone member (new); overlies Highland shale member (new).

Type locality: Along south side of Slate Creek in Wellington Township, T. 32 S., R. 1 W., Sumner County.

Slate Creek Member (of Wood River Formation)

Pennsylvanian (Desmoinesian-Missourian): Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Older than Lake Creek member (new); younger than Hailey conglomerate member (new).

Deposited in Muldoon trough, aligned N. 30° W.

Slate Hill Shale[1]

Carboniferous: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 320–330, 356, 364.

Exposed at Slate Hill, Middletown Township, Newport County.

**Slater Sandstone Member** (of Mingo Formation)[1]

Middle Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 40.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 99, 102, 104, 150. In Mingo formation between Puckett sandstone (above) and Creech coal.

Named for Slater Fork of Catron Creek, Bell County, Ky.

Slatestone Group

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 6, pls. 2, 3, 4, 6. Includes strata between top of Crooked Fork group (new) and base of Indian Bluff group (new). Thickness at type section about 635 feet; throughout most of the outcrop, thickness ranges from 420 to 720 feet; thins northwestward, and in parts of Gobey, Robbins, and Huntsville quadrangles thickness is only 300 feet. Includes (ascending) unnamed shale interval, Stephens sandstone (new), shale interval, Petros sandstones (new), shale interval, Sand Gap sandstone (new), and Newcomb sandstone (new). Jellico coal present at top.

Type locality: Between the Wye and Cross Mountain, Lake City quadrangle. Section begins with the Poplar Creek coal, along the railroad tracks and the road at the Wye, and ends on Militia Hill where Jellico coal occurs at an elevation of 1,445 feet. Named from town of Slatestone, 1 mile west of Briceville, Anderson County.

†Slatington Shale[1]

Silurian: Southwestern Arkansas and southeastern Oklahoma.

Original reference: A. H. Purdue, 1909, Geol. Soc. America Bull., v. 19, p. 557.

Probably named for Slatington, Montgomery County, Ark.

Slaughter Creek Member (of Pendleton Formation)

Eocene, lower: Northwestern Louisiana and northeastern Texas.

Richard Wasem and L. J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 184–187. Consists of a basal glauconitic sand about 5 feet thick overlain locally by 15 to 20 feet of fossiliferous, black lignitic clay in turn overlain by 20 feet of nonfossiliferous sand containing large calcareous concretions; this sequence is followed by the thin Stone Coal Bluff lignite (new), lignitic silts, and Beulah Church sand lentil (new). Overlies Bayou Lenann member (new); underlies High Bluff member (new).

Typically exposed along banks of Slaughter Creek, Sabine Parish, La.; typical section in steep bluff near headwaters of creek in SW cor. sec.

26, T. 6 N., R. 13 W. Traced from vicinity of Geneva, Tex., to Hagewood, Natchitoches Parish, La.

**Slaven Chert**

Middle and Upper(?) Devonian: North-central Nevada.

James Gilluly, 1955, *in* Pacific Petroleum Geologist, v. 9, no. 8, p. 1. Above Elder formation lie over 4,000 feet of the Middle Devonian Slaven chert.

Slesse Diorite[1]

Miocene(?): British Columbia, Canada, and northern Washington.

Original reference: R. A. Daly, 1913, Canada Dept. Int. Rept. Chief Asst., 1910, v. 2, p. 532.

Slide Mountain Conglomerate[1]

Upper Devonian: Eastern New York.

Original reference: G. H. Chadwick, 1933, Am. Jour. Sci., 5th ser., v. 26, p. 480, 482, 483.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Slide Mountain conglomerate listed on correlation chart. Upper Devonian.

Occurs only on Slide Mountain, highest peak in Catskill Mountains.

**Sligo Formation**

Lower Cretaceous: Subsurface in northwestern Louisiana, southern Arkansas, and eastern and southern Texas.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 30–32. Proposed by Shreveport Geological Society for gray to brown shale containing local lenses of sandstone and limestone which represent the lowest beds of the Lower Glen Rose formation; in northern Louisiana, contains locally one or two porous oolitic limestone lentils known as Pettet limestone. Thickness ranges from about 300 feet in Louisiana and Texas to less than 100 feet in Arkansas; thins to north and not represented in outcrop in Arkansas. Base is defined by uppermost red beds of Hosston formation and top by highest of three limestone units which is called the Three Finger limestone.

R. W. Imlay, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 10, p. 1434–1441. Described in south Texas as mainly gray, yellowish-gray, and brown limestone separated by many partings and thin units of black shale that amounts to about 20 percent of entire formation; lower 40 to 50 feet contains sandy limestone and a few thin beds of sandstone, indicating a transitional relationship with the Hosston, but contact is easily selected within a few feet; contact with overlying shale and sandstone at base of Pearsall formation is abrupt. Shreveport Geological Society recognized term Pettet limestone (sometimes spelled Pettit) as an informal name for local porous limestone lentils within the Sligo; Pettet was not considered acceptable as a formation name because it was commonly used in Arkansas and Louisiana for a zone or zones of porosity; geologists in east Texas suggested Sligo be abandoned in favor of Pettet in order to conform with common usage in that area.

Type locality: Sligo field, Bossier Parish, northwestern Louisiana. Type well not designated, but formation is described in Stanolind Oil and Gas Co.'s Dillon Heirs No. 131 well, located in sec. 14, T. 21 N., R. 15

W., Caddo Parish, La., and in Amerada Petroleum Corp.'s Halff and Oppenheimer No. 8 well, southwest of Pearsall, Frio County, Tex.

**Slim Sam Formation**

Upper Cretaceous: Southwestern Montana.

V. C. DeMunck, 1956, Montana Bur. Mines and Geology Inf. Circ. 13, p. 9. Name mentioned in a discussion of the iron deposits in Montana.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 4 (table), 26 (table), 28–31, pl. 1. Described as sequence of coarse-grained clastic rocks. Lower part of sequence consists predominantly of gray, greenish-gray, and yellowish-gray quartz-chert sandstone and upper part of feldspathic quartz- and chert-poor sandstone with abundant beds of tuff and sedimentary tuff near the top. Thickness 800 to 1,200 feet. Underlies Elkhorn Mountains volcanics (new) with local unconformity and overlies Colorado formation. Derivation of name.

Named for exposures along east margin of Slim Sam basin, in sec. 22, T. 6 N., R. 1 W., Broadwater County, about 1 mile east of the map area.

Slippery Creek Greenstone Volcanics (in Evington Group)

Lower Paleozoic(?): South-central Virginia.

W. R. Brown, 1951, (abs.) Virginia Jour. Sci., new ser., v. 2, no. 4, p. 347. Incidental mention.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1). Dark-green to gray schistose to gneissose lava flows (dacite-andesite?). Amygdaloidal in part. Tuffaceous(?) schist at base. Thickness 1,000 to 3,000 feet. Uppermost unit in Evington group (new). Overlies Mount Athos formation. Paleozoic(?). Type locality designated.

W .R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2), 29 (table 5), 37–38, 49, pl. 1. Age shown on columnar section as Lower Paleozoic(?).

Type locality: Along Slippery Creek 5½ miles east of Lynchburg, Campbell County. Lynchburg quadrangle.

Sloan Formation (in Marble Falls Group)

Sloan Member (of Marble Falls Formation)

Pennsylvanian: Central Texas.

F. B. Plummer, 1944, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 33, p. 8. Member mentioned in report on limestones suitable for manufacture of rock wool.

F. B. Plummer, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 65, 66–67, pl. 2. Marble Falls is divided into (ascending) Gibbons conglomerate lentil, Sloan, Big Saline, and Lemons Bluff members. Sloan is distinctly thin bedded; beds are uneven, have rough surfaces, and contain distinctive fossils. Basal bed is commonly a subcrystalline to crystalline dense black cherty limestone 4 to 16 feet thick that commonly carries more than 40 percent black chert. This cherty zone is overlain by 50 to 100 feet of thin-bedded black subcrystalline fossiliferous limestone. In some areas, calcareous shale partings, 2 to 30 inches thick, are inrado River below Marble Falls, just above Barnett formation, from Cherokee Creek across San Saba County to Pontotoc-San Saba Highway in Wallace Creek valley. Present in most synclinal areas in San Saba County; absent on structural highs where it was either never deposited or removed by erosion before deposition of Big Saline and Lemons Bluff members.

F. B. Plummer, 1947, Jour. Paleontology, v. 21, no. 2, p. 142; Jour. Geology, v. 55, no. 3, pt. 2, p. 196 (table 2). Sloan formation underlies Big Saline formation which here includes (ascending) Gibbons, Aylor, Lemons Bluff, and Brister formations.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 47, 52–57. Formation included in Marble Falls group. Thickness at designated type section 81½ feet.

Type section: On San Saba River opposite Lemons Camp, San Saba County. Well exposed along San Saba River and its branches on the Sloan, Lemons, and Gibbons Ranches, southwest of San Saba and along Colorado River above Alexander dam site at Marble Falls in Burnet County.

Sloan Canyon Formation[1] (in Dockum Group)

Triassic: Northeastern New Mexico.

Original reference: B. H. Parker, 1930, Kansas Geol. Soc. 4th Ann. Field Conf., p. 132, mimeo; 1933, Jour. Geology, v. 41, p. 38–51.

J. W. Stovall and D. E. Savage, 1939, Jour. Geology, v. 47, no. 7, p. 764, 765, 766. Triassic. Entire section of Triassic in Union County should be included in Dockum group, a conclusion supported by fossil evidence.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 35 (table 2), 39-40, pl. 1d. Light-green and red mudstone. Thickness as much as 150 feet. Overlies Travesser formation (new); underlies Sheep Pen sandstone. In Dockum group.

Typically exposed throughout lower part of valley of Sloan Canyon in east-central part of T. 31 N., R. 35 E., Union County.

†Sloans Valley Limestone (in Chester Group)[1]

Mississippian: Southeastern Illinois and western Kentucky.

Original references: A. D. Brokaw, 1916, Illinois Geol. Survey Bull. 35 [preprint]; 1917, Illinois Geol. Survey Bull. 35, p. 12, pl. 1.

Occurs in Saline, Johnson, Pope, Williamson, Union, and Jackson Counties, Ill.

**Slocum Alluvium**

Pleistocene (Illinois or Sangamon): Northeastern Colorado.

C. W. Hibbard and D. W. Taylor, 1960, Michigan Univ. Mus. Paleontology Contr., v. 16, no. 1, p. 33. Incidental mention in discussion of late Pleistocene faunas of southwestern Kansas. Name credited to G. R. Scott (in preparation).

G. R. Scott, 1960, Geol. Soc. America Bull., v. 71, no. 10, p. 1542. Name applied to alluvial deposit that lies 150 feet below older Verdos alluvium (new) and 100 feet above the modern streams. Consists of 10 to 90 feet of moderate reddish-brown, well-stratified, clayey coarse sand with lenticular beds of pebbles and silt. Older than Louviers alluvium (new).

Type locality: Along one face of limestone quarry on Slocum Ranch in SW¼NW¼ sec. 35, T. 6 S., R. 69 W., Kassler quadrangle.

Slollicum Series[1]

Triassic: Central northern Washington, and adjacent British Columbia, Canada.

Original reference: C. H. Crickmay, 1930, Geol. Mag., v. 7, p. 488, 489, map.

Derivation of name not stated.

**Sloway Formation** (in Missoula Group)

Precambrian (Belt Series): Northwestern Montana.

A. B. Campbell, 1960, U.S. Geol. Survey Bull. 1082–I, p. 565–567, pl. 28. Heterogeneous sequence of thin- to medium-bedded argillaceous quartzite, viterous quartzite, quartzose argillite, and argillite; more argillaceous toward top of section. Colors are tints of red, purple, and green ranging from pale to bright. No complete section, but total thickness of about 5,000 feet estimated on basis of several partial sections which constitute type section. Conformably overlies Lupine quartzite (new); conformably underlies Bouchard formation (new).

Type section: Partial sections in secs. 7 and 18, T. 16 N., R. 26 W.; secs. 29, 33, and 34, T. 17 N., R. 26 W.; and secs. 3, 4, 10, 11, 14, and 23, T. 16 N., R. 26 W. Named from exposures in secs. 14, 15, and 16, T. 17 N., R. 27 W., near mouth of Sloway Gulch, St. Regis-Superior area, Mineral County.

**Slow Fork Glaciation**

Pleistocene: South-central Alaska.

A. T. Fernald, 1960, U.S. Geol. Bull. 1071–G, p. 232 (chart). Named on correlation chart. Correlated with Selatna, Healy, and Delta glaciations. Older than Wonder Lake glaciation (new). Name credited to J. C. Reed, Jr.

In Mount McKinley area.

Sly Gap Formation

Upper Devonian: Central southern New Mexico.

F. V. Stevenson, 1941, (abs.) Oil and Gas Jour., v. 39, no. 47, p. 65; 1941, (abs.). Illinois Acad. Sci. Trans., v. 34, no. 2, p. 163. Comprises 114 feet of siltstones, shales, and a few limestones at type locality. Underlies Percha shale. Devonian.

F. V. Stevenson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 18, p. 23. Chiefly thin alternating layers of shale and siltstone, with a few beds of limestone. A zone 8 to 10 feet thick at base is more massive than rest of formation and has red-brown color, which is in contrast to lighter colors of sediments above and below. Shales range from black, fissile, and carbonaceous to light buff or tan. Siltstones and limestones, in general, buff. Thickness averages approximately 100 feet in Sacramento Mountains, 110 to 135 feet in San Andres Mountains, and 80 to 90 feet in westernmost exposure in Mud Springs Mountains near Hot Springs. Overlies Canutillo formation at south end of San Andres Mountains; Fusselman limestone in central part; and Montoya limestone north of Rhodes Pass. Unconformably overlies Canutillo in south and central parts of Sacramento Mountains; and Fusselman in area to the north. Late Devonian.

F. V. Stevenson, 1944, Dallas Digest (Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Joint Ann. Mtg.), p. 94–95. Underlies Contadero formation (new).

F. V. Stevenson, 1945, Jour. Geology, v. 53, no. 4, p. 217, 219, 222. Overlies Onate formation (new), formerly identified as "Canutillo formation," in Sacramento and San Andres Mountains.

V. C. Kelly and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology v, p. 77–78. Units such as Onate and Sly Gap not distinguishable lithologically, and hence, are not mappable in New Mexico. These are no more than faunal zones at best, and prior and well-established term Percha formation should be retained and applied widely to this lithologically and topographically distinct unit in New Mexico.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 29–30. Thicknesses of section in San Andres Mountains, excluding the basal beds with an anomalous fauna that may be Middle Devonian in age and which are included in Onate formation, vary from north to south: 57 feet at type section on Sheep Mountain, 31 feet at Rhodes Canyon, 70 feet at Hembrillo Canyon, and 75 feet at Ash Canyon.

Type locality: At Sly Gap, south of Sheep Mountain, in northern extension of San Andres Mountains, sec. 25, T. 11 S., R. 4 E. Crops out the entire length of San Andres Range, and throughout Sacramento and Sierra Caballo Mountains.

**Smackover Formation**

Smackover Limestone

Upper Jurassic: Subsurface in Arkansas, Alabama Louisiana, Mississippi, and Texas.

D. H. Bingham, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 8, p. 1068, 1072. Smackover limestone encountered at depth of 4,900 feet at north edge of Smackover field. Limestone is 700 feet thick. Age undetermined; thought to be lower than Trinity and younger than Paleozoic.

W. B. Weeks, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 8, p. 959 (fig. 2), 960 (fig. 3), 964–965. Overlies Eagle Mills formation; underlies Buckner formation. Pre-Comanche.

W. B. Weeks, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 28, 29. In Snow Hill area, Arkansas, Buckner anhydrite is absent and Smackover underlies Cotton Valley.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 16–21, cross sections. Termed formation. In southern Arkansas, divisible into two members of which upper consists of oolitic to chalky limestone and lower of dense limestone with argillaceous bands. These limestone facies grade southward in northern Louisiana into an interbedded limestone, shale, and sandstone facies which is included in Smackover formation. Term Smackover limestone is used in this report only in reference to limestone facies. Thickness 502 to about 1,230 feet. Fossils indicate Middle or Upper Jurassic age.

R. W. Imlay, 1943, Am. Assoc Petroleum Geologists Bull., v. 27, no. 11, p. 1437 (table 1), 1440–1451. Detailed discussion with Jurassic formations of Gulf Coast region. Upper Jurassic (Argovian).

R. T. Hazzard, W. T. Spooner, and B. W. Blanpied, [1947], Shreveport Geol. Soc. 1945, Ref. Rept., v. 2, p. 483, 484, 488. Overlies Norphlet formation (new).

First known from Lion Oil Refining Co.'s Hayes No. 9–A, sec. 9, T. 16 S., R. 15 W., Union County, Ark. Named for Smackover field.

Smalls Falls Formation

Age not stated: West-central Maine.

I. E. Furlong, 1960, Dissert, Abs., v. 21, no. 4, p. 848. Characterized by dark maroon-stained thinly bedded highly sulfidic argillaceous rock with minor intercalated arenaceous and calcareous units. Oldest stratigraphic unit in area. Underlies Madrid formation.

Present in Farmington quadrangle.

Smarts Mountain Granite

Smarts Mountain Group

Upper Devonian(?): West-central New Hampshire.

Katharine Fowler-Lunn and Louise Kingsley, 1937, Geol. Soc. America Bull., v. 48, no. 10, p. 1382, pl. 3. Granite included in Oliverian magma series. Intrudes Ammonoosuc volcanics. Upper Devonian in age.

Katharine Fowler-Billings and Louise Kingsley, 1940, Geologic map and structure sections of the Cardigan quadrangle, New Hampshire (1:62,500): New Hampshire Highway Dept. Group consists of fine-grained white to gray weakly-foliated quartz diorite and granodiorite. Age designated probably Upper Devonian.

Mapped in extreme northwestern corner of Cardigan quadrangle.

Smelter Granite[1]

Jurassic: British Columbia, Canada, and northern Washington.

Original reference: R. A. Daly, 1913, Canada Dept. Int. Rept. Chief Ast., v. 2, p. 381.

Smetana Sandstone (in Yegua Group)

Eocene (Claiborne): Eastern Texas.

A. A. L. Mathews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 1–3, geol. map. Name applied to basal unit of group. Characteristically dark-red iron-sandstone with basal conglomerate. Beds are from 1 to 8 inches thick; and in some areas are separated by thin seams of yellow shale. Estimated thickness 138 feet. Underlies Bryan sandstone; unconformably overlies Mount Tabor shales. Stenzel (1940) placed base of Yegua above Mount Tabor shales but included Serbin sand lentil in upper part of Mount Tabor. [It is not clear whether author intended to replace Serbin by Smetana or not.]

Name derived from community of Smetana, 4.4 miles west of B.M. 0900 along Highway 21 at Bryan, Brazos County. Well exposed at Fairview 3.5 miles west of the same bench mark, but name Fairview is preoccupied.

Smethport magnafacies[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 27.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 44–45, 52–53. Shown in faciological diagram of Upper Devonian strata in northern Pennsylvania.

Named from town of Smethport, McKean County.

†Smethport Shale Member (of Knapp Formation)[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 203.

Smith Basin Formation

Lower Ordovician: East-central New York.

John Rodgers *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., 1952, Guidebook for field trips in New England: Geol. Soc. America, p. 35 (table 2). Described as cherty dolomite with limestone layers below the dolomite. Thickness 90 feet. Underlies Fort Cassin formation. Refers to R. H. Flower (unpub. ms.).

Occurs in Fort Ann quadrangle.

†Smithfield Limestone Member (of Marlboro Formation)[1]

Precambrian: Northeastern Rhode Island.

Original reference: Ebenezer Emmons, 1843, New York Nat. History Agric., v. 1, p. 90–91.

A. W. Quinn, R. G. Ray, and W. L. Seymour, 1948, *in* A. W. Quinn and others, 1948, Rhode Island Port and Indus. Comm. Geol. Bull. 3, p. 10. Name abandoned in Pawtucket area. Marble beds considered part of Mussey Brook schist (new).

Named for occurrence in town of Smithfield; outcrops area subsequently became part of town of Lincoln, Providence County.

**Smith Fork Glaciation**

Smith Fork glacial stage[1]

Pleistocene: Northeastern Utah.

Original reference: W. H. Bradley, 1936, U.S. Geol. Survey Prof. Paper 185.

Ernst Antevs, 1945, Am. Jour. Sci., v. 243–A, table 2. Correlates with Tahoe (Wisconsin).

Name changed to Smith Fork Glaciation to comply with 1961 Stratigraphic Code.

Named for train of lateral moraines left by its glaciers in valley of East Fork of Smith Fork.

†Smith River Lake Beds[1]

Miocene, middle: Central southern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Atlas, Folio 56.

Deposited in lake that once filled valley of Smith River, between Little Belt and Big Belt Ranges, Little Belt Mountains region.

Smiths Corner Member (of Lockatong Formation)

Triassic: Southeastern Pennsylvania.

D. B. McLaughlin, 1944, Pennsylvania Acad. Sci. Proc., v. 18, p. 65, 67. Name given to thin red argillite member. Thickness 11 to 50 feet. Occurs between two black hard argillite units of the formation, $A_1$ below and $A_2$ above.

D. B. McLaughlin, 1948, Michigan Acad. Sci. Arts and Letters Papers, v. 32, p. 298, 299. Termed Smith Corner member. Thickens rapidly southwest of Tohickon Creek and merges with lower red shales which have replaced $A_1$.

Exposed in a brook at Smith's Corner, Bucks County, and in bed of Tohickon Creek on both sides of the "loop" south of the "high rocks" and also south of the "big bend."

Smith Valley Beds

Pliocene, middle and upper (Hemphillian-Blancan): West-central Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 62 (fig. 4), 67. Name applied to beds that contain Smith Valley fauna. Further study may indicate desirability of retaining separate names for Morgan Ranch formation (new) and Smith Valley beds though they now appear to be facies of same basin of deposition.

Exposed along eastern side of Smith[s] Valley and south of Wilson Canyon, near Nevada-California line.

†Smithville Chert Lentil (in Stanley Shale)[1]

Mississippian: Southeastern Oklahoma.

Original reference: H. D. Miser and C. W. Honess, 1927, Oklahoma Geol. Survey Bull. 44, p. 11.

C. C. Branson, 1957. Oklahoma Geology Notes, v. 17, no. 11, p. 102. Abandoned by Oklahoma Geological Survey. Name has not been used if allowed to stand preoccupies well-known name of Lower Ordovician Smithville limestone of Arkansas.

O. B. Shelburne, 1960. Oklahoma Geol. Survey Bull. 88, p. 18. Renamed Battiest chert member of Tenmile Creek formation.

Named for village of Smithville, McCurtain County.

**Smithville Formation**[1]

Lower Ordovician: Northern Arkansas and southeastern Missouri.

Original reference: G. C. Branner, 1929. Geologic map of Arkansas.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65. no. 3, chart 2 (columns 52, 53). Shown on correlation chart above Powell formation and below Black Rock limestone in northern Arkansas and below Everton formation in southeastern Missouri.

First mapped at and around Smithville, Lawrence County, Ark.

**Smithwick Shale** (in Bend Group)[1]

Smithwick Group

Lower and Middle Pennsylvanian: Central Texas.

Original reference: S. Paige, 1911, U.S. Geol. Survey Bull. 450, p. 25.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 85–86. Smithwick beds are excluded from Morrow and Strawn (Des Moines) series and assigned to intervening Lampasas series (new). Overlies Big Saline group (new); underlies Millsap Lake group in Strawn series. In subsurface, includes (ascending) Eastland Lake, Caddo Pool, and Parks formations (all new).

F. B. Plummer, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 69–73. Formation in Bend series. At type locality, includes strata above Lemons Bluff beds in Marble Falls formation and below typical Strawn beds.

M. G. Cheney, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 207 (chart 1), 209. Chart shows Smithwick formation in Bend group. Formation is restricted above to exclude Caddo Pool and Parks formations which are included in Kickapoo Creek group (new). Overlies Big Saline formation.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 77–83. Formation, at type locality, includes strata above Brister Bluff [Brister limestone member] and Lemons Bluff beds in Big Saline formation. Through west and central San Saba County, it includes all shale below Strawn group and above black Marble Falls limestone. In eastern San Saba County near Bend, basal Smithwick is 60 feet above top of limestone and base is marked by first appearance of coral *Hadrophyllum aplatum* Cummins, now named *Cumminsia aplata* (Cummins) by Moore and Jeffords. Thickness at type locality 301 feet. Siltstone, fissile black shale, and conglomerate facies recognized.

Type locality (Plummer): Along Colorado River west of Smithwick, Burnet County. Section measured from Marble Falls limestone outcrop on Wall Ranch eastward to river bank opposite and old Smithwick. Named for town of Smithwick, Burnet County.

**Smoke Creek Glaciation**

Pleistocene (pre-Wisconsin): Northeastern Montana and northwestern North Dakota.

A. D. Howard, 1960, U.S. Geol. Survey Prof. Paper 326, p. 26. Considerations of regional history indirectly support validity of a pre-Wisconsin Smoke Creek glaciation.

Name derived from Smoke Creek, Roosevelt County, Mont.

**Smoky Hill Chalk Member** (of Niobrara Formation)[1]

**Smoky Hill Marl Member** (of Niobrara Formation)[1]

**Smoky Hill Shale Member** (of Niobrara Formation)

Upper Cretaceous: Western Kansas, eastern Colorado, northeastern New Mexico, and southeastern South Dakota.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 51.

R. L. Griggs, 1948, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 1, p. 31–33. Described in Colfax County, N. Mex. Here unit is more shale than marl. Approximate thickness 900 feet (based on subsurface data). Overlies Fort Hays limestone member; conformably underlies Pierre shale.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 99. In Gove County, Kans., chalk member underlies Pleistocene Grand Island member of Meade formation.

E. J. Bolin, 1952, South Dakota Acad. Sci. Proc., v. 31, p. 190. Geographically extended into southeastern South Dakota. Difficult to distinguish Smoky Hill and Fort Hays members on basis of lithology, but this investigation demonstrated that they can be distinguished on basis of microfossils. Thickness of Smoky Hill 77 to 125 feet.

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–146. Marl member described in La Veta area, Huerfano County, Colo. Conformably overlies Fort Hays limestone member and gradationally underlies Pierre shale. Consists of about 500 feet of thin beds of white limestone alternating with much thicker beds of yellow chalk; includes some thin bands of bentonitic claystone. East of Raton Mesa region, grades northward from a gray shale facies into yellow-orange limestone and chalk facies.

M. A. Jenkins, Jr., 1957, Rocky Mountain Assoc. Geologists Guidebook to the geology of North and Middle Parks Basins, Colorado, p. 53, pl. 1.

Described in Red Dirt area, Grand County, Colo., where it is 410 feet thick and predominantly shale. Overlies Fort Hays member and underlies Pierre shale. Believed that names Smoky Hill and Fort Hayes have priority over terms Apishapa and Timpas, and if used they would help standardize Niobrara terminology in west-central Colorado.

D. M. Sheridan and others, 1958, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–179. Referred to as shale member; consists of light-gray to dusty-yellow calcareous shale and two thick shaly chalk beds. Report discusses Ralston Buttes quadrangle, Jefferson County, Colo.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as Smoky Hill chalk member of Niobrara chalk. Overlies Fort Hays limestone member; underlies Sharon Springs shale member of Pierre shale.

Named for Smoky Hill River, Kans.

Snake Creek Beds[1]

Snake Creek Formation (in Ogallala Group)

Pliocene, middle to upper: Western Nebraska and eastern Wyoming.

Original reference: W. D. Matthew and H. J. Cook, 1909, Am. Mus. Nat. History Bull., v. 26, art. 27, p. 362–363.

A. L. Lugn, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1254–1258, 1266 (table 2). Discussion of confusion in use of terms Snake Creek and Sheep Creek formations, both named by Matthew and Cook (1909). Typical "Snake Creek" formation, or at least the so-called "upper Snake Creek," is correlative with some part of upper Ogallala group. Snake Creek has been incorrectly(?) applied to beds, mainly channel fills, as late as Pleistocene and to other beds as old as Miocene. Much of the Miocene "Snake Creek" or perhaps the so-called "lower Snake Creek" seems to be in part not Snake Creek but Sheep Creek channel beds in place and in proper stratigraphic sequence. Some of the Miocene and "Sheep Creek" vertebrate fossils collected from "Snake Creek" channel deposits have come from very large blocks of Sheep Creek formation, which were broken away from banks of Snake Creek streams and lie buried in younger silt and sand, the true Snake Creek sediment, which is always channel-fill material. Original definition of Snake Creek and Sheep Creek formations may be essentially valid, and it is proposed to continue use of these names to apply to correctly differentiated formations. Table 2 shows Snake Creek formation (middle to late Pliocene) in Ogallala group between Sidney gravel above and Ash Hollow formation below. Sheep Creek formation (late upper Miocene) is assigned to Hemingford group.

Named for occurrence on Snake Creek, Sioux County, Nebr.

**Snake Hill Formation[1]**

Snake Hill Shale or Beds

Middle Ordovician: Eastern New York.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 27.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 265 (fig. 10), 272–273, pl. 4. Discussion of stratigraphy of Trenton group. Snake Hill formation is discussed under heading of formations of Sherman Fall age. Snake Hill beds were defined to comprise Middle Ordovician silty shales of Hudson Valley that were considered equivalent to Canajoharie shale and had previously been identified with Magog shale of Quebec. Upper and lower contacts of formation are not known, and thickness has been estimated at about 3,000 feet. Formation crops out in belt extending northward along Hudson River from northeastern part of Helderberg Plateau. Similar beds have been described farther south on northwest side of the Highlands—the Reading Prong of New England Upland—in which region they overlie limestones of Black River and low Trenton age. Figure 10 and plate 4 show Snake Hill underlying Schenectady.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 47 (table), 89 [1946]. Ordovician system represented in eastern (Levis) trough by Snake Hill shale (at top), Tackawasick limestone and shale, Rysedorph conglomerate, and Normanskill shale. In Hudson Valley, Snake Hill beds form broad belt of shales between Normanskill shales and Wappinger limestone at bank of river to Skunnemunk Mountains and has computed thickness of 1,500 to 2,000 feet in Orange County. Middle Ordovician.

F. M. Swartz, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1574–1575. Where Mohawk Valley joins Hudson Valley near Albany, upper part of type Canajoharie shale is replaced by 1,500 to 2,000 feet of Schenectady shale. Earlier Canajoharie shales found beneath the western part of the Schenectady, are replaced in Albany area by 1,200 to 2,000 feet of grayish, silty, and sandy Snake Hill shales. Snake Hill shales may have been shifted by Taconic faults of Albany region, and it is not certain that they belong beneath the outcropping Schenectady shales in normal stratigraphic succession.

R. V. Cushman, 1953, New York State Water Power and Control Comm. Bull. GW–33, p. 10 (table 3), 15, pl. 2. Thickness about 600 feet in Washington County. Table 3 shows Snake Hill formation above Walloomsac slate. Middle Ordovician.

Name is from fossiliferous beds at Snake Hill on east side of Saratoga Lake.

**Snake River Group**

Snake River Basalt[1]

Snake River Lava

Pleistocene and Recent: Southern Idaho and southwestern Montana.

Original reference: Waldemar Lindgren, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, pl. 8.

I. C. Russell, 1902, U.S. Geol. Survey Bull. 199, p. 38, 59, map. Name Snake River lava proposed and geographic area described.

C. P. Ross and J. D. Forrester, 1947, Geologic map of the State of Idaho (1:500,000): U.S. Geol. Survey. Quaternary and possible Tertiary.

J. C. Bayless, 1950, Michigan Acad. Sci., Arts, and Letters, Papers, v. 34, p. 219. Lava proposed as general term by which to designate the basaltic rocks that underlie by far the larger part of Snake River Plains and that to a great extent form their actual surfaces. Described in southeastern part of Snake River Plains as mostly gray to black, fine grained, and vesicular, commonly having small feldspar and olivine phenocrysts visible to unaided eye.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 377, pl. 1. Geographically extended to Beaverhead County, Mont.

R. T. Littleton and E. G. Crosthwaite, 1957, U.S. Geol. Survey Water-Supply Paper 1460–D, p. 158 (table), 165–166. Chiefly olivine basalt flows. Occurs as cap rock on north rim of Snake River Canyon and on buttes immediately south of river, and locally as intracanyon basalt. Thickness 3 to 250 feet. Occurs above Idaho formation. Pliocene to Recent.

U.S. Geological Survey currently classifies the Snake River as a group on the basis of a study now in progress.

Named for occurrence in Snake River area, Idaho.

Snake River Series[1]

Permian(?): Northern Idaho.

Original reference: V. R. D. Kirkham, 1927, Idaho Bur. Mines and Geology Pamph. 24, p. 3–6.

Exposed in Clearwater River Canyon near Asahka [Ahsahka], Clearwater County.

Snake River Stage[1]

Pliocene: Northwestern Nebraska.

Original reference: E. H. Barbour, 1915, Am. Jour. Sci., 4th, v. 39, p. 87.

Occurs along a stream variously termed Snake Creek and Snake River near Burge, Cherry County.

**Sneech Pond Schist** (in Blackstone Series)

Precambrian(?): Northeastern Rhode Island.

Alonzo Quinn, R. G. Ray, and W. L. Seymour, 1948, *in* Alonzo Quinn and others, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 3, p. 12, geol. map; A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Quad. Map [GQ–1]. Chiefly fine-grained gray or greenish-gray quartz-mica schist with relatively thin interbeds of quartzite and conglomerate. Contains beds, sills, and dikes of Hunting Hill greenstone (new) and thin, discontinuous marble beds. Included in Blackstone series.

Named for good exposures on west shore of Sneech Pond and in quarries east of pond, Pawtucket quadrangle, Providence County.

**Sneed Andesite**

Tertiary, middle(?): Southwestern Arizona.

James Gilluly, 1937, Arizona Bur. Mines Bull. 141, Geol. Ser. 9, p. 15 (table 1), 45–46, pl. 1. Chiefly reddish porphyritic lava with phenocrysts of hornblende and white plagioclase in a dense base. Most of the lava consists of andesine and green hornblende phenocrysts in an andesitic groundmass. Some breccias north of Salt Well. Estimated thickness at Tule Well 3,000 feet. Unconformably overlies Locomotive fanglomerate (new), Chico Shunie quartz monzonite (new), and Cardigan gneiss (new) near Tule Well, and probably the Cornelia quartz monzonite (new). Unconformably underlies Daniels conglomerate (new) and Black Mountain andesite (new).

James Gilluly, 1946, U.S. Geol. Survey Prof. Paper 209, p. 9, 41–42, pl. 3 [1947]. Disconformably underlies Batamote andesite at south end of Childs Mountain. Type locality designated.

Type locality: At Sneed Ranch in sec. 5, T. 12 S., R. 6 W., Ajo quadrangle, Pima County. Crops out on northwest slope of Little Ajo Mountains and at south end of Childs Mountain.

**Sneeds Limestone Lentil** (of Everton Limestone)[1]

Middle Ordovician: Northern Arkansas.

Original reference: A. H. Purdue and H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

Occurs in Hemmed-in Hollow, 2 miles south of Compton, Newton County. Typically exposed on Sneeds Creek.

†Sneedville Limestone[1]

Upper Silurian: Eastern Tennessee.

Original reference: J. M. Safford, 1856, Geol. reconn. Tennessee, 1st Rept., p. 157.

Named for Sneedville, Hancock County.

**Sneffels Member** (of San Juan Tuff)[1]

Miocene(?): Southwestern Colorado.

Original reference: W. S. Burbank, 1930, Colorado Sci. Soc. Proc., v. 12, p. 187.

In vicinity of Canyon Creek, Sneffels, and Ouray, Ouray district.

**Snelson Granite**

Precambrian: Central western Georgia.

D. F. Hewett and G. W. Crickmay, 1937, U.S. Geol. Survey Water-Supply Paper 819, p. 26–27, pl. 1. Made up largely of oligoclase, microcline, quartz, and biotite; most of biotite flakes are in rudely parallel layers so that rock has persistent foliation, foliation shows small folds and minute plications, granite is cut by numerous pegmatite dikes. Considered to be younger than Carolina gneiss.

Well exposed near Snelson's Crossroads, 2½ miles east of Harris, Meriwether County. Underlies large area in northwest quarter of Warm Springs quadrangle north of Towaliga fault.

Sniabar Limestone[1] (in Swope Limestone)

Sniabar Limestone Member (of Hertha Formation)

Pennsylvanian (Missouri Series): Northwestern Missouri and eastern Kansas.

Original references: J. M. Jewett, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 99, 100, 103; R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 85, 90, 97.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 193. Uppermost member of Hertha. Overlies Mound City shale member; underlies Ladore shale. Thickness as much as 10 feet; average about 5 feet.

Named for Sniabar Creek just east of Kansas City, Mo.

Sni Mills Limestone[1] Member (of Lenapah Formation)

Pennsylvanian (Des Moines Series): Northwestern Missouri and northeastern Kansas.

Original reference: F. C. Greene *in* R. C. Moore and others, 1936, Kansas Geol. Soc. Guidebook 10th Ann. Field Conf., p. 19, 20.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 9. Allocated to member status in Lenapah formation. Uppermost member; overlies Perry Farm shale member; underlies Memorial formation.

L. M. Cline and F. C. Greene, 1950, Missouri Geol. Survey and Water Resources Rept. Inv. 12, p. 25. Name Sni Mills has priority over name Idenbro, and term Idenbro is suppressed as a synonym for Sni Mills.

Named for outcrops at Sni Mills, Jackson County, Mo.

Snipes Conglomerates

Miocene, upper, or Pliocene: Central Washington.

R. C. Treasher, 1937, Geol. Soc. Oregon Country News Letter, v. 3, no. 20, p. 218–220. Name applied to persistent stratum of conglomerate, quartzite-bearing gravels, tuffaceous sandstones, and arkosic sands which overlie Wenas basalt and underlie valley silts. Thickness at type locality 238 feet. The conglomerate unit was included in Satsop formation by Bretz (1917) and placed at base of Ellensburg by other workers.

Type locality: SW¼ sec. 34, T. 10 N., R. 22 E., Yakima County.

**Snitz Creek Formation** (in Conococheague Group)

Snitz Creek Member (of Conococheague Formation)

Upper Cambrian: Southeastern Pennsylvania.

Carlyle Gray, A. R. Geyer, and D. B. McLaughlin, 1958, Geologic map of the Richland quadrangle, Pennsylvania (1:24,000): Pennsylvania Geol. Survey, 4th ser., Atlas 167–D. Name applied to dolomite sequence that stratigraphically overlies Buffalo Springs member (new); underlies Schaefferstown member (new). Composed of thick-bedded light- to medium-gray dolomite, commonly oolitic, with medium-light-gray limestone or medium-gray shaly limestone interbeds; where coarsely crystalline, dolomite is commonly vuggy; shaly partings, often stylolitic, occur in dolomite; sandstone beds 1 to 1½ feet thick present near top and base, with thinner sandy beds occurring throughout member; dark-gray to grayish-black chert locally abundant. Estimated thickness 350 feet; partial section (type) 62 feet, neither top nor base exposed.

Carlyle Gray and A. A. Socolow, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 148–150. Upper Cambrian. Member has same stratigraphic position of, and is lithologically similar to, Big Spring Station member (Wilson, 1952) of Conococheague.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Conococheague group.

Type section: Partial section measured along Cornwall Railroad tracks about one-half mile south of Midway Church, Lebanon County. No satisfactory type section available in Lebanon County but best partial section has been measured and used as type section.

Snomac Limestone Member (of Ada Formation)

Pennsylvanian (Virgil Series): East-central Oklahoma.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 100, 101, pl. 1. Name applied to a sequence of thin dull-white finely crystalline limestone beds that occur in the lowest third of the formation; commonly

only a single limestone is exposed at one locality. Member occurs high in a 45-foot shale interval that overlies the basal Ada sandstone.

Named after Snomac townsite in secs. 10, 11, and 14, T. 7 N., R. 6 E., Seminole County. Member extends from center of sec. 26, T. 8 N., R. 6 E., north of Little River, to secs. 14 and 15, T. 7 N., R. 6 E., south of Little River.

**Snoqualmie Granodiorite**[1]

Miocene and Pliocene, lower: Central Washington.

Original reference: G. O. Smith and F. C. Calkins, 1906, U.S. Geol. Survey Geol. Atlas, Folio 139.

W. C. Warren, 1941, Jour. Geology, v. 49, no. 8, p. 795, 797 (fig. 2). Probably intermediate in age between lower part of Keechelus andesitic series and the Fifes Peak andesite (new). Map legend shows age as Oligocene(?). Area of report is Mount Aix quadrangle.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 121–123, pl. 1. Predominantly granodiorite; locally includes both more basic and more felsic rocks. Intrudes Denny (new), Guye (restricted), Naches, and Keechelus formations. Youngest formation intruded is Keechelus which may be Oligocene or Miocene. In area of this report [northern parts of Mount Stuart and Snoqualmie folios], the Snoqualmie is not in contact with any younger rocks, so no upper limit can be placed on its age. Relationship of Keechelus and Snoqualmie in area discussed by Warren (1941) to rocks in area of this study is not known. Age determination of Snoqualmie (using zircon method) is reported to be 60 million years —this is usually considered Paleocene or Eocene.

Named for exposures about headwaters of Snoqualmie River, Snoqualmie quadrangle. Forms peaks and ridges, such as Granite, Denny, and Snoqualmie Mountains.

**Snowbank Granite**[1]

Precambrian (lower or middle Huronian): Northeastern Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. Nat. History Survey Final Rept., v. 4.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1610. Snowbank granite and Snowbank stock mentioned in report on Knife Lake district.

First described in Vermilion district.

†Snowbank Lake Granite[1]

Precambrian (lower or middle Huronian): Northeastern Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. Nat. History Survey Final Rept., v. 4.

Occurs in Snowbank Lake and vicinity, Vermilion district.

**Snowbird Group**

Snowbird Formation[1]

Precambrian (Ocoee Series): Western North Carolina and eastern Tennessee.

Original reference: A. Keith, 1904, U.S. Geol. Survey Geol. Atlas, Folio 116, p. 5.

G. W. Stose and A. J. Stose, 1944, Am. Jour. Sci., v. 242, no. 7, p. 390. Keith (in later publications) used names Snowbird formation and

Hiwassee slate for Cambrian rocks below Cochran conglomerate. These two names are names of Ocoee formations and should not be used for Cambrian formations.

G. W. Stose and A. J. Stose, 1947, Am. Jour. Sci., v. 245, no. 10, p. 627. Name Vann quartzite proposed to replace term Snowbird formation as used by Keith in Hot Springs area, North Carolina.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 271–272. Name Hurricane is applied to the graywacke which underlies Great Smoky quartzite and is basal formation of Ocoee series. In Asheville and several other folios, Keith (1904, 1905, 1907, and Mount Guyot folio, unpub.) used name Snowbird formation for these beds which he assigned to Lower Cambrian; he included part of Great Smoky conglomerate in Snowbird formation at type locality and elsewhere; in 1904 and 1907, he applied name Snowbird also to well-established Lower Cambrian rocks; hence, name Snowbird is misleading, and new name applied.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 13 (table 3), 25–30. In this report on Hot Springs area, North Carolina, term Snowbird is retained for unit below Sandsuck. This is area in which Stose and Stose used names Vann quartzite and Hurricane graywacke.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 68. no. 9, p. 953 (fig. 2), 954–957, 963. Rank raised to group in Ocoee series. North of and below Greenbrier fault, includes Metcalf formation (new) in western part of area; in eastern part of area, includes (ascending) Wading Branch formation, Longarm quartzite, Roaring Fork sandstone (all new), and Pigeon siltstone. South of and above Greenbrier fault, includes Wading Branch formation, Longarm quartzite, and Roaring Fork sandstone. At type section, group rests on granitic rocks and is succeeded conformably by Rich Butt sandstone (new). South and above Greenbrier fault, conformably underlies Great Smoky group and overlies granitic and gneissic rocks.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 34–35; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Mapped as Snowbird formation, Ocoee series, Upper Precambrian. Subdivided into five unnamed units. Thickness over 15,000 feet in vicinity of Snowbird Mountain and Pigeon River.

Type section (group): Along Pigeon River at southwest and south base of Snowbird Mountain, Haywood County, N.C.

**Snow Creek Porphyry**[1]

Post-Cretaceous(?): Central Montana.

Original reference: P. A. Schafer, 1935, Montana Bur. Mines and Geology Mem. 13, p. 10–15, map.

U.S. Geological Survey currently designates the Snow Creek Porphyry as post-Cretaceous(?) on the basis of a study now in progress.

Exposed continuously from vicinity of I.X.L. mine across lower end of Poverty Ridge, a short distance above junction of Snow and Carpenter Creeks, across Carpenter Creek near mouths of Hegener and Mackey Creeks, and extending to divide at heads of those Creeks, Neihart district, Cascade County.

Snowcrest Granite

Eocene: Southwestern Montana.

Robert Scholten, K. A. Keenmon, and W. O. Kupsch, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 372, pl. 1. Coarse-grained strongly jointed granite that disintegrates into small angular fragments. Snowcrest intrusive cuts through Mississippian rocks and is unconformably overlain by Blacktail Deer Creek formation (new).

Occurs as a small stock that crops out at southwestern end of Snowcrest Range, in sec. 20, T. 13 S., R. 7 W., Beaverhead County.

Snowden Member (of Harpers Formation)

Lower Cambrian: Central Virginia.

R. O. Bloomer and H. J. Werner, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 596, pl. 1. Distinctive quartzite member which occurs 100–300 feet above bottom of formation. Thickness 50 feet.

Named for exposure on U.S. Highway 501 in James River Gorge about 0.2 mile west of Snowden post office, Amherst County.

Snow Fork Limestone (in Allegheny Formation)[1]

Snow Fork ironstone member

Pennsylvania: Southeastern Ohio.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, p. 889, 897, pls. facing p. 889, 921.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 69–70. Snow Fork ironstone (Salem limestone) member included in Middle Kittanning cyclothem in report on Athens County. Average thickness about 4 feet. Member is shale with abundant plant fossils and numerous clay ironstones. Allegheny series.

Named for Snow Fork on Monday Creek, Hocking County.

**Snow Hill Marl Member** (of Black Creek Formation)[1]

Upper Cretaceous: Southern North Carolina and eastern South Carolina.

Original reference: L. W. Stephenson, 1923, North Carolina Geol. and Econ. Survey, v. 5, pt. 1, p. 9–10.

H. E. Le Grand and P. M. Brown, 1955, Carolina Geol. Soc. Guidebook Oct. 8–9, p. 7, 24–25. Stop 1 of field trip considered type locality of Snow Hill member. Authors assume this to be fossil locality mentioned by Conrad (1871, Am. Jour. Sci., 3d ser., v. 1, 468–469). At this site, Snow Hill member consists of 5 or 6 feet of drab-black arenaceous and micaceous clays containing abundant assemblage of megafossils. Thickness of exposed section is variable with seasonal fluctuations in river level. Uppermost part of Black Creek formation; underlies Peedee formation.

C. E. Brett, 1959, Elisha Mitchell Sci. Soc. Jour., v. 75, no. 2, p. 69–70. On basis of present study, it is believed that term Snow Hill calcareous member of Black Creek formation should be dropped from literature and that sediments at Snow Hill be included in Peedee formation.

Type locality: On farm of L. C. Daniels along Contentea Creek, about 2 miles below Snow Hill, Greene County, N.C.

Snowshoe Formation (in Izee Group)

Middle Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 259–263. Consists of approximately 2,800 feet of black shale and fine-grained dark-gray laminated sandstone in the upper part of Izee group. Unconformably underlies Trowbridge shale (new); overlies Hyde formation (new).

W. R. Dickinson, 1960, Dissert. Abs., v. 20, no. 11, p. 4367. Weberg, Warm Springs, and Basey (new) formations are lateral equivalents of Snowshoe formation.

Type area: On southeast limb of Mowich anticline; exposures lie in narrow belt extending from Snow Mountain northeastward across South Fork valley, Crook County. Named for the "Snowshoe country" on headwaters of Silvies River.

**Snowy Range Formation**

Snowy Range Limestone Member (of Gallatin Limestone)

Snowy Range Member (of Boysen Formation)

Upper Cambrian: Southern Montana and northwestern Wyoming.

Erling Dorf and Christina Lochman, 1938. (abs.) Geol. Soc. America Proc. 1937, p. 276; 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 545–547. Formation comprises: lower member of thin sandstones and gray-green fissile shales (average 75 feet thick) with, at top, a few limestone pebble conglomerates and thin persistent horizon (about 10 feet thick) of dense light-gray limestone with distinctive columnar structure; upper member of intercalated gray-green fissile shales and innumerable beds and lenses of glauconitic limestone flat pebble conglomerates (average 150 feet thick). Thickness at type locality 259 feet. Underlies Grove Creek formation (new); overlies Maurice formation (new). Franconia equivalent. Term Gallatin formation not applicable in this area [southern Montana].

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1093–1094, 1101 (fig. 3), 1105. Rank reduced to member status in Boysen formation (new) in Wind River area, Wyoming. Underlies Grove Creek member; overlies Maurice member. Thickness 308 feet in type section of Boysen.

V. E. Nelson and Victor Church, 1943, Jour. Geology, v. 51, no. 3, p. 145 (fig. 2). Stratigraphic chart of Gros Ventre and northern Hoback Ranges, Wyo., shows Snowy Range as upper member of Gallatin limestone.

Christina Lochman, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2202 (fig. 1), 2212, 2214 (fig. 2). Formation includes (ascending) Dry Creek shale member and Sage pebble conglomerate member (new). In area of this report [central Montana], overlies Maurice formation and underlies Maywood formation. Thickness 15 to 130 feet.

A. M. Hanson, 1952, Montana Bur. Mines and Geology Mem. 33, p. 19. In part of Montana adjacent to and northeast of Yellowstone Park, strata of same age as Red Lion formation consist of interbedded greenish-gray shales and limestones and lime-pebble conglomerates. This unit has been named Snowy Range by Dorf and Lochman.

P. W. Richards, 1957, U.S. Geol. Survey Bull. 1021–L, p. 397, 400–402. Formation described east and southeast of Livingston, Mont., where it is 175 feet thick and consists of a lower 36 feet of greenish-gray shale, a middle 33 feet of flat-pebble limestone conglomerate overlain by columnar limestone, and an upper 106 feet of interbedded poorly exposed greenish-gray shale and light-gray dense crystalline glauconitic limestone; of these beds, the lower 34 feet are seemingly stratigraphic equivalents of Peale's (1893) Dry Creek shales and remainder of the formation is in part correlative with and in part younger than Peale's Pebbly limestone. Underlies Grove Creek formation; overlies Pilgrim limestone (used here in preference to Maurice).

R. E. Grant, 1958, Dissert. Abs., v. 18, no. 6, p. 2107. Formation consists of (ascending) Dry Creek shale, Sage, and Grove Creek members. Overlies Pilgrim limestone; underlies Maywood unit.

Type locality: On south slope of Castle Rock about 2 miles downstream from Snowy Range Ranch at junction of the East Fork with Mill Creek, Park County, Mont. Section measured in N½SE¼ sec. 13, T. 6 S., R. 9 E.

Snowy Range Series

Precambrian: Southeastern Wyoming.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Proposed for formations described by Blackwelder (1926, Geol. Soc. America Bull., v. 37, p. 622–647) from conglomerate at base of Deep Lake metaquartzite upward and including French slate. Occurs above Centennial series (new). [Formations described by Blackwelder include (ascending) Deep Lake Metaquartzite, Headquarters Schist, Heart Metagraywacke, Medicine Peak Metaquartzite, Lookout Schist, Sugarloaf Metaquartzite, Nash Marble Series, Anderson Phyllite, Ranger Marble, Towner Greenstone, and French Slate.]

C. L. Fenton and M. A. Fenton, 1957, Geol. Soc. America Mem. 67, p. 104–106. Series contains at least 24,000 feet of metamorphosed conglomerates, quartzites, graywackes, shales, and dolomites which reveal no angular unconformities, though minor disconformities are present. Terrestrial environment is indicated by three tillite deposits 125, 25, and 100 feet thick, the first of which appears about 2,000 feet above base of series. Believed to be early Huronian.

Crops out in Medicine Bow Mountains, west of Laramie basin, Wyoming.

Snyder Limestone

Snyder Member (of Benner Limestone)

Middle Ordovician (Bolarian): Central and south-central Pennsylvania, western Virginia, and southern West Virginia.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Named as member of Benner limestone and described as sublithographic light-colored oolitic and pebbly limestone. Thickness 96 feet at type locality.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 15–17. Lower member of Benner. At type section, consists of 98 feet of light-colored detrital limestone, with limestone pebble conglomerate, and white-weathering dense relatively pure sublithographic limestone. Latter type usually present in upper part of unit. Lithology similar throughout central Pennsylvania from Union Furnace, Huntingdon County, to Bedford County; conglomerate with white limestone pebbles particularly characteristic. Contains a thin metabentonite at Oak Hall. Maximum thickness 110 feet; diminishes to extinction in western Cumberland Valley. Conformably underlies Stover member, except in Blacklog and

Path Valleys, Pa., where it underlies Nealmont limestone or Mercersburg limestone. Overlies Hostler member of Hatter formation; often difficult to distinguish the two. Derivation of name and more exact location of type section stated.

Marshall Kay, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1199. Limestone included in upper Bolarian (Hunterian) series.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (columns 21, 22). Geographic extension; listed in stratigraphic column for Highland County, Va., and Monroe County, W. Va. [Limestone apparently has formational rank in these areas.]

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 74 (table 12), 78, 95, 103. Geographic restriction. New name McGlone limestone proposed for rocks in Virginia previously referred to as Snyder. Termed a formation.

Type section: In Pennsylvania Railroad cut at Union Furnace, Huntingdon County, Pa. Named for Snyder Township, Blair County, Pa., where exposed in southern quarry along Elk Run on southern boundary of township.

**Snyder Creek Shale**[1]

Upper Devonian: Central Missouri.

Original reference: J. A. Gallaher, 1900, Missouri Geol. Survey, v. 13, p. 153.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 145–151. Varies from largely shales through alternating shales and limestones to dominantly limestones. Thickness less than 10 feet to as much as 63 feet. Overlies Callaway limestone, in most places conformably. In most places, overlying formation is Bushberg, and unconformity is distinct. In some places, Chouteau limestone is unconformable on Snyder Creek. Burlington limestone is overlying formation in two or three places and Cherokee shale in one. Lower half of Upper Devonian and may represent lowest part of Upper Devonian.

Named for exposures on Snyder Creek which flows through Snyder Farm, Callaway County.

Snyder Hill Formation[1]

Snyder Hill Group

Permian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull. v. 47, p. 530–532, 536.

J. H. Feth, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 1, p. 86 (fig. 2), 87, 88–89 (fig. 3), 92–99. Name Snyder Hill formation applied to about 2,223 feet of Permian strata in northern Canelo Hills area.

E. D. Wilson, 1951, Arizona Bur. Mines Bull. 158, Geol. Ser. 19, p. 50. In Empire Mountains, overlies Andrada formation (new) and underlies unnamed Upper Cretaceous interval. Consists of thick-bedded limestone with several quartzite members. Thickness 1,250 to 2,250 feet.

D. L. Bryant, 1955, Dissert Abs., v. 15, no. 7, p. 1224. Rank raised to group. Includes (ascending) Scherrer formation, Concha limestone, and Rainvalley formation (new). This action restricts Naco group at top.

F. S. Sabins, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 498. Strata assigned to Snyder Hill by Feth (1948) appear to include beds equivalent to Colina, Scherrer, and Concha formations. Suggests term Snyder Hill be suppressed.

Type locality: Snyder Hill, an isolated hill about 10 miles southwest of Tucson, in Whetstone Mountains.

**Snyderville Shale[1] Member** (of Oread Limestone)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 32, 33, 38.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 147–148. Snyderville shale member of Oread formation; underlies Leavenworth limestone member; overlies Toronto limestone member. This is classification agreed upon by State Geological Surveys of Iowa. Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 26. In Nebraska, overlies Toronto (Weeping Water) limestone member. Type locality stated.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 419. Thickness 2 feet in measured section near Winterset, Madison County.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 38–40, pl. 1. In Douglas County, consists chiefly of green and gray argillaceous and silty shale, claystone, and siltstone. Thickness 1 to 45 feet; average 10 or 15 feet.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull 15, p. 23, fig. 5. Poorly exposed and thin limestone bed occurring at base is difficult to recognize. In Adair County, about 8 feet of shale. slightly silty and red at base, occurs between the Leavenworth and a limestone tentatively called the Toronto.

Type locality: In Heebner Creek valley, east of Snyderville quarry, about 3 miles west and 1¼ miles north of Nehawka, Cass County, Nebr.

**S O Volcanics**

Miocene or Pliocene: Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 110–115, pl. 5. Thick series of interbedded quartz latite tuffs and hornblende andesite flows. Highly variable both laterally and vertically. Broadly divisible into three members: basal series of quartz latite tuffs, breccias, and minor obsidian flows, with interbedded conglomerates, sandstones, and mudstones also largely of pyroclastic origin—thickness ranges from 1,600 feet on southeast face of Stockton Hill to knife edge just across valley to the south, and is missing within about a mile in that direction; intermediate member of hornblende andesite flows—probably about 1,000 feet thick east of S O Ranch and about 300 feet thick south of Reeves Ranch; and upper member of quartz latite tuff, with a few local intercalations of true rhyolite and hornblende andesite—thickness about 1,100 feet on Hay Mountain, elsewhere much less. Hornblende andesite flow member apparently the most uniform and continuous part of formation. Accumulated upon older erosion surface of considerable relief so that in various localities different members lie at stratigraphic base of formation and overlie various formations including Gleeson quartz monzonite (new) and Bisbee formation. Underlies undeformed late Quaternary alluvium at most localities. Probably not older than Miocene and early Pliocene seems an upper age limit for this volcanism.

Exposed near S O Ranch, from which it is named, in sec. 20, T. 20 S., R. 24 E. Well exposed between south end of Hay Mountain and the hills southwest of Reeves Ranch, about 8 miles to northwest. Other bodies occur south of Cowan Ranch—near Outlaw Mountain, on pediment extending northwest of Outlaw Mountain, and on west side of Dragoon Mountains near Bar O Ranch. Central Cochise County.

**Soap Creek Bentonite Bed** (in Belle Fourche Member of Cody Shale)

**Soap Creek Bentonite Bed** (in Frontier Formation)

Upper Cretaceous: Southeastern Montana and northern Wyoming.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–111, sheet 2. Olive-green bentonite bed 8 feet thick at top of Frontier formation. Locally more than 10 feet thick south of Soap Creek dome.

M. M. Knechtel and S. H. Patterson, 1952, U.S. Geol. Survey Circ. 150, pl. 1. Beds present in Yellowtail district, southeastern Montana and northern Wyoming.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 19, 20, pls. 1, 3. Bed in Belle Fourche member of Cody shale. Thickness 12 to 30 feet. Area of report, Hardin district, Montana and Wyoming. In this area, term Belle Fourche replaces Frontier formation as used in previous reports.

Well exposed on east flank of Soap Creek dome, sec. 35, T. 6 S., R. 32 E., Hardin area, Big Horn and Yellowstone Counties, Mont.

**Sobrante Sandstone**[1] (in Monterey Group)

Miocene, middle: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 69–70, pl. 12. Exposed in Martinez syncline, near Martinez. Thickness about 520 feet. Unconformably overlies San Ramon sandstone; underlies Briones sandstone.

G. C. Lutz, 1951, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 28, no. 13, p. 367–406. Term Sobrante used in redefined and restricted sense of Clark (1918, California Univ. Pub. Dept. Geol. Bull., v. 11, no. 2). Type section designated for Sobrante (restricted). Thickness at type locality about 150 feet. Underlies Claremont shale; overlies Concord formation(?).

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–88. Described in Hayward quadrangle. Usage here is roughly equivalent to Sobrante sandstone (restricted) of Clark (1918) and Lutz (1951). Middle Miocene.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 15–16, fig. 2, geol. map. Sobrante sandstone in Pleasanton area, Alameda and Contra Costa Counties, overlies Tolman formation (new); underlies Claremont shale. Thickness about 200 feet. Term Monterey group not considered appropriate in this region.

Type section of Sobrante sandstone (restricted): Along Bear Creek Road summit between Oursan Ridge and Lawson Hill, Contra Costa County.

Social Island Limestone Member (of Row Park Limestone)

Middle Ordovician: Central southern Pennsylvania.

F. M. Swartz and R. R. Thompson, 1958, Pennsylvania State Univ. Mineral Industries Expt. Sta. Bull. 71, p. 4, 5. Microcrystalline or vaughanitic limestone. Underlies Browns Mills limestone member (new); overlies Beekmantown dolomite. Name credited to J. G. Palacas (unpub. thesis).

In Franklin County.

Sockanosset Sandstone[1]

Pennsylvanian: Eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 159–163.

Well exposed in Sockanosset Ridge, east and west of reservoir near Providence, Providence County.

Socorran series[1]

Mississippian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1906, Science, new ser., v. 23, p. 921.

Soda Lake Formation

Miocene, lower: Southern California.

T. W. Dibblee, Jr., 1952, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Explor. Geophysicists Guidebook, Joint Ann. Mtg., Los Angeles, p. 82, 84. Marine shale and basal sandstone 1,200 feet thick. Underlies Painted Rock formation (new); overlies Simmler formation (new). Outcrops noted in road log. [This appears to be unit that was defined by Hill, Carlson, and Dibblee (1958) as the Soda Lake Shale and Soda Lake Sandstone Members of Vaqueros Formation.]

Occurs in Caliente Range, a low mountainous ridge trending northwesterly for about 30 miles between Cuyama Valley and Carrizo Plain. Range is an anticlinal uplift developed in a thick series of Tertiary sediments and is partially overturned and thrustfaulted southwestward toward Cuyama Valley.

Soda Lake Sandstone Member (of Vaqueros Formation)

Miocene, lower (Zemorrian): Southern California.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2978 (fig. 3), 2982 (fig. 5), 2984. Southeast of Caliente Mountain, the Vaqueros formation consists of three members (ascending): Soda Lake sandstone, Soda Lake shale, and Painted Rock sandstone. At type locality, the sandstone is characteristically gray white, weathering to light buff, massive bedded, fine to medium grained, well sorted, and firmly indurated; commonly crossbedded with foreset beds dipping in westerly direction. Thickness at type section 300 feet; thins westward by probable gradation into Soda Lake shale and toward southeast becomes undifferentiated from overlying Painted Rock sandstone; overlies Simmler formation.

Type locality: T. 10 N., R. 25 W., southeastern Caliente Range, east of Cuyama Ranch quadrangle.

Soda Lake Shale Member (of Vaqueros Formation)

Miocene, lower (Saucesian): Southern California.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2974 (fig. 1), 2978 (fig. 3), 2984–2986. From Caliente Mountain northwestward, the Vaqueros consists of two members, Soda Lake shale below and Painted Rock sandstone above. Thickness in type area, about 1,200 feet. Overlies Simmler redbeds. On southwest slope of Caliente Mountain, thickness is about 1,100 feet, base concealed; here it was mapped by Eaton and others (1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2) as Oligocene(?) silt and inferred to be correlative with middle Sespe and Gaviota formations of Santa Ynez Mountains; thickness in southeastern part of Caliente Range about 900 feet, this section grades into sandstone as does the 800-foot section in Cuyama Badlands.

Type locality: Northwestern Caliente Range near Soda Lake, T. 31 S., R. 19 E., Simmler quadrangle.

Soda Mountain Formation

Triassic-Jurassic: Southern California.

L. T. Grose, 1956, Dissert. Abs., v. 16, no. 1, p. 100; 1959, Geol. Soc. America Bull., v. 70, no. 12, pt. 1, p. 1526–1529, pl. 1. Thick series of volcanic flow breccia and sandstone. Rocks range from massive andesite flows through flow breccia, pyroclastic rocks, and welded tuff to volcanic sandstone and finally to nearly pure quartzite. Relative abundance of each type varies extremely and unpredictably within short distances vertically and laterally; volumetrically, flow breccia predominates and is followed by volcanic sandstone; massive flows, welded tuff, and pure quartzite are only locally abundant; yellow, gray, red, purple, and green colors common. Displays little bedding, except where interbedded sandstones and pyroclastics occur; hence, over large areas structure is almost unknown; where bedding is visible it is steep, vertical or locally overturned. Formation is generally bound in complex fault-block relations by Upper Paleozoic limestones and is intruded by Upper Mesozoic plutonic rocks. At type location, disconformably overlies Lower Triassic sedimentary rocks. No rocks are known to overlie formation stratigraphically in mapped area or elsewhere in region. Estimated minimum thickness 7,000 feet. On basis of field relations, formation is post-Early Triassic and pre-Cretaceous. Type location is selected but truly representative stratigraphic section is impossible to find (six reasons listed).

Type location: North end of Spectre Spur, northeastern Soda Mountains, San Bernardino County. This section is the most nearly complete, most orderly, and least metamorphosed and intruded of any in Soda Mountains or immediate surroundings.

**Sodus Shale** (in Clinton Group)

Sodus Shale Member (of Clinton Formation)[1]

Middle Silurian: Central and western New York.

Original reference: J. M. Clarke, 1906, New York State Mus. 2d Rept. Dir. Sci. Div. 1905, p. 12.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1982 (fig. 3). Sodus shale, 15½ feet thick, overlies Reynales limestone; underlies Williamson shale. Clintonian.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. No. 1. Shown on chart as Lower and Upper Sodus shale. Underlies Wolcott limestone; overlies Wallington limestone (new) which replaces limestone formerly known as Reynales at Rochester and eastward, and Bear Creek gray shale. Clinton group.

Named for town of Sodus, Wayne County.

**Solberg Schist** (in Dickinson Group)

Precambrian: Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 32. Middle formation of group. The more northerly (stratigraphically lower) parts of unit are dark fine-grained hornblende and biotite schists; some exposures show banding, parallel or nearly parallel to the steeply dipping foliation that may represent original layering; more southerly exposures are massive gray quartz-mica schist and micaceous quartzite. Aggregate thickness about 3,000 feet. The 100-foot iron-rich Skunk Creek member occurs about 1,000 feet below top of formation. Underlies Six-Mile Lake amphibolite (new); overlies East Branch arkose (new).

Named for Solberg Lake, in secs. 17 and 20, T. 42 N., R. 29 W., Dickinson County. Exposed east of lake in scattered outcrops for about 10 miles in a belt 1 to 2½ miles wide.

**Soldier Creek Shale Member** (of Bern Limestone)

Soldier Creek Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad Sci. Trans., v. 15, p. 30.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 309 (fig. 14). Graphic section of Pennsylvanian in Adams County shows Soldier Creek shale occurring below Wakarusa limestone and above Burlingame limestone.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 18. Formation contains two quite well defined limestones and three shale members in southeastern Nebraska and adjacent area of Kansas; formerly three limestones and two lower shales were classed with the Burlingame in Nebraska.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2277. Rank reduced to member status in Bern limestone (new). Overlies Burlingame limestone member; underlies Wakarusa limestone member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 13, fig. 5. Gray shale at top and bottom with maroon shale near top; near center is micaceous gray sandstone and siltstone. Thickness about 30 feet. Underlies Wakarusa limestone; overlies Burlingame limestone. Wabaunsee group.

Type locality not designated but presumably on "Big and Little Soldier Creeks about 3 miles from Silver Lake," Shawnee County, Kans.

Soldiers Limestone Member (of Big Saline Formation)

Lower Pennsylvanian: Central Texas.

F. B. Plummer, 1947, Jour. Paleontology, v. 21, no. 2, p. 142, 143, 145; 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 196 (table 2), 197, 198. Consists of light-gray coarsely crystalline, massively bedded, crinoidal fossiliferous limestone. Thinnest southwest of Rochelle, thickens westward to 75 feet at Brady, and nearly 200 feet at Big Saline Creek, Kimble County. West of Cavern Ridge, overlies Brook Ranch member (new) and, near Cavern Ridge, lies above beds with same lithology as that of Lemons Bluff spiculite at Lemons Bluff. Its stratigraphic position above beds of Lemons Bluff lithology suggests that Soldiers member has stratigraphic position similar to that of Brister member east of Cavern Ridge, although it differs from the Brister.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 70–71. Soldiers Hole lentil is massive reeflike series of limestone beds that form upper layers of Big Saline formation in Kimble, Mason, and McCulloch Counties. Extends from Big Saline Creek in Kimble County to Ellenburger ridges south of Hall near San Saba-McCulloch County line. Measured section at Soldiers Hole shows 28 feet of lentil above Lemons Bluff beds.

Soldiers Hole is 6 miles east and 2½ miles north of Brady, McCulloch County.

Soldiers Hole Lentil or Member (of Big Saline Formation)

*See* Soldiers Limestone Member (of Big Saline Formation).

Solduc Formation

*See* Soleduck Formation.

Solebury Member (of Stockton Formation)

[Upper] Triassic: West-central New Jersey.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 39, 53 (table), 61. Thick-bedded to massive coarse quartz-arkose conglomerate with interbedded arkose, red shale, and sandstone. Thickness 387 feet. May or may not include overlying 671 feet of red sandstone and gray arkose, and underlying 720 feet of arkose, red shale, sandstone, and conglomerate [see Stockton formation]. Older than Prallsville member (new).

In area along Delaware River from Stockton northward to 3 miles west of Milford, Hunterdon County.

†Soledad division[1]

Miocene, upper: Southern California.

Original reference: O. H. Hershey, 1902, Am. Geologist, v. 29, p. 349–372.

Named for exposures in Soledad Canyon, near Saugus, Los Angeles County.

Soledad Group[1]

Oligocene or Miocene, lower: Southern California.

Original reference: D. S. Jordan, 1919, Leland Stanford Jr. Univ. Pub., Univ. ser., Fossil fishes of southern California, p. 3–5.

Well developed about Soledad Pass, in extreme northern part of Los Angeles County, about 40 miles north of Los Angeles.

Soledad Rhyolite[1]

Eocene or Oligocene: Central southern New Mexico.

Original reference: K. C. Dunham, 1935, New Mexico School Mines Bull. 11, p. 53, 56.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 114 (fig. 14). Eocene or Oligocene on correlation chart.

Type locality: In mountains adjacent to Soledad Canyon, Dona Ana County.

**Soledad Volcanic Conglomerate Member** (of Catahoula Tuff)[1]

Oligocene or Miocene, lower: Southwestern Texas.

Original reference: T. L. Bailey, 1926, Texas Univ. Bull. 2645, p. 65, 80–89, 178–179.

H. H. Cooper, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 11, p. 1423. Shown on table of formations in Laredo district as Soledad member of Catahoula tuff. Consists of coarse brownish-gray to greenish sandstone and beds of volcanic ash, containing igneous gravel and cobbles; thickness about 600 feet. Underlies Chusa member; overlies Fant member.

Named for occurrence on Soledad Hills, western Duval County.

Soleduck Formation[1]

Cretaceous and Tertiary: Northwestern Washington.

Original reference: A. B. Reagan, 1909, Kansas Acad. Sci. Trans., v. 22, p. 161.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 17. Name Solduc suggested for non-Tertiary part of original Hoh formation.

C. E. Weaver, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 10, p. 1399. Rocks of interior Olympic Mountains are known only in general way. They consist of more than 10,000 feet of nonfossiliferous arkosic sandstone named Solduc formation. Middle Miocene sandstones of the Astoria resemble lithologically the sandstones of the Solduc of pre-Tertiary age and at one time were mapped with them as single unit—the Hoh formation. Astoria rocks should be differentiated from Solduc sandstones in future mapping.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1060, Geol. Soc. America Bull., v. 71, no. 10, chart 10e (column 55). Soleduck formation shown on Cretaceous correlation chart with note that formation is mostly Tertiary.

First described from occurrences along Soleduck River, Clallam County.

Solitario Formation[1]

Upper Ordovician(?): Southwestern Texas.

Original reference: W. A. J. M. Van der Gracht, 1931, K. Akad. Wetensch. Amsterdam Verb., Afd. Natuurk, Deel 27, No. 3, table Vc, p. 64.

W. B. N. Berry and H. M. Nielsen, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2254–2259. Van der Gracht published table of formations in the Solitario (furnished by Baker) in which name Solitario formation was applied to 15 to 20 feet of bright-green siliceous and argillaceous shale between Maravillas and Caballos formations. Sellards (1932) described a green shale, 25 or 50 feet thick, overlying Maravillas chert in the Solitario. King (1937) mentioned a few feet of dark-green shale between the Maravillas and Caballos in the Rough Creek exposure. Wilson (1954) proposed name Persimmon Gap shale for shale between Caballos and Maravillas formations. Thus, Solitario formation of Baker and Sellards and Persimmon Gap shale of Wilson are same rock unit. Caballos novaculite is herein restricted to the two lower members as described by King (1937), and term Santiago revived and applied to upper three members of King's Caballos novaculite; hence, there is no need for names Persimmon Gap shale and Solitario formation.

In vicinity of Solitario Peak, Brewster-Presidio Counties.

Solitario slate[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 11.

Exposed in Solitario Mountain, northwest of Las Vegas, San Miguel County.

**Solitude Granite**[1]

Upper Cretaceous or lower Tertiary: Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

U.S. Geological Survey currently designates the age of the Solitude Granite as Upper Cretaceous or lower Tertiary on the basis of a study now in progress.

Occurs at head of Solitude Gulch, Globe quadrangle.

Solitude limestone (in Kwaguntan series)

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 113. Massive concretionary bed of limestone, about 25 feet in thickness. Forms prominent projecting ledge amidst shales and soft shaly sandstones associated. Underlies Carbon Butte shales (new); overlies Oveja formation (new).

Well exposed in Chuar Valley sides about opposite Cape Solitude, at mouth of Little Colorado River; Grand Canyon region.

Solomon Formation (in Dakota Group)

Cretaceous (Comanche Series): Northwestern Kansas.

R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]. Dark-gray and black shale and brown sandstone, mostly marine. Thickness 15 to 100 feet. Includes sandstone at top and Hodgeman sandstone below. Unconformable above Ellsworth formation (new); underlies Graneros shale.

R. C. Moore and K. K. Landes, 1937, Geologic map of Kansas (1:500,000): Kansas Geol. Survey. Mapped with Dakota group.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Dakota formation, as herein defined contains stratigraphic units formerly called "Rocktown channel sandstone," "Ellsworth formation," "Solomon formation," "Reeder sandstone," "Marquette sandstone," "Spring Creek clay," and others.

Derivation of name not given. Dakota group is mapped along Solomon River.

Solomon Gypsum (in Sumner Group)[1]

Permian: Central Kansas.

Original reference: G. P. Grimsley, 1899, Kansas Univ. Geol. Survey, v. 5, p. 58–61.

Crops out one-fourth mile south of Dillon mill, 2 miles west of Hope shaft at Solomon gypsum mine, Dickinson County.

**Solomon Schist**[1]

Pre-Ordovician(?): Northwestern Alaska.

Original reference: P. S. Smith, 1910, U.S. Geol. Survey Bull. 433, p. 50–53, maps.

Exposed along Solomon River, Seward Peninsula.

Solomon Creek Member (of Seguin Formation)[1]

Solomon Creek Member (of Wills Point Formation)

Paleocene: Southeastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 575, 576, 577.

M. W. Beckman and F. E. Turner, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 608–621. Redefined and reallocated to member status in Wills Point formation. As originally defined, the Seguin straddles the Midway-Wilcox boundary; a disconformity occurs within the Solomon Creek member which is here restricted to the beds below the disconformity. Where it is possible to recognize the divisions as redefined, the Solomon Creek should be regarded as a member of the Wills Point formation. Where divisions cannot be differentiated, it may be necessary to continue use of Seguin formation, recognizing that it contains the break between the Midway and the Wilcox.

Type locality: Solomon's Creek, 6 miles southwest of Elgin, Bastrop County.

Solomonsville Beds

Solomonsville Beds (in Gila Conglomerate)

Pliocene to Pleistocene: Southeastern Arizona.

W. L. Van Horn, 1958, Arizona Geol. Soc. Digest, p. 45. Sequence of poorly to medium well consolidated sediments. Consist of lacustrine deposits overlain by terrace gravels and alluvium. Upper beds are post-early Kansan in age.

P. A. Wood, 1959, Arizona Geol. Soc. Guidebook 2, p. 60. In Gila conglomerate. Consist of massive conglomerate which intertongues with and grades into sandy to silty beds toward center of valley. Exposed thickness about 300 feet; total thickness, including subsurface deposits, may be about 2,000 feet. Conformably underlie Frye Mesa beds (new); disconformably overlie Bonita beds (new). Range in age from Pliocene to Pleistocene, possibly into Kansan.

In eastern part of Safford Valley, Graham County.

Solon Limestone[1]

Solon Limestone Member (of Cedar Valley Formation)

Upper Devonian: Central eastern Iowa.

Original reference: W. H. Norton, 1897, Iowa Geol. Survey, v. 6, p. 148.

G. A. Cooper, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1751, chart 4. Shown on correlation chart as basal member of Cedar Valley formation. Underlies Rapid limestone member; overlies Wapsipinicon limestone. Middle Devonian. Age of entire Cedar Valley is difficult to establish, and dating of some of its parts presents problems. The Solon (sometimes called Linwood) is linked with the main body of the formation by common presence of crinoid *Sterocrinus*.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 157. Independence shale is stratigraphically below the Cedar Valley and above the Wap sipinicon. The Independence, by its fossils, is lower Upper Devonian;

hence, the Cedar Valley limestone is Upper Devonian in age and post-Independence.

Named for Solon, Johnson County.

Solsberry Formation[1]

Mississippian: Southwestern Indiana.

Original reference: F. C. Greene, 1911, Indiana Acad. Sci. Proc. 1910, p. 275, 281.

Named for Solsberry, Greene County.

Solsville Member[1] (of Marcellus Formation)

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 133, 219.

[G. A. Cooper], 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., [p. 10, 11]. Thickness 45 to 50 feet. Underlies Pecksport member; overlies Bridgewater member.

Type section: Woods Gully, 2 miles northwest of Solsville, Madison County.

Somerset Member (of Pottsville Formation)[1]

Pennsylvanian: Southern Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 311–312.

Named for exposures in vicinity of Somerset, Saline County.

**Somerset Shale Member** (of Warsaw Formation)[1]

Somerset Member (of Salem Limestone)

Upper Mississippian: Southeastern Kentucky.

Original reference: Charles Butts, 1922, Kentucky Geol. Survey, ser. 6, v. 7, p. 89, 104.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 223, 224, 227, pls. 6, 26. Throughout Kentucky belt, Butts (1922) identified three members of the Warsaw (ascending): Wildie sandstone, Somerset shale, and Garrett Mill sandstone. Somerset shale member of Butts has been traced from southern Indiana to type locality at Somerset, Pulaski County, and is interpreted as being a basal argillaceous phase of the Salem limestone at top of Harrodsburg division of Warsaw. The Wildie sandstone of Butts is included in Wildie siltstone member of Muldraugh formation (new); Garrett Mill of Butts is in upper part of Salem.

Named for Somerset, Pulaski County, where it is well exposed in railroad cut a short distance north of the station.

Somerville Granite[1]

Precambrian: Northeastern Virginia.

Original reference: J. T. Lonsdale, 1927, Virginia Geol. Survey Bull. 30.

Typically developed near Somerville, Fauquier County.

†Somerville Limestone[1]

Pennsylvanian: Southwestern Indiana.

Original reference: M. L. Fuller and G. H. Ashley, 1902, U.S. Geol. Survey Geol. Atlas, Folio 84, p. 2.

F. E. Kottlowski, 1954, U.S. Geol. Survey Coal Inv. Map C–11. Replaced by West Franklin limestone.

Named for Somerville, Gibson County.

†Somerville Slate[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: G. R. Mansfield, 1906, Harvard Coll. Mus. Comp. Zoology Bull., v. 49, geol. ser., v. 8, no. 4, p. 196–197.

Occurs at and around Somerville, Middlesex County.

Sonoita Group

Upper Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 297 (table). Named on table. Includes Fort Crittenden formation (new). Older than Duncan group (new); younger than Santa Cruz group (new). Early Tertiary.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 59. Great series of sedimentary strata. Consists of two divisions: the lower, Fort Buchanan formation (new), and the upper, Fort Crittenden formation. Late Cretaceous.

E. D. McKee, 1952, Arizona Geol. Soc. Guide Book, Field Trip Apr. 10–14, p. 2. Beds of conglomerate, hard gray and yellow sandstones, and shales of various colors. Thickness in Santa Rita Mountains 4,000 feet. Type [area] cited.

Type area: Sonoita flats near Patagonia.

Sonoma Tuff[1]

Pliocene: Northern California.

Original reference: V. C. Osmont, 1904, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 39–87.

Probably named for exposures in Sonoma Mountains, Sonoma County.

**Sonoma Volcanics[1]**

Sonoma Group[1]

Pliocene: Northern California.

Original reference: R. E. Dickerson, 1922, California Acad. Sci. Proc., 4th ser., v. 11, no. 19, maps.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 110 (table 24), 118, 122–128, pls. 6, 7, 10. Name Sonoma volcanics used for a complex series of lava flows and tuff beds that in some areas are interbedded with sandstone, gravel, and conglomerate. Lava flows which constitute more than 60 percent of entire sequence are prevailingly andesitic but in many places approach basalt. Includes St. Helena rhyolite member which forms upper part of sequence. Dickerson (1922) used name Sonoma group to include original Sonoma tuff, Mark West andesite, and St. Helena rhyolite. Detailed studies show that entire sequence beneath St. Helena rhyolite member, including the "Mark West andesite," varies greatly from place to place; hence, the sequence is regarded as a single geologic unit. Lavas and tuffs of the Sonoma volcanics, excluding the St. Helena rhyolite member, are exposed over an area of more than 350 square miles. Thickness in Howell Mountains, exclusive of St. Helena rhyolite, about 1,290 feet. Unconformably overlies San Pablo, Petaluma, and older formations; in some areas, interfingers with Merced formation. Volcanics were involved in folding which preceded Pleistocene deposition. Patches of lava exposed west of Tolay Creek near Lakeville School were regarded as outcrops of Tolay volcanics by Morse and Bailey (1935).

They are here mapped as part of Sonoma volcanics. Area of report is the coast ranges north of San Francisco Bay region.

W. K. Gealey, 1951, California Div. Mines Bull. 161, p. 11 (fig. 2), 22–24, pls. 1, 3. Described in Healdsburg quadrangle as Sonoma group. Includes heterogeneous series of lava flows, agglomerates, and tuffs interbedded with nonmarine conglomerate, sandstone, and clay. Maximum thickness 4,000 feet (on east limb of Windsor syncline). Overlies faulted, folded Mesozoic rocks; nonmarine Sonoma sands and gravels grade into Merced formation.

G. T. Cardwell, 1958, U.S. Geol. Survey Water-Supply Paper 1427, p. 27 (table 6), 35–58, pl. 1. Sonoma volcanics described in Santa Rosa and Petaluma Valleys. Exposures are restricted mainly to eastern part of area where they have been intensely folded and faulted to form Sonoma and Mayacmas Mountains. On southwestern flanks of Sonoma Mountains, volcanics are in depositional contact with underlying Petaluma formation. Underlie and interfinger with Merced formation. In vicinity of Petaluma, the volcanics, for most part, directly overlie Franciscan group, although individual flows may be intercalated with Merced formation. Underlie Glen Ellen formation, locally some interbedding occurs. Where not overlain by Glen Ellen, volcanics dip beneath alluvium at valley margins. Thickness 0 to about 2,000 feet. Includes lower part of Sonoma group of Gealey (1950 [1951]). Tolay volcanics of Morse and Baley (1935) are mapped with Sonoma.

Fred Kunkel and J. E. Upson, 1960, U.S. Geol. Survey Water-Supply Paper 1495, p. 15–25. As defined and exposed in Napa and Sonoma Valleys. Sonoma volcanics constitute thick and highly variable series of continental volcanic rocks, including andesite, basalt, and minor rhyolite flows with interbedded coarse- to fine-grained pyroclastic tuff and breccia, redeposited tuff and pumice, and diatomaceous mud, silt, and sand; also a prominent body of rhyolite flows and tuff with some obsidian and perlitic glass. Unconformably overlie Neroly sandstone of Miocene age, and St. Helena rhyolite member underlies with some unconformity the Huichica formation of supposed Pleistocene age.

Named for typical exposures on west flanks of Sonoma Mountains, Sonoma County.

**Sonoma Range Formation**

Ordovician(?): North-central Nevada.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Dark chert, dark siliceous argillite and slate, altered andesitic lava, limestone lenses associated with pillow lava, and a little quartzite. Contains interbedded light-gray chert and quartzite. Thickness more than 3,000 feet. Underlies Valmy formation.

Type locality: West flank of Sonoma Range between Clear Creek and Water Canyon.

Sonora Sandstone[1]

Mississippian: Northwestern Illinois and southeastern and central eastern Iowa.

Original reference: C. R. Keyes, 1895, Iowa Geol. Survey, v. 3, p. 320, 344–350.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 812. Beds referred to Salem limestone at Warsaw, Ill., consist of 4 to 8 feet of more or less crossbedded yellowish limestone that grades laterally into calcareous sandstone, which has been termed Sonora sandstone.

Named for Sonora quarries on Illinois side of Mississippi River opposite Nashville and below Belfast, Lee County, Iowa.

Sonora shale[1]

Pennsylvanian: Missouri.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 252.

Derivation of name not stated.

**Sonsela Sandstone Bed** (in Petrified Forest Member of Chinle Formation)

Upper Triassic: Northeastern Arizona and northwestern New Mexico.

G. A. Kiersch, 1955, Mineral Resources Navajo-Hopi Indian Reservations, Arizona-Utah, v. 2, p. 4 (fig. 1), 5. In eastern exposures of member. Name credited to Harshbarger and others, (in press).

J. P. Akers, M. E. Cooley, and C. A. Repenning, 1958, New Mexico Geol. Soc. Guidebook 9th Field Conf., p. 91 (fig. 3), 93. At type section, comprises two conglomeratic sandstone units separated by a siltstone unit. Lower sandstone is 25-foot ledge-forming unit consisting of very light gray very fine to very coarse grained subrounded to subangular frosted, clear and stained quartz. Upper sandstone forms irregular ledge more than 60 feet high. Threefold division of the Sonsela sandstone bed at its type section is not characteristic of unit in all areas. In most areas, the Sonsela consists of a main sandstone bed and numerous sandstone tongues separated by intervening mudstone units. Thickness 50 to 200 feet depending upon local abundance of sandstone units.

Type section: About 3½ miles north of western Sonsela Butte on east flank of Defiance uplift.

Sonson Limestone

Pleistocene: Mariana Island (Tinian).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 57, table 4 [English translation in library of U.S. Geol. Survey, p. 68]. Correlated with Chatcha [Chacha] limestone on Saipan, Rota limestone on Rota, and Barrigada limestone on Guam. [Appears to be same unit as Asuncion limestone (Tayama, 1939)].

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 57. Consists of hard foraminiferal limestone; dips seaward at angle of 10°. Commonly below Mariana limestone; a forereef detrital facies of Mariana. Name credited to M. Kodaira (unpub. ms.). Data on type locality.

Type locality: Pepeinigl, Puerto (Sonson), Tinian. Also well exposed at Tachinya, Tinian.

**Sonyea[1] Formation**

Upper Devonian: Western New York.

Original reference: G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, no. 2, p. 96, 98.

G. W. Colton and Wallace de Witt, Jr., 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC-54. Formation includes (ascending) Middlesex shale, Pulteney shale (new), Rock Stream siltstone, and Cashaqua shale members. Underlies Rhinestreet shale member of West Falls formation; overlies West River shale. Thickness 183 feet at reference section (herein designated); 45 feet in exposures along Lake Erie and along Eighteenmile Creek in southwestern Erie County; about 484 feet near Watkins Glen in south-central Schuyler County.

Type exposure (Chadwick): Outcrops on Keshequa Creek southwest of Sonyea in Groveland Township, Livingston County. Reference section: Outcrops on Buck Creek in Mount Morris Township 3 miles northwest of Sonyea.

**Sooke Formation**[1]

Oligocene or Miocene or both: British Columbia, Canada, and northwestern Washington.

Original reference: J. C. Merriam, 1896, California Univ. Dept. Geol. Bull., v. 2, p. 105–108.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 104, 115–116. Age given as upper Oligocene.

Probably named for occurrence near Sooke, on south coast of Vancouver Island.

†Sopchoppy Limestone[1]

Miocene, lower: Northwestern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 119–122, 158, 334.

Named for exposures at Sopchoppy, Wakulla County.

Sopris Coal group (in Vermejo Formation)[1]

Upper Cretaceous: Eastern Colorado.

Original reference: R. C. Hills, 1899, U.S. Geol. Survey Geol. Atlas, Folio 58.

Elmoro region.

**Soquel Member** (of Puente Formation)

Miocene, upper: Southern California.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM-154. Consists mainly of massive to moderately well bedded coarse-grained to gritty feldspathic sandstone. Maximum exposed thickness about 2,500 feet. Underlies Yorba member (new) with contact gradational throughout most of Puente Hills; where Yorba member is missing, Sycamore Canyon member rests on Soquel. In Carbon Canyon, the Soquel overlies La Vida member (new), contact gradational; south of Pomona, the Soquel overlaps older rocks and rests directly on the basement complex; south of Santiago Creek, the Soquel is locally unconformable successively on La Vida member, Topanga formation, and Sespe and Vaqueros formations undivided.

Named for the canyon that lies north of Telegraph Canyon and joins Carbon Canyon near the boundary between secs. 10 and 11, T. 3 S., R. 9 W., in southeastern part of Puente Hills. Typical exposures are in Carbon Canyon from Gilman Peak north 1½ miles to vicinity of Carbon Canyon Mineral Springs.

Sorento cyclothem (in Bond Formation)

Sorento cyclothem (in McLeansboro Group)

Pennsylvanian: South-central Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). Name appears in list of cyclothems in McLeansboro group. Occurs above Shoal Creek cyclothem and below Bunje cyclothem (new).

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 6. 7, 11, pl. 1. Simon (1946, unpub. thesis) worked out sequence above Shoal Creek limestone in Bond County and proposed terms (ascending) Sorento Bunje and Flat Creek for cyclothemic units in lower half of interval. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 52 (table 2), pl. 1. In Bond formation (new). Above Shoal Creek cyclothem and below Bunje cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illlinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Edge E½ secs. 6, 7, T. 6 N., R. 4 W., Bond County. Named for village of Sorento, east of type outcrop.

Sorento Limestone Member (of Bond Formation)

Pennsylvanian: Central and southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), 72–74, pls. 1. Name applied to limestone in lower part of formation. Mainly dark-bluish-gray limestone. Thickness as much as 2 feet. Stratigraphically above McWain sandstone member and below Bunje limestone member (new). Name credited to J. A. Simon, unpub. ms. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NE¼ sec. 6, T. 6 N., R. 4 W., Bond County. Named for exposures just west of village of Sorento.

Sosa Hill Basalt

Miocene, lower; Panamá Canal Zone.

S. M. Jones, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 898 (table 2). Listed on correlation chart. Unconformable above La Boca formation, and below Charges alluvium, Charges gravel, and Pacific muck. "Basalt" is used in this paper as field term applied to basic fine-grained igneous rocks including "andesite" and "basalt".

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 346. Poorly defined name. Miraflores basalt has precedence, should a name be necessary.

Occurs near Balboa, in Pacific area of Panamá Canal Zone.

**Soudan Iron-Formation**[1]

Precambrian (Keewatin): Northeastern Minnesota.

Original reference: C. R. Van Hise and J. M. Clements, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 401–409, map.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1027–1029. Lies near top and partly within Ely greenstone; in some areas, is in plunging folds. Dominant rock type is referred to as "jasper" although only part of it falls strictly under this designation; slate and conglomerate also present. Thickness presumed to be several thousand feet. Probably intruded by pre-Knife Lake granite. Keewatin group.

G. M. Schwartz and I. L. Reid, 1955, Mining Eng., v. 7, no. 3, p. 298. Name Soudan formation has been applied to series of beds and lenses of jasper interbedded with original flows and tuffs of Ely greenstone. In Vermilion district, term jaspilite has been used for interbedded jasper and hematite. According to modern usage these jasper or jaspilite beds do not comprise formation separate from Ely. Soudan beds should be considered member of upper part of Ely greenstone.

Named for occurrence on Soudan Hill, Vermilion district.

Sougahatchee Granite[1]

Age(?): Central eastern Alabama.

Original reference: G. I. Adams, 1933, Jour. Geology, v. 41, p. 168–169.

Named from creek near which it is exposed at many places in southwest border of Dadeville belt, Tallapoosa County.

Sour Dough Limestone[1] (in Telescope Group)

Sour Dough Limestone Member (of Kingston Peak Formation)

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 311, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July-October 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Dept. Geol. Sci., v. 30, no. 5, p. 360, 365, figs. 1, 3. Redefined as middle member of Kingston Peak formation. Consists of alternating bands of dark- and medium-gray limestone with well-defined bedding planes that are laterally persistent and spaced at 3 to 30 millimeters. Thickness as much as 170 feet. Underlies South Park member (new); overlies Surprise member. Area of report Manly Peak quadrangle.

Named on basis of exposures in Sour Dough Canyon, near Panamint City, southern part of Panamint Range, Inyo County.

Sourdough Mountain Breccias

*See* Keechelus Andesitic Series.

**Souris River Formation**

Upper Devonian: Subsurface in North Dakota, and Saskatchewan and Manitoba, Canada.

W. M. Laird, 1953, Interstate Oil Compart Quart. Bull., v. 12, no. 2, p. 74. New term for part of Devonian known only in subsurface. Overlies Dawson Bay formation; underlies Duperow formation.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2299 (fig. 2), 2309 (fig. 5), 2310–2313. Souris River was named at February 1953 meeting of Williston Basin Nomenclature Committee of American Association of Petroleum Geologists. Type section designated as California Co.'s Thompson Well 1, Bottineau County, N. Dak. Report of Committee was not published; hence Souris River has not been formally proposed or adequately defined. Standard subsurface section is here proposed. Formation lies between depths of 10,743 and 11,052 feet in standard section. Consists of thin interbedded gray, greenish-gray, and brownish-gray argillaceous dolomite, argillaceous limestone, shale, siltstone, and anhydrite. Upper Devonian.

Standard section: Mobil Producing Co.'s Birdbear Well 1, center SE¼NW¼ sec. 22, T. 149 N., R. 91 W., Dunn County, N. Dak.

South Amboy fire clay[1] (in Raritan Formation)

Cretaceous: Northeastern New Jersey.

Original references: G. H. Cook and J. C. Smock, 1877, Map of clay district of Middlesex County: New Jersey Geol. Survey; G. H. Cook, 1878, New Jersey Geol. Survey Rept., on clays, p. 34.

H. C. Barksdale and others, 1943, The ground-water supplies of Middlesex County, New Jersey: New Jersey State Water Policy Comm. [Spec. Rept. 8], p. 66, 101. Thickness as much as 25 feet along outcrop. Overlies Sayreville sand member (new); underlies Old Bridge sand member (new).

Middlesex County.

**South Bend Limestone Member** (of Stanton Limestone)[1]

Pennsylvanian (Missouri Series): Southeastern Nebraska, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 7, 23.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 51. South Bend limestone was named in Nebraska but was named Little Kaw limestone by Newell (1935) from Kaw Valley area, Kansas. On basis of subsequent studies, it is now agreed that original name is valid.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 119. South Bend limestone member of Stanton formation; overlies Rock Lake shale member; underlies Weston shale of Pedee group. This classification was agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32. Thickness 8 to 12 feet in Platte and Weeping Water Valleys; 4 to 5 feet in northwestern Missouri; 4 to 6 feet in Kansas. Top of this subdivision in Nebraska exposures is at the post-Missourian contact and shows evidence of shoreline deposition. Type locality stated.

Type locality: In Platte River bluffs 1½ miles northwest of South Bend, Cass County, Nebr.

South Bend Sandstone and Shale (in Graham Formation)[1]

Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31, 37; 1922, Texas Univ. Bull. 2132, p. 127–136.

Typically exposed at South Bend, Young County.

South Bosque Marl[1]

Upper Cretaceous: Central Texas.

Original reference: J. K. Prather, 1902, Texas Acad. Sci. Trans., v. 4, pt. 2, no. 8.

W. S. Adkins and F. E. Lozo *in* F. E. Lozo, 1951, Fondren Sci. Series, no. 4, p. 120–123, fig. 25. Revived and emended to exclude basal 20 feet of original section. So emended, formation consists of upper predominantly clay part and a lower part of platy salmon-colored thin-bedded limestones alternating with "bentonitic" shales. Thickness about 120 feet. Underlies Austin chalk; overlies Bouldin member (new) of Lake Waco formation (new); basal contact characterized by change from platy limestones and "bentonitic" shales to more blocky grayish silty limestones interbedded with dark shales and bentonitic seams.

Type area and section: Bosque escarpment, from Waco westward to South Bosque; typical and well-exposed section is in Universal Atlas Cement Co. shale pit and along Cloice Branch, 1 mile east of South Bosque, McLennan County.

South Boss Marl (in Eagle Ford Group)

Probably lapsus for South Bosque Marl.

South Britain Conglomerate[1]

Upper Triassic: Western Connecticut.

Original reference: W. H. Hobbs, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 40–43, 49–51, 63–64.

Occurs in village of South Britain, New Haven County.

**South Butler Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survery Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for its occurrence south of Butler amygdaloid, in Ontonagon County.

**South Butler Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for its occurrence south of Butler amygdaloid, in Ontonagon County.

**South Canyon Creek Member** (of Maroon Formation)

South Canyon Creek Member (of State Bridge Formation)

Permian: Northwestern Colorado.

N. W. Bass and S. A. Northrop, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 7, p. 1540–1551. Proposed as South Canyon Creek dolomite member. Commonly consists of basal unit of medium-gray very fine-grained dolomite; middle unit of light-gray to light-buff dense dolomite; top unit, 1 foot thick or less, of thinly laminated fossiliferous limestone. Thickness 1½ to 6⅓ feet. Dolomite is 480 feet stratigraphically below base of Entrada sandstone on South Canyon Creek and 380 feet below base of Entrada on Main Elk Creek. Brill (1944, Geol. Soc. America Bull., v. 55, no. 5) assigned limestone here called South Canyon Creek dolomite member to Triassic Dinwoody or Moenkopi formation. Fauna appears to be Permian of Phosphoria age.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 823–825. Since Maroon formation is here limited to beds that underlie Schoolhouse tongue of Weber sandstone, south Canyon [Creek] dolomite seems to be member of State Bridge formation.

Named for exposures in South Canyon Creek, which is 4½ miles west of Glenwood Springs. Crops out northwestward for 22 miles.

South Carrollton Limestone[1]

Pennsylvanian: Western Kentucky.

Original reference: C. J. Norwood, 1878, Kentucky Geol. Survey, 2d ser., v. 4, pt. 7, p. 296–301, 319.

Exposed in bluff one-half mile northwest of South Carrollton, Muhlenberg County.

Southern Belle Quartzite[1]

Middle Cambrian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1933, Geol. America Bull., v. 47, no. 4, p. 476–477, 482.

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 110. Overlies Santa Catalina formation; underlies Abrigo formation. Thickness 30 feet.

In Peppersauce Canyon, Santa Catalina Mountains.

South Flat Formation

Upper Cretaceous (Montanan): Central Utah.

R. E. Hunt, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 1, p. 118–128. Sequence of piedmont and flood-plain sediments. Divided into three members, each having differing distributions. Lower member of sandstones, conglomerates, a single limestone, and a discontinuous coal, is 840 feet thick. Sandstones medium-grained to gritty and dominantly gray, tan, and brown. Commonly speckled by white. Conglomerates are gray and brown, containing stones as much as 5 inches in diameter. Middle member of massive red and gray conglomerate and minor sandstones is 600 feet thick. Upper member is coal-bearing sequence of varicolored sandstones, shales, and clays 1,360 feet thick. Dominantly sandstones in middle part of which is 60 feet interval of shales, clays, and coals. Total thickness at type section 2,854 feet. Underlies Price River formation; overlies Indianola group.

Type section: Measured from SW¼ sec. 17, T. 14 S., R. 2 E., in Fourmile Canyon, northeast to South Flat (SW¼ sec. 9), then south to approximately center of sec. 21. Recognized only in northern part of Gunnison Plateau.

South Fork Limestone[1]

South Fork Limestone Member (of Burlingame Formation)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, and northeastern Kansas.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 5, 10.

E. H. Wenberg, 1942, Iowa Acad. Sci. Trans., v. 49, p. 343 (fig. 6). Listed as South Fork limestone in insoluble residue correlations of Missouri and Virgil strata in Iowa.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 45–46. In Nebraska, Burlingame limestone includes (ascending) Taylor Branch limestone, Winnebago shale, and South Fork limestone members.

Well exposed in hill on west side of South Fork Valley three-fourths mile southwest of DuBois, Pawnee County, Nebr.

South Fork Mountain schist

Upper Jurassic: Northwestern California.

W. P. Irwin, 1960, California Div. Mines Bull. 179, p. 28–30. Name applied in California to schists that have been referred to as southwestern belt of schists and South Fork Mountain belt of schists by Diller (1903, Am. Jour. Sci., 4th, v. 15), Weitchpec schist by Hershey (1904; 1906, Am. Jour. Sci., 4th, v. 21), and Kerr Ranch schist by Manning and Ogle (1950). In southwestern Oregon, seemingly related rocks were named Colebrooke schist by Diller (1903). Age and formational affiliation of South Fork Mountain schist is not entirely clear, but generally the schist has been considered pre-Devonian, or perhaps Precambrian, and genetically unrelated to adjacent formations. South Fork Mountain schist has most commonly been correlated with Abrams formation of central metamorphic belt of Klamath Mountains arc. However, more than one adjacent formation is at least in part a lithologically suitable prototype for the schist, and one of these, the Galice, appears to grade into the schist near Weitchpec. The schist may represent narrow zone of dynamic metamorphism, and although the metamorphism may have transgressed formational boundaries, most if not all of the schist is likely a metamorphic equivalent of the slaty and phyllitic rocks herein correlated with Galice formation of middle Late Jurassic age. On west slope of South Fork Mountains and northward to near Weitchpec, the schist is in contact with nonmetamorphic rocks of Franciscan formation. Rocks of late Late Jurassic and Cretaceous age are not known to be in depositional contact with South Fork Mountain schist in California. In southwestern Oregon, the younger Mesozoic rocks are in depositional contact with Colebrooke schist, and the Colebrooke is considered correlative with South Fork Mountain schist.

Underlies a continuous even-crested ridge that marks the southern and most of the western boundary of Klamath Mountains provinces. Southwestern boundary of province is South Fork Mountains which trend N. 30° W. for about 50 miles along west side of South Fork by Trinity River.

Southgate Formation (in Eden Group)

Southgate Member (of Eden Formation)

Southgate Member (of Latonia Shale)[1]

Upper Ordovician: North-central Kentucky, southeastern Indiana, and southwestern Ohio.

Original reference: R. S. Bassler, 1906, U.S. Natl. Mus. Proc., v. 30, p. 9.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. Shown on correlation chart as middle formation of Eden group in Indiana. Underlies McMicken formation; overlies Economy formation. Consists of shale 70 to 120 feet thick.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030–1031. Middle member of Eden formation. Overlies Economy member; underlies McMicken member.

Named for Southgate, Campbell County, Ky.

South Hampton Granite[1]

Age(?): Southeastern New Hampshire.

Original reference: E. Hitchcock, 1823, Am. Jour. Sci., 1st, v. 6, p. 3–6.

At South Hampton, Rockingham County.

South Mapleton Andesite[1]

Paleozoic: Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 113, 169, 173.

Crops out in fields in southern part of Mapleton Township to north and south of Mapleton-Presque Isle Road, Aroostook County.

South Moat Flows[1]

Devonian(?): Northern New Hampshire.

Original reference: M. Billings, 1928, Am. Acad. Arts and Sci. Proc., v. 63, no. 3, p. 72, 92, map.

Typically exposed on South Moat Mountain, North Conway quadrangle, White Mountains.

South Mountain Andesite Flows

Oligocene: Northern Utah.

R. E. Marsell and R. L. Threet, 1960, Geologic map of Salt Lake County, Utah (1:62,500); supp, to Bull. 69 [not yet published]: Utah Geol. and Mineralog. Survey. Named of map legend. Occurs above Rose Canyon latite-andesite volcanics (new) and below Salt Lake group.

Mapped in southern part of Salt Lake County. Largest area mapped surrounds South Mountain.

South Mountain Quartzite[1]

Lower Cambrian: Western Maryland and Pennsylvania.

Original references: C. D. Walcott, 1894, Am. Jour. Sci., 3d, v. 47, p. 37–41; 1896, U.S. Geol. Survey Bull. 134, p. 33.

South Mountain.

South Mountain Slates[1]

Cambrian: Southern Pennsylvania.

Original reference: F. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. $H_2$, p. xxiv.

South Park Member (of Kingston Peak Formation)

Precambrian: Southeastern California.

B. K. Johnson, 1957, California Univ. Dept. Geol. Sci., v. 30, no. 5, p. 360, 365–367, figs. 1, 3. Defined as youngest member of formation. Consists of well-bedded platy quartz-rich sandstones, argillaceous rocks, massive quartzite, cobble conglomerate, and conglomeratic and nonconglomeratic massive subgraywacke. Thickens northward; 285 feet at mouth of Goler Wash; 1,000 feet in South Park Canyon. Overlies Sour Dough member. It is correlative of Middle Park formation, Mountain Girl conglomerate-quartzite, and Wildrose formation of Telescope group as defined by Murphy (1930).

Named for fact it is well exposed near South Park basin in northern part of Manly Peak quadrangle, in southern part of Panamint Range, just west of Death Valley, Inyo County.

†South Pass Group[1]

Pliocene: Northwestern Wyoming.

Original reference: T. B. Comstock, 1874, Rept. of reconn. of northwestern Wyoming, made in 1873 by W. A. Jones, table opposite p. 103.

**South Pewabic Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 52, 76, 77, chart.

Named for occurrence in old South Pewabic mine, Houghton County.

**South Pewabic Flow**[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for occurrence in old South Pewabic mine, Houghton County.

**South Platte Formation** (in Dakota Group)

Lower Cretaceous: North-central Colorado.

K. M. Waagé, 1955, U.S. Geol. Survey Prof. Paper 274–B, p. 27–34, figs. 10, 17, 19. Upper part of pre-Benton Cretaceous sequence, lying between Lytle formation and Benton shale, is here treated as single unit in northern Front Range foothills and named South Platte formation. It is equivalent to the upper sandstone, upper shale, middle sandstone, and uppermost black shale part of lower shale of Lee's (1927) Dakota group. Formation grades laterally northward from dominantly nonmarine clastic phase in Kassler quadrangle to dominantly marine shale phase in Larimer County. Consists of 200 to 350 feet of alternating units of gray to black shale and brown-weathering sandstone. Sandstone chiefly fine grained, but coarser fractions common locally in nonmarine phase. Individual sandstone units have considerable lateral extent and vary laterally in thickness, nature of bedding, and amount of contained argillaceous matter. Shale units in nonmarine phase consist of hard laminated noncalcareous silty shale that is commonly interlaminated or thinly interbedded with siltstone and fine-grained sandstone. Thin beds of white, yellow, or light-gray claystone common in the shale. Comprises (ascending) Plainview sandstone member (new), third shale, third sandstone, second shale, Kassler sandstone member (new), Van Bibber shale member (new), and first sandstone. Underlies Benton shale and overlies Lytle formation with disconformable contacts. No single exposure typical for unit over its entire area of outcrop. Three localities are designated for standards of reference.

Type exposures: In south end of hogback on north side of gap made by South Platte River, about 0.5 mile north of Kassler in NE¼NW¼SE¼ sec. 27, T. 6 S., R. 69 W., Jefferson County. This is also standard reference section for southern nonmarine phase. Standard reference section for intermediate phase is on west-facing scarp of a local prominence just south of Little Thompson Creek in SW¼NW¼ sec. 2, T. 3 N., R. 70 W. Standard for northern marine phase is located 0.25 to 0.5 mile north of Boxelder Creek in W½NE¼ sec. 9, T. 10 N., R. 69 W., Larimer County. This is about same locality described by Lee (1927) about 2 miles east of Greenacre Ranch along Boxelder Creek. Named for South Platte River. Entire outcrop area of formation in northern foothills lies within drainage basin of South Platte River.

South Prairie Formation[1]

Eocene: Western Washington.

Original reference: B. Willis, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 424–430.

Exposed on South Prairie Creek, Puget Sound region.

South Range Member (of Virginia Formation)

Precambrian: Northeastern Minnesota.

F. F. Grout and J. F. Wolff, 1955, Minnesota Geol. Survey Bull. 36, p. 3, 4, 7, 56, pl. 6. Virginia formation comprises (ascending) lower states, South Range iron-bearing member, and upper slates.

Named for occurrence in South Range, Cuyuna district.

South Ridge Sandstone

Permian (Wolfcampian): East-central Nevada.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 93 (chart), 102. Name applied to thick sequence of fine- to medium-grained thin- to thick-bedded tan to yellowish-tan weathering calcareous cemented quartz sandstone with thin interbedded grayish-tan silty limestone. Stratigraphically above Ely limestone (restricted) and below Riepe Spring limestone (new).

Type section: SE¼ sec. 25, T. 17 N., R. 61 E., White Pine County. Named for South Ridge bench mark, NE¼SE¼ sec. 27, T. 17 N., R. 61 E., 2 miles due west of type section.

South Ross Clay (in Golden Valley Formation)

Eocene: Western North Dakota.

Great Northern Railway Co. Mineral Research and Development Department, 1958, Great Northern Railway Co. Mineral Research and Devel. Dept. Rept. 5, p. 2, 3, 12, 14, 15, map. A bed of white clay about 15 feet thick in Golden Valley formation. White Earth, Lakeside, and East Tioga clays occur in same general area.

Occurs in Little Knife River valley, south of town of Ross, Mountrail County.

South Tunnel Bed[1]

Silurian (Niagaran): Western Tennessee.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 397, 402.

Named for South Tunnel, Sumner County.

South Tyler Formation

Cretaceous (Comanche Series): Northeastern Texas (subsurface).

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 475, 476, 477. Term applied to sand and mottled red and gray shale sequence between base of Dexter sand and top of Buda limestone. Includes Maness shale at base. In discovery well, occurs between depths of 5,675 to 6,065 feet.

Named after south Tyler field in Smith County, where formation is typically developed in wells. Discovery well, Phillips Petroleum No. 1 Mrs. W. T. McMinn well in the M. M. Long Survey.

South Valley Limestone[1]

Triassic: Pennsylvania.

Original reference: J. P. Lesley, 1885, Pennsylvania Geol. Survey Rept. X, map.

†South Valley Hill Slates and Mica Schists[1]

Precambrian (Glenarm Series): Southeastern Pennsylvania.

Original reference: C. E. Hall, 1881, Pennsylvania 2d Geol. Survey Rept. $C_6$, p. 31.

Form prominent ridge on South Valley Hill.

**South Wales Member** (of Perrysburg Formation)

South Wales Shale (in Canadaway Group)

Upper Devonian: Western and west-central New York.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Composed of gray silty shale, gray silty mudstone, small amounts of black, brown, and very dark gray shale, and some thin-bedded gray siltstone. Thickness 64 feet near South Wales; thins to minimum of about 20 feet near Dalton in Nunda quadrangle; thickens to about 87 feet near Cameron. At some places, top of member is sharply marked where uppermost siltstone is overlain by black shale of Gowanda member; at other places, contact between the two is gradational; east of Genesee River Valley, member is overlain by Canaseraga sandstone member, into basal part of which upper beds of South Wales grade laterally in places. In area between Lake Erie and Genesee River valley, member is overlain by interbedded black, brown, and very dark-gray shales.

L. V. Rickard, 1957, New York Geol. Soc. Guidebook 29th Ann. Mtg., p. 15, 18. In Wellsville area, term Perrysburg formation is not applied. South Wales shale is considered formation in Canadaway group. Thickness about 20 feet.

Named for exposures on unnamed tributary of east branch of Cazenovia Creek, 3 miles south of South Wales, Erie County. Traced from shore of Lake Erie west of Van Buren Point eastward to vicinity of Cameron in Woodhull quadrangle.

†Southward Bridge Formation (in Chester Group)[1]

Mississippian: Northeastern Mississippi and northwestern Alabama.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Name abandoned. Strata included in Sandfall member and Mynot sandstone member of Pride Mountain formation (all new).

Type locality: Southward Bridge, near old village of Mingo, at confluence of Bear Creek and Cedar Creek valleys, Tishomingo County, Miss.

†Southward Pond Formation (in Chester Group)[1]

Mississippian: Northeastern Mississippi and northwestern Alabama.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Replaced by Wagnon member of Pride Mountain formation (both new).

Named for exposures in bluffs of Southward (or Cypress) Pond, at Southward homestead, Tishomingo County, Miss.

**Southward Spring Sandstone Member** (of Pride Mountain Formation)

Southward Spring Sandstone (in Chester Group)[1]

Upper Mississippian: Northeastern Mississippi and northwestern Alabama.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Rank reduced to member status in Pride Mountain formation (new). Overlies Wagnon member (new); underlies Sandfall member (new).

Named for exposures at Southward Spring, about 3 miles east of Tishomingo, Miss., in SE¼ sec. 18, T. 5 S., R. 11 E.

**South Wells Limestone Member** (of Cherry Canyon Formation)

Permian (Guadalupe Series): Western Texas.

P. B. King *in* A. K. Miller and W. M. Furnish, 1940, Geol. Soc. America Spec. Paper 26, p. 9. Incidental mention.

P. B. King *in* F. E. Lewis, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 92. Cherry Canyon formation is subdivided into (ascending) Getaway, South Wells, and Manzanita limestone members.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 580, 585 (fig. 7), pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 36, pl. 3 [1949]. At type locality, consists of several thin black or gray fossiliferous limestone beds in an interval of 75 feet; farther northwest, near base of Reef Escarpment, these change into buff or drab, sandy, dolomitic limestones; locally member grades laterally into sandstones. Lies above Getaway member, or about 600 feet above base of formation; lies about 100 feet below Manzanita member.

Type locality: On both sides of valley near the South Wells of D Ranch, 11 miles southeast of Guadalupe Peak, Culberson County.

**Sowik Limestone**[1]

Ordovician(?): Northwestern Alaska.

Original reference: P. S. Smith, 1910, U.S. Geol. Survey Bull. 433, p. 50, 54.

Occurs near and named for Sowik, Seward Peninsula.

Spadra Felsophyre (in Glendora Volcanics)

Miocene, middle or older: Southern California.

J. S. Shelton, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 55–56, pl. 1. Referred to as Spadra felsophyre member of Glendora volcanics. Autobreccias constitute at least 80 percent, and laminated flows about 20 percent of the member. Local lenses of limestone up to about 40 feet thick occur along basal contact where felsophyre rests on basement complex. Maximum thickness about 350 feet.

Occurs in isolated area east of Spadra and 2 miles southwest of Pomona, Los Angeles County.

†Spadra Shale[1]

Pennsylvanian: Western Arkansas.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Named for Spadra, Johnson County.

Spafford Member[1] (of Ludlowville Formation)

Middle Devonian: Central New York.

Original reference: Burnett Smith, 1935, New York State Mus. Bull. 300, p. 11, 50.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Spafford member shown on correlation chart above Ivy Point member and below Owasco member.

Type section: In first ravine north of Ivy (or Willow) Point on east side of Skaneateles Lake, about three-fourths mile north and slightly west of Spafford Landing, Skaneateles quadrangle.

**Spaniard Limestone Member** (of Savanna Sandstone)[1]

Pennsylvanian (Des Moines Series): East-central Oklahoma.

Original reference: S. W. Lowman, 1933, Tulsa Geol. Soc. Digest, p. 31.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 51–52, pl. 3. Basal member of Savanna. Underlies Sam Creek limestone member; overlies Keota sandstone herein reallocated to member status in McAlester formation.

Named for exposure in Spaniard Creek, south of Muskogee, about center of N½ sec. 11, T. 13 N., R. 18 E., Muskogee County.

†Spanish Formation[1]

Mississippian: Northern California.

Original reference: J. S. Diller, 1892, U.S. Geol. Survey Geol. Atlas, Folio 15, prelim. proofsheet ed.

Named for fact it surrounds northern end of Spanish Peak, Lassen Peak region.

**Spanish Canyon Formation**

Miocene: Southern California.

F. M. Byers, Jr., 1960, U.S. Geol. Survey Bull. 1089–A, p. 22–26, pls. 1, 2. Sandstone, conglomerate, tuff, and basalt flows. About 300 feet thick at type locality but wedges out southwestward within half mile. North of type locality, westward dipping beds of formation extend along west side of Spanish Canyon and Cross Canyon near east boundary of sec. 19, where formation swings eastward around nose of Spanish Canyon anticline; on east side of Spanish Canyon anticline, a fault of large displacement cuts off southern extension of formation. Overlies Alvord Peak basalt (new) and where Alvord Peak is missing rests on Clews on fanglomerate (new). Conformably underlies Barstow formation. Tentatively inferred that Spanish Canyon is of middle Miocene age.

Type locality: Near center sec. 30, west of Spanish Canyon, Alvord Mountain quadrangle, San Bernardino County.

Spanish Valley Stage

Recent: Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain sec. [Guidebook] 2d Ann. Field Trip, Oct. 4–5, correlation chart. In proposed time-stratigraphic standard for Rocky Mountains, Recent epoch includes (ascending) Castle Valley, Temple Lake, Spanish Valley, and Gannett Peak stages.

Twin Lakes area.

**Spann Limestone Member** (of Pennington Shale)[1]

Upper Mississippian: Southern Kentucky.

Original reference: M. J. Munn, 1914, U.S. Geol. Survey Bull. 579, p. 33.

Named for Spann, Wayne County.

**Sparks Schist**

Precambrian: Central western Georgia.

D. F. Hewett and G. W. Crickmay, 1937, U.S. Geol. Survey Water-Supply Paper 819, p. 27, pl. 1. Includes several varieties of mica schist, biotite gneiss, and quartzite which are so interlayered as not to be separable in areal mapping. Underies Hollis quartzite. Considered oldest rocks in area south of Towaliga fault.

Well exposed along Sparks Creek which flows southward near western border of Warm Springs quadrangle. Confined to belt 3 to 5 miles wide that extends across quadrangle between Pine and Oak Mountains.

Sparksville facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 172–178.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. Sparksville facies shown in Carwood formation.

Name derived from village of Sparksville, near White River, in SW cor. NE¼SE¼ sec. 13, T. 4 N., R. 2 E., Jackson County.

Sparland cyclothem (in Carbondale-Modesto Formations)

Sparland cyclothem[1] (in McLeansboro Group)

Pennsylvanian: Western, northern, and southeastern Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 182, 192.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. Type locality given. Shown on chart as overlying Jamestown cyclothem.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 60, 114–116, 189, 190, pl. 5. Thickness 8 to 80 feet. Includes (ascending) Copperas Creek sandstone, Sparland (No. 7) coal, and Farmington shale. Underlies Gimlet cyclothem; overlies Pokeberry cyclothem (new); believed to be equivalent to Jamestown cyclothem. Derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), 56 (table 3), pl. 1. In Carbondale-Modesto (new) formations. Above Jamestown cyclothem and below Gimlet cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: Sec. 2, T. 12 N., R. 9 E., Marshall County. Named for exposures of Thenius Creek, about 1½ miles north of Sparland.

Spar Mountain Sandstone (in Fredonia Member of Ste. Genevieve Formation)

Mississippian: Southern Illinois.

F. E. Tippie, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 11, p. 1657 (figs. 2, 3), 1658. Name applied to middle sandstone member of the Fredonia; this unit has been known as a "sub-Rosiclare sandstone." Typically light-gray to greenish calcareous glauconitic sandstone or siltstone grading to very sandy limestone. Thickness 8 to 15 feet.

Named for exposures on south slope of Spar Mountain in secs. 3 and 4. T. 12 S., R. 9 E., Hardin County, about 4 miles northwest of Cave in Rock.

**Sparta Sand**[1]
Sparta Formation } (in Claiborne Group)

Eocene, middle: Northwestern Louisiana, Mississippi, and northeastern Texas.

Original references: W. C. Spooner, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, no. 1, p. 7; no. 3, p. 220, 224, 227, 237.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 59, 114–120 [1938]. Sparta formation (sand), in Leon County, consists of well-bedded loose sands which are rich in dark grains of chert like most of other Eocene sediments of region. Individual sand beds are separated by thin layers of finer material, shale or silt. Thickness probably varies from 210 to 330 feet. Overlies Weches formation; underlies Stone City formation.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Sparta sand mapped in central Mississippi.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart shows Sparta sand in Mississippi. Overlies Zilpha clay; underlies Archusa marl member of Cook Mountain formation. Mississippi Geological Survey uses term Kosciusko sand instead of Sparta sand and Wautubbee formation instead of Cook Mountain formation.

Named for development near Sparta, Bienville Parish, La.

†Sparta Sands[1]

Tertiary: Northern Louisiana.

Original reference: T. W. Vaughan, 1895, Am. Geologist, v. 15, p. 225.

Named for development near Sparta, Bienville Parish.

Sparta Shale[1]

Upper Cambrian: Southwestern Wisconsin.

Original reference: W. D. Shipton, 1916, Iowa Acad. Sci. Proc., v. 23, p. 142–145.

In Sparta quadrangle, Monroe County.

**Spaulding Quartz Diorite** (in New Hampshire Plutonic Series)

Upper Devonian(?): Southwestern New Hampshire.

Katharine Fowler-Billings, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1250, 1266–1268, pl. 1. Dark-gray medium-grained granodiorite and quartz diorite. Black to brown on weathered surfaces. Larger bodies are massive, smaller ones are foliated. Has distinctive spotted appearance. Younger than Kinsman quartz monzonite; older than Concord granite. Belongs to New Hampshire magma series.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Included in New Hampshire plutonic series.

Type locality: Spaulding Hill in Dublin Township, Cheshire County. Crops out in central part of Monadnock area.

Spavinaw Granite[1]

Precambrian: Northeastern Oklahoma.

Original reference: N. F. Drake, 1897, Am. Phil. Soc. Proc., v. 36, p. 338–341.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 15–18. Base of granite unknown; unconformably overlain by Cotter dolomite. Precambrian.

Named for exposures along Spavinaw Creek, Mayes County.

**Spearfish Formation**[1]

Permian and Triassic: Western South Dakota, northwestern Nebraska, and eastern Wyoming.

Original references: N. H. Darton, 1899, Geol. Soc. America Bull., v. 10, p. 387; 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 4, p. 516.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2, 6; 1950, Nebraska Geol. Survey Bull. 13–A, p. 9. Redefined to apply to section between Phosphoria group and the Sundance, or at places, the section from the Phosphoria to base of Jelm formation; in places where Dinwoody is present, to the interval between the Dinwoody and the Sundance.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 235, 237–240. Underlies Gypsum Spring formation, geographically extended into Black Hills area. Contact sharp, apparently unconformable. Gypsiferous facies of Gypsum Spring was included by Darton in top of the Spearfish, but it contains marine Jurassic fossils, interfingers laterally with dolomite and limestone that contains marine fossils. In Fall River County, underlies Nugget(?) sandstone.

W. J. Mapel and M. H. Bergendahl, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 1, p. 88, 90–93. In Black Hills, the Gypsum Spring rests with sharp undulating contact on sequence several hundred feet thick of red claystone, siltstone, and sandstone assigned to Spearfish formation. Thick deposits of primary gypsum occur in lower part of Spearfish. Measured sections give thickness 30 to 50 feet. Triassic.

N. C. Privrasky and others, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 48–55. In Powder River basin, the Spearfish is restricted to include only those sediments lying below Sundance formation and above Goose Egg formation. Subsurface data.

S. S. Oriel, 1959, *in* E. D. McKee and others, U.S. Geol. Survey Misc. Geol. Inv. Map I–300, p. 3. In present report [Paleotectonic map of Triassic], all beds between Minnekahta limestone and base of Gypsum Spring formation as used by Mapel and Bergendahl (1956) are included in Spearfish. As thus defined, formation includes rocks of both Permian and Triassic age.

Named for Spearfish, Lawrence County, S. Dak.

**Spearhead Rhyolite**[1]

Pliocene: Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 71.

U.S. Geological Survey currently designates the age of the Spearhead Rhyolite as Pliocene on the basis of a study now in progress.

Occurs at and around Spearhead Point, Goldfield district.

Spears Member (of Datil Formation)

Miocene, upper(?): Southwestern New Mexico.

W. H. Tonking, 1954, Dissert. Abs., v. 14, no. 2, p. 340. Quartz latite tuff, agglomerate, breccia, and volcanic sandstone and conglomerate. Underlies Hells Mesa member (new).

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 26, 27–29, fig. 2, pl. 1 [preprint? 1954]. At Hells Mesa, lower 1,000 feet consist of monotonous sequence of medium-gray to grayish-purple fine- to thick-bedded tuffaceous sandstones, conglomerates, flow breccias, and agglomerates, with intercalated thin beds of silt and clay; overlain by local 18-foot bed of white vitric rhyolite tuff; overlain by 300 feet of reddish-brown volcanic conglomerates and sandstones. Disconformably overlies Baca formation. Type section designated.

D. B. Givens, 1957, New Mexico Bur. Mines Mineral Resources Bull. 58, p. 14–15, pl. 1. Referred to as Spears Ranch member of Datil in Dog Springs quadrangle. Underlies Hells Mesa member.

Type section: Measured approximately 1 mile south of Spears Ranch headquarters, where complete section is exposed. Named for Guy Spears Ranch in sec. 8, T. 1 N., R. 4 W., Puertecito quadrangle, Socorro County.

Spears Ranch Member (of Datil Formation)

*See* Spears Member (of Datil Formation).

**Spechts Ferry Shale Member**[1] (of Decorah Formation)

Spechts Ferry Formation (in Galena Group)

Middle Ordovician: Northeastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

Original reference: G. M. Kay, 1928, Science, new ser., v. 67, p. 16.

A. F. Agnew and A. V. Heyl, Jr., 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 9, p. 1585–1587. Overlies Quimbys Mill member (new) of Platteville formation. Limestone unit included in Quimbys Mill has sometimes been referred to as lithologic facies of the Spechts Ferry.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2045 (fig. 3), 2064, 2065. Spechts Ferry shale member of Decorah geographically extended into St. Louis County, Mo., where it overlies Macy formation (new) of Plattin group.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, fig. 3. Considered basal formation in Galena group in Dixon-Oregon area, Illinois.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 263 (fig. 36), 268 (fig. 38), 286–289. Spechts Ferry shale member consists of green fossiliferous shale, greenish-buff fine-grained limestone, phosphatic nodules near top; bentonite near base. Thickness at type locality about 8 feet; thins to east, 3 feet at Shullsburg, Wis. Underlies Guttenberg member; near Decorah, Iowa, basal green shale of Spechts Ferry thickens at expense of Guttenberg limestone.

Type locality: Ravine southwest of Chicago, Milwaukee, and St. Paul Railroad station at Spechts Ferry, Dubuque County, Iowa.

Specimen Mountain Volcanics

Age not stated: Colorado.

E. E. Wahlstrom, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1951. Incidental mention.

No type locality designated and derivation of name not stated.

†Speck Mountain Clay (in Thrifty Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann Rept., pt. 1, p. 387, 407.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315-D, p. 71. In Brown and Coleman Counties, Ivan limestone member of Graham formation is separated from overlying Speck Mountain limestone member of Thrifty formation by shale unit called Speck Mountain clay bed by Drake (1893).

Named for Speck Mountain, Coleman County.

**Speck Mountain Limestone Member** (of Thrifty Formation)[1]

Speck Mountain Formation (in Thrifty Group)

Upper Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 408.

C. O. Nickell, 1938, *in* Wallace Lee and others, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 122, 124-125. Termed Speck Mountain limestone member of Thrifty formation. Thickness 3 to 5 feet. Underlies Lohn shale member; overlies unnamed shale member which Drake (1894 [1893]) called Speck Mountain clay.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 91. Rank raised to formation in Thrifty group. Underlies Breckenridge formation; overlies Ivan formation. Limestone at top of Speck Mountain has lithographic appearance of Blach Ranch limestone of Brazos River section.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17-19, p. 50. Shown on composite stratigraphic section as basal member of Thrifty formation. Consists of gray slabby very fine grained limestone; contains fusulinids. In some areas, cut out by overlying Parks Mountain sandstone member; stratigraphically above Ivan limestone member of Graham formation.

D. A. Myers, 1958, Jour. Paleontology, v. 32, no. 4, p. 678 (fig. 1). Member shown on stratigraphic column as occurring below Breckenridge member.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315-D, p. 71, 72, pl. 27. Basal member of Thrifty. In eastern Brown and northwestern Coleman Counties, separated from overlying Breckenridge member by shale interval. Separated from underlying Ivan limestone member of Graham formation by shale interval.

Named for Speck Mountain, Coleman County.

**Speeds Limestone Member** (of Sellersburg Limestone)

Speeds Formation (in Hamilton Group)

Middle Devonian: Southern Indiana.

D. G. Sutton and A. H. Sutton, 1937, Jour. Geology, v. 45, no. 3, p. 326, 328. Shaly limestone about 18 inches thick underlying Silver Creek member of Sellersburg at Speeds quarry.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1060. Rank raised to formation. In region of fullest development, a hard blue crystalline limestone which weathers to irregular thin layers and spalls. Thickness 1 to 3 feet at Sellersburg, 13 feet at Lexington, and 1 to 3 feet in Jennings County. In some areas, lies between Jeffersonville formation below and Silver Creek formation above; in other areas, underlies Deputy formation (new).

J. B. Patton and T. A. Dawson, 1955, *in* H. H. Murray, Indiana Geol. Survey Field Conf. Guidebook 8, p. 42, pl. 1. Names Speed and Silver Creek are applied to lithofacies of Hamilton rocks; these lithofacies may be used as members in southern part of outcrop belt.

Named for occurrence in Speeds quarry, near Sellersburg, Clark County.

Speers Ferry Formation

Middle Ordovician (Chazyan): Tennessee.

E. O. Ulrich, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 106. On correlation chart, Speers Ferry formation of Clinton and Pearisburg troughs of Tennessee is shown stratigraphically below the Pierce (of central Tennessee) and above the Ottosee of Knoxville and Athens troughs of Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 91. No formal description of unit has been published. According to present understanding of Appalachian stratigraphy, the position of the Speers Ferry between the Ottosee below and Pierce formation above is impossible. The Speers Ferry may have been designed for beds now called Wardell.

**Speiser Shale** (in Council Grove Group)[1]

Permian: Southeastern Nebraska, and eastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 232, 234.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46. As currently defined in Kansas, consists of shale and limestone; upper part is gray fossiliferous shale underlain by fairly persistent limestone bed which is commonly less than 1 foot thick and occurs about 3 feet below Threemile limestone member of Wreford formation; remainder of formation consists of beds of varicolored shale, red being predominant; contains lenticular bed of sandstone near middle, in southern part of State. Thickness 18 feet in northern and central part of State and about 35 feet in southern. Overlies Funston limestone.

Type locality: W½ sec. 35, T. 1 N., R. 13 E., Speiser Township, Richardson County, Nebr.

**Spence Shale Member** (of Ute Limestone)[1]

Spence Shale Member (of Langston Formation)

Middle Cambrian: Southeastern Idaho and northeastern Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 5, 6, 8.

J. S. Williams and G. B. Maxey, 1941, Am. Jour. Sci., v. 239, no. 4, p. 276, 280–281. Spence shale is not properly a member of Ute formation since it is not present in type locality of the Ute. Furthermore, faunal studies indicate that the shale is lateral facies of dolomite found at base of Langston formation at its type locality. Therefore, the shale is considered to be a member low in Langston formation, not the basal member of Ute formation.

H. W. Coulter, 1956, Idaho Bur. Mines and Geology Pamph. 107, p. 11–12. Because of the long history of misapplication of the term Spence shale both in the literature and in general use, the advisability of William's and Maxey's usage is questioned, and it is suggested that it [the term] should be dropped.

Type locality: Spence Gulch, a ravine running up into Danish Flat from Mill Canyon, about 5 miles west-southwest of Liberty, Bear Lake County, Idaho.

Spencer Chert[1]

Upper Ordovician (Richmond) : Central Missouri.

Original reference: G. H. Scherer, 1905, Bradley Geol. Field Sta. Drury Coll. Bull., v. 1, pt. 2, p. 59.

Crops out just north of Decaturville Hotel, in road from Decaturville, Camden County, to Lebanon, Laclede County.

**Spencer Formation**

Eocene: Western Oregon.

F. E. Turner, 1938, Geol. Soc. America Spec. Paper 10, p. 23–24. Name proposed for marine sandstones and shales of undetermined thickness in vicinity of Spencer and Coyote Creeks about 10 miles west southwest of Eugene. Beds along west side of Willamette Valley are also considered a part of the formation. Contact with overlying Comstock formation not directly observable; unconformity indicated.

H. E. Vokes, P. D. Snavely, Jr., and D. A. Meyers, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–110. Redefined to include beds Turner (1938) referred to Comstock formation. Subdivided to include Lorane shale member (new) at base. As redefined, Spencer formation has thickness of 2,700 to 3,400 feet; thickness increases southward; lower 600 feet assigned to Lorane shale member. Unconformably overlies Tyee formation; underlies Fisher formation. Upper Eocene.

H. E. Vokes, D. A. Myers, and Linn Hoover, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–150. Mapping in Corvallis-Monroe area indicates that Lorane shale member is more closely related to Tyee formation than to Spencer formation.

West and southwest of Eugene, Lane County.

Spencer Canyon Member (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 94–95. Medium- to dark-gray aphanitic limestone, mottled with red-brown siltstone. Average thickness about 40 feet. Beds comprising basal 20 feet are thick, massive, and cliff forming; next 10 feet is thin bedded and frequently weathers into a slope; uppermost 10 feet resembles bottom part and is also cliff forming. Younger than Sanup Plateau member (new); older than Peach Springs member (new).

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 512. Member has shale at its base at Peach Springs Canyon and becomes progressively more shaly towards Fort Rock, where it is a light-green fissile shale containing thin beds of brown miscaceous sandstone and glauconitic limestones.

Extends eastward from Grand Wash Cliffs almost to Diamond Creek; in Grand Canyon.

**Spencer Hill Volcanics** (in East Greenwich Group)

Mississippian(?) : Central Rhode Island.

A. W. Quinn, 1952, Bedrock geology of the East Greenwich quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad. Map [GQ–17]. Includes rhyolite flows with interbedded pyroclastics and conglomerate.

Rhyolite is gray, pink, or purple, fine grained, and porphyritic in part and has well-developed flow structure. Pyroclastic breccia consists of angular rhyolite fragments in rhyolitic matrix. Rhyolite pebbles of various sizes occur in the conglomerate. Intruded by thin sill of Cowesett granite (new). Included in East Greenwich group.

Named for occurrence on Spencer Hill, Kent County, where it is well exposed in roadcut on Route 2 at crest of hill and in nearby fields.

Spergen Formation

†Spergen Limestone (in Meramec Group)[1]

Mississippian (Meramecian): Southern Indiana, southern Illinois, eastern Iowa, western Kentucky, and eastern Missouri.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, 2d ser., v. 2, p. 110.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 811. Two names, Salem and Spergen, both taken from localities in Washington County, Ind., have been applied to limestone from which Bedford, Ind., building stone is obtained. Name Salem, which was proposed first and has been used consistently by Indiana Geological Survey, is preferable to name Spergen.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5. Shown on correlation chart in Meramecian series.

C. N. Brown, chm., 1957, Tri-State Geol. Soc. Guidebook 21st Ann. Field Conf., p. 16, 17, 23, 24, 34, 35. Spergen formation described in three outcrops in southeastern Iowa. Predominantly dolomite with some limestone. Thickness 4 to 12½ feet.

U.S. Geological Survey has abandoned the name Spergen Limestone in preference to the Salem Limestone, the more widely accepted term.

Named for Spergen Hill, near railroad station of Harristown, a few miles southeast of Salem, Washington County, Ind.

**Sphinx Conglomerate**[1]

Eocene: Southwestern Montana.

Original reference: A. C. Peale, 1896, U.S. Geol. Survey Geol. Atlas, Folio 24.

W. C. Alden, 1953, U.S. Geol. Survey Prof. Paper 231, p. 6–7. Unconformably overlies volcanic material which Peale correlated with Livingston formation and which, in turn, unconformably overlies upturned and folded Cretaceous strata. Eocene.

Exposed in Sphinx Mountains, a peak in the Madison Range.

Spickert Knob facies[1] (of Locust Point Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 127–137.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. In a north to south direction, Locust Point formation comprises Belmont, Nelson Hill, Schooner Hill, and Spickert Knob facies.

Name derived from Spickert Knob of the Knobstone escarpment, located chiefly in NE¼ sec. 21, T. 2 S., R. 6 E., 1 mile northeast of Floyds Knob post office, Floyd County.

Spieden Formation[1]

Lower Cretaceous: Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington [State] Univ. Pub. in Geology, v. 2, p. 93, 113–118.

W. P. Popenoe, R. W. Imlay, and M. A. Murphy, 1960, Geol. Soc. America Bull., v. 71, no. 10, p. 1533, chart 10e (column 58). Valanginian beds on Spieden Island consist mostly of sandy conglomerate. Thickness more than 2,000 feet.

Present on Spieden Island, Sentinel Island, and Sentinel Rock, San Juan Islands.

Spiller Sand Member (of Cook Mountain Formation)

Spiller Sand Member (of Crockett Formation)

Eocene, middle: Eastern Texas.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table 1), 125, 149–150. Lignitic argillaceous sands underlying Mount Tabor shale member and overlying Landrum shale member of Crockett formation. Characteristic beds of member are gray or brown, commonly lenticular or crossbedded; thickness of beds a few inches to about 2 feet; shale partings carry lignitized plant fragments. Estimated thickness 105 feet. Overlying and underlying contacts transitional.

H. B. Stenzel, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 9, p. 1664, 1665, 1671 (fig. 3). Reallocated to Cook Mountain formation.

Type locality: Upper reaches of Pine Branch in William Johnson survey, Leon County. Name derived from Spiller's store in southeastern part of County.

Spillway Breccia

Tertiary: Northwestern Arizona and southeastern Nevada.

U.S. Bur. Reclamation, 1950, U.S. Bur. Reclamation, Boulder Canyon Proj. Final Repts., pt. 3, Preparatory Exams., Geol. Inv., Bull. 1, p. 95–96, fig. 34 (geol. map). Intervolcanic deposit of variable character. For the most part, consists of fragments of volcanic rock, principally latite, many of which are more than 2 feet in diameter, whereas masses 6 feet in diameter are not uncommon. Coarse material grades here and there into grits, sandstones, and conglomerate with well-defined regular bedding. Overlies latite flow breccia and underlies basic latite. Younger than Dam breccia (new) and older than Dry Camp breccia (new). Part of younger volcanic series of area. Name credited to F. L. Ransome (unpub. ms.).

Named because of its prominence in Arizona spillway basin, at Hoover Dam, Black Canyon.

†Spiro Sandstone Member (of Savanna Sandstone)[1]

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., 1937, Oklahoma Geol. Survey Bull. 57, p. 50–51. Described in Muskogee-Porum district. Uppermost member of Savanna formation. Overlies Sam Creek limestone member. Maximum thickness 20 feet.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 50–52. Term Spiro sandstone member, used in Muskogee County, is not applicable in Haskell County.

Caps ridge in secs. 13 and 14, T. 9 N., R. 25 E., just north and northeast of Spiro, Le Flore County.

Spitzenberg Conglomerate[1]

Triassic(?) : Southeastern Pennsylvania.

Original reference: Lawrence Whitcomb and J. A. Engel, 1934, Pennsylvania Acad. Sci. Proc., v. 8, p. 37–43.

Lawrence Whitcomb and J. A. Engel, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 755–764. Triassic age not definitely proved, but there is strong evidence in its favor. If Spitzenberg is Triassic outlier it becomes highly significant in discussion of Triassic sedimentation in Pennsylvania.

Named for occurrence on top of Spitzenberg, a hill 2½ miles northeast of Lenhartsville, Berks County.

**Split Creek Sandstone Member** (of Katalla Formation)

Split Creek Shale and Sandstone Member[1] (of Katalla Formation)

Oligocene: Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 771–775.

D. J. Miller, D. L. Rossman, and C. A. Hickcox, 1945, Preliminary report on petroleum possibilities in the Katalla area, Alaska: U.S. Geol. Survey, p. 7 (table), 8–9; 1945, Geologic and topographic map and sections of the Katalla area, Alaska: U.S. Geol. Survey War-Minerals Inv. Prelim. Map. Stratigraphically restricted. Composed principally of massive thick-bedded medium- to coarse-grained brownish-gray sandstone and evenly banded fine- to medium-grained thin-bedded sandstone. Banded sandstone cross-bedded locally. Member contains a few thin shale beds. Thickness 700 to 1,400 feet; average of 1,000 feet at head of Split Creek where it is best exposed and shows characteristic lithology. Overlies unnamed shale member; underlies Basin Creek member (new). Unit raised to formational rank (to include Split Creek shale below and Split Creek sandstone above) in unpublished manuscript by oil-company geologists.

Exposed in northern part of Controller Bay region, in drainage to Bering Lake, in very narrow belt along Bering River, and in northern part of ridge between Redwood Creek and Katalla River. Best exposed at head of Split Creek.

Split Mountain Formation

Miocene(?) : Southern California.

L. A. Tarbet and W. H. Holman, 1944, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1781. Nonmarine fanglomerates and sandstones intercalated with marine sandstones and shales. Thickness as much as 2,700 feet. Unconformably overlies basement complex. Underlies Alverson Canyon formation (new).

W. E. Ver Planck, 1952, California Div. Mines Bull. 163, p. 30–31, pl. 20. Described in connection with gypsum deposits of Imperial County. In the

774–954—vol. 3—66——51

area, Split Mountain formation is divisible into two members, a lower, noticeably red, and an upper that is gray. Above gray member is at least 100 feet of massive gypsum.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 22 (fig. 1), 23 (fig. 2). Split Mountain formation, 0 to 2,700 feet; underlies Alverson andesite in southwestern Imperial Valley. Overlies pre-Tertiary schist, limestone, gneiss, and granitic intrusives. Split Mountain conglomerate, 0 to 400 feet, underlies Imperial formation in northwestern Imperial Valley.

Occurs on west side of Imperial Valley.

Split-Rock slate[1]

Precambrian: Northwestern Iowa.

Original references: C. R. Keyes, 1914, Iowa Acad. Sci. Proc., v. 21, p. 187; 1914, Science, new ser., v. 40, p. 144.

Derivation of name not stated.

Spokane Drift

Spokane Glaciation[1]

Spokane Stage

Pleistocene: Northeastern Washington.

Original reference: J. H. Bretz, 1923, Geol. Soc. America Bull., v. 34, p. 580.

R. F. Flint, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 222. Three bodies of drift occur in Creston-Spokane district; till on the plateau ("old drift"); rest of plateau drift, chiefly stratified (Spokane drift); and stratified till in deep valleys (Wisconsin outwash). It is possible that drift on plateau dates from glaciation earlier than one responsible for valley fill; it is even possible that all three bodies may be of different glacial ages. Such difference is not demonstrated from facts now known, which point to single common age for all—namely, Wisconsin.

Ernst Antevs, 1945, Am. Jour. Sci., v. 243–A, p. 8. If Spokane drift of eastern Washington is comparable to early Wisconsin drift of eastern Montana, it may be of early Wisconsin (Iowan) age.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 18. Spokane stage of glaciation is older than last or late Wisconsin stage and presumably early Wisconsin; it may prove to be somewhat older.

Named for occurrence in vicinity of Spokane.

**Spokane Shale**[1] or **Formation**[1] (in Missoula Group)

Spokane Formation or Shale (in Piegan Group)

Precambrian (Belt Series): Western and central southern Montana.

Original reference: C. D. Walcott, 1899, Geol. Soc. America Bull., v. 10, p. 199–215.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1897–1898. Formation comprises argillaceous and arenaceous strata lying between calcareo-magnesian formations of Piegan group. Beds range from sandstones and soft shales to quartzites and argillites; dominantly red and green, through brown, buff, and gray also seen. Thickness, 180 to 7,400 feet. Recognized in Glacier National Park; southward, in both Blackfoot Canyon and Meagher facies the formation thickens. In typical Meagher facies, it contains (ascending) Greyson, Prickly Peak (new), and Empire members.

D. A. Andrews, G. S. Lambert, and G. W. Stose, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 25, sheet 1. Spokane formation shown on map legend as part of Siyeh group.

J. B. Lyons, 1944, Geol. Soc. America Bull., v. 55, no. 4, p. 450. In area of Lewis overthrust, overrides Upper Cretaceous Adel Mountain volcanics (new).

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Name has been used over a wide area in Montana but in a strict sense can be used safely only in general vicinity of Helena. Provisionally included in Piegan group.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 4 (table), 5–6, pls. 1, 2. Thickness as much as 1,700 feet in southern Elkhorn Mountains. Overlies Greyson shale with contact gradational; grades upward into Empire shale. Where Empire is absent, overlain by Flathead quartzite.

U.S. Geological Survey currently classifies the Spokane as a formation in Missoula Group on the basis of a study now in progress.

Type locality: In Spokane Hills, 15 miles east of Helena.

**Spoon Formation** (in Kewanee Group)

Middle Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1), 26 (fig. 4), 27, 32–33, 45–46 (table 1), pl. 1, geol. sections. Proposed for strata from top of Bernadotte sandstone member of Abbott formation (new) to base of Colchester (No. 2) coal member of Carbondale formation. Maximum thickness about 350 feet in southern Illinois; ranges from a few feet to nearly 100 feet in western Illinois. Members—southeastern Illinois—Bidwell coal (new), New Burnside coal (new), O'Nan coal (new), Granger sandstone (new), Creal Springs limestone, Mount Rorah coal (new), Wise Ridge coal (new), Stonefort limestone, Davis coal, DeKoven coal, Palzo sandstone; southwestern Illinois—Murphysboro, Litchfield, and Assumption coals, Vergennes sandstone, Seahorne limestone, Davis coal, De Koven coal, and Cheltenham clay; western Illinois—Rock Island (No. 1) coal, Seville limestone, Hermon coal (new), Brush coal (new), De Long coal, Seahorne limestone, Wiley coal, Greenbush coal, Isabel sandstone, Abingdon coal, Browning sandstone, and Cheltenham clay; northern Illinois—Cheltenham clay; and eastern Illinois—Seeleyville coal. Presentation of new rock-stratigraphic classification for Illinois. Cyclical classification retained but is independent of rock-stratigraphic classification.

Type locality: Sec. 22, T. 6 N., R. 1 E., Fulton County. Name derived from Spoon River. Formation is exposed in railroad cut of T. P. and W. Railroad about one-fourth mile west of Spoon River.

Spoon Butte Beds[1]

Miocene, upper, and Pliocene, lower: Eastern Wyoming and western Nebraska.

Original reference: O. A. Peterson, 1909, Carnegie Mus. Mem., v. 4, no. 3, p. 74–77.

Named for Spoon Butte, Laramie County, Wyo.

Spoon River Sandstone and Shale (in Pottsville Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

Well exposed along Spoon River, Fulton County.

Spotted Bear Limestone Member (of Jefferson Limestone)[1]

Upper Devonian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 44.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4 (facing p. 1788). Correlation chart shows age as Upper Devonian.

Well exposed between elevations of 6,880 and 7,005 feet on northwest slope of Spotted Bear Mountain, in NE¼ sec. 26, T. 25 N., R. 15 W. Also in Pentagon and Monitor Mountains.

**Spotted Ridge Formation**

Pennsylvanian: Central Oregon.

C. W. Merriam, 1942, Jour. Paleontology, v. 16, no. 3, p. 372. Coarse conglomerate, carbonaceous sandstone and indurated mudstone, bedded cherts; in part terrestrial with Pennsylvanian flora. Thickness 1,000 to 1,500 feet. Unconformably underlies Coyote Butte formation (new).

C. W. Merriam and S. A. Berthiaume, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 151–156. Type locality designated.

S. H. Mamay and C. B. Read, 1956, U.S. Geol. Survey Prof. Paper 274–I, p. 211–223. Studies indicate that on basis of fossil plants alone precise age of Spotted Ridge formation within Pennsylvanian cannot be determined with any great degree of confidence.

Type locality: On west flank of Spotted Ridge, about 15 miles southeast of Paulina, Crook County.

Spottedtail Member (of Sheep Creek Formation)

Miocene (Hemingford): Northwestern Nebraska.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 128–129. Lowermost member of formation. Includes all rocks originally included in Sheep Creek by Matthew and Cook (1909) except uppermost 10 to 20 feet in midst of which is dark-gray volcanic ash. From base up, member is composed of unconsolidated greenish to pinkish sandy clays about 60 feet thick which are similar to Box Butte clays except they do not contain concretions; above clays are pinkish sand and thin layer of light-bluish-gray volcanic ash; uppermost 105 feet is largely unconsolidated silty sands with several hard zones of "mortar beds"; about middle of upper part and about 50 feet below top is a bed of white marl 2 to 3 feet thick, and the sand below it is pinkish brown and above is buff to greenish. Total thickness more than 170 feet. Contains herbaceous flora. Underlies Sand Canyon member (new); overlies eroded surface of Harrison formation.

Type locality: About 15 miles south and 1 mile east of Agate, Sioux County, in West Kilpatrick, Aphelops, and Pliohippus draws at head of Spottedtail Creek which is tributary to North Platte River.

Spout Spring Oolite (in Bangor Limestone)

Mississippian: Northwestern Alabama.

W. B. Jones, 1939, Econ. Geology, v. 34, no. 5, p. 575, 578. Name applied to 50-foot massive-bedded hard gray oolite near base of Bangor limestone. [Appears to be stratigraphically below Rockwood oolite member.]

Occurs at Spout Spring, about 2 miles west of Rockwood, Franklin County.

Spraberry Sandstone

Permian (Leonard): Western Texas (subsurface).

Lamar McLennan, Jr., and W. H. Bradley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 4, p. 899–903, 904–908. At type locality, consists of upper sand member about 300 feet thick and lower sand member of about same thickness; the two zones are separated by about 250 feet of shaly gray to brown limestone and streaks of brown calcareous sand. Occurs between depths of 6,400 and 7,290 feet in type well. About 260 feet above Dean sand (new). Lower Leonard.

Type section: Seaboard's Spraberry No. 6–D, sec. 38, Block 34, T. 5 N., in Spraberry field, Dawson County. Depth 6,400 to 6,636 feet not cored in Spraberry 6–D; core description from Robison 6–A substituted for this interval. Named by Seaboard geologists from first well drilled on A. J. Spraberry lease.

Sprague Glacial Substage

Pleistocene (Wisconsin): Southern Rocky Mountains.

L. L. Ray, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 2007; 1940, Geol. Soc. America Bull., v. 51, no. 12, pt. 1, p. 1862–1863. Fifth, or youngest, substage in southern Rocky Mountains. Represented in some cirques by protalus ramparts.

Named for moraine in front of Sprague Glacier in Rocky Mountain National Park.

Sprakers[1]

Sprakers Shale Member (of Canajoharie Shale)

Middle Ordovician: Eastern New York.

Original reference: Rudolf Ruedemann and G. H. Chadwick, 1935, Science, new ser., v. 81, no. 2104, p. 400.

Rudolf Ruedemann, 1947, Geol. Soc. America Mem. 19, p. 118. Referred to as Sprakers shale member of Canajoharie. Overlies Gansevoort shale member; underlies Morphy shale member.

Type locality and derivation of name not given but may have been named for Sprakers, Montgomery County.

**Spring Branch Limestone Member** (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 44, 47.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 152–153; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 17. Spring Branch limestone member of Lecompton formation; underlies Doniphan shale member; overlies Stull shale member of Kanwaka shale. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24. Average thickness 3 to 5 feet. In Nebraska, Iowa, Missouri, and northeastern Kansas, member was formerly miscorrelated with Oread limestone. Type locality and derivation of name stated.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 20, fig. 5. Massive gray cherty limestone separated into two or three beds by thin shales. Thickness 5 to 10 feet. Underlies Doniphan shale member; overlies Kanwaka shale.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 43, pl. 1. Thickness 8 to 14 feet in Douglas County. Lowest 5 feet is massive light tan or light gray brown in unweathered state but yellow brown where weathered; overlying part made up of shaly limestone, shale, and limestone commonly 3 to 8 feet thick. Underlies Doniphan shale member; overlies Stull shale member of Kanwaka shale.

Type locality: On Spring Branch north of Big Springs, Douglas County, Kans.

Spring Brook Shale Member (of Ludlowville Formation)

Middle Devonian: Western New York.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, no. 5–6, p. 365, 366. Described as shale and impure limestone. Thickness about 20 feet. Overlies Ledyard shale member; underlies Eighteenmile Creek member. Name attributed to G. A. Cooper (unpub. thesis); later included in Wanakah shale member by Cooper [1930].

Exposed in section along Lackawanna Railroad tracks, 3½ miles west of village of East Bethany, Batavia quadrangle.

†Spring Canyon coal group (in Blackhawk Formation)[1]

Spring Canyon Coal Member (of Blackhawk Formation)

Upper Cretaceous: Central eastern Utah.

Original reference: F. R. Clark, 1928, U.S. Geol. Survey Bull. 793.

R. G. Young, 1954, (abs.) Jour. Paleontology, v. 28, no. 4, p. 504. Member about 100 feet thick. Separated from overlying Aberdeen member by thin tongue of Mancos shale; overlies Spring Canyon tongue of Star Point sandstone.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183–184. Coal group included in newly defined Spring Canyon member of Blackhawk formation.

In Book Cliffs, Castlegate quadrangle, Carbon County.

Spring Canyon Member (of Blackhawk Formation)

Upper Cretaceous (Montana): Central eastern Utah.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183–184, figs. 2, 3, pl. 3. Includes strata previously assigned to Spring Canyon coal group (Clark, 1928) above and Spring Canyon sandstone tongue below. Member consists of 60 to 100 feet of coal-bearing shales and sandstones of fresh- and brackish-water origin resting directly upon massive basal sandstone of the Spring Canyon, which has average thickness of about 150 feet in Spring Canyon. Underlies tongue of Mancos shale with slight disconformity. Basal sandstone absent to west and southwest, where member becomes part of undifferentiated coal-bearing rocks of Blackhawk formation. Two massive offshore bar sandstones near Helper occupy almost the entire interval between basal sandstone of overlying Aberdeen member and basal sandstone of Spring Canyon member. Coal-bearing rocks of Spring Canyon member were deposited behind these bars, which mark eastern limits of coal-producing swamps. At least three important coal beds in member; lowest and most important is Hiawatha coal, named for typical occurrence at Hiawatha in Wasatch Plateau; ranges from 8 inches to 7 feet 4 inches in thickness.

Measured in Spring Canyon, Book Cliffs, northern part of Castlegate quadrangle, Carbon County.

Spring Canyon Member (of Frontier Formation)

Lower Cretaceous(?) : Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 138, 139 (fig. 1), 140. Name applied to coaly and carbonaceous sequence overlying Longwall sandstone member (new) and underlying Chalk Creek member (new). Contains five coal beds ranging in thickness from 1 to 3½ feet. Outcrop thickness 350 feet.

Well exposed in Spring Canyon, 3¼ miles southeast of Coalville, Summit County. Also well exposed north of Chalk Creek Narrows, sec. 1, T. 2 N., R. 5 E., Summit County.

**Spring Canyon Tongue** (of Star Point Sandstone)[1]

Spring Canyon Member (of Star Point Sandstone)

Upper Cretaceous: Central eastern Utah.

Original reference: F. R. Clark, 1928, U.S. Geol. Survey Bull. 793.

R. G. Young, 1954, (abs.) Jour. Paleontology, v. 28, no. 4, p. 504. Underlies Spring Canyon coal member of Blackhawk formation.

P. J. Katich, Jr., 1954, Intermountain Assoc. Petroleum Geologists [Guidebook] 5th Ann. Field Conf.. p. 43 (fig. 1). Uppermost member of Star Point. Thickness 50 to 150 feet. Overlies Storrs member; underlies Aberdeen sandstone member of Blackhawk formation.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183–184. Base of Blackhawk formation is at base of Spring Canyon sandstone of Clark. Spring Canyon sandstone tongue is included in Spring Canyon member (new) of Blackhawk formation.

Forms conspicuous white cliffs in Spring Canyon in Book Cliffs, northern part of Castlegate quadrangle, Carbon County.

Spring Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Section [Guidebook] Spring Mtg., p. 77. Bluish sandy clay, 300 feet thick, with 50 feet of sandstone near middle. Underlies Cottonwood Creek bed; overlies Brown Creek bed.

D. H. Eargle, 1960, U.S. Geol. Survey, Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to base of Drake's Ricker bed.

Named for Spring Creek, San Saba County.

Spring Creek Clays[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: C. N. Gould, 1898, Am. Jour. Sci., 4th, v. 5, p. 170–174.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Dakota formation, as herein defined, contains stratigraphic units formerly called "Rocktown channel sandstone," "Ellsworth formation," "Solomon formation," "Reeder sandstone," "Marquette sandstone," "Spring Creek clay," and others.

Named for Spring Creek, 12 miles south of Belvidere, Kiowa County.

Spring Creek deposits

Pleistocene: Western and northwestern Texas.

G. L. Evans and G. E. Meade, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 495. Name given to lacustrine deposits similar in lithology to, and believed to be equivalent of Tule formation.

Occur along Double Mountain Fork of Brazos River and a tributary stream known as Spring Creek in western Garza and eastern Linn Counties.

**Spring Creek Granite**[1]

Precambrian: Eastern Colorado.

Original reference: W. Cross, 1895, U.S. Geol. Survey 16th Ann. Rept., pt. 2, p. 23.

Occurs only on southwest half of Red Mountain and on hill to south on opposite side of Spring Creek, Cripple Creek district.

†Spring Creek Limestone (in Moorefield Shale)[1]

Mississippian: Northern Arkansas.

Original reference: H. S. Williams, 1895, Am. Jour. Sci., 3d, v. 49, p. 94–101.

Mackenzie Gordon, Jr., 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 11, p. 1631. Moorefield formation in Batesville district, consists of lower member of black calcareous shale and limestone and upper member of dark-gray fissile clay shale; lower member has been known as Spring Creek limestone (name preoccupied) and grades laterally into chert that has been incorrectly mapped as Boone. It is recommended that the Moorefield be restricted to lower member.

Named for Spring Creek, 2 miles west of Batesville, Independence County.

Spring Creek Member (of Stonehenge Limestone)

Lower Ordovician (Canadian): Central Pennsylvania.

A. C. Donaldson, 1960, Dissert. Abs., v. 20, no. 9, p. 3693. Basal member; contains oolites in contrast to overlying Graysville member (new).

Type locality and derivation of name not stated.

**Springdale Sandstone Member** (of Moenave Formation)

Springdale Sandstone Member (of Chinle Formation)

Upper Triassic(?): Southern Utah and northeastern Arizona.

H. E. Gregory and N. C. Williams, 1947, Geol. Soc. America Bull., v. 58, no. 3, p. 223 (table 1), 228, 233; H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 52 (table), 67, 68, strat. sections. Member of Chinle. Consists of light-red sandstone streaked with white; indistinct lenticular beds 2 to 10 feet thick, separated in places by thin layers of imbricated shale; includes pellets of concretionary limestone and clay; ripple marks common. Thickness 40 to 180 feet. Underlies unnamed sandstone; overlies Petrified Forest member.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2519–2520. Reallocated to member status in Moenave formation. Overlies Dinosaur Canyon sandstone member; underlies Kayenta formation. In Echo Cliffs area, the Springdale and underlying Dinosaur Canyon member were mapped as Wingate sandstone and described separately as the upper and lower parts of the formation (Wanek and Stephens, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–145). At Cedar City, in Coal Creek section of Chinle, measured by Thomas and Taylor (1946) and republished by Gregory (1950, Utah Geol. and Mineralog. Survey Bull. 37), the Springdale comprises units 24, 23, and possibly upper part of unit 22 as designated by Thomas and Taylor, and units 19, 18, and possibly upper part of unit 17 as designated by Gregory—not unit 14 as designated by Gregory. Thickness 60 to 225 feet; typically about 175 feet.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 16–17, 62. Geographically extended into Arizona. In most parts of Navajo country, member is 100 to 150 feet thick, though thickness differs locally owing to lenticular nature of its sandstone units; 221 feet at Lees Ferry; 77 feet at Moenave. Overlies Dinosaur Canyon member, contact commonly gradational; underlies Kayenta formation and in many areas cannot be distinguished from it. In Echo Cliffs area, unit has been referred to as Wingate sandstone by several workers.

Name derived from village of Springdale, Washington County, Utah, where unit forms prominent cliff. Traceable by nearly continuous outcrops, from Kanab, Utah, along Vermilion Cliffs to Lees Ferry, Ariz., and southward along Echo Cliffs.

## Springer Formation[1] or Shale

Springer Group

Mississippian and Pennsylvanian (Chester and Morrow Series): Oklahoma.

Original reference: W. L. Goldston, Jr., 1922, Am. Assoc. Petroleum Geologists Bull., v. 6, no. 1.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Group comprises (ascending) "Caney" shale, Rod Club sandstone, Overbrook sandstone, Lake Ardmore sandstone, and Primrose sandstone. Underlies Dornick Hills group. Morrow series.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 7–13. Springer group is here defined as including both Goddard formation and Springeran series. Goldston's (1922) original Springer member of Glenn formation likewise included both. Boundary between Mississippian and Pennsylvanian systems probably falls within Springer group as here defined. Group includes maximum of about 4,500 feet of sediments of which Springeran series comprises upper half. Lower half of group contains Goddard formation and upper half three sandstones: Rod Club, Overbrook, and Lake Ardmore. Overlies the Caney; underlies Dornick Hills group.

Lynn Jacobson, 1959, Oklahoma Geol. Survey Bull. 79, p. 27–29. Formation conformably overlies Goddard shale. Consists of about 2,000 feet of dark-gray shale marked by presence of four or six prominent sandstone members. Springer has been widely accepted as early Pennsylvanian age and has been used as type section for Springeran stage by Moore and Thompson (1949) in their revision of Pennsylvanian system. However, no unequivocal paleontologic or stratigraphic evidence as to the age of the Springer is now known.

Well exposed at Springer, Carter County.

Springer Series

Springeran Stage or Age

Lower Pennsylvanian: Midcontinent region.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 140 (chart 2), 142–144. Revision of Goldston's (1922) Springer member to include all Pennsylvanian beds below base of Primrose sandstone, and for elevating Springer division to rank of series will be recommended in forthcoming paper by R. H. Dott. As revised, Springer series is about 4,000 feet thick in type area north of Ardmore. About 2,000 feet of dark shales below Rod Club sandstone are now included in Springer series. These lower Springer shales, heretofore called "Pennsylvanian Caney" have been named Goddard shale. Name Springer is used in preference to Harlton's (1938) Pushmataha series partly because of priority and usage, but chiefly to avoid placing type locality of series in less accessible area where stratigraphic relationships are uncertain owing to complex overthrust faulting and folding. Series in Ouachita basin of southeastern Oklahoma and west-central Arkansas attains estimated thickness of 15,000 feet, on assumption that Hot Springs sandstone, Stanley shale, and Jackfork sandstone are all of post-Chester age, and properly assigned to Pennsylvanian.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 286, 288 (fig. 1). Springeran stage (Age) included in newly defined Ardian series (Epoch).

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma—a symposium v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 4–7. Term Springeran series comprises approximately upper half of sediments covered by original definition of series by Cheney (1945). Upper limit is base of Primrose sandstone, uppermost member of Springer formation as defined by Tomlinson (1929, Oklahoma Geol. Survey Bull. 46). Lower limit is base of Rod Club sandstone. Underlying Goddard formation is excluded because it is now believed to be of Chesterian age. As thus limited, Springeran series is coextensive with Tomlinson's (1929) Springer formation where Jolliff conglomerate forms base of overlying Dornick Hills group. Some paleontologists do not recognize Springeran as a series but consider it included in Morrowan series. However, no part of Springeran series as here described is known to be represented by sediments of contemporaneous origin, either in type Morrowan of northwest Arkansas or in type Chesterian of Illinois and Missouri. Springeran series comprises upper half of Springer group as herein defined.

Type locality: Ardmore basin, Oklahoma.

Springfield Clay[1]

Pleistocene: Southwestern Ohio.

Original reference: E. Orton, 1873, Ohio Geol. Survey, v. 1, p. 431, 443.

Named for Springfield, Clark County.

Springfield Coal Member (of Carbondale Formation)

Pennsylvanian: Western and northern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), 66, pl. 1. Assigned member status in Carbondale formation (redefined). Occurs above Covel conglomerate member and below St. David limestone member. Thickness about 5 feet. Coal named by Worthen (1883, *in* Geology and Paleontology, v. 7, Illinois Geol. Survey). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Sec. 16, T. 16 N., R. 4 W., Sangamon County. Named from subsurface exposures in coal mines.

Springfield Conglomerate[1]

Cambrian(?): Southeastern Vermont.

Original reference: C. H. Richardson, 1931, Vermont State Geologist 17th Rept., p. 200–201.

Occurs on east side of Spencer Hollow Road, a few rods east of Spencer Schoolhouse, 1½ miles east of Springfield, Windsor County.

Springfield Granodiorite

Springfield Microcline Gneiss

Age unknown: Southeastern Pennsylvania.

A. W. Postel, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2004–2005; 1941, Acad. Nat. Sci. Philadelphia Proc., v. 92, p. 125–133. Igneous rocks in Wissahickon schist in Philadelphia region originated in two ways: definite magmatic intrusions into Wissahickon and hydrothermal replacement of Wissahickon by potash and soda-rich solutions. Springfield aplitic granodiorite and Ridley Park granodiorite (new) are products of magmatic intrusion; Springfield porphyroblastic granodiorite is product of hydrothermal reaction. Precise chronological position cannot be assigned to the igneous rocks because age of Wissahickon is in doubt. Relative age sequence is considered to be (oldest to youngest) metagabbro, Springfield porphyroblastic granodiorite, Springfield aplitic granodiorite, and Ridley Park granodiorite.

Chi-shang Ch'ih, 1950, Geol. Soc. America Bull., v. 61, no. 9, p. 925, 926, 929, 937, 949–951. Referred to as Springfield microcline gneiss in discussion of petrology of Wissahickon schist.

A. W. Postel and H. W. Jaffe, 1957, Pennsylvania Acad. Sci. Proc., v. 31, p. 120. Renamed Swarthmore granodiorite. Name Springfield preempted.

Area mapped is roughly rectangular, bounded on northwest by Narbeth, on northeast by Manayunk, and on southwest by Chester and on southeast by Philadelphia. Springfield is in Delaware County.

**Springfield Limestone**[1] or **Dolomite**

Springfield Dolomite (in Durbin Group)

Middle Silurian: Southwestern Ohio.

Original reference: E. Orton, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 271, 274–277, 301.

C. K. Swartz, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as dolomite in Durbin group.

R. J. Bernhagen, chm., 1960, Ohio Acad. Sci., Geology Sec., Guidebook 35th Ann. Field Conf., p. 13, 17–18, 21. Silurian section in Yellow Springs region shows Springfield dolomite, 10 feet thick, above Euphemia dolomite and below Cedarville dolomite. Niagaran.

Type locality: Springfield, Clark County.

Springfield Center Member (of Onondaga Formation)

Middle Devonian: East-central New York.

R. E. Stevenson, 1949, New York State Sci. Service Rept. Inv. 3, p. 6–7. Grey to dark-grey medium- to thin-bedded fine- to medium-grained fossiliferous limestone. Massive coral reef within 5 feet of base in most localities. Thickness 3 to 30 feet. Underlies Babcock Hill member (new); overlies Carlisle Center formation. Onondaga is used both as group and formation in this report.

Named for occurrence in vicinity of Springfield Center, Otsego County.

Spring Grove Member (of Wapsipinicon Limestone)[1]

Middle Devonian: Eastern Iowa.

Original reference: A. C. Trowbridge, M. L. Thompson, and E. H. Scobey, 1935, Kansas Geol. Soc. 9th Ann. Field Conf., Guide Book, p. 36, 424, figs. 1, 2.

E. H. Scobey, 1940, Jour. Sed. Petrology, v. 10, no. 1, p. 38 (fig. 1), 41–42. Underlies Davenport member; overlies Kenwood member. In Fayette County, lies unconformably on the Silurian, overlapping lower members of the Wapsipinicon and the Gower formation. Middle Devonian(?).

Type locality: In right bank of Wapsipinicon River in central sec. 24, Spring Grove Township, Linn County.

**Spring Hill Limestone[1] Member** (of Plattsburg Limestone)

Pennsylvanian (Missouri Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 93, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 116. Spring Hill limestone member of Plattsburg formation; overlies Hickory Creek shale member; underlies Vilas shale. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 33. Consists of two limestones separated by shale. Thickness in Kansas 6 to 40 feet; average 15 feet; 4 to 6 feet in Nebraska. Type locality stated.

Type locality: In railroad cut near center east side of sec. 14, T. 15 S., R. 23 E., southern Johnson County, Kans.

Springler Knob facies[1] (of Edwardsville Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Dept. Conserv., Div. Geology Pub. 98, p. 76, 222–227.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Springler Knob facies listed in Edwardsville formation.

Name derived from Springler Knob on Knobstone Escarpment near center NE¼ sec. 10, T. 2 S., R. 6 E., 3½ miles southwest of St. Joseph, 5 miles north of New Albany, Floyd County.

Spring Mount Sandstone Member (of Bald Eagle Sandstone)

Upper Ordovician: Central Pennsylvania.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geology Contr. 3, 58 p. Upper member of Bald Eagle in vicinity of Tyrone Gap. [Spring Mount is "ridge making member of Bald Eagle" referred to by Swartz, 1948.] Overlies Centennial School sandstone and shale member (new); to the east, interfingers with Lost Run conglomerate. Underlies Juniata strata. [Swartz refers to his 1955 report *in* Pennsylvania Geologists Guidebook 21st Ann. Field Conf. Compiler was unable to locate this reference.]

Type locality and derivation of name not given.

Spring Mountain[s] Formation

Permian (Wolfcampian-Leonardian): Western Nevada.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). As shown on diagrams and correlation chart, Spring Mountain formation overlies Bird Spring formation and underlies Kaibab formation.

Present in Spring Mountains area.

**Spring Point Greenstone** (in Casco Bay Group)[1]

Pennsylvanian(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

Named for exposures at Spring Point, South Portland, Cumberland County.

Spring River Sandstone[1]

Pennsylvanian: Southwestern Missouri.

Original reference: D. White, 1897, Geol. Soc. America Bull., v. 8, p. 288.

Named for Spring River, Jasper County.

†Spring Rock limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow and F. Hawn, 1865, Kansas Geol. Survey Rept. on Miami County, p. 9.

Named for springs which come to surface from crevices in the rock.

†Spring Rock series[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 21.

Probably named for Spring Rock, the source of many springs.

†Springvale Beds[1]

Mississippian: Southeastern Iowa.

Original reference: H. F. Bain, 1895, Am. Geologist, v. 15, p. 320.

Named for old Springvale mill, 5 miles south of Delta, Keokuk County.

Springvale Sandstone[1] (in Onondaga Limestone)

Middle Devonian: Ontario, Canada and central New York.

Original reference: C. R. Stauffer, 1913, 12th Int. Geol. Cong. Guidebook 4, p. 83–85, 89.

W. A. Oliver, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 7, p. 625, 627, 631 (fig. 2), 632, 635, 641. Chadwick (1919, New York State Mus. Bull. Nos. 207–208) extended name Springvale sandstone into New York. Springvale zone or horizon is recognized at base of Edgecliff member (new) of Onondaga formation.

Well exposed near Springvale, in region around Hagerville, Ontario, Canada.

Spring Valley Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: G. H. Cady, 1921, Illinois Geol. Survey Cooperative Mining Ser. Bull. 26, p. 36, 38.

Springville Shale[1]

Mississippian (Valmeyer Series): Southwestern Illinois.

Original reference: T. E. Savage, 1920, Am. Jour. Sci., 4th, v. 49, p. 169–178.

C. C. Collinson and A. J. Scott, 1958, Illinois Geol. Survey Circ. 254, p. 1–12. This report, based on study of outcrops and conodont faunas, correlates the two lowermost units of the Springville, as originally defined, with Hannibal shale and Chouteau limestone, both of Kinderhook age, and restricts name Springville to beds overlying the Chouteau. A 15-inch shale at base of the redefined Springville is named State Pond member. There is no definite age concerning top of Springville, but it is overlain by beds that are referred to Burlington-Keokuk formation.

Well exposed in bed and banks of a creek northwest of Springville, SE¼ sec. 13, T. 13 S., R. 1 W., Union County. Best contemporary exposures are west of Jonesboro near north line of sec. 23, T. 12 S., R. 2 W., near State Pond Dam in sec. 14 and along Darty Creek in SW¼ sec. 11, both mentioned in Savage's description.

Sprout Brook Limestone[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey, 1907, New York State Mus. Bull. 107, p. 361–378.

Occurs in Westchester and Putnam Counties.

**Spruce Formation** (in Missoula Group)

Precambrian (Belt Series): Northwestern Montana.

A. B. Campbell, 1960, U.S. Geol. Survey Bull. 1082–I, p. 560–563, pl. 28. Thin-bedded fine-grained greenish-gray impure quartzite containing many thick zones of thinly interlaminated greenish-gray quartzose argillite and impure quartzite and a few zones of pale-purplish-gray quartzite. Lower 300 feet and upper 700 to 800 feet partly dolomitic. Weathers buff to brown. Thickness about 3,500 feet. Underlies Lupine quartzite (new); conformably overlies Wallace formation.

Type locality: Spruce Ridge, secs. 32, 33, and 34, T. 17 N., R. 27 W., St. Regis-Superior area. Exposed on north slope Sheep Mountain, secs. 5 and 6, T. 16 N., R. 27 W., St. Regis-Superior area, Mineral County.

Spruce Pine Alaskite

Age not stated: Western North Carolina.

C. E. Hunter and P. W. Mattocks, 1936, TVA Div. Geology Bull. 4, p. 10–11. Extremely coarse-textured granite containing a small amount of biotite locally. Feldspar crystals as much as 2 feet across are quite common.

Outcrops principally over an area around the town of Spruce Pine in Mitchell County and in smaller areas in Brushy Creek and Ingalls sections of Avery County.

**Spud Mountain Volcanics** (in Alder Group)

Precambrian (Yavapai Series) : Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 21–26, pl. 1. Comprises four lithologic units: andesitic breccia and interbedded tuffaceous sedimentary rocks—maximum outcrop width about 5,500 feet; fine-grained andesitic tuffaceous rocks—maximum outcrop width about 5,000 feet; intercalated andesitic flows—maximum outcrop width 1,000 feet; and interbedded rhyolitic tuff—maximum outcrop width 1,500 feet. Outcrop widths may about equal stratigraphic thickness for local or partial sections. Underlies Iron King volcanics (new) and overlies Indian Hills volcanics (new) with gradational contacts.

Named from exposures on and near Spud Mountain in Jerome area, Yavapai County. Representative section exposed in area from Spud Mountain to the Iron King mine.

**Spurwink Limestone** (in Casco Bay Group)[1]

Pennsylvanian(?) : Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

Named for exposures on Spurwink River, in Scarboro and Cape Elizabeth, Cumberland County.

**Squam Granite**[1]

Early Carboniferous: Northeastern Massachusetts.

Original reference: C. H. Clapp, 1910, Igneous rocks of Essex County, Mass, p. 9, 10, 12.

Occurs along Squam River and in Danvers, Essex County.

†Squankum Marl[1]

Eocene: Eastern New Jersey.

Original reference: T. A. Conrad, 1869, Am. Jour. Sci., 2d, v. 47, p. 363–364.

Occurs around Squankum, Monmouth County.

†Squantum Slates[1]

Mississippian(?) : Massachusetts.

Original reference: F. H. Lahee, 1914, Am. Jour. Sci., 4th, v. 37, p. 316.

**Squantum Tillite Member** (of Roxbury Conglomerate)[1]

Squantum Tillite

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: R. W. Sayles, 1914, Harvard Coll. Mus. Comp. Zoology Bull., v. 56, p. 141–170.

M. P. Billings, F. B. Loomis, Jr., and G. W. Stewart, 1939, Geol. Soc. America Bull., v. 50, no. 12, p. 1867, 1868. Tillite overlies Roxbury conglomerate of Carboniferous age.

Named for peninsula of Squantum in Quincy.

**Square Lake Limestone**[1]

Lower Devonian: Northeastern Maine.

Original reference: H. S. Williams, 1900, U.S. Geol. Survey Bull. 165, p. 21, 22, 26, 30–33, 51, 54–78.

J. M. Trefethen, 1947, Maine State Geologist Rept. 1945–1946, p. 70. Gray highly fossiliferous limestone, resembling the younger Ashland limestone in appearance. Devonian.

Named for exposures on west shore of Square Lake (or Sedgwick Lake), Aroostook County.

**Square Peak Volcanics**

Square Peak Volcanic Series

Tertiary: Western Texas.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 1027–1033, 1038–1039. Name Square Peak volcanic series proposed for lavas and pyroclastic rocks, approximately 3,500 feet thick, which constitute single unit covering 16 square miles in center of northern Quitman Mountains. Consist mostly of varicolored rhyolites with alternating flows of trachyte, quartz latite, andesite, and basalt and beds of tuff, flow conglomerate, and volcanic breccia. Volcanic rocks are commonly surrounded by folded sedimentary rocks on the north and west; at south flows are in contact with Quitman quartz monzonite; on northwestern Bug Hill, lavas of series lie on Bluff limestones.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 558. Probably in part equivalent to Buck Hill volcanic series.

Named for Square Peak in Quitman Mountains, southern Hudspeth County.

Squaw Flows

Tertiary: Northwestern Wyoming.

R. D. Krushensky, 1960, Dissert. Abs., v. 21, no. 4, p. 849. Augite-olivine andesites with some minor autobrecciated flows. Overlie Papoose volcanics and underlie Closed volcanics (both new).

Hurricane Mesa area, Park County.

**Squaw Bay Limestone**[1] (in Traverse Group)

Upper Devonian: Northeastern Michigan.

Original reference: A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 524–526.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3), 594–595. Described in Thunder Bay region. Thickness at type section 8 feet; subsurface data indicates greater thickness elsewhere. Overlies Thunder Bay limestone; considered top of Traverse group; an overlying shale or "transition zone" is not included in the Traverse.

Type locality: Squaw Bay shoreline of Partridge Point, center south line sec. 11, T. 30 N., R. 8 E., Alpena County. At high stages of Lake Huron, outcrop is covered by water.

Squaw Creek Diatomite Member (of Yakima Basalt)

[Miocene]: South-central Washington.

J. H. Mackin, 1947, (abs.) Northwest Sci., v. 21, no. 1, p. 33. Defined as occurring one flow below top of Yakima basalt. In Squaw Creek syncline, member consists of bed of essentially pure diatomite 7 to 17 feet thick, overlain conformably by lacustine siltstone as much as 10 feet thick.

Occurs in Yakima-Ellensburg area.

Squire Creek Quartz Diorite

Age not stated: Northwestern Washington.

J. W. Mills, 1960, Mining Eng., v. 12, no. 3, p. 274. Light-colored medium- to coarse-grained quartz diorite composed of plagioclase, hornblende, brown biotite, and minor quartz. Cut by fine-grained alplite dikes. Name credited to J. A. Vance (unpub. thesis).

Occurs on Jumbo Mountain, Snohomish County.

†Squirrel Creek Formation[1]

Eocene: Southern Texas.

Original reference: R. A. Liddle, 1921, Texas Univ. Bull. 1860, p. 77, map, columnar section.

Named for its largest exposure on east and west branches of Squirrel Creek, above old Capt. Smith ranchhouse, in Medina County.

**Squirrel Gulch Latite**[1]

Tertiary: Southern Colorado.

Original reference: W. S. Burbank, 1932, U.S. Geol. Survey Prof. Paper 169.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 195, 196. In Greater Bonanza district, the volcanics in order of succession are Rawley andesite, Bonanza latite, Squirrel Gulch latite, Porphyry Peak rhyolite, and Bremer [Brewer] Creek latite. In South Bonanza district, the volcanic sequence is roughly the same except Porphyry Peak rhyolite is missing and the Bonanza latite is replaced by Hayden Peak latite.

Well exposed at upper part of Squirrel Creek and in north-south ridges west of Kerber Creek in sec. 23, Bonanza district, Saguache County.

**Stacy Dolomite Member** (of Gatesburg Formation)[1]

Upper Cambrian: Central Pennsylvania.

Original reference: Charles Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 527, 534, 537.

J. L. Wilson, 1952, Geol. Soc. America Bull., v. 63, no. 3, p. 282, pls. 1, 4. In Everett quadrangle, consists of about 130 feet of alternating dark crystalline massive dolomite and less resistant thin-bedded lighter dolomite. Separated from overlying Ore Hill dolomite member by a 400-foot interval referred to as lower sandy Gatesburg member; separated from underlying Warrior limestone by 50 feet of covered strata.

Named for Stacy Hill, a knob 4 miles slightly west of south of Williamsburg, Blair County.

**Staendebach Member** (of Tanyard Formation)

Lower Ordovician: Central Texas.

V. E. Barnes and P. E. Cloud, Jr., 1945, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 34, p. 2, 19–27. Top member of formation. Thickness at type section 300 feet. Consists of calcitic facies 176 feet thick and dolomitic facies 124 feet. Overlies Threadgill member; underlies Gorman formation (new). Cherokee Creek section, San Saba County described.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 36, 37, 137, 158, 195, 211–227, pls. 2, 7, 37 [1946]. Thickness at type section 300 feet; elsewhere ranges from 229 feet in western part of Llano uplift to 356 feet in the east. As a rule, upper one- to two-thirds of member is limestone in northeastern part of Llano region and in Riley Mountains of Llano County, but in the southeast and west dolomite predominates and limestone is rare or absent. Member characteristically contains abundance of sparingly dolomoldic porcelaneous to semiporcelaneous chalcedonic to semichalcedonic chert. Type section and local stratigraphy described in detail.

Type section: Part of Cherokee Creek section, Cherokee area, southeastern San Saba County. Name derived from Staendebach survey, a part of the T. H. Young Ranch which includes upper beds of type section. Cherokee area, between towns of Cherokee and San Saba, is approximately bounded by Cherokee and Little Llano River fault zones on east, Simpson Creek fault zone on north, Cherokee-San Saba Road (State Highway 16) on west, and Cherokee-Chappel Road on south.

**Staff Limestone Member** (of Graford Formation)[1]

Staff Limestone (in Graford Group)

Upper Pennsylvanian: Central northern Texas.

Original reference: F. Reeves, 1922, U.S. Geol. Survey Bull. 736–E, p. 120.

Robert Roth, 1956, North Texas Geol. Soc. Guidebook Field Trip May 25–26, fig. 2. Shown on generalized columnar section as limestone in Graford group. Occurs above Wolf Mountain shales and sandstones and below unnamed shale below Winchell limestone. Canyon series.

Named for outcrops near Staff, Eastland County.

Stafford Limestone Member (of Marcellus Formation)

Stafford Limestone Member (of Skaneateles Shale)[1]

Middle Devonian: Western and central New York.

Original reference: J. M. Clarke, 1894, New York State Museum 47th Ann. Rept., p. 342, 351.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1772, chart 4. Reallocated to Marcellus formation. West of Cayuga Lake continuous with Mottville. Overlies Oatka Creek black shale; underlies Levanna black shale.

Named for development at Stafford, Genesee County.

Stafford Store Quartz Monzonite[1]

Post-Ordovician: Northeastern Virginia.

Original reference: J. T. Lonsdale, 1927, Virginia Geol. Survey Bull. 30, p. 40.

Typically developed near Stafford Store post office, Stafford County.

Staghorn Point Submember[1] (of Otisco Member of Ludlowville Formation)

Middle Devonian: Central New York.

Original reference: Burnett Smith, 1935, New York State Mus. Bull. 300, p. 46–47.

W. A. Oliver, Jr., 1951, Am. Jour. Sci., v. 249, no. 10, p. 707, 708, 713–716, fig. 6 (facing p. 724). Consists of mass of closely packed rugose coral skeletons; interstices filled with same shaly sediment as that constituting body of Otisco member. Interfingers laterally with surrounding shales; upper and lower contacts sharply defined except in fringing areas where complete gradation into normal shales may occur. Thickness few inches to 12 feet. Greatest in central part.

Typically shown just south of Staghorn Point on east side of Skaneateles Lake, about 1⅕ miles northwest from Spafford Landing, Skaneateles quadrangle. Traced over 15 miles from Skaneateles Lake to east of Tully quadrangle.

†Staked Plains Formation[1]

Pliocene: Northwestern Texas.

Original reference: R. T. Hill, 1890, Am. Assoc. Adv. Sci. Proc., v. 38, p. 243.

On the Staked Plains or Llano Estacado.

Stallard Limestone

Middle Ordovician: Southwestern Virginia.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 103. Listed in glossary of stratigraphic units. Attributes name to [B. N.?] Cooper (unpub. rept.).

Type locality: In Lee County.

**Stambaugh Formation** (in Paint River Group)

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 38. Iron-rich rocks that range from chlorite mudstone and slate to laminated cherty siderite-magnetic rock; only formation that is consistently magnetic over most of district. Underlies Fortune Lakes slate (new); overlies Hiawatha graywacke (new).

Named for town of Stambaugh, Iron County. Hill on which town is built is in large part underlain by the formation (here compressed into a tight complex syncline).

**Stamford Granite Gneiss**[1]

Precambrian: Southwestern Vermont and western Massachusetts.

Original reference: C. H. Hitchcock, 1861, Rept. geology Vermont, v. 2, p. 601.

Named for exposures at Stamford, Bennington County, Vt.

Stanaker Formation

Stanaker Member (of Ankareh Formation)

Upper Triassic: Northeastern Utah.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, pt. 1, p. 1260 (fig. 2), 1266 (fig. 5), 1271–1275. Formation name applied to basal conglomerate and overlying varicolored shales and sandstone which were included in the Nugget by Boutwell (1912, U.S. Geol. Survey Prof. Paper 77) and classed as Ankareh(?) by Sears (1924, U.S. Geol. Survey Bull. 751–G). Basal conglomerate is here named Gartra grit member. Main body of formation comprises alternation of shales which vary from maroon to red, pink, lavender, ocher, and green, and sandstones which are gray, red, purple, or yellow. Thickness of Gartra 18 to 88 feet; thickness of upper part of Stanaker, exclusive of Gartra, 120 to 394 feet. Underlies Nugget or Navajo sandstone; at type section, overlies Woodside shale; in western Uinta and central Wasatch Ranges, overlies Ankareh formation.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 166 (fig. 18), 180. Rank reduced to member status in Ankareh formation.

W. F. Scott, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 102, 103 (fig. 2), 104 (fig. 3). Units Stanaker and Gartra grit as used by Thomas and Krueger (1946) are included in units referred to in this report as Chinle and Shinarump(?).

Type section: At point where Vernal-Manila Highway crosses Brush Creek, about 10 miles north of Vernal, in north part sec. 6, T. 3 S., R. 22 E., Uintah County. Name derived from Stanaker Draw which lies in eastern part of T 3 S., R. 21 E., Uintah County.

**Standing Pond Volcanics**

Standing Pond Amphibolite Member (of Memphremagog Formation)

Standing Pond Amphibolite Member (of Waits River Formation)

Middle Ordovician(?): Eastern Vermont and western New Hampshire.

C. G. Doll, 1945, Vermont State Geologist 24th Rept., p. 16, 17, pl. 4. Named as member of Memphremagog formation. Fine- to medium-grained greenish-gray or black needle amphibolite with thin layers of banded hornblende schist. Thickness 10 to 300 feet. Occurs either entirely within the limestones or along their contact with the mica schists of the Memphremagog. Middle Silurian. Plate 4 shows age also as probably Lower Devonian.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Rank raised. Overlies Waits River formation. Geographically extended to New Hampshire. Middle Ordovician(?).

J. B. Lyons, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 108, 109, pl. 1. Rank reduced to member of Waits River formation. Transgresses from near top of Waits River into overlying Gile Mountain formation.

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 27, pls. 1, 3. Referred to as Standing Pond lava of Waits River formation [plate 1] and as Standing Pond volcanics [plate 3]. Lower to Middle Devonian(?).

L. M. Hall, 1959, Vermont Geol. Survey Bull. 13, p. 19–27, 38–39. Age of Waits River Silurian(?) and (or) Devonian.

Named from exposures impounding waters of Standing Pond at its west end, Strafford quadrangle, Vermont.

†Standish Flagstone (in Genesee Group)[1]

Upper Devonian: West-central New York.

Original reference: J. M. Clarke and D. D. Luther, 1904, New York State Mus. Bull. 63, p. 29.

I. W. Fox, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 7, p. 681–683. Consists of two distinct divisions: sandstones below and shales above. Subdivided to include Crosby sandstone at base and Keuka flagstone about midway between upper and lower divisions.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 11, pl. 3. Unit, along with West River shale, occupies interval between Middlesex shale above and Genundewa limestone lentil of Geneseo shale below. Complementary to West River shale; thickens eastward and latter thickens westward. Near base at south end of Seneca Lake is a 2-foot bed of dense massive fine-grained muddy sandstone or siltstone. Northwestward near Keuka Lake, base is marked by dense massive flagstone. Included in Genesee group.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 44, 63, 64, 66, 73. Term abandoned. Not recognized as stratigraphic unit distinct from West River shale in type area. Lenses originally defined as Standish do not correlate with Starkey tongue (new) of Sherburne formation or Milo tongue (new) of West River shale, both of which have erroneously been called Standish.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2819. Standish flagstones of Clark and Luther (1904) included in West River shale, redefined as member of Genesee formation. The Standish flags are insufficiently different lithologically to warrant separation from the West River.

Named for Standish Gully, town of Italy, Yates County.

**Standpipe Limestone Member** (of Arroyo Formation)

Standpipe Limestone Member (of Clear Fork Formation)[1]

Permian (Leonard Series): North-central Texas.

Original reference: M. G. Cheney, 1929, Texas Univ. Bull. 2913, p. 27, pl. 1.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on chart as uppermost member of Arroyo formation. Overlies Lytle limestone member; lies stratigraphically below Bullwagon dolomite member of Vale formation.

Type locality: At base of hill upon which is located standpipe in eastern part of Abilene, Taylor County.

Standpipe Sandstone (in Elmdale Formation)[1]

Pennsylvanian: Central northern Oklahoma.

Original reference: F. C. Greene, 1928, Oklahoma Geol. Survey Bull. 40CC.

In Pawnee County.

**Stanford Conglomerate**[1]

Probably Tertiary, upper: Central northern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

Occurs in very prominent hills rising above flat prairie near Stanford, Judith Basin County.

**Staniukovich Shale**[1]

Upper Jurassic: Southwestern Alaska.

Original reference: W. W. Atwood, 1911, U.S. Geol. Survey Bull. 467, p. 25, 38.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 978. Of Portlandian (Upper Jurassic) age.

Exposed on Herendeen Bay, also on Staniukovich Mountain, and east to Port Moller; Alaska Peninsula.

**Stanley Shale**[1]

Stanley Group

Mississippian: Central southern and southeastern Oklahoma and western Arkansas.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

H. D. Miser, 1920, Geol. Soc. America Bull., v. 31, p. 125. Includes Hatton tuff lentil (new).

N. H. Stearn *in* J. M. Hansell and J. C. Reed, 1935, Am. Inst. Mining Metall. Engineers Trans., v. 115, p. 245; N. H. Stearn, 1936, Econ. Geology, v. 31, no. 1, p. 12–16. Thickness of shale about 2,500 feet in Little Missouri River part of Arkansas quicksilver district. Includes Parker Hill and Gap Ridge members (both new) in lower part.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 856, 864–878. Rank raised to group. Divided into (ascending) Ten Mile Creek, Moyers, and Chickasaw Creek formations (all new). Maximum thickness about 7,000 feet. Underlies Jackfork group. Basal group of Pushmataha series (new) which is included in the Bendian.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 35). Stanley shale shown on correlation chart above Hot Springs sandstone and below Jackfork sandstone. Morrow series.

C. L. Cooper, 1945, Jour. Geology, v. 53, no. 6, p. 390–397. Stanley and Jackfork formations have been correlated with Pennsylvanian, but their exact age is still a problem. Flora from these formations is unlike any known flora in North America and is younger than that from Wedington sandstone member of Fayetteville shale (Chester) and older than that in Baldwin coal in Bloyd shale of Morrow group (middle Pottsville).

B. H. Harlton, 1947, Tulsa Geol. Soc. Guidebook Field Conf., May 9 and 10, p. 41. Includes Albion shale (new).

W. H. Hass, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 7, p. 1578. On basis of conodont studies, it is believed that some part of Stanley shale—including Hatton tuff lentil and barite deposits of Arkansas—is Mississippian (Meramec) in age and correlative with Caney shale of Oklahoma and Barnett formation of Texas.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Shale mapped as Mississippian and Pennsylvanian.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 22–41, pl. 1. Group attains best development in central Ouachitas where it comprises about 11,000 feet of strata, prevailingly shaly but with sandstone becoming prominent in upper 1,500 feet. Includes (ascending) Tenmile Creek, Moyers, and Chickasaw Creek formations. Underlies Jackfork group. Mississippian, Meramecian.

H. D. Miser and T. A. Hendricks, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1829–1834. Age Mississippian. Presentation of brief summary of development of different age interpretations that have been given for Stanley shale, Jackfork sandstone, and Johns Valley shale.

Named for Stanley, Pushmataha County, Okla.

Stansbury Formation

Devonian-Mississippian(?): Northwestern Utah.

W. L. Stokes and D. E. Arnold, 1958, Utah Geol. Soc. Guidebook 13, p. 135–148; J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 36–39, geol. map. Includes clastic section which underlies Pinyon Peak limestone and overlies pronounced Late Devonian unconformity. Varies rapidly in facies and thickness from place to place. Pebble and cobble conglomerate characterize formation at its northern outcrops near Flux. Southward, in Mining Canyon, formation is predominantly siltstone and vitreous sandstone with minor thin beds of platy dark-gray limestone and dolomite; quartzitic sandstone overlies entire unit with some angularity within the formation. Along the southern and western side of the range consists of minor conglomerate beds with interbedded limestone and dolomite. Thickness about 1,700 feet at northern end of range. Overlies Simonson(?) dolomite. Devonian-Mississippian(?).

J. K. Rigby, 1959, Utah Geol. Soc. Guidebook 14, p. 14 (fig. 1), 29 (fig. 9), 30–31, pl. 1. Described in southern Oquirrh Mountains where it is 10 to 190 feet thick; underlies Gardner dolomite and overlies Opex dolomite. Upper Devonian.

Type section: Well exposed and continuous outcrop lying partly in sec. 6, T. 2 S., R. 6 W., and continuing westward into sec. 1, T. 2 S., R. 7 W. No one section is entirely "typical," but all constituent lithologic types are best exposed in Stansbury Mountain section. Name taken from Stansbury Range, Tooele County.

Stanton facies (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 121–125. Southernmost facies of formation. Merges with Boone Gap facies (new) to the west and with Bluestone facies (new) to the northeast. Consists almost entirely of clayey shale, generally blue gray or drab with persistent, though thin, Clay City siltstone member (new) near base. Thickness ranges from 275 to 300 feet or more. Underlies Christy Creek member of Brodhead formation, Morehead facies (all new); overlies Sunbury black shale.

Typical exposure: Along secondary road leading from Stanton to Hatcher Creek Church and School, at north side of Red River, 1 mile north-northeast of Louisville and Nashville Railroad Station at Stanton, Powell County. Named for city of Stanton.

**Stanton Limestone** (in Lansing Group)[1]

Stanton Limestone Member (of Lansing Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: G. C. Swallow and F. Hawn, 1865, Kansas Geol. Survey Rept. on Miami County, p. 6.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 117; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 14. Stanton formation in Lansing group; overlies Vilas shale; underlies Weston shale of Pedee group;

includes (ascending) Captain Creek limestone, Eudora shale, Stoner limestone, Rock Lake shale, and South Bend limestone members. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 24, fig. 5. Uppermost formation of Lansing group. Present only in western Madison, eastern Adair, and southern Ringgold Counties. In Ringgold County, consists of 13 feet of light- to dark-gray thinly bedded argillaceous limestone containing shale partings and many white brachiopod and gastropod sections. In Adair and Madison Counties, unit is 8 feet thick and commonly is a sequence of three gray and black nodular limestones separated by shales. Upper shale is gray and fossiliferous with brachiopod and crinoid fragments. Lower shale is black and carbonaceous. Overlies Vilas shale; underlies Douglas-Pedee group.

Type locality: In roadcut near SE cor. sec. 3, T. 13 S., R. 21 E., and adjacent area along Captain Creek. Named for Stanton, Miami County, Kans.

†Stanton limestone series[1]

Pennsylvanian: Eastern Kansas.

Original reference: G. C. Swallow, 1866, Kansas Geol. Survey Prelim. Rept., p. 20.

Probably named for its topmost member, the Stanton limestone.

Stapp Conglomerate Member (of Union Valley Formation)

Pennsylvanian (Morrow Series): Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 890, 893–895. Proposed for the conglomerate occurring at base of formation. Consists of rounded pebbles and boulders of chert and limestone, ranging in thickness from fraction of an inch to masses 3 feet in diameter; bedding planes absent; intercalated thin lenses of sandstone and conglomeratic sandstone show crossbedding; near top is thin black shale which is overlain by coarse loosely consolidated conglomerate. Overlies Wesley formation (new). Unit formerly considered as base of the Atoka.

Well exposed in Kansas City Southern Railway cut, 1 mile south of Stapp in SW¼SW¼ sec. 7, T. 3 N., R. 26 E., Le Flore County.

†Staran series[1]

Upper(?) Triassic: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 59.

Named for exposures in Star Peak Mountain, Humboldt County.

Starbo altered tuffs

*See* Keechelus Andesitic Series.

**Stark Complex**

Precambrian: Northeastern New York.

A. F. Buddington, 1948, Geol. Soc. America Mem. 28, p. 24, 25–28. Quartz syenitic complex. Attitudes of foliation, arrangement of various lithologic facies of the complex, and structural relationships to country rock are all consistent with hypothesis that Stark, Loon Lake (new), and Jennings Mountain (new) complexes are all exposed on core of domes or anticlines which are either closely folded or isoclinally overturned. Pyroxene quartz syenite is exposed on core of each, and hornblende quartz syenite and hornblende granite overlie it.

Forms elongate mass extending southwest from Santa Clara, Franklin County. Complex is about 45 miles long and underlies about 275 square miles.

**Stark Shale[1] Member** (of Dennis Limestone or Formation)

Stark Shale Member (of Hogshooter Formation)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, western Missouri, and northern Oklahoma.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 91, 97.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 43; 1952, Oklahoma Geol. Survey Bull. 69, p. 59. In Oklahoma, considered member of Hogshooter formation. Overlies Canville limestone member; underlies Winterset limestone. Thickness 3 to 10 feet.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Shale member of Dennis formation. Overlies Canville limestone member; underlies Winterset limestone member. This is classification agreed upon by State Geological Survey of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11–12. Galesburg formation redefined to exclude Canville limestone and Stark shale. Latter units included in Dennis formation.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 421. Thickness about 4 feet near Winterset, Iowa.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Member of Dennis limestone. Dark gray and fossiliferous at top; black fissile at base. Thickness 1.8 to 2.9 feet in Madison County; 5 feet in cores from Pottawattamie County. Overlies Canville limestone member; underlies Winterset limestone member.

Type locality: Near Stark, Neosho County, Kans.

Starkey Tongue (of Sherburne Formation)

Upper Devonian: West-central New York.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 66–68. Name proposed for interbedded medium quartz siltstone flags, gritty micaceous blue-gray and dark-gray shales, and some black shales; flags become thinner westward. Thickness 140 feet in type area; maximum 240 feet. In type locality, top is marked by Keuka flagstone lentil, and base is placed at Crosby lentil; first appearance of heavy and closely spaced flags identifies base in area to the east where Crosby not recognized. Penetrates West River shale between Penn Yan tongue (new) below and Milo tongue (new) above. Unit erroneously termed Standish; highest calcareous crinoidal bed was erroneously designated Parrish limestone, and a black shale band was incorrectly called Rhinestreet shale.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2825 In vicinity of Keuka and Seneca

Lakes, Ithaca member of Genesee formation of this report was named Starkey tongue of Sherburne formation by Grossman. However, this sequence of silty rocks is lateral extension of Ithaca member from its type area and is not tongue of Sherburne as Grossman believed.

Type locality: Crosby Gully on east side of Keuka Lake. Named from Starkey Township, Yates County, on west side of Seneca Lake. Extends from Cayuga Lake area to within few miles of east shore of Canandaigua Lake.

Starmount Limestone[1]

Middle Cambrian: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, 435, map.

Named for Starmount mine, Elkhorn mining district, Elkhorn region.

Star Mountain Rhyolite (in McCutcheon Volcanic Series)

Tertiary: Southwestern Texas.

G. K. Eifler, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 4, p. 345, pl. 1. Named applied to thick rhyolitic lavas overlying Huelster formation (new) and underlying Seven Springs formation (new). Rock is typically black to brownish black, but some parts, particularly the lower, are green, greenish gray, and purplish lavender. Thickness at type locality 496 feet; thins to northeast; north of Jeff Ranch it is 262 feet thick.

Type locality: Star Mountain, Barrilla Mountains, Reeves County.

**Star Peak Formation**[1]

**Star Peak Group**

Middle and Upper Triassic: Northern Nevada.

Original references: C. King, 1876, U.S. Geol. Expl. 40th Par. Atlas, map 5; 1878, U.S. Geol. Expl. 40th Par., v. 1, p. 267–278, 544.

H. E. Wheeler, 1940, 6th Pacific Sci. Cong. Proc., v. 1, p. 369, 373 (fig. 2) [preprint 1939]. Middle Triassic. Overlies Weaver rhyolite.

R. E. Wallace and others, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–220. Rank raised to group. Includes Prida formation below and Natchez Pass formation. Overlies Weaver rhyolite of Koipato group with angular unconformity. Underlies Grass Valley formation, possible disconformity. Middle and Upper Triassic.

Named for development at Star Peak Mountain in West Humboldt Range.

**Star Point Sandstone** (in Mesaverde Group)[1]

Star Point Sandstone

Upper Cretaceous: Central eastern Utah.

Original reference: E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc America Bull., v. 36, p. 442.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 182–183, fig. 2, pl. 3. Redefined in area to north and east of Spring Canyon, keeping base as base of Panther sandstone, but placing upper boundary at top of Storrs sandstone. Spring Canyon tongue reassigned to overlying Blackhawk formation. Change of upper boundary impractical to the west and south in Wasatch Plateau where Spring Canyon, Storrs, and Panther sandstones unite to form single massive littoral marine tongue. Dated as medial Montana. Not included in Mesaverde group—a term no longer used in Book Cliffs. Present only in western part of Book Cliffs.

Named from Star Point, a striking headland of Gentry Mountain southwest of Price, and about 3 miles west of southwest corner of Castlegate quadrangle, Carbon County. In Wasatch Plateau and Book Cliffs.

†Starr Conglomerate[1]

†Starrs Conglomerate[1]

Lower Cambrian: Southeastern Tennessee.

Original reference: C. W. Hayes, 1895, U.S. Geol. Survey Geol. Atlas, Folio 20, p. 2.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 29. Starr conglomerate is a synonym of Cochran conglomerate and should be abandoned.

Named for exposure near Starr Mountain, Monroe County.

Starrs Cave Formation (in North Hill Group)

Mississippian (Kinderhook Series): Southeastern Iowa and northwestern Illinois.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 31, pl. 1. Proposed for a buff to light-brownish-gray coarsely oolitic limestone that is locally dolomitic and contains small amounts of silt. Thickness 2⅔ feet; in six wells in Hancock County, Ill., 2 to 12 feet. Conformably overlies Prospect Hill siltstone; unconformably underlies Burlington limestone. Name credited to Charles Collison.

Type section: Flint River bluff near Starrs Cave, NW¼NW¼ sec. 19, R. 2 W., T. 70 N., Des Moines County, Iowa.

Starrucca Sandstone[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: C. S. Prosser, 1894, U.S. Geol. Survey Bull. 120, p. 78.

Starrucca Shale (in Catskill or Chemung Formation)[1]

Starrucca (Starucca) Shale (in Cayuta monothem)

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. $G_5$, p. 59, 70, 73.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7), 47, 50. Starruca shale was originally differentiated by White (1881) from overlying New Milford red shale and from underlying "Chemung," but draftsman apparently included it by mistake with New Milford red shale. Just where Willard would draw boundary of his Kingsley, which is White's New Milford under new geographic name, is not clear. It is herein considered that the Starruca is a distinct unit, which comes at about proper position to constitute top of Cayuta shale monothem.

Well exposed along Jefferson Branch Railroad above Starucca [Starrucca] Bridge, also near mouth of Starucca Creek, Susquehanna County.

State Bridge Siltstone

State Bridge Siltstone Member (of Maroon Formation)

Permian(?): Northwestern Colorado.

C. F. Bassett, 1939, Geol. Soc. America Bull., v. 50, no. 12, pt. 1, p. 1853, 1864. Upper member of Maroon formation. Overlies Rock Creek member (new). Chiefly thin-bedded micaceous brick-red siltstone, shale, and fine limy sandstone. Thickness 525 feet. Name credited to H. F. Donner (unpub. thesis).

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1392–1393. Donner's manuscript name State Bridge is used as formation and applied in Gore area to upper Pennsylvanian or Permian sediments which lie between Battle Mountain formation and the Triassic. Thickness on North Fork of Piney River 225 feet; 750 feet on Red and White Mountain. Donner's type locality stated; there formation is 525 feet thick, conformably overlies McCoy formation, and disconformably underlies Shinarump conglomerate.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 823–825. Permian (Guadalupian). On eastern side of McCoy area, State Bridge overlies Maroon formation, but on western side, Schoolhouse tongue of Weber sandstone lies between Maroon and State Bridge. Since Maroon formation is here limited to beds that underlie Schoolhouse tongue, unit termed South Canyon [Creek] dolomite member of Maroon (Bass and Northrop, 1950), in vicinity of Glenwood Springs appears to be member of State Bridge formation.

Type section: South slope of Yarmony Mountain, 0.3 mile north of State Bridge, Eagle County.

State Farm Gneiss

Precambrian: Central Virginia.

C. B. Brown, 1937, Virginia Geol. Survey Bull. 48, p. 13–14. Relatively uniform even-banded gneiss with well-developed foliation. Light to dark gray and medium grained. Shows only limited amount of folding in any single outcrop; and shows numerous divergences in structure from regional trend.

Type locality: State Farm quarries on Chesapeake and Ohio Railway, Goochland County. Named from typical outcrops near State Farm.

†State Line Serpentine[1]

Precambrian: Northeastern Maryland and southeastern Pennsylvania.

Original reference: F. D. Chester, 1889, Pennsylvania 2d Geol. Survey Ann. Rept. 1887, p. 93–105.

Named for fact it occurs fully 16 miles along boundary between Pennsylvania and Maryland.

Staten Island Serpentine[1]

Precambrian(?): Southeastern New York and New Jersey.

Original reference: F. J. H. Merrill, 1898, New York State Mus. 15th Ann. Rept. v. 1, p. 21–31.

Forms elevated part of Staten Island, N.Y., and the Knob at Castle Point, in Hoboken, Hudson County, N.J.

State Pond Member (of Springville Shale)

Mississippian (Valmeyer): Southern Illinois.

Charles Collinson and A. J. Scott, 1958, Illinois Geol. Survey Circ. 254, p. 1, 3, 4, 5. Proposed for unit of soft shale at base of redefined Springville shale. Lower part is greenish and calcareous; upper 1½ inches consists of dark-green to black phosphate nodules. Thickness 14 to 15 inches. Overlies Chouteau formation; underlies hard tannish to greenish-gray poorly laminated shale characteristic of upper part of Springville.

Exposed in south bank of stream below spillway of State Pond Dam in NW¼SE¼ sec. 14, T. 12 S., R. 2 W., Union County.

**State Quarry Limestone**[1]

Upper Devonian: Central eastern Iowa.

Original reference: S. Calvin, 1897, Iowa Acad. Sci. Proc., v. 4, p. 16–21.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1783, chart 4. Occupies erosion pockets in Cedar Valley limestone in limited area. Fauna suggests a position low in Upper Devonian, and formation has been placed at top of Genesee group; possibly it should be placed higher in Naples stage (Ithaca).

Named for State quarry (or North Ben quarries), Penn Township, Johnson County.

†State Road Conglomerate[1]

Precambrian (lower Huronian): Northwestern Michigan.

Original reference: C. R. Van Hise and C. K. Leith, 1911, U.S. Geol. Survey Mon. 52, p. 257.

Occurs north of Mud Lake and along an old road known as State Road in Marquette district.

**Staunton Formation**[1]

Middle Pennsylvanian: Southwestern Indiana.

Original reference: E. R. Cumings, 1922, Handb. Indiana Geology, pt. 4, Sep. Pub. 21, p. 408, 525, 529, chart.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 25). Shown on correlation chart as including Velpen limestone.

C. E. Wier, 1950, U.S. Geol. Survey Coal Inv. Map C–1. Described in Clay, Greene, and Sullivan Counties. As defined by Cumings contained Coals III, IIIa, and IV. Stratigraphic break is present above Coal III and Staunton is here restricted to rocks above this break and unconformity above Coal II. Restricted Staunton comprises sandstone and shale, and averages about 85 feet in thickness. Remainder of Staunton as originally defined is assigned to Linton formation (new). Overlies Brazil formation (not exposed in area of this report, Jasonville quadrangle).

Named for Staunton, Clay County.

Stayton Lavas[1]

Miocene, middle: Northwestern and central northern Oregon.

Original reference: T. P. Thayer, 1933, Pan-Am. Geologist, v. 59, no. 4, p. 317.

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 8–9, fig. 1. Stayton lavas overlie Illahe formation in Salem Hills and have been traced eastward continuously to crest of Mehama anticline. Maximum thickness about 400 feet in Salem Hills; increase in thickness toward the northeast; less than 200 feet thick east and southeast of Stayton. Unconformable above Illahe and Mehama formations Stayton lavas may be marginal flows of Columbia River basalt and are tentatively correlated with them. Middle Miocene.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 5. Columbia River basalts in vicinity of Salem and Stayton, Oreg., were named Stayton lavas by Thayer (1939) because Columbia River basalt had not yet been traced southward into that area. However, it seems advisable to drop name Stayton lavas in preference to Columbia River basalt, and except for intervening alluvial fill of Willamette River, exposures would be continuous.

R. E. Corcoran and F. W. Libbey, 1956, Oregon Dept. Geology and Mineral Industries Bull. 46, p. 7–8, pl. 1. In Salem Hills area. Eugene formation is overlain unconformably by series of basalts called Salem lavas in Salem quadrangle by Mundorff (1939, unpub. thesis) and Stayton lavas in that general region by Thayer (1939). Salem-Stayton lavas are time-rock equivalents of Columbia River basalt, if not actually part of same series of flows.

I. S. Allison and W. M. Felts, 1956, Geology of the Lebanon quadrangle, Oregon (1:62,500): Oregon Dept. Geology and Mineral Industries. Thickness 500 to 600 feet in Lebanon quadrangle. Unconformably overlies Eugene formation.

Forms Salem Hills, southwest of Salem and also Stayton Basin east of Salem, Marion County.

**Steamboat Limestone**[1]

Middle Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 37.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1089–1090. Middle Cambrian section in Lewis and Clark Range redefined. Steamboat limestone has proved to be part of upper Dearborn limestone which was repeated in Dearborn section by low angle overthrust. Therefore, rocks to which name Steamboat was applied do not exist, and this name is herein applied to limestone and shale formerly designated Gordon Mountain limestone which lies betwen Pagoda or Pentagon and overlying Switchback formation. Thickness about 216 feet.

Charles Deiss, 1939, Geol. Soc. America Spec. Paper 18, p. 45. Overlies Pentagon shale in northern sections and Pagoda limestone in central and southern sections. Thickness 216 feet near Pentagon Mountain; 353 feet on ridge between Kid and Gordon Mountains. Type section described in detail.

Type locality: Crest of Prairie Reef from 54 feet below top of peak northwestward to base of Switchback shale. Name taken from Steamboat Mountain, which lies just north of Dearborn River [Lewis and Clark County].

**Steamboat Hills Rhyolite**

Pliocene or Pleistocene: Central western Nevada.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 58–59, pl. 3. Described as extrusive domes of fresh pumiceous rhyolite, containing very sparse phenocrysts of sanidine, quartz, plagioclase, and biotite. Some of the rhyolite is perlite and very little is obsidian. Younger than Lousetown formation in Virginia City quadrangle.

Named for occurrence in Steamboat Hills, 2½ miles west of Virginia City quadrangle. Also occurs in two widely separated areas within quadrangle, one along west base of Virginia Range, northeast of Steamboat Hills, and other at Sutro Springs, on east side of Flowery Range.

Stearns Magma Series

Precambrian (middle Keweenawan) : Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1001, 1002, 1005–1009, pl. 1. Includes (ascending) Crystal Gray quartz monzonite, quartz latite porphyry, porphyritic granite, Rockville quartz monzonite, and St. Cloud Red granite.

Occurs in parts of Stearns, Wright, Sherburne, Benton, and Mille Lacs Counties.

**Stearns Shale** (in Council Grove Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 230, 233, 234, 235, 237.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46; K. L. Walters, 1954, Kansas Geol. Survey Bull. 106, p. 48, pl. 1. Contains minor amount of impure limestone; mostly gray to olive but red shale occurs in middle and lower parts; locally contains thin coal bed in Lyon and Morris Counties, Kans. Thickness ranges from about 7 feet in southern Kansas to about 20 feet in northern part of State. Underlies Eiss limestone member of Bader limestone; overlies Morrill limestone member of Beattie limestone. Wolfcamp series.

Type locality: South of Stearns School, 1½ miles northeast of Humboldt, Richardson County, Nebr. Type section now obscured, but member typically exposed along a north-south road, 6 miles south and 1½ miles east of Humboldt.

**Steele Shale** (in Montana Group)[1]

Upper Cretaceous: Eastern and central Wyoming.

Original reference: N. H. Darton, Eliot Blackwelder, and C. E. Siebenthal, 1910, U.S. Geol. Survey Geol. Atlas, Folio 173.

C. J. Hares and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 51. Stratigraphic section [northeastern part of Wind River basin and adjacent areas in central Wyoming] shows that term Cody shale replaces terms Carlile shale, Niobrara shale, and Steele shale as used in this area by Hares (1916, U.S. Geol. Survey Bull. 641–I).

G. H. Horn, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–164. Thickness in Sussex and Meadow Creek oil fields, Johnson and Natrona Counties, 2,240 feet, a little more than one-half of formation exposed. Includes (ascending) Shannon sandstone member and Sussex sandstone member (both exposed). Underlies Parkman member of Mesaverde formation; overlies Niobrara formation.

J. M. Parker, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 90, 98. Stratigraphic unit terms Lewis, Mesaverde, Steele, Cody, Ferguson, and Ash Creek are believed to be misnomers and should not be used in Powder River basin.

J. R. Bergstrom, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 114 (columnar section). In southeastern Wyoming, underlies Allen Ridge formation (new).

Type locality: Fort Steele on North Platte River, Carbon County.

Steele Valley Granodiorite[1]

Upper Jurassic(?): Southern California.

Original reference: P. H. Dudley, 1935, California Jour. Mines and Geology, v. 31, no. 4, p. 491, 502, map.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 76. Rocks called Steele Valley granodiorite by Dudley (1935) belong to Woodson Mountain granodiorite, which is considered Cretaceous.

Occurs in Steele Valley, in southern part of Perris-Elsinore area, Riverside County.

Steels Knob chert facies (of Muldraugh Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 75, 201–211. Characterized by bedded chert, in layers up to 4 feet thick, which constitutes as much as 50 percent of the formation at places. Thickness 60 to 75 feet. Underlies Harrodsburg limestone; overlies Floyds Knob formation. Merges with West Point facies (new) on the west and Maretburg facies (new) on the east.

Well exposed along State Highway 49, Casey County, at steep hill from plateau to valley of Martins Creek, around Steels Knob. Name taken from topographic promontory in Casey County known as Steels Knob.

**Steens Basalt**[1]

Pliocene, middle: Southeastern Oregon.

Original reference: R. E. Fuller, 1931, Washington Univ. Pub. Geol., v. 3, no. 1, p. 7–130.

A. M. Piper, 1936, Oregon Country Geol. Soc. News Letter, v. 2, no. 8, p. 10. Steens basalt unconformably overlies siliceous extrusives in marginal upland along eastern half of Harney basin. Maximum thickness 3,000 feet. Underlies Danforth formation (new).

A. M. Piper, T. W. Robinson, and C. F. Park, Jr., 1939, U.S. Geol. Survey Water-Supply Paper 841, p. 26 (table), 49–51, pl. 2. Basalt series named Steens Mountain basalt by Fuller (1931) is here designated Steens basalt. At type section, series is more than 3,000 feet thick and comprises many layers whose thickness varies but averages about 10 feet. Underlies Danforth formation; in type area, overlies an andesitic series. Miocene.

Howel Williams, and R. R. Compton, 1953, U.S. Geol. Survey Bull. 995–B, p. 24 (table), 29–30, pl. 9. Described as cliff-forming flows of olivine basalt with rare partings of tuff. Overlies Steens Mountain volcanic series; in the High Steens, a distinct unconformity separates the two units, but below Smith Flat the two series are either conformable or their divergence of dip is so slight as to be imperceptible. Middle Pliocene.

Type section: Along highest part of east face of Steens Mountain, about 20 miles east of head of Donner and Blitzen Valleys, Harney County.

†Steens Mountain Basalt[1]

Miocene: Southeastern Oregon.

Original reference: R. E. Fuller, 1931, Washington [State] Univ. Pub. in Geology, v. 3, no. 1, p. 7–130.

A. M. Piper, T. W. Robinson, and C. F. Park, Jr., 1931, U.S. Geol. Survey Water-Supply Paper 841, p. 49. Basalt series named Steens Mountain basalt by Fuller (1931) is here designated Steens basalt.

Exposed almost continuously for 100 miles on east scarp of Steens and Pueblo Mountains.

Steens Mountain Formation[1]

Pliocene: Southeastern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Typically exposed on Steens Mountain, Harney County.

**Steens Mountain Volcanic Series**

Steens Mountain Andesitic Series[1]

Pliocene, lower: Southeastern Oregon.

Original reference: R. E. Fuller, 1931, Washington [State] Univ. Pub. in Geology, v. 3, no. 1, p. 7–130.

Howel Williams and R. R. Compton, 1953, U.S. Geol. Survey Bull. 995–B, p. 24 (table), 28–29, pls. 8, 9. Described as Steens Mountain volcanic series. Consists of olivine and augite basalts and amygdaloidal andesites rich in zeolites. Locally thick sheets of dacite and rhyolite cap the basic lavas. Pyroclastic interbeds rare and thin. Total thickness more than 3,000 feet in Southern Steens and Pueblo Mountains. Underlies Steens basalt; unconformably overlies Pike Creek volcanic series. Early Pliocene.

Occurs in area of Steens Mountain, Harney County.

**Steep Gully Member** (of Foley Formation)

Pliocene: Southwestern Louisiana (subsurface)

P. H. Jones *in* P. H. Jones, A. N. Turcan, Jr., and H. E. Skibitzke, 1954, Louisiana Dept. Conserv. Geol. Bull. 30, p. 59–60. Comprises basal deposits of Foley penetrated below a depth of 200 feet by water wells and oil-test wells in vicinity of Elizabeth. Consists of a sequence of medium- to fine-grained sands interbedded with light-gray, gray-green, and blue structureless to thinly laminated clays. Beds dip south-southwestward at rates ranging from about 60 to 80 feet per mile; estimated that bottom of formation is at a depth of about 2,500 feet at Mamou, about 18 miles downdip from [Oakdale]. Underlies Mamou member (new) with contact gradational.

Named from Steep Gully Branch near town of Elizabeth in T. 2 S., R. 4 W., in Allen Parish, about 8 miles northwest of Oakdale. Most reliable records of member were obtained during drilling wells at Oakdale.

**Steilacoom Gravel**[1]

Pleistocene (Wisconsin): Western Washington.

Original reference: B. Willis, 1898, Geol. Soc. America Bull., v. 9, p. 111.

Type section: The Steilacoom Plains, which extend for many miles south and southwest from Tacoma, Puget Sound region.

Steins Mountain Quartz Latite Porphyry

Tertiary: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 69, table 1, pl. 1. Columnar jointed flows and devitrified tuffs. Rock is pinkish-gray porphyritic-aphanitic, with quartz and feldspar phenocrysts and numerous lithic and vitric fragments, many of which are flattened and elongated, imparting an eutaxitic structure to the rock. Conformably overlies unnamed basalt. No rock overlies unit in mapped area, but it is intruded by latite porphyry dikes.

Mapped in north-central part of Peloncillo Mountains, Hidalgo County, where it forms upper part of Steins Mountain and the hills to the east. North and northwest of mapped area it is extensively exposed.

Stennett Limestone (in Shawnee Formation)[1]

Pennsylvanian: Southwestern Iowa.

Original reference: S. W. Beyer and I. A. Williams, 1907, Iowa Geol. Survey, v. 17, p. 480.

Typically developed at Stennett, Montgomery County.

**Stensgar Dolomite** (in Deer Trail Group)

Stensgar Dolomite Member[1] (of Deer Trail Argillite)

Precambrian (Belt Series): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, v. 57, map.

W. A. G. Bennett, 1941, Washington Div. Geology Rept. Inv. 5, p. 7. Termed a dolomite in Deer Trail group.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Named as next to youngest of five formations in Deer Trail group. Overlies McHale slate (new); underlies Buffalo Hump formation (new).

Occurs near Stensgar Mountain, Stevens County.

Stephens Sandstone (in Slatestone Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Includes both massive and thin phases. Near Stephens siding, consists of about 40 feet of laminated silty sandstone with an alternation of dark- and light-colored fine sand and silt. Separated from underlying Crooked Fork group (new) by shale interval 30 to 140 feet thick; separated from overlying Petros sandstones (new) by shale interval 40 to 240 feet thick that contains Coal Creek coal.

Named from exposures along State Highway 62, south of Stephens siding, Petros quadrangle, Morgan County.

†Stephensport Bed (in Chester Group)[1]

Mississippian: Northwestern Kentucky and southwestern Indiana.

Original reference: A. F. Foerste, 1910, Kentucky Geol. Survey Rept. Prog. 1908–1909, p. 84.

Named for Stephensport, Breckinridge County, Ky.

Stephensport Group[1]

Mississippian (Chester Series): Western Kentucky, Illinois, and southern Indiana.

Original reference: E. R. Cumings, 1922, Indiana Dept. Conserv. Pub. 21, pt. 4, p. 514 (footnote).

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 37–44, pl. 1. Cumings (1922) suggested name Stephensport as a group to include formations now known as Glen Dean, Hardinsburg, Golconda, and Big Clifty. Term was little used. Proposed here to revive Cuming's group name, Stephensport. As here redefined consists of (ascending) Beech Creek limestone, Big Clifty formation, Golconda limestone (restricted), Hardinsburg formation, and Glen Dean limestone (restricted). Thickness 128 to 158 feet. Overlies West Baden group (redefined); unconformably underlies Mansfield formation.

Named for town of Stephensport, Breckinridge County, Ky., in vicinity of which all formations of group are exposed.

Stepovak Series[1]

Eocene: Southwestern Alaska.

Original reference: Charles Palache, 1904, Harriman Alaska Expedition, v. 4, p. 74.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, p. 12. "Lower beds" of series exposed in vicinity of Chichagof Peak, about 85 miles northeast of Belkofski Bay, described as pyroclastics of early Eocene age.

Occupies most of area studied about Chicagof Cove, Stepovak Bay, on Alaska Peninsula.

Steptoean series[1]

Lower Ordovician: Nevada.

Original references: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53; 1924, Pan-Am. Geologist, v. 41, p. 78.

Named for development in Egan Mountains, which faces Steptoe Valley.

**Sterling Granite Gneiss**[1]

Carboniferous or post-Carboniferous: Eastern Connecticut and Rhode Island.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 131–136, 152, 154, 155, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 56–65, pl. 1. Discussed as an orthogneiss. Variety of granitic rocks associated with unit. Pre-Permian.

A. W. Quinn, 1951, Bedrock geology of the North Scituate quadrangle, Rhode Island: U.S. Geol. Survey Quad. Map [GQ–13]. Geographically restricted from eastern Rhode Island. Since unit has been assigned a late Carboniferous or post-Carboniferous age, it seems desirable to give a new name, Scituate granite gneiss, to pre-Pennsylvanian granite gneiss mapped in North Scituate quadrangle.

G. E. Moore, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–105. Unit herein named Ten Rod granite gneiss was included in Sterling granite gneiss by Gregory (1906).

C. B. Sclar, 1958, Connecticut Geol. Nat. History Bull. 88, p. 126–128, geol. map. Results of a study of bedrock geology of 55 square miles in eastern part of New London County, Conn. Bedrock consists of a group of metamorphic foliates known collectively as Putnam gneiss, a basic magmatic intrusive mass known as Preston gabbro, and gneisses of granitic composition referred to as Sterling granitic gneisses. Sterling consists of two mappable units, a granitic augen gneiss and an alaskitic to microalaskitic gneiss.

Crops out in Sterling Township, Windham County, Conn.

Sterling Station iron ore[1]

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 49. Hematitic limestone horizon occurring at top of Reynales on Salmon Creek and in Wolcott core and, in upper part of Bear Creek shale is remarkably persistent. Chadwick (1918) named the horizon Sterling Station iron ore. The objection to considering it as a formation is its thinness and the fact that it occurs as stringers imbedded in uppermost part of underlying formation and not as a distinct unit in itself.

Named for occurrence at Sterling Station, Cayuga County.

Stetson Brook Limestone (in Tacoma Series)

Cambro-Ordovician(?): Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Listed in table of formations. Belongs to Tacoma series (new). Older than Hill Ridge biotite schist (new); younger than Thorncrag limy gneiss (new).

Occurs in Lewiston area, Androscoggin County.

Steuben Limestone Member (of Cobourg Formation)

Middle Ordovician (Mohawkian): East-central New York.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 601, 602. Name proposed for upper member of formation in Utica quadrangle and vicinity. Described as coarse-textured calcite sandstone. Maximum thickness about 60 feet; 26 feet exposed above dam on Steuben Creek. Overlies newly defined Rust limestone member; underlies Holland Patent shale.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 61. Disappears by unconformity west of Poland. Outcrop areas described.

Typically exposed in small quarries and along streams south of road south of Steuben Creek for a mile from its mouth. Named from creek where exposed above dam at Prospect Bridge, Oneida County.

Steussy Shale Member (of Lazy Bend Formation)

Steussy Shale Member (of Millsap Lake Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107. From manuscript of report by G. Scott and J. M. Armstrong, on geology of Parker County.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 16–17, pl. Steussy shale member of Lazy Bend formation defined as those beds occurring between Meek Bend limestone bed of Hill Creek member and lower Brannon Bridge limestone member. Total thickness 180 feet. Lower 90 feet of shale are overlain by 40 feet of sandstone. Upper 30 feet are intermittently exposed along Steussy scarp below capping Brannon Bridge limestone. Origin of name Steussy not clear in original description. Upper part of shale is exposed on scarp northwest of Rocky Creek west of Brazos River. This feature is called Steussy Scarp in original reference, giving the impression that the geological name is after topographic feature bearing that name. Type section designated.

Type section: Exposures on west side of hill (located on southeast side of Rocky Creek) and in cuts of ranch road crossing Steussy Scarp to north, Parker County. Rocky Creek flows from southwest into Brazos River just north of Lazy Bend.

Stevens Series[1]

Silurian: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 49, map.

W. W. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 11, p. 2495. Silurian.

As originally defined, included the following units: Addy quartzite, Boundary argillite, Cedar Creek argillite, Chewelah argillite, Clugston limestone, Colville quartzite, Deep Lake argillite, Deer Lake argillite. Deer Trail argillite, Eagle Mountain quartzite, Fish Creek argillite, Lead Point argillite, Mission argillites, Old Dominion limestone, Red Top limestone, and Republican Creek limestone. Most of these units have been redefined or are no longer used.

Named for occurrence in Stevens County.

Stevens Creek Limestone (in Borden Group)[1]

Mississippian: Southeastern Indiana.

Original reference: C. A. Malott, 1922, Indiana Dept. Conserv. Pub. 21, pt. 2, p. 193.

Exposed in middle of the Borden in Stevens Creek and in Brummets Creek, Norman upland, Monroe County.

Stevens Creek Slates[1]

Precambrian: Northwestern South Carolina.

Original references: E. Sloan, 1908, Repts. and resolutions of General Assembly of South Carolina, regular sess., commencing Jan. 14, 1908, v. 1, p. 648–651; 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 414–417.

Probably named for exposures on Stevens Creek, Edgefield County.

Stewarts Landing facies[1] (of Edwardsville Formation)

Lower Mississippian: Southern Indiana and northern Kentucky.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 228–230.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Stewarts Landing facies listed in Edwardsville formation.

Name derived from Stewarts Landing, southeastern Harrison County, Ind.

†Stewartsville Group[1]

Eocene: Western California.

Original reference: B. L. Clark, 1918, Geol. Soc. America Bull., v. 29, p. 94.

†Stewart Valley Limestone

Mississippian: Southern California.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 275 (fig. 3), 332–334. A unit about 1,180 feet thick in which three unnamed members are recognized. The lowest, about 690 feet, is predominantly light- to dark-gray limestone in beds averaging 1 to 5 feet thick; the middle, 240 feet thick, is a dense light-creamy-gray limestone with porcelainlike texture, interbeds of dark-gray limestone in lower and upper parts; the upper, 50 feet thick, is a fossiliferous dark-gray limestone and dolomite. Unconformably underlies Monte Cristo(?) limestone; overlies Sultan dolomite.

J. C. Hazzard, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881. Name abandoned. Unit originally described as Stewart Valley is now known to include beds of both Devonian and Mississippian age. Suggestion made that Mississippian beds previously ascribed to Stewart Valley be assigned to Dawn limestone member of Monte Cristo limestone, and the Devonian beds be assigned to Crystal Pass and Valentine members of Sultan limestone.

Present on both western and eastern slopes of Nopah Range, Inyo County. Beds crop out to east of Devonian rocks and form major part of cliffs along northern range summit.

**Stewartville Member** (of Galena Dolomite)

Stewartville Dolomite[1]

Stewartville Member (of Wise Lake Formation)

Middle Ordovician: Southeastern Minnesota, northwestern Illinois, and northeastern Iowa.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 27.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 88–90. Uppermost member of Galena formation. Overlies Prosser member; underlies Dubuque member of Maquoketa formation. Ulrich did not designate type locality. It is probable that name was taken from town of Stewartville and that outcrop there is to be considered the type. Thickness 50 to 55 feet; about 30 feet where typically exposed at old quarry one-half mile west of Stewartville. Mohawkian.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Cong., fig. 3. In Dixon-Oregon area, Illinois, considered upper member of Wise Lake formation (new). Overlies Sinsinawa member (new); underlies Dubuque formation.

A. F. Agnew, 1956, U. S. Geol. Survey Prof. Paper 274–K, p. 261, 297–298. Middle member of the Galena. Overlies Prosser member; underlies Dubuque member. In Zinc-lead district, consists of yellowish-buff thick-bedded vuggy dolomite with *Receptaculites* in lower part. Thickness 37 to 47 feet.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1029 (fig. 1), 1039–1040. Considered uppermost member of Galena formation in this report [Fillmore County, Minn.]. Member is dolomitic limestone, pale yellowish- gray to grayish yellow, which weathers to yellowish orange. Thickness about 85 feet, where completely exposed at Mahood's Creek, near Greenleafton. Overlies Prosser member; underlies Dubuque formation.

Probably named for exposures near Stewartville, Olmsted County, Minn. Typical exposure measured at Old Quarry, north bank of Root River one-half mile above dam at Stewartville.

Stice cyclothem (in Cheorokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 40 (fig. 9), 45. Approximately 45 feet of beds occurring above Bevier cyclothem are here designated Stice cyclothem. Strata underlie persistent, relatively prominent sandstone called "Squirrel", which is interpreted as part of Breezy Hill cyclothem.

Derivation of name not given. Stice coal occurs in upper Cherokee shale in eastern Labette County.

**Stiles Phyllite**[1]

Lower Cambrian: Southwestern Vermont.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 400.

Named for occurrence at Stiles Mountain, 4 miles southwest of Brandon, in Brandon quadrangle, Rutland County.

Stillaguamish Group

Middle to Upper Permian: Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. Argillites, ribbon cherts and volcanic rocks.

On Mount Baring, Gunn Peak, and Merchant Peak, in Skykomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

**Stillaguamish Sand Member** (of Vashon Drift)

Pleistocene: Northwestern Washington.

R. C. Newcomb, 1952, U.S. Geol. Survey Water-Supply Paper 1135, p. 26, 27, pl. 1. An outwash deposit consisting largely of fine sand and clay with coarser material near top. Thickness about 300 feet. Underlies Arlington gravel member (new).

Area: Snohomish County; contains Tps. 26 to 32 N. of the Willamette base line.

Stillman Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 15A. Shown on columnar section as underlying Clement member (new) and overlying Walgreen member (new). Thickness 4 to 7 feet.

Occurs in Dixon-Oregon area.

Still Ridge Formation (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 50–52, table 1, pl. 1. Silty and sandy limestone, sandstone, calcareous sandstone, and limestone pebble conglomerate. The limestone pebble conglomerate, which is prominent in the sequence, consists of black limestone pebbles which weather light gray in a dark-gray to black limestone matrix which weathers brown. Interbedded volcanic rocks. Thickness 658 feet on south slope of Still Ridge and 575 feet on east side of ridge in Rs. 20 and 21 W., T. 25 S. Underlies Johnny Bull sandstone (new) and overlies Carbonate Hill limestone (new) with conformable contacts.

Named from exposures on Still Ridge, just north of Carbonate Hill mine. Excellently exposed on south side of Still Ridge; likewise on crest and upper slopes of small ridge in Rs. 20 and 21 W., T. 25 S., Peloncillo Mountains, Hidalgo County.

**Stillwater Complex**[1]

Precambrian: Montana:

Original reference: J. W. Peoples, 1933, Pan-Am. Geologist, v. 60, p. 152.

H. H. Hess, 1960, Geol. Soc. America Mem. 80, p. 1–230, plates. Complex is intrusion of lopolithic form. Floor and about 16,000 feet of layered rocks are exposed on East Boulder plateau. Estimated that another 40 percent of complex and its roof are hidden beneath cover of Paleozoic rocks. A quantitative mineralogical study. Comparisons with Bushveld complex, Great Dyke, and Skaergaard intrusion.

W. R. Jones, J. W. Peoples, and A. L. Howland, 1960, U.S. Geol. Survey Bull. 1071–H, p. 281–340, pls. 23, 24, 25. An upturned and previously beveled edge of Stillwater complex, a Precambrian stratiform sheet about 18,000 feet thick, crops out in belt 30 miles long on northeast margin of Beartooth Mountains. As subdivided in this report, complex consists of four zones: basal, 200 feet thick, of medium-grained noritic rocks; ultramafic zone, 4,000 to 6,000 feet, a succession of layers of bronzitite, granular, harzburgite, poikilitic harzburgite, and chromite; banded zone and upper zone, aggregate thickness 14,000 feet, of layers of norite, anorthosite, troctolite, and gabbro. Flathead sandstone is basal Cambrian unit throughout Beartooth Mountains except at contact of Cambrian with the complex where the overlying Wolsey is the basal unit. Tectonic structures and igneous activity discussed.

Named for exposures in Stillwater River area.

Stillwater Formation[1]

Permian: Central and northern Oklahoma.

Original reference: C. N. Gould, 1901, Kansas Acad. Sci. Trans., v. 17, p. 181.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., 21, no. 12, p. 1519 (fig. 1). Shown on graphic section as occurring in interval between Herington limestone above and Cottonwood limestone below. Falls within Wanette time division of the Permian.

Typically exposed near Stillwater, Payne County.

**Stillwater Formation**[1]

Eocene: Southeastern Alaska.

Original reference: G. C. Martin, 1908, U.S. Geol. Survey Bull. 335, p. 24, 30.

Arthur Troutman, ed., 1958, The Alaskan oil and gas handbook: Austin Tex. Oil Frontiers, p. 43 (strat. section). Stillwater formation believed to thin eastward forming marine tongue in coal-bearing Kushtaka formation. Eocene.

Occupies entire valley of Stillwater Creek and extends for some distance up valleys of Trout and Clear Creeks.

Stillwater Glacial Stage

Pleistocene (Illinoian): North-central Colorado.

R. L. Ives, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 75. Oldest of four ice advances recognized in Monarch Valley. Older than River glacial stage (new). Evidenced by terminal moraine.

R. L. Ives, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1056, 1062. Time covered by deposition of outer series of moraines in Monarch Valley, mapped as moraine one.

Moraines of Stillwater age forced Colorado River to adopt new channel, part of which took over valley of Stillwater Creek, Monarch Valley, Grand County.

†Stillwater Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Eastern Ohio.

Original reference: J. S. Newberry, 1874, Ohio Geol. Survey, v. 2, p. 131, pl. opposite p. 81.

Named for Big Stillwater Creek, Tuscarawas County.

Stillwater Creek Member (of Cowlitz Formation)

Eocene, upper: Southwestern Washington.

Named as basal member of Cowlitz. Underlies Pe Ell volcanics member. D. A. Henriksen, 1954, Dissert, Abs., v. 14, no. 12, p. 2316.

D. A. Henriksen, 1956, Washington Div. Mines and Geology Bull. 43, p. 36–37, 38–45, pl. 1. Consists largely of soft to indurated laminated to massive marine shales, siltstone, silty sandstones, and mudstones, together with massive to crossbedded or laminated friable to compact fine-grained arkoses, feldspathic sandstone. and sandy siltstones; locally includes thin interbedded basalt flows, pyroclastic material, and tuffaceous and basaltic sandstones. Pe Ell volcanics member is intercalated in lower part of Stillwater Creek member. Minimum thickness 2,100 to 2,600 feet near Pe Ell; maximum thickness 5,400 feet along Stillwater Creek. Overlies Metchosin volcanic series with contact gradational.

Type section: A section across widest part of roughly shaped belt of outcrop around northern and eastern margins of Willapa Hills [Lewis County]. Exposed along Stillwater Creek from contact with Metchosin Volcanic Series about 3 miles west of Ryderwood eastward to mouth of Brim Creek, 3½ miles northeast of Ryderwood.

**Stine Shale Bed** (in Hamlin Shale Member of Janesville Shale)

Stine Shale[1]

Permian: Southeastern Nebraska and northeastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, p. 83, 84, 89.

R. C. Moore and M. R. Mudge. 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1). Rank reduced to bed in Hamlin shale herein reduced to member status in Janesville shale (new). Wolfcamp series.

Named for exposures south of Stine, Nemaha County, Nebr.

Stinking Water Formation

Miocene, middle: Oregon.

Jane Gray, 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1768. Incidental mention in note on fossil green algae from the Miocene of the Columbia Plateau.

**Stirling Quartzite**[1]

Precambrian: Southeastern Nevada and eastern California.

Original reference: T. B. Nolan, 1928, Am. Jour. Sci., 5th, v. 17, p. 461–472.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 278–279, 306–307. Geographically extended into Nopah-Resting Springs Mountains, Calif., where it is 2,593 feet thick, underlies Wood Canyon formation and disconformably overlies Johnnie(?) formation.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 19. Considered synonym for Prospect Mountain quartzite.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 146 (fig. 2). On correlation chart of recommended revision of stratigraphic units in Great Basin region, Stirling quartzite replaces Prospect Mountain quartzite in Death Valley, Providence Mountains, and Nopah-Resting Springs Mountains.

B. K. Johnson, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p. 375–377, 378 (fig. 7), figs. 1 (geol. map), 2 (columnar section). Described in Manly Peak quadrangle where it conformably overlies Johnnie formation. Thickness (incomplete section) about 1,000 feet. Late Precambrian or Algonkian.

Named for exposures on Mount Stirling, about 5 miles east of Johnnie mine, Spring Mountains, Clark County, Nev.

**Stissing Dolomite**[1]

Lower and Middle Cambrian: Southeastern New York.

Original reference: C. D. Walcott, 1891, U.S. Geol. Survey Bull. 81, p. 360.

E. B. Knopf, 1946, (abs.) Geol. Soc. America Bull. 57, no. 12, pt. 2, p. 1212. Light-colored dolomites carrying *Hyolithellus micans* Billings in four localities. Upper dark dolomites carry *Paterina stissingensis* Dwight and *Prozacanthoides stissingensis* Dwight in two localities. Indicates late early Cambrian age. Thickness 500 feet. Underlies Pine Plains formation (new). Overlies Poughquag quartzite.

E. B. Knopf, 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1817. Lithologic and palentologic study indicate five characteristic lithologic zones in Stissing dolomite of Early and Middle Cambrian age. Thickness 500 feet. Overlies Poughquag quartzite; underlies Upper(?) Cambrian Pine Plains formation. Top of Stissing marked by dark beds that carry *Prozacanthoides stissingensis* Dwight and *Paterina stissingensis* Dwight.

Named from Stissing Mountain, northern Dutchess County.

†Stissing Quartzite[1]

Cambrian(?): Eastern New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, chart.

Occurs on south and east slopes of Stissing Mountain, Dutchess County.

Stobo Limestone Lens (in Borden Group)[1]

Mississippian: Southwestern Indiana.

Original reference: A. B. Reagan, 1904, Indiana Acad. Sci. Proc. 1903, p. 214.

Occurs in SE¼ sec. 33, T. 9 N., R. 1 E., and NE¼ sec. 4, T. 8 N., R. 1 E., near old Stobo post office, 6½ miles east of Bloomington, Monroe County.

**Stockade Beaver Shale Member** (of Sundance Formation)

Stockdale Beaver Shale Member (of Rierdon Formation)

Upper Jurassic: Southwestern South Dakota and northwestern Wyoming.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 251–255, geol. sections. Medium- to dark-gray soft fissile calcareous shale which ranges in thickness from about 5 to 85 feet; average thickness about 50 feet; at type locality 63 feet. Overlies Canyon Springs member (new) and underlies Hulett sandstone member (new). Locally overlies Gypsum Spring formation or Spearfish formation.

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 466 (table 2), 475, 482. Reallocated to member status in Rierdon formation herein assigned to Sundance group.

Type section: West side of Stockdale Beaver Creek about 5 miles northeast of Newcastle in sec. 18, T. 45 N., R. 60 W., Weston County, Wyo.

**Stockbridge Limestone[1] or Group**

Stockbridge Marble

Cambrian and Ordovician: Western Massachusetts, western Connecticut, eastern New York, and southwestern Vermont.

Original reference: Ebenezer Emmons, 1842, Geology New York, pt. 2, div., 4, Geology of 2d dist., p. 135–164.

R. V. Cushman, 1950, New York State Water Power and Control Comm. Bull. GW–21, p. 9 (table 2), 11, pl. 2. In Rensselaer County, Stockbridge limestone directly underlies Walloomsac slate; overlies rocks of Lower Cambrian age. Thickness not known.

John Rodgers and others, 1956, Preliminary geological map of Connecticut: Connecticut Geol. Nat. History Survey. Referred to as marble in Connecticut.

J. W. Clarke, 1958, Connecticut Geol. Nat. History Survey Quad. Rept. 7, p. 18. In this report [Danbury quadrangle], unit mapped as Inwood marble was called Stockbridge limestone on State Geological Map of 1906. Moore (1935, Connecticut Geol. Nat. History Survey Bull. 56) used term Stockbridge series.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Stockbridge limestone as formerly used is equivalent to at least seven formations of west-central Vermont that range in age from Early Cambrian to Early Ordovician. Stockbridge is raised to group to include (ascending) Kitchen Brook dolomite (new), Clarendon Springs dolomite, Shelburne marble, and Bascom formation. Overlies Cheshire quartzite; underlies Berkshire schist. Report is Cheshire quadrangle, Massachusetts.

Named for prominent development and quarries around Stockbridge and West Stockbridge, Berkshire County, Mass.

Stockstill Sandstone (in Indian Bluff Group)

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 11, pls. 2, 3, 4. In some areas, massive; in other areas, poorly cemented. Thickness 20 to 80 feet. Separated from overlying Indian

Fork sandstone (new) by shale interval that ranges in thickness from 25 to 100 feet; separated from underlying Seeber Flats sandstone (new) by shale interval that ranges in thickness from 40 to 120 feet.

Exposed on State Highway 116 between Petros and Armes Gap, Morgan County. Named for Stockstill Creek.

**Stockton Formation** (in Newark Group)[1]

Stockton lithofacies (of Newark Group)

Upper Triassic: New Jersey, New York, and southeastern Pennsylvania.

Original references: H. B. Kummel, 1897, New Jersey Geol. Survey Ann. Rept. State Geologists, 1896, p. 35–40; 1897, Jour. Geology, v. 5, p. 543–544.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 52–53 (table), pl. 1. Stratigraphic section shows Stockton formation includes (ascending) arkose, red shale, and sandstone, 720 feet; thick-bedded to massive coarse quartz-arkose conglomerate (Solebury member, new), 387 feet; thick-bedded gray arkose, 224 feet; red sandstone, 447 feet; thick-bedded white and yellow arkose (Lower Prallsville member, new), 474 feet; red and brown sandstone, 136 feet; thick-bedded medium to coarse arkose (Upper Prallsville member, new), 205 feet; red and brown sandstone and red shale, 373 feet; medium to coarse thick-bedded arkose with interbeds of red-brown sandstone (Cutalossa member, new), 232 feet; red and gray sandstone and red shale, 787 feet; massive medium to coarse white and gray arkose (Raven Rock member, new), 293 feet; and red and brown sandstone, 724 feet. Underlies Lockatong formation; overlies Paleozoic limestone.

D. B. McLaughlin, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. C–9, p. 62–77. Lithofacies discussed in detail in report on Bucks County. Term lithofacies used rather than formation because of intertonguing nature of units which prevents drawing distinct boundaries.

N. M. Perlmutter, 1959, New York State Water Power and Control Comm. Bull. GW–42, p. 7–9, 15–16, pls. 2, 3. Present in Rockland County, N.Y.

Named for exposures in quarries near Stockton, Hunterdon County, N.J.

Stockton Shale (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 326–327.

Probably named for fact that the coal was mined by Mr. Stockton.

Stockton Slate (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 152, 409–410.

**Stockwether Limestone Member** (of Pueblo Formation)[1]

Stockwether Formation (in Pueblo Group)

Permian (Wolfcamp Series): Central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 417.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in the Pueblo here given group status. Includes Coon Mountain sandstone member. Underlies Camp Colorado formation; overlies Saddle Creek formation.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Prelim. Map 80, sheet 2. Described in Colorado River valley as limestone member of Pueblo formation. Typically fine-grained limestone containing numerous thin clear calcite veinlets and white porcelainlike foraminiferal remains; beds are uneven, to medium in thickness, and weather slabby. Thickness 5 to 30 feet, average 20 feet. Underlies Salt Creek Blend shale member; overlies Camp Creek shale member.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1801-G, p. 268-269. Stockwether member geographically extended into Brazos River valley. Thickness ½ to 3 feet. Overlies Camp Creek shale member; underlies Salt Creek Bend shale member.

Named for Stockwether Ranch, on Bull Creek, Coleman County.

Stoddard Member (of Oneota Formation)

Lower Ordovician: Southwestern Wisconsin.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 45, p. 90-91, 94. At type locality lower part comprises 37 feet of massive gray crystalline-granular cherty dolomite; virtually without bedding planes, vuggy and traversed by irregular porous areas. Above is 6-foot thickness of thin-bedded cryptocrystalline dolomite. If member is restricted to strata between thin beds of dolomite above and Genoa member (new) below, thickness would range from more than 50 feet in the northwest to about 25 feet in the southwest part of quadrangle. Conversely, on basis of high level chert float of Oneota type, member may reach thickness of more than 130 feet.

Type locality: Quarry and Mississippi bluff in NW¼NE¼ sec. 33, T. 14 N., R. 7 W., Stoddard quadrangle, 1 mile south of Stoddard, Vernon County.

Stoddard Canyon Quartz Monzonite

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 301-302, geol. map. A fine-grained massive light-gray plutonic rock. Occurs as dikes and small irregular-shaped bodies ranging from a few to several hundred feet or more in width, in El Dorado Ridge-Stoddard Canyon pluton, cutting across gneissosity of El Dorado Ridge quartz diorite (new). Intrudes Rainbow Flat group (new).

Exposed in Cucamonga quadrangle, San Bernardino County.

†Stokes Sandstone (in Cheyenne Sandstone)[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 361, 367.

Named for Stokes Draw, which proceeds from foot of Stokes Hill and south of Lanphier Draw, in southeastern corner of Kiowa County.

†Stokes Hill Sandstone[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: W. H. Twenhofel, 1924, Kansas Geol. Survey Bull. 9, p. 13.

Named for Stokes or Black Hill, a few miles west of Sun City, Barber County.

Stonberger Shale

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). Named on cross section and structure section in report on Paleozoic continental margin in central Nevada. Underlies Antelope Valley formation.

Toquima Range, Nye County.

†Stonebreaker Limestone Member (of Buck Creek Formation)[1]

Pennsylvanian (Virgil Series): Central northern Oklahoma.

Original reference: K. C. Heald, 1918, U.S. Geol. Survey Bull. 686–K, p. 130–131.

U.S. Geological Survey has abandoned the Buck Creek Formation and the Stonebreaker Member.

Named for Stonebreaker Ranch, Pawhuska quadrangle, Osage County.

Stone Cabin Tuff

Tertiary: Eastern Nevada.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 140 (fig. 4). Crystal-vitric ignimbrite; upper two-thirds moderately to highly welded pale purple, grading down abruptly into highly welded red-purple zone which in turn gives way downward to cavernous lightly welded to nonwelded tuff at base. Thickness 540 to 690 feet. Occurs below Currant tuff.

Present in Grant Range.

Stone City Beds or Formation (in Claiborne Group)[1]

Stone City Member (of Crockett Formation)

Eocene, middle: Eastern Texas.

Original reference: H. B. Stenzel, 1935, Texas Univ. Bull. 3501, p. 267–279.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20, 120–124 [1939]. Formation underlies Wheelock member (new) of Crockett formation; overlies Sparta formation. Thickness 80 to 120 feet.

G. D. Harris, 1941, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 33, p. 13, 15. Rank reduced to member status in Crockett formation. Thickness about 19 feet in Lee County.

H. B. Stenzel, E. K. Krause, and J. T. Twining, 1957, Texas Univ. Bur. Econ. Geology Pub. 5704, 237 p. Thickness 61.1 feet at type locality. Overlies Sparta sand; underlies Wheelock member of Cook Mountain formation. Includes Moseley limestone of Renick and Stenzel (1931), Term Moseley no longer used. Pelecypod fauna described. Middle Eocene.

Type locality: Stone City bluff on Brazos River, Burleson County. Beds traceable to Atascosa County in southwestern Texas and to Sabine River at Texas-Louisiana boundary.

Stone Coal Bluff Lignite (in Slaughter Creek Member of Pendleton Formation)

Eocene, lower: Northwestern Louisiana.

Richard Wasem and L. J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 184 (fig. 4), 187. Occurs about 50 feet above base of member. Thickness varies from 1 to 6 feet. Occupies constant stratigraphic position and has been traced for 14 miles along strike of formation.

Named for its outcrop at Stone Coal Bluff on Sabine River, Sabine Parish.

**Stone Corral Formation** (in Sumner Group)

Stone Corral Dolomite (in Enid Formation)

Stone Corral[1] Member (of Harper Sandstone)

Permian: Central Kansas.

G. H. Norton, 1935, (abs.) Am. Assoc. Petroleum Geologists Program 20th Ann. Mtg., March 21, 22, p. 17. Dolomitic limestone, 6 feet maximum thickness at its northern limit in Rice County; can be traced southward about 50 miles, splitting into two or three thin layers and finally disappearing as a distinct unit north of Oklahoma line and identifiable only as zone of huge halite casts. Occurs in middle part of Harper sandstone.

E. A. Koester, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 10, p. 1410. Name Stone Corral used in table where it is placed in Cimarron series.

R. C. Moore and K. K. Landes, 1937, Geologic map of Kansas (1:500,000): Kansas Geol. Survey. Mapped as dolomite member of Enid formation. Cimarron series.

G. H. Norton, 1937, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1774–1781. Middle member of Harper sandstone. Overlies Ninnescah shale member (new); underlies Chikaskia sandstone member (new).

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1774–1781. Harper sandstone restricted below to exclude Stone Corral dolomite and Ninnescah shale. Overlies Runnymede sandstone member (new) of Ninnescah shale. Included in Cimarron series. Type locality stated.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 91. Sumner group comprises Wellington shale, Ninnescah shale, and Stone Corral dolomite. Leonard series.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Chart shows Stone Corral formation at top of Sumner group. Underlies Chikaskia siltstone. Member of Harper siltstone; overlies Runnymede siltstone member of Ninnescah shale.

Type locality: Sec. 11, T. 20 S., R. 6 W., Rice County. Named for exposures near historic Stone Corral Fort, where wagon trains of pioneers forded Little Arkansas River on Santa Fe Trail.

Stone Creek Member (of Brallier Shale)

Upper Devonian: Central Pennsylvania.

R. R. Conlin and others, 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 274, 276. Incidental mention only as basal member.

Forms first foothills of Allegheny Front along northwesterly margin of alluvial plain of Bald Eagle Creek, between Harrisburg and Tyrone.

Stonefort cyclothem (in Spoon Formation)

Stonefort cyclothem (in Tradewater Group)

Pennsylvanian: Southeastern Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 15 (fig. 2) [1943]. Stonefort cyclothem occurs below Davis cyclothem and above Macedonia cyclothem. Includes Curlew sandstone, Bald Knob coal, and Stonefort limestone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 5, 9, pl. 1. Includes (ascending) Curlew sandstone, Bald Hill coal, Stonefort coal, and Stonefort limestone; underlies Colbert cyclothem (formerly termed Davis). Type locality designated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 53 (table 2), pl. 1. In Spoon formation (new). Above Macedonia cyclothem and below Colbert cyclothem. Type locality given; Wanless (1956) reference in error. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: NE¼SE¼ sec. 25, T. 10 S., R. 4 E., Williamson County.

**Stonefort Limestone Member** (of Spoon Formation)

**Stonefort Limestone Member** (of Tradewater Formation)[1]

Stonefort Limestone (in Tradewater Group)

Middle Pennsylvanian: Southeastern Illinois and western Kentucky.

Original reference: L. G. Henbest, 1928, Jour. Paleontology, v. 2, p. 70–71.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, *in* C. O. Dunbar and L. G. Henbest, Illinois Geol. Survey Bull. 67, p. 15 (fig. 2), 18 (table), 21–22 [1943]. Stonefort limestone in Tradewater group is a persistent bed 1 to 2 feet thick that is medium gray, weathers brownish, and is sparingly fossiliferous. Occurs in midst of succession of thin beds including several coals. A thin limestone without marine fossils occurs locally a few feet above the Stonefort, which is the first marine horizon above Curlew limestone. Included in Stonefort cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 33, 46. Included in Spoon formation (new). Overlies Wise Ridge coal member; underlies Davis coal member. Type locality corrected. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification retained but is independent of rock-stratigraphic classification.

U.S. Geological Survey has discontinued the use of the term Tradewater in Illinois.

Type locality: In roadcut and in ravines east of road in NE¼SE¼ sec. 25, T. 10 S., R. 4 E., Williamson County, Ill. Name derived from town of Stonefort, Saline County.

**Stonehenge Limestone** (in Beekmantown Group)

Stonehenge Limestone Member (of Beekmantown Limestone)[1]

Lower Ordovician: Central and central southern Pennsylvania, western Maryland, and northwestern Virginia.

Original reference: G. W. Stose, 1908, Jour. Geology, v. 16, p. 703.

B. N. Cooper, 1936, Virginia Geol. Survey Bull. 46–L, p. 138–139. Formation described in Marion area, Virginia, where it is dove-gray massive vaughanite about 25 feet thick. Conformable with underlying Chepultepec; in some areas, contact is "welded" in a single bed. Canadian system.

H. P. Woodward, 1951, West Virginia Geol. Survey, v. 21, p. 53–54, 58–59. Term Stonehenge has priority over Chepultepec in event the names are judged to be completely synonymous; however, term Chepultepec-Stonehenge is used in this report. Chepultepec-Stonehenge not included in Beekmantown group.

W. J. Sando, 1956, Geol. Soc. America Bull., v. 67, no. 7, p. 935–936. Basal formation in Beekmantown group. Comprises two unnamed members of approximately equal thickness: a lower division of dominantly algal limestone and an upper division of thin-bedded silty mechanical limestone. Underlies Rockdale Run formation (new); overlies Conococheague limestone. Base of formation is placed at contact of massive limestone of lower member with thin-bedded limestones that form persistent lithologic unit at top of Conococheague limestone. Inasmuch as *Symphysurina* and *Clelandia* have been recovered 30 feet below top of Conococheague, at least uppermost 30 feet of this formation is of Early Ordovician age; hence, Stonehenge-Conococheague contact does not exactly coincide with Cambrian and Ordovician systems. Type section designated.

W. J. Sando, 1957, Geol. Soc. America Mem. 68, p. 18–21, 60, 76–78, pl. 1. Thickness at Maryland reference section 726½ feet. Thickness at reference section of Beekmantown group 909 feet.

J. P. Hobson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 12, p. 2713–2715, 2716–2717 (fig. 3). Formation, in Berks County, Pa., consists of 250 feet of thick- to thin-bedded limestone and dolomite. In reference section (herein designated), divided into three members: upper or calcilutite member, middle or calcirudite member, and lower interbedded limestone and dolomite member. Underlies Rickenbach formation (new). In southern Pennsylvania and Maryland, contact between Stonehenge limestone and Conococheague limestone has been placed between relatively pure limestone of lower Stonehenge and more impure beds of the Conococheague. This contact appears to be similar to the relatively sharp lithological break between upper and middle members of Stonehenge as mapped in this report. Clastic beds beneath this contact in central Berks County are more similar lithologically and paleontologically to the Beekmantown than to the highest exposed Conococheague-Elbrook limestones as indicated on Geologic Map of Pennsylvania (Stose and Ljungstedt, 1932). An unmetamorphosed section in uppermost 300 feet of exposed part of Conococheague in vicinity of Reading was examined. A covered interval with apparent stratigraphic thickness of 500 to 600 feet overlies this section and is persistent throughout Berks County. Beds overlying the concealed interval throughout Berks County are included in Stonehenge limestone.

W. J. Sando, 1958, Geol. Soc. America Bull., v. 69, no. 7, p. 837–841, geol. sections. Described near Chambersburg, Pa. Base of Stonehenge was originally placed at contact of pure fine-grained massive limestones with underlying sandy conglomeratic thin-bedded limestone included in upper part of Conococheague formation. Cambrian-Ordovician boundary was placed at this contact. The lower thin-bedded limestones form persistent stratigraphic unit in southern Pennsylvania, Maryland, and West Virginia and bear diagnostic Lower Ordovician trilobite assemblage. These beds are here named Stoufferstown member of Stonehenge. Upper member of Stonehenge as used in this paper is equivalent to upper and lower members of Maryland (Sando, 1957). Underlies Rockdale Run formation. Thickness about 1,000 feet; Stoufferstown member 217 feet in its type section.

A. C. Donaldson, 1960, Dissert. Abs., v. 20, no. 9, p. 2693. In central Pennsylvania, subdivided into (ascending) Spring Creek, Graysville, Baileyville, and Logan Branch members. Thickness 430 to 485 feet. Larke dolomite subdivided into four unnamed members which are lateral extensions of members in the Stonehenge.

Type section: On Hoover Farm just north of U.S. Route 30, 2 miles southeast of center of Chambersburg, Franklin County, Pa. Reference section (Maryland): Section begins in pasture northeast of barn on Forsythe Farm located 1 mile S. 5° E. of St. Paul's Church, Washington County.

Reference section (Pennsylvania): Along northwest bank of Schuylkill River in borough of Glenside, a suburb of Reading, Berks County.

Stonehengian division (of Ozarkian Series)

Lower Ordovician: Eastern United States.

A. W. Grabau, 1937, Paleozoic formations in the light of the pulsation theory, v. 3, Cambrovician pulsation, pt. 2, Appalachian, Palaeocordilleran, Pre-Andean, Himalayan, and Cathaysian geosynclines. Peiping, China, Univ. Press, Natl. Univ. Peking, p. 10, 13 (table), 15, 282 (table). The Stonehenge and Tribeshill (its Mohawk Valley partial equivalent) represent essentially the Tremadoc of the Caledonian geosyncline, and for them the same Stonehengian is proposed. The Stonehenge and Tribeshill represent the last of the transgressive series from the southern Appalachian geosyncline.

Stone Mill Member (of Ludlowville Formation)

Middle Devonian: Central New York.

G. A. Cooper and A. S. Warthin, 1941, Washington Acad. Sci. Jour., v. 31, no. 6, p. 259. Name proposed for thin bed of limestone consisting mostly of crinoidal and fragmentary shell material with considerable sand. Thickness 1 to 3 feet.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1783, chart 4. Underlies shaly sandstone of the formation; overlies Chenango sandstone.

Type section: In bed and banks of Stone Mill Brook 4½ miles (airline) southeast of Lebanon and about 1½ miles northwest of Earlville, Madison County. Exposed on both sides of Chenango Valley in Morrisville quadrangle.

Stone Mountain Granite

Permian(?): Northwestern Georgia.

T. L. Watson, 1902, Georgia Geol. Survey Bull. 9-A, p. 114–119. Name applied to granite quarried at Stone Mountain. An even-textured medium-grained light-gray biotite-bearing muscovite granite.

L. A. Herrmann, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1362; 1954, Georgia Geol. Survey Bull. 61, p. 29–32, 55–61. Stone Mountain granite (Permian?) was introduced during a late stage of the Appalachian orogeny. Intrudes Lithonia gneiss.

Named for occurrence at Stone Mountain, DeKalb County.

**Stoner Limestone Member** (of Stanton Limestone)[1]

Pennsylvanian (Missouri Series): Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, 2d ser., p. 11, 26, 27, 31, 33, 34.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 118–119. Overlies Eudora shale member; underlies Rock Lake shale member (this is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947). Thickness along Kansas River and elsewhere in northeastern Kansas 11 to 15 feet; in parts of southern Kansas about 50 feet.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32. In Nebraska, includes (ascending) Dyson Hollow limestone zone (new), Kiewitz shale zone, and unnamed limestone. Thickness at type locality 15 or 16 feet.

Type locality: On Stoner Farm, northwest of South Bend, Cass County, Nebr.

**Stones River Group[1] or Limestone[1]**

Middle Ordovician: Tennessee, western Maryland, northeastern Mississippi, southern Pennsylvania, western Virginia, and northeastern West Virginia.

Original reference: J. M. Safford, 1851, Am. Jour. Sci., 2d v. 12, p. 353, 354–356.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 819–886. Lower Middle Ordovician succession of Tazewell County, Va., studied in detail, and revised stratigraphic nomenclature proposed. Study revealed inconsistencies in use of names Stones River, Murfreesboro, Mosheim, Lenoir, Blount, Holston, Ottosee, Lowville, and Moccasin. Succession of beds described is post-Beekmantown. Boundary between Chazy and Black River is not clearly defined in Tazewell County. The Chazy of southern Appalachian Valley and Ridge province is, according to Ulrich, composed of Stones River and Blount groups (possibly also Ulrich's Speers Ferry group). According to Ulrich, Murfreesboro limestone is oldest formation of Stones River group which is lower Chazy. In Tazewell County, part of Ulrich's Blount group (upper Chazy) occurs beneath beds containing fauna of Murfreesboro limestone of Central basin of Tennessee. Such anomalies result from an erroneous determination of stratigraphic succession used by Ulrich in setting forth relations of Stones River and Blount groups. Neither group name should now be used. In revised terminology proposed herein, the succession of beds is grouped into eight formations. Series and group classification of the formations described in this report can be made only after regional studies between New York localities and Tazewell County have been completed.

B. N. Cooper, 1945, Jour. Geology, v. 53, no. 4, p. 263–275. Discussion of Stones River equivalents in Appalachian region. Commonly accepted correlation of Stones River group of central Tennessee with Chazy of New York and with beds immediately succeeding the Beekmantown or Knox dolomite in Appalachian Valley—the Stones River and overlying Blount—was based upon mistaken identification of formations. Both the stratigraphic position of Stones River equivalents in Appalachian region and character of Stones River faunas indicate that entire Stones River group is post-Chazyan. "Stones River" as a general time-rock term should no longer be used, nor should name be revived if a post-Chazyan, pre-Black River group is recognized. Report gives detailed history of usage of name and table of classifications of Stones River group as used through 1929.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 715–717, geol. sections. Discussion of lower Middle Ordovician of south-central Pennsylvania. Limestone beds overlying Beekmantown and underlying the Chambersburg in Franklin County, were called Stones River by Stose (1906, Jour. Geology, v. 14; 1908, Jour. Geology, v. 16). Cooper (1945) has shown that beds in Appalachian region of Virginia have been consistently miscorrelated with true Stones River of central Tennessee. Correlation from south-central Pennsylvania to Virginia indicates that term Stones River was misused in Chambersburg area and that equivalents of true Stones River are probably within Shippensburg formation. Term "Stones River" is used in this report for limestone underlying Shippensburg formation.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 24–75. Proposed in this report to return Carters limestone to top of Stones River group, thus making group consists of (ascending) Murfreesboro, Pierce, Ridley, Lebanon, and Carters limestones in accordance with Safford's original definition of Stones River in 1851. Contact between Carters and Hermitage formations is by far most pronounced stratigraphic break in this part of Ordovician section. Underlies Nashville group (redefined).

R. B. Neuman, 1951, Geol. Soc. America Bull., v. 62, no. 3, p. 267–324. Term St. Paul group introduced as substitute for "Stones River" group as mapped through West Virginia, Maryland, and Mercersburg-Chambersburg quadrangles in Pennsylvania. Need for substitution has been apparent since Cooper and Prouty (1943) demonstrated that central Tennessee Stones River was younger than Appalachian "Stones River."

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 87, pls. For purposes of present map, term "unit 1" of Chickamauga limestone replaces (in belts northwest of Whiteoak Mountain and Hunter Valley faults) the term Stones River of middle Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 91–92. Term Stones River group is appropriate to Central basin of Tennessee and possibly parts of Alabama but not to most parts of the Appalachians to which it has already been applied. For years this term has been used for lower or "Chazyan" part (Lenoir through Lincolnshire) of Appalachian section from Pennsylvania to Alabama. It was also just as inappropriately applied to parts of Minnesota section. Identification of Carters formation of the Central basin as Lowville, because of presence of *Tetradium cellulosum*, was chief factor in declaring subjacent beds, Lebanon through Murfreesboro, as Chazyan in age. Similar error was made in Appalachians in identifying all formations below *Cryptophragmus* and *Tetradium cellulosum*-bearing "Lowville" as Chazyan in age. This threw the lower formations of the Appalachians into correlation with Stones River formations. Thus, because of common presence of *Maclurites* and the position in relation to "Mosheim" rocks, Lenoir and Ridley were correlated, and from these false premises many other errors were brought about. Examination of fossils of Stones River formations of Central basin of Tennessee shows that affinities of this group are with the old Black River-Trenton (Wilderness stage, new) assemblage of formations rather than with the Chazy (Marmor stage, new). Stones River as group term should be dropped from the Appalachians.

Named for exposures on Stones River near Nashville, Tenn.

**Stones Switch Sandstone Member** (of Whitsett Formation)

Stones Switch Sand[1]

Eocene, upper: South-central Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1314.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626 (table 1), 2632. Basal member of Whitsett as defined in this paper. Underlies Dubose member; overlies Conquista clay member (new) of McElroy formation (redefined). Chiefly crossbedded sandstone containing borings of marine crustacean(?) *Halymenites major* and, locally, marine or brackish-water fossils, as well as thin lenses of carbonaceous shale and bentonitic clay. Uppermost bed is generally an indurated plant-root-bearing sandstone, or, in some places, an oyster-shell bank. Note on derivation of name.

Named for railroad siding (now abandoned) from which a spur track led to a quarry on bluff overlooking Atascosa River 2½ miles north of Whitsett Bluff and 4.4 miles S. 5° W. of Campbellton, Atascosa County.

Stoneville Member (of Fox Hills Sandstone)

Upper Cretaceous: Western South Dakota.

W. V. Searight, 1934, South Dakota Geol. Survey Rept. Inv. 22, p. 4, 5, 8–11; E. P. Rothrock, 1944, South Dakota Geol. Survey Bull. 15, p. 83, 84. A succession of clay, sandstone, and coal beds in upper one-third of formation. Thickness 10 to 45 feet. Underlies unnamed upper sandstone member and overlies unnamed lower sandstone member.

Named for exposures near Stoneville, Meade County.

Stoneville Flats Limestone (in Greenhorn Formation)

Upper Cretaceous: Southeastern Montana and northeastern Wyoming.

M. N. Bramlette and W. W. Rubey *in* R. C. Moore, 1949, Geol. Soc. America Mem. 39, p. 27 (fig. 18). In lower chalk marl facies of formation. Older than Crow Creek sandy limestone; younger than Bull Creek sandy limestone (new).

Carter County, Mont., and Crook County, Wyo.

**Stonewall Formation**

**Stonewall Quartz Diorite**[1]

Jurassic(?): Southern California.

Original reference: F. S. Hudson, 1922, California Univ. Pub., Dept. Geol. Sci. Bull., v. 13, no. 6, p. 181, 191–193, map.

Richard Merriam, 1946, Geol. Soc. America Bull., v. 57, no. 3, p. 230–232, pl. 1. Described in Ramona quadrangle as Stonewall formation. Unit subdivided into Stonewall granodiorite and Stonewall quartz diorite. Each mapped separately. Shown as older than San Marcos gabbro.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 43. Probably pre-Triassic.

D. L. Everhart, 1951, California Div. Mines Bull. 159, p. 61–65, pls. 2, 3, 4, 5. A typical granodiorite, megascopically medium- to coarse-grained, with subhedral granular texture. Younger than Julian schist. Gives historical summary of name. Terms formation and granodiorite have both been applied to unit.

Richard Merriam, 1958, California Div. Mines Bull. 177, p. 11, pl. 1. Term Stonewall quartz diorite used in this report [Santa Ysabel quadrangle] though unit as mapped includes a variety of rock types. Younger than Julian schist; older than San Marcos gabbro.

H. W. Jaffe and others, 1959, U.S. Geol. Survey Bull. 1097–B, p. 86. Lead-alpha age 96 million years.

Named after Stonewall Peak, which is composed of this rock. Cuyamaca region, San Diego County.

Stonewall Creek Shale Member (of Lykins Formation)

Permo-Triassic: Northern Colorado.

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Underlies Park Creek limestone member (new); overlies Poudre limestone member (new).

Stonington Beds[1] or Member (of Richmond Formation)

Upper Ordovician: Northern Michigan.

Original reference: R. C. Hussey, 1926, Michigan Univ. Mus. Geol. Contr., v. 2, no. 8, p. 113–150.

R. C. Hussey, 1952, Michigan Dept. Conserv. Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 14 (table), 42, 44, 52. Predominantly argillaceous limestones. Includes Bay de Noc member below and Ogontz beds [member] above. [Reference refers to Ogontz beds which lie above the Stonington but also states that "this member" was deposited under relatively clear water conditions.] Underlies Big Hill beds [or member]; overlies Bills Creek beds [or member] (restricted).

Named for exposures 1 mile north of Stonington post office, on east side of Little Bay de Noc, Delta County.

Stonington Gneiss[1]

Pre-Triassic: Southeastern Connecticut.

Original reference: L. H. Martin, 1925, Connecticut Geol. Nat. History Survey Bull. 33.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as gray, rarely pink, fine- to medium-grained gneiss. Many inclusions of biotite and hornblende gneiss and schist. Pre-Triassic. Derivation of name stated.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 61, pl. 1. Same as Mamacoke gneiss and mapped as latter.

Named for town of Stonington, New London County.

Stony Brook Beds (in Chemung Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1883, Pennsylvania 2d Geol. Survey Rept. $G_7$, p. 68–73, 216–217.

Well exposed at cutting along road where it crosses Stony Brook, Orange Township, Columbia County.

Stonybrook Quartzite[1]

Precambrian: Eastern Massachusetts.

Original reference: W. E. Hobbs, 1899, Am. Geologist, v. 23, p. 110.

Named for exposures at Stonybrook, Middlesex County.

Stony Clove Sandstone Member (of Katsberg Redbeds)

Stony Clove Sandstones

Upper Devonian (Senecan): Southeastern New York.

G. H. Chadwick, 1940, New York State Geol. Assoc. 16th Ann. Mtg. Field Guide Leaflets, p. 2. Listed in table of formations as sandstones. Consists of continental gray flags and shale. Thickness 900 feet. Underlies Katsberg redbeds; overlies Onteora redbeds.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 130–135, 136. Included in Katsberg redbeds as basal member for mapping purposes. Possibly unit belongs with Onteora redbeds. Underlies Wittenberg conglomerate member. Considered continuation of Kattel gray flagstones. Outcrop area described.

Exposed in Stony Clove, a pass in Kaaterskill quadrangle.

Stony Creek Basalt

Pliocene: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

Stony Creek Granite Gneiss[1] or Granite

Pre-Triassic: South-central Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 147, 152, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Unit referred to as a granitic gneiss. Described as medium- to very coarse-grained variably foliated red or pink gneiss or granite. Large phenocrysts and porphyroblasts of potash feldspar. Inclusions of dark hornblende and biotite gneiss common. Grades through a lit-par-lit or migmatitic zone into Middletown gneiss. Pegmatite very common. Part of East Haven granitic body, a structural unit.

H. M. Mikami and R. E. Digman, 1957, Connecticut Geol. Nat. History Survey Bull. 86, p. 7–12, 24–25, pl. 1. Stony Creek granite and Branford quartz monzonite compose Branford-Stony Creek massif. Normal Stony Creek granite is pink to reddish and is speckled by black biotite flakes. Name credited to Kemp (1899, Geol. Soc. America Bull., v. 10, p. 369–370). [Kemp referred to Stony Creek types and granites at Stony Creek. Two varieties, Stony Creek red, and Stony Creek gray.]

Named for occurrence at Stony Creek, a town in Branford Township, New Haven County.

**Stony Gap Sandstone Member** (of Hinton Formation)[1]

Stony Gap Sandstone (in Hinton Group)

Stony Gap Sandstone Member (of Pennington Formation)

Upper Mississippian: Southeastern West Virginia, northeastern Kentucky, and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 298, 371.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey, Greenbrier County, p. 255, 261–262. Basal formation in Hinton group, Mauch Chunk series.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 398, 399. Basal member of Pennington formation in Greendale syncline.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Basal member of Hinton formation. Underlies middle red member of formation; overlies Bluefield formation. Occurrences in Kentucky noted.

Type locality: At village of Stony Gap, Mercer County, W. Va., on both sides of Bluefield-Princeton Road. Identifiable from Pennington Gap, Va., to Princeton, W. Va., and from Pineville, Ky., northeastward on Pine Mountain to Osborn Gap, Ky.

Stony Hills Formation[1]

Permian: Southern Kansas and western Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 358, 363.

C. C. Branson, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey.

Named for Stony Hills, east of Watonga, Blaine County, Okla.

Stony Hollow Member (of Marcellus Formation)

Middle Devonian: Southeastern New York and northeastern Pennsylvania.

G. A. Cooper, 1941, Washington Acad. Sci. Jour., v. 31, no. 5, p. 179–180. Chiefly fine-grained calcareous sandstone 75 to 100 feet thick. Underlies Mount Marion formation of Grabau at its type section. Beds formerly classified as "Marcellus" shale (Bakoven of Chadwick) immediately underlie Stony Hollow member and are now proved to be equivalent of Union Springs member. Southwest of Albany, layers of limestone appear in upper part of sandstone which has thinned to 24 feet; west of Onesquethaw Creek, these limestones of the Stony Hollow become the Cherry Valley limestone as exposed in Stony Creek, Schoharie Valley.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1783, chart 4. Age given on correlation chart as Middle Devonian.

Type section: At bend of New York State Highway 28 and along railroad opposite bend at entrance to valley leading up to settlement of Stony Hollow, 1¾ to 2 miles northwest of bridge over Esopus Creek on west side of Kingston, Ulster County. Also present along U.S. Highway 209 near Echo Lake, Pa.

Stony Lonesome Bed[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1935, Geol. Soc. America Bull., v. 46, no. 2, p. 334, 337–339.

Stony Lonesome, east of Warren, Warren County.

Stony Mountain Diorite

Miocene: Southwestern Colorado.

McClelland Dings, 1941, Geol. Soc. America Bull., v. 52, no. 5, p. 698 (fig. 1), 712–714. Name applied to diorite in Stony Mountain stock which penetrated Miocene volcanic rocks of San Juan, Silverton and Potosi series. Younger than Governor diorite (new).

Vertically exposed for 1,320 feet on east side of Stony Mountain, about 5 miles southwest of Ouray in San Juan Mountains.

**Stony Mountain Formation**[1] (in Bighorn Group)

Upper Ordovician: Surface and subsurface in Manitoba and Saskatchewan, Canada, and subsurface in Montana, North Dakota, and Wyoming.

Original reference: D. B. Dowling, 1901, Canada Geol. Survey Ann. Rept., new ser., v. 11, p. 46F.

V. H. Kline, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 3, p. 339, 360–361. Geographically extended into subsurface in North Dakota.

R. J. Ross, Jr., 1957, U.S. Geol. Survey Bull. 1021–M, p. 446 (fig. 88), 447–448, pl. 44. Discussion of Ordovician fossils from wells in Williston Basin, Mont. Stony Mountain formation, which comprises a lower shale member and an upper dolomitic member, is upper formation in Bighorn group in subsurface. Overlies Red River formation.

M. R. McCoy, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 27 (fig. 1), 29. Discussion of Ordovician rocks of northern Powder River basin and Black Hills uplift areas, Montana, Wyoming, and South Dakota. Correlation chart shows Stony Mountain in northern Powder River basin, Williston basin, and northern Big Horn Mountains. In first two areas, overlies Red River formation, and in Big Horn Mountains, overlies Bighorn [dolomite].

Named for exposures at Stony Mountain, near Winnipeg, Manitoba, Canada.

Stony Point Shale[1] (in Trenton Group)

Middle Ordovician: Northeastern New York and western Vermont, and Quebec, Canada.

Original reference: R. Ruedemann, 1921, New York State Mus. Bull. 227, 228, p. 112, 115–116.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 275. Discussed under heading of formations of Sherman Fall age in Trenton group. Overlies Cumberland Head shaly limestone, and has exposed thickness of 215 feet in section on Hero Island, Vt. It is prevalent black shale in northern Lake Champlain region, and in southern Quebec is overlain by Iberville shale of questionably Utica age. About 500 feet thick in type area. Overlies Lacolle conglomerate in Quebec.

David Hawley, 1957, Geol. Soc. America Bull., v. 68, no. 1, p. 58–62, pl. 1. Formation described in northern Champlain Valley, Vt., where it is predominantly calcareous shale in lower part, grading upward to predominantly quartz-silty argillaceous limestone. Thickness 1,000 to 1,500 feet. Overlies Cumberland Head formation; underlies Iberville formation. Trentonian.

Named for occurence at Stony Point, 1½ miles south of Rouses Point, Clinton County, N.Y.

Storm King Granite[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey, 1907, New York State Mus. Bull. 107 p. 364, 377.

K. E. Lowe, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 144–148, 157–188, pls. 1, 2, 3. In vicinity of Bear Mountain, occupies core of syncline in earlier crystalline complex here termed Hudson Highlands complex. It is part of a larger synclinal pluton whose accordance with the northeast-plunging structure is shown by conformable contacts and mineral alignment in both the granite and the country rocks. Storm King represents last major invasion of magmatic origin in Hudson Highlands area. In contrast to great variety of rock types in Hudson Highlands complex and their involved field relations, this granite occurs in large masses of rather uniform character; hence, it is the most distinct lithologic unit in the crystallines of the Hudson Highlands area.

Named for occurrence on Storm King Mountain, Putnam and Orange Counties.

Storm King Mountain Gneissoid Granite[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey, 1911, New York State Mus. Bull. 107, p. 364, 377.

Constitutes whole of Storm King mountain and larger part of Crows Nest on west side of Hudson River; also forms chief rock of Bull Hill and Breakneck Ridge in Putnam and Orange Counties.

Stormont Limestone Member (of Pierson Point Shale)

Pennsylvanian (Virgil Series): Northeastern Kansas.

H. G. O'Connor, 1953, Kansas Geol. Survey [Reports], v. 12, pt. 1, p. 18–19, pl. 1. Name applied to the lowest of three limestones near middle of Pierson Point shale. Member is variable in character but generally is sandy or silty and nonresistant to weathering; fossiliferous. Thickness averages 1 to 4 feet. At type locality, occurs about 12 feet below Maple Hill limestone and 13½ feet above Tarkio limestone. Occurs 12 to 18 feet above Tarkio limestone where Tarkio is present and about 10 to 20 feet above the Elmont where the Tarkio is absent. Because of its position between the Elmont and Maple Hill limestones, it has been erroneously called the Tarkio in parts of Lyon County where the Tarkio is absent.

Type locality: Along road and in ravines in NW¼ sec. 9, T. 14 S., R. 14 E., about 1 mile northwest of former Stormont post office, Osage County, where overlying Maple Hill and underlying Tarkio are also typically exposed.

Stormville Conglomerate[1]

Stormville Sandstone[1]

Stormville Sandstone Member (of Coeymans Limestone)

Lower Devonian: Northern New Jersey and northeastern Pennsylvania.

Original references: (Conglomerate) I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. $G_6$, p. 76, 132–133; (Sandstone) S. Weller, 1900, New Jersey Geol. Survey Ann. Rept. State Geologist 1899, p. 3–46.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 51–53. At Nearpass quarries in New Jersey, the Coeymans contains no appreciable amount of sand. In eastern Monroe County, Pa., 8 to 10 feet of calcareous sandstone occur at top of the Coeymans. I. C. White (1882) named this sandstone the Stormville conglomerate from exposures at that village about 3 miles southwest of Stroudsburg, where the sandstone is pebbly and 17½ feet thick, according to White's measurements. White also reported pebbles in parts of the 30 feet of limestone underlying main body of pebbly sandstone at Stormville. White applied name Stormville not only to this sandstone but also to underlying limestones and overlying shales of diverse ages. Name must be modified or discarded. Believed that name will be useful if restricted to above described sandstone member of Coeymans.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1158–1160. White's (1882) section at Stormville reexamined. Section is much concealed. Its lower part crosses minor anticline. It terminates above a sharp syncline. Stormville conglomerate is correlated with upper part of Coeymans limestone.

Named for occurrence in vicinity of Stormville, Monroe County, Pa.

Stormville Hydraulic Cement Bed[1]

Stormville Water Lime[1]

Lower Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. $G_6$, p. 136–137.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1160, 1171. White's Stormville hydraulic cement rock ("pethstone") included in Rondout limestone.

Named for occurrence in vicinity of Stormville, Monroe County.

Stormville Limestone[1]

Lower Devonian: Northeastern Pennsylvania and northern New Jersey.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. $G_6$, p. 76, 133–135.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 51–53. At Nearpass quarries in New Jersey, the Coeymans contains very little sand. In eastern Monroe County, Pa., 8 to 10 feet of calcareous sandstone occur at top of the Coeymans. White (1882) named this sandstone the Stormville conglomerate. White applied name Stormville not only to sandstone (conglomerate) but also to underlying limestones and overlying shales of diverse ages. Name must be modified or discarded. Believed that name Stormville is appropriate if restricted to sandstone which is here termed member of Coeymans limestone.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1160. White's (1882) Stormville section reexamined. Stormville limestone correlated with Manlius limestone.

Named for occurrence in vicinity of Stormville, Monroe County, Pa.

Stormville Shale[1]

Lower Devonian: Northern New Jersey and northeastern Pennsylvania.

Original reference: I. C. White, 1882, Pennsylvania 2d Geol. Survey Rept. $G_6$, p. 76, 131–132.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 51–53. White (1882) applied name Stormville not only to sandstone (conglomerate) but also to underlying limestones and overlying shales of diverse ages. Name must be modified or discarded. Believed that name Stormville is appropriate if restricted to sandstone which is here termed member of Coeymans limestone.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1158–1160. White's (1882) section at Stormville reexamined. Section is much concealed. Its lower part crosses minor anticline. It terminates above sharp syncline. Stormville conglomerate is overlain by Stormville shale to which White assigns thickness of 160 feet. Latter is succeeded by Oriskany sandstone. Stormville shale crops out in belt nearly 1,000 feet wide, measured perpendicular to strike. It is largely concealed, and its strikes and dips are unknown. It is bounded by beds with high dips. Evidently thickness of these beds cannot be as little as 160 feet, unless there is much concealed minor folding. Six miles east of Stormville, this interval is occupied by four geologic horizons—New Scotland, Becraft, Port Ewen, and Oriskany—with combined thickness of about 300 feet. Stormville shale is correlated with Oriskany shale.

Named for exposures at Stormville, Monroe County, Pa.

**Storrs Tongue** (of Star Point Sandstone)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: F. R. Clark, 1928, U.S. Geol. Survey Bull. 793.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, fig. 2. Has sharply defined top and grades downward from thick-bedded medium-grained sandstone into sandy shale and shale. About 30 feet thick at Storrs and thins to the east, disappearing about 1 mile east of Kenilworth. Separated from underlying Panther and overlying Spring Canyon sandstone tongues by westward-pointing tongues of Mancos shale. Of Montana age.

Named from exposure at Storrs, in Castlegate quadrangle, Carbon County, where it forms prominent cliff.

Story Formation (in Hansonburg Group)

Pennsylvanian (Missouri Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 63, 65–66. Name proposed for upper 58½ feet of type section of Hansonburg group (new). Formation includes 19½ feet of reddish brown shale, arkosic and micaceous sandstone, and gray shale at base; upper 38 feet is light-gray massive to massively bedded fossiliferous limestone. Underlies Del Cuerto formation (new); overlies Burrego formation (new).

Type locality: Northeast side of Oscura Mountains, Socorro County. Name derived from Story Tank, about 3 miles west of west-central front of Oscura Mountains.

**Stotler Limestone** (in Wabaunsee Group)

Pennsylvanian (Virgil Series): East-central Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Defined to include strata underlying Root shale (new) and overlying Pillsbury shale (new). Thickness ranges from 5 to 35 feet; average 14 feet. Includes (ascending) Dover limestone, Dry shale, and Grandhaven limestone members.

Type section: In spillway and along south side of pond in SE¼ sec. 13, T. 16 S., R. 12 E., Lyon County, about 2 miles west of Miller. Name derived from old Stotler post office which was in SW¼ sec. 10, T. 16 S., R. 13 E.

**Stoufferstown Member** (of Stonehenge Limestone)

Lower Ordovician: Central southern Pennsylvania, western Maryland, and West Virginia.

W. J. Sando, 1958, Geol. Soc. America Bull., v. 69, no. 7, p. 838 (fig. 2), 839, 846, 847. Thin-bedded limestone at base of Stonehenge. Thickness 217 to 224 feet. Underlies upper member (unnamed); overlies Conococheague formation. In Maryland, beds called upper member of Conococheague by Sando (1957, Geol. Soc. America Mem. 68) are now referred to Stoufferstown member.

Named for occurrence in vicinity of Stoufferstown, Chambersburg area, Franklin County, Pa.

**Stovall Limestone Member** (of Winfield Limestone)

Stovall Limestone (in Chase Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 49.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44. Member of Winfield limestone. Consists of dense gray limestone with an abundance of steel-gray flint where thin in northern Kansas; becomes thicker and noncherty in central and southern parts; fossils rare. Thickness commonly about 1 foot. Underlies Grant shale member; overlies Gage shale member of Doyle shale. Wolfcamp series.

Type locality: In bluffs of Doyle Creek valley, southeast of Stovall elevator and farm, 7 miles southwest of Florence, Marion County, Kans.

Stover Limestone

Stover Member (of Benner Limestone)

Middle Ordovician (Bolarian): Central and south-central Pennsylvania, western Virginia, and southern West Virginia.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Member of Benner limestone. Described as dark heavy ledged limestone Thickness 93 feet at type locality.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 17–19. Upper member of Benner. Described at type section as 91 feet of dark principally dense heavy ledged limestone. Ledges have thin stylotitic partings and fucoidal mottling. One thick metabentonite exposed in several sections. Thickness decreases southeastward. Overlies Snyder member. Underlies Valley View member of Curtin limestone in northern Centre, Clinton, and Lycoming Counties; southeastward disconformably underlies Nealmont limestone. Derivation of name and more exact location of type section stated.

Marshall Kay, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1199. Limestone included in upper Bolarian (Hunterian) series.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2, columns 21, 22. Geographic extension; listed in stratigraphic column for Highland County, Va., and Monroe County, W. Va. [Limestone apparently has formational rank in these areas.]

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 74 (table 12), 78, 95, 103. Geographic restriction. New name McGraw limestone proposed for rocks in Virginia previously referred to as Stover. Termed a formation.

Type section: In Pennsylvania Railroad cut at Union Furnace, Huntingdon County, Pa. Named for station of Stover northeast of Nealmont, Blair County, Pa., where well exposed in quarries.

**Stowe Formation**

Upper Cambrian(?) and Lower Ordovician(?): Central Vermont.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 65–66, 116. Described as pale-green albite-quartz-chlorite-muscovite schist. Includes Brackett member along eastern border of Rochester area. Thickness cannot be measured, possibly about 3.000 feet in this area. Underlies Moretown formation; overlies Ottauquechee formation. Lower Cambrian. Name attributed to Cady.

W. M. Cady, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–79. Ordovician. Derivation of name given.

A. L. Albee, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–102. In Hyde Park quadrangle, underlies Umbrella Hill formation (new). Ordovician.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, pl. 5. Upper Cambrian(?) and lower Ordovician(?).

Occurs on summits of Braintree Mountain and extends eastward beyond eastern border of Rochester quadrangle. Named for typical occurrence in southeastern part of Stowe Township, Lamoille County.

**Straight Cliffs Sandstone**[1]

Upper Cretaceous: Central southern Utah.

Original reference: H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164.

H. E. Gregory, 1950, Utah Geol. and Mineralog. Survey Bull. 37, p. 26 (table), 46–50. Generally in southern Utah, wherever recognized subdivisions of Cretaceous are clearly defined, Tropic formation is overlain in turn by Straight Cliffs sandstone and Wahweap sandstone. In this report [Iron County], the Straight Cliffs is recognizable and Wahweap is probably present but no plane of separation could be noted; hence, the two are described together. Combined thickness 700 to 1,150 feet.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 105–107, 128–129, pl. 5. Westward from type locality, formation changes rapidly. In Kaiparowits Plateau, consists of massive thick buff-gray sandstones, subordinate sandy shales, and coal including beds 3 to 10 feet thick. Along base of Paunsaugunt Plateau, number of thick sandstone beds decreases, the thin ones increase, and coal beds decrease in number, thickness, and purity. In Zion Park region, sandstones more than 10 feet thick make up about 50 percent of the beds; thinner sandstone beds, 45 percent; calcareous and argillaceous shale, 5 percent; coal is represented by earthy lignite or carbonaceous shale. In Santa Clara Valley, both shale and coal are absent. Conformably underlies Wahweap sandstone but in some the two units cannot be differentiated; overlies Tropic formation. Thickness of Straight Cliffs and Wahweap 1,406 feet in Zion Park region.

Named from Straight Cliffs in Escalante Valley, Utah.

**Straight Ridge Sandstone Member** (of Pottsville Formation)[1]

Lower Pennsylvanian: Central Alabama.

Original reference: C. Butts, 1927, U.S. Geol Survey Geol. Atlas, Folio 221.

Named for fact it forms Straight Ridge, which extends along west side and south end of Yellowleaf Basin, in Vandiver quadrangle.

Strain Shale Member (of Lykins Formation)

Triassic: North-central Colorado.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 31, 42–44, fig. 7. Red arenaceous shales and mudstones and fine argillaceous red sandstones with the shales and mudstones predominating. Thickness ranges from 290 to 320 feet. Overlies Glennon limestone member (new); underlies Ralston formation (new).

Named from Strain Gulch, which enters Bear Creek just east of town of Morrison, Jefferson County.

Strange Formation (in Arbuckle Group)

Lower Ordovician: Southwestern Oklahoma.

C. E. Decker, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1313, 1319, table 1; 1939, Oklahoma Geol. Survey Circ. 22, p. 15, 24–25. Name proposed for dolomite beds exposed in only four outcrops on south side of Wichita Mountains. Thickness 60 to 80 feet. Occurs below Cool

Creek formation and above McKenzie Hill formation. Name substituted for preoccupied Wolf Creek dolomite (Decker, 1933).

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey. Dolomitization is localized within McKenzie Hill, and the dolomite facies is not stratigraphically significant.

Type section: Caps top of McKenzie Hill in sec. 8 and extends down its southeast slope. Name taken from Strange Ranch on which two outcrops occur in secs. 8 and 9, T. 2 N., R. 12 W., Comanche County.

**Stranger Formation**[1] (in Douglas Group)

Pennsylvanian (Virgil Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 15–16. In Missouri, formation includes Tonganoxie sandstone, Vinland shale, and Haskell limestone members. Underlies Lawrence formation; overlies Iatan limestone.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 29–30. Stranger beds are exposed in three small areas in Table Rock-Richfield anticline in Cass and Sarpy Counties, Nebr. Stranger section in Cass County is (descending) Robbins shale, Cass formation, and Plattford formation.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 29–33. Formation includes (ascending) Tonganoxie Sandstone, Westphalia Limestone, Vinland Shale, Haskell Limestone, and Robbins Shale Members. Maximum thickness about 160 feet (Douglas County). Overlies Weston Shale; underlies Lawrence Shale.

Typically exposed along east side of sec. 3, T. 12 S., R. 21 E., Leavenworth County. Named from Stranger Creek near Tonganoxie, Kans.

Strasburg cyclothem

Pennsylvanian (Allegheny Series): Southeastern Ohio.

Incidental mention in road log: N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 14.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., p. 47–48, table 1, geol. map. Includes (ascending) Strasburg shale and (or) sandstone, 10 feet; Oak Hill clay, 7 feet; and Strasburg coal. Occurs below Middle Kittanning cyclothem and above Lower Kittanning cyclothem. In area of this report [Perry County], the Allegheny series is described on a cyclothemic basis; nine cyclothems are named. [For sequence see Brookville cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 64–68. Includes (ascending) Strasburg shale and (or) sandstone member, Hamden limestone member, Oak Hill underclay member, and Strasburg coal member. Occurs above Lower Kittanning cyclothem and below Middle Kittanning cyclothem. In this report [Athens County], the Allegheny series is described on a cyclothemic basis; 13 cyclothems are named. [For complete sequence see Brookville cyclothem.]

Town of Strasburg is in Tuscarawas County.

Strasburg Formation or Limestone

Middle Ordovician (Chazyan): Tennessee.

E. O. Ulrich, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 106. On correlation chart, Strasburg formation of Clinton and Pearisburg troughs of Tennessee is shown stratigraphically below Holston formation and above Lenoir formation of Knoxville and Athens troughs of Tennessee.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 75. Name Strasburg limestone was introduced without definition by Ulrich (1939) for a part of succession herein identified as Lincolnshire. Since name Strasburg has received no precise definition or description at time Lincolnshire was introduced (1943), Strasburg is considered invalid.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 92. No formal description of unit has been published. Because Strasburg appears on Ulrich's chart between Lenoir below and Holston above, it is in position of Lincolnshire formation.

Occurs in Shenandoah Valley.

Strasburg Shale

Strasburg shale and (or) sandstone member

Pennsylvanian (Allegheny Series): Eastern Ohio.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 118 (table), 145–160. Overlying Lower Kittanning coal horizon and extending up to next persistent and widely distributed member, Middle Kittanning clay, is series consisting chiefly of shale with ironstone concretions known as Strasburg shale, but also containing sandstone, limestone, coal, and clay of more or less widespread but patchy distribution. Where complete series occurs, succession is (ascending) Hamden limestone, shale, Oak Hill clay, Strasburg coal, shale, and Salem limestone. Upper and lower limits of Strasburg shale member are clearly defined across State. Thickness of horizon variable but averages about 20 feet. Allegheny series.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 47, 48, table 1. Strasburg shale and (or) sandstone included in Strasburg cyclothem (new). Table shows sequence (ascending) Strasburg shale and (or) sandstone, Oak Hill clay, and Strasburg coal.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 64–66. Strasburg shale and (or) sandstone member of Strasburg cyclothem in report on Athens County. Average thickness about 14 feet. At base of cyclothem; underlies Hamden limestone member. Allegheny series.

Town of Strasburg is in Tuscarawas County.

**Stratford Formation**[1] (in Pontotoc Group)

Permian: Central southern Oklahoma.

Original reference: G. D. Morgan, 1924, Oklahoma Bur. Geology Bull. 2, p. 137–140, pls. 3, 27, map.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Permian. Includes Hart limestone member at base in Pontotoc, Garvin, and Murray Counties.

Named for exposures at and around Stratford, Garvin County.

Strathearn Formation

Upper Pennsylvanian and Permian (Missourian-Wolfcampian): Northeastern Nevada.

R. H. Dott, Jr., 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 11, p. 2249–2255, figs. 2, 5. Quartz-silty limestones and thin commonly crossbedded chert-granule and pebble conglomerate. Poorly exposed except where topography is rugged. Crinoidal calcarenite important constituent. Few individual units exceed 20 feet in thickness, except near base where some limestone units are as thick as 40 feet. Stratification indistinctly thin- to thick-bedded in purer limestone, but more distinct and thinner in sandy or conglomeratic units. Grayish yellow-weathering, calcareous quartz siltstones common and characteristically contain fusulinids. At type section, lower 200 to 300 feet fairly pure limestone, middle 500 to 800 feet contain most of typical chert-granule beds interspersed with impure limestone, and upper few hundred feet have thicker limestones and siltstones with some associated conglomerate. In type area, composite section is 1,200 to 1,500 feet thick. Thickness at Carlin Canyon and Buckskin Mountain at least 800 to 1,000 feet. Overlies older formations with angular discordance.

T. G. Fails, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 10, p. 1693, 1695 (fig. 1). In Carlin Canyon, conformably underlies Buckskin Mountain formation (new).

Grant Steele, 1960, Dissert. Abs., v. 20, no. 12, p. 4635. Underlies Jakes Creek formation (new).

Type section: At west side of head of lower canyon of South Fork of Humboldt River, 4 miles southeast of Strathearn Ranch and northeast of Grindstone Mountain (SW¼ sec. 19, T. 33 N., R. 55 E., and along south line of sec. 24, T. 33 N., R. 55 E). Supplementary section containing higher strata occurs 1½ miles farther south, and on east side of river at mouth of the upper canyon of South Fork (NW¼ sec. 31, T. 33 N., R. 55 E.). Named for Strathearn Cattle Co. which owns ranch in Humboldt Valley, 3½ miles north of Grindstone Mountain and 2 miles east of Moleen (sec. 8, T. 33 N., R. 54 E.).

Stratton-Kennebago Granite

Upper Devonian(?) to Lower Mississippian(?): Central western Maine.

R. J. Willard, 1959, Dissert. Abs., v. 19, no. 11, p. 2918. Calci-alkalic granite.

In Kennebago Lake quadrangle.

**Straven Conglomerate Member** (of Pottsville Formation)[1]

Pennsylvanian: Central Alabama.

Original reference: Charles Butts, 1927, U.S. Geol. Survey Geol. Atlas, Folio 221.

H. E. Rothrock, 1949, Alabama Geol. Survey Bull. 61, pt. 1, p. 29–30. Mentioned in discussion of age relation of subdivisions of Pottsville formation. Straven conglomerate, thickness about 2,000 feet, lies immediately above Thompson coal bed, which Butts (1926, Alabama Geol. Survey Spec. Rept. 1) includes with "middle Pottsville" strata. Beds of "upper Pottsville" age occur a short distance above Straven conglomerate member.

Named for Straven, in Montevallo quadrangle, Shelby County.

774-954—vol. 3—66——55

Strawbridge Member (of Quimbys Mill Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9, 15C. Dolomite, cherty, medium bedded. Thickness 2½ to 4½ feet. Shown on columnar section as underlying Garnavillo member (new) of Guttenberg formation (Spechts Ferry formation absent) and overlying Shullsburg member (new) of Quimbys Mill formation.

In copy of guidebook used by compiler, in figure 9, name Garnavillo has been crossed out and name Garnet written in. The compiler had no way to determine what change, if any, had been made in other guidebooks.

Occurs in Dixon-Oregon area.

**Straw Hollow Diorite**[1]

Upper Paleozoic(?): Northeastern Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 219–220, map.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 46–47, pl. 1. Described in Hudson quadrangle as chiefly medium-gray medium-grained diorite. In part is a finer grained rock of same composition. Commonly exhibits linear structure. Rarely shows foliation. Contact with Gospel Hill gneiss (new) appears sharp. Late Paleozoic(?).

Type locality: Straw Hollow in Northboro, Worcester County.

**Strawn Group**[1]

Strawn Formation

Strawn Series

Middle Pennsylvanian: Central and northern Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., pl. 3, p. lxvi.

N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 373–387. Strawn division comprises following beds (ascending): Lynch Creek, Burnt Branch, Elliott Creek, Shadrick Mill, Bed no. 8, Fox Ford, Horse Creek, Bull Creek, Big Valley, Brown Creek, Spring Creek, Cottonwood Creek, Hanna Valley, Rough Creek, Buffalo Creek, Wilbarger Creek, Comanche Creek, Antelope Creek, Indian Creek, and Ricker. Underlies Canyon division with Coral limestone bed at base.

C. O. Nickell *in* Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 91–94, pl. 8. In this report [Brown and Coleman Counties], Capps limestone is treated as member of Mineral Wells formation, upper formation of Strawn group.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 87–89. Proposed to use term Strawn series for deposits occurring above unconformity at top of Smithwick group and related beds of Lampasas series (new) and below unconformity or disconformity which separates Lake Pinto sand (Canyon series) from East Mountain shale at Mineral Wells. This places upper boundary above highest occurrence of *Mesolobus* and *Fusulina*, which characterize the Des Moines but are absent in overlying Missouri series of northern mid-continent. This upper boundary falls within Mineral Wells formation of earlier reports. Term Mineral Wells formation dropped. As defined herein, series comprises Millsap Lake and Lone Camp (new) groups.

M. G. Cheney, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 206–211. Lampasas-Strawn series boundary placed at disconformity between Dennis Bridge limestone and overlying conglomerate. As thus restricted, Strawn series of Brazos River section is about 2,000 feet thick. Comprises Millsap Lake group below and Lone Camp group above. Overlies Kickapoo Creek group (new) of Lampasas series.

R. J. Cordell and D. A. Zimmerman, 1954, Abilene Geol. Soc. Guidebook Field Trip, Nov. 19–20, p. 46 (fig. 38), 47–48. Concluded that lower Brownwood of Brown County is probably of late Strawn age and upper Brownwood is early Canyon. Hence, base of conglomerate separating these two parts of Brownwood shale should be regarded as Canyon-Strawn contact. This would increase Strawn interval in Brown County by about 125 feet at expense of the Canyon. Believed that Canyon-Strawn contact in Palo Pinto County should be at base of Turkey Creek sandstone. Turkey Creek sandstone is immediately overlain by Keechi Creek shale near top of which *Triticites* (post Strawn age) has been found.

J. W. Shelton, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1515–1524. Strawn-Canyon boundary, placed at prominent surfaces as paleontologic evidence allows, is drawn at top of Capps limestone in Colorado River valley, at top of Village Bend limestone ("boulder beds") in Comanche and Eastland Counties, and at base of Lake Pinto sandstone in northeastern part of Brazos River valley. Zonation based on fusulinids is best criterion for defining boundary. Strawn series is characterized by genus *Fusulina*, Canyon series by *Triticites*.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58–62, pl. 27. Sandstone and shale beds that constitute Strawn group in Colorado River valley were first called Richland sandstone by Tarr (1890, Texas Geol. Survey 1st Ann. Rept.). These and correlative beds in Brazos River valley were called Richland-Gordon sandstones by Dumble (1890). Drake (1893) separated these rocks into 20 units or "beds" and numbered those of Strawn group, from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, but that name has been restricted to prominent sandstone at base of Drake's Ricker bed. Drake referred these units to Strawn division of Cummin's (1891, Texas Geol. Survey 2d Ann. Rept.) which he considered to include all rocks above Bend division and below his Coral limestone bed, the Capps limestone of later authors. Plummer and Moore (1921, Texas Univ. Bull. 2132) considered Strawn in Colorado River valley to be equivalent to their Mineral Wells and Millsap formations of Brazos River valley. They limited Strawn group to rocks that overlie Smithwick shale of Bend group and underlie Rochelle conglomerate. This placed Drake's Coral limestone bed, named Capps limestone lentil by Plummer and Moore, in Canyon group. The Capps was thought to overlie Rochelle conglomerate and was regarded as part of Brownwood shale member of Graford formation. Sellards (1933, Texas Univ. Bull. 3232, v. 1) transferred Capps back to Strawn group and considered it upper member of Mineral Wells formation. Rocks of Strawn group in Brazos River valley have been studied in detail and classified into units. Strawn group in present report [Brown and Coleman Counties, Colorado River valley] represents only upper part of group elsewhere. Term Strawn group is used herein for all rocks in Colorado River valley between top of Smithwick shale of Bend group and base of Brownwood shale member of Graford formation of Canyon group. Term Mineral Wells not used in this area. The Strawn becomes thinner from central Brown County, where it is reported to be 1,100 feet thick in wells, to 500 feet in north-central Coleman County, and from 1,235 feet in northern Brown County to about 250 feet in southwestern Brown County and southeastern Coleman County. Group includes (ascending) Ricker Station limestone of Cheney (1949), Ricker sandstone member of Nickell (1938) and Capps limestone lentil of Plummer and Moore (1921).

Named for Strawn, Palo Pinto County.

†Strawn Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 110.

Named for Strawn, Coffey County.

Street Road Limestone[1]

Cambrian: Southeastern Pennsylvania.

Original reference: T. D. Rand, 1900, Philadelphia Acad. Nat. Sci. Proc. 1900, pt. 1.

**Strelna Formation[1]**

Mississippian: Southeastern Alaska.

Original reference: F. H. Moffit and J. B. Mertie, Jr., 1923, U.S. Geol. Survey Bull. 745, p. 18–19, 21–28, table opposite p. 28, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legends.

Named for occurrence in valley of Strelna Creek, Kotsina-Kuskulana district, Copper River region.

**Stribling Formation**

Lower or Middle Devonian: Central Texas.

V. E. Barnes and P. E. Cloud, Jr., 1945, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 34, p. 31. Limestone—microgranular, medium-gray to reddish-buff, beige, and ivory; chert—chalcedonic to subchalcedonic and brownish to grayish in lower part, occurring as irregular lenses and false joint fillings; some lenticles of yellowish siliceous limestone about 1 to 2 feet above base; basal 1 foot noncherty. Thickness 10 feet. Overlies Honeycut formation (new); underlies unnamed chert breccia. Section described is at Honeycut Bend, Blanco County.

V. E. Barnes, P. E. Cloud, Jr., and L. E. Warren, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 169–174, 175 (fig. 46), pl. 6 [1945]. Thickness at designated type locality 11 feet. Here a pocket of Devonian rocks filling a cave in limestone of Ellenburger group may be a correlative of Pillar Bluff limestone.

V. E. Barnes, P. E. Cloud, Jr., and Helen Duncan, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 1031, 1033. In Llano uplift, overlies Burnam limestone (new) and in some parts of area overlies Honeycut formation.

Type locality: Five mlies due east of Johnson City, at foot of bluff on south bank in reach of Pedernales River known as Honeycut Bend. Located in Peter Jackson survey and is on Clayton and Olla Stribling (7L) Ranch.

Strickler Limestone (in Sumner Group)[1]

Strickler Limestone Member (of Donegal Limestone)

Permian: Northeastern Kansas.

Original reference: R. C. Moore, 1936, Kansas Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12 (graphic section).

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 30. Term Wellington is used for section between top of Herington limestone and base of Ninnescah formation. Of the 10 subdivisions listed, the Strickler limestone and Newbern shale members of the Donegal limestone (Moore, 1936) are not very persistent; name Donegal limestone is not well founded.

Type locality and derivation of name not stated.

†Stringtown Shale[1]

Lower and Middle(?) Ordovician: Southeastern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

Named for Stringtown, Atoka County.

**Striped Peak Formation**[1] (in Missoula Group)

Precambrian (Belt Series): Northeastern Idaho and northwestern Montana.

Original reference: F. L. Ransome, 1905, U.S. Geol. Survey Bull. 260, p. 277–285.

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 92, p. 44, pl. 11. Sandstones, siliceous, generally flaggy to shaly; mostly green and purple; characterized by shallow-water features, such as ripple marks and sun cracks. Top removed by erosion. Thickness about 1,000 feet. Overlies Wallace formation.

Russell Gibson, 1948, U.S. Geol. Survey Bull. 956, p. 16–17, pl. 1. Described in Libby quadrangle, Montana, where it is 2,000 to 2,500 feet thick, underlies Libby formation (new) and overlies Wallace formation.

C. P. Ross, 1949, (Abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 113. Included in Missoula group.

J. W. Hosterman, 1956, U.S. Geol. Survey Bull. 1027–P, p. 730, pl. 57. Described in Shoshone County, Idaho. Youngest unit of Belt series. In northern exposure, conformably overlies Wallace formation and in southern exposure is bounded by two faults. Consists of grayish-purple to dark-red impure quartzite in beds that range from 1 to 4 inches in thickness.

Named for extensive development near Striped Peak, Idaho.

**Striped Rock Granite**

Precambrian: Southwestern Virginia.

A. J. Stose, 1942, (abs.) Am. Geophys. Union Trans., 23d Ann. Mtg., pt. 2, p. 342. An injection complex of early Precambrian age is exposed in Elk Creek anticline in Grayson County. There, sedimentary rocks and diorite have been intruded by the Striped Rock and Carsonville granites.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 26–32, pl. 1. Predominantly biotite granite, fine-grained aplite, and pegmatite; contains garnet in places; locally, as near Peach Bottom Church, contains xenolithic inclusions. A syenite facies forms a narrow body within southern part of main granite area where it parallels the strike of the main granitic mass; syenite is bordered in places by narrow bands of Saddle gneiss which separate the syenite from the Striped Rock granite. There are small inclusions and shred of Saddle gneiss and Cattron diorite in the Striped Rock. Bordered on the northern and northeastern sides and intruded by Carsonville granite.

Named from Striped Rock, a smooth-faced cliff of granite 300 feet high on spur of Point Lookout Mountain. Granite forms an elliptical area 8 miles long by 3 miles wide on southeast side of Point Lookout and Buck Mountains. Main area extends from near Pilgrims Rest Church southwestward to Saddle Creek; its greatest width is northwest of Independence.

Strites Pond Formation[1] or Limestone

Upper Cambrian or Lower Ordovician: Northwestern Vermont, and southeastern Quebec, Canada.

Original reference: H. W. McGerrigle, [1931], Vermont State Geologist 17th Rept., p. 182, 184, 185.

J. A. Dresser and T. C. Denis, 1944, Quebec Dept. Mines Geol. Rept. 20, v. 2, p. 396, 397. Overlies Rock River dolomite; underlies Wallace Creek limestone. Thickness about 400 feet. Philipsburg series. Beekmantown.

Exposed from northern part of St. Albans quadrangle, Vermont, across the international border for about 20 miles into Quebec.

†Strong Flint (in Chase Group)[1]

Permian: Central Kansas.

Original reference: C. S. Prosser, 1895, Jour. Geology, v. 3, p. 771–786, 799.

Named for Strong City, Chase County.

†Strong City Beds[1]

Permian: Central Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Probably named for Strong City, Chase County.

**Stronghold Granite**

Eocene(?) to lower Pliocene(?): Southeastern Arizona.

D. J. Cederstrom, 1946, Am. Jour. Sci., v. 244, no. 9, p. 610–611. In most places, is white where fresh and light yellow where weathered, medium- to coarse-grained texture, and may be described as porphyritic, although porphyritic character not everywhere readily apparent in hand specimens. Intrusive into Mesozoic rocks and considered to have been implaced during Laramide Revolution.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 9 (table), 106–108, pl. 5. Three major facies recognized: Main facies, rather coarse-grained granite ranging from light gray to light pink and weathers buff; border facies, porphyritic, though not conspicuously so; and aplitic facies, differs only slightly from border facies though it seems to contain even less biotite. Youngest major intrusion in region. Cuts Dragoon thrust sheets in many places, and at one place or another it is in intrusive contact with representatives of all rocks from Pinal schist to Bisbee formation. Younger than Cochise Peak quartz monzonite. Mapped as Eocene(?) to lower Pliocene(?).

Makes up Cochise Stronghold mass, a natural fortress within northern part of Dragoon Mountains, and extends southward as narrow bands in the Dragoon Mountains, Cochise County.

Strongsville Member (of Cuyahoga Formation)

Lower Mississippian (Kinderhookian): Northern Ohio.

E. J. Szmuc, 1957, Dissert. Abs., v. 18, no. 6, p. 2109. Silty shale unit intercalated between two siltstones. Underlies Meadville member; overlies Sharpsville member.

In Cuyahoga, Summit, Medina, and Lorain Counties.

Stroudsburgian Stage

Middle Devonian: Eastern Pennsylvania.

Bradford Willard *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G-19, p. 131 (footnote).

Name proposed to include Onondaga group, including so-called Esopus. Ulsterian stage of New York, which includes Onondaga and Schoharie, not applicable here since it does not include the Esopus, and the Schoharie is not recognized in Pennsylvania.

Named from Stroudsburg, Monroe County, where best observed.

Stuart Glacial Stage

Stuart Till

Pleistocene: Central Washington.

B. M. Page, 1939, Jour. Geology, v. 47, no. 8, p. 785, 805-814. Latest of three successive stages of valley glaciation in Leavenworth area. Characterized by deposition of Stuart till. Followed Leavenworth stage and has lingered almost to present time. Probably equivalent to all or part of Wisconsin stage.

Evidence of the stage present in vicinity of Mount Stuart, especially at junction of Rat Creek and Icicle Creek, Chelan County.

Stuart Shale[1] (in Cabaniss Group)

Pennsylvanian (Des Moines Series): Central southern and eastern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas Folio 74.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1525. Assigned to Cabaniss group (new).

Named for Stuart, Hughes County. Town is located on outcrop of formation.

**Stuck Drift, Till, Glaciation**

Pleistocene, middle(?): Northwestern Washington.

D. R. Crandell, D. R. Mullineaux, and H. H. Waldron, 1958, Am. Jour. Sci., v. 256, no. 6, p. 385, 390, 391-392. Consists chiefly of till and sand and gravel of northern derivation; where typically exposed, includes an unoxidized or only slightly oxidized till sheet 5 to 20 feet thick, which is overlain and underlain by oxidized sand and gravel 10 to 20 feet thick; pebble-sized fraction of till typically includes 10 to 15 percent of northern rock types and the rest is of Cascade origin; upper part of drift contains lacustrine sand and silt; locally lacustine sediments include lenticular masses of glacial sand and gravel and scattered glacial boulders, and in places beds are tilted and faulted. Separated from underlying Alderton formation (new) by erosional unconformity; underlies Puyallup formation. In sequence, Stuck glaciation followed Orting glaciation and preceded Salmon Springs glaciation (new).

Typically exposed in west wall of Puyallup-Duwanish Valley in gullies under transmission line of Bonneville Power Administration in center sec. 1, T. 19 N., R. 4 E., about one-half mile southwest of Alderton, Pierce County. Name derived from Stuck River which joins Puyallup River near Sumner.

**Stull Shale Member** (of Kanwaka Shale)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 94, 96 (table).

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24. Thickness 4 feet in Weeping Water valley, Cass County.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii, 17. Columnar section shows Stull shale member at top of Kanwaka formation. [Text does not discuss unit in Missouri.]

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 62 (fig. 23), 67. Yellowish-brown sandy shale, locally one or more coal beds; sandstone containing land plant remains and partly filling channels occurs in upper part in northern Kansas; much or all of Elgin sandstone in southern part of State may belong in this division. Thickness about 25 to at least 45 feet. Overlies Clay Creek limestone member; underlies Spring Branch limestone member of Lecompton limestone.

Type locality: SE cor. sec. 26, T. 12 S., R. 18 E., near village of Stull, Douglas County, Kans.

**Stump Sandstone**[1]

Upper Jurassic: Southeastern Idaho and western Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98, p. 76, 81.

L. S. Gardner, 1944, U.S. Geol. Survey Bull. 944–A, p. 7. Section in Irwin quadrangle, Teton basin, shows Stump sandstone, 140 feet thick; overlies Preuss sandstone; underlies Ephraim conglomerate of Gannett group.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, p. 1269 (fig. 6), 1276 (fig. 8), 1278–1279, 1280 (fig. 10). Name Stump is used in this report [Uinta Mountains] in Weber River, Duchesne River, and Lake Fork areas so that southeastern Idaho Jurassic terminology is uniformly used in all western sections; east of Lake Fork, name Curtis is used. Thickness 223 feet, Weber River area; 210 feet, Duchesne River area; and 130 feet, Lake Fork area. Overlies Preuss sandstone; unconformity in some areas; underlies Morrison.

H. L. Foster, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1538 (strat. column), 1566–1567. In Teton County, Wyo., is about 350 feet thick and consists of greenish sandstones with some interbedded siltstone and shale. Underlies Cloverly formation; overlies Twin Creek limestone, the Preuss sandstone, which overlies Twin Creek farther west, not definitely recognized in area of this report.

E. R. Cressman, 1957, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–118. As mapped in Snowdrift Mountain quadrangle, Caribou County, Idaho, overlies Preuss sandstone and underlies Bechler and Ephraim conglomerates undifferentiated. Thickness 400 to 500 feet.

Named for Stump Peak, east head of north fork of Stump Creek about center of T. 6 S., R. 45 E., Boise meridian, Freedom quadrangle [Caribou County], Idaho.

**Stump Arroyo Member** (of Crooked Creek Formation)

Pleistocene: Southwestern Kansas.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no. 4, p. 69 (fig. 1), 71–73. Name applied to basal part of Crooked Creek formation. Consists of coarse sand, reddish to light tan, and well sorted, containing white quartz pebbles; grades upward into finer more poorly sorted sand, with calcareous nodules at top. Thickness a little more than 10 feet. Unconformably overlies Missler member (new) of Meade formation (redefined). In some areas where the Crooked Creek is not extensively developed, Pearlette Ash member rests directly on the Stump Arroyo.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1), 57. Underlies Atwater member (new).

Type locality: Sec. 21, T. 33 S., R. 28 W., Meade County. Gravels of member form high surface rubble in sec. 10, T. 33 S., R. 29 W., along tributary of Stump Arroyo north of the Deer Park and west of the northwest corner of Deer Park. Name derived from tributary of Crooked Creek which flows through Meade County State Park and empties into Crooked Creek in sec. 29, T. 33 S., R. 28 W.

**Stuntz Conglomerate Member** (of Knife Lake Group)[1]

Precambrian (pre-Huronian) : Northeastern Minnesota.

Original reference: A. Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept., p. 350.

Named for exposures in vicinity of Stuntz Bay of Vermilion Lake in Vermilion district.

†Stuntz Island Agglomerate[1]

Precambrian: Minnesota.

Original reference: N. H. Winchell and H. V. Winchell, 1890, Minnesota Geol. Nat. History Survey Bull. 6.

**Sturgeon Quartzite**[1] (in Chocolay Group)

Precambrian (Animikie Series) : Northern Michigan.

Original reference: H. L. Smyth, 1889, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 105.

F. J. Pettijohn and F. A. Hildebrand, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1927. Overlies Fern Creek formation (new).

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Assigned to newly defined Chocolay group.

Named for exposures along Sturgeon River, Iron County.

Sturm Limestone (in Lawrence Shale)[1]

Pennsylvanian: Southeastern Nebraska.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 6, 33.

Well exposed near Sturm's Schoolhouse, sec. 12, T. 10 N., R. 12 E., and along North Branch of Weeping Water Creek, 2 to 4 miles north of Nehawka, Cass County.

**Stuver Member** (of Kanayut Conglomerate)

Stuver Series[1]

Upper Devonian: Northern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 240.

A. L. Bowsher and J. T. Dutro, Jr., 1957, U.S. Geol. Survey Prof. Paper 303–A, p. 3, 5, 11–13, figs. 2–4, pl. 2. Schrader gave name Stuver series to conglomeratic sequence beneath Lisburne formation in central Brooks Range. Although name Stuver later fell into disuse, it is herein reestablished and applied to top member of Kanayut conglomerate (new). In Shainin Lake area [this report], member restricted to upper part of Kanayut conglomerate because these beds most closely resemble those exposed on Mount Stuver from which Schrader took the name. Consists of about 860 feet of orthoquartzite, gray, red, and green shale, and conglomerate. Overlies unnamed middle conglomerate member; underlies Kayak shale (new).

Type locality of member: On ridge 0.7 mile south of Mount Wachsmuth, Shainin Lake area, central Brooks Range. Named for Mount Stuver, east of Anaktuvuk River.

Stuyvesant Beds

Primordial: Southeastern New York.

S. W. Ford, 1884, Am. Jour. Sci., 3d ser., v. 28, no. 165, p. 206. Mentioned in discussion of age of the glazed and contorted slaty rocks in vicinity of Schodack Landing, Rensselaer County. A fault intervenes between these beds and the slaty rocks which resemble Hudson River group.

Occurs near Stuyvesant, Columbia County.

†sub-Blairsville red shale member (of Chemung Formation)[1]

Upper Devonian: Western Pennsylvania.

Original reference: M. R. Campbell, 1904, U.S. Geol. Survey Geol. Atlas, Folio 110.

Named for occurrence in wells in vicinity of Blairsville, Indiana County.

†sub-Clarksville Sand[1]

Upper Cretaceous (Gulf Series): Northeastern Texas and Southwestern Arkansas.

Original reference: A. C. Veatch, 1906, U.S. Geol. Survey Prof. Paper 46, p. 24–25, table opp. p. 16.

C. L. McNulty, Jr., 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 2, p. 336–337. Lake Crockett formation (new) includes at base, a gray sand that is equivalent to former sub-Clarksville of east Texas basin.

Named for development in wells at Clarksville, Red River County, Tex.

Sublett Member (of Wells Formation)

Pennsylvanian (Desmoinesian-Virgilian): Idaho.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). Name appears on chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. Underlies Indian Fork member (new); overlies Heglar Canyon member (new).

Present in Sublett Mountain area.

†Sucarnooche Clay (in Midway Group)[1]

Eocene, lower: Southwestern Alabama.

Original reference: E. A. Smith, 1892, Sketch of geology of Alabama, pam., 36 p., Birmingham, Ala., Roberts and Son.

F. S. MacNeil, 1946, U.S. Geol. Survey Strat. Minerals Inv. Prelim, Rept. 3-195, p. 10. Name Sucarnooche clay, formerly used for entire Porters Creek clay of western Alabama as well as for calcareous clay east of Tombigbee River, is abandoned.

Named for exposures on Sucarnooche Creek at Black Bluff, Sumter County.

Sucker Creek Beds, sediments, deposits

Miocene: Eastern Oregon.

D. W. Scharf, 1935, Carnegie Inst. Washington Pub. 453, p. 98-118. Description of a Miocene mammalian fauna from Sucker Creek. The Sucker Creek beds are directly related to Payette formation as shown by the flora and such comparison as can be made between the fossil mammals obtained at Sucker Creek and those from type section of the Payette. Future geologic mapping may show that Sucker Creek beds are an integral part of Payette formation. The beds carrying the fossils consist of fine- to medium-grained pyroclastics, varying from white to green and brown. Presence of fish vertebrae and ostracod shells indicates deposition of at least part of the sediments in body of water.

Occur along lower course of Sucker Creek in eastern Malheur County. Important collecting localities are about 9 miles north of Rockville, Oreg., and about 5 miles west of Oregon-Idaho border.

**Sudbury Marble**[1]

Middle Ordovician (Chazy): Southwestern Vermont.

Original reference: A. Wing, 1877, Am. Jour. Sci., 3d, v. 13, p. 334-347, 404-419.

Crops out in town of Sudbury, northwest end of Taconic Range, in Rutland County.

†Suffolk Porphyry[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 81, 176, 177.

Occurs on Old Suffolk mining location, Praysville, Keweenaw Point.

Sugar Creek Shale in (Bethany Falls Limestone)[1]

Pennsylvanian: Missouri-Kansas.

Original reference: C. O. Dunbar and G. E. Condra, 1932, Nebraska Geol. Survey Bull. 5, 2d ser., p. 17.

In vicinity of Kansas City.

Sugar Hill Quartz Monzonite[1] (in New Hampshire Magma Series)

Upper Devonian or Upper Carboniferous: West-central New Hampshire.

Original reference: M. P. Billings, 1935, Geology of Littleton and Moosilauke quadrangles, New Hampshire, p. 28, Moosilauke map.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 502, 508, pl. 12. New Hampshire magma series represented in Littleton-Moosilauke area by Moulton diorite, Bethlehem gneiss, Kinsman quartz monzonite, Remick tonalite, Sugar Hill quartz monzonite, French Pond granite, Moody Ledge granite, Pond Hill granite, and Scrag granite. Relative ages of units not determined for in few places are they in contact with one another.

Mapped on Ore Hill, southeast of Sugar Hill, in northeastern corner of Moosilauke quadrangle.

Sugarloaf Andesite

Miocene or Pliocene: Central Washington.

Mentioned as being a remnant of a lava cap: B. M. Page, 1940, Stanford Univ. Abs. Dissert., v. 15, p. 119.

Occurs in Entiate Mountains, near Wenatchee, Chelan County.

**Sugar Loaf Basalt**[1] (in Honolulu Volcanic Series)

Pleistocene, upper, or Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 131–132. Voluminous lava flow of melilite-nepheline basalt; contains many pegmatoid veinlets; locally columnar joint. Commonly 40 feet thick. Overlies reef limestone of plus 25–foot (Waimanalo) stand of sea. Probably simultaneous with Tantalus basalt.

Named for Sugar Loaf (Puu Kakea), the cinder cone at vent from which it issued. Well exposed in Moiliili quarry. Covers about 1 square mile in lower end of Manoa Valley, on south side of Koolau Range about 11 miles west of Makapuu Head.

**Sugarloaf Formation**

Sugarloaf Arkose (in Newark Group)[1]

Upper Triassic: Central Massachusetts and central Connecticut.

Original references: B. K. Emerson, 1891, Geol. Soc. America Bull., v. 2, p. 452; 1898, U.S. Geol. Survey Geol. Atlas, Folio 50.

G. W. Bain, 1941, Am. Jour. Sci., v. 239, no. 4, p. 266, 267. Underlies Holyoke lava flow in Holyoke Range, Mass. Thickness approximately 4,000 feet.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Redefined as formation which includes Sugarloaf arkose of Emerson (1898) and that part of Emerson's Mount Toby conglomerate which underlies lava and is gradational with arkose. Red arkose grades laterally into coarse arkosic conglomerate toward southeast.

Named for occurrence at Sugarloaf Mountain, Deerfield Township, Franklin County, Mass.

Sugarloaf Metaquartzite[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 623, 635.

J. J. Runner, 1928, (abs.), Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included in Snowy Range series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consists of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

Exposed on northeast side of Sugarloaf Peak, Medicine Bow Mountains.

**Sugarloaf Quartz Latite**

Cretaceous or Tertiary: Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 90–93, pls. 5, 12. Rocks generally light gray or dense white, with slightly pinkish-gray hue on fresh fractures. In some areas, contains phenocrysts of biotite, quartz, and chalky feldspar that range up to 2 mm and average 1 mm in length. Groundmass is aphanitic. Estimated thickness at Sugarloaf Hill about 1,500 feet. Nearly all contacts with other formations are faults. Accordingly, a complete section would be still thicker. At no other point in area is a thickness of more than 500 feet exposed.

Type locality: At Sugarloaf Hill, about 1 mile southeast of Gleeson, in central Cochise County. Recognized in Courtland-Gleeson area.

Sugarloaf Sandstone[1] or Quartzite

Lower Cambrian: Central northern Maryland.

Original reference: C. R. Keyes. 1891, Geol. Soc. America Bull., v. 2, p. 306, 320–322.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 347. Name replaced by Sugarloaf Mountain quartzite because name Sugarloaf arkose, of Triassic age, has become established formation name in Massachusetts.

Ernst Cloos and C. W. Cooke, 1953, Geologic map of Montgomery County and the District of Columbia (1:62,500): Maryland Dept. Geology, Mines and Water Resources. Massive light quartzite composed of round white or blue quartz grains. Layers below more schistose and interbedded with shale or purple phyllite. Series consists of four prominent beds with phyllite interbeds. Underlies Harpers phyllite. Mapped as Cambrian.

At Sugarloaf Mountain, Frederick County.

Sugarloaf Series

Cenozoic: Southeastern Arizona.

H. E. Enlows, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 106 (fig. 1). Comprises (ascending) pink to gray rhyolite—thickness 140 feet; soft gray rhyolite tuff—80 feet; brownish red rhyolite—30 feet; gray rhyolite tuff—20 feet; and black to gray, vesicular augite dacite—220 feet. Overlies Rhyolite Canyon series (new).

Section measured in Rhyolite Canyon, Chiricahua National Monument, Cochise County.

**Sugarloaf Mountain Quartzite**

Cambrian(?): Western Maryland.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 347. Consists of massive white quartzite about 200 feet thick, which caps Sugarloaf Peak, lower massive quartzite, 100 to 150 feet thick, which makes prominent cliffs and ledges on upper slopes of peak and forms summits of most of the lower peaks and ridges, and thinner bedded quartzites about 150 feet between the two massive ledges. Overlies Urbana phyllite (new). Lower Cambrian(?). Formation was named Sugarloaf sandstone by Keyes (1891) but because name Sugarloaf arkose, of Triassic age, has become established formation name in Massachusetts, name Sugarloaf Mountain is applied for Maryland formation.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12] Carroll and Frederick Counties, p. 71–74. Beds similar to Sugarloaf Mountain quartzite, which crop out at Park Mills, on Brush Creek and Linganore Creek, and south of Libertytown, have been placed in Urbana phyllite and may be Sugarloaf Mountain quartzite. Sugarloaf Mountain is synclinal and fold is overturned toward northwest.

D. M. Scotford, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 48. Quartzites on Sugarloaf Mountain were considered Lower Cambrian and therefore Weverton by such early workers as J. P. Lesley, G. H. Williams, and C. R. Keyes. Jonas and Stose (1938) mapped these rocks as Sugarloaf Mountain quartzites and assigned them to probable Lower Cambrian. These rocks are here considered equivalent of Lower Cambrian Weverton quartzite because Sugarloaf Mountain is an anticline rather than a syncline, as reported by Stose and Stose (1946).

Named for occurrence on Sugarloaf Mountain, Frederick County.

**Sugarlump Tuffs**

Tertiary: Southwestern New Mexico.

F. J. Kuellmer and others, 1953, *in* New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 42 (map), 50 (map). Name appears on legends for maps of parts of southwestern New Mexico. Called latitic tuffs.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 23–25, pl. 1. Latite and rhyolite tuffs, sandy tuffs, tuffaceous sandstones, ignimbrites, and conglomerates. Some units only local, others widespread. Usually green or white, with occasional pink or brown layers. Thickness 50 to 1,400 feet. Reach maximum thickness around Sugarlump Mountain and thin toward the south, north, and northwest. Overlies Rubio Peak flows. Derivation of name.

Named after hill in NE¼ sec. 5, T. 19 S., R. 10 W., Dwyer quadrangle.

Suicide Grit

Upper Triassic: Northeastern Utah.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 474–475. Manuscript name used by R. E. Marsell to apply to grit in Ankareh formation as defined by Boutwell (1912 U.S. Geol. Survey Prof. Paper 77). Eastward this grit is recognized as typical Shinarump conglomerate and northward is identical with Higham grit.

Well exposed at mouth of Parleys Canyon east of Salt Lake City along roadcut of Wasatch Boulevard and in Suicide Rock.

†Suisun Marble[1]

Age(?): Western California.

Original reference: J. D. Whitney, 1865, California Geol. Survey, v. 1, p. 104.

Probably named for Suisun, Solano County.

Sulfur Creek Formation

Upper Jurassic[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Lowermost formation in area studied. Underlies Blue Ridge member of Crack Canyon formation (both new): Overlies an unnamed group of sediments, volcanics, and associated igneous and metamorphic rocks. The Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Sulfur Well facies (of Lexington Formation)

*See* Sulphur Well Member (of Cynthiana Formation).

Sully Member (of Pierre Formation)

Upper Cretaceous: Central South Dakota.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 21–34, pls. 2, 3. Defined to include body of shales lying between chalk beds of upper Gregory member (new) and base of bentonitic beds at base of Virginia Creek member (new). Includes (ascending) Agency shale of Russell (1930), Oacoma, and Verendrye shale zones. Thickness 134 to about 315 feet.

W. V. Searight, 1938, Iowa Acad, Sci. Proc., v. 45, p. 135–137; A. L. Moxon and others, 1938, Am. Jour. Botany, v. 25, no. 10, p. 795 (chart 1), 796. Redefined and stratigraphically extended at base to include a fourth zone, Gregory marl. As thus redefined, overlies Sharon Springs member.

J. P. Gries and E. P. Rothrock, 1941, South Dakota Geol. Survey Rept. Inv. 38, p. 5 (pl. 1), 14–38. Redefined. Name Gregory marl dropped and term Crow Creek marl substituted for basal zone. As thus redefined, overlies Gregory member and underlies Virgin Creek member. Thickness 126 to 365 feet.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 1), 2343–2345. Abandoned. Crow Creek and Verendrye zones raised to member rank; Agency-Oacoma zones redefined as DeGrey member of Pierre.

Named for exposures along both sides of Missouri River in and opposite western Sully County. Typical exposures occur at the Little Bend opposite site of old Fort Bennett and few miles north of one of sites of Fort Sully.

**Sulphur Canyon Sandstone Member** or **Bed** (in Neslen Formation)

Sulphur Canyon Sandstone Bed (in Price River Formation)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: D. J. Fisher, 1935, U.S. Geol. Survey Bull. 852.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10b (column 39). Shown on correlation chart as uppermost member of Neslen formation. Overlies Thompson Canyon sandstone member; underlies Farrar formation.

D. J. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 17. Referred to as bed in Neslen formation.

Named for Sulphur Canyon, T. 9 S., R. 100 W. Traced from Buck Canyon to Colorado line.

†Sulphur Creek Group[1]

Upper Cretaceous: Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 50, 154.

Occurs in hills near Hilliard, Uinta County, Wyo.

**Sulphur Springs Formation[1]**

Sulphur Springs Group

Mississippian: Central eastern Missouri and southwestern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, 2d ser., v. 2, p. 110.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 39–57. In classification in Boone County, Sulphur Springs is listed as group including Grassy Creek, Bushberg, and Chouteau formations. Kinderhookian.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 75–76. It must be assumed that Ulrich meant type locality to be vicinity of Sulphur Springs. This is a station on Missouri Pacific Railroad along Mississippi River bluff in Jefferson County, Mo. Choice of name was unfortunate because in the place of the best exposures, 0.3 mile north of station, there is no evidence of strata that may be assigned to the Glen Park, and the sandstone at the "base of the Kinderhook" does not fit Ulrich's description of the Bushberg. It is likely that it was the shale of this locality that led to Ulrich's stated maximum thickness of 15 feet for the bottom shale member of the Sulphur Springs. The shale here, about 15 feet thick, includes a black fissile shale at the top containing sporangites and conodonts of Upper Devonian age. The lower several feet of the shale section is Maquoketa (Ordovician): Neither the Bushberg nor the Glen Park are coextensive with widespread upper Devonian black shales of Missouri; the Bushberg is unconformable on the Glen Park. It appears incongruous to group Devonian black shale with the Glen Park and Bushberg sandstone as a formation or as members of a group. Recommended that term Sulphur Springs as a group or formation name be dropped from Missouri stratigraphic column.

Named for exposures at Sulphur Springs, Jefferson County, Mo.

**Sulphur Springs Mountain Andesite**

Tertiary(?): Northwestern California.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 110 (table 24), 116–117, pl. 12. Fine-grained greatly altered reddish andesite that occurs as small intrusive masses which have penetrated serpentines associated with the Franciscan on Sulphur Springs Mountain and shales and sandstones of Knoxville formation in upper Sulphur Springs Valley.

Mapped in Carquinez quadrangle, Solano County.

Sulphur Well Member (of Cynthiana Formation)

Ordovician: Central Kentucky.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 11 (footnote), 20–22. Proposed for beds below Greendale member of formation.

A. C. McFarlan and W. H. White, 1948. Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1643. Sulfur Well member (pre-Greendale) is recognized as facies of the upper Lexington; contains a Cynthiana fauna.

Named for Sulphur Well, 4 miles southeast of Nicholasville, Jessamine County. Exposures are along Kentucky River fault.

**Sultan Limestone**[1]

Middle and Upper Devonian: Southeastern Nevada and eastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 13.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 276 (fig. 3b), 328–331. Geographically extended into Nopah and Resting Springs Mountains, Inyo County, Calif., where it is about 890 feet thick, underlies Stewart Valley limestone and overlies unnamed Silurian(?).

J. C. Hazzard, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881, 884 (fig. 3). Thickness in Nopah Range, 1,720 feet. Herein suggested that name Stewart Valley limestone be abandoned and that Devonian beds previously ascribed to it be assigned to Crystal Pass and Valentine limestone members of Sultan. Underlies Dawn limestone member of Monte Cristo limestone. Middle Devonian.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 40–41. Described in Ivanpah quadrangle, California and Nevada. Ironside dolomite, Valentine limestone, and Crystal Pass limestone members appear to be present throughout region in which formation is recognized. Thickness 250 to 640 feet. Underlies Monte Cristo limestone.

Ben Bowyer, E. H. Pampeyan, and C. R. Longwell, 1958, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–138. Mapped as Middle and Upper Devonian.

Well exposed in vicinity of Sultan mine, Goodspring quadrangle, Nevada.

Sumas Shales (in Chuckanut Formation)

[Eocene]: Northwestern Washington.

S. L. Glover, 1941, Washington Div. Mines and Geology Bull. 24, p. 308–311. A series of interbedded shales, sandstones, and conglomerates in basal part of Chuckanut formation near Sumas. Predominantly bright-red plastic shales, turquoise-blue flint clays, and clear-colored bluish-gray fire clays. Total area covered by series not known. Deposited upon pre-Tertiary argillites and quartzites; above well-marked unconformity is massive basal conglomerate overlain by shales and sandstones.

Exposed in prospect pit or tunnels at several places near Sumas, Whatcom County.

Sumay Limestone

Pliocene or Pleistocene: Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 55, table 4 [English translation in library of U.S.

Geol. Survey, p. 66]. Very similar to and correlated with Naftan (Nafutan) limestone.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 58. Pleistocene.

Type locality: Sumay, Guam.

Summer Formation[1]

Recent: Central southern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Type locality: On east side of Summer Lake, Lake County.

†Summerfield Limestone (in Conemaugh Formation)[1]

Pennsylvanian (Conemaugh Series): Eastern Ohio.

Original reference: D. D. Condit, 1912, Ohio Geol. Survey, 4th ser., Bull. 17, p. 20, 23.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 61. Ohio Geological Survey has abandoned term Summerfield limestone in favor of term Lower Pittsburgh limestone and shale member (Conemaugh series).

Named for Summerfield, Noble County.

**Summerhill Sandstone Member** (of Conemaugh Formation)[1]

Upper Pennsylvanian: Western Pennsylvania.

Original reference: C. Butts, 1905, U.S. Geol. Survey Geol. Atlas, Folio 133.

Crops out in bold ledge, about 50 feet thick, high in bluff east of Summerhill, Cambria County.

Summers Member (of Mesaverde Sandstone)

Upper Cretaceous: Northeastern Arizona.

G. K. Sirrine, 1959, Dissert. Abs., v. 19, no. 8, p. 2064. Incidental mention:

Springerville-St. Johns area, Apache County.

Summers Series

Pennsylvanian (post-Chester, pre-Morrow): West Virginia.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 19. Future work may demonstrate presence in Appalachians and in Midcontinent of a post-Chester-pre-Morrow series to which names Pushmataha (in the west) and possibly Summers (in the east) can be applied.

Named for Summers County, where the upper Mauch Chunk formations are well exposed.

**Summerville Formation** (in San Rafael Group)[1]

Upper Jurassic: Southeastern Utah, northeastern Arizona, southwestern Colorado, and northwestern New Mexico.

Original reference: J. Gilluly and J. B. Reeside, Jr., 1926, U.S. Geol. Survey Press Bull. 6064, March 30.

James Gilluly and J. B. Reeside, Jr., 1928, U.S. Geol. Survey Prof. Paper 150–D, p. 79–80, table. At type section, includes 163 feet of thin alternating beds of chocolate-colored gypsiferous mudstone and well-laminated sandstone with some red clays toward base. Thickens southward for some distance; 285 feet at Horn Silver Gulch; 331 feet at Drunk Man's Point. Overlies Curtis formation with boundary gradational; underlies Morrison formation.

J. W. Harshbarger, C. A. Repenning, and R. L. Jackson, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 97–98. In Navajo country, Summerville formation, Bluff sandstone member, and Recapture shale member of Morrison grade laterally southwestward into distinct sand facies here named Cow Spring sandstone.

W. L. Stokes, 1952, Utah Geol. and Mineralog. Survey Bull. 46, p. 9 (table 1), 10–11, pl. 1. In Thompson area, Grand County, averages about 50 feet in thickness, overlies Entrada sandstone and underlies Morrison formation (Salt Wash member).

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 38 (table), 63–64, 66, 67, 69 (figs. 14, 15), 73–75. Described in Henry Mountains region where it is 40 to 250 feet thick. Consists generally of evenly bedded reddish-brown sandstone and sandy shale with minor amounts of greenish-white sandstone, gypsum, and limestone. Uppermost formation of group; overlies Curtis formation; underlies Morrison formation.

L. W. Kilgore, 1955, Four Corners Geol. Soc. Guidebook [no. 1], p. 20, cross section. Shown on cross sections of Animas River valley, Colorado, as underlying Junction Creek sandstone and overlying Todilto formation.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 39–42, strat. sections. Described in Navajo country. Throughout the area it is divisible into an upper sandy facies and a lower silty facies, similar to type locality. Overlies Entrada sandstone in central part of area and Todilto limestone in eastern part. In some places, underlies Bluff sandstone (here considered upper formation of San Rafael group); in eastern, northern, and western parts of area, tongues and grades laterally into Cow Springs sandstone. Thickness 57 to 213 feet. Unit here assigned to Summerville has been assigned to Wanakah by other workers. Correlation of Summerville from San Rafael Swell to Bluff, Utah, is well established. From Bluff, the formation is traceable throughout eastern part of Navajo country and is here correlated with the "buff shale and brown-buff sandstone members of Morrison formation" (Kelley and Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47) in Laguna-Lucero area of New Mexico.

E. B. Ekren and F. N. Houser, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–221. Mapped in Moqui SE quadrangle, Colorado, where it consists of flat- and thin-bedded brick-red argillaceous sandstone and siltstone 120 to 130 feet thick. Underlies Junction Creek sandstone with contact gradational; overlies Entrada sandstone. San Rafael group. Upper Jurassic.

Named for exposures at Summerville Point, southeast of head of Summerville Wash, in north end of San Rafael Swell, southeastern Utah.

Summit Conglomerate

Miocene and Pliocene: Central Washington.

B. M. Page, 1940, Stanford Univ. Abs. Dissert., v. 15, p. 119. Name applied to fluviatile sediments capping Mount Natapoc.

C. L. Willis, 1953, Am. Jour. Sci., v. 251, no. 11, p. 796, fig. 1. Consists of approximately 200 feet of horizontal beds of andesite stream-laid gravel.

Area described is northwest of Wenatchee, Chelan County.

Summit Gabbro

Paleozoic(?) or Mesozoic(?): Southern California.

W. J. Miller and R. W. Webb, 1940, California Jour. Mines and Geology, v. 36, no. 4, p. 353–354, 378 (fig. 31), pl. 2. Typically medium to fine grained with occasional coarse-grained facies. Intrudes Kernville series and is intruded by Sacatar quartz diorite (new).

Named because of prominent exposures along crest of the Sierra in northwestern part of Kernville quadrangle, Kern County.

Summit Limestone (in Cherokee Shale)[1]

Pennsylvanian: Northeastern Missouri.

Original reference: W. J. McGee, 1892, St. Louis Acad. Sci. Trans., v. 5, p. 331.

Occurs in Macon County.

†Summit Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: I. C. White, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$, p. 25–26.

Occurs in high knobs of Perry Township, Lawrence County. Named for Summit cut on P. F. W. & C. Railroad in northwestern part of Beaver County.

†Summit Series (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: E. V. d'Invilliers, 1895, Pennsylvania 2d Geol. Survey, v. 3, pt. 2, p. 2377.

Occurs in northern part of Clarion County.

Summit Springs Evaporite Member (of Pequop Formation)

Permian (Leonardian): East-central Nevada (subsurface).

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 106. Middle Leonardian evaporite sequence drilled at 4,400 to 5,400 feet. Underlies an evaporite dated lower Guadalupian and assigned on basis of stratigraphic position and faunal control, to Loray formation (new). Little surface expression of this member.

Recognized in Standard of California-Continental's Summit Springs Unit No. 1, NW¼ sec. 30, T. 20 N., R. 60 E., White Pine County.

†Summitville Andesite (in Potosi Volcanic Series)[1]

Miocene: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13, p. 20, 35–38.

Named for extensive development in vicinity of Summitville, Rio Grande County.

Summum Coal Member (of Carbondale Formation)

Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 36, 47 (table 1), 66, pl. 1. Assigned member status in Carbondale formation (redefined). In southern area, occurs above Roodhouse coal member and below Hanover limestone member; in western and northern area occurs above Kerton Creek coal member and below Hanover limestone member; in eastern area, occurs above Shawneetown coal member and below Harrisburg (No. 5) coal member. About 3 inches thick. Coal named by Wanless (1931, Illinois Geol. Survey Bull. 60). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Northeast of Summum, NE¼ sec. 3, T. 3 N., R. 2 E., Fulton County.

Summum cyclothem (in Carbondale Formation)

Summum cyclothem[1] (in Carbondale Group)

Pennsylvanian: Western, central, and southern Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 182, 192.

H. B. Willman, 1942, Illinois Geol. Survey Bull. 66, p. 106 (fig. 50), 107–118. Commonly between 20 and 25 feet thick. Includes Pleasantview sandstone (at base), Hanover limestone, Covel conglomerate, and intervening unnamed units. Directly overlies Lowell cyclothem (new) where latter is present, and Liverpool cyclothem where Lowell is absent or unrecognized; despite this seeming overlap it is apparently conformable with both because Pleasantview sandstone seems to grade into underlying uppermost sandy shales of both cyclothems; apparently conformable with overlying St. David cyclothem.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 61–62, 94–102, 204–205, pl. 5. In Beardstown-Glasford-Havana-Vermont area, cyclothem is as much as 85 feet thick, maximum thickness in channel areas of basal Pleasantview sandstone. Separated from underlying Liverpool by one of most prominent erosional unconformities in Illinois Pennsylvanian. Type locality and derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 53 (table 2), pl. 1. In Carbondale formation (redefined). Above Lowell cyclothem and below St. David cyclothem. Type locality given; reference in Wanless (1957) in error. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: NE¼ sec. 3, T. 3 N., R. 2 E., Fulton County, near Summum.

Summum Sandstone (in Carbondale Formation)[1]

Pennsylvanian: Northwestern Illinois.

Original reference: T. E. Savage, 1930, Illinois Acad. Sci. Trans., v. 22, p. 498.

**Sumner Group**[1]

Permian: Eastern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 9, 48.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 91–93. Sumner group lies between Herington limestone and Harper sandstone. Comprises Wellington shale, Ninnescah shale, and Stone Corral dolomite. Leonard series.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 159–160. Group comprises about 1,000 feet of strata at outcrop. Predominantly gray shale with beds of red and green shale and deposits of dolomite, limestone, gypsum, and anhydrite. Underlies Harper sandstone of Nippewalla group; overlies Nolans limestone of Chase group.

Named for Sumner County, Kans.

†Sumpter Epoch[1]

†Sumter Epoch[1]

Miocene and Pliocene: Eastern South Carolina.

Original reference: J. D. Dana, 1863, Manual of Geology, p. 506, 511, 522, 798.

Named for development in Sumter district, Sumter County.

†Sunbeam Monzonite[1]

Post-Eocene: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 644, 656–657, pls. 75, 77.

Named for Sunbeam mine, Tintic district.

†Sunbury calciferous sandrock[1]

Devonian(?) and Mississippian: Central Ohio.

Original reference: L. E. Hicks, 1878, Am. Jour. Sci., 3d v. 16, p. 216, 220–222.

Named for Sunbury, Delaware County.

**Sunbury Member** (of Orangeville Shale)

**Sunbury Shale**[1]

Mississippian: Ohio and northeastern Kentucky.

Original reference: L. E. Hicks, 1878, Am. Jour. Sci., 3d, v. 16, p. 216, 220.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1163. Member of Orangeville shale. Underlies Aurora siltstone member; overlies Berea sandstone. In central and eastern Cuyahoga County, Ohio, where Sunbury shale is separated from Orangeville by local siltstones, the Sunbury can be regarded as distinct formation. This separation is impossible in much of northern Ohio where Orangeville consists of very dark gray and black shales and local siltstones are absent. Therefore, Sunbury is treated as member of Orangeville as far east as the typical zone of *Orbiculoidea herzeri* and *Lingula melie* can be found. This zone of fossils disappears from section in vicinity of Andover in eastern Ashtabula County, and Sunbury member is not recognized across State line in Pennsylvania.

Named for Sunbury, Delaware County, Ohio.

Sun Creek Dacite Flow

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 34–35. Discussion of geology and petrography of Crater Lake National Park. Mount Mazama is name given to prominent peak that once stood on what is now rim of Crater Lake. Lavas in Mount Mazama were of three types—andesites, dacites, and basalts. Immediate rim of Crater Lake is made up wholly of andesites and dacites, chiefly the former; basalts are limited to outer slope. Dacite flows named are Sun Creek, Cloud Cap, Grouse Hill, Llao Rock, Wineglass, Cleetwood Cove, and Rugged Crest. [For basalt flows see Timber Crater Basalt Flow.] Canyon of Sun Creek below falls has on the west a number of cliffs and terraces due to successive dacite flows, exposing total thickness of about 600 feet. At 6,300 feet east of Crater Peak, cliffs begin. First 200 feet is solid dacite flow. Nut terrace, at 5,900 feet, exposes perlitic and spherulitic banded rhyolite and forms bluff 75 feet in height. At 5,700 feet is a plain of fine material, filling the valley to width of three-fourths mile. Sun Creek has cut canyon 200 feet deep in this soft material. Layer of pumice covers nearly everything beyond canyon, so that nature of underlying rock is a matter of doubt. Sun Creek dacite is the oldest about Crater Lake.

Sun Creek Flows

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 89. Sun Creek flows were result of glowing avalanches of pumice and scoria that discharged through Sun Notch on southern slope of Mount Mazama. Avalanches deposited their load after they passed beyond snout of Sun Creek glacier 1½ miles below the notch. Glowing avalanches were part of final activity of Mount Mazama and followed what is termed main pumice fall.

Sun Creek flows southward from Crater Lake.

**Sundance Formation**[1]

Sundance Group

Upper Jurassic: Southwestern South Dakota, central northern Colorado, central southern Montana, northwestern Nebraska, and southwestern Wyoming.

Original reference: N. H. Darton, 1899, Geol. Soc. America Bull., v. 10, p. 387-393.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 229, 232-234, 238 (fig. 2), 239 (fig. 3), 244-264, strat. sections. Formation, in Black Hills area, South Dakota and Wyoming, subdivided into (ascending) Canyon Springs sandstone, Stockade Beaver shale, Hulett sandstone, Lak, and Redwater shale members (all new). Thickness 200 to 350 feet. Overlies Gypsum Spring formation; underlies Morrison formation. Outcrops near Sundance, which is actually 18 miles southwest of Belle Fourche quadrangle, restudied and considered inadequate to serve as type section. Standard reference section of Sundance is 327 feet thick and includes all members except Canyon Springs. Represents Callovian and Oxfordian stages.

G. N. Pipiringos, 1953, Wyoming Geol. Assoc. Guidebook 8th Ann. Field Conf., p. 34-37; 1957, Wyoming Geol. Survey Bull. 47, p. 6-8, 9 (table 1), 11-13, 19-25. Formation described in Laramie basin, Wyoming. Comprises following members (ascending): Canyon Springs, Stockade Beaver, Hulett, Lak, unnamed member B, Redwater, and unnamed member A. Member A is persistent sandstone unit, 4 to 30 feet thick, that bevels from north to south all underlying members except the Canyon Springs. This unit is distinct from other members of Sundance but is also distinct from overlying Morrison and for convenience is placed in Sundance. Overlies Nugget formation.

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 464 (table 1), 465-500. Proposed that, in eastern Wyoming and western South Dakota, Sundance formation be raised to rank of group comprising two units of formational rank which are correlated with Swift and Rierdon formations of Ellis group of Montana. Because of historical significance, term Sundance should be retained, and, despite its correlation with upper units of Ellis group, term Sundance group is here applied to marine Upper Jurassic rocks of the Black Hills and vicinity, northernmost part of Colorado, subsurface of northwestern Nebraska, and all but westernmost Wyoming.

R. K. Hose, 1956, U.S. Geol. Survey Bull. 1027-B, p. 54–55, pl. 6. Described in Johnson County, Wyo., where it is approximately 285 feet thick and consists of sandstone, shale, and minor amounts of oolitic limestone. Underlies Morrison formation; unconformably overlies Gypsum Spring formation, and locally overlies Crow Mountain sandstone member of Chugwater formation.

J. C. Stewart, 1958, Geology of the Dryhead-Garvin Basin, Bighorn and Carbon Counties, Montana (1:63,360): Montana Bur. Mines and Geology. As mapped, group includes Piper, Rierdon, and Swift formations.

J. D. Love, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 64–68. Formation described in southern part of Powder River basin where it consists of a lower and an upper unit. Canyon Springs member questionably present locally. Underlies Morrison formation; overlies Gypsum Spring formation, Nugget sandstone, and members of Chugwater formation.

T. P. Storey, 1958, Alberta Soc. Petroleum Geologists Jour., v. 6, no. 4, p. 90–104. Discussion of Jurassic of Williston basin and adjacent areas. On basis of regional extent and significance of sub-Swift and sub-Rierdon unconformities, a different stratigraphic interpretation is presented. The Swift is divided into Lower, Middle, and Upper units. Lower Swift is so designated because it is considered to be lithologically similar to and regionally conformable with Middle and Upper Swift which correspond to type Swift of western Montana. Lower Swift of Williston basin and equivalent Stockade Beaver and Hulett members of Lower Sundance in Black Hills are considered to lie unconformably on the Rierdon and therefore to be younger than the Rierdon and older than the Swift as designated by Cobban. This correlation is offered in lieu of the more general belief that Lower Sundance and Rierdon are equivalent in age. Thus, Lak and Redwater members of the Sundance are considered equivalent to type Swift of western Montana.

Type locality: Above Sundance which is 18 miles southwest of Belle Fourche quadrangle, South Dakota. Reference section: About one-fourth mile north-northeast of center of Spearfish in sec. 3, T. 6 N., R. 2 E., Lawrence County, S. Dak.

## Sunday Quartzite[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: C. R. Van Hise and C. K. Leith, 1911, U.S. Geol. Survey Mon. 52, p. 225, 227, chart opposite p. 598, 605.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 85 (table 1). Included in Animikie series. Underlies Bad River dolomite; unconformable above granite.

Named for two exposures east of Sunday Lake, one a short distance east of Little Presque Isle River and other near Newport mine, Penokee-Gogebic district, Mich.

**Sunday Mountain Volcanic Member** (of Orfordville Formation)

Sunday Mountain Volcanics

Middle Ordovician(?): Western New Hampshire and eastern Vermont.

J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle (1:62,500); C. A. Chapman and others, 1938, Geologic map and structure sections of the Mascoma quadrangle, New Hampshire (1:62,500): New Hampshire Highway Dept. Member consists of schistose greenstones in low-grade metamorphic zone of formation, and chiefly fine- to medium-grained amphibolite with some fine-grained biotite gneiss and black graphitic quartzite in middle-grade zone. Occurs near top of Orfordville formation above Hardy Hill quartzite member (new). Middle Ordovician(?).

J. B. Hadley, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 119, 123. Maximum thickness 400 feet.

J. B. Hadley, 1950, Vermont Geol. Survey Bull. 1, p. 15–16. Metamorphic equivalent of rhyolite and dacite tuffs and possibly some flows. Geographically extended to Vermont. Ordovician.

R. J. Bean, 1953, Geol. Soc. America Bull., v. 64, no. 5, pl. 2. Mapped together with Post Pond volcanics as a unit overlying Orfordville formation. Map legend shows Upper(?) Ordovician age.

J. B. Lyons, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 114–116. Stratigraphic revision of Orfordville formation implies that the lithologically similar Post Pond and Sunday Mountain volcanic members are essentially equivalent, and the latter is not mapped separately.

Named for outcrops on and near Sunday Mountain, Orford Township, Grafton County.

**Sunderland Formation** (in Columbia Group)[1]

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

Original reference: G. B. Shattuck, 1901, Johns Hopkins Univ. Circ., v. 20, no. 152, p. 73–75.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Mineral Resources Bull. 10, p. 45–47, 48. Described in Prince Georges County, Md., and District of Columbia. Consists almost entirely of valley fill; lies unconformably on deposits ranging in age from ancient crystalline rocks to the Pliocene. In northern end of Potomac estuary, lies much lower than Brandywine gravel, but at southern end of county lies nearly as high. The Wicomico formation is sunk below base of the Sunderland and is separated from it by a slope exposing older rocks. Thickness about 40 or 50 feet. As here interpreted, formation spans interval between first low-water stage of the Pleistocene and the beginning of the next; therefore, presumably accumulated in early Pleistocene during first (Nebraskan) glacial stage and first (Aftonian) interglacial stage. As defined in this region, appears to be equivalent to combined Sunderland and Coharie formations of North Carolina.

J. T. Hack, 1955, U.S. Geol. Survey Prof. Paper 267–A, p. 8, 29–31. Problem of separating upland deposits in Coastal Plain into formations is discussed. No basis is found for separating the Sunderland from the Brandywine; both formations at their type localities are underlain by a littoral deposit, North Keys sand (new) of Miocene(?) age. Part of the

Sunderland as mapped by earlier workers is here included in North Keys sand.

Name derived from hamlet of Sunderland, Calvert County, Md.

**Sunniland Limestone**

Lower Cretaceous: Southern Florida (subsurface).

P. L. Applin, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B209–B211. Term "Sunniland", as applied to rock unit, was published by Pressler (1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10) who referred to "Sunniland zone," "Sunniland limestone," and "the formation." Neither Pressler nor later writers defined the unit or described type section. Common usage has established name "Sunniland limestone" in geologic nomenclature of Florida. Name is here used to designate subsurface unit of middle Trinity (Comanche) age in southern Florida. Composed chiefly of limestone, dolomite, and shale. Overlies the so-called "thick anhydrite" or "lower anhydrite" unit, and underlies so-called "upper anhydrite" unit, both of Trinity age. Thickness 250 to 275 feet in wells in and near Sunniland field. Penetrated in about 60 deep test wells in central and southern Florida.

Sunniland oil field, Collier County.

**Sunnybrook Volcanics** (in Amador Group)

Jurassic: East-central California.

G. R. Heyl and J. H. Eric, 1948, California Div. Mines Bull. 144, pt. 1, p. 51, 52, 53, pl. 7. A series of schists and greenstone in Newton mine area (near Jackson, Amador County), tentatively correlated with Jurassic Amador group described by Taliaferro (1942), is subdivided into four formations (descending): Mountain Spring volcanics, Dufrene slate, Newton Mine volcanics, and Sunnybrook volcanics. The Sunnybrook, a sequence of undetermined thickness, consists dominantly of gray felsic rocks, including bedded feldspathic tuff and felsitic quartz-bearing tuff of rhyolite composition; within the felsitic rocks is a zone, approximately 400 feet thick, of dark-green chlorite-uralite schist, probably derived from pyroclastics. Thickness at least 1,500 feet. Measured section, along Mountain Spring Creek from Mariposa slate eastward, dips steeply to east; relation of beds to Mariposa slate suggests that section is overturned and is on west limb of an overturned anticline or its faulted equivalent.

Name derived from Sunnybrook Crossing in eastern part of Newton mine area.

Sunnyside Member (of Blackhawk Formation)

Upper Cretaceous (Montana): Central eastern Utah.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, 185–186, figs. 2, 3, pl. 3. Composed of massive basal sandstone tongue and the overlying coal-bearing rocks which are replaced eastward by offshore bar sandstones. Basal sandstone is medium grained, buff, and massive; maximum thickness of about 50 feet at Pace Canyon, grading downward and eastward into tongue of Mancos shale which, in turn, rests disconformably on Kenilworth member (new) of Blackhawk formation. Coal-bearing rocks consist of about 25 feet of sandstone, shale, and coal which, at point about 4 miles northeast of Desert, are replaced by last of series of six offshore bar sandstones. Two important coal beds present in member, the Upper and Lower Sunnyside coals. Upper coal about 22 feet thick at Horse Canyon; Lower coal maximum thickness about 5 feet. Separated from Grassy member (new) above by tongue of Mancos shale.

Named for exposures near town of Sunnyside, Carbon County. In Book Cliffs.

Sunol Series

Upper Cretaceous: California.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Grouped under marine sediments on map legend.

**Sunrise Formation**[1]

Lower Jurassic: Southwestern Nevada.

Original reference: S. W. Muller and H. G. Ferguson, 1936, Geol. Soc. America Bull., v. 47, p. 241–252.

H. G. Ferguson, S. W. Miller, and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–45. Black, gray, and brown shale, locally altered to slate and hornfels, with interbedded argillaceous, cherty, and arenaceous limestone, locally grading into calcareous sandstone. One bed, 10 feet, of oolitic limestone in lower part. Overlies Gabbs formation; unconformably underlies Dunlap formation.

Type section: Upper part of New York Canyon, west of Sunrise Flat. Named for Sunrise Flat in Gabbs Valley Range.

†Sunrise Series[1] or Group[1]

Paleozoic and Mesozoic: Southern Alaska.

Original reference: W. C. Mendenhall, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 305–307.

Crops out on western shores of Prince William Sound. Probably named for Sunrise City, which is in center of Turnagain Arm mining district.

Sunrise Springs Series[1]

Tertiary or Pleistocene: Northeastern Arizona.

Original reference: A. B. Reagan, 1932, Kansas Acad. Sci. Trans., v. 35, p. 253–258.

In Cornfields-Sunrise Springs district.

Sun River Dolomite (in Madison Group)

Upper Mississippian: Northwestern Montana.

V. R. Chamberlain, 1955, Billings Geol. Soc. Guidebook 6th Ann Field Conf., p. 78, 79. Typically consists of very light yellowish white dolomitic limestone and limy dolomite with occasional bed of chert. Distinguished from Charles formation by its anhydrite free limestones and dolomites. Overlies Mission Canyon formation with apparent conformity.

Well exposed along Sun River west of Great Falls in Hannon Gulch.

Sunset Member (of Arnheim Formation)

Sunset division (in Arnheim Formation)[1]

Upper Ordovician: North-central Kentucky and southwestern Ohio.

Original reference: A. F. Foerste, 1910, Denison Univ. Sci. Lab. Bull. 16, p. 18.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on generalized section of Ohio as lower member of Arnheim formation. Underlies Oregonia member; overlies Mount Auburn member of McMillan formation. Consists of calcareous shales and nodular limestones. Thickness about 60 feet. Richmond series.

Named for Sunset, Fleming County, Ky.

Sunset Point Formation

Cambrian: Southern and central Wisconsin.

G. O. Raasch, 1951, Illinois Acad. Sci. Trans., v. 44, p. 150. Dominantly sand with varied proportions of dolomite. Underlies Oneota formation; overlies Jordan member of Trempealeau formation. Name proposed to replace term Madison to alleviate much confusion, owing especially to widespread use of the same name, Madison, for a Mississippian limestone unit in Montana and Wyoming.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 45, p. 85. In Stoddard quadrangle, underlies Hickory Ridge member (new) of Oneota formation.

Named after bluff of that name at Madison sandstone type locality, Madison, Wis.

**Sunshine Peak Rhyolite**[1] (in Potosi Volcanic Series)

Tertiary, middle and late: Southwestern Colorado.

Original reference: E. S. Larsen, 1935, U.S. Geol. Survey Bull. 843.

U.S. Geological Survey currently classifies the Sunshine Peak Rhyolite as part of Potosi Volcanic Series and designates the age as middle and late Tertiary on the basis of a study now in progress.

Named for exposures on Sunshine Peak, San Cristobal quadrangle.

**Sunshine Ranch Member** (of Saugus Formation)

Sunshine Ranch member (of Pico Formation)

Pliocene: Southern California.

G. B. Oakeshott, 1950, California Jour. Mines and Geology, v. 46, no. 1, p. 50 (table), 58 (fig. 3), 59–61, pls. 14, 16. Term Sunshine Ranch member of Pico formation applied to upper Pliocene continental beds lying below continental lower Pleistocene Saugus formation and above marine beds commonly called Pico. As described in unpublished report by J. C. Hazzard, Sunshine Ranch formation in its type area consists of a 20-foot basal portion of crossbedded to cobbly sandstone overlain by a coquina reef bed which averages 35 feet in thickness. This is followed by an interbedded series of gray coarse-grained to pebbly friable sandstone and gray to greenish-gray very fine grained sandstone, silty sandstone, and sandy siltstone. In Placerita oil field, thickness is approximately 1,300 feet; member has been folded into an asymmetrical syncline; here it disconformably underlies Saugus formation; overlies Mint Canyon formation with angular unconformity.

E. L. Winterer, 1955, *in* Pacific Petroleum Geologist Newsletter, v. 9, no. 6, p. 2. Reallocated to member of Saugus formation.

E. L. Winterer and D. L. Durham, 1958, U.S. Geol. Survey Oil and Gas Inv. Map OM–196. Term Sunshine Ranch was introduced by Hazzard (in Oakeshott, 1950) for interfingering marine, brackish-water, and nonmarine beds lying between Pico and Saugus formations in vicinity of San Fernando Reservoir in San Fernando Valley, a short distance south of the area of this report. Sunshine Ranch is here considered member of

Saugus formation and of Pliocene age. At Hazzard's type locality, Sunshine Ranch is about 3,000 feet thick.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 22 (fig. 2), 23 (fig. 3), 78, 82–83, pl. 1. Member of Pico formation. Exposed both north and south of San Gabriel fault in San Fernando quadrangle where it unconformably underlies Saugus formation. Thickness 3,000 feet where exposed in steeply north-dipping section in Mission Hills near San Fernando Reservoir. North of fault, on Sierra Highway, approximately 1,300 feet thick. South of fault, unconformably overlies fossiliferous Lower Pico; north of fault, overlies lower Pliocene Repetto formation and also upper Miocene Mint Canyon formation with angular unconformity. Upper Pliocene. Sunshine Ranch member is roughly equivalent to "lower Saugus" of earlier workers.

Type area: In foothills area north of Sunshine Ranch between axial region of Reservoir anticline and Balboa Avenue, west of San Fernando Reservoir.

**Supai Formation** (in Aubrey Group)[1]

Pennsylvanian and Permian: Northern Arizona, eastern California, eastern Nevada, western New Mexico, and southern Utah.

Original reference: N. H. Darton, 1910, U.S. Geol. Survey Bull. 435, p. 21, 22, 25.

D. White, 1929, Carnegie Inst. Washington Pub. 405, p. 11. Includes Esplanade sandstone member.

A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 525, 533–534. In Fort Apache Reservation, about 979 feet thick and includes Fort Apache limestone and Kinishba beds (both new).

J. W. Huddle and E. Dobrovolny, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 10. In central and northeastern Arizona, divided into three members which are in part contemporaneous and grade laterally into each other. Thickness ranges from 1,700 to 1,800 feet in outcrops along Mogollon Rim and thickens northward to nearly 2,500 feet in wells; thins northeastward toward Fort Defiance and Zuni uplifts; probably more than 2,500 feet thick beneath Black Mesa basin. Formation transgresses time lines and probably varies in age from Des Moines through Leonard. Overlies Naco formation; contact drawn above sequence of gray limestone and shale and below a sequence of red sandstone, shale, and limestone. Underlies Conconino sandstone; contact arbitrarily drawn at base of lowest massive sandstone with well-developed Coconino-type cross-bedding.

G. S. Campbell, 1951, Utah Geol. Soc. Guidebook 6, p. 63, 64 (fig. 15). Described in Confusion Range, Utah, where it consists of 3,000 feet of varicolored sandstones, the basal part of which is considered to be Wolfcampian in age. Overlies Bird Springs formation; underlies Kaibab limestone.

S. S. Winters, 1951, Plateau, v. 24, no. 1, p. 12–14. In Fort Apache Reservation, comprises four members: lowest consists of 330 feet of reddish-brown very fine-grained noncalcareous sandstone and siltstone; about 475 feet of slope-forming reddish-brown calcareous mudstone that alternates with ledge-forming gypsum beds, light-colored very calcareous claystones and gray limestones; Fort Apache limestone 95 to 118 feet thick; 370 feet of alternating slope-forming reddish-brown calcareous mudstones and siltstones, and ledge-forming beds of light-colored very calcareous claystones, gray limestones, and gypsum. Underlies Coconino sandstone; overlies Naco formation.

R. L. Jackson, 1951, Plateau, v. 24, no. 2, p. 90 (fig. 2). In Fort Apache area, Winters (unpub. thesis) subdivided Supai into (ascending) Amos Wash, Big "A", Apache, and Corduroy members. In Fossil Creek area [this report], the Supai comprises (ascending) Packard member (new), Oak Creek member (new), Big A sand facies, Apache member, and Corduroy member. Overlies and interfingers with Naco formation; underlies Coconino sandstone.

P. W. Hughes, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 635–657. Described in Chino Valley, Yavapai County, Ariz. Consists of two members: lower, 145 to 156 feet thick, is slope-forming unit of red sandstones and siltstones, capped by cliff-forming unit of cherty limestone; upper, about 938 feet thick, is alternating red sandstones and siltstones interbedded with a few strata of structureless claystone and some aphanitic limestone. Unconformably overlies Redwall limestone; underlies Coconino sandstone with contact gradational. Basal Supai is Lower Pennsylvanian.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 45, pl. 1. Mapped in San Bernardino County, Calif., where it overlies Bird Spring formation and underlies Kaibab limestone.

R. E. Lehner, 1958, U.S. Geol. Survey Bull. 1021–N, p. 533–540. Described in Clarkdale quadrangle, Arizona. Subdivided into three members: lower, 580 to 625 feet thick, is chiefly sandstone and siltstone with minor amounts of shaly mudstone; middle, 250 to 300 feet thick, present only north of Verde River, is principally siltstone intercalated with conglomerate, sandstone, and some limestone; and upper, 650 to 750 feet thick, present only north of Verde River, is sequence of sandstone and a few interbedded siltstone beds. Unconformably overlies Redwall limestone; intertongues with overlying Coconino. In Grand Canyon area, Hermit shale separates Supai from Coconino. Pennsylvanian and Permian.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2174. Proposed that terms Supai(?) and Supai equivalents as used by Newell (1948, Geol. Soc. America Bull., v. 59, no. 10) and Supai sandstone as used by Campbell (1951) be abandoned in Confusion Range and term Arcturus be used.

In Defiance uplift area and near Toadlena, N. Mex., term Supai is used for bedded rocks that dominantly underlie and locally interfinger with the DeChelly.

Named from exposures at Supai Village, in Havasu (Cataract) Canyon, northern Arizona. Havasu Canyon drains northward into Grand Canyon of Colorado and joins it about 85 miles north of Black Mesa. Supai is contraction of word Havasupai.

Supaian series[1]

Carbonic: Northwestern Arizona.

C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, no. 3, p. 251 (table). Includes (ascending) Pierce shales (new), Seligman limestones (new), Yampai shales (new), and Shiwits sandstones (new). Underlies Verdan series.

In Grand Canyon region.

Supan Tuff and Sand Member (of Tuscan Formation)

[Pliocene]: Northern California.

R. C. Treasher, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1257. Tuscan formation is subdivided into five members. Supan tuff and sand is oldest in sequence. Underlies Bald Hill agglomerate member.

Occurs at Iron Canyon dam site near Red Bluff, Tehama County.

**Superior Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Superior mine, Houghton County.

**Superior Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for occurrence in Superior mine, Houghton County.

**Superior West Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

In Superior mine, Houghton County.

**Superior West Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

In Superior mine, Houghton County.

Suplee Formation (in Mowich Group)

Lower Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 239, 242. Consists of gradations of granular gray limestone and calcareous sandstone; poorly stratified or massive. Thickness ranges from 35 to 150 feet. Conformably underlies Nicely shale (new); overlies Robertson formation (new) in type area and Bear Valley area; where Robertson is absent, the Suplee lies discordantly upon Triassic beds.

Type area: Along headwaters of South Fork of Beaver Creek, 7 miles southeast of Suplee post office, in secs. 26, 27, 28, and 29, T. 18 S., R. 26 E. Named for Suplee post office, Crook County.

Sur Series[1]

Pre-Franciscan: Southern California.

Original reference: P. D. Trask, 1926, California Univ. Dept. Geol. Bull., v. 16, no. 6.

Parry Reiche, 1937, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 24, no. 7, p. 116–132, geol. map. Name Sur series was applied by Trask (1926) to metamorphic rocks of Santa Lucia Range. Previous to that time, these rocks had been known variously as part of Santa Lucia formation and of Coast complex, although associated plutonic material had been distinguished by Lawson as Santa Lucia formation [Santa Lucia granite]. Present report uses Trask's term Sur series, but Trask's perpetuation of name Gabilan for the marbles, which occur at various horizons, spaced irregularly over several thousands of feet stratigraphically, seems ill advised. Series in Santa Lucia quadrangle comprises variety of generally phanerocrystalline metamorphic rocks including quartzose schists and gneisses, quartz biotite schists, marbles, and plagioclase amphibolites. Series crops out over much of northern Santa Lucia Range; similar rocks are exposed in northern part of Gavilan Range, and sporadic areas have been mapped in Santa Cruz Mountains. Thickness uncertain because of possibility of unrecognized structural complexities. Assuming homoclinal structure with average dip of 35°, there must be minimum of 7,000 feet near northwest corner of quadrangle. If Sur series east of Coast Ridge fault is not repetition of rocks of this northwest area, total thickness may be approximately 10,000 feet. Paleozoic(?).

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 18–19, pls. Term Sur series used to include pre-Franciscan schist and quartzite and pre-Franciscan limestone on Point Reyes, Peninsula. Two exposures of quartzite and schist, each less than 2 acres, occur associated with quartz diorite along an intrusive contact. One exposure is about 7,000 feet southwest of Inverness on northeastern slope of Point Reyes Mountain and is less than 50 feet thick. The other exposure, which is on western shore of Tomales Bay about 1¼ miles north of Inverness, consists of a narrow strip of banded quartz-mica schist about 500 feet long and 25 feet thick. It rests upon quartz diorite and dips at a low angle eastward beneath Tomales Bay and supposedly abuts San Andreas fault. A belt of crystalline limestone a little less than 1,000 feet wide lies about 1 mile west of Point Reyes Station. It is faulted into quartz diorite so that the eastern side abuts the quartz diorite and western side passes beneath Miocene sandstone. Southern tip of belt wedges into igneous rock.

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 118. Names Sur series, Gabilan limestone, and Santa Lucia granodiorite are essentially petrographic and not formational in usual sense since rocks of very different ages might be included under any one of the names.

O. E. Bowen, Jr., and C. H. Gray, Jr., 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1676. An 8,200-foot section of strongly metamorphosed sediments of Sur series is exposed astride Fremont Peak 10 miles northeast of Salinas at north end of Gabilan Range. Homoclinal sequence strikes east and dips 70° N. Three units recognized: 1,400-foot upper schist; 3,300-foot middle carbonate schist; and 3,500-foot lower schist. Neither top nor bottom of sequence exposed; boundaries have been obliterated by quartz monzonite intrusions. Fremont Peak section is within 5,000- to 10,000-foot range of thickness suggested by Reiche and Trask for series in Lucia and Point Sur quadrangles of Santa Lucia Mountains. Indistinct forms in limestone suggestive of cup corals together with clastic debris possibly derived from round-section crinoids, observed one-half mile west of Fremont Peak on Rocky Ridge, yield only age-suggestive features of series. Part of sequence is possibly Paleozoic.

Named for exposures along Sur River.

Surgener Formation

Middle Ordovician (Mohawkian): Southwestern Virginia and northeastern Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 93, chart 1 (facing p. 130). Name proposed for chalky weathering dark limestone, cherty dark limestone, gray to buff mudstone, and maroon mudstone. Underlies Dryden formation (new). At Hagan, Va., sequence includes Poteet, Rob Camp, and Martin Creek formations of Miller and Brosge (1950) ; also Dot formation [according to chart]. Name attributed to B. N. Cooper and G. A. Cooper.

Type section: Just east of Hagan Switchback on the L. and N. Railroad, 4½ miles due north of Surgener Cemetery, Rose Hill quadrangle, Lee County, Va. Named for cemetery which is one-half mile east of section along Yellow Creek.

Surprise Formation[1]

Surprise Member (of Kingston Peak Formation)

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 309–311, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Dept. Geol. Sci., v. 30, no. 5, p. 360, 363, figs. 1, 3. Redefined as member of Kingston Peak formation. Characteristically a conglomeratic subgraywacke or conglomeratic mudstone, locally hornfelsed and phyllitic; in one area, a nonpebbly graywacke occurs within the conglomeratic rocks. Thickness 370 feet in Goler Wash; more than 1,600 feet near mouth of Woodland Canyon; base of formation not exposed north of Coyote Canyon so actual thickness of member is not known. Basal member of formation; overlies Archean gneiss; underlies Sour Dough member. Area of report Manly Peak quadrangle.

Named for exposures along Surprise Canyon, southern part of Panamint Range, Inyo County.

Susanville Gravels

Eocene: Northern California.

Howel Williams, 1932, California Univ. Pub. Bull., Dept. Geol. Sci., v. 21, no. 8, p. 215. Susanville gravels, lying southeast of Lassen and containing an admixture of rhyolitic tuff, may be correlated tentatively with Montgomery Creek formation( new). Name credited to R. D. Russell.

Town of Susanville is in Lassen County.

**Susitna Slate[1]**

Jurassic(?) and Cretaceous: Southern Alaska.

Original reference: G. H. Eldridge, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 14–20, map.

Exposed up Sushitna [Susitna] River for 50 miles, from 15 miles above mouth of the Chulitna to considerable distance above mouth of Indian Creek, Cook Inlet region.

**Suslota Limestone[1]**

Pennsylvanian: Central eastern Alaska.

Original reference: W. C. Mendenhall and F. C. Schrader, 1903, U.S. Geol. Survey Prof. Paper 15, p. 46–47.

Occurs west of Suslota Pass, Mentasta Mountain region.

Suspension Bridge Dolomite Member (of Lockport Dolomite)

Silurian: Western New York, and Ontario, Canada.

E. R. Cumings, 1939, Geologie der Erde, North America, v. 1, p. 596 (fig. 7), 597. Finely saccharoidal medium-bedded dolomite; sparsely fossiliferous about 50 feet. Middle member of Lockport; overlies Gasport dolomite member; underlies Eramosa dolomite member.

B. F. Howell and J. T. Sanford, 1947, Wagner Free Inst. Sci. Bull., v. 22, no. 4, p. 34. Replaced by term Goat Island member; name Suspension Bridge preoccupied.

Exposed in Niagara Gorge.

**Susquehanna Group**

Susquehanna Series[1]

Upper Devonian: Pennsylvania.

Original reference: G. H. Ashley, 1923, Eng. Mining Jour.-Press, v. 115, p. 1106–1108.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3. Susquehanna group defined as all units between highest Catskill red beds at top and base of Tully limestone at bottom. Includes Catskill formation, transition beds (named locally), and Upper Devonian marine beds. North of confluence of Susquehanna and Juniata Rivers, Susquehanna group is of order of 7,000 feet thick, characterized by about 3,500 feet of red beds in upper part. Transition unit about 1,500 feet thick north of confluence of Susquehanna and Juniata Rivers. Lowermost unit (2,000 feet in Susquehanna River area) consists of marine medium-gray sandstones and siltstones with dark-gray shale near base. Base of this unit placed at base of Tully limestone member. This lower unit is synonymous with Fort Littleton and Rush formations where they are mapped, and possibly some "Chemung" may be included. Middle and Upper Devonian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Map bracket shows group, in central and eastern Pennsylvania, includes (ascending) marine beds (contains "Chemung" beds and "Portage" beds including Burket, Brallier, Harrell, and Trimmers Rock; Tully limestone at base), Catskill formation, and Oswayo formation. Upper Devonian.

Named for occurrence in Susquehanna River area.

†Susquehanna Mica Schist[1]

Precambrian: Northern Maryland.

Original reference: W. B. Clark, E. B. Mathews, and E. W. Berry, 1918, Maryland Geol. Survey, v. 10, p. 69 (table).

**Sussex Sandstone Member** (of Cody Shale)

Sussex Sandstone Member (of Steele Shale)

Upper Cretaceous: Wyoming (subsurface and surface).

J. B. Wilson, 1951, Wyoming Geol. Survey Rept. Inv. 3, p. 3–11. Member of Cody shale known primarily in subsurface. Light-gray fine-grained glauconitic marine sandstone about 40 feet thick where best developed in Sussex and North Meadow Creek oil fields. Occurs above Shannon sandstone member and below Parkman sandstone member.

J D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Mapped as member of Cody shale. Member is 2,500 feet above base of Cody.

G. H. Horn, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM-164. Shown on map legend as member of Steele shale.

Present in Powder River Basin. Exposed at surface near Salt Creek oil field.

Sutherland Falls Marble[1]

Sutherland Falls Marble Member (of Boardman Formation)

Sutherland Falls Marble Member (of Shelburne Formation)

Lower Ordovician: Western Vermont.

Original reference: Edward Hitchcock, 1861, Vermont Geol. Rept., v. 2, p. 767.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 25, 26. Rank reduced to lowest member of Boardman formation (new). Thin-bedded green-streaked white and cream-colored marble with contorted chains of dolomite crystals standing out on weathered surfaces; contains a central siliceous band, the Hen Hawk layer. Thickness regularly 90 to 100 feet. Underlies Intermediate dolomite member of Boardman; overlies Clarendon Springs dolomite. Type locality designated.

J. B. Thompson, Jr., 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 75 (table 1). In Clarendon-Dorset area, basal member of Shelburne formation. Thickness 50 to 100 feet. Underlies Intermediate marble member. Overlies Clarendon Springs formation.

Type locality: Probably a quarry 2,000 feet west of Sutherland Falls in Proctor, Rutland County. Name apparently taken from Sutherland Falls on Otter Creek.

**Sutro Member** (of Alta Formation)

Sutro Tuffs

Oligocene(?): Western Nevada.

V. P. Gianella, 1934, Mining and Metallurgy, v. 15, no. 331, p. 299. Tuffs, about 400 feet thick, are water laid and interbedded with Forman volcanics; Miocene.

V. P. Gianella, 1936, Nevada Univ. Bull., v. 30, no. 9, p. 56–59, pl. 1. Tuff member of Alta andesite composed of fine volcanic dust and ash with particles as much as one-fourth inch, occasionally much coarser. Color usually creamy yellow to light buff. Occurs 500 feet stratigraphically above base of Alta andesites. Derivation of name given.

D. I. Axelrod, 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1935. Oligocene age indicated on basis of flora.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 51–52, pl. 3. A member of Alta formation ranging in texture from shale to conglomerate, with grayish-green shale especially characteristic. Oligocene(?). Only of local extent.

Named for exposures in Sutro Tunnel. Present only in Comstock Lode district, Virginia City quadrangle.

**Sutter Formation**[1]

Tertiary, upper: Northern California.

Original reference: R. E. Dickerson, 1916, California Univ. Pub., Dept. Geol. Bull., v. 9, p. 404–406.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34, sheet 2. Expanded below to include about 150 feet of coarse gravels here termed the Butte gravel member. Upper Tertiary.

Named for occurrence in Sutter County, in what is now known as Marysville Buttes (formerly Sutter Buttes).

Sutter Mountain unit

Carboniferous(?): Northern Washington.

R. W. Jones, 1959, Dissert. Abs., v. 20, no. 3, p. 994. Consists of unmetamorphosed sedimentary and intermediate to basic volcanic rocks. These rocks are the lower plate of the Shuksan-Whitechuck overthrust which is east of map area. To the southwest, the Sutter Mountain unit is in high angle fault contact with Gold Mountain phyllite (new)

Report discusses geology of Finney Peak area, northern Cascades.

†Sutton Gneiss[1]

Precambrian: Central southern Massachusetts and northwestern Rhode Island.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18.

Named for exposures east of Sutton, Worcester County, Mass.

Sutton Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1917, West Virginia Geol. Survey Rept. Braxton and Clay Counties, p. 218.

Exposed just east of B. & O. Railroad Station at Sutton, Braxton County.

Sutton Island Series[1]

Precambrian or Camrbian(?): Southeastern Maine.

Original reference: N. S. Shaler, 1889, U.S. Geol. Survey 8th Ann. Rept., pt. 2, p. 1037, 1041–1043, 1061, map.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1797. Sutton Island abandoned; synonymous with Frenchmans Bay series (new) of Silurian age.

Named for development on Sutton Island, south of Mount Desert Island, Hancock County.

Suwanee Basalt Flow[1]

Pleistocene: New Mexico.

Original reference: R. L. Nichols, 1934, Geol. Soc. America Proc. 1933, p. 453.

Occurs in San Jose Valley, Valencia County.

**Suwannee Limestone**

Suwannee Limestone (in Vicksburg Group)[1]

Oligocene, upper: Eastern Florida and south-central Georgia.

Original reference: C. W. Cooke and W. C. Mansfield, 1936, Geol. Soc. America Proc. 1935, p. 71–72.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1314, 1315 (fig. 1). Vicksburg group restricted to exclude Suwannee limestone.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 173–178. As used in this report, Suwannee limestone includes all beds of Oligocene age in Citrus and Levy Counties. Upper part of formation is considered to be equivalent to lower Chickasawhay marl of eastern Mississippi, and lower part possibly equivalent of Byram formation and Marianna limestone of Florida. Thickness 59 to 120 feet. Unconformably overlies Ocala limestone (restricted) ; unconformably underlies Hawthorn formation; where Hawthorn is absent, Suwannee is covered by sediments of early Pleistocene or Alachua formation, terrestrial Miocene. Upper Oligocene.

W. E. Moore, 1955, Florida Geol. Survey Bull. 37, p. 51–58. As exposed in Jackson County, consists of tan- to buff-colored limestones, dolomitic limestones, and dolomitic to calcareous clays that underlie Tampa formation and overlie Marianna limestone. Thickness 5 to 12 feet in central area of county; maximum thickness about 210 feet (in water well at Sink Creek).

Typically exposed along Suwannee River in Florida, from Ellaville almost to White Springs.

Swakane Gneiss[1]

Pre-Ordovician: Central Washington.

Original reference: A. C. Waters, 1932, Jour. Geology, v. 40, no. 7, p. 603–633.

Well exposed along canyon of Swakane Creek, for which it is named.

Swan Creek Limestone[1]

Upper Ordovician: Western Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 43–44.

Named for Swan Creek, Hickman County.

Swan Creek phosphate[1]

Upper Devonian or Mississippian: Western Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 104, 136, 137, 138, 142.

Named for Swan Creek, Lewis and Hickman Counties.

Swan Creek Sandstone[1]

Mississippian: Southwestern Illinois.

Original reference: E. O. Ulrich, 1923, Geol. Soc. America Bull., v. 33, p. 831.

Exposed along Swan Creek, 1½ to 2½ miles east of Anna, Union County.

**Swandyke Hornblende Gneiss**[1]

Precambrian (Gunnison River Series) : Central Colorado.

Original reference: T. S. Lovering, 1935, U.S. Geol. Survey Prof. Paper 178.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 20, 73, pl. 1. In type locality, consists chiefly of hornblende schist and hornblende gneiss interlayered with thin beds of quartz latite; thickness approximately 6,000 feet. Lithologic character and structural relations indicate that dioritic intrusives and related extrusives and intercalated sediments were in part contemporaneous with and in part younger than upper part of Idaho Springs formation. At Coal Creek, overlain by series of quartzites and quartz pebble conglomerates at least 14,000 feet thick.

Type locality: At Swandyke, about 10 miles east of Breckenridge, Summit County.

Swan Lake Glaciation

Pleistocene (early Wisconsin): Central southern Alaska.

T. N. V. Karlstrom *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 4, 13 (table 1). At least four major Quaternary glaciations recognized in Upper Cook Inlet area. Succeeded Caribou Hills glaciation, preceded Naptowne glaciation (new). Represented by distinct moraine near Swan Lake and by discontinuous lateral moraines found along lower slopes of mountain fronts, generally 1,000 to 2,000 feet above sea level, and in major mountain valleys. Drift, in general, retains hummocky aspect, but kettle depressions partly or completely filled.

Represented near Swan Lake which is in northwest part of Kenai Mountains, Upper Cook Inlet area.

Swannanoa Formation

[Lower Cambrian]: Western Virginia.

W. A. Nelson, 1949, (abs.) Virginia Acad. Sci. Proc. 1948–1949, p. 139. Lower part of Unicoi up to top of a 300-foot acid lava flow is named Swannanoa formation and upper part of Unicoi is named East Waynesboro formation.

Report discusses structure and stratigraphy of the Blue Ridge in Albemarle and adjacent counties. Main Blue Ridge mountain is an overturned anticline, with axial plane dipping 28° SE., and a thrust fault bordering it on its western edge.

**Swan Peak Formation**

Swan Peak Quartzite[1]

Middle Ordovician: Northeastern Utah and southeastern Idaho.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 407, 409.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1136–1137, pl. 1. In Logan quadrangle, Utah, formation consists of three persistent members: lower, black shale; middle brown quartzite; and upper buff quartzite. Thickness 399 feet. Conformable and intergrading with underlying Garden City; unconformable below Fish Haven dolomite. Ordovician (Champlainian).

R. J. Ross, Jr., 1949, Am. Jour. Sci., v. 247, no. 7, p. 479, 483, 484. Formation discussed in area of its type section where it overlies Garden City limestone and underlies Fish Haven dolomite. Thickness at type section 315 feet.

G. W. Webb, 1956, Utah Geol. and Mineralog. Survey Bull. 57, p. 11–12, 35, 37–38, 39–40, 42–43 (fig. 11), 44. In Millard County, Utah, includes Watson Ranch tongue (new). Thickness 129 to 711 feet. In Ibex area, underlies Crystal Peak dolomite (new); elsewhere underlies Eureka quartzite; overlies Lehman formation.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 75–78, pls. 1, 20. In Sheeprock Mountains, Utah, overlies Kanosh shale and underlies Fish Haven dolomite. Thickness 348 to 462 feet. Kanosh shale is approximate age equivalent of lower part of Swan Peak formation of Ross (1949) of northeastern Utah and of Orient shale member of Orient formation in West Tintic mining district. Proposed that names Orient formation and its subdivisions Orient shale and Orient quartzite be supplanted by Kanosh shale and Swan Peak quartzite.

Named for Swan Peak, Rich County, Utah.

†Swan Pond Granite[1]

Late Carboniferous or post-Carboniferous: Northeastern Massachusetts.

Original reference: J. H. Sears, 1905, Phys. geog., min., and pal. of Essex County, Massachusetts, p. 141.

Well developed on shore of Swan Pond.

**Swansea Quartz Monzonite**

Swansea Rhyolite[1]

Eocene, middle: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, map.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 34. Discussion of Swansea quartz monzonite stock in East Tintic district.

D. R. Cook, 1957, Utah Geol. Soc. Guidebook 12, p. 65 (fig. 6). As shown on correlation chart, Swansea quartz monzonite overlies Laguna latite series (new) and underlies Silver City monzonite (new). Middle or upper Eocene.

Exposed in Swansea and South Swansea mines, Tintic district.

†Swanton Conglomerate[1]

Lower Cambrian to Lower Ordovician: Northwestern Vermont.

Original reference: A. Keith, 1923, Am. Jour, Sci., 5th, v. 5, p. 118–126.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1045. Beds called Swanton by Keith (1923) and later renamed Corliss breccia are herein renamed Rockledge limestone breccia.

Named for exposures in eastern part of Swanton Township, Franklin County.

†Swanton Slate[1]

Lower Cambrian: Northwestern Vermont.

Original reference: J. B. Perry, 1868, Boston Soc. Nat. History Proc., v. 11, p. 347.

Occurs at Highgate Springs, Franklin County.

Swanville Formation (in Hamilton Group)

Middle Devonian: Southeastern Indiana.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1057, 1063–1064, 1067. A gray crystalline limestone overlies Silver Creek formation and underlies New Albany shale throughout area of Hamilton outcrop. Heretofore, it has been regarded as a continuous bed of the Beechwood, but it represents two distinct formations—the Beechwood and the Swanville. The Swanville, a thick-bedded hard bluish to gray crystalline limestone, is difficult to distinguish from Beechwood on lithology alone but the two have not been found in the same section at any place. Maximum thickness 6 feet; at type section 5 feet.

J. B. Patton and T. A. Dawson *in* H. H. Murray, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 42, pl. 1. Swanville and Deputy "formations" appear to be only faunal facies of units previously recognized and named, or combinations of such units; they might better be called "zones" or "faunal facies" of Sellersburg (North Vernon) limestone.

Type section: Scott-Jefferson County line on Highway 256, about 1 mile west of Swanville. Occurs in continuous bed from near Commiskey, Jennings County, to southeast corner of Scott County.

**Swarbrick Formation**[1]

Cambrian: South-central Nevada.

Original reference: H. G. Ferguson, 1933, Nevada Univ. Bull. 27, no. 3, p. 13–25.

W. H. Easton, chm., 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 148. Listed among names not used in revision of stratigraphic units in Great Basin.

Forms hanging wall of ore-bearing fissure in Swarbrick prospect, in eastern part of Tybo district.

**Swarthmore Granodiorite**

Late Paleozoic: Southeastern Pennsylvania.

A. W. Postel and H. W. Jaffe, 1957, Pennsylvania Acad. Sci. Proc., v. 31, p. 120–123. Introduced to replace preempted name Springfield granodiorite. Study indicates that lead-alpha ages of ziron of Wissahickon schist are older than those of Swarthmore granodiorite and related rocks and that all of the ages are younger than Precambrian.

Type locality not stated. Postel (1941) reported exposures of Springfield granodiorite in vicinity of Swarthmore, Delaware County.

Swartz Rhyolite

Tertiary: Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 36, pl. 1. Porphyritic rhyolite flows, tuffs, and flow breccias associated with one or more domelike porphyritic rhyolite intrusive bodies and small dikes. The rhyolite consists of alternating brown and gray bands, about 3 mm wide. Flow folds common. Angular unconformities separate it from Bear Springs basalt below and Santa Fe fanglomerates above.

Named after small abandoned settlement near junction of Tom Brown Canyon and Mimbres River. A local formation found only in secs. 26, 27, 34, and 36, T. 18 S., R. 10 W., Dwyer quadrangle.

**Swasey Formation**[1]

Middle Cambrian: western Utah and southeastern Nevada.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 9, 11.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1133–1134, 1141, 1145–1146. Because Walcott's section of Swasey was not part of a continuous section and original definition was not sufficiently precise, Swasey is herein redefined and type section assigned. As emended, formation consists of a lower unit 117 feet thick and an upper unit 278 feet thick. Lower unit consists of 38 feet of interbedded dull-gray fine-grained platy argillaceous limestone and clay shale with well-preserved cranidia and pygidia of *Ehmania;* 50 feet of dull- and dark-gray platy and a few arenaceous limestones with several beds of *Ehmania*-coquina at top; and 29-foot zone of green micaceous chunky and fissile shale and interbedded gray thin-bedded limestones which increase in amount upward. Upper 278 feet consist of dark- and black-gray medium-grained massive and irregular-bedded limestone which contains oolites in the lower, and small algae (*Girvinella?*) in upper part. Overlies Dome limestone (emended); underlies Wheeler shale (emended).

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 39–40, fig. 5. Geographically extended into Nevada, where it is same as units F–G of Highland Peak limestone as described by Wheeler and Lemmon (1939). Overlies Dome limestone also extended into Nevada. Lower 117 feet of type Swasey as described by Deiss is herein named Condor member.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 35, 47, 139–140, 145–146, 150, pl. 1. In Sheeprock Mountains, stratigraphically restricted at base to exclude Condor member herein raised to formational status. Thickness 169 feet.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 43–52. Name Swasey herein restricted to cliff-forming limestone unit that overlies Whirlwind formation (new) and that underlies Wheeler shale. Term Condor member of Swasey considered invalid.

Type section: Marjum Canyon, House Range, Millard County, Utah. Here formation forms part of the continuous emended Cambrian section.

†Swatara Iron Sandstone (in Clinton Formation)[1]

Silurian (Niagaran): Southeastern Pennsylvania.

Original reference: C. K. Swartz and F. M. Swartz, 1931, Geol. Soc. America Bull., v. 42, p. 637, 638.

Occurs on Swatara Creek, Swatara Gap, 11 miles northwest of Lebanon, Lebanon County.

**Swauger Quartzite**

Precambrian (Belt Series): Southern central Idaho.

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1096, 1097–1099, pl. 1. Mostly rather pure quartzite that varies from purple through deep-brownish-lavender and pinkish shades to almost pure white. Near base and locally at higher horizons are beds of green relatively impure quartzite. Most quartzite is distinctly bedded and some is cross-bedded. A few lenses of conglomerate and rusty impure dolomite are included. Variegated argillite is present at several horizons but is most conspicuous in lower part of formation. Beds of different colors and lithologies interfinger with each other. Unit has not been satisfactorily measured, but in vicinity of Flatiron Mountain the exposed thickness appears to be at least 1 mile. Underlies Kinnikinic quartzite and overlies Lemhi quartzite (new) with gradational contact.

A. L. Anderson, 1959, Idaho Bur. Mines and Geology Pamp. 118, p. 18–21. Thickness about 10,000 feet in Lemhi quadrangle. Overlies Lemhi quartzite.

Occupies most of southern and eastern parts of the small part of Lemhi Range included in Borah Peak quadrangle. Named after Swauger Ranch whose grazing lands include much of area in which it crops out within quadrangle.

**Swauk Formation**[1]

Eocene: Central and central northern Washington.

Original reference: I. C. Russell, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 2, p. 100–137.

R. L. Lupher, 1944, Washington Div. Geology Rept. Inv. 11, p. 7, 12–15, pl. 2. Overlies Cle Elum formation (new).

H. A. Coombs, 1950, Am. Jour. Sci., v. 248, no. 6, p. 369–377. Discussion of granitization in the Swauk. Structurally formation rests unconformably on Swakane gneiss which has been considered pre-Ordovician. Presumably in late Eocene time, beds were folded into series of anticlines and synclines whose axes trend grenerally in northwest-southeast direction.

R. S. Yeats, 1958, Dissert, Abs., v. 19, no. 4, p. 775. In Skykomish area, Temple Mountain andesite (new) overlies Swauk with angular unconformity. Paleobotanical evidence suggests Paleocene age for Swauk, though part may be Upper Cretaceous.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 101 (table 1), 103–105, pl. 1. Predominantly arkose with some shale and minor conglomerate; rock types distributed irregularly; beds range from a few inches to more than 100 feet thick and grain size changes abruptly both laterally and vertically; most of formation massive, but crossbedding not uncommon. Thickness at least 4,000 feet, may be more. Unconformably underlies Teanaway basalt in most of area; locally, between Kachess and Cle Elum Lakes, unconformably covers pre-Tertiary peridotite and Easton schist. Where Swauk unconformably overlies peridotite, lateritic iron ores have been formed. Most authors have considered these laterites basal Swauk, but Lupher (1944) proposed name Cle Elum for these deposits. Age of Swauk has been much debated. When Knowlton (*in* G. O. Smith, 1904, U.S. Geol. Survey Geol. Atlas, Folio 106) identified fossil leaves as Eocene, term Paleocene had not come into use. It seems clear from Knowlton's reference to what are now considered Cretaceous and Paleocene formations that he regarded the Swauk as being near Cretaceous-Teritary boundary, not Eocene as we use it today. Paleocene or Late Cretaceous age based on paleobotany is in accord with stratigraphic relationship. The Swauk unconformably overlies metamorphic basement of unknown age. Unconformably above Swauk is Teanaway basalt, and concordantly above Teanaway is Roslyn arkose that contains middle or upper Eocene fossils. Area of this report is northern part of Mount Stuart and Snoqualmie folios, central Cascade Mountains.

Named for Swauk Creek and Swauk mining district, about 15 miles north of Ellensburg, Kittitas County.

**Swearinger Slate**[1]

Upper Triassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

C. W. Averill, 1937, California Jour. Mines and Geology, v. 33, no. 2, p. 85, 86. Composed chiefly of dark slaty shale, with thin beds of limestone and chert forming small proportion of whole mass. Thickness 200 to 400 feet. Overlies Hosselkus limestone; underlies Trail formation.

Named for fact it occurs near Swearinger's house, on north side of Genesee Valley, Plumas County.

Swede Pond Quartzite[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Faxon limestone and below Catamount schist.

Type locality: Swede Pond, Hague Township, Warren County.

**Sweetland Creek Shale**[1]

Upper Devonian or Mississippian: Southeastern Iowa and western Illinois.

Original reference: J. A. Udden, 1899, Jour. Geology, v. 7, p. 65–78.

Walter Youngquist and A. K. Miller, 1948, Jour. Paleontology, v. 22, no. 4, p. 440–450. Recent conodont studies in vicinity of type section confirms evidence that Sweetland Creek is referable to Upper Devonian and is approximately contemporaneous with Grassy Creek shale of Missouri. Formation is only of local occurrence in Iowa.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 39. Sweetland Creek beds at their type locality represent only a relatively small part of the almost 200 feet of similar beds called Grassy Creek in northwestern Illinois. Therefore name Sweetland Creek is discarded in Illinois.

Named for exposures on Sweetland Creek, about 4 miles from Muscatine, Muscatine County, Iowa.

Sweetwater Dolomite[1]

Permian: Central northern Texas.

Original reference: A. M. Lloyd and W. C. Thompson, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 953, pl. 10.

Named for outcrops in Sweetwater, Nolan County.

Sweetwater Group[1]

Oligocene: Central Wyoming.

Original reference: F. V. Hayden, 1871, U.S. Geol. Survey Terr., 4th Ann. Rept., p. 29.

Occurs along Sweetwater River and continues north to hills opposite Seminoe Pass in Sweetwater Valley.

Sweetwater Member[1] (of White River Group)

Oligocene: Western Wyoming.

Original reference: C. M. Bauer, 1934, Geol. Soc. America Bull., v. 45, p. 665–695.

Occurs along Sweetwater escarpment from Lander-Rawlins Road as far east as Alcova, Natrona County, a distance of 80 miles.

Sweitzer Formation

Pliocene or Pleistocene: Southern California.

L. G. Hertlein, 1929, Stanford Univ. Abs. Dissert., v. 4, p. 82. A conglomerate 1 to 3 meters thick. Usually unconformably overlies beds of known Pliocene age.

L. G. Hertlein and U.S. Grant, 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 63 (fig. 4), 71. Described as brown and brownish-red conglomerate or pebbly sandstone 5 to 30 feet thick. Unconformably overlies San Diego formation and caps most of the tops of mesas in area. Columnar section shows Sweitzer formation underlying Bay Point formation (new).

Type locality: Sweitzer Canyon in Balboa Park, San Diego County.

Swenson Gypsum Member[1] (of Peacock Formation)

Permian: Central northern Texas.

Original reference: L. T. Patton, 1930, Texas Univ. Bull. 3027, p. 45.

L. T. Patton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 927. Swenson gypsum is same as Wagon Yard gypsum. Name Swenson gypsum member was proposed by writer [Patton] when his manuscript was submitted in 1927. Name Wagon Yard was not proposed until 1929. The writer [Patton] retained the name originally proposed when his manuscript was revised in 1930.

Named for exposures near town of Swenson, Stonewall County. Forms prominent escarpment extending from southern border of county to near Swenson, where escarpment dies down and gypsum bed disappears.

Swett Tuff Member (of Quichapa Formation)

Oligocene: Eastern Nevada and southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 92 (fig. 2), 94. At type locality, underlies Bauers tuff member and overlies Leach Canyon tuff member (both new); elsewhere lava flows or other volcanic rocks, local in extent and origin, present at contacts. Thickness 30 to 45 feet in Swett Hills. An ignimbrite similar to Bauers tuff. Zircon age of Leach Canyon tuff member is 28 million years; this suggests that Quichapa formation is Oligocene. Report is discussion of ignimbrites of area.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 138 (fig. 3). Geographically extended into eastern Nevada.

Type locality: West-facing scarp of Swett Hills, Desert Mound quadrangle, Iron Springs district, Utah.

**Swift Formation** (in Ellis Group)

Swift Formation (in Sundance Group)

Upper Jurassic: North-central Montana, western South Dakota, and eastern Wyoming.

W. A. Cobban, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 9, p. 1264 (fig. 1), 1281–1286, 1288 (fig. 5), 1289 (fig. 6), strat. sections. At type locality, consists of two members; lower is dark-gray noncalcareous shale 54½ feet thick; upper member is flaggy ripple-marked sandstone 80 feet thick containing abundant black-gray fissile shale partings. Lithologic character of type locality persists along mountain front from south boundary of Glacier National Park southeast almost to Sun River. From Sun River southeast along mountain front, formation becomes increasingly sandy. On South arch, formation consists of fine-grained flaggy sandstone which is locally pebbly at base. In vicinity of Little Belt Mountains, formation is massive fine-grained sandstone containing prominent basal conglomerate. Thicknesses: 135 feet at type locality; 106 feet, Rierdon Gulch; 118 feet, Sun River section, Lewis and Clark County; 101 feet, southwest of Craig. At type section, underlies Morrison formation; overlies Rierdon formation (new); in areas where Rierdon is absent, unconformably overlies Sawtooth formation (new).

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 466 (table 2), 480, 481, 482, 483, 491–504, 505. Swift-Rierdon nomenclature of Ellis group in Montana is applied in eastern Wyoming and western South Dakota to formational units of Sundance group. Indications are that the names are applicable to marine Upper Jurassic throughout most of Wyoming and western South Dakota, but term Sundance should be retained because of historical significance. Thicknesses in outcrop sections of Swift vary from 63 feet in Laramie County to 289 feet in Johnson County. Overlies Rierdon formation; underlies Morrison formation.

T. P. Storey, 1958, Alberta Soc. Petroleum Geologists Jour., v. 6, no. 4, p. 90–104. Discussion of Jurassic of Williston basin and adjacent areas. On basis of regional extent and significance of sub-Swift and sub-Rierdon unconformities, a different stratigraphic interpretation is presented. Swift is divided into Lower, Middle, and Upper units. Lower Swift is so designated because it is considered to be lithologically similar to and regionally conformable with the Middle and Upper Swift which correspond to type Swift formation of western Montana. Lower Swift of Williston basin and equivalent Stockade Beaver and Hulett members of Lower Sundance in Black Hills, are considered to lie unconformably on the Rierdon and therefore are younger than the Rierdon and older than the Swift as designated by Cobban. This correlation is offered in lieu of general belief that Lower Sundance and Rierdon are equivalent in age. Thus, Lak and Redwater members of Sundance are considered equivalent to type Swift formation.

Type locality: Vicinity of Swift Reservoir, T. 28 N., R. 10 W., Pondera County, Mont. Section measured on north shore in NE¼ sec. 27.

**Swift Run Formation**

Swift Run Tuff

Precambrian: Northern Virginia, and Maryland.

G. W. Stose and A. J. Stose, 1944, Am. Jour. Sci., v. 242, no. 8, p. 410. A series of tuffaceous and arkosic sediments that underlie Catoctin basalt and overlie injection complex on west limb of Catoctin Mountain-Blue Ridge anticlinorium.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12] Carroll and Frederick Counties, p. 18–20. Geographically extended into Maryland where it underlies Catoctin metabasalt and lies directly on injection complex. Beds comprise blue and green blebby tuff, sericite schist, and a sericitic quartzite with glassy and blue quartz grains; also includes some marble just above the basal quartzose beds. Parts of unit here described as Swift Run had formerly been mapped as part of Loudoun formation by early workers. Derivation of name given.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 311. In central Virginia, Oronoco formation (Bloomer and Bloomer, 1947) is equivalent to Swift Run tuff which had previously been mapped as far south as this part of Virginia.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 9–12, pl. 1. In Elkton, Va., area, termed Swift Run formation because unit is varied in character and tuffaceous element is subordinate. Underlies Catoctin greenstone, probably conformable. Crops out in narrow belt around inliers of injection complex.

R. O. Bloomer and H. J. Werner, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 487–589, pl. 1. Formation in Blue Ridge area, central Virginia, consists mainly of graywackes, subgraywackes, and volcanics 0 to 400 feet thick. Beds are from a fraction of an inch to about 20 feet thick. Where formation overlies Pedlar migmatite, lower part is conglomerate graywacke with clasts composed of quartz, potash feldspar, and granite in an equigranular matrix that unconformably overlies basement complex and conformably underlies Catoctin greenstone; overlaps basement complex from east to west. Separated from unaltered basement rock by a saprolite 10 to 100 feet thick.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 43, 72. Referred to as tuff member of Catoctin metavolcanics.

Named from exposures on U.S. Highway 33 just east of Swift Run Gap, Va., and on Skyline Drive just north of the gap.

**Swift Water Formation**[1]

Probably Cambrian: Northwestern New Hampshire.

Original reference: C. H. Hitchcock, 1874, Am. Jour. Sci., 3d, v. 7, p. 468–476.

In region from Swiftwater and Woodville on south to north of Littleton, Grafton County.

Swisshelm Formation

Upper Devonian: Southeastern Arizona.

R. C. Epis, C. M. Gilbert, and R. L. Langenheim, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2243–2256. In general, upper third of formation is largely impure limestone, whereas quartz sandstone, siltstone, and marl predominate in lower two thirds. Mostly thin bedded and nonresistant. Wherever well exposed, sandy and marly strata are shades of brown and yellow. Thickness 400 to 600 feet. underlies Escabrosa limestone; overlies El Paso limestone.

In Swisshelm and Pedregosa Mountains, southeastern Cochise County.

Swissvale Gypsum Member (of Minturn Formation)

Pennsylvanian (Desmoinesian): South-central Colorado.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 821, 833, pl. 1. A bed of gypsum which lies about 2,000 feet above base of formation in Arkansas River section west of Canyon City. Gypsum cannot be traced continuously through the area. It may rise in section toward southeast or may have been injected between different beds in different parts of area.

Named from exposures about a quarter mile northeast of Swissvale switch (Denver and Rio Grande Western Railroad), Fremont County. Crops out sporadically from vicinity of Meeker southward to Coaldale.

**Switchback Shale**

Switchback Limestone[1]

Middle and Upper Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 5, 39.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1078, 1084, 1089, 1090 (fig. 2); 1939, Geol. Soc. America Spec. Paper 18, p. 6, 8–9, 16, 29, 32, 46, 54 (fig. 6). Referred to as Switchback shale; overlies Steamboat limestone (as used here replaces Gordon Mountain limestone of 1933 sequence); underlies Devils Glen dolomite. Thickness at type locality 253 feet; average thickness 111 feet. Middle Cambrian.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 8, p. 1131 (table 1), 1133. Described in Sawtooth Range where it is 125 to 175 feet thick; underlies Devils Glen dolomite; overlies Steamboat limestone. Middle and Upper Cambrian.

Type locality: On ridge east of Kid Mountain and west of cirque on southwest side of Gordon Mountain, in SW¼ sec. 9, T. 19 N., R. 13 W., northern Lewis and Clark Range. Named from Switchback Pass approximately 2 miles southeast of Pentagon Mountain.

**Swope Limestone[1] or Formation[1]** (in Kansas City Group)

Swope Limestone (in Bronson Group)

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: C. O. Dunbar and G. E. Condra, 1932, Nebraska Geol. Survey Bull. 5, 2d ser., p. 17, table C.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Swope limestone included in Kansas City group (redefined). Underlies Galesburg shale; overlies Ladore shale.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 192–193. Swope limestone in Bronson group includes (ascending) Middle Creek limestone, Hushpuckney shale, and Bethany Falls limestone members. Average thickness 23 feet. Overlies Ladore shale; underlies Galesburg shale. Missouri series.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2028–2029, 2031 (fig. 4). Included in Kansas City group (redefined in Kansas and Nebraska). Comprises (ascending) Middle Creek limestone, Hushpuckney shale, and Bethany Falls limestone members. Overlies Ladore formation; underlies Galesburg formation. Bronson reduced to subgroup of Kansas City group (redefined). This is classification agreed upon by Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 421. Included in Kansas City group. Thickness about 27 feet. Comprises (ascending) Middle Creek limestone, Hushpuckney shale, and Bethany Falls limestone members. Overlies Ladore shale; underlies Galesburg shale.

Named for Swope Park, Kansas City, Mo.

Sybille Tongue (of Phosphoria Formation)[1]

Permian: Central southern Wyoming.

Original reference: H. D. Thomas, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1664.

H. D. Thomas, 1940, Kansas Geol. Soc. Guidebook 14th Ann. Field Conf., p. 124. Suggests that name be abandoned in favor of Minnekahta.

Type locality: Around Sybille anticline near Sybille Springs in Laramie Basin.

Sycamore Conglomerate

Miocene and Pliocene: Southern California.

G. J. Bellemin, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 652 (fig. 1), 656. Named as one of five conglomerates interbedded in Miocene and Pliocene shales of Puente Hills, Los Angeles County.

Named for its occurrence in Sycamore Canyon.

**Sycamore Limestone**[1]

Mississippian: Central southern Oklahoma.

Original reference: J. A. Taff, 1903, U.S. Geol. Survey Geol. Atlas, Folio 98.

J. D. Prestridge, 1959, *in* Petroleum Geology of southern Oklahoma, v. 2: Tulsa, Am. Assoc. Petroleum Geologists, p. 156–164. In Ardmore basin, formation occupies stratigraphic interval between Caney (Meramecian) and Woodford (upper part-Kinderhookian) formations. Divisible into two members, herein named Cornell Ranch (lower) and Worthey (upper). Comprises up to 350 feet of slate-blue tough silty to finely sandy limestone with calcareous shales ranging from very thin partings to lentils up to 30 feet thick. Lower part contains cherty limestones and calcareous shales, with a green shale at base. Near base is bed of limestone, typically glauconitic at base, becoming cherty in upper part.

M. K. Elias and C. C. Branson, 1959, Oklahoma Geol. Survey Circ. 52, p. 22, 23. Sycamore sandstone exposed below Caney type section is unlike Sycamore of its type area and may be facies grading into Ahloso member of Caney.

Named for Sycamore Creek, Johnston County, which crosses its outcrop in T. 3 S., R. 4 E.

Sycamore Member (of Travis Peak Formation)

Sycamore Sand

Sycamore Sand (in Travis Peak Formation)[1]

Lower Cretaceous (Comanche Series): Central Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 141, 142.

R. H. Cuyler, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 5, p. 631–632. Member consists primarily of sands and conglomerates. Thickness 30 to 90 feet. Underlies Cow Creek member. Hill's Sycamore has priority over Taff's Sycamore limestone in Mississippian of Oklahoma.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 5, 6–7 (fig. 1), 8. Marble Falls limestone and Smithwick shale are truncated, and deposited across them is massive conglomerate of Cretaceous age belonging to Sycamore sand member of Travis Peak formation.

F. E. Lozo and F. L. Stricklin, Jr., 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 69, figs. Referred to as Sycamore sand. Cartographic rock unit ordinarily mapped with the Sycamore but originally included in Hill's definition of Cow Creek beds is distinct unit between Sycamore sands below and Cow Creek limestone above. It is here named Hammet shale.

Named for exposures on Sycamore Creek, Burnet County.

**Sycamore Canyon Member** (of Puente Formation)

Sycamore Canyon Formation

Miocene, upper: Southern California.

M. L. Krueger, 1936, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 20, no. 11, p. 1520. Name Sycamore Canyon formation applied to a 3,800-foot interval of alternating conglomerates, sands, silts, and shales in Whittier Hills. Underlies Repetto formation; unconformably overlies upper Puente member of Puente formation.

S. N. Daviess and A. O. Woodford, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 83. Described in Whittier area. Rank reduced to member of Puente formation. Lower beds of conglomerate lens out within map area and in places interfinger with beds of underlying siltstone.

C. J. Kundert, 1952, California Div. Mines Spec. Rept. 18, p. 6–7. In Whittier-La Habra area member subdivided into Central Fee sandstone below and Hoover conglomerate above.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–154. Use of name extended to include the massive- to well-bedded feldspathic sandstones, gray to brown siltstone, and local conglomerates that crop out in southeastern end of Puente Hills, between Chino and Santa Ana River, and on Burruel Ridge south of Santa Ana River. On Burruel Ridge, the Sycamore Canyon is unconformably overlain by Repetto(?) and gradationally overlies Yorba member (new) of Puente.

Whittier Hills area is in Los Angeles County.

Sycamore Creek Sandstone[1]

Upper Devonian: Northeastern and central Arizona.

Original reference: C. Lausen and E. D. Wilson, 1925, Arizona Univ. Bur. Mines Bull. 120, p. 7, 12–13.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228. Sycamore sandstone designated the middle part of the Jeromian series (new). Underlies East Verde limestone (new); overlies Vecol limestone (new). Thickness 75 feet.

Best exposed at Sycamore Creek, a tributary of East Verde River, Coconino and Yavapai Counties.

Sykes Mountain Formation

Lower Cretaceous: Northwestern Wyoming.

Ralph Moberly, Jr., 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1139 (fig. 1), 1143 (fig. 2), 1149–1150, 1151 (fig. 5), pl. 1. Composed of thinly interbedded siltstones, sandstones, and shales, commonly containing some thicker blanket-shaped sandstone, especially near base, and thin beds of ironstones, all of which show some marine and some nonmarine features and weather yellowish brown. Lies with sharp contact on Himes member (new) of Cloverly formation; grades upward and interfingers with marine black bentonitic clayshale of Thermopolis shale. Thickness ranges from 100 to about 300 feet; at type section 136 feet. At type section, formation displays its characteristic increase in proportion of black shale in its upper part; upper contact is placed above uppermost sandstones, siltstones, and ironstones. Formation includes the "rusty beds", Dakota silt, Dakota sandstones, and Greybull member of Cloverly formation, of various authors. Because no existing name is adequate, new name is proposed. Formations in this report—Morrison, Cloverly, and Sykes Mountain—are defined on lithogenitic basis.

Type section: Northwest of Sykes Mountain between Crooked Creek and Gypsum Creek about 1 mile south of Montana State line in NE¼ sec. 25 T. 58 N., R. 96 W., Big Horn County, Wyo.

**Sykesville Formation**

Sykesville Granite[1]

Paleozoic: Central northern Maryland.

Original reference: A. I. Jonas, 1928, Maryland Geol. Survey Carroll County map.

A. J. Stose and G. W. Stose, 1944, U.S. Geol. Survey Prof. Paper 204, p. 53–54. Intrudes Peters Creek quartzite and an amphibolite schist in a belt that parallels the Peach Bottom syncline from Hartford County, Md., to Potomac River. In part of the area, the Sykesville has a steep-axis structure and a series of prominent joints at right angles to the linear direction of the fold axis. The Sykesville was intruded before development of the steep-axis structure and has shared the regional deformation with the adjoining schists of the Glenarm series, which is tentatively assigned to Precambrian.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 42 (table 7), 63. At least three periods of granite formation are recognized in the Maryland rocks. The oldest granites are the probable migmatites associated with the Baltimore gneiss. Those of second period cut the Glenarm series. Representatives of the third period are Woodstock, Ellicott City, and Sykesville. The Sykesville is not a homogeneous rock; parts of it are a product of migmatization of the country rock and other parts show little deformation. It may include rocks of both the second and third periods of the formation of granitic rocks, and the migmatized and gneissic areas may represent the older period. Age shown on table as Devonian.

U.S. Geological Survey currently designates the age of the Sykesville Formation as Paleozoic on the basis of a study now in progress.

First described in Carroll County. Probably named from occurrence near Sykesville.

**Sylacauga Marble Member** (of Talladega Slate)[1]

Precambrian or Paleozoic: Eastern Alabama.

Original reference: C. Butts, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 51, map.

Named for exposures and quarries around Sylacauga, Talladega County.

**Sylamore Sandstone Member** (of Chattanooga Shale)[1]

Sylamore Formation (in Champ Clark Group)

Upper Devonian: Northern Arkansas, Illinois, southwestern Missouri, and eastern Oklahoma.

Original reference: R. A. F. Penrose, Jr., 1891, Arkansas Geol. Survey Ann. Rept. 1890, v. 1, p. 113, 114.

J. G. Grohskopf, E. L. Clark, and S. P. Ellison, 1943, Missouri Geol. Survey and Water Resources 62d Bienn. Rept., App. 4, p. 7–8. Sylamore formation as used in this report is applied to sandstone that underlies Chattanooga shale or Compton formation and rests on Cotter dolomite or Fortune formation (new). Mississippian (Kinderhook).

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 185, p. 14. Sylamore formation included in Champ Clark group (new). Rarely more than 5 feet thick and commonly not more than a few inches thick. Underlies Grassy Creek formation. At base of Kinderhook series. Correlated with Sylamore sandstone of Arkansas, Misener sandstone of Oklahoma, and Hardin sandstone of Tennessee. Name Sylamore has been used for the sandstone in Missouri and western Illinois and is accepted for use throughout Illinois. It has priority over Hardin and Misener.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 38–39. Member described on south and west flanks of Ozark uplift. White, phosphatic sandstone with salt and pepper appearance on fresh surface. Basal part consists of dark-gray sandy shale and bluish-gray phosphatic limy sandstone. Maximum thickness 18 feet; thins northward and is absent in most of area. Unconformably overlies St. Clair, Frisco, and Sallisaw formations in southern part of area; northward unconformably overlies Tyner formation near Murphy and the Burgen and Cotter along Spavinaw Creek. Succeeded conformably by black shale member of formation. Age debatable; final determination awaits precise dating of overlying black shale.

G. G. Huffman and J. M. Starke, 1960, Oklahoma Geology Notes, v. 20, no. 7, p. 159–160. Chattanooga shale divided into Sylamore sandstone member below and Noel shale member above. On basis of conodonts, Noel shale appears to be Late Devonian and Early Mississippian. Distribution noted.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 66–69. Discussion of use of term Sylamore. Examination of strata involved at or near type locality does not give satisfactory answer concerning either its [Sylamore] age or relationships. There is no way of determining to which of the several sands in the section either Branner or Penrose (1891) wished to apply name Sylamore. At present there is no uniformity in the interpretation of term Sylamore. One solution lies in redefinition of term, but it seems unlikely there would be general acceptance of such a definition. It is here recommended that Sylamore be omitted from stratigraphic names in Missouri.

Named for exposures on Sylamore Creek, Stone County, Ark.

**Sylvan Shale**[1]

Sylvan Shale (in Patterson Ranch Group)

Upper Ordovician: Southwestern, central southern, central eastern, and northeastern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

R. A. Maxwell, 1936, Northwestern Univ. Summ. Doctoral Dissert., v. 4, p. 133. Unconformably underlies Hawkins limestone member (new) of Chimneyhill limestone

C. E. Decker, 1942, Oklahoma Acad. Sci. Proc., v. 22, p. 153, 154 (table 1). Uppermost formation in Patterson Ranch group (new).

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in southwestern, central southern, central eastern, and northeastern Oklahoma.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), fig. 4 (facing p. 8). Underlies Ideal Quarry member (new) of Chimneyhill formation.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 27–29, measured sections, pls. Described on north and west flanks of Ozark uplift, northeastern Oklahoma. Ranges from dark green and fissile to brown silty shale with concretionary weathering. Locally, thin stringers of brown dolomitic sandstone present in lower parts. Thickness 12 to 36 feet. Conformably overlies Fernvale limestone. Near Qualls and on Blackgum Mountain, succeeded unconformably by St. Clair limestone of Silurian age; northward in Nigger Hollow and in Horseshoe Bend section, overlain unconformably by Chattanooga black shale of late Devonian and early Mississippian age. Upper Ordovician, Cincinnatian.

Named for exposures near former village of Sylvan, Johnston County.

**Sylvania Sandstone**[1] or **Formation**

**Sylvania Sandstone Member** (of Amherstburg Formation)

Sylvania Sandstone (in Detroit River Group)

Middle Devonian: Northwestern Ohio and southeastern Michigan, and Ontario, Canada.

Original reference: E. Orton, 1888, Ohio Geol. Survey, v. 6, p. 4, 18.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Lower or Middle Devonian.

K. K. Landes, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 28. Sylvania formation crops out in Monroe County, Mich., and across Ohio line in vicinity of Sylvania. Underlies Detroit River formation; overlies Bois Blanc formation. Middle Devonian.

G. M. Ehlers, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1455–1456. Sylvania sandstone, oldest unit of Detroit River group, is succeeded by Amherstburg dolomite.

K. K. Landes, 1951, U.S. Geol. Survey Circ. 133, p. 1, 2 (fig. 2). In subsurface, Sylvania sandstone is considered member of Amherstburg formation. Thickness as much as 300 feet.

J. E. Carman, 1960, Fieldiana: Geology, v. 14, no. 1, p. 1–5. In northern Ohio, overlies Holland Quarry shale (new).

Named for Sylvania, Lucas County, Ohio.

†Symonds Formation

Lower Cretaceous(?): Southeastern Alaska.

Fred Barker, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–100. Fine- to coarse-grained carbonaceous plagioclase-quartz-sericite-chlorite graywacke, much of which is laminated in layers one-quarter inch to several inches thick, forms bulk of formation. Very fine grained black graywacke and black slate next in abundance. Augite-bearing volcanic flow breccia conformably interlayered with the graywacke and slate on Horse and Douglas Islands. A 15-foot thick layer of brown marble forms basal unit of formation at contact with Barlow Cove formation (new) on Hump Island. Greenstone sills, dikes, and flows(?) lie in slate of formation in some areas and range in thickness from several inches to several feet. Formation largely concealed by water but believed to be at least 5,000 and possibly 10,000 feet thick. Strata as exposed on Shelter Island may grade by facies change into Shelter formation (new). Overlies Barlow Cove formation (new).

Type locality: Symonds Point, Juneau (B–3) quadrangle. Crops out along eastern shore of Admiralty Island from Symonds Point to southern boundary of quadrangle, on Horse, Colt, and Portland Islands, and on parts of Lincoln, Shelter, Hump, and Douglas Islands.

**Syracuse Salt** (in Salina Group)

Syracuse Formation (in Salina Group)

Syracuse Salt Member (of Camillus Formation)

Syracuse Salt Member (of Salina Formation)[1]

Upper Silurian: Western to east-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 18–19, chart.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Syracuse salt in Saline group. Cayugan series.

R. E. Griswold, 1951, New York State Water and Power Control Comm. Bull. GW–29, p. 10. Salina formation consists of (ascending) Pittsford shale, Vernon shale, Syracuse salt, Camillus shale, and Bertie limestone members, of which only the Vernon and Camillus have been definitely recognized in Wayne County.

W. P. Leutze, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 7, p. 1693–1697. Term Syracuse formation is modification of term Syracuse salt. Since salt is not present at outcrop, the change seems appropriate. At outcrop (Onondoga and Madison Counties), formation is predominantly brown dolomites and gray shales. Beds of structureless clay, containing brecciated shale and dolomite or a few blocks of bedded gypsum, mark former horizons of soluble evaporite beds. Top of formation is transition from brown thin-bedded dolomite into overlying olive-colored Camillus shale. Base of formation is marked by a conglomerate of shale and dolomite pebbles and sand grains in a dolomite matrix. Overlies Vernon shale. Subdivided into (ascending) transition member, 90 to 120 feet thick; lower clay member, 10 to 15 feet; middle dolomite member, 35 to 50 feet; upper clay member 10 to 20 feet; and upper dolomite member 8 to 24 feet. Includes three faunal zones. Prior to this study, all rocks between Vernon shale and Bertie waterlime were called Camillus shale at outcrop, and consequently most publications list fossils from the Syracuse as coming from Camillus shale.

W. L. Kreidler, 1957, New York State Mus. Bull. 361, p. 6. Referred to as member of Camillus formation.

First recognized in wells near Syracuse.

Syracuse Serpentine[1]

Age(?): New York.

Original reference: G. H. Williams, 1890, Geol. Soc. America Bull., v. 1, p. 533–534.

Occurs in James Street Hill, Syracuse, Onondaga County.

**Syrena Formation** (in Magdalena Group)[1]

Pennsylvanian: Southwestern New Mexico.

Original reference: A. C. Spencer and S. Paige, 1935, U.S. Geol. Survey Bull. 859.

M. L. Thompson, 1942, New Mexico Bur. Mines and Mineral Resources Bull. 17, p. 23. Studies indicate that Syrena and Oswald formations each include large parts of at least two series of the Pennsylvanian. They are not useful as regional stratigraphic units and will not be considered in this report on Pennsylvanian of New Mexico.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 283 (fig. 5), 284–285. Divided into Mountain Home shale, 110–130 feet thick below and Humboldt limestone (Don limestone) 250 feet thick. Where exposed in Santa Rita pit along margin of granodiorite stock, upper Syrena has been extensively metamorphosed. Entire formation has been highly silicified and chloritized. Overlies Oswald limestone; unconformably underlies Cretaceous Beartooth quartzite. In some areas, overlain by sandstone, shales, and limestone correlated with Permian Abo sandstone; where Abo is missing, Syrena is directly overlain by Cretaceous rocks. In some areas, beds considered Abo by various workers could not be distinguished from metamorphosed Syrena and for this report are considered part of Syrena.

Named for Syrena patented mining claim about 1 mile south of Hanover post office, Santa Rita mining district.

**Tabernacle Flow**

Pleistocene, upper: Central Utah.

G. B. Maxey, 1946, Am. Jour. Sci., v. 244, no. 5, p. 328. Overlies Pavant flow (new). Extruded in late Pleistocene, probably during later part of Bonneville stage or during Provo stage of Pleistocene Lake Bonneville.

P. E. Dennis, G. B. Maxey, and H. E. Thomas, 1946, Utah State Engineer Tech. Pub. 3, p. 27, pl. 1. Basalt tuff, lapilli, scoria, and lava in flows 30 feet or more thick. Maximum thickness 300 feet.

Covers small area approximately 7 miles west of Meadow, in Pavant Range, Millard County.

Table Creek Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 80.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 42. Name Table Creek included beds between Dover limestone and what was supposed to be Tarkio limestone; later it was found that lower boundary of "Table Creek" at this place is top of Elmont limestone and that the Tarkio is represented higher in the section by a sandstone located about 15 feet below the Dover. This means that the so-called

"Table Creek shale" represents three formations: shale below the Dover (with Maple Hill limestone missing), plus sandstone equivalent of the Tarkio, plus the Willard shale. Consequently name Table Creek is discarded and name Langdon shale proposed for shale between base of Dover limestone and top of Maple Hill limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12. Gray sandstone at top, reddish calcareous shale near center, sandy shale near base. Nyman coal near top of formation. At SW cor. SE¼SE¼ sec. 13, T. 67 N., R. 42 W., Fremont County, formation is 3¾ feet thick. Condra and Reed (1943) proposed "Langdon" for the interval. Underlies Dover limestone. The three formations immediately below the Table Creek are not generally recognized in area. In part of Fremont County, beds are exposed that are tentatively correlated with part of Table Creek-Willard interval; basal part of Pierson Point shale is at top of this section. Wabaunsee group.

Named for outcrops on Table Creek at Nebraska City, Otoe County, Nebr.

Table Mountain Andesite[1] or Basalt

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 311 (diagram).

O. P. Jenkins, 1943, California Div. Mines Bull. 118, pt. 4, p. 685. Cenozoic.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, p. 77 (table 2). Listed on table accompanying report on uranium geochemistry of Lassen volcanic rocks.

Composes Table Mountain, northwest of Lassen Peak.

Table Mountain Basalt Flows

Table Mountain Formation

Paleocene: North-central Colorado.

R. L. Ives, 1938, Geol. Soc. America Bull.. v. 49, no. 7, p. 1049. Interbedded sandstones, shales, and basalt flows. Thickness about 900 feet. Unconformably overlies Precambrian rocks. Interpreted as preglacial. Lovering classifies beds as Miocene, and lithologically similar beds in upper part of Middle Park formation classified as very late Upper Cretaceous or Paleocene.

S. O. Reichert, 1956, Geol. Soc. America Bull., v. 67, no. 1, pl. 1 (facing p. 107). Mapped as Table Mountain basalt flows of Paleocene age.

In Denver Basin.

Table Mountain Formation[1] or Gravels

Tertiary: Southern California.

Original reference: W. J. Miller, 1935, California Jour. Mines and Geology, v. 31, no. 2, p. 138, map.

Baylor Brooks and Ellis Roberts, 1954, California Div. Mines Bull. 170, map sheet 23. Mapped as Table Mountain gravels. Older than Jacumba pyroclastics and younger than La Posta quartz diorite. Tertiary.

Well exposed in Table Mountain, 4 miles northeast of Jacumba, San Diego County.

Table Mountain Flow, Latite, or Formation

Pliocene or Pleistocene: Central California.

F. L. Ransome, 1898, U.S. Geol. Survey Bull. 89, p. 14–27, 28–46. Discussion of lava flows on western slope of the Sierra Nevada in region drained by Stanislaus River. The latites belong to at least three distinct flows. The oldest, Table Mountain flow (or facies), consists of dark compact augite-latite of somewhat basaltic aspect, with conspicuous tabular crystals of labradorite and smaller phenocrysts of augite. Older than Dardanelle flow. Rests on a variety of rocks, in some places granite and in some places on limestone or quartzite of Calaveras formation. Miocene and Pliocene.

N. L. Taliaferro and A. J. Solari, 1946, California Div. Mines Bull. 145, pls. 1, 2 [text not pub.]. Consists of lava flows in former channel of Stanislaus River. Unconformable above Mehrten formation. Pliocene or Pleistocene.

Named for occurrence on Table Mountain, Tuolumne County. Longest flow of series. Traced from the West Dardanelle where its surface is at elevation of 8,600 feet, down to Knight's Ferry where it forms plateaus at elevation of about 500 feet.

†Table Mountain Sandstone[1]

Permian: Central southern Oklahoma.

Original reference: C. N. Gould, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, no. 3, p. 324–341.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey. If used, would invalidate Table Mountain formation, Cenozoic of California.

Named for Table Mountain in Garvey County.

Table Rock Granite[1]

Carboniferous(?): Northwestern South Carolina.

Original reference: E. Sloan, 1907, Summary of mineral resources of South Carolina, p. 7, 8.

Named for development at Table Rock Mountain, Pickens County.

†Table Rock Sandstone[1]

Upper Devonian: Southwestern New York.

Original reference: G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, no. 2, p. 96–98.

J. F. Pepper and Wallace de Witt, Jr., 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart. 37. Abandoned. Naming of some massive siltstones in the Gardeau shale, such as Table Rock sandstone, serves little purpose since they cannot be positively identified beyond their type occurrence.

Occurs at top of lower Portage Falls, Genesee River region.

Tabor Member (of Crockett Formation)

Eocene (Claiborne): Central Texas.

G. D. Harris, 1941, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 33, p. 13, 14, 18, 19, 20. Crockett, as exposed in Lee County, is divided into (ascending) Stone City, Wheelock, Two Mile (new), and Tabor members. Tabor consists of sand, sandstone, and clay. Thickness as much as 47 feet. Member capped by Bryan sand. Name is from manuscript of H. B. Stenzel.

This may or may not be same unit as Mount Tabor Member (Stenzel, 1938).

Type locality and derivation of name not stated.

†Tachatna Series[1]

Middle Devonian: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 157–159, 179.

Extends from some distance below junction of Kuskokwim with East Fork down to junction of Tachatna [Takotna] River, and from the Tachatna to below Vinasale, Kuskokwim region.

Tackawasick Limestone[1]

Middle Ordovician: Eastern New York.

Original reference: R. Ruedemann, 1929, Geol. Soc. America Bull., v. 40, p. 410, 414.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Correlation chart for Vermont shows Tackawasick limestone in Taconic sequence above Ryesdorph conglomerate. Taconic sequence occupies a range that extends southward from Brandon, Vt., into Massachusetts and Connecticut.

Type locality and derivation of name not given. Unit first described in Capital district, eastern New York.

Tacoma Series

Middle Silurian: Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Includes (ascending) Thorncrag limy gneiss, Stetson Brook limestone, Hill Ridge biotite schist, Minwah limy gneiss, and Sabattus garnet schist (all new). Older than post-Silurian pegmatites, aplites and granites; younger than Bates limestone (new). Cambro-Ordovician(?).

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. In Lewiston area are seven formations (ascending): Danville injection gneiss (new), Androscoggin gneiss, Bates crystalline limestone, Deer Rips lime-silicate gneiss (new), Thorncrag biotite-sillimanite gneiss, Tacoma lime-silicate series, and Sabbatus quartz-sillimanite-biotite schist. Middle Silurian.

Occurs in Lewiston area, Androscoggin County.

Taconic Limestone[1]

Cambrian and Ordovician: Maine and southwestern Vermont.

Original reference: E. Hitchcock, 1862, Geology Maine, Prelim. Rept., v. 2, p. 245–259.

†Taconic Slate[1]

Ordovician: New York.

Original reference: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, geology of 2d dist., p. 135–164.

Occurs at western base of Taconic Range.

†Taconic System[1]

Precambrian, Cambrian, and Silurian: Eastern North America.

Original reference: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, geology of 2d dist., p. 135–164, 429.

**Taft Granite**[1]

Cretaceous: Eastern California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 122, map.

Named for fact it composes Taft Point, Yosemite National Park.

**Taft Sandstone Member** (of Boggy Shale)[1]

Pennsylvanian (Des Moines Series) : Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 56–57. Taft sandstone forms prominent escarpment ranging up to 200 feet in height above Crekola-Inola plain. At type locality in T. 15 N., unit consists of about 20 feet of coarse-grained massive sandstone. Upper third of the division consists of silty to sandy shale. Farther south, in T. 14 N., a series of massive sandstones and interbedded shales, amounting in aggregate to some 80 feet of beds, surmounts the Taft escarpment. Probably outcrops around Taft are equivalent only to lower part of sandstone section in T. 14 N. More work needed to determine logical boundaries of Taft member. Separated from underlying Inola limestone member by unnamed shale member.

Named for exposures south of Taft, sec. 19, T. 15 N., R. 17 E., Muskogee County.

**Taft Hill Member** (of Blackleaf Formation)

Lower Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2790, 2792 (fig. 3) ; 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 90. Approximate percentages of various lithologic types are: gray bentonitic siltstone, 48; sandstone, 32; nonbentonitic marine shale and siltstone, 20. A widespread 30-foot-thick massive bed of greenish-gray impure glauconitic sandstone has its top about 100 feet above base of member. A few 2-foot-thick glauconitic sandstone beds also present. Many of the sandstone beds are coarse grained. Type section has over-all thickness of about 240 feet. Underlies Vaughn bentonitic member (new) ; overlies Flood member (new).

Type section: A composite from measurements at four localities between east face of Taft Hill and a point 5 miles farther east. Named for exposures along east slope of Taft Hill, a dissected prominent bench 1½ to 6 miles south of Vaughn, Cascade County.

**Taggard Red Member** (of Greenbrier Limestone)

Taggard Limestone (in Greenbrier Limestone)[1]

Taggard Shales (in Greenbrier Limestone)[1]

Upper Mississippian: Southern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 450, 476–479.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Term Taggard was applied by Reger (1926) to three lithologic units, a lower and upper Taggard shale with an intervening Taggard limestone. In this report, these have been combined into one unit, Taggard red member of Greenbrier limestone. Member consists of maroon red and dense limestone and calcareous mudstone. Thickness 3 to 50 feet. Commonly present from 50 to 100 feet above Hillsdale member.

Dana Wells, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 5, p. 902–918. Name Denmar formation proposed for sequence of gray slightly cherty calcarenite and calcilutite beds that are younger than top of Hillsdale in its type section and older than the Taggard [limestone and shale] in its type section.

Type locality (Reger, 1926): On Taggard Branch of Indian Creek, Monroe County, W. Va.

Taghanic (Taughannock) Stage

Taughannock Group

Middle Devonian (Erian): North America.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1733, chart 4. Devonian is subdivided into 10 stages of which the Taghanic (Taughannock) is sixth in sequence (ascending). [For complete sequence see Helderberg stage this reference.] Follows Tioughnioga stage (new) and is succeeded by Finger Lakes stage (new). Includes sediments of Tully and Geneseo with their correlates elsewhere on the continent.

A. T. Cross and J. H. Hoskins, 1951, Jour. Paleontology, v. 25, no. 6, p. 718 (fig. 3). Shown on composite stratigraphic column of western New York and northwestern Pennsylvania as Taughannock group. Includes Tully and Genesee formations. Overlies Tioughnioga group; underlies Finger Lakes group.

Type section: In Taghanic (Taughannock) Falls Park, northwest of Ithaca, west side of Cayuga Lake, N.Y.

**Tagpochau Limestone**

Miocene, lower: Mariana Islands (Saipan).

Risaburo Tayama, 1938, Geomorphology, geology, and coral reefs of Saipan Island: Tropical Industry Inst., Palau, South Sea Islands, Bull. 1 [English translation in library of U.S. Geol. Survey, p. 63–68]. The Tappocho is a coral limestone, pink, hard, fine-textured; conglomeratic or agglomeratic near base. Lower Miocene.

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 62–77, pl. 2, chart 2. Tagpochau limestone, as used here, has been revised to include both the Tappocho and Laulau limestones of Tayama. Six lithic facies and two members are mapped within Tagpochau limestone, as follows: Donni sandstone member; Machegit conglomerate member (new); transitional facies of calcareous tuff, marl, and calcareous andesitic conglomerate; tuffaceous facies of poorly indurated, very impure limestones; marly limestone facies; rubbly limestone facies; equigranular limestone facies; and dominant inequigranular limestone facies. In several areas south from Mount Tagpochau, it is not possible to differentiate these facies. Thickness ranges from featheredge to 820 feet at type section and 900 feet in northern Saipan. Type section designated.

Type section: Extends from base of Miocene succession to head of valley that runs westward from Nicholson Spring upward to summit of Mount

Tagpochau. Tayama gave locality as summit of Mount Tappocho which is Mount Tagpochau (Ogso Tagpochau). Spelling of formational name is revised to conform with Chamorro usage.

Tahana Member (of Purisima Formation)

Pliocene: Northern California.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1325. Consists of 2,150 feet of tuffaceous mudstone, siltstones, and lithic arenites believed to have been largely derived from Mehrten formation. Underlies Pomponio member (new); overlies Monterey formation.

Area of report is in Santa Cruz Mountains, 30 to 40 miles south of San Francisco.

**Tahkandit Limestone**[1]

Permian: Northeastern Alaska.

Original reference: J. B. Mertie, Jr., 1930, U.S. Geol. Survey Bull. 816, p. 121.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Type locality: Along Yukon just above mouth of Nation River, where a belt of the rocks crosses the Yukon, trending northeast, Eagle-Circle district.

†Tahkandit Series[1]

Permian and Pennsylvanian(?): Eastern Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 169–174.

Yukon River region.

Tahlequah Member (of Moorefield Formation)

Mississippian (Chesterian): Northeastern Oklahoma.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 49–51, pls. 1–5. Massive light to dark-gray medium-crystalline glauconitic limestone that in some areas contains crinoidal coquinite and nodules and stringers of whitish-tan chert; large scale crossbedding developed locally. Thickness as much as 30 feet. Conformably underlies Bayou Manard (new); at type locality, it is in fault contact with younger units of formation; unconformably overlies parts of "Boone" chert, Keokuk chert, Reed Springs chert, and Short Creek oolite.

Type locality: Along south side of a small creek south of city limits of Tahlequah, Cherokee County.

**Tahoe Glaciation**

**Tahoe Till**

Tahoe glacial stage[1]

Pleistocene: Eastern California.

Original reference: E. Blackwelder, 1931, Geol. Soc. America Bull., v. 42, p. 865–922.

W. C. Putnam, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1290–1291. At least four ice advances occurred in Pleistocene: earliest, here named Aeolian Buttes, was followed by Sherwin, Tahoe, and Tioga, previously named by Blackwelder. Rhyolitic ash and pumice, now Bishop welded tuff, were erupted in interval between Aeolian Buttes and Sherwin glacial stages.

W. C. Putnam, 1960, California Univ. Pubs. in Geol. Sci., v. 34, no. 5, p. 235, 237–238, map 1. Sherwin till is pre- rather than post-Bishop tuff. Name Aeolian Buttes considered invalid as representing an earlier Pleistocene, pre-Sherwin glacial stage. Hence, glacial sequence is McGee, Sherwin, Tahoe, and Tioga.

Name amended to glaciation in compliance with 1961 Code of Stratigraphic Nomenclature.

Named for Lake Tahoe on eastern slope of the Sierra Nevada. Moraines of stage flank Rock Creek Canyon in Sierra Nevada west of Highway 395, Mono County.

Tahoka Clay

Pleistocene (Wisconsin) : Western Texas and eastern New Mexico.

G. L. Evans and G. E. Meade, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 495–498. Mainly bluish-gray calcareous and gypsiferous clays and gray sands which grade marginally to coarser sands and gravels; thin discontinuous beds and small lentils of fresh-water limestone present locally in basinward facies of deposit. Thickness 21 to 35 feet. Unconformably overlies older strata—in some places Triassic shales or Cretaceous limestones; around margin of basins, overlaps older Quaternary or upper Tertiary strata which are resting upon Triassic or Cretaceous. Disconformably underlies local developments of dune and playa deposits. Late Pleistocene (Wisconsin) indicated for main body of deposit.

Named for town of Tahoka, Lynn County, Tex., which is near Tahoka Lake, Mound Lake, and other playas around which the deposit is typically developed and well exposed. Extends into eastern New Mexico.

Taholah Formation

Pleistocene, lower: Northwestern Washington.

S. L. Glover, 1940, Northwest Sci., v. 14, no. 3, p. 69–71. Name applied to early Pleistocene deposits on coastal area of Olympic Peninsula. Probably correlate with sediments of Admiralty age in Puget Sound region. Formation is generally horizontal and composed of sands, gravels, and clays. Total thickness may exceed 1,500 feet. Underlies Queets bed (new) ; overlies Quinault formation.

S. L. Glover, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2022–2023. Immediately overlies Browns Point formation (new).

Well exposed in Taholah-Moclips vicinity, Grays Harbor County.

Taihamu Limestone

*See* Taihanom (Taihanomu) Limestone.

Taihanom (Taihanomu) Limestone

Aquitanian: Mariana Island (Rota).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation table) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 52, table 4 [English translation in library of U.S. Geol. Survey, p. 62]. Correlated with Kasutesho limestone on Tinian, and Laulau limestone on Saipan. Oligocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 59–60. Consists of marly limestone, calcareous sandstone, sandy limestone, and limestone-breccia (ascending order). Unconformably overlies Mariiru limestone. Aquitanian. Refers to S. Sugawara (1939, unpub. ms.) and K. Asano (1939, Jubil. Pub. Yabe's 60th birthday).

South coast of Rota Island.

**Takotna Formation**[1]

Middle Devonian: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 157–159, 179.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Extends from some distance below junction of Kuskokwim with East Fork down to junction of Tachatna [Takotna] River, and from the Tachatna to below Vinasale; upper Kuskokwim region.

Talawag Member (of Mutual ? Formation)

Precambrian: Western Utah.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 26–27, 127, 128, pls. 1, 4, 8. Mutual(?) formation is divided into two units: a basal slate or argillite and an upper conglomeratic quartzite herein referred to as Talawag member. Thickness 706 feet on north slope of Talawag Peak.

Named for occurrences on Talawag Peak and in Talawag Canyon, Sheeprock Mountains.

**Talbot Formation** (in Columbia Group)[1]

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

Original reference: G. B. Shattuck, 1901, Johns Hopkins Univ. Circ., v. 20, no. 152, p. 73–75.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 75–77, pls. 2, 3. In southern Florida, the Talbot, Penholoway, and Wicomico formations comprise a conformable sequence of deposits whose differentiation is based mainly on location of their respective shore lines—42, 70, and 100 feet above present sea level. The Talbot merges downward into the Penholoway and Wicomico successively. Sequence unconformably overlies Caloosahatchee marl and is likewise separated by stratigraphic break from Pamlico formation, which fringes around it. Boundary between Talbot and Pamlico very inconspicuous.

Named for Talbot County, eastern shore of Maryland. Well exposed in Florida along Highway 18, the Childs-Okeechobee Road and west of Lake Okeechobee; also present on Immokalee Island.

**Talcott Basalt** (in Newark Group)

Talcott Diabase (in Newark Group)[1]

Talcott Lava Member (of Meriden Formation)

Upper Triassic: Central Connecticut.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 476.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Rank reduced to basal member of Meriden formation. Described as greenish-black rock weathering bright orange, grading from basalt near contacts to coarse dolerite in interiors. Interior parts are massive and commonly show good columnar jointing; upper parts are commonly vesicular, and upper and lower parts may show flow brecciation. Contains pillows. Underlies lower sedimentary member of Meridan formation.

E. P. Lehmann, 1959, Connecticut Geol. Nat. History Survey Quad. Rept. 8, p. 8 (table 1), 10–11, pl. 1. Term Meriden not used in this report [Middletown quadrangle]; Talcott basalt included in Newark group. Stratigraphically lowest lava flow in quadrangle. Crops out along low ridges trending east of north along west margin of map area. Estimated stratigraphic thickness about 150 feet. Contact with underlying New Haven arkose not exposed. Underlies Shuttle Meadow formation (new).

R. W. Schnabel, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–134. Talcott basalt described in Avon quadrangle, Connecticut, where it ranges in thickness from about 120 feet at northern boundary to about 200 feet at southern boundary. Apparently conformable with enclosing sedimentary rocks, New Haven arkose below and Shuttle Meadow formation above.

Named for occurrence at Talcott.

Talcott Shale (in Bluefield Formation[1] or Group)

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 418.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 263. Incidental mention in report on Greenbrier County.

Type locality: On south side of Greenbrier River, 0.6 mile southeast of Talcott, Summers County.

†Talford Schist[1]

Lower Devonian: Central New Hampshire.

Original reference: M. P. Billings and C. R. Williams, 1935, Geology of Franconia quadrangle, p. 8, 13.

C. R. Williams and M. P. Billings, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1015, 1019. Abandoned. Littleton formation is extended to those areas of the Franconia quadrangle where Talford schist was formerly recognized as distinct unit.

Named for Talford Brook in southern part of Franconia quadrangle.

†Talihina Chert[1]

Ordovician, Silurian, and Devonian: Southeastern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey. Sequence is now divided into formations.

Named for exposures in Potato Hills, southwest of Talihina, Le Flore County.

**Talisman Quartzite**[1]

Pennsylvanian(?): Southwestern Utah.

Original reference: B. S. Butler, 1913, U.S. Geol. Survey Prof. Paper 80.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 703, pl. 1 (column 53a). Correlation chart shows quartzite to be of Morrow and Lampasas age; text states that no fossils have been recovered from the unit.

Type locality: Talisman mine, southeast of Frisco district.

**Talkeetna Formation**[1]

Lower Jurassic: Central southern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 218, 219.

R. A. Eckhart, 1953, U.S. Geol. Survey Bull. 989–C, p. 41–42, pl. 5. Largely of interbedded tuffs, lavas, and volcanic breccias in Sheep Mountain, adjacent to upper Matanuska Valley.

In Matanuska Valley and eastern part of Talkeetna Mountains, Cook Inlet region.

**Talladega Slate**[1] or **Formation**

Talladega Series

Precambrian(?) to Carboniferous (?): Eastern Alabama, Georgia, North Carolina, and Tennessee.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–1888, geol. map of Alabama, no description.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1371–1392. Series has been traced from Alabama, where it is typically exposed, across northwest Georgia, into North Carolina and Tennessee. Occupies belt trending northeast, 300 miles in length and 1 to 25 miles in width. Believed to be Precambrian.

G. W. Stose and A. J. Stose, 1944, Am. Jour. Sci., v. 242, no. 8, p. 412–415. Term series is preferred to slate. Precambrian.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27–30. Discussion of crystalline rocks of Georgia. Rocks are grouped into 11 belts, in part using names proposed by Adams (1933, Jour. Geology, v. 41, no. 2). Talladega belt in Georgia divided geographically into two parts: one extending west and southwest from Allatoona, Bartow County, and the other north and northeast of that village. West of Allatoona, the series resembles typical expression in Alabama with phyllites predominating. North of Allatoona, the series comprises more highly metamorphic rocks, which have been grouped into 10 formations (ascending) Pinelog quartzite, Hiawassee [Hiwassee] slate, Great Smoky formation, Nantahala schist, Tusquitee quartzite, Brasstown schist, Valleytown schist, Murphy marble, Andrews schist, and Nottely quartzite. Precambrian.

Named for exposures on Talladega Creek, Talladega County, Ala.

**Tallahassee Limestone**

Tallahassee Limestone (in Claiborne Group)

Eocene, middle: Western Florida (subsurface)

P. L. Applin and E. R. Applin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1680, 1688–1693, 1747 (fig. 32). Name applied to lower unit of late middle Eocene. Ordinarily underlies Avon Park limestone (new) but in some wells occurs below the Ocala; overlies early middle Eocene beds, either the clastic sediments of Cook Mountain age or Lake City limestone (new). Composed chiefly of cream-colored and tan crystalline limestone with some softer argillaceous limestone; also with minor amounts of chert and gypsum. Thickness ranges from more than 75 feet in wells near its western edge to 550 feet in Wakulla County and 650 feet in Jefferson County. Tentatively correlated with Yegua formation (Claiborne). Avon Park limestone, Tallahassee limestone, and Lake City limestone represent Claiborne group in peninsular Florida, and, where all three units are present, they appear to make, in most places, a conformable sequence.

Unit is confined to a few wells in vicinity of Tallahassee.

**Tallahatta Formation** (in Claiborne Group)[1]

Eocene, middle: Southern Alabama, western Georgia, and Mississippi.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 344, chart.

R. E. Grim, 1936, Mississippi Geol. Survey Bull. 30, p. 20, 121 (fig. 18), 122, 123–128. Tallahatta formation divided into (ascending) Meridian, Basic, and Winona members. Thickness as much as 205 feet. Basal formation in Claiborne series; overlies Lisbon formation.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 42, p. 15–28, pls. Includes Basic claystone member below and Neshoba sand member (new) above. Overlies Meridian sand, herein excluded from Tallahatta; underlies Winona greensand, herein raised to formational rank.

G. F. Brown and R. W. Adams, 1943, Mississippi Geol. Survey Bull. 55, p. 14 (table), 43–56. Formation divided into Meridian sand member at base and Basic City shale member (new) at top. Underlies Winona sand member of Lisbon formation; overlies Holly Springs formation (Wilcox series). Thickness as much as 380 feet.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Chart shows Tallahatta undifferentiated in Alabama and Georgia; underlies Lisbon formation; overlies Hatchetigbee formation. In northern Mississippi includes Holly Springs sand member; elsewhere includes (ascending) Meridian sand, Basic City, and Neshoba sand members; underlies Winona formation; overlies Wilcox formation.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 93–100. Described in Choctaw County where it is 90 to 120 feet thick, overlies Hatchetigbee formation and underlies Lisbon formation.

T. W. Lusk, 1956, Mississippi Geol. Survey Bull. 80, p. 54–61. In Benton County, overlies Meridian formation and underlies Koskiusko formation, but the Winona and Zilpha are absent in area.

Named for development in Tallahatta Hills, Choctaw County, Ala.

**Tallant Formation** (in Ochelata Group)

Pennsylvanian (Missouri Series): North-central Oklahoma.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 119–120, 121–122. Consists of sandstone and shale. Contains two principal sandstone members (ascending), Bigheart and Revard. In addition there are other sandstone units, some of which may be extensive enough to be mapped, eventually, as members. Unconformably overlies Barnsdall formation (new); unconformably underlies sandstone in the lower part of the Vamoosa formation. Thickness about 200 feet.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 32–39, pl. 1. Includes four fairly persistent members: Bigheart sandstone at base, unnamed shale, Revard sandstone, and a second unnamed shale. In addition, several sandstone beds have been assigned, either correctly or incorrectly, to the Tallant; among them are Buck Point, Gap, Hay Hollow, Hulah, Mission, and Possum.

Named from Tallant, sec. 35, T. 25 N., R. 10 E., Osage County.

Tallery Limestone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 341.

Type locality: On Tallery Mountain Road, southeast of True, Summers County, W. Va.

Tallery Sandstone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 340.

Type locality: On Tallery Mountain, Summers County, W. Va.

Tallery Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 296, 342–343.

Type locality: On Tallery Mountain Road, southeast of True, Summers County, W. Va.

**Tallman Fanglomerate**

Permian: North-central Nevada.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Consists of large angular to subangular blocks of quartzite and chert, small slate fragments; thin bed of chert pebbles at base. Thickness uncertain, may be 2,000 to 5,000 feet. Underlies Koipato formation; overlies Harmony formation with angular unconformity.

Local deposit, present only near Tallman Ranch at mouth of Thomas Canyon, Sonoma Range.

Tallulah Falls Quartzite[1]

Precambrian or Lower Cambrian: Northeastern Georgia.

Original reference: S. L. Galpin, 1915, Georgia Geol. Survey Bull. 30, p. 119.

C. E. Hunter, 1946, Tennessee Valley Authority Regional Products Research Div. Rept. C, p. 46. Incidental mention in report on minerals and structural materials of western North Carolina and northern Georgia.

Named for development in vicinity of Tallulah Falls, Rabun County.

Talofofo Peat-Bearing Beds or Formation

Pliocene or Pleistocene: Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 55–56, table 4 [English translation in library of U.S. Geol. Survey, p. 66]. Gravel, sandy clay, and gray clay with layer of peat. Abundant mollusca and dendritic reef-bearing corals in gray clay. Correlated with Sumay (Mariana) limestone.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 60. Pleistocene.

Type locality: Along upper course of Talofofo River, Guam.

Taloga Formation (in Cimarron Group)[1]

Taloga Formation (in Quartermaster Group)

Permian (Guadalupe Series): Southern Kansas.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 362–363.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 36 (fig. 15), 37. As used in Kansas, the Taloga is included in the Quartermaster group and consists of silty shale, siltstone, and very fine feldspathic sandstone (called "Big Basin" in some reports). Lower 25 feet is chiefly silty shale. Maximum thickness about 45 feet. Strata are seemingly equivalent, all or in part, to the Quartermaster formation in Oklahoma. Occurs above Day Creek dolomite.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey. Cragin applied the name to Cloud Chief and Quartermaster rocks.

Named for Taloga, Dewey County, Oklahoma. In Kansas, crops out in western Clark and eastern Meade Counties.

**Talpa Limestone Member** (of Clyde Formation)[1]

Talpa Formation (in Clyde Group)

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 428.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in the Clyde herein given group status.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. In Colorado River valley, constitutes upper two-fifths of formation. Consists of even, relatively thin beds of limestone and shale similar to underlying Grape Creek member but differs in the harder, more brittle nature of the beds and the commonly slightly darker color. Thickness about 180 feet. Underlies Lueders limestone. Division of the Clyde into members in this area is not as natural as in the area north of Abilene; in area mapped herein, units might appropriately be treated as formations. Type "Paint Rock" in Concho County has been traced into type exposure of the Talpa limestone; "Paint Rock" is a synonym for Talpa limestone and preference in nomenclature is given latter term.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 275–276. Member Geographically extended into Brazos River valley where it is 45 to 55 feet thick and consists of alternating gray limestone and shale beds with less siltstone. Separated from underlying Grape Creek limestone member by unnamed shale member and from overlying Lueders limestone by an unnamed shale interval.

Named for Talpa, Coleman County.

**Tamaha Sandstone Member** (of McAlester Formation)

Tamaha Sandstone Member (of Savanna Sandstone)[1]

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 40. Reallocated to member status in McAlester formation. New type locality designated.

Type locality: Sec. 30, T. 11 N., R. 22 E., some 2 miles west of Tamaha, Haskell County. Base of member makes prominent escarpment in SW¼ of this section.

Tamarack Formation[1]

Pre-Cretaceous: Northern California.

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 226.

Klamath Mountain region.

**Tamiami Formation**

Tamiami Limestone

Miocene, upper: Florida.

W. C. Mansfield, 1939, Florida Geol. Survey Bull. 18, p. 8, 15. Proposed for a limestone penetrated in digging shallow ditches to form roadbed of Tamiami Trail over a distance of about 34 miles in Collier and Monroe Counties. Consists mainly of dirty-white to gray rather hard porous nonoolitic limestone with inclusions of clear quartz grains. Underlies Buckingham limestone (new). Tentatively placed at base of Pliocene below Caloosahatchee.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 62–65. Tamiami formation was first noted by Sanford (1909) who named it Lostmans River limestone. Cooke and Mossom (1929, Florida Geol. Survey 20th Ann. Rept.) rejected Lostmans River limestone as valid formation and divided its rocks between Miami oolite on south and Caloosahatchee marl on north. Mansfield's (1939) Tamiami limestone is same limestone that Cook and Mossom correlated with Caloosahatchee marl. Place name Tamiami is preferred to Lostmans River because exposures on Tamiami Trail are more accessible than those of Lostmans River area. Term limestone is not appropriate because formation generally contains too much sand. Formation is, in general, a wedge-shaped deposit that thickens toward southeast and east. Thickness about 15 feet on Tamiami Trail 40 miles west of Miami; about 100 feet near shore of Biscayne Bay at Silver Bluff.

G. G. Parker, 1951, Am. Water Works Assoc. Jour., v. 43, no. 10, p. 823. Tamiami formation is of upper Miocene age and, as here indicated, includes all deposits of that age in Florida. As thus defined, includes Tamiami limestone and Buckingham limestone of Mansfield and part of Hawthorn formation of Parker and Cooke (1944, Florida Geol. Survey Bull. 27).

J. R. DuBar, 1957, Illinois Acad. Sci. Trans., v. 50, p. 192 (table 1); 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 132–133, 136–139. Formation underlies Fort Denaud member (new) of Caloosahatchee marl. Contact with Caloosahatchee unconformable.

C. W. Cooke, 1959, U.S. Geol. Survey Prof. Paper 321, p. 2 (table 1). Upper Miocene.

Named for exposures along Tamiami Trail, Collier and Monroe Counties.

Tamihy Series[1] or Group

Jurassic: Central northern Washington, and southwestern British Columbia, Canada.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 16.

Hans Frebold, 1953, Geol. Soc. America Bull., v. 64, no. 10, p. 1232, chart 8d. Shown on correlation chart as Tamihi group. Probably younger than Cultus formation. Jurassic.

Mapped along Tamihy Creek, Wash., and British Columbia.

†Tampa Group[1]

Miocene, lower and middle: Northern and southern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 112–113, 157, 335.

Named for exposures on Tampa Bay.

**Tampa Limestone**[1]

Tampa Formation or Stage

Miocene, lower: Central and northern Florida and southern Georgia.

Original reference: L. C. Johnson, 1888, Am. Jour. Sci., 3d, v. 36, p. 235.

C. W. Cooke and W. C. Mansfield, 1936, Geol. Soc. America Proc. 1935, p. 71–72. Name Suwannee limestone proposed for yellowish limestone typically exposed along Suwannee River in Florida; unit has been considered part of Tampa limestone.

R. O. Vernon, 1942, Florida Geol. Survey Bull. 21, p. 67–73. As used in this report [Holmes and Washington Counties], term Tampa applies to all sediments lying above Suwannee limestone and below Alum Bluff group.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 111–136. In Hillsborough, Pasco, and Pinellas Counties, which include type area, Tampa is commonly a fairly hard dense light-colored to yellowish limestone; locally closely packed with impressions of mollusks. In Chattahoochee area, soft beds alternate with hard, and much of the rock has chalky appearance. Thickest natural exposure is in Gadsden County, where 117 feet are exposed above low water in Apalachicola River at Chattahoochee. Underlies Suwannee limestone; in some areas, merges upward into Hawthorn formation. Presumably unconformable on Flint River where that is underlying formation. Lower Miocene.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 16 (table 1), 17–21. Stage includes all Miocene sediments lying between Oligocene series and Alum Bluff stage (new). Definition includes such sediments exposed in Florida panhandle and their equivalents in central and western Gulf States. Stage includes all sediments deposited between post-Vicksburg (*Nodosaria blanpiedi* zone of Chickasawhay limestone) and pre-Alum Bluff ages. In Florida panhandle, two lithofacies recognized: calcareous St. Marks facies downdip and silty Chattahoochee facies updip.

R. C. Heath and P. C. Smith, 1954, Florida Geol. Survey Rept. Inv. 12, p. 13. Referred to as formation. This is usage of Florida Geological Survey.

K. B. Ketner and L. J. McGreevy, 1959, U.S. Geol. Survey Bull. 1074–C, p. 54 (table 1), 59–65. As used in this report [area between Hernando and Hardee Counties], Tampa includes lower Miocene Tampa limestone as defined by Cooke (1945) and lower Miocene strata commonly included in Alachua formation of Sellards (1914, Florida Geol. Survey 6th Ann. Rept.). In northern part of area, consists of lower phosphorite unit about 10 feet thick and upper clay unit about 25 feet thick; in southern part of area, represented by limestone unit about 100 feet thick, phosphorite and clay units not present. Overlies Suwannee limestone; underlies Hawthorn formation.

Named for exposures at Tampa, Fla.

Tampico Shale Member (of Piper Formation)

Middle Jurassic: Montana (subsurface and surface) and western North Dakota (subsurface), and Saskatchewan, Canada (subsurface).

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 97, 101. Consists of 86 feet of gray-green calcareous shale which is slightly silty in middle of unit in type well. In some wells, unit contains large amount of interbedded red shale and occasionally thin beds of dense buff to brown limestone, gypsum, and white calcareous sandstone. Sandstones become well developed northward in Saskatchewan. Red shales become more dominant southward in central and southern Montana. Maintains fairly uniform thickness. Upper and lower boundaries more clearly defined in subsurface of northern Montana than in outcrops in central and southern Montana. Underlies Firemoon limestone member (new). In subsurface, overlies Nesson formation (new) with apparent conformity throughout most of area of distribution. Unconformably overlies Madison limestone west of Bowdoin dome and unconformably overlies beds ranging from Upper Mississippian through Triassic in central and south-central Montana.

Type section: From interval 3,858 to 3,944 feet in Gulf Oil Corp. No. 1 Cornwell, center SW¼NE¼ sec. 14, T. 30 N., R. 38 E., Valley County, Mont. Named for town of Tampico which is 5 miles southwest of type well. Easily recognized as far east as Nesson anticline, and correlated westward to west side of Bearpaw Mountains where it pinches out by nondeposition. Crops out in central and southern Montana.

Tamworth Granite

Upper Devonian(?): East-central New Hampshire.

A. P. Smith and others, 1938, Geologic map and structure sections of the Mt. Chocorua quadrangle, New Hampshire (1:62,500): New Hampshire State Highway Dept. Described as medium-grained pink granite. Belongs to New Hampshire magma series.

Crops out around village of South Tamworth in southeastern part of Mt. Chocorua quadrangle.

†Tanak Volcanics

Quaternary: Southwestern Alaska.

F. M. Byers, Jr., and others, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 3, p. 28, 31, pl. 3. Thick beds of tuff-breccia, with many thin beds of agglomerate and a few interbedded lava flows. Tuff-breccia beds average about 150 feet in thickness but locally thicken to 350 feet; include small lenses of water-laid sediments locally. Tuff-breccia is neutral gray on fresh surfaces; weathers to light reddish yellow; contains fragments of all types of precaldera rocks and minor quantities of bombs and lava fragments. Accidental material ranges in size from small grains up to blocks a foot in diameter. Weathering develops conspicuous "hoodoos." Near rim of caldera, well-indurated gray agglomerate is interbedded with tuff-breccia; within a mile of the caldera, it grades laterally into black vesicular agglomerate. Lava flows decrease in abundance away from caldera. Individual flows 20 to 80 feet thick and composed of light- to medium-gray aphanitic basalt. Many tuff-breccias probably nuée ardente deposits.

F. M. Byers, Jr., 1959, U.S. Geol. Survey Bull. 1028–L, p. 314. Included in Okmok volcanics (redefined).

Crops out high on walls of caldera of Mount Okmok, and on outer slopes it covers lowlands and fills precaldera valleys to depth of several hundred feet. Named from exposures on Cape Tanak on Umnak Island in eastern part of Aleutian Islands.

†Tanana Schist[1]

Precambrian: Eastern Alaska.

Original reference: A. H. Brooks, 1900; U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 468–469, 478, 483.

Well exposed along Tanana River.

**Tanapag Limestone**

Pleistocene or Recent: Mariana Islands (Saipan).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 58, table 4 [English translation in library of U.S. Geol. Survey, p. 69]. Consists primarily of coral limestone and secondarily of Nullipore limestone. Correlated with Dankura limestone on Tinian, Mirikattan limestone of Rota, and Merizo limestone of Guam. Raised coral reef. Recent.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 60–61. Early Holocene.

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 86–88, pl. 1, chart 1. Mainly dirty-white to brownish coral-algal reef and bioclastic limestone; contains fossil corals and coralline algae, many of which occur in position of growth. Thickness at type site herein designated, about 10 feet; probable maximum thickness not more than 50 feet. Includes rocks which Tayama has called Chacha limestone as well as his typical Tanapag limestone. Pleistocene.

Type site: West coast of Saipan between Tanapag and Matansa.

**Taneum Andesite**[1]

Miocene: Central Washington.

Original reference: G. O. Smith, 1904, U.S. Geol. Survey Geol. Atlas, Folio 106.

W. C. Warren, 1941, Jour. Geology, v. 49, no. 8, p. 809. In Mount Stuart quadrangle, underlies Yakima basalt.

Well exposed on south branch of Taneum Creek, Mount Stuart quadrangle, Chelan County.

Taneytown facies[1]

Upper Triassic: Maryland.

Original reference: G. E. Dorsey, 1919, Geol. Soc. America Bull., v. 30, p. 155–156.

Probably named for occurrence at or near Taneytown, Carroll County.

Tank Volcanics[1]

Quaternary(?): Southern California.

Original reference: A. C. Lawson, 1906, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 431–462.

Well exposed in vicinity of railway tank, 2 miles below Tehachapi Station, on Tehachapi Creek, Kern County.

**Tank Hill Limestone**[1]

Tank Hill Limestone (in Pogonip Group)

Lower Ordovician: Eastern Nevada.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171.

L. F. Hintze, 1952, Utah Geol. and Mineralog. Survey Bull. 48, p. 48–50, 51–52. In Ely Springs Range, Pogonip group includes Yellow Hill limestone and Tank Hill limestone (top of Ordovician sequence). Inasmuch as both upper and lower limits of the Yellow Hill are fault bounded, as is lower limit of the Tank Hill, it is not considered advisable to carry these formations as stratigraphic units into other areas.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 63). Shown on correlation chart below Eureka quartzite and above Yellow Hill limestone. Chazyan.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 129. Consists of 450 feet of gray thin-bedded limestone, conglomeratic in lower part. Upper 50 feet is shaly limestone with abundant fossils.

Named for exposures on west face of Tank Hill, Ely Springs Range, Pioche region.

Tanner shale[1]

Lower Triassic: Northeastern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 250, 338.

Crops out at Tanner's Crossing of Little Colorado River.

Tanners Hill Quarry Rock (in Conewango Formation)[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: F. A. Randall, 1883, Pennsylvania 2d Geol. Survey Rept. $I_4$, p. 297, 304–308, well sections by J. F. Carll.

Occurs in Tanners Hill section, Warren County.

†Tanners Hill red (in Conewango Formation)[1]

Tanners Hill red zone (in Chadakoin Formation)

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

Original reference: J. F. Carll, 1875, Pennsylvania 2d Geol. Survey Rept. I.

Bradford Willard *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. G–19, p. 14, 243, 252. Discussed as a red zone and reallocated to top of Chadakoin formation.

Overlies Ellicott shale member; underlies Panama conglomerate member of Venango formation. Upper Devonian.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Tanner Hill shown as occurring below Haymaker beds of Chadakoin formation in sections for Genesee Valley and Lake Erie areas, New York, and northwestern Pennsylvania.

Exposed on Tanner's Hill, Warren County, Pa.

**Tansill Anhydrite** or **Formation** (in Artesia Group)

**Tansill Formation** (in Whitehorse Group)

Tansill Anhydrite or Formation (in Carlsbad Group)

Permian (Guadalupe Series): Southeastern New Mexico and western Texas.

R. K. DeFord *in* Addison Young, Max David, and E. A. Wahlstrom, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 10, p. 1551. Tansill formation in Whitehorse group, name to be proposed by DeFord, Riggs, and Wills.

R. K. DeFord and G. D. Riggs, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1713–1728. Presentation of formal definition of Tansill formation and detailed measurement and description of section at type locality. Thickness 123½ feet at type locality; here formation is divided into 13 units (I–XIII, ascending); units VIII, IX, and X inclusive are termed Ocotillo member. Formation is pre-Salado. Formation is a body of limestone, silt, and anhydrite that forms widespread layer of earth's crust in southeastern New Mexico and West Texas. Limestone on south and west grades into anhydrite on north and east; limestone lies around rim of Delaware basin. Time horizon at top of Tansill limestone can be traced basinward where it becomes top of Capitan reef dipping steeply downward 1,500 feet into basin—where it becomes in turn top of Delaware Mountain group; this horizon can also be traced lagoonward where it becomes top of Tansill anhydrite and is in most places somewhat below horizon known as "base of the salt." The horizon that forms top of Tansill formation is boundary between Guadalupe and Ochoa series. In this region, the Tansill is top formation of Whitehorse group of Guadalupe series. Time horizon at base is top of the Yates. Lang's (1937) Three Twins member of Chalk Bluff formation seems to include both the Tansill formation and the Yates sand; but, if so, the two units are described as intergradational, and superposition of Tansill on Yates is not clearly recognized; Lang's Chalk Bluff formation is essentially the Whitehorse group of subsurface geologists.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 68, 101 (fig. 12). Chart shows Tansill formation as uppermost unit in Whitehorse group in subsurface in Midland basin; overlies Yates formation. Formations of the Whitehorse group are delimited and traced in both the Chalk Bluff and Carlsbad facies of present usage.

N. D. Newell, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 46–47. Uppermost formation of Carlsbad group. Formation is 123 feet thick at type locality but expands rapidly reefward as it changes to calcarenite facies. At south side of Walnut Canyon, at edge of shelf, it is 320 feet thick.

P. T. Hayes, 1957, U.S. Geol. Survey Geol. Quad. Map GQ-98. Formation described in Carlsbad Caverns East quadrangle, New Mexico, where it is uppermost unit of Carlsbad group. Top has been removed by erosion in this quadrangle and at type locality. In subsurface, underlies Salado formation.

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 375. In Kent quadrangle, Texas, underlies Yearwood formation (new).

Term Carlsbad abandoned. Term Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4) applied in New Mexico.

Type locality: On Carlsbad-Artesia Highway (U.S. 285), 3.7 miles from Eddy County Courthouse in Carlsbad. In W½ sec. 26, T. 21 S., R. 26 E., of New Mexico Principal Meridian, Eddy County, N. Mex. Name derived from Tansill power dam. Locality is on east flank of elongate dome that forms prominent topographic feature northwest of Carlsbad.

**Tantalus Basalt**[1] (in Honolulu Volcanic Series)

Pleistocene, upper, or Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis in Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 132. Lava flow of melilite-nepheline basalt, with thick mantle of clinker and lava balls, and thick underlying clinker, that cascaded from Tantalus cone into Pauoa Valley. Cinder and clinker in valley below source cone 100 to 300 feet thick; maximum thickness of massive phase of lava about 40 feet. Unconformably overlies Koolau volcanic series and older alluvium; locally rests on black ash formed by same eruption. Probably simultaneous with Sugar Loaf basalt.

Named for Tantalus, the cinder cone at its vent. Covers about 0.3 square miles in Pauoa Valley, on southside of Koolau Range, 11 miles west of Makapuu Head.

**Tanyard Formation** (in Ellenburger Group)

Lower Ordovician: Central Texas.

V. E. Barnes and P. E. Cloud, Jr., 1945, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 34, p. 1, 19–29. Basal formation of group. Underlies Gorman formation (new). A sequence of limestones and dolomites. Thickness 560 feet. Comprises (ascending) Threadgill and Staendebach (new) members. Cherokee Creek section, San Saba County described.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 142–144, 151, 156–157, pls. 5, 6 [1945]. Proposed for rocks similar to and partially correlative with Lower Ordovician rocks exposed at type section at the Tanyard. Consists of fine- to coarse-grained, commonly vuggy to porous, light-yellowish to woodash-gray and pearl-gray, irregularly bedded dolomites and sublithographic, pearl- to woodash-gray and old-ivory, thickly to thinly bedded limestones, both essentially nonglauconite; locally formation is dolomite throughout. Thickness 518 to 658 feet; at type section about 550 feet. On basis of chert and grain-size differences in the dolomites, it is divided into Threadgill member below and Staendebach member above. Overlies Pedernales member or San Saba member of Wilberns formation.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 35–38, 136–137, 157–158, 194–195, 244–250, 256, 291, 312, pl. 8 [1946]. Type section and local stratigraphy described in detail.

Type section: The Tanyard on east bank of Buchanan Lake (Colorado River) opposite mouth of John Jim Creek and Cedar Hollow and 2 to 3 miles north of mouth of Fall Creek, northwestern Burnet County. Tanyard is well known locality, having given its name to Tanyard Spring, Tanyard Camp and Tanyard Crossing.

**Tanyard Branch Member** (of Pride Mountain Formation)

Upper Mississippian: Northern Alabama.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Light-olive-gray to buff very fine to fine-grained thin to medium uneven bedded sandstone 15 feet thick (at base); olive-gray shale 5 feet thick; light-olive-gray to buff, very fine to fine-grained sandstone rubble 10 feet thick (at top). Maximum thickness about 35 feet near Alabama-Mississippi State line; thins eastward to an average of about 20 feet through most of Colbert County. Underlies Wagnon member (new); overlies Alsobrook member.

Named for its exposure on a small hill on east side of Tanyard Branch just south of U.S. Highway 72 in south-central SE½ sec. 2, T. 4 S., R. 13 W., Colbert County.

Taosan series[1]

Precambrian: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 11.

Named for Taos County.

Tapaliza Formation or Group

Oligocene, upper, and Miocene, lower: Panamá.

Charles Schuchert, 1935, Historical geology of the Antellean-Caribbean region: New York, John Wiley and Sons, p. 563, 660. Dark foraminiferal shales.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, Geol. Sci., p. 234 (chart), 241. Tapaliza [group] includes Arusa and Aguagua formations. Chart shows Tapaliza above Capeti limestones and below Gatún formation. Upper Oligocene and lower Miocene.

In Darien area. Tapaliza is name of village on tributary of Río Pucro.

**Tapeats Sandstone** (in Tonto Group)[1]

Lower and Middle Cambrian: Central and northern Arizona, southeastern California, and southern Nevada.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

E. D. Wilson, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1126. In central Arizona, the Tapeats overlies, with pronounced angular unconformity, rocks of Precambrian City Creek series (new).

E. T. Schenk and H. E. Wheeler, 1942, Jour. Geology, v. 50, no. 7, p. 885, 888. Since Prospect Mountain and Tapeats formations are lithogenetically the same, the former name is employed because of its priority of definition.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 15–17, 38–39. Coarse-grained sandstone is by far the most extensive of the several lithologic facies represented in Tapeats sandstone. Fairly uniform in character throughout eastern Grand Canyon, although locally variable, and normally weathers into single sheer cliff of chocolate-brown color.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 32–34, fig. 4, pl. 1. Widely distributed throughout eastern half of Ivanpah quadrangle, California and Nevada. Thickness along eastern limits, in a general north-south direction, ranges from 130 to 600 feet. Underlies Bright Angel shale; overlies Precambrian granite. Age given as Lower Cambrian for exposures in this area.

T. F. Stipp and H. M. Beikman, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–201. Age given as Lower and Middle Cambrian for occurrences in northwestern and central Arizona.

Named for Tapeats Creek, below mouth of which, just north of Shinumo quadrangle, the bed of Colorado River lies within this sandstone; Arizona.

Tapotchau Limestone

*See* **Tagpochau Limestone.**

Tappan Lava Flow

Quaternary: North-central Arizona.

H. S. Colton, 1937, Mus. Northern Arizona Bull. 10, p. 20 (fig.), 21–22. Longest flow that can be demonstrated in San Francisco Mountain volcanic field. Over most of its course, flow is very narrow, 1 to 300 feet. Age not stated but may be contemporary with basalt action of Pleistocene.

D. N. Hinckley, 1955, U.S. Atomic Energy Comm. [Pub.] RME–81 (rev.), p. 8. Quaternary.

At Tappan Springs about 3 miles southwest of Cameron. Traced from Lockett Tank to Cameron and down Little Colorado River to Hopi Trail Canyon, and to point 9 miles below Cameron, Coconino County.

Tappocho Limestone

*See* **Tagpochau Limestone.**

**Taputapu Volcanics**

Pliocene(?): Samoa Islands (Tutuila).

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285 (table 1), 1305–1306, pl. 1. Comprise lava flows, dikes, cones, and tuff deposits making up volcanic dome 6 miles long, 3 miles wide, and 1,500 feet high, and here referred to as Taputapu Volcano. Most flows are olivine basalts 6 to 50 feet thick; they contain much clinker, have thin flow units, and are capped in places with thicker flows of porphyritic and nonporphyritic olivine-poor basalt and andesite. Beds of red vitric tuff a few inches to several feet thick and thick lenses of cinder are common between flows. Thickness about 1,639 feet. Pliocene and upper Pleistocene(?).

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 214–215. Appears to overlap Pago volcanic series. Pliocene(?).

Type locality: Cape Taputapu, west end of island. Exposed over western one-fourth of island.

Tarantula Formation

Cretaceous: Western Texas.

R. M. Huffington, 1947, Harvard Univ. Summ. of Theses, 1943–45, p. 196. Strata of Washita Taranutula formation, 680 feet thick, are probably Georgetown and Grayson in age. Overlies beds of Fredericksburg Finlay formation; underlies Lasca formation (new).

Area of report is northern Quitman Mountains, southern Hudspeth County.

Tarantula Gravel

Tertiary: Southwestern Texas.

R. K. DeFord and L. W. Bridges, 1959, Texas Jour. Sci., v. 11, no. 3, p. 286–295. Predominantly conglomerate; basalt flow interbedded in lower part. Pale yellowish brown where orthoquartzite fragments are plentiful and somewhat whiter where there are more tuff fragments; in places has reddish cast; basal strata cemented with calcite, and amount of cement decreases upward. Thickness at least 300 feet but may be more than 400 feet. At MS1 of type section, typical Tarantula overlies Capote Mountain tuff (new); within 6 miles north-northwestward, oversteps entire Vieja group and rests on Cox sandstone, Bluff limestone, and Yucca formation.

Type section: A composite of three measured sections (MS1, MS2, and MS3). MS1(30°36.1′N., 104°47.8′W.) extends S. 50° E. from its top at top of small hill to its base in a stream bed, adjacent to and south of main body of basalt in Rim Rock fault; MS2 (30°37.3′N., 104°50.4′W.) extends in northerly direction from its top at top of a small hill to base of a vertical exposure in stream bed, 100 feet SE of county road (Porvenir mail route); MS3 (30°35.8′N., 104°49.6′W.) extends in westerly direction from top of long gentle slope to base of steep hill in middle of Tarantula Hills. Named for Tarantula Hills, Jeff Davis County.

Target Limestone Member (of Springer Formation)

Lower Pennsylvanian: Southern Oklahoma.

A. P. Bennison, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 913–914. Gray argillaceous limestone grading laterally into impure sandy marl. Average thickness about 6 feet, and maximum thickness probably does not exceed 10 feet; this includes varying amount of interbedded clay shale. Stratigraphically about 60 feet below massive fine-grained sandstone member probably equivalent to Lake Ardmore sandstone.

Named for intermittent Target Creek flowing across limestone near target range of Ardmore Air Force Base, Carter County. Areal extent limited to secs. 2 and 3, T. 3 S., R. 2 E.

**Tarkio Limestone Member** (of Zeandale Limestone)

Tarkio Limestone (in Wabaunsee Group)

Tarkio Limestone Member (of Wabaunsee Formation)[1]

Pennsylvanian (Virgil Series): Southwestern Iowa, eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: S. Calvin, 1901, Iowa Geol. Survey, v. 11, p. 420, 422, 430–437.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, pl. 5. In Missouri, Tarkio limestone is basal formation in Wabaunsee group. Overlies Willard shale and underlies Pierson Point shale.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. viii (fig. 4), 19, 20. Wabaunsee group is redefined for Missouri to accord with interstate agreement. Tarkio limestone overlies Willard shale and underlies Wamego shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 16–17. In 1910 Condra, traced Swallow's (1866 [1867], Am. Assoc. Adv. Sci. Proc., v. 15) so-called "Chocolate" limestone through outcrops in Mill Creek and Kansas River valleys of Kansas, also in southeastern Nebraska and northwestern Missouri and into division 1 of Calvin's section near Coin, Iowa. After it was realized that all of Calvin's "Tarkio", except the thin to missing top division, had been named in Kansas, Condra and Bengston (1915, Nebraska Acad. Sci. Pub., v. 9, no. 2) applied name Tarkio to top subdivision of Nemaha "formation," now called a subgroup. After it was realized that Chocolate limestone is not a geographic name and that name Tarkio could be applied to the "Chocolate" limestone, Condra (1935) [compiler unable to locate this reference] designated a type locality for the revised Tarkio, where the formation is well exposed in section extending from the Maple Hill limestone down to below the Reading limestone. Moore (1936, Kansas Geol. Survey Bull. 22) selected a type locality in Kansas. The Tarkio is a distinctive unit from northwestern Missouri and southeastern Nebraska to south-central Kansas. Thickness ranges between 2 and 11 feet, being greatest in east-central Kansas. The Tarkio, as redefined by Condra, is distinctive unit in east-central Kansas, in Richardson and Pawnee Counties, Nebr., and in Missouri River bluffs north of Corning County, Mo., but grades into sandy shale at McKissick Grove, Iowa, and Nebraska City, Nebr. Elmont limestone, as exposed in the two northern locations cited above closely resembles the type Tarkio and has been erroneously correlated as Tarkio by some earlier workers. In Nebraska, underlies Pierson Point (Wamego) formation; overlies Willard shale.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276. Rank reduced to member status in Zeandale limestone (new). Underlies Wamego shale member; overlies Willard shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12, fig. 5. Formation in Wabaunsee group. The three formations immediately below Table Creek shale are not generally recognized in area of this report. In N½SE¼SW¼ sec. 36, T. 70 N., R. 43 W., Fremont County, beds are exposed which are tentatively correlated with a part of Table Creek shale—Willard shale interval. At top of this section, 3½ feet of green and gray shale is identified as basal part of Pierson Point shale. Below this is Tarkio limestone, recognized as two limestone beds with an intervening fossiliferous gray shale. Overlies Willard shale. Tarkio described here is in accordance with Kansas usage and not Tarkio as described by Calvin.

Type locality (Condra): In Missouri River bluffs northeast of Corning, Holt County, Mo. This location is west of Tarkio Valley in Missouri.

Type locality (Moore): On Mill Creek southwest of Maple Hill, Wabaunsee County, Kans. This area noted by Swallow under designation of "Chocolate limestone." Calvin applied Tarkio to rocks on Tarkio Creek, north of Coin, Page County, Iowa.

†Tarrant Formation[1] (in Eagle Ford Group)

Tarrant Member (of Eagle Ford Formation)

Upper Cretaceous: Eastern Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 239, 270, 425.

W. L. Moreman, 1942, Jour. Paleontology, v. 16, no. 2, p. 192. Basal formation in Eagle Ford group. Underlies Britton formation.

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 480. Shown on correlation chart as member of Eagle Ford formation, surface and subsurface in eastern Texas.

W. L. Turner, 1951, Field and Lab., v. 19, no. 2, p. 53–54. Adkin's classification not applicable to rocks exposed in Eagle Ford quadrangle; hence, term Tarrant not used in this report.

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 242, p. 3. In this report the "Tarrant" unit is included in Lewisville member of Woodbine formation.

U.S. Geological Survey has abandoned the term Tarrant.

Type locality: One mile east of Tarrant Station, Tarrant County, at crossing of St. Louis, San Francisco & Texas Railway over tributary of Bear Creek.

Tarryall Formation[1]

Carboniferous and Triassic(?): Central Colorado.

Original reference: G. A. Muilenbrug, 1925, Colorado Geol. Survey Bull. 31, p. 12–25.

Exposed in and around Tarryall Creek, Park County.

**Tar Springs Sandstone**[1]

Tar Springs Sandstone (in Elvira Group)

Upper Mississippian (Chester Series): Western Kentucky, southern Illinois, southwestern Indiana, and southeastern Missouri.

Original references: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, p. 174, geol. section; 1857, Kentucky Geol. Survey, v. 2, p. 85–88.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 137; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 835–836. Assigned to Elvira group (new). Sandstone is 50 to 75 feet thick in Union County, Ill., and southeastern Perry County, Mo. In standard Mississippian section, underlies Vienna limestone and overlies Glen Dean limestone.

D. J. McGregor, T. G. Perry, and W. J. Wayne, 1957, Indiana Geol. Survey Field Conf. Guidebook 9, p. 6. Unconformably underlies Pennsylvanian Mansfield formation in some areas of southwestern Indiana.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 27, pl. 1. In Indiana Tar Springs is commonly light-gray to light-brown rust-spotted thick-bedded to massive fine- and medium-grained sandstone which is locally crossbedded and laminated. Thickness 40 to 90 feet. Shown on stratigraphic column below Vienna limestone and above Glen Dean limestone. Term Elvira group not used in Indiana.

Named for Tar Springs, 3 miles south of Cloverport, Breckinridge County, Ky.

Tartar cyclothem

*See* Tarter cyclothem.

Tarter Coal Member (of Abbott Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1). Assigned to member status in Abbott formation (new). Occurs above Manley coal member (new) and below Pope Creek coal member. Name Tarter sandstone previously applied to sandstone below Tarter coal is discontinued in order to retain name for the coal. No name given to sandstone. Coal named by Wanless (1939, Geol. Soc. America Spec. Paper 17). Presentation of new rock-stratigraphic classification of Pennsylvanian in Illinois. Cyclical classification retained but is independent of rock-stratigraphic classification.

Type locality: SE¼ sec. 2, T. 5 N., R. 1 E.. Fulton County.

Tarter cyclothem (in Abbott Formation)

Tarter cyclothem (in Tradewater Group)

Pennsylvanian: Western Illinois.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 14 (fig. 1). Shown on columnar section at top of Caseyville group. Overlies Babylon cyclothem; underlies Pope Creek cyclothem.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 64, 66–67, 202. In outcrops, cyclothem is from 3 to 10 feet thick. Includes Tarter sandstone and coal. Separated from underlying and overlying cyclothems by minor unconformities; base of Tarter sandstone is from 2 to 15 feet above Babylon coal; in many places, upper Tarter strata are truncated by Pope Creek sandstone which in one place cuts out Tarter coal; locally, Bernadotte sandstone cuts out entire Pope Creek cyclothem and rests on Tarter strata. Type locality and derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Abbott formation (new). Above Babylon cyclothem and below Pope Creek cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type section: Ravine, one-fourth mile southwest of bridge, in SE¼ sec. 2, T. 5 N., R. 1 E., Vermont quadrangle, Fulton County. Named for Tarter Bridge over Spoon River.

**Tarter Member** (of Abbott Formation)

Tarter Member (of Tradewater Formation)

Tarter Sandstone (in Tradewater Group)

Lower Pennsylvanian: Western Illinois.

C. B. Read, 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 275. Incidental mention as member of Tradewater formation in discussion of Pennsylvanian floral zones and provinces.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 66, 67, geol. sections 5, 7, 26, 33–35, 41. A sandstone in Tarter cyclothem. Light gray or bluish gray locally discolored by carbonaceous matter; commonly argillaceous; at several localities, consists of irregular nodular masses at base of underclay. Thickness a few inches to 3 feet; where more than 1 foot thick, sandstone appears to be rather massive. Base of sandstone varies from 2 to 15 feet above Babylon coal.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31. Name Tarter sandstone discontinued so that term Tarter may be applied to coal member of Abbott formation (new). Sandstone is only locally present and no replacement name is considered necessary.

Type locality (cyclothem): Ravine one-fourth mile southwest of bridge in SE¼ sec. 2, T. 5 N., R. 1 E., Fulton County. Named for Tarter Bridge over Spoon River.

Tascotal Formation (in Buck Hill Volcanic Series)

Oligocene and younger (?): Western Texas.

S. S. Goldich and C. L. Seward, 1948, West Texas Geol. Soc. [Guidebook] Fall Field Trip Oct. 29–31, p. 14 (table 1), 17 (fig. 3), 21–22. In Tascotal quadrangle, consists of two lithologic facies: (1) thin-bedded flaggy sandy light-colored tuff in lower part, and (2) coarse-grained crossbedded tuffaceous gray-buff sand in upper part; some conglomerate, breccia, and ash beds occur in both facies. Approximately 800 feet thick. Lies on eroded surface of Mitchell Mesa rhyolite; underlies flows of Rawls basalt. Tertiary.

R. L. Erickson, 1953, Geol. Soc. America Bull., v. 64, no. 12, pt. 1, p. 1358 (table 1), 1365–1368, pl. 1. At type locality, where it is 797 feet thick, it is divided into two members: (1) a lower member of tuff and sandy tuff beds, and (2) an upper member of sandstone, tuffaceous sandstone, and conglomerate. Overlies Mitchell Mesa tuff-flow; underlies Rawls basalt.

W. N. McAnulty, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 536 (table 1), 555, pl. 1. Described in Cathedral Mountain quadrangle where it has a maximum thickness of 462 feet; thins northward to 50 feet on butte west of McIntyre Peak where it is capped by Rawls basalt. Oligocene and younger (?).

Type locality: At Wire Gap, Presidio County. Named for high mesa in Tascotal Mesa quadrangle.

Tassia Wash Group

Tertiary (?) (pre-Pliocene): Northwestern Arizona.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, p. 1414–1415, pl. 1. Consists of (ascending): fine-grained compact limestone and sandstone with calcareous cement, in layers 3 to 10 feet thick, over 200 feet thick; limestone and sandstone interbedded with buff siltstone, thickness about 50 feet; buff siltstone, weathering to earthy incoherent silt, thickness about 50 feet; and coarse limestone breccia [this may or may not be unit referred to as Greggs breccia], firmly cemented, with reddish sandy matrix, thickness 60 feet. In structural conformity with underlying Kaibab.

In Tassai Wash east of gap where wash cuts through Tassai Ridge.

†Tassajara (lake?) Bed[1]

Pliocene (?): Western California.

Original reference: J. G. Cooper, 1894, California Acad. Sci. Proc., 2d ser., v. 4, p. 170.

Probably named for exposures on Tassajero (Tassajara) Creek, Alameda County.

**Tassajero Formation**[1]

Pliocene or Pleistocene: Western California.

Original reference: B. L. Clark, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 151.

B. L. Clark, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1957. Underlies Green Valley formation.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 585, chart 11. At type section, consists largely of lacustral deposits, mostly sandstones and shales with thin beds of fresh-water limestones. At base is 200 to 300 feet of volcanic ash referred to as "Moraga" tuff. Overlies Green Valley formation. Lower Pliocene.

Type section: On south and southeast side of Mount Diablo where it is crossed by Tassajero Creek, Contra Costa County.

†Tatalina Group[1]

Precambrian, Cambrian(?), and lower Ordovician: Northeastern Alaska.

Original reference: L. M. Prindle, 1913, U.S. Geol. Survey Bull. 525, p. 37–38.

Typically exposed in valley of Tatalina River, Yukon-Tanana region.

Tate Formation (in McMillan Group)

Tate Member (in McMillan Formation)[1]

Upper Ordovician: Central Kentucky and southwestern Ohio.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 19, 212.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 26–27. In southern Blue Grass region, McMillan group includes (ascending) Tate formation, Gilbert limestone, and Mount Auburn formation. The Tate is a comparatively nonfossiliferous gray shale and fine-grained argillaceous limestone occupying interval between the Fairmount and the Gilbert. Northward on eastern flank of Cincinnati arch, the Bellevue wedges in at the base. Thickness 60 to 80 feet.

Traceable from Casey and Boyle Counties, Ky., to Adams County, Ohio. Derivation of name not stated.

**Tatina Group**[1]

Ordovician and Silurian(?): Central southern Alaska.

Original reference: A. H. Brooks, 1911, U.S. Geol. Survey Prof. Paper 70, p. 55, 69–73, map.

Type exposure: In upper basin of Tatina River, formerly called Rohn River, in Mount McKinley region.

**Tatman Formation**[1]

Eocene, lower: Northern Wyoming.

Original reference: W. J. Sinclair and W. Granger, 1912, Am. Mus. Nat. History Bull., v. 31, p. 60–62.

F. B. Van Houton, 1944, Geol. Soc. America Bull., v. 55, no. 2, p. 185 (table 2), 191–199. Conformably overlies Willwood formation (new). Consists of about 870 feet of alternating fine-grained sandstone and laminated brown carbonaceous shale, swamp and lake deposits.

R. L. Hay, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1880, 1886. In Absaroka Range, overlies Willwood formation and underlies Pitchfork formation (new).

Named for Tatman Mountain. Bighorn Basin.

Tatman Mountain Gravels[1]

Oligocene(?) or Eocene: Northern Wyoming.

Original reference: W. J. Sinclair and W. Granger, 1911, Am. Mus. Nat. History Bull., v. 30, p. 88, 105–111.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 32. Age post-Wasatchian but otherwise uncertain.

Occur on Tatman Mountain, Bighorn Basin.

Tatow Limestone

Lower Cambrian: Central western Utah.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1138–1139, 1141 (fig. 5), 1143–1144. Walcott, in his House Range section (1908, Smithsonian Misc. Colln., v. 53, no. 1812), doubtfully correlated limestone above Pioche shale with the Langston of Blacksmith Fork and assigned it to Middle Cambrian. Rocks overlying Pioche form cliffs in House Range, weather to red-brown slopes similar to those formed of Langston limestone in Blacksmith Fork, and occupy relatively same position in section. However, these rocks in House Range are not dolomitic, contain more arenaceous shale, and also contain a *Poulsenia* fauna considered to be Lower Cambrian in age. These rocks cannot be correlated with Middle Cambrian Langston and are here named Tatow limestone. Lower 40 feet consist of gray fine-grained limestone which contains tan clay flakes and nodules, calcareous platy sandstone, and micaceous shale partings. Upper 125 feet composed of steel-, tan-, and blue-gray more or less oolitic and arenaceous limestone; interbedded with green-gray argillaceous calcareous thin-bedded sandstone; irregular zones or partings of fissile to chunky arenaceous and micaceous shale. Poorly preserved fossils in limestones 50 feet above base and 32 feet below top. Overlies Pioche shale; underlies Howell limestone (emended); boundary between Tatow and Howell placed arbitarily. Lower Cambrian (Waucobian).

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 28–32. Unit termed Tatow limestone by Deiss is here assigned to Busby quartzite which is geographically extended into House Range. Pinches out in vicinity of Pioche, Nev.

Type section: Measured 1½ miles north of Marjum Pass, House Range, Millard County. Name derived from Tatow Knob 14 miles north of Marjum Pass.

Tau Trachyte

Pliocene and lower Pleistocene(?): Samoa Island (Tutuila).

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285 (table 1). Named in list of eight trachytes, which are described as dense jointed cream-colored trachytic dikes, plugs, and crater fills later than most of Pliocene volcanics. Thickness of series 2,141 feet or more. Tau plug associated with Pago volcanic series (new).

Taunton Clays[1]

Pleistocene: Massachusetts.

Original reference: J. B. Woodworth, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 986.

Occurs near Taunton, Bristol County.

**Taylor Marl[1]**

Taylor Group

Upper Cretaceous (Gulf Series): Central and eastern Texas.

Original reference: R. T. Hill, 1892, Artesian Invest. Final Rept., pt. 3, p. 73, Cong., 1st Sess., S. Ex. Doc. 41, pt. 3.

L. W. Stephenson, 1918, U.S. Geol. Survey Prof. Paper 120–H, p. 154–157. Taylor marl overlies Austin chalk and underlies Navarro formation. Includes Pecan Gap chalk and Wolfe City sand members (both new).

L. W. Stephenson, 1937, U.S. Geol. Survey Prof. Paper 186–G, p. 133–146. Unconformity of regional extent separates Austin chalk and beds of Austin age from overlying Taylor marl and beds of Taylor age. Time value of unconformity varies greatly from place to place along strike, owing in part to unequal erosion at top of Austin and in part to differential warping in early Taylor time. Differential warping caused deposition of Taylor sediments to begin earlier in Waco area than elsewhere; there thickness of lower Taylor sediments below Pecan Gap chalk member is 900 feet; minimum thickness or complete absence of lower Taylor sediments beneath beds of Pecan Gap age is between New Braunfels and San Antonio. Field relations of traceable beds in Red River and Lamar Counties indicate that Annona chalk as a whole is time equivalent of lower part of Taylor marl, Wolfe City sand member, and the typical Pecan Gap chalk.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 37–45. Taylor group is oldest of formations exposed in Leon County [this report]. At the outcrops, the group consists of several formations which change considerably in thickness along strike. Some of the formations wedge out completely. On account of these lateral changes, the subsurface section of the Taylor is more readily comparable with surface section of the Taylor in counties along Red River. In counties along Red River, the group is divided into (ascending) Brownstown marl, Gober chalk, lower Taylor marl (partial equivalent of Ozan formation of Arkansas), Wolfe City sand, Pecan Gap chalk, upper Taylor marl (equivalent of Marlbook marl of Arkansas).

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 39–49. Group comprises (ascending) lower marl, Annona chalk, Wolfe City sand, Pecan Gap chalk, Anacacho limestone (upper part), upper marl, and Neylandville marl. Overlies Austin strata; underlies Navarro group restricted to exclude Neylandville marl. Foraminifera described.

Named for Taylor Prairie, central Texas. Typically developed in vicinity of Taylor, Williamson County, and in Travis County.

**Taylor Meta-Andesite[1]**

Mississippian: Northern California.

Original reference: J. S. Diller, 1908, U.S. Geol. Survey Bull. 353.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 14). Shown on correlation chart above Arlington formation and below Pennsylvanian (?) Shoofly formation.

Named for exposures around Taylor Rock, Taylorsville region.

Taylor Sandstone (in Greene Formation)[1]

Permian: Southwestern Pennsylvania and northern West Virginia.

Original reference: R. V. Hennen, 1909, West Virginia Geol. Survey Rept. Marshall, Wetzel, and Tyler Counties, p. 173.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 17 (table 2). Listed in summary of stratigraphic sections of Dunkard group in Harrison County. Thickness about 30 feet. Lies between middle and upper Rockport limestones.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table). Listed in Greene series.

Named for Taylor Township, Greene County, Pa.

Taylor Branch Limestone[1]

Taylor Branch Limestone Member (of Burlingame Formation)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, and northeastern Kansas.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 5, 10.

E. H. Wenberg, 1942, Iowa Acad. Sci. Proc., v. 49, p. 343 (fig. 6). Listed as Taylor Branch limestone in insoluble residue correlations of Missouri and Virgil strata in Iowa.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 45–46. In Nebraska, Burlingame limestone includes (ascending) Taylor Branch limestone, Winnebago shale, and South Fork limestone members.

Type locality: In clay pit south of Taylor Branch south of Table Rock, Pawnee County, Nebr.

Taylor Brook Formation or Injection Gneiss

Cambrian (?): Southwestern Maine.

L. W. Fisher, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 81. Five mappable units established in area formerly mapped as Precambrian in southwestern Maine. Sequence (ascending) Danville-Pejepscot (new) series; Taylor Brook injection gneiss (new) including a sedimentary amphibolite; Androscoggin series; and Thorncrag-Sabbatus series. Middle Silurian.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 115–117, pl. 1, table 1 (facing p. 112). Coarse-grained quartz-feldspar-biotite gneiss with a few finely granulated quartzite lenses. Thickness 3,500 feet. Conformably underlies Androscoggin formation overlies Pejepscot formation. Cambrian (?). Type locality given.

Type locality: In Taylor Brook in western part of city of Auburn, Androscoggin County. Covers an area of about 10 square miles.

Taylors Falls Member (of Franconia Formation)

Upper Cambrian (St. Croixian): East-central Minnesota.

C. R. Stauffer, G. M. Schwartz, and G. M. Thiel, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1901–1902. Named in a list of

Minnesota Upper Cambrian formations. Underlies Minneiska member (new) or Hudson member; overlies Ironton member.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1238 (table 2), 1239. Typically a sandstone but may include much shaly sandstone, glauconitic sand, and even some dolomitic beds as traced away from type locality. Member is a northward continuation of type section of Franconia sandstone and, hence, of *Conapsis* zone. In Minnesota, name is preferred to term Goodenough member as used by Twenhofel, Raasch, and Thwaites (1935) for same faunal zone. Underlies Hudson member; overlies Ironton member. Derivation of name given.

R. R. Berg, 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 867. Abandoned in preference to Mazomanie member.

Named from outcrop along Taylors Falls Highway near southwest corner of Interstate Park at the Dalles of St. Croix River, Chisago County.

**Taylorsville Formation**[1]

Silurian: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

C. W. Merriam, 1940. Geol. Soc. America Spec. Paper 25, p. 48. Devonian age questioned because of lack of faunal evidence.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California (1:250,000): Westwood sheet, California Div. Mines. Largely slate and graywacke, with lesser amounts of conglomerate, breccia and metamorphosed dikes and sills. Mapped with Silurian marine sedimentary and metasedimentary rocks.

Named for exposures on east face of spur above the limestone about 1 mile south of Taylorsville, Plumas County.

Taylortown Limestone (in Washington Formation)[1]

Permian: Southwestern Pennsylvania.

Original reference: E. V. d'Invilliers, 1895, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 3, pt. 2, p. 2577.

Probably named for Taylorstown or Taylorstown Station, Washington County.

**Tazewell Stade**

Tazewell Loess,[1] Drift, Till

Tazewell (Tazewellian) Substage[1] and Subage

Pleistocene (Wisconsin): Mississippi Valley.

Original reference: M. M. Leighton, 1933, Science, v. 77, p. 168.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 24, 36, 37, 44, 50, 52, 123, 128. Bradyan subage (new) occurs between Tazewellian and Caryan subages. Report also mentions Tazewell substage, loess and till.

R. V. Ruhe, Meyer Rubin, and W. H. Scholtes, 1957, Am. Jour. Sci., v. 255, no. 10, p. 671–689. New radiocarbon dates in Iowa permit a grouping of age values and raise new problems in stratigraphic correlation of late Pleistocene deposits in Iowa and adjacent regions. An older group of ages greater than 29,000 years dates Iowan substage and pre-Iowan deposits.

An old group of ages of 22,900 to 25,100 years dates the Farmdale substage. An intermediate group of ages ranges 14,000 to 17,000 years. Deposition of Tazewell loess occurred in central Iowa during period 15,000 to 17,000 years before present. Minimum date of Tazewell-Cary interstadial is 15,000 years.

V. C. Shepps, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G-32, p. 22-30. Advance during Tazewell substage in northwestern Pennsylvania is named Mogadore. Till deposited is named Mogadore.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 7. Presentation of revised time-stratigraphic classification of Wisconsinan stage in Lake Michigan glacial lobe. From former classification, the Woodfordian substage (new) includes Iowan substage of Illinois usage (but not of the type), the Tazewell and Cary substages.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529-552. Presentation of classification of Wisconsin glacial stage of north-central United States. Tazewell glacial substage is separated from older Iowan glacial substage by Gardena intraglacial substage and from younger Cary glacial substage by St. Charles intraglacial substage. Author [Leighton] disagrees with classification presented by Frye and Willman (1960) in which they included Iowan substage (of Illinois), Tazewell substage, and Cary substage in Woodfordian substage. Leighton believes that Frye and Willman overlooked fact that some of Tazewell and Cary drifts in eastern Illinois which they include in their "Woodfordian" are from Saginaw lobe, not Michigan lobe, Frye and Willman named Tazewell loess Richland; this name is superfluous.

Name amended to Tazewell Stade to comply with Stratigraphic Code adopted 1961.

Name derived from Tazewell, Tazewell County, Ill.

**Teanaway Basalt**[1]

Eocene: Central Washington.

Original reference: G. O. Smith and B. Willis, 1901, Am. Inst. Min. Engineers Trans., v. 30, p. 359.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 26 (table), 38-39. Basaltic lava flows and intercalated tuffs, possibly in part equivalent to Metchosin volcanics of western Washington. Thickness 100 to 4,000 feet. Lower to middle Eocene.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 101 (table 1), 107-108, pl. 1. Area herein discussed [northern parts of Mount Stuart and Snoqualmie folios] contains main body of Teanaway which is composed of basaltic lava complexly interbedded with sedimentary and pyroclastic rocks. In type area, more than 5,000 feet thick and consists of basaltic lava, tuff, and lapilli-tuff; upper part of section primarily clastic with tuff and lapilli-tuff predominating; some columnar basalt. Lies unconformably above Swauk formation, and locally Silver Pass volcanic rocks (new). Overlain by Roslyn formation, Yakima basalt, and post-Roslyn rhyolite; the Roslyn, oldest of the three formations, concordantly overlies the Teanaway; the other two are unconformable. Unfossiliferous. Stratigraphic relationships suggest a tentative Eocene age.

Type area (Weaver, 1937): Basin of Teanaway River where lavas are exposed on south flank of Wenatchee Mountains and dip in southerly direction beneath later sedimentary and volcanic formations in Yakima

Valley. Type area (Foster, 1960): Along Middle Fork of Teanaway River. [This is interpreted by Foster to be area that Smith intended for type.] Crops out in an arcuate band, up to 4 miles wide, extending from east of Kachess Lake to Table Mountain. Exposures of Teanaway essentially represent a cross section through a volcanic field.

**Teapot Sandstone Member** (of Mesaverde Formation)[1]

Teapot Sandstone Member (of Parkman Sandstone)

Upper Cretaceous: Eastern Wyoming.

Original reference: V. H. Barnett, 1915, U.S. Geol. Survey Bull. 581, p. 113.

C. H. Wegemann, 1918, U.S. Geol. Survey Bull. 670, p. 22–23. Uppermost member of Mesaverde formation in Salt Creek oil field, Wyoming. Thickness about 50 feet. Separated from underlying Parkman sandstone member by about 325 feet of shale (unnamed). Underlies Lewis shale.

E. I. Rich, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2435–2436. Forms top of Mesaverde formation in southwestern part of Powder River and southeastern part of Wind River basin. Overlies unnamed middle member. Underlies Lewis shale in some areas and in other areas Meeteetse formation. In southeastern part of Wind River basin, member is overlain by rocks containing marine faunal assemblage characteristic of Bearpaw shale of Montana and is underlain by rocks probably equivalent to upper Claggett shale or lower part of Judith River formation. Age limits are restricted and the Teapot member is, in area of this report, of late Judith River or early Bearpaw age. Not recognized in surface or subsurface in Big Horn basin.

J. M. Parker, Jr., 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 90, 98. Present subsurface and outcrop control makes it possible to show that type Teapot is part of original Parkman, as first described near Parkman and later defined on Crow Indian Reservation. Hence, Parkman should be treated as formation with Teapot sandstone as uppermost member.

Named for Teapot Rock, a topographic feature carved from this sandstone about one-half mile east of Casper-Salt Creek Road.

**Teapot Mountain Porphyry**[1]

Tertiary, lower (?): Central Arizona.

Original reference: F. L. Ransome, 1919, U.S. Geol. Survey Prof. Paper 115, p. 126, pl. 45.

E. D. Wilson, 1952, Arizona Geol. Soc. Guidebook for Field Trip Excursions in southern Arizona, p. 8. Age shown as Laramide (Late Cretaceous to early Tertiary).

Largest exposure of Teapot Mountain porphyry is on ridge south of Teapot Mountain and west of the metallized schist area, Ray district.

Teay Formation[1]

Pleistocene: Southwestern West Virginia.

Original reference: M. R. Campbell, 1900, U.S. Geol. Survey Geol. Atlas, Folio 69.

Forms floor of Teay Valley, Cabell County.

Tebo Formation (in Cabaniss Group)

Tebo Formation (in Cherokee Group)

Pennsylvanian (Des Moines Series): Missouri and Kansas.

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, 2d ser., p. 78–83, 100, 101, 102, 103, measured sections, pl. 5. Name Tebo was originally given to coal seam, type locality of which is on Tebo Creek, Henry County. Associated with coal is an underclay and overlying black roof slate which appear to make a unit. Name Tebo formation is applied to this unit. Unconformably overlies Loutre formation; unconformably underlies Ardmore formation. Thickness as much as 9 feet.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Stratigraphic column shows Tebo formation above Weir formation and below Scammon formation. Cabaniss group.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as coal cycle in Senora formation, Cabaniss group in Oklahoma.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 22 (fig. 11), 23 (fig. 12). Thickness about 17½ feet in Vernon County, Mo. Underlies Tiawah limestone in Scammon formation, Cabaniss group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 48–52, measured sections. In southeastern Kansas, the following divisions recognized: dark- to light-gray silty to sandy shale at base, impure limestone, underclay, and Tebo coal. Thickness ranges from few inches to about 26 feet. Overlies Weir formation; underlies Scammon formation. Cabaniss subgroup of Cherokee group.

Type locality: Tebo Creek, Henry County, Mo.

Tecolote Member (of Santa Rosa Island Formation)

Pleistocene: Santa Rosa Island, California.

P. C. Orr, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1113, 1115 (fig. 2), 1116–1118. Consists of buff-colored clays and clay sands, old soil profiles, and thin lenses of subangular gravel; many minor unconformities representing stream channelling and at least one major unconformity in which thick layer of coarse gravel was deposited about midway in member. In some areas, earth has been burned brick red; many of these fire areas contain charred bones of dwarf mammoth and are attributed to activities of early man. One fire area about midpoint in sequence radiocarbon dated at 29,700 ± 3,000 years B. P. Upper part of sequence dated 12,000 years B. P. Thickness about 60 feet. Uppermost member of formation. Overlies Fox member.

Tecopa Shale

Lower and Middle Cambrian: Southeastern California and southeastern Nevada.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 27–28, fig. 5. Name applied to shales that lie between Zabriskie quartzite below and Lyndon limestone above. Thickness 1,119 feet. Cadiz formation of Hazzard and Mason (1936) not considered valid lithologic unit, nor is it applicable to strata in question; neither is Bright Angel as used by Nolan (1929, Am. Jour. Sci., 5th, v. 17, no. 101) in Spring Mountain area, Nevada, applicable, hence new name proposed.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 148. In suggested revision of stratigraphic units in Great Basin area, Tecopa shale is included in Wood Canyon formation.

Type section: About 6 miles northeast of Tecopa, Inyo County, Calif., near southern end of Resting Springs Range. This is Hazzard's (1938 [1937], California Jour. Mines and Geology, v. 33, no. 4) section extending from top of Zabriskie quartzite (unit 4H) to base of Lyndon limestone (unit 5E) in cross-section B–B'. Present at west base of Eagle Mountain, near Death Valley Junction, and on west side of mountains immediately west of Shoshone.

**Tecovas Formation** (in Dockum Group)[1]

Upper Triassic: Northwestern Texas.

Original reference: C. N. Gould, 1907, U.S. Geol. Survey Water-Supply Paper 191, p. 20–29.

G. Maxwell, 1954, *in* Panhandle Geol. Soc. [Guidebook] Field Trip May 1, p. 15. Underlies Trujillo formation; west-central Potter County where the Trujillo is absent, the Tecovas underlies Tertiary sediments.

Named for exposures on Tecovas Creek, Potter County.

Tecumseh Sandstone (in Silver Reef Sandstone Member of Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 25, 28–29, pl. 2. Thin-bedded to massive and commonly lavender colored. A buff to yellow sandstone, prominently iron-stained and as much as 6 feet thick, occurs near middle of unit on Tecumseh Hill and along east face of White Reef near Thompson mine. Thickness on Tecumseh Hill in main mining area about 35 to 40 feet; to the north near Barbee mine about 30 feet or less, and on East Reef at Duffin mine about 50 feet. Thickness increases east of Leeds. Underlies Duffin sandstone and shale (new) with local unconformity; overlies Leeds sandstone (new) with local unconformity.

Named for exposures on Tecumseh Hill, Silver Reef (Harrisburg) Mining District, Washington County.

**Tecumseh Shale** (in Shawnee Group)[1]

Tecumseh Shale Member (of Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 28.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 23. As currently defined, underlies Ozawkie limestone member of Deer Creek formation and overlies Avoca limestone member of Lecompton formation. In Nebraska, divided into (ascending) Kenosha shale, Ost limestone, and Rakes Creek shale formation. Thickness in Nebraska about 36 feet; 65 feet at type locality; 12 feet at south line of Kansas.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 18–19, fig. 5. Comprises (descending) Rakes Creek shale, Ost limestone, and Kenosha shale members. Not differentiated in some areas. Where the two lower members of Deer Creek cannot be differentiated they are often included in the Tecumseh. Thickness about 10 ft. Underlies Deer Creek formation; overlies Lecompton formation. Shawnee group.

Type locality: Tecumseh, Shawnee County, Kans.

Tecuya Beds[1] or Formation

Oligocene or Miocene: Southern California.

Original reference: C. Stock, 1920, California Univ. Pub., Dept. Geol. Bull., v. 12, no. 4.

J. G. Marks, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1922. Referred to as Tecuya formation consisting of continental deposits of Oligocene or Miocene age. Unconformably overlies Tejon formation at its type locality; in Reed and Grapevine Canyons, underlies Tertiary dacite agglomerate and a flow of andesite.

Exposed in vicinity of Tecuja [Tecuya] Canyon in lower part of San Joaquin Valley, Kern County.

**Teewinot Formation**

Pliocene, middle: Northwestern Wyoming.

J. D. Love, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1899, 1907–1911, fig. 1. Succession of white limestone, tuff, pumicite, claystone, and conglomerate. Three facies developed in type area: a basal conglomerate, at least 1,400 feet thick; a middle limestone and pumicite, over 3,300 feet thick; and an upper claystone and pumicite, more than 400 feet thick. Unconformably overlain by Bivouac formation (new). Unconformably overlies rocks ranging in age from Cambrian to Miocene.

Type section: In and adjacent to Jackson Hole National Elk Refuge, Teton County, in T. 42 N., R. 115 W., and sec. 36, T. 42 N., R. 116 W. Name derived from Mount Teewinot, a sharp peak east-northeast of the Grand Teton, overlooking type area of formation in bottom of Jackson Hole at the east.

Tehachapi Formation[1]

Quaternary (?): Southern California.

Original reference: H. G. Hanks, 1886, California State Mining Bur. 6th Ann. Rept., pt. 1, p. 23.

Occurs one-half mile from town of Tehachapi, Kern County, on road to Caliente, also 9 miles west of Tehachapi, in Bright's Valley.

Tehachapi Marble[1]

Age not stated: Southern California.

Original reference: H. G. Hanks, 1886, California State Mining Bur. 6th Ann. Rept. State Mineralogist, pt. 1, p. 23.

Probably named for town of Tehachapi, Kern County.

**Tehama Formation**[1]

Pliocene: Northern California.

Original reference: R. D. Russell and V. L. Vander Hoof, 1931, California Univ. Pub., Dept. Geol. Sci. Bull., v. 20, no. 2, p. 11–21.

C. A. Anderson and R. D. Russell, 1939, California Jour. Mines and Geology, v. 35, no. 3, p. 232–235, pl. 3. Consists of silts, silty clays, sands, and gravels, predominantly pale and yellowish to greenish gray, weathering pale buff to yellow brown. Nomlaki tuff member at base. Thickness more than 2,000 feet in central part of Pliocene valley in which it accumulated, with Nomlaki tuff about 700 feet from base. Contemporaneous with Tuscan formation and interfingers with it in their zone of junction. Capped by Red Bluff gravels.

Named for Tehama County.

†Tehuacana Formation[1]

Eocene, lower: Eastern Texas.

Original reference: Julia Gardner, 1932, Geol. map of Texas, prelim. ed.

Tehuacana Bluff, the steep hill just west of town of Tehuacana, Limestone County.

**Tehuacana Member** (of Kincaid Formation)[1]

Paleocene: Eastern Texas.

Original reference: G. D. Harris, 1896, Bulls. Am. Paleontology, v. 1, no. 4, p. 129, 155.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 13–14. Uppermost member of formation in Texas. Overlies Pisgah member. Consists of grayish-white fossiliferous limestone and greenish-gray calcareous sandstone.

G. R. Kellough, 1959, Gulf Coast Assoc. Geol. Soc. Trans., v. 9, p. 153, 159–160. In Tehuacana Creek section, Tehuacana member includes 35 feet of shaly sands and sandy limestones containing minor amounts of fine-grained glauconite. Overlies Pisgah member; underlies Mexia member of Wills Point.

Type locality: Abandoned quarry at Tehuacana, Limestone County

**Tejon Formation**[1]

Tejon Group

Tejon Stage

Eocene, upper: Western California.

Original reference: W. M. Gabb, 1869, California Geol. Survey Pal., v. 2, p. xiii as reported by J. D. Whitney from unpublished paper by Gabb, and footnote by Gabb, p. 129.

B. L. Clark and H. E. Vokes, 1936, Geol. Soc. America Bull., v. 47, p. 853 (fig. 1), 864–868. Used as a stage name based on faunal assemblages. Occupies the interval between a transition stage above the Domengine stage and below the Gaviota stage.

J. G. Marks, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1922; 1943, California Div. Mines Bull. 118, pt. 3, p. 534–535. Formation subdivided into four members in type area (ascending): Uvas conglomerate, Liveoak, Metralla sandstone, and Reed Canyon silt. Type area designated; here Tejon marine sediments form a wedge of steeply dipping strata 410 feet thick at Pastoria Creek and 4,380 feet in Reed Canyon a quarter mile east of Tecuya Creek. Underlies Tecuya formation; overlies basement complex.

E. A. Watson, 1942, Am. Midland Naturalist, v. 28, no. 2, p. 451–456. Eocene section in Pacheco syncline is conformable sequence about 5,400 feet thick. Strata were mapped as two formations, Martinez and Tejon, by Merriam (1897, Jour. Geology, v. 5, no. 8), Dickerson (1914, California Univ. Dept., Geol. Sci. Bull. 8, no. 6), Lawson (1914, U.S. Geol. Survey Geol. Atlas, Folio 193), and Weaver (*in* Tolman, 1932, California Dept. Public Works Water Resources Bull. 28). Name Tejon was applied to upper 2,800 feet of beds on basis of supposed equivalence in age rather than on similarity in lithology to type Tejon in Kern County. Since exact contemporaneity is difficult to prove, and since these strata are far removed from type locality and cannot be traced into them, another formational name might be advisable or term Markley used instead. In present report, the strata in question are called "Tejon." Shales of lower 1,500 feet of formation carry foraminiferal faunules that probably fall in "Tejon and Transition stage" of Clark and Vokes (1936). Upper part of section thought to be equivalent in age to Kreyenhagen as mapped by Taff (1935, Geol. Soc. America Bull. v. 46, no. 7) on north side of Mount

Diablo. Overlies Martinez with contact gradational; underlies San Ramon formation.

W. C. Putnam, 1942, Geol. Soc. America Bull., v. 53, no. 5, p. 697 (fig. 3). Used as a group term in Ventura region; includes (ascending) Matilija, Cozy Dell, and Coldwater formations. Underlies Sespe formation; overlies undifferentiated Eocene.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 587–588, chart 11. Foraminifera of lower 250 feet of "Tejon" formation in Pacheco syncline suggest a correlation of this part of section with Canoas silt (basal) member of Kreyenhagen. Not certain whether basal part of Tejon of this syncline or upper part of Martinez formation should be correlated with type Domengine. On northeast flank of syncline, about 800 feet above base of "Tejon" are beds containing *Turritella uvasana aedificata*, which is also abundant in sandstone of "Domengine stage" on south side of Mount Diablo. Upper part of "Tejon" occupies same stratigraphic position and has same foraminiferal species at top as does Markley formation at its type locality.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), 29–30, pls. 1, 2, 7. Described and mapped in Lower Lake quadrangle. Consists principally of a white conglomeratic sandstone about 1,000 feet thick. Unconformably underlies Cache formation; unconformably overlies Martinez formation.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology 7, p. 5, 19 (correlation table). Eocene rocks south of Martinez in Concord quadrangle were mapped by Lawson (1914, U.S. Geol. Survey Geol. Atlas, Folio 193) as Martinez and Tejon formations. Contact as shown on maps of the San Francisco folio between the Martinez and Tejon on west limb of Pacheco syncline corresponds approximately to boundary between Escobar and Muir sandstones (both new) of present report. The Tejon of west limb of syncline is herein classified as Escobar sandstone and overlying Alhambra shale (new) with its three divisions. Tejon as mapped on east limb in San Francisco folio now includes the middle Eocene Muir sandstone, the upper Eocene Escobar sandstone, and Alhambra shale.

Type area: On north slope of Tehachapi Mountains at extreme south end of Joaquin Valley, between Pastoria Creek on the east and Tecuya Creek on the west. Named for occurrence in vicinity of Fort Tejon, Kern County.

Tejon Lookout Granite

Jurassic(?): Southern California.

J. C. Crowell, 1952, California Div. Mines Spec. Rept. 24, p. 10, pls. 1, 2. A light-buff medium- to coarse-grained biotite granite. Intrudes rocks similar to Lebec quartz monzonite (new); the Lebec and Tejon Lookout are probably related although now separated by Garlock fault.

Crops out in wedge-shaped area between San Andreas and Garlock faults and well exposed near Tejon Lookout, Lebec quadrangle.

Telegraph Canyon Member (of Nevada Formation)

Devonian: Northeastern Nevada.

Donald Carlisle and others, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2178 (fig. 2), 2181, 2183–2184. Thin- to thick-bedded mottled dolomite in alternating light- to dark-brown or dark-gray layers, and including a tongue (15 to 450 feet thick) of well-bedded gray limestone. At type section, represented by 2,000 feet of dolomite, uppermost beds cut out by faulting; 1,950 feet thick at Williams Canyon; 800 feet in northern Pinyon Range. Overlies Union Mountain member (new); underlies Devils Gate limestone.

Type locality: Telegraph Canyon, Sulphur Springs Range, Mineral Hill quadrangle.

**Telegraph Creek Formation** (in Montana Group)[1]

**Telegraph Creek Member** (of Cody Shale or Colorado Shale)

Upper Cretaceous: Central southern Montana.

Original reference: W. T. Thom, Jr., 1922, U.S. Geol. Survey Bull. 736–B, p. 38.

W. A. Cobban, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1899–1900. Formation extended into Sweetgrass arch area, Montana. Unit has been included into Virgelle sandstone, mapped as separate formation and referred to as Transition zone, and termed Telegraph Creek(?). Fossil evidence definitely establishes Telegraph Creek age, and term can be used without query in this area.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–111. Rank reduced to member status in Cody shale. Thickness 867 feet. Overlies Niobrara shale member; underlies shale member equivalent to Eagle sandstone. Report covers Hardin area, Big Horn, and Yellowstone Counties, Mont.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:65,000): U.S. Geol. Survey. Montana group as mapped in northwestern Wyoming includes Telegraph Creek, Eagle sandstone, Claggett shale, and Judith River formation.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2792 (fig. 3), 2793. In Sweetgrass arch and East Glacier-Marias Pass areas, Montana, formation overlies Kevin shale member of Marias River shale (both new).

M. R. Mudge, 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 19. Described in Sun River Canyon area, Montana, where it is 340 feet thick, underlies Virgelle sandstone and overlies Kevin shale member of Marias River formation. Divisible into three parts: lower fine-grained calcareous dark-gray sandstone with many 1- to 3-inch-thick beds of fine-grained calcareous dark-gray sandstone and sandy shale partings; middle, mostly beds of calcareous hard dense dark-gray sandstone, 0.4 to 1 foot thick, in places ripple marked and crossbedded; upper, beds (as much as 4 feet thick) of light-gray calcareous poorly indurated sandstone alternating with beds of equal thickness of gray calcareous sandy shale.

U.S. Geological Survey currently classifies the Telegraph Creek as a member of the Colorado Shale in the Bearpaw Mountains area, Montana, on the basis of a study now in progress.

Typically developed at head of Telegraph Creek, T. 2 S., Rs. 28 and 29 E., Crow Creek Indian Reservation, Mont.

†Telegraph Hill Sandstone (in Franciscan Group)[1]

Jurassic(?): Western California.

Original reference: R. Crandall, 1907, Am. Philos. Soc. Proc., v. 46, p. 3–58.

Named for exposures at Telegraph Hill, San Francisco.

Telescope Group[1]

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 311, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July–Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Pub. Geol. Sci., v. 30, no. 5, p. 355, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible correlation of formations defined by Murphy (1930, 1932 [1933]) in Telescope Peak quadrangle with formations now commonly used in Death Valley region. Relationships of Murphy's formations to standard Death Valley section have not been generally understood. Murphy tentatively assigned all units above the Panamint metamorphic complex to the Lower Paleozoic. Units of the Telescope group—Sour Dough limestone, Middle Park formation, Mountain Girl conglomerate, Wildrose formation, Sentinel dolomite, Redlands dolomitic limestone, and Hanaupah formation—are here correlated with Precambrian Kingston Peak, Noonday, and Johnnie formations.

Appears to be named for Telescope Peak, south part of Panamint Range, on and around which formations of group are mapped.

Television Sandstone (in Panoche Group)

Upper Cretaceous: Central California.

M. B. Payne, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Section, Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Black-weathering concretionary sandstone 100 feet thick. Overlies Marlife shale (new); underlies Uhalde sandstone and shale (new). Name credited to D. W. Sutton (unpub. thesis).

Type locality: Moreno Gulch, Fresno County. Name derived from Television Hill, NW cor. sec. 10, T. 14 S., R. 11 E.

Tellera or Tellara limestone[1]

Pennsylvanian(?): Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 3, 11.

Exposed on east flank of Sandia Range in Sandia Mountains. Derivation of name not stated.

**Tellico Sandstone or Formation**

Tellico Sandstone (in Blount Group)[1]

Middle Ordovician: Southeastern Tennessee, northwestern Georgia, and western North Carolina.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 4.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1155, 1156. In Knoxville area, overlies Farragut limestone. Name proposed to replace "Holston" marble.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 29, geol. map. Formation in northwestern Georgia is predominantly a coarse-grained ferruginous sandstone with some shale and, in places, a conglomerate at base. Occurs as single narrow belt along extreme northeastern edge of Paleozoic area, extending southwestward a distance of about 8 miles from Tennessee-Georgia line to within 4 miles north of Eton, Murray County. Thickness about 500 feet. Blount group.

John Rodgers, 1952, Geology of the Athens quadrangle, Tennessee (1:24,000): U.S. Geol. Survey Geol. Quad. Map. The red quartzose limestone overlying the Athens has hitherto been called Tellico sandstone, but typical Tellico on Tellico River has quite different lithologic character and is probably of different age. Also, the red quartzose limestone that is usually called Tellico sandstone is associated with and grades laterally into red quartz-free limestone or "marble," and the two together form a mappable unit that seemingly is equivalent to typical Holston limestone.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 69, 73, 75, 77, 78, 79, 80. In belt between Saltville fault and Knoxville and Rocky Valley faults, rocks that Keith and others have mapped as Tellico sandstone are included in Holston formation. On basis of this correlation, in belts southeast of Chestuee and Dumplin Valley faults and of Saltville fault northeast of Morristown, the typical Tellico sandstone of Keith occurs within the Athens shale and becomes the Tellico sandstone member of the Athens shale.

B. N. Cooper, 1953, Geol. Soc. America Mem. 55, p. 3 (fig. 1), 4. Discussion of trilobites of Appalachian Valley. Tellico sandstone is ferruginous clastic facies which is time equivalent of beds identified elsewhere as Athens, Sevier, or Ottosee.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 145 (table), 154–155, pl. 28. Term Tellico formation is applied in this report [Tellico-Sevier belt, eastern Tennessee] to a sequence of gray silty, sandy calcareous shale and calcareous sandstone 2,700 to 4,500 feet thick. Dominant rock is shale in which sandstone forms lenticular units. In general, sandstone units are concentrated near middle of formation, and it is to this part that Keith originally applied term Tellico sandstone. Formation as used in present report includes rocks above and below those originally included in term by Keith. As herein defined, it includes upper part of Athens formation, the Tellico formation, and that part of the Sevier formation beneath the "sandstone lentil" of the Knoxville and Loudon folios. Overlies Blockhouse shale (new) with contact gradational; conformably underlies Chota formation (new). Middle Ordovician. Classification used in this report differs from that used by Rodgers (1953).

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 93–94. In its type belt, the Tellico overlies shales (Blockhouse) with graptolites that are partly equivalent to Athens formation and is overlain by shales and sandstones (Sevier) of uncertain correlation. In belts passing through Friendsville and Knoxville, the sands and calcarenites mistaken for Tellico overlie "Holston" marble (equivalent to Red Knobs) and are overlain by Sevier formation. In this belt, "Tellico" fossils are clearly related to those of Arline formation (new) and possibly fossils occurring as high as Benbolt. Probable that type Tellico is actually older than that of belts north of Athens. Entire interval of shales and sandstones from the Knox to base of Sevier formation is equivalent on basis of fossils to interval from top of Knox through the "Tellico"-Red Knobs of belts south of Knoxville.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 57. Term Blount group discarded.

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–76. In Shooks Gap and Bearden quadrangles, Tennessee, strata previously mapped as Tellico are named Chapman Ridge sandstone.

Named for exposures in cut on Tellico River, Monroe County, Tenn.

Tellowa Formation (in Pottsville Group)[1]

Pennsylvanian: Southwestern Virginia and southern West Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44.

Type locality not stated.

**Telluride Conglomerate[1] or Formation**

Oligocene(?): Southwestern Colorado.

Original reference: W. Cross, 1901, U.S. Geol. Survey Bull. 182, p. 29–39.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 14, 60, pl. 1. Predominantly coarse conglomerate containing pebbles and boulders of schist, granite, quartzite, limestone, and other rocks derived from Paleozoic sediments; local bodies of sandy limestone. As much as 1,000 feet thick. Unconformably overlies Cretaceous and older rocks and, locally, glacial till; underlies San Juan tuff. Contains no determinable fossils; age judged by relations to other formations. Believed to be nearly same age as Blanco Basin formation which is tentatively placed in Oligocene.

F. B. Van Houten, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 386, 387 (table 1), 388. There is no good evidence for assigning Telluride and apparently equivalent Blanco Basin formations an Oligocene(?) age. They are more probably arkosic border facies of upper Paleocene and lower Eocene San Jose (Wasatch formation).

Named for exposures about town of Telluride and throughout Telluride quadrangle.

**Temblor Formation[1] or Sandstone**

Temblor Group or Stage

Miocene, lower and middle: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 168–187.

R. Anderson and R. W. Pack, 1915, U.S. Geol. Survey Bull. 603. Includes Big Blue serpentinous member (new).

J. E. Eaton, U. S. Grant, and H. B. Allen, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 196 (fig. 1), 204–205 (fig. 3), 212–213, 217 (fig. 4), 224–230. Discussion of Miocene of Caliente Range and environs. Marine Miocene is a transgressive series, essentially conformable basinward, but revealing, strandward, the occurrence of two oscillations which respectively inaugurate and divide its upper third. It comprises three nearly equal divisions, Vaqueros, Temblor, and Monterey stages, which approximate lower, middle, and upper Miocene. Each of these has more or less distinctive epeiorgenic history, fauna, and average physical aspect. At Caliente Mountain, a homoclinal section exposes about 1,100 feet of upper Oligocene(?), 4,500 feet of Vaqueros, 4,700 feet of Temblor, and 4,600 feet of Monterey strata.

774–954—vol. 3—66——61

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 213–215, 226 (fig. 5). Temblor group, in San Benito quadrangle, is represented by three mappable units: lower sandstone, 100 to 500 feet thick; shale in middle of section, 300 to 1,000 feet thick; and upper sandstone, 400 feet thick. They are exposed along axis of Butts Ranch syncline and are youngest rocks affected by the folding. Disconformably overlies Kreyenhagen shale. Middle Miocene.

A. M. Keen, 1943, San Diego Soc. Nat. History Trans., v. 10, no. 2, p. 25–60. Correlation chart of Kern River area shows Temblor comprises (ascending) Pyramid Hill sand, Freeman-Jewett silts, Olcese sand, and Round Mountain silt members. Principal cartographic unit in area is Round Mountain silt member; less widespread are Olcese sand and the Freeman-Jewett silt. Additional members of Temblor underlie the area but outcrop beyond borders of map.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 22 (fig. 4), 35–36, pl. 1. In San Jose-Mount Hamilton quadrangle, formation is 500 to 1,000 feet thick; continuous section not measured. Conformably overlies Franciscan and grades upward into Monterey shale; underlies Briones. Formation is limited on west by fault of the Calaveras system.

H. H. Heikkila and G. M. MacLeod, 1951, California Div. Mines Spec. Rept. 6, p. 4 (table 1), 5 (table 2), 7–11, pl. 1. Formation, in Bitterwater Creek area, Kern County, comprises (ascending) Agua sandstone, Santos undifferentiated, upper Santos shale, Carneros sandstone, and Media shale members, and unit termed "Button bed." Thickness as much as 5,350 feet. Overlies Point of Rocks formation; underlies Monterey shale. Lower and middle Miocene.

H. P. Smith, 1956, California Univ. Pubs. Geol. Sci., v. 32, no. 2, p. 68 (fig. 2), 71–72, geol. map. In Devils Den district, overlies Wagonwheel formation.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2986, 2989. Upper 900 feet of unit herein named Painted Rock sandstone member of Vaqueros formation was included by Eaton and others (1941) in their Temblor. Saltos shale member (new) of Monterey was mapped by Eaton and others as upper part of Temblor.

Named for exposures on Temblor Ranch, McKittrick district, Kern County.

Temecula Arkose

Pleistocene: Southern California.

J. F. Mann, Jr., 1955, California Div. Mines Spec. Rept. 43, p. 3, 9, 11–13, pl. 1. White to buff to greenish arkose, buff soil zone, brown silts, silicified algal marls, white tuff; about 600 feet thick. Underlies Pauba formation (new) with angular unconformity; overlies sediments tentatively considered as Paleocene.

Widely distributed in Elsinore fault zone in western Riverside and northern San Diego Counties. Named for exposures on Pechanga Indian Reservation, southeast of Temecula, Riverside County.

**Temescal Formation**[1]

Pleistocene: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

D. H. Radbruch, 1957, U.S. Geol. Survey Misc. Geol. Inv. Map I–239. Clayey gravel, silty sandy clay, and sand-clay-silt mixtures. Pale yellowish orange to dark yellowish orange. Thickness 5 to 60 feet. Grades laterally into Merritt sand; overlies Alameda formation. Pleistocene.

Named for development along Temescal Creek, Alameda County.

Temescal Porphyry[1]

Upper Jurassic(?): Southern California.

Original reference: P. H. Dudley, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 223.

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 528. Name replaced by Temescal Wash dacite porphyry.

Occurs between towns of Riverside, San Jacinto, Corona, and Elsinore, Riverside County.

**Temescal Wash Quartz Latite Porphyry**

Temescal Wash Dacite Porphyry

Jurassic(?): Southern California.

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 528. Referred to as Temescal Wash dacite porphyry. Dark-colored rock with plagioclase and quartz phenocrysts and inconspicuous biotite or hornblende. Replaces name Temescal dacite porphyry (Dudley, 1936).

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 36–38, pl. 1. Described as Temescal Wash quartz latite porphyry. Considered older than Woodson Mountain granodiorite. Relation to San Marcos gabbro not positively determined.

Exposed over wide area a few miles southeast of Puente Hills, southeast of Los Angeles.

Tempa Schist

Age not stated: Western North Carolina.

C. E. Hunter and P. W. Mattocks, 1936, Tennessee Valley Auth. Div. Geology Bull. 4, p. 13. Composed of muscovite, quartz, biotite, chlorite, and sometimes feldspar. Cut by hornblende intrusions which are very likely same age as gabbro from which Roan gneiss was derived.

Crops out on Tempa Mountain just east of Spruce Pine, Mitchell County. This mass has a width of a little over 1 mile and a length of 4 miles.

Temperance River Group[1]

Precambrian (Keweenawan): Northeastern Minnesota.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 143–146, pl. 14.

Occurs along Temperance River.

Temperance River member[1]

Precambrian (Keweenawan): Northeastern Minnesota.

Original reference: A. H. Elftman, 1898, Am. Geologist, v. 21, p. 90–109, 175–188.

†Temple Bar Conglomerate[1]

Pleistocene, lower: Northwestern Arizona.

Original reference: W. T. Lee, 1908, U.S. Geol. Survey Bull. 352, p. 17.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1443. Term is confusing and should be abandoned because it was applied by Lee to deposits of widely different lithology and origin.

G. S. Lasky and B. N. Webber, 1949, U.S. Geol. Survey Bull. 961, p. 38. Name apparently applied to most of deformed valley deposits of northwestern Arizona which are now included in Sandtrap conglomerate (new), Chapin Wash formation (new), and Artillery formation (new).

Typically exposed near mouth of Virgin River at Temple Bar, northwest corner of Mohave County.

**Temple Butte Limestone**[1]

Upper(?) Devonian: Northern Arizona.

Original reference: C. D. Walcott, 1889, Geol. Soc. America Bull., v. 1, p. 50.

R. H. Denison, 1951, Fieldiana: Geology, v. 11, no. 5, p. 254. In Upper Devonian (Chemung stage).

T. F. Stipp and H. M. Beikman, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–201. Included in stratigraphic section of rocks in northwestern and central Arizona. Upper(?) Devonian.

Named for Temple Butte, 3 miles south of junction of Little Colorado River with Colorado River.

**Temple Cap Member** (of Navajo Sandstone)

Jurassic: Southwestern Utah.

R. K. Grater, 1948, Am. Jour. Sci., v. 246, no. 5, p. 312, 313. Sandstone composed of crossbedded, red, tan, or yellowish deposits. Uppermost part of Navajo; overlies several hundred feet of white crossbedded sandstone.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51 (table), 89, pl. 5. Upper part of member is cliff-forming sandstone, generally massive and strongly crossbedded but in places obscurely or definitely separated into layers 5 to 20 feet thick, most of them crossbedded. Lower part is miscellaneous assemblage of irregularly bedded shaly calcareous sandstones, siliceous limestones, and limestone conglomerates colored red, gray, or brown. Entire member not everywhere present and Carmel formation lies directly on central massive Navajo bed. Along Zion-Carmel highway, upper part, 70 to 180 feet thick, is intricately crossbedded mass divisible into thick beds, and lower part, 6 to 30 feet thick, a series of lenticular sandstones; east of Kanab Canyon upper division becomes thinner, less massive, and more varied in composition and lower part becomes thicker and more calcareous; from Hurricane Cliffs westward into Santa Clara Valley entire member is represented by yellow-gray sandy shale. Some fluvial and eolian beds here treated as Temple Cap have been assigned to Carmel formation by some workers. Jurassic(?). Derivation of name given.

U.S. Geological Survey currently designates the age of the Temple Cap Member as Jurassic on the basis of a study now in progress.

Unit forms an entablature for East Temple, West Temple, and similar lofty structures in Zion Park and vicinity.

**Temple Lake Stade, Till**

Temple Lake glacial stage

Recent: Rocky Mountain Region.

J. H. Moss, 1951, Early man in the Eden Valley: Philadelphia, Pa., Univ. Pennsylvania, Univ. Mus., p. 56–62. Name Temple Lake moraine is applied to moraine and associated outwash plain that dam Lower Temple Lake on north. The advance to the moraine is named Temple Lake readvance.

J. H. Moss, 1951, Am. Jour. Sci., v. 249, no. 12, p. 865–883. Discussion of late glacial advances in southern Wind River Mountains, Wyo. Temple Lake substage has an antiquity intermediate between late Pinedale and the present. If Pinedale is equivalent to Mankato (Wisconsin 3) relative weathering characteristics would indicate that Temple Lake advance occurred just before or soon after climatic optimum.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Section. [Guidebook] 2d Ann. Field Trip Oct. 4–5, correlation chart. In proposed time-stratigraphic standard for Rocky Mountain region, Recent epoch comprises (ascending) Castle Valley (new), Temple Lake, Spanish Valley (new), and Gannett Peak (new) stages.

G. M. Richmond, 1957, Internat. Assoc. for Quaternary Research, 5th Cong., Madrid. Two stages of Recent glaciation recognized in Rocky Mountain region: early Recent stage, Temple Lake; and late Recent stage, Gannett Peak. The Temple Lake (radiocarbon age 2800 200 years B. P.) is represented by cirque moraines, locally by two, that support scrub spruce on tundra and have thin azonal soil.

Temple Mountain Andesite

[Eocene or younger]: Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. At least two separate feeders for the extrusive andesites are recognized within area. In feeders, porphyritic andesite predominates; in extrusive andesites, breccias and amygdaloids predominate, with lahars common near base. Propylitization of andesites is due to endomorphism, not regional hydrothermal metamorphism. Underlies large body of quartz latite breccia, which possibly is extrusive phase of Grotto batholith. These andesites in part overlie the Swauk with angular unconformity, and in part intrude Swauk and Tonga (new) formations.

In eastern part of Skykomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

**Temple Mountain Member** (of Chinle Formation)

Upper Triassic: Southeastern Utah.

R. C. Robeck, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 10, p. 2499–2506. Consists of siltstone, mudstone, and sandstone; siltstone commonly light gray to some shade of mottled or banded purple and white; locally, layers of mudstone or lenses of sandstone impart bedding effect to siltstone; mudstone is purplish red, or mottled purple and white; sandstones light gray with tendency to weather light brown. Composition of member varies within area and lithologic types interfinger. In southwest, consists mostly of purple and white mudstone with lenses and layers of jasper; toward central part, siltstone ledges and sandstone lenses more abundant; at the north end, consists of alternating beds of siltstone, mudstone, and numerous sandstone channels and lenses which may be present at any interval in member. Thickness at type section 33 feet; elsewhere ranges from 5 to 101 feet. Unconformably underlies Moss

Back member; unconformably overlies Moenkopi formation, contact difficult to determine in places.

J. H. Stewart, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 3, p. 446–449; J. H. Stewart and others, 1959, U.S. Geol. Survey Bull. 1046–Q, p. 501–504. Some strata outside San Rafael Swell may be correlated with Temple Mountain member, but these correlations are questionable, and it seems best at present to restrict member to the Swell. Locally strata similar to Temple Mountain underlies Shinarump member, suggesting that Temple Mountain member may be oldest member of Chinle.

Type section: Northeast side of South Temple Mountain at lat 38°41'04", long 110°40'20", on southeast flank of San Rafael Swell, Emery County.

Temples Peak Flows (of Chico Phonolites)

Quaternary: Northeastern New Mexico.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1036. Bright- to gray-green porphyritic phonolite with white orthoclase phenocrysts and abundant aegirine. Topography of flows is gently rolling with sharp canyons; boundaries lobate in plan, and rise as abrupt rounded hill forms with many reentrants. Upper surface covered with thin soil and tetrahedral joint blocks.

West rim of J. T. Rincon sec. 11, T. 26 N., R. 26 E., Colfax County, and flow area 3 miles north and west.

Temples Peak Formation

[Triassic or older]: Northeastern New Mexico.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1035. Coarse white quartz-pebble conglomerate of an allover cream to buff color which weathers brown to dark brown. Strongly lithified and locally jointed into large blocks. Total exposed thickness of 19 feet, including 2 feet or less of an underlying gray-brown sandstone member whose base is covered. Underlies Dockum conglomerate horizontally.

Type locality: In bottom of the J. T. Rincon or bowl at east base of Temples Peak, Colfax County. The only other exposure of formation is in upturned sediments on east flank of Palo Blanco, Colfax County.

**Templeton Member** (of Woodbine Formation)

Upper Cretaceous: Northeastern Texas.

H. R. Bergquist, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 98. Defined to include fossiliferous sedimentary rocks that lie between beds of Lewisville member and flags which mark base of typical Eagle Ford shale. Consists largely of smooth gray shale with lenses of glauconitic gray and tan soft sand. Thickness 70 to 80 feet.

Type locality: In pasture and in series of bluffs along Templeton Branch on A. P. Templeton property a short distance north and east of Highway 69 underpass of Texas and Pacific Railroad at Bells, Grayson County.

**Tenderfoot Member** (of Moenkopi Formation)

Triassic(?): Southwestern Colorado and southeastern Utah.

E. M. Shoemaker and W. L. Newman, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1814, 1843–1845. Dominantly muddy or silty poorly sorted sandstone. Commonly at base, generally directly overlying Cutler formation, is sequence of beds up to 20 feet thick composed of weathered coarse arkosic detritus which is locally overlain by gypsum as much as 7 feet thick; next is unit of brick-red or orange- to dark-brown poorly sorted sandy mudstone to silty sandstone, which at most places makes up more than 80 percent of member; at most localities, this unit is succeeded by sequence of distinctly bedded sandstone. Thickness ranges from featheredge to 290 feet. In vicinity of Gateway, Colo., thins toward Uncompahgre Plateau; thinning due to overlap of basal beds and to truncation of top of member by overlying Chinle formation; locally cut out over salt intrusions by angular unconformity at base of overlying Ali Baba member (new) in Sinbad and Paradox Valleys, Colo., and probably in Fisher Valley, Utah. Locally overlies Paradox member of Hermosa formation.

J. H. Stewart, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1858. Correlated with Hoskinnini herein reallocated to member status in Moenkopi.

Type section: East side Sinbad Valley, sec. 15, T. 49 N., R. 19 W., Mesa County, Colo. Named for Tenderfoot Mesa, where it constitutes whole of formation on north side of mesa.

Tenley Formation[1]

Pliocene(?): District of Columbia.

Original reference: C. K. Wentworth, 1930, Virginia Geol. Survey Bull. 32, p. 37.

Named for exposures at Tenleytown.

**Tenmile Granite**[1]

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 131.

Named for Tenmile Creek, which enters Animas River, southeast of Snowdon Peak.

Tenmile Gravel

Pleistocene, lower: Southwestern Idaho.

C. N. Savage, 1958, Idaho Bur. Mines and Geology County Rept. 3, p. 20 (table 1), 26, 38–39, 48, figs. 3, 4. Characteristically, a torrential deposit of well-rounded to subangular crystalline rock. Silt, sand, gravel, and cobbles, nonconsolidated to poorly consolidated. Some caliche. Fluviatile, crossbedded, channeled, and stratified. Thickness about 500 feet. Underlies intermediate Snake River eruptives and overlies Idaho formation with unconformable contacts.

In Boise Valley, Ada and Canyon Counties.

Tenmile Limestone (in Greene Formation)[1]

Permian: Southwestern Pennsylvania.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 97, 105.

In Washington and Greene Counties.

†Tenmile Sands[1]

Pleistocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 20.

Named for exposures at Ten Mile Hill, on Charleston-Lanes Railway (A. C. L. Railroad) and at Ten Mile Hill, on Charleston-Branchville Railway (S. C. Railroad), Charleston County.

Tenmile Creek Dolomite

Middle Devonian: Northwestern Ohio.

G. A. Stewart, 1938, Geol. Soc. America Spec. Paper 8, p. 6, 7, 13. Three distinct lithologic units recognized in interval between Columbus limestone and Ohio shale. Name Tenmile Creek dolomite proposed for upper division. Fossiliferous. Thickness about 40 feet. Overlies Silica shale. Lower part may be time equivalent of Prouty limestone in north-central Ohio. Name credited to J. E. Carman (unpub. ms.). Name Traverse has been applied to interval between Columbus limestone and Ohio shale.

K. V. Hoover, 1960, Ohio Geol. Inf. Circ. 27, p. 8–15. Stratigraphic position and correlation of Olentangy shale discussed. It is here suggested that Olentangy, Plum Brook shale, Prout limestone, Silica shale, and Ten Mile Creek dolomite are stratigraphically correlatable, with the reservation that the Olentangy is probably Upper Devonian. Ten Mile Creek, which overlies Silica formation in northwestern Ohio, shows faunal affinity with Prout limestone of northern Ohio. Field relationships between limestone beds of Silica formation and Ten Mile Creek dolomite are similar. Both are bluish gray, argillaceous to crystalline, and thin to massive bedded. Regional information regarding thickness of Plum Brook shale-Prout limestone or Silica formation-Ten Mile Creek dolomite has not been worked out. Combined thickness of Silica formation and Ten Mile Creek dolomite has been reported in Lucas County exposures.

Tenmile Creek (also Ten Mile Creek) is just south of Silica, Lucas County.

Tenmile Creek Formation (in Stanley Group)

Pennsylvanian: Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 856, 864–870. Proposed for lowermost formation in group. Consists of alternating sandstones and shales; aggregate thickness 5,650 feet. Basal part overlapped to south by Cretaceous Trinity sandstone; underlies Moyers formation (new). Pushmataha series (new).

R. M. Becker, chm., 1954, Ardmore Geol. Soc. [Guidebook] Field Trip Oct. 1954, chart facing p. 1. Shown on chart as Mississippian (Meramecian); overlies Albion formation.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 25 (table 2), 29–36, pls. Includes Tuskahoma siliceous shale bed (member).

O. B. Shelburne, Jr., 1960, Oklahoma Geol. Survey Bull. 88, p. 16–19, pl. 1. In this report [Boktukola syncline], formation is mapped in two units: lower part of Tenmile Creek formation and upper part of Tenmile Creek formation. The units are separated by Battiest chert member (new). Thickness more than 7,600 feet. Underlies Moyers formation.

Type section: Three miles east of Miller, T. 3 S., R. 15 E., Pushmataha County. Name derived from Tenmile Creek at south end of Tuskahoma syncline.

Tenmile River Beds[1]

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 164–173.

Occurs in Tenmile River, Mass.

†Tennessee Sandstone[1]

Pennsylvanian: Western Arkansas.

Original reference: A. J. Collier, 1907, U.S. Geol. Survey Bull. 326, p. 19.

Typically exposed in Tennessee Ridge, Sebastian County.

Tennesseean Series

†Tennesseean System[1]

Mississippian: Eastern United States.

Original reference: E. O. Ulrich, 1905, U.S. Geol. Survey Prof. Paper 36, p. 24 (table).

R. C. Moore, 1948, Jour. Geology, v. 56, no. 4, p. 1. Upper Mississippian formations, which are classed as belonging to Meramecian and Chesterian parts of the American succession, collectively named "Tennesseean series," are judged on paleontological grounds to represent Visean and Namurian deposits of European continent.

Tennessee River Gravels[1]

Pleistocene: Western Kentucky.

Original reference: R. H. Loughridge, 1888, Kentucky Geol. Survey Rept. Jackson's Purchase region.

Probably named for exposures along Tennessee River.

†Tennessee River Group[1]

*See* Harpeth and Tennessee River Group.

**Tenney Canyon Tongue** (of Kayenta Formation)

Upper Triassic(?): Northeastern Arizona and southeastern Utah.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2522. Name applied to rocks in Kanab area that were classified by Gregory (1950) as Kayenta formation. Consists of very thin bedded to laminated pale-reddish-brown siltstone, mudstone, and very fine grained sandstone considered to be of fluvial origin. Contacts of unit with overlying Navajo sandstone and underlying Lamb Point tongue (new) of Navajo are sharp and even, marked by pronounced change in color, lithologic character, and crossbedding. Thickness 120 feet in Kanab Canyon; thins eastward from Kanab and pinches out between units of Navajo west of Paria; southwest of Kanab, tongue thickens gradually to 172 feet at Moki Mountain and 220 feet near Moccasin, Ariz.; west of Sevier fault coalesces with main body of Kayenta. Name credited to R. F. Wilson (in press).

J. S. Detterman, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–137. Mapped in Tenney Canyon, where it overlies Lamb Point tongue of Navajo sandstone.

U.S. Geological Survey currently designates the age of the Tenney Canyon Tongue as Upper Triassic(?). This designation made on the basis of recent studies of the Kayenta.

Name applied to rocks in Kanab area, Utah. Tenney Canyon, a side canyon to Kanab Canyon, is approximately 3 miles north of Kanab, Kane County, Utah.

Tennison Creek Shale[1]

Pennsylvanian: Eastern Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 90, 97.

Named for Tennison Creek, in western part of Bourbon County.

**Ten Rod Granite Gneiss**

Mississippian(?) or older: Southern Rhode Island.

G. E. Moore, Jr., 1958, U.S. Geol. Survey Geol. Quad. Map GQ–105. Pinkish- to medium-gray, fine- to medium grained porphyritic granite gneiss, with strong lineation and moderate foliation in most places. Phenocrysts of salmon-colored potash feldspar average about 30 mm long and constitute as much as 15 percent of rock. Flattened rod-shaped aggregates of quartz and streaks of thin elongate lenses of biotite locally present. Cuts Scituate granite gneiss. Devonian(?) or older. Has been included in Sterling gneiss by early workers.

U.S. Geological Survey currently designates the age of the Ten Rod Granite Gneiss as Mississippian(?) or older on the basis of a study now in progress.

Typically exposed in roadcut on Ten Rod Road, 0.85 mile west of Millville, Hope Valley quadrangle. Exposed in discontinuous belt of varying width that extends northwesterly across quadrangle from vicinity of Richmond School on southern boundary of quadrangle and in small bodies elsewhere in quadrangle.

**Tensleep Sandstone[1]**

Tensleep Formation

Tensleep Sandstone (in Montchauve Group)

Pennsylvanian and Lower Permian: Wyoming and Montana.

Original reference: N. H. Darton, 1904, Geol. Soc. America Bull., v. 15, p. 394–401.

C. C. Branson, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1199–1226. Tensleep sandstone of Darton is only locally recognizable as lithologic unit in central Wyoming and is not true stratigraphic unit. No boundary can be drawn to separate it from Amsden formation, and fauna of upper part of Amsden is indistinguishable from that of Tensleep sandstone. Name Tensleep is here retained as name of formation which includes entire Pennsylvanian sequence in central Wyoming; that is, Tensleep sandstone of Darton, the upper part of the Amsden, and some unnamed beds above Tensleep sandstone. Marine fossils indicate Des Moines age for entire formation. Measured sections show thickness varies from 180 to 535 feet. Underlies Phosphoria or Chugwater formation; overlies Sacajawea formation; in some areas, separated from the Sacajawea by unnamed limestone interval referred to as beds of Chester(?) age.

D. C. Skeels, 1939, Jour. Geology, v. 47, no. 8, p. 817 (table 1). Discussion of structural geology of Trail Creek-Canyon Mountain area, Montana. Table 1 lists Tensleep formation, 150 feet thick, above Amsden formation and below Ellis formation. Pennsylvanian.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 3 [revised 1950]. Discussion of correlation of formations of Laramie Range, Hartville uplift, Black Hills, and western Nebraska. Tensleep (Darton, 1904) is herein recognized as sandstone facies of Cassa group (new), but some geologists use term at its type locality to include also sandy beds of Embar age or older.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 126 (fig. 2), 131–132. Discussion of Wind River Mountain area. Tensleep formation, 398 to 535 feet thick, overlies Sacajawea formation and disconformably underlies the Phosphoria. Tensleep, as herein defined, includes upper part of Amsden formation of Darton and that name is dropped. On Bull Lake Creek, 60 feet of laminated limestone without fossils lies with irregular contact on the Sacajawea and is overlain disconformably by Tensleep formation. This sequence of laminated limestones may constitute another formation, possibly of Chester age.

Helen Foster, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1539 (table), 1558–1559. Tensleep formation described in Teton County, Wyo., where it is about 300 feet thick; overlies Amsden formation and underlies Phosphoria formation. Name Wells formation has been applied to Tensleep rocks in this part of Wyoming, but Wells formation probably includes not only beds equivalent to Tensleep but also younger Pennsylvanian rocks.

H. D. Thomas, 1948, Wyoming Geol. Assoc. Guidebook 3d Ann. Field Conf., p. 87, 88–89. Branson described Sacajawea formation, classed it as Ste. Genevieve, and carried name Tensleep down to base of sandstone he described (1939) as resting with marked disconformity on thin limestone he thought might be of Chester age. Now seems clear that Branson's type Sacajawea lies below Darwin sandstone and that his basal "Tensleep" sandstone, which he described as resting disconformably on older beds, is actually Darwin sandstone. Distinctive Tensleep sandstone can be recognized everywhere around Wind River basin. Lithologically it is massive crossbedded tan sandstone which in places may be pinkish or white. Locally, thin limestones, dolomites, or cherty layers are intercalated. Thickness commonly 300 to 400 feet. In Casper Mountain-Alcova area, at southeastern end of Wind River basin, name Casper has been used for Pennsylvanian rocks. Here the Casper is 400 to 500 feet thick and is therefore comparable to combined thickness of Amsden and Tensleep to west. Many geologists have divided the section into Amsden and Tensleep. Upper part of Casper is thick tan crossbedded sandstone which resembles Tensleep of areas to west, and has been called Tensleep by some geologists. However, entire Casper of this area seems completely younger than any part of Tensleep. Puzzling factor is that Tensleep sandstone of Wind River area is continuous with, and lithologically similar to, the "Tensleep" sandstone of Casper area, as proved by surface and subsurface data. Tensleep sandstone seems to be major lithologic facies which persists as a unit but which crosses time lines and becomes progressively younger to eastward.

R. S. Agatston, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 521–528. Tensleep sandstone was named by Darton (1904) and described as series of crossbedded sandstones underlying Permian red shales and limestones. Recommended herein that Tensleep be given formation status, that Darton's upper limit be retained, but that base be defined as top of massive generally cherty carbonate rocks of Amsden formation. Formation is composed of white, tan, and pink, fine- to medium-grained crossbedded massive sandstone with dolomite, limestone, and some shale and anhydrite beds. Throughout a large part of the research area, Amsden and Tensleep contact is sharp, and the two formations are conformable. Minor unconformities present locally. North of Tensleep is a related condition of alternating sandstone, shale, dolomite, and anhydrite beds at base of Tensleep, indicating instability in that area at that time. Tensleep or equivalent beds distributed throughout Big Horn basin, Big Horn Mountains, Powder River basin, Wind River basin and Mountains, Hartville uplift, and Black Hills. Lower Desmoinesian.

L. W. Henbest, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 58–63. Biostratigraphic range from latest part of "*Fusulinella*" zone (probably late Atoka age) through *Wedekindellina euthysepta*-zone (most of early half of Des Moines age) is indicated for beds in Tensleep formation in which collections were made. Information from unpublished dissertations as cited by Love (1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf.) reports discovery of *Triticites* in upper part of Tensleep in Jackson area. Illustrations have not been published, and determinations have not been verified in print. Some of the collections described in present report were found in chert nodules. Age determinations were of necessity based entirely on content of the nodules. Problem of possible redeposition in rocks of later age should be considered in future collecting from Amsden and Tensleep formations.

C. A. Burk and H. D. Thomas, 1956, Wyoming Geol. Survey Rept. Inv. 6, p. 10. Goose Egg formation (new) rests unconformably on Pennsylvanian or early Permian strata of the Tensleep, Casper, Hartville, or Minnelusa formations throughout Wyoming.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 23–25. Sandstone described in Buffalo-Lake De Smet area, Wyoming, where it is 280 feet thick. Overlies Amsden formation; separated from overlying Chugwater formation by unnamed gypsum and red shale sequence 180 feet thick.

T. W. Todd, 1959, Dissert. Abs., v. 20, no. 6, p. 2230–2231. Lithologically defined Sacajawea, Amsden formation, and Tensleep sandstone are products of marine transgressive-regressive cycle that took place on Wyoming cratonic shelf during Pennsylvanian period as one phase in development of eastern Cordilleran geosyncline. Name Montchauve group is suggested in recognition of natural unit of these formations.

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Discussion of regional stratigraphy of Pennsylvanian system in northeastern Utah, western Wyoming, northwestern Colorado, and southeastern Idaho. Suggested that Quadrant and Casper formational names be abandoned and Tensleep-Amsden-Sacajawea terminology be extended to include strata formerly referred to by these names.

Named for exposures in walls of lower canyon of Tensleep Creek, Washakie County, Wyo.

Tepee zone[1] (in Pierre Shale or Formation)

Cretaceous: Colorado.

[Original reference]: G. K. Gilbert, 1897, U.S. Geol. Survey Geol. Atlas, Folio 36.

M. O. Griffitts, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 12, p. 2020. Pierre formation subdivided into four zones (ascending): Sharon

Springs shale zone, Rusty zone, Hygiene zone, and Transition zone. These zone terms are recognized and used as formal stratigraphic names in present paper. Many geologists have noted a Tepee zone in eastern Colorado. Tepee zone should be correlated with Rocky Ridge member of Hygiene zone of northern Colorado.

Tepee Creek Formation

Permian: Southwestern Oklahoma.

C. A. Merritt and W. E. Ham, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 287, 290–299. Name applied to formation composed principally of zeolites and opal with variable amounts of dolomite and calcite; appears to be stratified. Maximum thickness 47 feet. Rests with erosional unconformity on anorthosite. Intruded by several small granite dikes of Precambrian age.

G. W. Chase, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2028, 2034. Name Tepee Creek dropped from formal nomenclature. Replaced by Post Oak conglomerate member of Wichita formation.

W. E. Ham, C. A. Merritt, and E. A. Frederickson, 1957, Panhandle Geol. Soc. [Guidebook] May 2, 3, 4, p. 26–28. As now used, term Tepee Creek is applied to zeolite-opal sediments that were deposited as anorthosite conglomerates and sandstones unconformably on basic igneous rocks in central part of Wichita Mountain region. Their age can no longer be accepted as Precambrian. Instead these sediments probably are coarse-clastic shoreward facies of shales in Wichita formation of lower Permian age. Type locality stated.

Type locality: SW¼SW¼ sec. 6, T. 4 N., R. 18 W., Kiowa County. Occurs as four scattered outcrops in interior part of Wichita Mountains. Named for exposures near junction of Tepee Creek and North Fork of Red River.

**Tepee Trail Formation**

Eocene, upper: Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 10, 11 (fig. 2), 73–79, pls. 13, 17. Proposed for upper Eocene sequence unconformably overlying Aycross formation (new) and all older rocks and, in turn, unconformably overlain by Oligocene(?) rocks. Chiefly green and olive-drab basic andesite volcanic conglomerates; tuffs, flows, and thin carbonaceous beds. Thickness 2,000 feet. In most localities, beds are gently folded. Unconformably underlies Wiggins formation (new).

H. A. Tourtelot, 1957, Smithsonian Misc. Colln., v. 134, pt. 1, no. 4, p. 5–19. Described in northeastern Wind River basin where it forms belt of outcrop along south side of Owl Creek and Big Horn Mountains. Southern boundary of belt is marked by normal fault along which Tepee Trail has been dropped down against Wind River formation. Consists of sequence of green, brown, and gray strata rich in volcanic material of andesitic composition. Sequence divided into a lower unit referred to green and brown member and upper unit named Hendry Ranch member. Maximum thickness not determinable because formation overlaps on topography of mountains and base is not exposed; thickness composite section about 700 feet. Top of formation is everywhere an erosional surface. Middle(?) and upper Eocene.

Type section: Slopes and cliffs on eastern side of East Fork River, directly opposite Castle Rock. Name derived from Tepee Trail which crosses East

Fork Creek divide midway between Castle Rock and Steamboat Rock, descends Boulder Creek, and joins East Fork Ranger Trail at junction of Boulder Creek with East Fork River. Type section is just east of junction of the two trails. Area is southern margin of Absaroka Range.

Tequepis Sandstone[1]

Miocene: Southern California.

Original reference: R. N. Nelson, 1924, Geol. Soc. America Bull., v. 35, p. 166–167.

Occurs on north side of Santa Ynez River, one-half mile east of Redrock Canyon. Named for exposures on Tequepis Rancho.

**Tererro Formation**

Mississippian: Northern New Mexico.

E. H. Baltz and C. B. Read, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1754 (fig. 5), 1755 (figs. 6, 7), 1756 (fig. 8), 1759–1768, 1769–1773. Sequence of limestone breccia and conglomerate, crystalline limestone, and calcarenite. Thickness ranges from trace to 130 feet in southern part of Sangre de Cristo Mountains and from 6 to 48 feet farther south; thickness at type locality 118 feet. Comprises (ascending) Macho, Manuelitas, and Cowles members (all new). Overlies Espiritu Santo formation (new) with erosional unconformity; unconformably underlies Sandia formation. Sparse faunule found in Manuelitas member indicates Early Mississippian for that part of formation; Macho member is, in part, possibly as old as Devonian(?) and, in part, Early Mississippian; because of its unconformable relation to Manuelitas member, Cowles member may be of Late Mississippian age. Further studies must precede correlation, firm assignments of age, and adjustments in terminology of Tererro, Espiritu Santo, and Arroyo Penasco formations.

Type locality: On slope and slightly north of quarry designated as type locality for Espiritu Santo formation, west of Holy Ghost Creek at Tererro, San Miguel County.

**Terlingua Clay**[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 33–41.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol. Survey Prof. Paper 312, p. 13–14, pl. 1. As mapped in Terlingua district, consists of about 1,000 feet of structureless clay and a few thin beds of impure limestone. Included are only the upper three-fourths of formation of Udden; lower three-fourths of formation is included in upper Boquillas as herein described. Likewise unit only includes upper half of what Adkins (1933, Texas Univ. Bull. 3232) called Terlingua formation (restricted) but includes in addition all of Adkins' Taylor formation. Overlies Boquillas flags; underlies Aguja formation.

Named for exposures along Terlingua Creek, Brewster County, in Terlingua quadrangle.

Terra Blanca Formation[1]

Quaternary: Texas.

Original reference: R. T. Hill, 1890, Am. Geologist, v. 5, p. 69.

In valley of Canadian River in Staked Plains. Terra Blanca is name used by Mexican inhabitants of valley.

**Terra Cotta Clay Member** (of Dakota Formation)

Terra Cotta Shale Member (of Ellsworth Formation)

Cretaceous: Central and southern Kansas.

R. C. Moore, 1935, Rock formations of Kansas, *in* Kansas Geol. Soc., Wichita: [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23.] Named on chart as lower member of Ellsworth formation. Underlies Rocktown sandstone. Overlies Mentor sandstone member of Belvidere formation.

Norman Plummer and J. F. Romary, 1942, Kansas Geol. Survey Bull. 41, pt. 9, p. 319, 329–336. Defined to include massive clay, silt, and sandstone comprising approximately lower two-thirds of Dakota formation; most conspicuous feature of member is widespread distribution of gray- and red-mottled massive clay. Thickness up to 170 feet. Underlies Janssen clay member, contact is not sharp but in most places can be drawn within 5-foot zone; in this report contact is arbitrarily placed at top of zone of concentrated concretionary siderite, limonite, or hematite, which is overlain by bed of gray massive clay containing varying amounts of siderite pellets and with yellow to yellow-orange coloring along oblique joints. Overlies Kiowa shale. Derivation of name given.

Entire section well exposed in school district of Terra Cotta, comprising part of T. 15 S., R. 6 W., in east-central part of Ellsworth County.

Terra Cotta Series[1]

Ordovician, Silurian, and Devonian(?): Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 156–157, 180.

Named for Terra Cotta Mountains.

Terra Loma Member (of Moreno Formation)

*See* Tierra Loma Shale Member (of Moreno Formation).

Terry Limestone (in Hinton Formation)[1]

Mississippian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western Mercer and Summers Counties, p. 69.

Occurs at Terry, Raleigh County.

**Terry Sandstone Member** (of Pierre Shale)[1]

Upper Cretaceous: Central northern Colorado.

Original reference: M. W. Ball, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, no. 1, p. 81–87.

G. R. Scott and W. A. Cobban, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf. Symposium, p. 128, 129 (fig. 3). Olive-gray massive fine-grained sandstone makes up member at type locality. Highly fossiliferous calcareous sandstone concretions 6 to 18 inches in diameter common. Thickness 10 to 20 feet. Separated from younger Rocky Ridge sandstone member by 511 to 604 feet of sandy and nonsandy shale; separated from older Hygiene sandstone member by as much as 387 feet of olive-gray sandy shale that locally includes Tepee-Butte limestone.

Named for exposures at Terry Lake 2 miles north of Fort Collins, Larimer County. Forms ridge between Terry Lake and Rocky Ridge Reservoir. North of Rocky Ridge extent of member not known.

Terry Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 295, 330.

Exposed in Mercer and Summers Counties, W. Va., and in Tazewell County, Va. Named for association with Terry limestone.

**Tesla Formation**

Eocene, middle: Central California.

A. S. Huey, 1937 (abs.) Geol. Soc. America Proc. 1936, p. 335. Incidental mention as formation of Eocene (Capay) age.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 16 (fig. 2), 33–38, pls. 1, 2, 3. Characterized by variety of sedimentary rocks including white quartz sand, buff sand, iron- and manganese-stained concretionary sand, dark carbonaceous shales, lignite seams, and white to light-blue clays. Maximum thickness about 2,000 feet near Tesla. East of Tesla, Corral Hollow fault cuts out about 700 feet of upper part of formation, and west of Tesla upper part of formation is progressively overlapped by Cierbo formation. Overlies Moreno Grande formation (new). Tesla, as mapped in this area, was called Tejon by Anderson and Pack (1915, U.S. Geol. Survey Bull. 603).

Typically and most completely exposed near former mining camp of Tesla, Tesla quadrangle, about 40 miles southeast of Berkeley.

**Tesnus Formation**[1]

Pennsylvanian: Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 45.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 53). Shown on correlation chart as Upper Mississippian and Lower Pennsylvanian.

W. B. N. Berry and H. M. Nielsen, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2257–2258, 2259. Overlies Santiago formation (revived). At many places, the two units grade into each other without any apparent depositional break. Santiago formation of this report contains fauna interpreted to be Late Devonian.

Named for exposures around Tesnus, Brewster County.

**Tessey Limestone**[1]

Upper Permian (Ochoa Series): Western Texas.

Original reference: J. A. Udden, 1917, Texas Univ. Bull. 1753, p. 53.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 662–663, pl. 2. Tessey limestone, at top of Permian sequence in Glass Mountains, is an obscurely bedded, nondescript, dolomitic limestone about 1,000 feet thick, whose facies resembles that of beds laid down in back-reef area in northern Guadalupe Mountains. It may be at least in part the calcareous equivalent of some of the evaporites of Ochoa series farther north. Unconformable below Bissett conglomerate.

Named for post office once located about 2 miles north of mouth of Gilliam Canyon, Brewster County.

**Tesuque Formation** (in Santa Fe Group)

Miocene, middle(?) to Pliocene, lower: Central New Mexico.

F. E. Kottlowski, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 148 (chart). On chart only. Contains Bishops Lodge member (new) near base. Age shown as Miocene and Pliocene.

Brewster Baldwin and F. E. Kottlowski, 1955, New Mexico Bur. Mines Mineral Resources Scenic Trips to the Geol. Past, no. 1, p. 20, 21, 24. Characterized by ledge-forming soft pinkish-tan sandstones. Thickness nearly 10,000 feet near Santa Fe. Underlies Ancha formation.

Brewster Baldwin, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 118–119. Included in Santa Fe group. Includes Bishops Lodge member at base. Puye gravel (Smith, 1938), Ancha formation, and Tuerto gravel all rest with angular unconformity on deformed beds of Tesuque formation.

Typical exposure in Sangre de Cristo Mountains, 10 miles north of Santa Fe.

**Tete des Morts Member** (of Edgewood Dolomite)

Lower Silurian: Northeastern Iowa.

C. E. Brown and J. W. Whitlow, 1960, U.S. Geol. Survey Bull. 1123–A, p. 39–40, pl. 3. Massive-bedded medium-grained finely porous grayish-orange to grayish-yellow glauconitic dolomite having fine white siliceous specks. Where member is thick, nodular bands of chert occur in 3-foot zone in middle. Thickness commonly 20 to 22 feet; thinner over areas of thick Maquoketa shale. Overlies Mosalem member (new); underlies Kankakee formation.

Named for many cliffs formed by these rocks along headwater drainage of Tete des Morts River in Jackson and Dubuque Counties.

**Tetelna Volcanics**[1]

Carboniferous: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 36, map.

Derivation of name not stated, and map shows no geographic feature of that name, but formation is mapped along Indian Creek, the Indian name of which is Tetelna.

†Teton Formation[1]

Permian and Triassic: Northwestern Wyoming.

Original reference: W. H. Weed, 1896, U.S. Geol. Survey Geol. Atlas, Folio 30.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2835. Report is summary description of Phosphoria, Park City, and Shedhorn formations; new nomenclature proposed; term Teton formation abandoned.

Named for Teton Range southwest of Yellowstone Park.

**Tetro Limestone Member** (of Deseret Formation)

Tetro Limestone[1]

Mississippian: Central northern Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). Shown on correlation chart of recommended revision of stratigraphic units of Great Basin. Occurs below Humbug limestone and above Gardner dolomite.

U.S. Geological Survey currently classifies the Tetro as a member of Deseret Formation on the basis of a study now in progress.

Probably named for Tetro mine, Tintic district.

**Teutonia Quartz Monzonite**

Upper Cretaceous or Tertiary, lower: California and Nevada.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 61–65, pl. 1. Proposed for several large bodies of intrusive rock that crop out in broad belt extending across [Ivanpah] quadrangle and exceeding 250 square miles in area.

Named for Teutonia Peak where it is typically exposed. South-central part Ivanpah quadrangle, San Bernardino County, Calif.

**Teutonic Limestone**[1]

Teutonic Limestone (in Hartmann Group)

Middle Cambrian: Central northern Utah.

Original reference: G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 5 (fig. 2), 6. Described in East Tintic Mountains where it conformably overlies Ophir formation and conformably underlies Dagmar limestone. Thickness 375 to 425 feet. Type locality noted.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 13–16, 79. Described in Stansbury Mountains where it is 800 to 1,110 feet thick. Underlies Dagmar dolomite; overlies Condor formation of Ophir group.

J. K. Rigby, 1959, Utah Geol. Soc. Guidebook 14, p. 14 (table 1), 17–18. Assigned to Hartmann group in southern Oquirrh Mountains. Exposed in core of Ophir anticline above Ophir shale [Ophir group] on north side of Ophir Canyon. Underlies Herkimer limestone, contact gradational.

Type locality: At Teutonic Ridge, 1½ miles west of Eureka, Tintic district, Juab County.

†Texan System[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lvii, 276–282, pl. 3.

Named for State of Texas.

**Texas Creek Granodiorite**[1]

Jurassic or Cretaceous: Southeastern Alaska.

Original reference: A. F. Buddington, 1929, U.S. Geol. Survey Bull. 807, p. 22–27, 58–60, maps.

F. M. Byers, Jr., and C. L. Sainsbury, 1956, U.S. Geol. Survey Bull. 1024–F, p. 126, pl. 13. Confined chiefly to central part of Hyder district.

Named for Texas Creek, Hyder district.

**Texas Gulch Formation** (in Alder Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 28–30, pl. 1. Composed of alternating belts of rhyolitic tuff and purple slate. Rhyolitic tuff generally gray or white but also commonly cream or light green; ranges from fine- through coarse-grained tuff to pebble conglomerates or to cobble conglomerates in local zones south of road to Cherry. Bulk of tuff is medium grained. Formation has been deformed intensely. Thickness and stratigraphic relationship not known. Probably older than Indian Hills volcanics (new). Crops out in band about 2,500 feet wide along western slope of Black Hills.

Representative section exposed in Texas Gulch, Jerome area, Yavapai County. Formation extends from southern border of area northward for about 14 miles to a point north of Jerome Highway where it is covered by Paleozoic rocks.

Texhoman series[1]

Tertiary, upper: Kansas.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 255.

**Thacher Member** (of Manlius Formation)

Lower Devonian: Eastern and central New York.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7, 9 (strat. section). Basal member of Manlius formation. Underlies Olney member; overlies Rondout limestone. Thickness 0 to 50 feet. Only part of Manlius present in eastern New York.

L. V. Rickard, 1956, Dissert. Abs., v. 16, no. 1, p. 102. Evidence indicates that entire type Manlius formation near Syracuse, central New York, is equivalent in age to Lower Devonian Coeymans and Kalkberg formations of eastern New York. Its reference to Silurian can no longer be upheld. The so-called Manlius of eastern New York is entirely older; name Thacher limestone is proposed for this unit. It becomes thinner to west and is apparently replaced by underlying and thickening Rondout.

Type locality and derivation of name not given.

**Thane Volcanic Group**[1]

Lower or Middle Jurassic(?): Southeastern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 247, 251–252, chart opposite p. 270.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Thane volcanic group (in part) mapped with Middle Jurassic rocks.

Settlement of Thane, on Gastineau Channel, lies in midst of these rocks; Juneau region.

**Thatcher Limestone Member** (of Graneros Shale)

Upper Cretaceous: Southeastern Colorado.

N. W. Bass, C. E. Straub, and H. O. Woodbury, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 68. Consists of two beds of dense dark-gray limestone separated by dark-gray fissile shale, about 5 feet thick. Limestone beds weather rusty brown; lower bed is 4 to 6 inches thick and less persistent than upper bed which is about 18 inches thick. Occurs about 30 feet above base of shale.

Well exposed under east fence of U.S. Highway 350 across road from Keith's store at Thatcher, Las Animas County, and from that point northeastward for several miles. Forms prominent bench throughout Model anticline and adjacent region.

†Thayer Shale (in Kansas City Formation)[1]

Pennsylvanian: Eastern Kansas and northwestern Missouri.

Original references: E. Haworth, 1895, Kansas Univ. Quart., v. 3, p. 276, pl. facing p. 290; 1895, Am. Jour. Sci., 3d, v. 50, p. 459, pl. facing p. 466.

Named for exposures at Thayer, Neosho County, Kans.

**Thaynes Limestone,[1] Formation,** or **Group**

Lower Triassic: Northeastern Utah, southeastern Idaho, southwestern Montana, and southwestern Wyoming.

Original reference: J. M. Boutwell, 1907, Jour. Geology, v. 15, p. 439–458.

W. R. Lowell and M. R. Klepper, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 240, 241. At McKnight Canyon section of Beaverhead formation (new), base of section is marked by high-angle normal faults which have dropped Beaverhead formation against Triassic Thaynes formation and Mississippian Madison limestone.

Bernard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 171–179. In type region, Thaynes formation consists of 1,190 feet of limestone, calcareous sandstone, sandstone, shale, and, in middle, red shale member. At type area, overlies Woodside formation and underlies Ankareh formation. Extends over wide area in Utah, Idaho, Wyoming, and Montana. Along southern, eastern, and northern margins, formation intertongues with Ankareh formation or Chugwater formation. Areas of occurrence discussed in detail. In vicinity of Fort Hall Indian Reservation, Mansfield (1916, Washington Acad. Sci. Jour., v. 6), raised Thaynes to rank of group and subdivided it into (ascending) Ross Fork limestone, Fort Hall formation, and Portneuf limestone. Toward Salt River Range and toward Bear Lake Valley, Ross Fork and Fort Hall formations lose their identity, and Portneuf is much more distinctive unit and name is retained as member of Thaynes. In this area, Timothy sandstone is considered uppermost member of Thaynes. In Eastern Bear Lake-Sublette Ridge area, eight lithologic units are recognized in Thaynes including Lanes tongue (new) of Ankareh formation in Portneuf limestone member. In northeastern Utah, Thaynes underlies Mahogany member (new) of Ankareh formation. Variable sequence of beds, that are commonly red, lies between top of Thaynes and base of Nugget sandstone throughout western Wyoming, southeastern Idaho, and northern Utah. Boutwell (1907) named these beds Ankareh formation. Although they are still so defined in western Wyoming, they have since been subdivided and named differently in other areas. Consequently there has been confusion in nomenclature and correlation of these formations. [See Ankareh formation.] Overlies Dinwoody in some areas of Montana and southeastern Idaho.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2185–2189, 2194. Term Thaynes formation extended into Confusion Range where it replaces term Woodside as used by Newell (1948, Geol. Soc. America Bull., v. 59, no. 10). On lithologic basis sequence could be referred either to Thaynes of northern Utah and Idaho, or Moenkopi as recognized in southern Utah. Use of Thaynes seems more appropriate because of greater lithologic similarity of Confusion Range Lower Triassic sequence to type Thaynes formation as defined by Boutwell (1907) and refined by Kummel (1954). Divided informally into seven gross lithologic zones. Aggregate thickness about 1,935 feet. Overlies

Gerster limestone; faunal evidence indicates considerable hiatus between the two formations.

Named after Thaynes Canyon, Park City district, Utah.

**Thebes Sandstone** (in Richmond Group)[1]

Upper Ordovician: Southwestern Illinois and southeastern Missouri.

Original reference: A. H. Worthen, 1866, Illinois Geol. Survey, v. 1, p. 139.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 94. In eastern Missouri, shales [Maquoketa] grade into a sandstone which seems to be same sandstone that was named Thebes by Worthen (1866); the Thebes seems merely to represent a facies change.

E. P. Du Bois, 1945, Illinois Geol. Survey Rept. Inv. 105, p. 7. Specific names, such as Fernvale limestone, Divine limestone, and Thebes sandstone have been applied locally to parts of Maquoketa formation, but it appears that none of these, except possibly Divine limestone, are consistent stratigraphic units.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 52). Correlation chart shows Thebes sandstone underlying Orchard Creek shale and overlying Maquoketa shale in southeastern Missouri.

Named for Thebes, Alexander County, Ill.

Theodosia Formation (in Jefferson City Group)

Lower Ordovician: Southern Missouri and northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 15, 25–32, pl. 2. Predominantly dolomite, principally of the "cotton rock" type; some massive crystalline dolomite beds are present in southern part of area; generally light gray to buff; thin irregular buff to brown dolomitic sandstone lentils common; light- to dark-gray, oolitic and nonoolitic chert abundant; chert conglomerate and breccia common near base. Comprises the Lutie below and the Blackjack Knob member (both new). As defined, includes beds previously called "upper Jefferson City" and "lower Cotter dolomite." Thickness as much as 360 feet. Underlies Cotter formation with contact probably unconformable; unconformably overlies Rich Fountain formation (new).

Type section: Composed of two sections exposing two separate members; lower part, between post offices of Theodosia and Lutie in western part of Ozark County, Mo.; upper part, north side of Blackjack Knob, eastern Taney County, Mo. Lutie member is more wide-spread on outcrop in Missouri; Blackjack Knob member more widely distributed along boundary between the two States and in Arkansas.

**Theresa Dolomite**[1]

Upper Cambrian: Central to eastern New York.

Original reference: H. P. Cushing, 1908, Geol. Soc. America Bull., v. 19, p. 159–160.

R. H. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939. Cambro-Ordovician correlations revised in Champlain, Hudson, Mohawk, and St. Lawrence Valleys. Revisions involve definitions and succession of previously accepted Cambro-Ordovician formations: Potsdam, Theresa, Hoyt, and Little Falls of Upper Cambrian age and

Whitehall, Tribes Hill, and Beekmantown of Lower Ordovician age. Lower "typical" Theresa of Cambrian age is physically and faunally differentiated from "Upper Theresa" (now Heuvelton) member of Tribes Hill formation; Hoyt fauna occurs in lower half of emended Whitehall formation above Little Falls dolomite. Each revised unit is tied in with Divisions A through E of original "Calciferous" formation (Brainard and Seely, 1890, Am. Mus. Nat. History Bull., v. 3).

R. H. Wheeler, 1942, Am. Jour. Sci., v. 240, no. 7, p. 523–524. Corrected Skene Mountain section shows Theresa formation, about 80 feet thick, overlying Potsdam formation and underlying Little Falls formation.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 795–814. Evidence presented to substantiate radical change in interpretation of Paleozoic stratigraphy of Saratoga Springs region. Previously accepted sequence of beds (Potsdam sandstone, Theresa formation, Hoyt limestone, Little Falls dolomite, Amsterdam limestone, Trenton limestone, and Canajoharie shale) is revised to read Potsdam sandstone, Galway formation, Hoyt limestone, Ritchie limestone (new), Mosherville sandstone (new), Gailor dolomite, Lowville limestone, Amsterdam limestone, Trenton limestone (Rockland?, Hull, Sherman Fall representatives), and Canajoharie shale. Term "Theresa" is not applicable in this area; name Galway is reintroduced for strata younger than Potsdam and older than Hoyt.

Named for exposures in Theresa Township.

Theresa Syenite[1]

Precambrian: Northeastern New York.

Original reference: H. P. Cushing and others, 1910, New York State Mus. Bull. 145, p. 38, map.

Small intrusive mass, less than 2 miles in length and less than one-half mile broad, lying south of Theresa, Jefferson County.

**Thermopolis Shale**

Thermopolis Shale (in Colorado Group)[1]

Lower Cretaceous: Central northern Wyoming and central southern Montana.

Original reference: C. T. Lupton, 1916, U.S. Geol. Survey Bull. 621, p. 168.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. Chart shows Thermopolis shale above Kootenai formation and below Mowry shale. Includes Muddy sandstone member at top. Not included in Colorado group.

R. M. Thompson, J. D. Love, and H. A. Tourtelot, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 36; J. D. Love and others, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–43. Name Thermopolis has been used in different senses; these usages have evolved into two general and quite different classifications in central Wyoming. Classification preferred by authors of this report and used in subsurface studies restricts Thermopolis to Lower Cretaceous black shale below Muddy sandstone and above "Rusty beds" sandstone and shale member of Cloverly formation; Muddy sandstone is considered a formation directly overlain by Mowry shale. Classification used by U.S. Geological Survey divides Thermopolis into three units: lower black shale of Lower Cretaceous age, ranging in thickness from 100 to 200 feet, that overlies Cloverly formation; middle sandstone member, the Muddy, of Upper Cretaceous age [presently considered Lower Cretaceous]; and upper black shale which grades into Mowry shale.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 45–47. Described in Hardin area, Montana-Wyoming, where it is 425 feet thick; overlies Cloverly formation and underlies Mowry shale. Restricted to exclude Birdbear sandstone which is reallocated to member status in Cloverly. Lower Cretaceous.

M. M. Knechtel, 1959, U.S. Geol. Survey Bull. 1072–N, p. 739–740, pl. 52. Described in Little Rocky Mountains, Montana, where it consists chiefly of dark-bluish-gray shale and includes numerous thin bentonite beds. Near the middle is a prominent sandy unit herein named Cyprian sandstone member. In earlier publications in area, unit herein called Cyprian was tentatively designated Muddy sand. Thickness about 600 feet. Overlies Kootenai formation; underlies Mowry shale.

Ralph Moberly, Jr., 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1149. Overlies Sykes Mountain formation (new).

Arthur Mirsky, 1960, Dissert. Abs., v. 21, no. 4, p. 850. Term Rusty Beds formally named as member of Thermopolis.

D. L. Eicher, 1960, Yale Univ., Peabody Mus. Nat. History Bull. 15, 126 p. As defined here, includes only that part of Lupton's (1916) Thermopolis shale which lies below Muddy sandstone (herein given formational rank) and is about 300 feet thick in Big Horn basin. Consists of black shale, basal member of which contains tan and rusty interbedded siltstones and sandstones about 120 feet thick, commonly called "rusty beds." Shale sequence above rusty beds is divided near middle into lower and upper parts by tan-weathering silty shale about 30 feet thick. Lower shale, below middle silty shale, contains a few thin ironstones, siltstones, and silty limestones throughout, and dahllite concretions in lower part. Upper shale, above middle silty shale, is generally darker and contains nearly no siltstone or limestone. Overlies Cloverly formation. Upper sequence of black shale and bentonites, overlying Muddy sandstone and formerly included in Thermopolis is herein named Shell Creek shale. Lupton named Thermopolis shale for exposures in area of town of Thermopolis but designated no type section; he presented supplementary lithologic description generalized from subsurface samples from near basin, 50 miles north. Detailed description of Thermopolis in its type area has never been published; entire sequence is not well exposed at any one place near Thermopolis. Lower Cretaceous. Type section designated for redefined Thermopolis. Regional relationships discussed. Detailed discussion of problems of nomenclature.

Type section (Eicher): On northeast and southwest flanks of Lucerne anticline, east of Big Horn River, in NW sec. 16, T. 43 N., R. 94 W., Hot Springs County, Wyo. Named for exposures near Thermopolis, Wyo.

The Rocks Sandstone

Eocene: West-central California.

R. R. Thorup, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1958. Listed as underlying Berry conglomerate and overlying Lucia shale (both new). Thickness about 1,500 feet.

R. R. Thorup, 1943, California Div. Mines Bull. 118, pt. 3, p. 465. Described as tan massive thick-bedded fine- to medium-grained well-sorted feldspathic sandstone. Disconformably underlies Berry conglomerate; conformably overlies Lucia shale. Formerly considered part of Vaqueros which is herein stratigraphically restricted in its type area.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 55. Quite probable that some part of The Rocks formation is of Ulatisian age.

Type locality: Sec. 27, T. 20 S., R. 6 E., Junipero Serra quadrangle, Monterey County. Named because of its tendency to form rugged topography.

Therrill Formation

Therrill Member (of Weches Formation)

Eocene, middle: Eastern Texas.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 97, 106–108. Upper member of Weches formation. Composed of black to black-green clay with iron sulphide nodules, a small amount of glauconite, and few fossils where fresh, and of brown shales or yellow and red clays with some yellow calcareous clay-ironstone concretions where weathered. Thickness about 4 or 5 feet. Overlies Viesca member (new) with boundary transitional; underlies Sparta sand.

H. B. Stenzel, 1953, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists and Mineralogists, and Soc. Econ. Geologists Guidebook, Joint Ann. Mtg., Houston, p. 47, 49. Shown on road log as formation. Thickness as much as 52 feet.

Type locality: Waterfalls near Magnolia Brown pump station and tank farm near center of Magnolia Petroleum Co. tract, J. B. and J. E. Therrill survey, Leon County.

The Straits Schist Member (of Hartland Formation)

Pre-Triassic: Western Connecticut.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey; John Rodgers, R. M. Gates, and J. L. Rosenfeld, 1959, Connecticut Geol. Nat. History Survey Bull. 84, p. 14. Described as coarse to very coarse muscovite schist. Commonly crumpled and cut by quartz veins and pegmatite. Locally quartz, with feldspar, and mica dominate alternate layers, and rock approaches gneiss. Includes lenticular bodies of gneiss.

M. H. Carr, 1960, Connecticut Geol. Nat. History Survey Quad. Rept. 9, p. 7–8, pl. 1. Described and mapped in Naugatuck quadrangle. At base of Hartland.

Named for The Straits, a defile on the Bethany-Naugatuck Road or Litchfield Turnpike near north edge of town of Bethany, New Haven County.

Thetis group[1]

Upper Cretaceous: Northwestern Alaska.

Original reference: A. J. Collier, 1905, U.S. Geol. Survey Bull. 259, p. 179.

Mined at Thetis mine, East of Cape Lisburne.

Thiensville Formation[1]

Middle Devonian: Southeastern Wisconsin.

Original reference: E. R. Pohl, 1929, Pub. Mus. City Milwaukee Bull., v. 11, p. 7–8.

F. C. Foley, W. C. Walton, and W. J. Drescher, 1953, U.S. Geol. Survey Water-Supply Paper 1229, p. 14–15. Middle Devonian.

Type locality: Cut on Highway 57, 2 miles north of Thiensville, near middle of E½ sec. 10, T. 9 N., R. 21 E., Ozaukee County.

Thirteen Mile Rock Tuff

Miocene, upper: North-central Arizona.

B. E. Sabels, 1960, Dissert. Abs., v. 21, no. 3, p. 596. Incidental mention in discussion of late Cenozoic volcanism in San Francisco volcanic field.

Thirtynine Mile Volcanic Series

Oligocene, lower(?): Central Colorado.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 101–103, pl. 1. Flows, both dense and very vesicular, flow breccias, and agglomerates. Some vesicular lavas have abundant amygdules of calcite or chalcedony or both. Flow structure not well developed. Porphyritic facies subordinate to aphanitic facies. Little bedding or evidence of succession of flows and agglomerates can be seen. Composition of series ranges from andesite to basalt. Attains thickness of 2,000 feet on south side of Thirtynine Mile Mountain and in Pikes Peak quadrangle. In most places, it overlies the Precambrian complex. Patches of Cretaceous rocks and of Denver formation preserved here and there and protrude from under volcanic cover. Mapped as Thirty-nine Mile andesite on plate 1.

Well exposed in Thirtynine Mile Mountain in southeastern corner of South Park, Park County. Total area underlain by series, both within and outside the Park, is about 300 square miles.

Thomas Clay (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, pl. 7.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 121. In northern Appalachian region, Anderson underclay, which takes its name from overlying Anderson coal in Ohio, is known as (Lower) Bakerstown or Thomas clay.

Georges Creek Basin.

Thomas Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 60, 119, pl. 6.

Named for its position beneath Thomas coal in Upper Potomac Basin.

Thomas Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland and northeastern West Virginia.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 60, 119, pl. 6.

Named for its position above Thomas coal in Upper Potomac Basin, Md.

Thomas Hill Shale[1]

Pennsylvanian: Northeastern Missouri.

Original reference: H. A. Wheeler, 1893, Missouri Geol. Survey Sheet Rept. 2, v. 9, p. 63.

Named for exposures at Thomas Hill, Randolph County.

**Thomaston Granite**

Thomaston Granite Gneiss[1]

Upper Ordovician: Western Connecticut and southeastern New York.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 109–110, map.

Robert Balk, 1936, Geol. Soc. America Bull., v. 47, no. 5, p. 755–756, pl. 1. Geographically extended into New York.

T. W. Fluhr, 1948, Rocks and Minerals Mag., v. 23, no. 8, p. 699. In vicinity of New York, underlies Amawalk granite (new).

E. N. Cameron and others, 1954, U.S. Geol. Survey Prof. Paper 255, p. 22. Upper Ordovician.

R. M. Gates, 1954, Connecticut Geol. Nat. History Survey Quad. Rept. 3, p. 6. Name Thomaston granite should not be applied to the granite in Woodbury quadrangle [this report]. The Thomaston includes such a variety of granites, pegmatites, granitic gneisses, and feldspathic metasediments that it has a different meaning in every area. Granite in area of this report is herein named Nonewaug granite.

D. M. Scotford, 1956, Geol. Soc. America Bull., v. 67, no. 9, p. 1177. In area of this report [northeastern Westchester County], granite that was called Thomaston by Balk (1936) is herein named Siscowit granite. Rock is not continuous with Thomaston type area and bears little resemblance to the Thomaston.

Type locality: Abandoned quarry at Reynold's Bridge south of city of Thomaston, Litchfield County, Conn.

Thomasville Glacial Substage

Pleistocene (Iowan): West-central Colorado.

R. L. Nelson, 1954, Jour. Geology, v. 62, no. 4, p. 328–329, fig. 2, table 4. Time of oldest Wisconsin glaciation in Frying Pan Valley. Older than Biglow glacial substage (new); younger than Lime Creek glacial substage (new). Marked by moraine and outwash deposits.

An end-moraine thought to be the terminal of the Thomasville advance lies 1 mile upstream from Thomasville. In Frying Pan River drainage just west of Continental Divide in Sawatch Range.

**Thompson Limestone[1]**

Middle Jurassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, chart 8C (column 92). As shown on correlation chart, Thompson limestone occurs above Fant andesite and below Mormon sandstone. Middle Jurassic.

Named for exposures on Thompson's Ranch, on west slope of Mount Jura, east of Taylorsville, Plumas County.

Thompson Slate[1]

Precambrian: Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. and Nat. History Survey Final Rept., v. 4, p. 551.

*See* Thomson Slate or Formation.

Thompson Red Shale[1]

Middle Jurassic: Northern California.

Original reference: C. H. Crickmay, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 81.

Mount Jura.

**Thompson Canyon Sandstone Member** or **Bed** (in Neslen Formation)

Thompson Canyon Sandstone Bed (in Price River Formation)[1]

Upper Cretaceous: Central eastern Utah.

Original reference: D. J. Fisher, 1935, U.S. Geol. Survey Bull. 852.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, pl. 1 facing p. 1011 (column 39). Listed on correlation chart as member of Neslen formation.

D. J. Fisher, C. E. Erdman, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 17. Referred to as bed in Neslen formation.

Named for Thompson Canyon in Book Cliffs.

†Thompson Creek Beds[1]

Oligocene, lower: Western central Montana.

Original reference: E. Douglass, 1902, Am. Philos. Soc. Trans., v. 20, new ser., pt. 3, p. 237–245.

Probably named for exposures on Thompson Creek, 3 miles northwest of Three Forks, Broadwater County.

Thompson Valley Limestone

Middle Ordovician: Southwestern Virginia and northeastern Tennessee.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1152–1156. Proposed for thick-bedded light-gray commonly variegated coarse-grained limestone referred to as zone 6 of Tazewell County classification by Cooper and Prouty. This zone was included by them in their Ward Cove limestone (1943) which is here restricted to *Nidulites* beds (zone 7). Thickness 75 feet at type section; about 250 to 300 feet in Fountain City, Tenn. Underlies Ward Cove limestone; overlies Lincolnshire formation. In Saltville belt, beds similar to Thompson Valley limestone and exposed in McNutt Quarry, 1½ miles southeast of Sharon Springs, Va., were referred to as Effna limestone (Cooper, 1944). The Effna is below the Whitesburg, Athens, and Peery limestone sequence southeast of Saltville thrust. The Effna is thought to be partly equivalent to Thompson Valley but because relationships are indefinite, use of the two names seems advisable. Partially equivalent to Farragut limestone (new).

Type locality: Thompson Valley, Tazewell County, Va.

Thomson Formation

Thomson Slate[1]

Precambrian: Northeastern Minnesota and northwestern Wisconsin.

Original reference: J. E. Spurr, 1894, Am. Jour. Sci., 3d, v. 48, p. 159–166.

G. M. Schwartz, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1001–1020; 1949, Minnesota Geol. Survey Bull. 33, p. 18–36. Thomson formation has been referred to in literature as Thomson slate, St. Louis slates, Cloquet slates, and Carlton slate, but term Thomson slate has priority. Herein suggested that term Thomson formation replace Thomson slate, because more than 50 percent of exposed part of formation is graywacke. Thickness about 20,000 feet. Beds have been compressed into series of folds that strike east-west. Formation has been variously correlated but in recent years has usually been considered equivalent of Animikie-Virginia slate of Mesabi Range. Detailed work suggests that this correlation is untenable and that formation is pre-Algoman. Detailed evidence given, and progressive metamorphism of formation to south described. Revised correlation suggests the possibility of occurrence of upturned Biwabik iron formation in 50-mile covered interval between Cloquet and Mesabi Range. Data likewise throw doubt on correlations proposed for Cuyuna Range about due west of southern exposures of main Thomson area. The Thomson is separated from the Lower Keweenawan (Puckwunge formation) by pronounced angular unconformity. Possibility of Thomson formation and Knife Lake series being equivalent of formations classified as Archean in Canada is not excluded.

Named for exposures along St. Louis River not far from Duluth, near Thomson, Carlton, and Cloquet, Minn.

Thoreau Formation (in San Rafael Group)

Upper Jurassic: Northwestern New Mexico.

C. T. Smith, 1951, *in* New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 13 (chart), 38. Underlies Chavez member (new) of Morrison formation; overlies Todilto limestone.

C. T. Smith, 1954, New Mexico Bur. Mines Mineral Resources Bull. 31, p. 14–15. Consists of lower even-bedded sandstone and siltstone member and upper cross-laminated sandstone member; distinction between units not clear cut although upper member is generally more massive and coarser grained than lower. At type locality (herein designated), a little more than 200 feet of beds are assigned to lower member and 184 feet to upper member. Thins eastward; about 275 feet at eastern edge of quadrangle; most of thinning is in lower member. Local limestone lenses and limy siltstone mark gradation between Thoreau and underlying Todilto limestone.

J. A. Momper and W. W. Tyrrell, Jr., 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 23–24. Upper Jurassic.

Type section: On west edge of quadrangle south of Mount Powell in secs. 9 and 17, T. 14 N., R. 13 W. Named for exposures along cliffs north of Thoreau, McKinley County.

Thorn Group

Middle Silurian (Niagaran): Northern Illinois, northern Indiana, and southeastern Wisconsin.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 9 (fig. 2), 18. Includes all Niagaran formations exposed in Chicago region, in southeastern Wisconsin, and Wabash Valley of northern Indiana. It is predominant group of the low-clastic sedimentation belt; thins southward, forming tapering wedge that overlies Bainbridge group; at least 450 feet thick in syncline immediately west of La Salle anticlinal belt. Interreef strata are distinguished by their gray to greenish-gray color and abundance of chert; they differ from Bainbridge group in being predominantly dolomite and in containing reef-divided carbonate clastics. Local formation names are used in Chicago area and in northern Indiana. [Report deals with Niagaran reefs and their relation to oil accumulation; much data relative to thickness and distribution of units are based on subsurface studies.]

Essentially all lithologic types in group are represented in quarry at Thornton in southern suburbs of Chicago in secs. 28 and 33, T. 36 N., R. 14 E., about one-half mile west of Thorn Creek.

Thorncrag Biotite-Sillimanite Gneiss

Thorncrag Limy Gneiss (in Tacoma Series)

Middle Silurian: Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Listed in table of formations. Basal unit of Tacoma series (new). Older than Stetson Brook limestone (new); younger than Bates limestone (new). Cambro-Ordovician(?).

L. W. Fisher, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 71. In Lewiston area are seven formations (ascending): Danville injection gneiss (new), Androscoggin gneiss, Bates crystalline limestone, Deer Rips lime-silicate-gneiss (new), Thorncrag biotite-sillimanite gneiss, Tacoma lime-silicate series, and Sabbatus quartz-sillimanite biotite schist. Middle Silurian.

Occurs in Lewiston area, Androscoggin County.

Thorn Hill Formation[1]

Lower Ordovician: Northeastern Tennessee.

Original reference: G. M. Hall and H. C. Amick, 1934, Tennessee Acad. Sci. Jour., v. 9, no. 2, p. 158–161.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 23, 50, 54. Unit formerly termed Thorn Hill is now included in Kingsport limestone and Mascot dolomite.

Type exposure: On highway about one-half mile from Thorn Hill post office, Morristown quadrangle, Grainger County.

Thornton Fire Clay (in Conemaugh Formation)[1]

Thornton clay member

Pennsylvanian (Conemaugh Series): Northern West Virginia, western Maryland, and eastern Ohio.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 322.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 57, 60, table 1. Included in Mahoning cyclothem in Perry County.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 28–29, geol. map. In Morgan County, Thornton clay member (Conemaugh series) occurs between Mahoning limestone member and Mahoning coal; rests on Lower Mahoning sandstone and shale member in areas where the limestone is absent. Thickness about 2½ feet.

Named for Thornton, Taylor County, W. Va.

**Thorofare Andesite[1]**

Upper Silurian: Central southern Maine.

Original reference: G. O. Smith, 1896, Geology of the Fox Islands, Maine, p. 12, 30–45.

Named for development on shores of Fox Island Thorofare, between North Haven and Vinalhaven Islands, Penobscot Bay region.

**Thorold Sandstone** (in Albion Group)

Thorold Sandstone (in Clinton Group)

Thorold Sandstone Member (of Albion Sandstone)[1]

Lower Silurian: Ontario, Canada, and western New York.

Original reference: A. W. Grabau, 1913, Geol. Soc. America Bull., v. 24, p. 431, 460–463.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3, p. 15. Correlation chart shows Thorold sandstone at top of Albion group below Maplewood shale of Clinton group. Thorold is considered base of Clinton by some workers.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 13 (fig. 2), 15 (table 2), 24–29. Thorold can be traced from Niagara Gorge eastward through Lockport and Gasport outcrops to Genesee Gorge and eastward from the gorge to western Cayuga County. Overlies Grimsby sandstone; underlies (eastward) Neahga shale, Reynales limestone, Maplewood shale, and Bear Creek shale. Lower part of Clinton group.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Thorold sandstone occurs at base of Clinton group (Niagara Falls quadrangle); underlies Neahga shale; overlies Grimsby sandstone and shale of Medina group. Thorold of Gillette (1947) is not continuous with type Thorold; name Kodak sandstone (Chadwick, 1920 [?]) is revived for basal sandstone of Clinton group in New York.

Named for exposures on Welland Canal, at Thorold, Ontario.

Thoroughgood Formation

Devonian: Southern New Mexico.

R. H. Flower, 1958, Roswell Geol. Soc. Guidebook, 11th Field Conf., p. 74, 75. Yellow sands and silts with shaly interbeds. Thickness 12 feet. Only thinning edge of unit present in Rhodes Canyon where it underlies Rhodes Canyon formation (new) and overlies Contadero formation.

F. E. Kottlowski, 1959, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec., and Roswell Geol. Soc. Guidebook Joint Field Conf., Apr. 17–18, p. 265, 266. Thoroughgood and Rhodes Canyon formations are informal units not yet properly defined. "Thoroughgood" formation consists of tan blocky silty fine-grained sandstone and shaly calcareous siltstone; thins from 12 feet on Sheep Mountain to 24–6 inches in Rhodes Canyon.

In Rhodes Canyon [San Andres Mountains, Sierra County].

Thorp Springs Limestone[1]

Lower Cretaceous (Comanche Series): Central northern Texas.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 509.

Crops out for several miles along bed of river at Granbury and Thorp Springs, Hood County, and also in bed of Paluxy at Glen Rose, Somervell County.

Thousand Creek Beds[1] or Formation

Pliocene (Hemphillian): Northwestern Nevada and southeastern Oregon.

Original reference: J. C. Merriam, 1910, California Univ. Dept. Geology Bull., v. 6, no. 2, p. 43–50.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 33, pl. 1; D. J. Jones, M. D. Picard, and J. C. Wyeth, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2221 (table). Pliocene (Hemphillian).

D. O. Cochran, 1959, Oregon Dept. Geology and Mineral Industries Bull. 50, p. 10 (chart), 14. Thousand Creek formation listed with Cenozoic formations of Oregon. Light-colored stratified tuffs, containing rhyolite fragments and pumice. Thickness about 400 feet. Overlies Danforth(?) formation; underlies Mesa basalts.

Thousand Creek, Thousand Creek Ridge, Thousand Creek Canon (Canyon), and Thousand Creek Flats are in Humboldt County, Nev.

**Thousand Springs Basalt**[1] (in Snake River Group)

Pleistocene: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 30, 75–76, pl. 5. Thickness about 100 feet. Constitutes filling of ancient river channel carved in Hagerman lake beds. Younger than Malad basalt. Older than Burley lake beds and Sand Springs basalt.

U.S. Geological Survey currently classifies the Thousand Springs Basalt as a formation in the Snake River Group on the basis of a study now in progress.

Type locality: Thousand Springs, southwest of Wendell, in Gooding County, issue from this basalt.

†Thrall Limestone Member (of Foraker Limestone)[1]

Pennsylvanian: Southeastern Kansas.

Original reference: N. W. Bass, 1936, Kansas Geol. Survey Bull. 23.

Named for Thrall post office, Greenwood County.

**Threadgill Member** (of Tanyard Formation)

Threadgill Limestone

Lower Ordovician: Central Texas.

V. E. Barnes, 1942, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 54, p. 1, 2. Ordovician Threadgill limestone grades downward into Cambrian Wilberns limestone. Name credited to Bridge and Barnes (unpub. ms.).

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 143, 148, 151, 156, pl. 4 [1945]. Threadgill limestone revised to include equivalent dolomite as well and designated as Threadgill member of Tanyard formation. As a general rule, member is principally or wholly limestone in west, grading eastward to dolomitic facies and showing such abrupt lateral transitions from limestone to dolomite that it is difficult to determine whether a given contact is a lateral transition, a collapse contact, or a fault. At type section 280 feet from base to Cretaceous overlap; elsewhere thicknesses range from 91 feet in eastern part of Llano region to 313 feet in west. Underlies Staendebach member; overlies Pedernales dolomite member of Wilberns formation.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 37, 190–191 pl. 6 [1946]. Type section and local stratigraphy described in detail.

V. E. Barnes and W. C. Bell, 1954, San Angelo Geol. Soc. Guidebook, Mar. 19–20, p. 35. Name Pedernales member of Wilberns formation dropped. Section shows Treadgill member of Tanyard above San Saba member of Wilberns.

Type section: On Threadgill and Mormon Creeks, south of Lange's mill, northwestern Gillespie County.

**Three Forks Shale,[1] Limestone,[1] or Formation**

Upper Devonian and Lower Mississippian: Montana, Idaho, North Dakota, South Dakota, and Wyoming.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110.

G. W. Berry, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 14, 17 (fig. 4). Stratigraphically restricted at top to exclude about 60 feet of yellow sandstone herein named Sappington sandstone.

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1095, 110–111, pl. 1 Three Forks limestone described in Borah Peak quadrangle, Idaho, where it is about 250 feet thick, overlies Grand View dolomite and underlies Milligen formation. Upper Devonian.

L. L. Sloss and W. M. Laird, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 8, p. 1421. In this report, Sappington sandstone is considered local member of Three Forks formation. Thickness at Logan, Mont., 150 feet. Overlies Jefferson formation; underlies Lodgepole limestone of Madison group. Recommended that term Potlatch be used in subsurface in preference to Three Forks and Jefferson in Sweetgrass arch area.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2321 (fig. 7), 2322–2326. Peale (1893) described five lithologic units in Three Forks from top to base: (1) yellow laminated sandstone, 25 feet; (2) dark-bluish-drab or black argillaceous limestone, 45 feet; (3) fossiliferous green, purple, and black calcareous shale, 70 feet; (4) grayish-brown limestone, 15 to 20 feet; and (5) reddish and brownish-yellow calcareous shale, 65 feet. Berry's (1943) Sappington sandstone is Peales uppermost unit (1). In present report, the Sappington is considered a member of the Three Forks but is assigned a Late Devonian and Early Mississippian age. Sloss and Laird (1947) excluded Peale's lowermost units 4 and 5 from the Three Forks. This was done on incorrect assumption that Peale had included these units (which Sloss and Laird described as "breccias and associated shales") with Jefferson formation. It is herein recommended that lower contact of Three Forks as originally defined by Peale be reestablished. The "breccias and associated shales" unit of Sloss and Laird is integral part of Three Forks and has been correlated northward from Logan area to Sweetgrass arch area where is is equivalent to upper part of Potlatch anhydrite formation as defined by Perry (1928). It is herein designated Potlatch member of Three Forks. In standard subsurface section, herein designated, Three Forks overlies Birdbear formation (new) and underlies Bakken formation.

Type section (Sloss and Laird): North side of Gallatin River at Logan, Mont. Named for exposures at junction of Three Forks of Missouri River, near Three Forks, Mont.

Standard subsurface section: In Williston basin and Montana east of 111° meridian in interval between depths of 10,076 and 10,310 feet in Mobil Producing Co. Birdbear Well 1, center SE¼NW¼ sec. 22, T. 149 N., R. 91 W., Dunn County, N. Dak.

**Threemile Limestone Member** (of Wreford Limestone)

Threemile Limestone (in Chase Group)[1]

Permian: Northeastern Kansas.

Original reference: R. C. Moore, 1936, Kansas Geol. Soc. 10th Ann. Field Conf., Guidebook, p. 12.

D. E. Hattin, 1957, Kansas Geol. Survey Bull. 124, p. 29–39. Basal member of Wreford limestone. Consists of basal thick-bedded cherty limestone unit which is separated from main body of limestone by persistent calcareous shale or shaly to thin-bedded argillaceous limestone; locally contains algal bed at top. Thickness ranges from 6½ feet in Marshall County to slightly less than 33 feet in Wabaunsee County where reeflike expansion in upper part augments normal development. Underlies Havensville shale member. Type exposure defined as exact type locality has not been stated. Wolfcamp series.

Type exposure: In quarry in NW¼SW¼ sec. 11, T. 11 S., R. 6 E., on Fort Riley Military Reservation, near Threemile Creek, Geary County, a few miles southwest of Ogden, Riley County.

Three Rivers Schist (in Kaweah Series)

Triassic(?): Southern California.

Cordell Durrell, 1940, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 1, p. 15, 116, fig. 29, geol. map. Youngest of the four units included in series. Overlies Homer quartzite (new). Mica schists compose most abundant rock type with limestones next. Radiolarian type chert, acid and basic volcanic rocks, and argillaceous sediments present in lesser amounts. West of Sheep Creek, section is about 10,000 feet thick, top not present.

Occurs in southern Sierra Nevada, north-central Tulare County.

†Three Twins Member (of Chalk Bluff Formation)[1]

Permian: Southeastern New Mexico.

Original reference: W. B. Lang, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7.

G. E. Hendrickson and R. S. Jones, 1952, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 3, p. 16 (fig. 3), 20, 21. Described in Eddy County. Consists of evaporites, red beds, and dolomitic limestone. Overlies Seven Rivers gypsiferous member of Chalk Bluff and Azotea tongue of Carlsbad limestone. Grades southward into Carlsbad.

Term Three Twins abandoned as corollary action to abandonment of Chalk Bluff Formation.

Named for exposures in Spencer Draw in Three Twins Hills, northeast of Carlsbad, Eddy County. Exposed over small area in northern part of Azotea Mesa and large area east of Lake McMillan.

**Thrifty Formation** (in Cisco Group)[1]

Thrifty Group

Upper Pennsylvanian: Central and central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 152, 153; 1922, Jour. Geology, v. 30, p. 24.

Wallace Lee and others, 1938, Texas Univ. Bur. Econ Geology Pub. 3801, p, 54–61, 122–128. In Brazos River section, formation includes (ascending) Avis sandstone, Blach Ranch limestone, Ivan limestone, and Breckenridge limestone members. In Colorado River section, includes (ascending) Avis sandstone, *Bellerophon* limestone, Speck Mountain shale, Speck Mountain limestone, Lohn shale, Parks Mountain sandstone, and Chaffin limestone members. Overlies Graham formation; underlies Harpersville formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 90–92. Rank raised to group and expanded upward to redefined Pennsylvanian-Permian boundary. Systemic boundary falls within Harpersville formation which term is abandoned. Includes (ascending) Avis sandstone, Ivan (Rocky Mounds; *Bellerophon*). Specks Mountain (Blach Ranch), Breckenridge, Chaffin, and Obregon (new) formations. Overlies Graham group; underlies redefined Permian Pueblo group.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook May 25–26, fig. 4. Generalized columnar section shows base of Thrifty group at top of Breckenridge limestone. Includes Quinn clay, Crystal Falls limestone, and Saddle Creek limestone.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook Apr. 17–19, p. 50. Composite section of Brown and Coleman Counties shows formation includes (ascending) Speck Mountain limestone, Parks Mountain sandstone, and Chaffin limestone.

D. A. Myers, 1958, Jour. Paleontology, v. 32, no. 4, p. 678 (fig. 1). Columnar section shows formation includes (ascending) Speck Mountain, Breckenridge, and Chaffin members.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58 (table 1), 71–74, pl. 27. Plummer and Moore described Thrifty formation as including sandstone, shale, and limestone overlying their Wayland shale and extending to top of their Breckenridge limestone (the limestone at top of Drake's Chaffin bed). As redefined herein, Thrifty formation consists of (ascending) Speck Mountain limestone, Breckenridge limestone, Parks Mountain sandstone, and Chaffin limestone members. Thickness about 55 feet in southern Coleman County; average thickness about 100 feet in northern Brown County. Overlies Graham formation; underlies Pueblo formation of Wichita group.

Named for Thrifty, Brown County, Colorado River region.

**Thumb Formation**

Cretaceous(?): Southeastern Nevada.

C. R. Longwell, 1952, Utah Geol. Soc. Guidebook 7, p. 34 (fig. 4), 35. Between 2,000 and 3,000 feet of gypseous redbeds, fresh-water limestone, and conglomeratic sandstones interspersed with many extensive lenses of megabreccia. Basal conglomerate bevels Aztec, Chinle, and Moenkopi formations. Unconformably underlies Horse Spring formation.

Well exposed east of Frenchman Mountains.

**Thunder Bay Limestone**[1] (in Traverse Group)

Middle and Upper(?) Devonian: Northeastern Michigan.

Original reference: C. C. Douglass, 1839?, Michigan Leg. H. Doc. 27, between p. 97 and 111.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3) 593–594. Although Thunder Bay was first formation named from Alpena region, most authors have overlooked its description. Grabau (1902) used term Thunder Bay for series comprising all Traverse rocks above Alpena limestone, leaving Douglass' original beds without a specific name. Warthin and Cooper (1935) proposed term Partridge Point for exact sequence described by Douglass, but this name, together with Grabau's Thunder Bay series, should be abandoned in favor of earlier usage of name. At Partridge Point, section consists of basal bluish argillaceous limestone, weathering to rusty brown, 1 foot to lake level; 3-foot covered interval; shale, gray, calcareous, with limestone lenses, becoming predominantly granular limestone at top, 7½ feet; and limestone, gray, irregularly bedded, weathering to buff, 2 feet; here underlies glacial lake deposits. Stratigraphically above Potter Farm formation and below Squaw Bay limestone. Upper Devonian. Data on type locality.

Type locality: Bluffs on shore of Partridge Point, extending from center into SE¼ sec. 11, T. 30 N., R. 8 E., Alpena County. In original description locality is given as "the south cape of Thunder Bay." This is not South Point, near Alpena-Alcona County line, but Partridge Point, about 3 miles south of Alpena, Alpena County.

Thunder Bay Series[1]

Middle Devonian: Northeastern Michigan.

Original reference: A. W. Grabau, 1902, Michigan Geol. Survey Rept. 1901, p. 192.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 539. Should be abandoned in favor of earlier use of name, Thunder Bay limestone.

Named for exposures on Thunder Bay, at and around Alpena.

**Thunderhead Sandstone** (in Great Smoky Group)

Thunderhead Conglomerate (in Chilhowee Group)[1]

Precambrian (Ocoee Series): Eastern Tennessee and western North Carolina.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 2.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 958–959. Redescribed as sandstone. Reallocated to Great Smoky group. Thickness about 8,000 feet near Thunderhead Mountain; 6,000 feet on Mount Le Conte, and more than 10,000 feet in northeastern part of mountains. These thicknesses are not of wholly contemporaneous beds because span of formation becomes progressively higher eastward; lower part in west is equivalent to Elkmont sandstone (new) farther east, and upper part in east is equivalent to Anakeesta formation (new) farther west. Type Clingman is probably equivalent to upper beds of Thunderhead sandstone.

Named for development on Thunder Head, Blount County, Tenn., and Swain County, N.C. Thunderhead Mountain is in remote part of region; formation is better exposed on Mount Le Conte farther east where full section is present.

Thurman Formation

Oligocene and and Miocene: Southwestern New Mexico.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 114 (fig. 14), 121–123. Basal part of formation in Thurman Arroyo is dense cream- to tan-colored resistant rhyolite tuff-breccia about 50 to 100 feet thick. Above this bed are alternating and intercalated thinner units of pinkish sandy clay and thicker units of rather evenly bedded tuff and tuffaceous sandstone. White fine- to medium-grained crystal tuff dominates section. Locally, as at type locality, thin flow of dark amygdaloidal basalt intercalated with tuffaceous sandstone. Characteristically white to light buff in outcrops. Thickness about 2,100 feet at type locality where it unconformably underlies Santa Fe formation and conformably overlies Palm Park formation (new).

Type locality: Along road to Palm Park barite mine in secs. 35 and 36, T. 18 S., R. 3 W., Donna Ana County. Named from Thurman Arroyo at south end of Caballo Mountains.

**Thurman Sandstone**[1] (in Cabaniss Group)

Pennsylvanian (Des Moines Series): Eastern and central Oklahoma.

Original reference: J. A. Taff, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 439.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1524 (fig. 1), 1525. Basal formation of Cabaniss group (new).

J. V. A. Trumbull, 1957, U.S. Geol. Survey Bull. 1042–J, p. 335, pl. 1. In northwest Pittsburg County, Thurman is from 290 to 350 feet thick and consists of alternating beds of sandstone and shale, with basal bed of conglomerate or coarse sandstone in many places. Overlies Boggy formation; underlies Stuart shale.

Named for former village of Thurman, (about 6 miles west of Indianola) in northern part of Pittsburg County. Crops out in strip a few miles wide extending through northern Coal, western and northwestern Pittsburg, and western McIntosh Counties.

**Thurmond Formation** (in Pottsville Group)[1]

Middle Pennsylvanian: Southern West Virginia.

Original reference: M. R. Campbell, 1902, U.S. Geol. Survey Geol. Atlas, Folio 77.

Well exposed at town of Thurmond, Fayette County.

**Thursday Dolomite**

Middle Silurian: Northwestern Utah.

F. W. Osterwald, 1953, U.S. Geol. Survey Trace Elements Inv. Rept. TEI–330, p. 105; H. M. Staatz and F. H. Osterwald, 1959, U.S. Geol. Survey Bull. 1069, p. 19 (fig. 2), 28–29, pl. 1. Light-gray medium-grained friable rock; medium-grained gray dolomite bed about 15 feet thick with 1- to 4-inch bands of pink chert parallel to bedding present about 135 feet from base of formation in northern part of Spors Mountain; in northern part of district network of thin brown chert present in several beds about 340 feet above base of formation. Thickness about 329 feet. Overlies Lost Sheep dolomite (new); underlies Sevy dolomite. Complete sections rare; formation is either cut off by faults or covered by Lake Bonneville beds in most of district.

Type section: About 4,200 feet west-southwest of Thursday mine, Juab County. Well exposed in northern half of Spors Mountain where it caps a series of long northeast-trending ridges.

Tiawah Limestone Bed (in Scammon Formation)

Tiawah Limestone Member (of Cabaniss Formation or Senora Formation)

Tiawah Lime[1] (in Boggy Formation)

Pennsylvanian (Des Moines Series): Northeastern Oklahoma and southeastern Kansas.

Original reference: S. W. Lowman, 1932, Summaries and abstracts of technical papers presented before Tulsa Geol. Soc. 1932, unpaged, paper dated Dec. 19, 1932.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 26. In northeastern Oklahoma, included in Senora formation; stratigraphically below Chelsea sandstone member.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 54–55. Limestone bed in Scammon formation. In Crawford County, Kans., typically extremely dense, tough, and pyritic, forming a single resistant ledge. Thickness in Cherokee County, Kans., about 4 inches; in type area about 4 feet.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as limestone member of Cabaniss formation. Below Chelsea sandstone.

Well developed in hills around Tiawah, Rogers County, Okla.

Tibbit Hill Schist[1]

Precambrian or Lower Cambrian: Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1934, Geol. Soc. America Bull., v. 45, no. 1, p. 6, 10.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137–138. Chloritic and epidotic schists varying from very dark green to dull yellowish green. Less metamorphosed parts invariably fine textured. Amygdules sparingly present; occur in bands in several places. Included in discussion of Oak Hill series. Underlies Call Mill slate. Lower Cambrian or Precambrian. Type locality cited.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1135, 1136, 1138–1141. Geographically extended into Vermont. Thickness unknown since base nowhere exposed.

R. A. Christman, 1959, Vermont Geol. Survey Bull. 12, p. 14–23, geol. map. In Mount Mansfield quadrangle, underlies Camels Hump group. Occurs in core of Fletcher anticline. Cambrian.

Named for Tibbit Hill west of Brome Lake in Sutton quadrangle, Quebec. Hill is composed largely of the schist.

Tibes Diorite

Upper Cretaceous: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 112–113, geol. map. Intrudes lower Maestrichtian [Upper Cretaceous] rocks of Río Blanco formation. Does not intrude Eocene Jacaguas group.

Time of intrusion definitely post early Maestrichtian and probably pre-middle Eocene.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 85. Coarsely crystalline diorite made up of gray plagioclase feldspar and hornblende. Intrudes rocks of Río Chiquito formation. Footnote states name Río Chiquito no longer used; unit currently assigned to Río Blanco formation.

Occurs on western margin of Ponce quadrangle and extends several kilometers to west into Peñuelas quadrangle, south-central part of island.

**Tice Shale** (in Monterey Group)[1]

Miocene, upper: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

M. N. Bramlette, 1946, U.S. Geol. Survey Prof. Paper 212, pl. 2. Shown on stratigraphic section as occurring at base of Kleinpell's Mohnian stage, upper Miocene.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 70–71, pls. Described in Coast Ranges immediately north of San Francisco Bay region. Thickness 300 to 350 feet. Underlies Hambre sandstone; overlies Oursan sandstone. Locally faulted against Pinole tuff.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 19, fig. 2, geol. map. Thickness 250 to 900 feet in Pleasanton area, Alameda and Contra Costa Counties. Overlies Oursan sandstone; underlies Hambre sandstone. Term Monterey group not considered appropriate in this area.

Named for exposures along Tice Creek, Concord quadrangle.

**Tichenor Limestone Member** (of Ludlowville Shale)[1]

Tichenor Formation

Middle Devonian: Western to central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 22 and table.

A. J. Mozola, 1951, New York State Water Power and Control Comm. Bull. GW–26, p. 13. In Seneca County, Tichenor limestone member defines upper limit of Ludlowville. Composed of layers of dense light-colored limestone that are several inches thick overlain by hard calcareous shale about 5 feet thick. Underlies Moscow shale.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, no. 5–6, p. 369–371, pl. 1. Member, in eastern part of Batavia quadrangle, is 9 feet thick; thins toward east and west. Overlies Ledyard-Wanakah member; underlies Deep Run member.

T. B. Coley, 1954, Jour. Paleontology, v. 28, no. 4, p. 453, 454, 455 (fig. 2). Referred to as Tichenor formation. Thickness 1 foot, at Jacox Run near Geneseo. Overlies Wanakah formation; underlies Deep Run formation.

Type locality: Tichenor Point, on Canandaigua Lake, in Ontario County.

Tick Canyon Formation

Miocene, lower to middle: Southern California.

R. H. Jahns, 1939, Am. Jour. Sci., v. 237, no. 11, p. 819–821. Detailed mapping of so-called Mint Canyon formation north and northeast of

Saugus and study of new vertebrate material from lowermost beds have led to revision in stratigraphy. Lower beds are termed Tick Canyon formation; Mint Canyon formation is retained for middle and upper beds, and Mint Canyon series is applied to strata as a whole. Tick Canyon consists mainly of red and reddish-brown clay (in part lacustrine), siltstone, and sandstone, with irregular zone of cobble to boulder conglomerate at base. Thickness varies; average approximately 350 feet. Disconformably underlies Mint Canyon formation; overlies Vasquez series; between Mint and Vasquez Canyons, the Tick Canyon lies in a steeply dipping depositional contact upon basement complex of pre-Cretaceous schists, quartzites, granodiorites, and migmatic rock types.

R. H. Jahns, 1940, Carnegie Inst. Washington Pub. 514, p. 147–194, pls. Tick Canyon formation (basal beds of Hershey's, 1902, California Univ. Pub., Dept. Geol. Bull., v. 3, Mellenia series and Kew's, 1924, U.S. Geol. Survey Bull. 753 Mint Canyon formation) are traceable in narrow irregular band extending from Tick Canyon area northwesterly to point between Vasquez and Texas Canyons, where lack of exposures prevents their demarcation from overlying Mint Canyon strata. Thickness 593 at type locality herein designated.

R. H. Jahns and W. R. Muehlberger, 1954, California Div. Mines Bull. 170, map sheet 6. Generalized stratigraphic column for Soledad basin shows Tick Canyon 0 to 900 feet thick.

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 23 (fig. 3), 63, pl. 1. In San Fernando quadrangle, exposed in narrow band 2 miles long between Texas and Mint Canyons, and in separate area extending approximately 1 mile both east and west of Tick Canyon. Maximum thickness 593 feet (Jahns, 1940). Thins westward and is apparently overlapped by Mint Canyon formation before reaching Texas Canyon. Lies unconformably on Upper Jurassic(?) or Lower Cretaceous(?) gneissoid granite across Vasquez Canyon and, west of that canyon, was deposited across Vasquez Canyon fault and on eroded surface of Vasquez formation. Southeastern one-half mile of this contact southeast of Vasquez Canyon may be near-vertical fault. Present north of San Gabriel fault.

Type section: Between Mint and Vasquez Canyons in Humphreys quadrangle, Los Angeles County. Named for exposures about one-half mile down canyon from abandoned borax mine at head of Tick Canyon, as well as in vicinity of Tick Canyon-Mint Canyon divide, Lang quadrangle.

Ticklenaked Formation

Age not stated: Northeastern Vermont.

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 20, 26, 27. Overlies Barton River formation. Refers to mapping by W. S. White and J. H. Eric, (unpub. theses).

Occurrence: Vermont part of Littleton quadrangle, Vermont-New Hampshire.

**Tickville Rhyolite**[1]

Eocene(?): Central northern Utah.

Original reference: J. Gilluly, 1932, U.S. Geol. Survey Prof. Paper 173, p. 60–61.

Occurs near Tickville.

Ticonderoga Formation

Cambrian (Trempealeauian) : New York and Vermont.

C. W. Welby, 1959, New England Intercollegiate Geol. Conf., p. 23, 33, pl. 1. Consists of dark-weathering medium- to dark-gray medium and finely crystalline dolostones with interbedded coarse- and medium-grained quartz sandstones. Maximum exposed thickness about 90 feet at Thompson Point; outcrop width south of Vergennes suggests thickness of as much as 350 to 400 feet. Overlies Potsdam sandstone; underlies Whitehall formation. Name credited to J. Rodgers.

Type section: On Mount Hope at Ticonderoga, N.Y.

Tidioute shale member[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 116–119, table opposite p. 61.

Named for excellent exposure along Allegheny River at Tidioute, Warren County, and along State highway through Dennis Run, 1 mile southwest of Tidioute.

**Tie Gulch Dolomite Member** (of Manitou Formation)

Lower Ordovician: Central northwestern Colorado.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 892 (fig. 2), 893, 904 (fig. 9), 906–907. Proposed for regularly bedded thin-bedded medium-brown dolomite that forms upper part of formation. Thickness 47 to 66 feet. Overlies Dead Horse conglomerate member (new); underlies Parting member of Chaffee formation.

Type locality: Walls of Tie Gulch at east end of U.S. Highway 6 bridge over Tie Gulch, which enters Glenwood Canyon near center sec. 15, T. 5 S., R. 87 W., Garfield County.

Tierra Blanca Member (of Lake Valley Formation)

Mississippian (Osage) : Southwestern New Mexico.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 11, 13–14, 61, figs. 4, 29. Medium-bedded hard gray to brown coarse-grained criquina that carries considerable light-colored nodular chert. Most of the basal beds are interbedded with blue-gray marl so that line between Nunn and Tierra Blanca members is difficult to draw. Upper part invariably gray to brown criquina with up to 50 percent chert. Approximately 50 feet of section exposed at Lake Valley. Thickness ranges from 10 feet in parts of Sacramento Mountains to 125 feet in Percha Creek area. Rapid lateral changes in thickness common where biohermal structures are present. Cliff former and in most places makes vertical scarp along mountain front. Conformably underlies Arcente member.

F. E. Kottlowski, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 34. Member is typical biostromal and biohermal limestone in San Andres Mountains and grades laterally and vertically into overlying and underlying shaly members. Overlies Alamogordo member in Ash Canyon; elsewhere in range overlies Nunn member.

Type section: On Apache Hill at type section of Lake Valley formation near Lake Valley, NE¼NW¼ sec. 21, T. 18 S., R. 7 W., Sierra County. Named for Tierra Blanca Creek along which are excellent exposures in vicinity of Nunn Ranch.

Tierra Loma Shale Member (of Moreno Formation)

Upper Cretaceous: Southern California.

M. B. Payne, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1954; 1951, California Div. Mines Spec. Rept. 9, p. 6 (fig. 2), 8 (fig. 4), 9, 24, pls. 2, 3, 4, 5. Principally brown shale. Thickness about 1,200 feet. Includes 190-foot Mercy sandstone lentil (new) about 70 feet below top. Underlies Marca shale member (new); overlies Dosados sand and shale member (new). On basis of this mapping, it is concluded that Anderson and Pack (1915) show base of Moreno formation in Ortigalita Creek some 1,800 feet stratigraphically lower than their type Moreno in Moreno Gulch.

Type locality: Escarpado Canyon, secs. 7 and 8, T. 15 S., R. 12 E., Panoche Hills, Fresno County. Escarpado Canyon is 6 miles south of Moreno Gulch and 2 miles north of Panoche Creek. Named for Tierra Loma Schoolhouse on Tierra Loma quadrangle near E¼ cor. sec. 9, T. 14 S., R. 12 E.

**Tieton Andesite**[1]

Pleistocene: Central Washington.

Original reference: G. O. Smith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 86.

W. C. Warren, 1941, Jour. Geology, v. 49, no. 8, p. 797 (fig. 2), 806–808. Further described in discussion of relationship of Yakima basalt to Keechelus andesitic series. Younger than Yakima basalt. Area of report is Mount Ait quadrangle.

Probably named for occurrence in Tieton Canyon, Ellensburg quadrangle.

Tiff Member (of Goddard Formation)

Mississippian: Southern Oklahoma.

C. W. Tomlinson and Allan Bennison, 1960, Oklahoma Geology Notes, v. 20, no. 5, p. 123–124. Proposed to replace preoccupied name Grindstone Creek member of Goddard formation of Tomlinson (1959). Consists of 10 to 40 feet of light- to dark-gray pelletal or gritty claystone. About 500 feet below Rod Club member of Springer formation. Fossiliferous.

Type section: NE¼SE¼SE¼SE¼ sec. 16, T. 3 S., R. 1 E., in gully at north end of large cutbank at east side of Grindstone Creek. Tiff was rural community 1 mile north and 2 miles east of type section and was on Caddo anticline in Carter County.

Tiffanian Age

Paleocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 9, pl. 1. Provincial time term, based on Tiffany local fauna, often used in a more extended sense as a faunal level, northern rim of San Juan Basin, southwestern Colorado. Includes interval between Paleocene Torrejonian (older) and Clarkforkian ages. Report defines 18 provincial time terms, based on mammal-bearing units for North American continental Tertiary. [For sequence see under Puercan.]

Typical area: Mason pocket, sec. 20, T. 33 N., R. 6 W. [La Plata County, Colo.].

†Tiffany Beds (in Wasatch Formation)[1]

Paleocene: Southwestern Colorado and northwestern New Mexico.

Original reference: W. Granger, 1917, Am. Mus. Nat. History Bull. 37, p. 826–830.

H. E. Wood 2d, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 33. Tiffany could and should be defined as either a member or a formation; additional field work is desirable.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 275, 276 (fig. 2). Tiffany is faunal rather than stratigraphic term, but its rehabilitation in latter sense is probable outcome of still more detailed, combined paleontological and stratigraphic study. Tiffany local fauna is in lower part of San Jose formation as proposed in this report.

Type locality: Sec. 20, T. 33 N., R. 6 W., La Plata County, Colo. Named from Tiffany Station, on Denver & Rio Grande Railroad, 4 miles south of Mason Schoolhouse.

Tiflis Member (of Wahluke Formation)

Pleistocene, upper: Central Washington.

G. F. Beck, 1936, Mineralogist, v. 4, no. 11, p. 12. Name applied to upper part of formation. Member grades from water-laid materials at base to loess at top. Average thickness 15 feet.

Deposited in Tiflis downward north of Warden, Grant County.

**Tigaraha Schist**[1] (in Kigluaik Group)

Lower Paleozoic or older: Northwestern Alaska.

Original reference: F. H. Moffit, 1913, U.S. Geol. Survey Bull. 533, p. 20–33, maps.

Type locality: Includes sharp peak, near head of Buffalo Creek, named Tigaraha Mountain, Eskimo word for pointed.

**Tiger Formation**

Tertiary: Northeastern Washington.

C. F. Park, Jr., and R. S. Cannon, Jr., 1943, U.S. Geol. Survey Prof. Paper 202, p. 23, pl. 1. Name applied to semiconsolidated continental deposit consisting of conglomerates, sandstones, and clays; beds ill defined and materials poorly sorted. Maximum thickness about 1,000 feet. Overlies Metaline limestone.

M. C. Shroeder, 1952, Washington Div. Mines and Geology Bull. 40, p. 7 (chart), 20–21. Described in Bead Lake district where it unconformably overlies Pend Oreille andesite.

Extensively exposed in hills south of Tiger, Pend Oreille County.

†Tiger Creek Sandstone Member (of Bristow Formation)[1]

Pennsylvanian: Central Oklahoma.

Original reference: A. E. Fath, 1917, U.S. Geol. Survey Bull. 661B, p. 73–74, pl. 5.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey. Appears to be Paola "limestone" member of Oread formation.

Named for exposures in south part of sec. 6, T. 17 N., R. 10 E., on south side of small tributary of Tiger Creek.

**Tightner Formation**[1]

Mississippian: Northern California.

Original reference: H. G. Ferguson, 1929, Am. Inst. Mining and Metall. Engineers Tech. Pub. 211, p. 4.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 15). Shown on correlation chart above Blue Canyon formation and below Kanaka formation.

Named for fact it forms principal wall rock of Tightner mine. Extends from North Yuba [Sierra County] to South Yuba.

**Tiglukpuk Formation**

Upper Jurassic: Northern Alaska.

R. W. Imlay, 1955, U.S. Geol. Survey Prof. Paper 274–D, p. 70–71, Coarsely clastic facies of Jurassic sedimentary rocks in northern Alaska. Characterized by conglomerate, graywacke, sandstone, chertlike material (possibly devitrified tuff), tuffs, sills, pillow lavas, and a few thin beds of limestone. Interbedded with dark siltstone and shale which constitute as much as 50 percent of some sections and as little as 10 percent of others. Coarser constituents of conglomerate range in size from granules to boulders; matrix is graywacke. Sills identified only west of Anaktuvuk River, and lavas only between Nuka and Utukok Rivers. Limestone occurs as thin coquinas composed of pelecyod *Aucella*. Thickness ranges from featheredge to about 2,000 feet; highly variable along strike and absent locally within belt of outcrop. Overlies Triassic and older rocks with angular discordance in area between Utukok and Ipnavik Rivers. Grades northward into shale-siltstone facies.

W. W. Patton, Jr., *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 213, 215, 218, 220, figs. 2, 5. Shale, siltstone, and graywacke are principal components. Graywacke typically greenish-gray, slightly calcareous, highly argillaceous, poorly sorted sandstone or conglomerate. No complete unfaulted section known. Thickest composite section, compiled from scattered outcrops along Lupine River, is approximately 1,800 feet. Type section, approximately 1,450 feet thick, believed to be most complete section exposed in continuous outcrop. Overlies Shublik formation with little or no angular discordance; underlies Okpikruak formation or younger Cretaceous rocks, in some places with angular discordance. Underlies Fortress Mountain formation (new) at type locality of Fortress Mountain. Type section designated.

Type section: Along series of cutbanks on east side of Tiglukpuk Creek between lat. 68°22′ N. and lat. 68°22′30″ N. Recognized and mapped in Arctic Foothills from Lupine River west to Nuka River.

Tigre Limestone[1]

Oligocene: Panamá and Costa Rica.

Original reference: D. F. MacDonald and others, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 364.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 347. Undefined name. Appeared in table showing that limestone overlies Watsi and Mona shales. Note on type region.

Type region: In Bocas del Toro area, in foothills about 15 kilometers southwest of mouth of Río Sixaola. Tigre is local name for small stream flowing into tributary of Río San San.

**Tihvipah Limestone**

Pennsylvanian: Southern California.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 3, 14 (fig. 6), 26–27, pls. 1, 2, 3. Name applied to limestone and associated rocks above Rest Spring shale (new). Consists mostly of platy light-gray limestone, interbedded shaly limestone or calcareous shale, and some beds, 1 foot to 3 feet thick, fine-grained medium-gray limestone; shaly rocks range in color from very light gray to pale red or grayish pink. Some spherically concretionary dark-gray chert, unlike rounded chert pebbles which locally compose inconspicuous thin basal conglomerate. Thickness about 200 feet. In Quartz Spring area, top of Tihvipah limestone is eroded so its upper limit cannot be satisfactorily defined.

Type locality: On hill due east of Rest Spring, Inyo County. Named for exposure northwest of Tihvipah Spring, which is 2 miles N. 15 E. of Burro Spring. Name Tihvipah Spring does not appear on any previously published map, but in 1938 it was used by rangers of National Park Service in Death Valley.

Tijeras quartzite[1]

Precambrian: New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22 p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 11.

Well exposed in great Tijeras arch of pre-Cambric rocks at southern end of Sandia Range.

Tilden Formation[1]

Cambrian: Southwestern Montana.

Original reference: P. J. Shenon, 1931, Montana Bur. Mines and Geology Bull. 6.

Well exposed northwest of Ermont mine, Argenta, Beaverhead County.

**Tilden Limestone Lentil** (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 44, map, sections.

Named for Tilden mining claim, Bingham district.

Tilford Lens (in Newcastle Formation)

Upper Cretaceous: Western South Dakota.

R. M. Grace, 1952, Wyoming Geol. Survey Bull. 44, p. 14, 16. Composed almost entirely of friable sandstone. In this report, seven lenses are named in Newcastle.

Present northeast of Tilford, Meade County.

**Tillamook Volcanic Series**

Eocene: Northwestern Oregon.

W. C. Warren, Hans Norbisrath, and R. M. Grivetti, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 42. Name applied to series of basaltic lavas and tuffs which form backbone of Coast Range in south-central part of area mapped. Along west and north sides of series, lava is predominant rock type; toward east and south, tuffs, and, next tuffaceous shales become increasingly abundant. Thickness 6,000 to 10,000 feet along Trask River from mouth of its canyon to its forks. Oldest rocks in region; unconformably overlain by sedimentary beds containing Cowlitz (upper Eocene) fauna.

P. D. Snavely, Jr., and E. M. Baldwin, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 5, p. 806. Lower part of Tillamook volcanic series is equivalent to newly defined Siletz River volcanic series in Lincoln County.

Well exposed along most of large streams in eastern Tillamook County.

†Timber Belt beds[1]

Eocene: Eastern Texas.

Original reference: E. T. Dumble and R. A. F. Penrose, Jr., 1890, Texas Geol. Survey 1st Ann. Rept., p. xxxvi, 17, 22, pl. 3.

Named for great timber region.

Timber Canyon Fanglomerate[1]

Pleistocene, upper: Southern California.

Original reference: U. S. Grant 4th and H. R. Gale, 1931, San Diego Soc. Nat. History Mem., v. 1, p. 37, 38, 63.

Occurs on top of ridges beveling edges of upturned marine beds west of Timber Canyon, on north side of Santa Clara Valley, Ventura and Los Angeles Basins.

Timber Crater Basalt Flow, Lavas

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 23–31, 32–34. Discussion of geology and petrography of Crater Lake National Park. Mount Mazama is name given to prominent peak that once stood on what is now rim of Crater Lake. Lavas in Mount Mazama were of three types: andesites, dacites, and basalts. Immediate rim of Crater Lake is made up wholly of andesites and dacites, chiefly the former; basalts are limited to outer slope. None of the basalt flows came from central vent of Mount Mazama. Principal basalt flows are the Timber Crater, Red Cone, Desert Cone, Bald Crater, and Crater Peak.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 140–141, pl. 3. Mapped as Timber Crater lavas.

Timber Crater is 5 miles northeast of Crater Lake, Cascade Range. Slopes of Timber Crater cone are covered with pumice showing that its activity closed before that of Mount Mazama.

†Timber Creek Beds[1]

Upper Cretaceous: Eastern Texas.

Original reference: J. A. Taff, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 285.

†Timber Creek Beds[1]

Eocene: New Jersey.

Original reference: W. M. Gabb and G. H. Horn, 1862, Philadelphia Acad. Nat. Sci. Jour., 2d ser., v. 5, p. 111, 135.

Exposed on Timber Creek.

†Timber Creek Group[1]

Upper Cretaceous (Gulf Series): Eastern Texas.

Original references: R. T. Hill and C. A. White, 1887, Philadelphia Acad. Nat. Sci. Proc. 1887, p. 40, 44; 1887, Am. Jour. Sci., 3d, v. 33, p. 296, 298.

Crops out coextensive with region known as Lower Cross Timbers.

**Timbered Hills Group[1]**

Upper Cambrian: Southern Oklahoma.

Original reference: C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55–57.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 15–20. Includes (ascending) unnamed basal limestone 98 feet thick, Reagan sandstone, Cap Mountain formation, and Honey Creek formation. Derivation of name given.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, includes Honey Creek formation and Reagan sandstone.

Named because Reagan and Honey Creek are well exposed adjacent to East and West Timbered Hills in Arbuckle Mountains.

**Timber Lake Member** (of Fox Hills Formation)

Upper Cretaceous: North-central South Dakota and southern North Dakota.

R. E. Morgan and B. C. Petsch, 1945, South Dakota Geol. Survey Rept. Inv. 49, p. 15–17, fig. 4, pl. 3. Lower part commonly soft or uncemented uniform sand; upper part contains calcareous lens-shaped concretionary masses, thin limonitic claystones, and soft mottled sandstone. Thickness about 90 feet. Overlies Trail City member (new); underlies unnamed sandstones and shales in upper part of formation.

S. P. Fisher, 1952, North Dakota Geol. Survey Bull. 26, p. 11–12, 37. Geographically extended into Emmons County, N. Dak., where it is about 60 feet thick and consists of uncemented fine- to medium-grained green-brown and gray sands. Thins eastward. Overlies Trail City member.

R. E. Stevenson, 1957, Areal geology of the McIntosh quadrangle (1:62,500): South Dakota Geol. Survey. Underlies Bullhead member (new).

Named for exposures in and near town of Timber Lake, Dewey County, S. Dak.

**Times Porphyry[1]**

Tertiary, middle or upper: Northwestern Arizona.

Original references: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743; Carl Lausen, 1931, Arizona Bur. Mines Bull. 131, Geol. Ser. 6, p. 45, map.

Exposed in Times Gulch, Oatman district.

**Timms Point Silt Member** (of San Pedro Formation)

Timms Point Formation[1]

Timms Point Silt

Pleistocene, lower: Southern California.

Original reference: U.S. Grant, IV, and H. R. Gale, Nov. 3, 1931, San Diego Soc. Nat. History Mem., v. 1, p. 37, 42–43.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 42–53, pls. 1, 13, 14. Described as Timms Point silt. In San Pedro where units are superimposed, the sequence is (ascending) Lomita marl, Timms Point silt, and San Pedro sand. Exposed thickness 30 to 80 feet; minimum computed thickness about 120 feet. Lower Pleistocene.

J. F. Poland, A. M. Piper, and others, 1956, U.S. Geol. Survey Water-Supply Paper 1109, p. 38 (table), 61, pl. 3. Rank reduced to member of San Pedro formation.

Type section : Timms Point, Los Angeles County.

**Timothy Sandstone**[1]

**Timothy Sandstone Member** (of Thaynes Formation)

Timothy Formation

Lower Triassic: Southeastern Idaho, central northern Utah, and central western Wyoming.

Original references: G. R. Mansfield, 1920, Am. Jour. Sci., 4th v. 50, p. 62; 1920, U.S. Geol. Survey Bull. 713, p. 29, 50.

W. F. Scott, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1530. Formation comprises 1,310 feet of red shales and siltstones, with interbedded reddish-purple and reddish-brown sandstones in central Wasatch Mountains, Utah.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 33–34, pl. 1. Sandstone has conformable contacts with Portneuf limestone below and Higham grit above where mapped in Ammon and Paradise Valley quadrangles, Idaho. Upper Triassic.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 173, fig. 18. Upper member of Thaynes formation in southeastern Idaho where it overlies Portneuf limestone member. Correlation chart shows age to be both Lower and Upper Triassic.

W. F. Scott, 1954, Dissert. Abs., v. 14, no. 8, p. 1200. Included in Moenkopi group.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 45–46. Red shale, siltstone, and sandstone overlying Thaynes formation in northwestern Wyoming referred to Timothy sandstone. Thickness between 159 to 278 feet.

Named for Timothy Creek, in Lanes Creek and Freedom quadrangles, Idaho, which cuts formation.

Timpahutean series[1]

Timpahuten series[1]

Middle Silurian: Nevada.

Original references: C. R. Keyes, 1923, Pan-Am Geologist, v. 40, p. 53; 1924, Pan-Am. Geologist. v. 41, p. 78.

Name derived from Timpahute Peak, north of Las Vegas, Clark County.

Timpanogos (Tampanogos) shales[1]

Cambrian: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 38.

Derivation of name not stated.

†Timpas Limestone (in Colorado Group)[1]

Timpas Limestone Member (of Niobrara Formation)

Upper Cretaceous: Eastern Colorado and northeastern New Mexico.

Original reference: G. K. Gilbert, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 566.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10b (columns 48, 49, 52). Shown on correlation chart as member of Niobrara formation. Underlies Apishapa shale member.

K. M. Waagé, 1952, Colorado Sci. Soc. Proc., v. 15, no. 9, p. 375 (fig. 1). Shown on generalized stratigraphic section of rocks exposed in Denver-Golden area. Underlies Apishapa shale; overlies Benton shale. Thickness 30 feet.

M. A. Jenkins, Jr., 1957, Rocky Mountains Assoc. Geologists Guidebook to the geology of North and Middle Parks Basins, Colorado, p. 53. Believed that names Fort Hays and Smoky Hill have priority over terms Timpas and Apishapa and, is used, would help standardize Niobrara terminology in west-central Colorado.

Named for Timpas Creek, which enters Arkansas River below Rocky Ford, Otero County, Colo.

**Timpoweap Member** (of Moenkopi Formation)

Lower Triassic: Central southern Utah.

H. E. Gregory, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 226, 227; 1950, U.S. Geol. Survey Prof. Paper 220, p. 48 (fig. 24), 52 (table), 60–61. Consists of three unlike groups of strata: at base, conglomerates and breccia; higher up limestone; and at top variegated shales. Average thickness 170 feet. Conglomeratic beds unevenly distributed and variable in composition; shales, yellow, white, brown, and red, ferruginous, calcareous, arenaceous, and gypsiferous, includes calcareous sandstone in beds 1 to 3 feet thick. Basal member of formation; separated from overlying Virgin limestone member by 200-foot interval of sandstone termed lower red member; unconformably overlies Kaibab limestone.

Type locality: Near Virgin City, Washington County. Traced eastward from type locality to Paria River. [River map shows Virgin, Washington County, and Timpoweap Canyon of Virgin River, Washington County.]

Tina Limestone Member (of Altamont Limestone)

Pennsylvanian (Des Moines Series): Kansas and Missouri.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 29, 40. Proposed for lower limestone member of Altamont. Light-gray limestone; weathers buff. Thickness in Livingston and Carroll Counties, Mo., about 4 feet.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 2, p. 329–330. Geographically extended into eastern Kansas. Thickness as much as 16 feet. Underlies Lake Neosho shale member (new); overlies Bandera shale. It is unlikely that all limestone included in the Tina in Kansas is precisely equivalent to type Tina.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 7. Term Tina abandoned. Rocks chosen for type Tina have proved not to be Altamont. Name Amoret replaces Tina.

Typical exposures: About 2 miles southeast of Tina, Carroll County, Mo., in ravines in west-central part of sec. 7, T. 54 N., R. 22 W.

**Tinaquaic Sandstone Member** (of Sisquoc Formation)

Pliocene, lower and middle: Southern California.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1347–1352. Name applied to marginal facies of Sisquoc formation. Consists principally of sandstone; includes diatom-bearing siltstone and conglomerate. In type region, member is 1,400 feet thick and rests unconformably on Monterey.

W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 28, 29, pl. 1. Lower and middle Pliocene.

Type region: In Foxen Canyon-Sisquoc River area, Santa Maria district. Name derived from land grant in type region.

Tincanebits Member (of Lyndon Limestone)

Tincanebits Tongue [in Bright Angel Shale]

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 80–82. Rusty-brown dolomite tongue in Bright Angel shale of western Grand Canyon. Thickness ranges from 8½ to 30 feet. Separated from underlying red-brown cliff-forming unit of Bright Angel by 30 to 100 feet of micaceous green shale and thin-bedded brown siltstone. Lateral equivalent of certain limestone beds found in area west of Grand Canyon that probably constitute a member of the Muav, which is lower than any member within the Grand Canyon. Older than Meriwitica tongue (new).

H. E. Wheeler and V. S. Mallory, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 10, p. 2413 (fig. 2). In generalized paper on the designation of stratigraphic units, Tincanebits shown on diagram as member of Lyndon limestone.

In western Grand Canyon. Traced along walls of canyon for many miles.

**Tincup Quartz Monzonite Porphyry**

Paleocene(?) to Oligocene(?): Central Colorado.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof, Paper 289, p. 20–21, pl. 1. Typical rock consists of very conspicuous phenocrysts of white feldspar, colorless to slightly smoky quartz, and less abundant dark hornblende in a light-greenish-gray to grayish-green aphanitic groundmass. Porphyry masses occur in several forms, such as a stock, sills, a large tongue or wedge-shaped body, and two small irregular bodies with exposed lengths of less than half a mile. Probably older than Mount Princeton quartz monzonite.

Type locality: In a stock west of Napoleon Pass in Tincup mining district, Garfield quadrangle.

**Tindir Group**[1]

Precambrian and Lower Cambrian(?): Northeastern Alaska.

Original reference: D. D. Cairnes, 1914, Geol. Soc. America Bull., v. 25, p. 185–187.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Named for exposures along international boundary between Tindir, Cathedral, and Harrington Creeks. Yukon-Tanana region.

Tinian Beds

Oligocene (Aquitanian): Mariana Islands (Tinian).

Risaburo Tayama, 1936, Geomorphology, geology, and coral reefs of Tinian Island together with Aguijan and Naftan Islands: Tohoku Univ., Inst. Geology and Paleontology Contr. in Japanese language, no. 21, p. 20–21 [English translation in library of U.S. Geol. Survey, p. 19–20]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 53, table 4 [English translation in library of U.S. Geol. Survey, p. 63]. Andesitic tuff in lower part and tuffaceous and calcareous sandstone in upper part. Base is coarse-grained tuffaceous sandstone, overlain by sequence of white sandy tuff, light-pink sandy tuff, yellowish sandy tuff, and light-pink sandy tuff; several thin beds of light-yellow sandstone containing limestone blocks intercalated; contains many *Globigerina*. Thickness about 30 meters.

Typically exposed along cliff bounding northeastern margin of Carolinas plateau of Tinian Island.

Tinkers Creek shale facies (of Cuyahoga Formation)

Mississippian (Kinderhook): Northeastern Ohio.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology. v. 50, no. 1, p. 43 (fig. 2), 51–53. One of seven lithologic subdivisions in the formation. Includes Meadville shale, Sharpsville sandstone, and Orangeville shale members. Lies to northeast of River Styx facies (new).

Occurs in Cuyahoga, Geauga, Trumbull, and Ashtabula Counties.

Tinkers Falls Member[1] (of Tully Formation)

Middle Devonian: Central New York.

Original reference: G. A. Cooper and J. S. Williams, 1935, Geol. Soc. America Bull., v. 46, p. 790–806.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1787, chart 4. Middle Devonian.

R. E. Stevenson and W. S. Skinner, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 29–33. Tully type section consists of following members: Tinkers Falls, Apulia, and West Brook. In the clastic facies of the Tully, the Tinkers Falls is represented by New Lisbon member.

Type section: Just under main overhanging ledge in face of Tinkers Falls, Onondaga County.

Tinley Drift or Till

Pleistocene (Wisconsin): Northern Illinois.

J. H. Bretz, 1939, Illinois Geol. Survey Bull. 65, pt. 1, p. 55. Incidental mention.

Leland Horberg and P. E. Potter, 1955, Illinois Geol. Survey Rept. Inv. 185, p. 9 (fig. 2), 10. Clayey yellow-gray to gray calcareous till about 15 feet thick. Overlies Valparaiso till in some areas and in others Lemont till or drift.

Derivation of name not given; till is present in gravel pit at Worth, Cook County, not far from Tinley Park.

**Tin Mountain Limestone**

Lower Mississippian: Southern California.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 3, 14 (fig. 6), 20–22, pls. 1, 2, 3. Lower part consists of dark-gray limestone in beds 2 to 6 inches thick, separated by much thinner beds of light-brownish-gray to pale-red shale; upper part is medium-gray limestone in beds that range in thickness from a few inches to 2 feet; both upper and lower parts contain some dark-gray chert, that weathers dusky brown or dark yellowish brown; fossiliferous. Thickness 475 feet at type locality. Underlies Perdido formation (new); overlies Devonian Lost Burro formation (new).

R. L. Langenheim, Jr., and Herbert Tischler, 1960, California Univ. Pub. Geol. Sci., v. 38, no. 2, p. 92–97, 132–134, 135–136. In Quartz Spring area, overlies Quartz Spring sandstone member (new) of Lost Burro formation. Thickness about 366 feet. Underlies Perdido formation. Lower Mississippian.

Type locality: Southern slope of hills about 2½ miles southeast of Quartz Spring, Inyo County, and about 3,000 feet north of road to Rest Spring, where entire sequence is exposed. Named for Tin Mountain, northernmost peak in Panamint Range, Inyo County.

†Tintic Andesite[1]

Tertiary: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3.

Tintic district.

**Tintic Quartzite**[1]

Lower and Middle Cambrian: Central and northern Utah.

Original reference: G. O. Smith, 1900, U.S. Geol. Survey Geol. Atlas, Folio 65.

A. J. Eardley and R. A. Hatch, 1940, Geol. Soc. America Bull., v. 51, no. 6, p. 809 (fig. 3), 815. Extended northward to Willard Canyon [between Ogden and Brigham City] where it underlies Ophir shale and overlies Farmington Canyon complex.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 826 (table 1), 827–828. In north-central Wasatch Mountains, dominantly pink and gray quartzite, with some beds of buff, red, and blood-purple varieties; intraformational conglomerate beds common. Basal conglomerate 100 feet thick occurs in Cottonwood Canyon where it is in sedimentary contact with Farmington Canyon complex; basal conglomerate not present in Ogden Canyon. Approximately 1,000 feet thick in Cottonwood-Durst Peak area; 500 to 700 feet in front range of Wasatch. Unconformably overlies crystalline complex. Underlies Ophir shale. Name Tintic is preferred to Brigham quartzite in this area. Lower (?) Cambrian.

A. A. Baker, J. W. Huddle, and D. M. Kinney, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 7, p. 1165–1167. Extended into Uinta Basin. In Cottonwood-America Fork district about 800 feet thick; underlies Ophir formation; overlies Precambrian. Lower Cambrian.

A. E. Granger and others, 1952, Utah Geol. Soc. Guidebook 8, p. 7. In Wasatch Mountains, east of Salt Lake City, unconformably overlies Mutual formation (new). Underlies Ophir shale.

F. W. Christiansen, 1952, Geol. Soc. America Bull., v. 63, no. 7, p. 720 (table 1), 721–722. In Canyon Range 1,500 feet thick; underlies Ophir formation and overlies Precambrian.

N. C. Williams, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2736 (fig. 1), 2737 (fig. 2), 2738–2739. In western Uinta Mountains, overlies Red Pine shale (new), which replaces Ophir of previous reports. As used here, Tintic quartzite replaces Pine Valley quartzite.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 4, 5 (fig. 2). In East Tintic Mountains 2,300 to 3,200 feet thick; underlies Ophir formation and overlies Big Cottonwood (?) formation. Lower Cambrian.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 8–9, 14 (fig. 3). In Stansbury Mountains 4,200 feet thick with base not exposed; at least four subdivisions recognized. Underlies Pioche shale.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 667. Within area of this report [northern Utah and southeastern Idaho], rocks previously assigned to Tintic quartzite belong in Prospect Mountain formation.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 30–32, pl. 1. In Sheeprock Mountains 2,572 feet thick; underlies Ophir group, which includes Pioche shale at base, and unconformably overlies Talawag quartzite member (new) of Mutual (?) formation.

Named for exposures in Tintic Canyon and other places in Tintic district.

†Tintic Slate[1]

Lower and Middle Cambrian: Central northern Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

Tintic district.

**Tinton Sand Member** (of Red Bank Sand)[1]

Tinton Formation (in Monmouth Group)

Tinton Member (of Monmouth Formation)

Upper Cretaceous: New Jersey.

Original references: S. Weller, 1905, New Jersey Geol. Survey Ann. Rept. 1904, p. 147, 154–159; 1905, Jour. Geology, v. 13, p. 76, 81.

P. H. Jennings, 1936, Bulls. Am. Paleontology, v. 23, no. 78, p. 4, 5 (chart). Referred to as Tinton formation in Monmouth group.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 8 (fig. 4), 40, 51–52. Reallocated to member status in the Monmouth herein reduced to formational rank. Conformably overlies Red Bank member; conformably underlies Hornerstown formation. Where best developed in Monmouth County, reaches maximum thickness of 25 feet; dips about 20 feet per mile southeast and cannot be recognized south of Red Valley in southern part of county.

S. K. Fox, Jr., and R. K. Olsson, 1955, [abs.] Jour. Paleontology, v. 29, no. 4, p. 736. Upper Cretaceous Navesink, Red Bank, and Tinton are formations with distinct microfaunas indicating time differences. The Tinton may be post-Navarro and pre-Midway. Stratigraphic evidence indicates an unconformity between Cretaceous and Tertiary formations. Hornerstown rests successively from northeast to southwest on the Tinton, Red Bank and Navesink.

R. K. Olsson, 1959, Dissert. Abs., v. 19, no. 8, p. 2063–2064. In area of this report, New Egypt formation (new) of outcrop area is lateral equivalent of Tinton formation and in subsurface represents both Tinton and Hornerstown.

R. K. Olsson, 1960, Jour. Paleontology, v. 34, no. 1, p. 2, 4 (fig. 2). Overlies Shrewsbury member of Red Bank formation. Foraminifera described.

Exposed at Tinton Falls, Monmouth County.

**Tioga Bentonite Bed** (in Seneca Member of Onondaga Limestone)

Middle Devonian: Pennsylvania (subsurface), Maryland, New York, Ohio, Virginia, and West Virginia.

J. R. Ebright, C. R. Fettke, and A. I. Ingham, 1949, Pennsylvania Geol. Survey, 4th ser., Bull. M–30, p. 10; C. R. Fettke, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 10, p. 2038–2040. Thin but persistent seam of brown micaceous shale, commonly containing abundant pyrite; constitutes marker in Middle Devonian. Occurs at or near boundary between Hamilton group and Onondaga formation; shale seam appears to be bentonitic and will be referred to as Tioga bentonite.

W. A. Oliver, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 7, p. 629, 631 (fig. 2), pl. 1. At base of Seneca member in central New York is a uniform bed of clay 6 inches thick; this is Tioga bentonite which has been recognized in subsurface throughout Pennsylvania and adjacent parts of West Virginia, Ohio, and southwestern New York. Surface exposures of bentonite are deeply weathered and clean samples are rare.

J. M. Dennison, 1960, Dissert. Abs., v. 21, no. 3, p. 593. Top of Tioga metabentonite proposed as top of Onesquethaw stage. The Tioga is present in subsurface between New York and central Appalachian sections and crops out in New York in addition to 45 known localities in West Virginia, Virginia, and Maryland.

So named because it was first recognized in drill cuttings from Tioga gas field, Tioga County, Pa.

**Tioga Glaciation, Till**

Tioga glacial stage[1]

Pleistocene: Eastern California.

Original reference: E. Blackwelder, 1931, Geol. Soc. America Bull., v. 42, p. 865–922.

W. C. Putnam, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1281, 1291–1292. At least four ice advances occurred in Pleistocene: earliest, here named Aeolian Buttes, was followed by Sherwin, Tahoe, and Tioga, previously named by Blackwelder. Constructional forms have been destroyed on the two older tills but preserved on the later ones. Rhyolitic ash and pumice, now Bishop welded tuff, were erupted in interval between Aeolian Buttes and Sherwin glacial stages.

W. C. Putnam, 1960, California Univ. Pubs., Geol. Sci., v. 34, no. 5, p. 235, 238–239, map 1. Sherwin till is pre- rather than post-Bishop tuff. Name Aeolian Buttes considered invalid as representing an earlier Pleistocene, pre-Sherwin glacial stage. Hence glacial sequence is McGee, Sherwin, Tahoe, and Tioga.

Name amended to glaciation in compliance with 1961 Code of Stratigraphic Nomenclature.

Occurs in Tioga Pass area on eastern slope of Sierra Nevada.

Tioga magnafacies[1]

Upper Devonian: Central northern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 23.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 52 (fig. 9). Upper Devonian.

Tioga-Elkland region.

Tionesta Clay (in Pottsville Formation)[1]

Tionesta clay member or underclay member

Pennsylvanian (Pottsville Series) : Eastern Ohio.

Original reference: E. Orton, 1884, Ohio Geol. Survey, v. 5.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 39. Included in Tionesta cyclothem, Pottsville series.

R. E. Lamborn, 1956, Ohio Geol. Survey, 4th ser., Bull. 55, p. 44–49, geol. map. In Tuscarawas County, Tionesta clay member (Pottsville series) is dark gray, plastic, and 2 to 3 feet thick. Occurs below Tionesta coal and above Upper Mercer limestone member.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 46, 49 (table 7). Underclay member of Tionesta cyclothem in report on Athens County. Average thickness 1⅓ feet. Pottsville series.

Name derived from Tionesta, Forest County, Pa.

Tionesta cyclothem

Pennsylvanian (Pottsville Series) : Southeastern Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 39, table 1, geol. map. Includes (ascending) Tionesta shale and (or) sandstone, 5 feet; Tionesta clay, 6½ feet; Tionesta No. 3b coal. Occurs above Bedford cyclothem and below Brookville cyclothem of Allegheny series. In area of this report [Perry County], Pottsville series is described on a cyclothemic basis; 10 cyclothems are named. [For sequence see Anthony cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 44–46, 49 (table 7). Rogers (1858) named Tionesta group from exposures along Allegheny River near village of Tionesta, Forest County, Pa. Orton (1884) recognized Tionesta members in Ohio. Tionesta cyclothem is incomplete and in Athens County [this report] has only three members: Tionesta shale and sandstone, Tionesta underclay, and Tionesta coal. Uppermost cyclothem of Pottsville series.

Name derived from Tionesta, Forest County, Pa.

†Tionesta Group (in Pottsville Formation)[1]

Pennsylvanian: Northwestern Pennsylvania.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 474–477.

Named for exposures along Allegheny River near village of Tionesta, Forest County.

Tionesta Iron Shales (in Pottsville Formation)[1]

Pennsylvanian: Northwestern Pennsylvania.

Original reference: I. C. White, 1879, Pennsylvania Geol. Survey Rept. $Q_2$.

†Tionesta Sandstone (in Pottsville Formation)[1]

Tionesta sandstone and shale member

Pennsylvanian: Pennsylvania, Maryland, eastern Ohio, and northern West Virginia.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 474–477, 489, 490.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 46, 49 (table 7). Tionesta sandstone and shale member of Tionesta cyclothem in report on Athens County. Rogers (1858) applied name Tionesta to present

Homewood sandstone, but Tionesta, as now applied to clastic members is restricted to shale and sandstone below Tionesta underclay and overlying Upper Mercer cyclothem. Maximum thickness less than 12 feet. Full thickness not exposed in Athens County. Pottsville series.

Name derived from Tionesta, Forest County, Pa.

Tionesta Series[1]

Pennsylvanian: Western Pennsylvania.

Original reference: F. Platt, 1875, Pennsylvania 2d Geol. Survey Rept. H, p. 8–9.

Tioughnioga Group

Tioughnioga Stage

Middle Devonian (Erian): North America.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1733, chart 4. Devonian is subdivided into 10 stages of which the Tioughnioga is fifth in sequence (ascending). Follows Cazenovia and is followed by the Taghanic (or Taughannock). [For complete sequence see Helderberg stage this reference.] Interval embraced is from base of Centerfield to base of Tully limestone. Includes the Ludlowville and Moscow formations which are closely related faunally and are mainly restricted to eastern part of Devonian geosyncline. Except for the Centerfield and its equivalents, stage is not represented in Ohio and Mississippi Valleys.

A. T. Cross and J. H. Hoskins, 1951, Jour. Paleontology, v. 25, no. 6, p. 718 (fig. 3). Shown on composite stratigraphic column of western New York and northwestern Pennsylvania as Tioughnioga group. Includes Ludlowville and Moscow formations. Overlies Cazenovia group; underlies Taughannock group.

Name is taken from headwaters of Tioughnioga River in south half of Cazenovia quadrangle, New York.

**Tippah Sand Lentil** (in Porters Creek Clay)

Tippah Sandstone Member (of Porters Creek Clay)[1]

Paleocene: Northeastern Mississippi and southwestern Tennessee.

Original reference: E. N. Lowe, 1915, Mississippi Geol. Survey Bull. 12, p. 64.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 10–11. Rank reduced to lentil in lower part of Porters Creek clay. Formerly believed to lie at top of Porters Creek and correlated with Naheola formation of Alabama, however, it is lower stratigraphically than type exposures of Porters Creek. Consists of loose white to yellow glaucontic *Halymenites*-bearing sand with some calcareous ledges, especially at top and bottom. Type locality suggested as none designated previously.

Type locality: Exposures on south side of valley of Hurricane Creek in SW¼SE½, T. 2 S., R. 3 E., Tippah County, Miss.

Tippecanoe sequence

Ordovician (Chazyan to Mohawkian): Central and western United States.

L. L. Sloss, W. C. Krumbein, and E. C. Dapples *in* C. R. Longwell chm., 1949, Geol. Soc. America Mem. 39, p. 112 (table 2), 115. An "operational unit" for use in interregional facies analysis. Named from Tippecanoe County, Indiana. Wells drilled in area start in lower Mississippian or upper Devonian and penetrate a full section of sequence from base of New Albany shale to base of St. Peter sandstone. Formational limits in Kansas are Hunton dolomite-Simpson formations; in Wyoming Bighorn dolomite.

**Tippipah Limestone**

Lower Pennsylvanian to Lower Permian (?) : Southern Nevada.

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 360–363, pls. 32, 33. Subdivided into four units (ascending) A through D, all of which consist of limestone. Unit A, 295 feet thick, consists of four zones of alternating resistant and nonresistant limestone. Unit B, about 580 feet thick, consists of light-gray, buff, lavender, and light-purplish silty limestone. Unit C, about 2,035 feet thick, is alternating sequence of resistant and nonresistant light- to medium-gray and brown limestone. Unit D, 1,195 feet thick, consists of alternating resistant and nonresistant beds, but principal difference is that beds of D are thicker and definitely more massive than beds of C. Overlies Eleana formation (new) with conformable contact.

Named for exposures on Syncline Ridge, about a mile east of Tippipah Spring, Atomic Energy Commission Nevada proving grounds area, Nye County. Also exposed about one-half mile north of Syncline Ridge in single outcrop which is surrounded by alluvium, and in a few areas along north end of Mine Mountains.

Tipton sandstone[1]

Tiptonian series

Precambrian (Protozoic) : Northwestern Iowa.

Original references: C. R. Keyes, 1914, Iowa Acad. Sci. Proc., v. 21, p. 187; Science, new ser., v. 40, 144.

C. R. Keyes, 1937, Pan-Am. Geologist, v. 67, no. 4, p. 307–309. Referred to as Tiptonian series, Protozoic. Tiptonian series (sandstones) occur above Keeweenawan series. Beds do not crop out in Iowa but reach surface in Minnesota.

Derivation of name not stated.

**Tipton Shale Member or Tongue** (of Green River Formation)[1]

Eocene, lower: Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

Original reference: A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 101, 102. In its type area Tipton tongue separates Niland (new) and Cathedral Bluffs tongues of Wasatch formation. Thickness about 250 feet at type locality. Lower part of Tipton is probably early Eocene; age of upper part uncertain.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1073–1074. Underlies Wilkins Peak member (new).

H. R. Ritzma, 1959, Utah Geol. and Mineralog. Survey Bull. 66, p. 40 (fig. 4), 41–42. Geographically extended into Daggett County, Utah. Here Green River formation is broken by unconformity. Beds below unconformity are here considered Tipton tongue, and beds above unconformity as main body of Green River equivalent to Cathedral Bluffs member of Wasatch and Laney shale of Green River as mapped farther east.

Named for exposures in vicinity of Tipton, a station on Union Pacific Railroad in Sweetwater County, Wyo.

Tip Top Sand[1]

Mississippian (Chester) : Western Kentucky.

Original reference: A. H. Sutton, 1931, Kentucky Geol. Survey, ser. 6, v. 37, p. 275, 285.

L. L. Ray, A. P. Butler, Jr., and C. S. Denny, 1947, Kentucky Dept. Mines Minerals Geol. Div. ser. 8, Bull. 9, p. 16. Deposit at Tip Top, the so-called Tip Top sand, has been shown to be Chester in age and to be extension of lowest sandstone of Chester group, correlated with the Mooretown. Name Tip Top sand as proposed by Sutton (1931) is unnecessary and should be abandoned.

Exposed along Dixie Highway about one-quarter to one-half mile northwest of Illinois Central station of Tip Top. Deposit lies partly in Hardin and partly in Meade County.

†Tisbury Beds[1] or Gravel[1]

Pleistocene: Southeastern Massachusetts.

Original reference: J. B. Woodworth, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 975–988, chart.

Well exposed in Chilmark and West Tisbury [Marthas Vineyard], Dukes County.

**Tishomingo Granite**[1]

Precambrian: Central southern Oklahoma.

Original reference: R. T. Hill, 1891, Am. Jour. Sci., 3d, v. 42, p. 118.

C. W. Tomlinson, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1831. Washita Valley fault zone borders south side of Tishomingo anticline, which contains largest area of Precambrian rocks now exposed in Arbuckle Mountains; here the Tishomingo granite, with a narrow discontinuous border of overturned Reagan sandstone (Cambrian), is thrust southwestward on this fault plane over younger rocks to and including Caney shale (Mississippian), with maximum stratigraphic displacement about 11,000 feet.

Named for Tishomingo, Johnston County.

Titus Canyon Formation[1]

Oligocene, lower: Southeastern California.

Original reference: C. Stock and F. D. Bode, 1935, Nat. Acad. Sci. Proc., v. 21, no. 1, p. 571–579.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 33, pl. 1. Early Chadronian (lower Oligocene).

Type locality: Titus Canyon, near Leadfield. Area now in Death Valley National Monument.

Ti Valley Series

Pennsylvanian: Oklahoma, Iowa, Kansas, Missouri, and Texas.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2), 18–19; 1947, Jour. Geology, v. 55, no. 3, pt. 2, p. 268. Used to include all Pennsylvanian formations in the Midcontinent between base of Pennsylvanian system and base of Des Moines series. Name is suggested as a solution for the Morrow-Atoka-Lampasas-Marble Falls nomenclatural problem.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey.

Formations exposed in Ti Valley, on borderline between Arbuckle and Ouachita Mountains, east-central [Pittsburg County] Oklahoma contain beds ranging in age from Morrow through Atoka.

Tiverton Arkose[1]

Carboniferous: Southeastern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 378–379.

Extends along escarpmemt from Steep Brook to Tiverton Four Corners, eastern part of Newport County and exposed at several places in Tiverton.

**Tivola Tongue** (of Ocala Limestone)[1]

Tivola Member (of Ocala Limestone)

Eocene, upper: Central Georgia.

Original reference: C. W. Cooke and H. K. Shearer, 1918, U.S. Geol. Survey Prof. Paper 120–C, p. 51–56.

J. F. L. Connell, 1958, Southwestern Louisiana Jour., v. 2, no. 4, p. 331–333. In this report [Jackson group of Georgia], unit is termed Tivola member of Ocala limestone. Commonly a soft friable exceedingly fossiliferous limestone. North of Hawkinsville, Pulaski County, a massive bed of dense white argillaceous limestone, well stained with red iron oxide, is identified as the Tivola member on basis of a fossil assemblage of lower upper Ocala age. To west of main outcrop of the Tivola, a prominent thick outlier of the unit unconformably overlies eroded Tuscaloosa surface. Merges laterally into Twiggs clay member of Barnwell formation as far south as Dooling, Dooly County. Type locality stated.

Type locality: At village of Tivola, 1 mile north of Penn-Dixie cement quarry at Clinchfield, Houston County. Extends from Houston County northeastward in not too widely separated outcrops into Twiggs, Wilkinson, and Bleckley Counties. Northeasternmost exposure is south of Gordon, Wilkinson County.

Toa Vaca Formation

Upper Cretaceous (Santonian): Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 44–47. Composed of 90 percent tuff breccia, 5 percent andesite flows, and 5 percent tuffaceous mudstones and sandstone. Lack of altitude makes it impossible to calculate thickness of formation. Overlies Ildefonso formation (new). Unconformably overlain by Eocene Jacaguas group (new). Includes Río Jueyes and Guayama series of Hodge (1920).

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 83–84. Consists of about 11,000 feet of coarse pyroclastics; andesite flows comprise about 1 to 2 percent of unit. Overlies lower part of Santa Ana formation (new); interfingers with Santa Ana to east and with unnamed Cretaceous sediments to west. Footnote states that name Santa Ana is no longer used; unit is termed Idlefornso [Ildefonso].

Type area: Along bed of Río Toa Vaca north of Route 150 and south of Orocovis quadrangle. Toa Vaca River drains northwestern part of Río Descalabrado quadrangle.

**Tobin Formation**

Lower Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]. Coarse conglomerate, at base locally fanglomerate, followed by about 50 feet of massive sandy dolomite and several hundred feet of shales with occasional calcareous nodules and thin seams of shaly limestone. Andesite lava flow 100 feet thick near base at south end of Tobin Range. Thickness variable, generally about 500 feet. Maximum thickness of 1,000 feet in northwest part of Augusta Mountain. Underlies Dixie Valley formation (new); overlies Koipato formation with angular unconformity.

Type locality: South end of Tobin Range.

Toboso conglomerate facies[1] (of Cuyahoga Formation)

Mississippian (Kinderhook): Central Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 657, 667–669.

F. T. Holden, 1942, Jour. Geology, v. 50, no. 1, p. 44. Includes (descending) Berne, Black Hand conglomerate, and Pleasant Valley (new) members. Occurs between Killbuck shale facies (new) to northeast, and Granville shale facies to the southwest.

Probably named for occurrence at Toboso, Licking County.

†Tobucksy Sandstone[1]

Tobucksy Sandstone (in Hartshorne Formation)

Pennsylvanian (Des Moines Series): Southeastern Oklahoma.

Original reference: H. M. Chance, 1890, Am. Inst. Min. Engrs. Trans., v. 18, p. 658, 659.

C. C. Branson *in* E. W. Reed, S. L. Schoff, and C. C. Branson, 1955, Oklahoma Geol. Survey Bull. 72, p. 64. Hartshorne formation, at its type locality, consists of Upper Hartshorne coal, "Hartshorne sandstone", Lower Hartshorne coal and underclay, and shale tongues locally developed between these members; the specific sandstone called Hartshorne is given its older but seldom used name, Tobucksy sandstone, conferred upon it by Chance (1890).

Type locality of Hartshorne formation is in Pittsburg County.

Toccoa Quartzite[1]

Precambrian or Lower Cambrian: Northeastern Georgia.

Original reference: S. L. Galpin, 1915, Georgia Geol. Survey Bull. 30, p. 120.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 42, Toccoa quartzite of Galpin (1915) is fine-grained phase of Lithonia granite.

Crops out for 2 miles east of Ayersville to within about 1½ miles of Toccoa. Named from exposures in ballast quarry north of Southern Railway and about 2 miles west of Toccoa, Stephens County.

†Tocito Sandstone Lentil (of Mancos Shale)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. B. Reeside, Jr., 1924, U.S. Geol. Survey Prof. Paper 134.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 28–29. Unit sometimes called Tocito sandstone lentil of Mancos in area adjacent to San Juan River is correlative of Gallup sandstone member and part of Dilco coal member of Mesaverde of southern San Juan basin region. Suggested that name Tocito be dropped.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2156. In revised nomenclature of Mesaverde group in San Juan basin, New Mexico, name Gallup sandstone replaces Tocito sandstone lentil of Mancos shale.

Named for outcrops near Tocito trading post, San Juan County.

**Todd Valley Formation**[1] **or Sand**

Pleistocene: Eastern Nebraska.

Original reference: A. L. Lugn, 1934, Nebraska State Mus., v. 1, Bull. 41, p. 324, 349–350.

G. C. Lueninghoener, 1947, Nebraska Univ. Studies, new ser. no. 2, p. 17. Formation as defined by Lugn included all fluviatile sands and gravels in Todd Valley. Term is herein redefined to apply only to uppermost part of fill consisting of gray-white fine sands in Todd Valley and their equivalents in other valleys. Thickness of redefined formation ranges from 0 to 50 or more feet.

G. E. Condra, E. C. Reed, and E. D. Gordon, 1950, Nebraska Geol. Survey Bull. 15–A, p. 30–31. Sand rests unevenly on eroded Loveland loess, Crete sands and gravels, and older beds. Sand of this age and condition of occurrence are found at places in Platte Valley westward to near North Platte and generally in Elkhorn, Logan, Salt Creek, and other valleys. Upper surface of formation in Todd Valley was extensively wind modified after deposition resulting in loess-mantled dunelike topography. Age of Todd Valley deposition proper is Iowan, and only upper part of Lugn's Todd Valley formation at type locality is of this age.

Named for occurrence in Todd Valley, an old filled valley of Platte River, Saunders County.

**Todilto Limestone** (in San Rafael Group)

Todilto Limestone Member (of Morrison Formation)[1]

Todilto Limestone Member (of Wanakah Formation)

Upper Jurassic: Northwestern New Mexico, northeastern Arizona, and southwestern Colorado.

Original references: H. E. Gregory, 1916, U.S. Geol. Survey Water-Supply Paper 380; 1917, U.S. Geol. Survey Prof. Paper 93.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U.S. Geol. Survey Prof. Paper 183, p. 9, 55, pls. Member of Morrison formation.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 958–959. Todilto limestone can be correlated with San Rafael group and dated as Upper Jurassic by marine beds in group.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1668. Todilto is transitional downward into Entrada sandstone and at many localities is overlain on erosional unconformity by clastic beds of Morrison formation. Evidence seems to indicate that Todilto should be regarded as representative of the Curtis or perhaps the Summerville. Area of outcrop above the Entrada extends northward into area beneath which thinning edge of Kayenta formation dies out between merging sandstone of Navajo and Wingate. Todilto is removed from Morrison formation, and term Wanakah formation is extended into New Mexico and northeastern Arizona. Todilto and overlying gypsum beds, where present, are members of the Wanakah.

C. T. Smith, 1951, *in* New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 13 (chart), 38; C. T. Smith, 1954, New Mexico Bur. Mines Mineral Resources Bull. 31, p. 14–15, pl. 1. Underlies Thoreau formation (new).

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 38–39, 40 (fig. 26). Described in Navajo country where it is considered of formational rank and included in San Rafael group. At type locality, consists of (ascending) 16 feet of mudstone, 4 feet of limestone, and 5 feet of mudstone. In this area, lower and upper contacts are sharp and irregular. Underlies Summerville formation; overlies Entrada. Near Ysidro, N. Mex., (outside area of this report) formation includes section of gypsum 111 feet thick. Extends into southwestern Colorado.

Named for Todilto Park, McKinley County, N. Mex.

**Todos Santos Claystone Member** (of Sisquoc Formation)

Miocene and Pliocene: Southern California.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1340 (table 1). A somewhat procelaneous claystone forming about lower half of basin facies of Sisquoc formation in Casmalia Hills Thickness about 1,500 feet. Overlies Monterey shale, the boundary being drawn at base of lowest thick claystone unit. Underlies diatomaceous strata of Sisquoc.

W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 26–31, pl. 2. Miocene and Pliocene.

Type region: In Casmalia Hills northwest of Casmalia, Santa Barbara County.

Togiak Gravels[1]

Pleistocene: Southwestern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 177.

Occur along banks of Togiak River and Togiak Lake.

**Togo Formation** (in Deer Trail Group)

Precambrian (Belt Series): Northeastern Washington.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Named as oldest of five formations in group. Underlies Edna dolomite (new).

Report discusses magnesite belt of Stevens County.

**Tohachi Formation** (in Mesaverde Group)

Tohachi Shale[1]

Upper Cretaceous: Northwestern New Mexico and northeastern Arizona.

Original reference: H. E. Gregory, 1916, U.S. Geol. Survey Water-Supply Paper 380.

J. E. Allen, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 11, p. 2569–2571. Referred to as Tohatchi formation. Recent mapping has shown that type localities described by Gregory (1917, U.S. Geol. Survey Prof. Paper 93) for Tohatchi shale consist of Upper Cretaceous rocks which conformably overlie Menefee formation of Mesaverde group and unconformably underlie Chuska sandstone of Pliocene(?) age. Consists of lower carbonaceous member 850 feet thick and upper bentonitic member more than 500 feet thick. Included in Mesaverde group.

Caswell Silver, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 660–661. Discussion of article by Allen (1953). Allen quoted Gregory incompletely, and this gave the impression that Gregory misplaced an angular unconformity and misassigned the strata to the Tertiary. A complete reference to Gregory would note that the table (1917, p. 15) and graphic section (1917, pl. 3) made known existence of strata which were left undescribed and unnamed except for label "post-Mesaverde" (Upper Cretaceous) and which were excluded from Tohatchi shale. These beds which underlie the angular unconformity appear to be those labeled "Tohatchi formation" by Allen. Gregory did not describe the unit. It is likely Gregory misjudged the thickness, and in his reconnaissance he obviously mapped extent of Tohatchi shale incorrectly at south end of Chuska Mountains. Gregory's description of the Tohatchi appears to have been confused with upper part of post-Mesaverde strata. Thus, it would seem that the Tohatchi of Gregory should henceforth carry query—Tohatchi shale(?). Therefore, Allen should not have written that: "the Tohatchi shale lies conformably above the Menefee formation (the foregoing original description probably included the upper 500 feet of the Menefee) and may be divided lithologically into two units." At the very least, such a statement should read the redefined Tohatchi shale or the "Tohatchi formation." Tohatchi shale has been used and accepted for 36 years; the Tohatchi shale (or formation) of Allen is not the Tohatchi shale(?). Gregory's Tohatchi shale lies on "post-Mesaverde rocks." Strata in Tohatchi quadrangle called "post-Mesaverde rocks" by Gregory but apparently mapped in part by him as Tohatchi shale have a complex and confusing relationship. They appear to be angularly discordant to strata both above and below. Some local angular unconformities may even occur between individual beds. Existence of strata equivalent to Gregory's Tohatchi shale would be difficult to define unless restricted to relatively thin shaly lower part of Allen's Chuska sandstone.

J. E. Allen, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 661. Reply to Silver's article. Important fact is that rocks [Gregory] described at his two type localities are of Cretaceous age and lie below an unconformity marked by persistent conglomerate. Silty and ashy beds not over 250 feet thick crop out in a few places in Tohatchi quadrangle between conglomerate and overlying Chuska sandstone; they are dissimilar to any rocks described by Gregory, we [Gregory and Allen] both mapped them with the Chuska. Below the unconformably the "post-Mesaverde rocks" of Gregory are apparently similar to upper member of my [Allen] Tohatchi formation. They do not have "a complex and confusing relationship" and they are not "angularly discordant to the strata . . . below." Lithological type described by Gregory (p. 80) as "Tohatchi shale" occurs below and not above type of lithology which Gregory designates as "post-Mesaverde".

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 96–97. Because of diverse lithology and revised spelling adopted by Board on Geographic Names, name of unit is herein changed from "Tohachi shale" to Tohatchi formation. Tohatchi shale of Gregory's two type localities lies conformably above shales and sandstones of Menefee formation (original description included at least upper 200 feet of Menefee) and may be divided into two units. Base of lower cliff-making unit of redefined Tohatchi formation has been arbitrarily placed at top of highest massive channel sandstone of the Menefee. Above this point, 400 to 850 feet of sandstones of lower member of Tohatchi are thin to medium bedded with about 50 percent shale interbeds. Upper member consists of at least 500 feet of generally uniform light-olive- to yellow-gray indistinctly thin-bedded highly bentonitic shales which are carboniferous near base. These are probably not the "post-Mesaverde" beds, which, although not discarded by Gregory (1917, p. 75) in his text, are shown in table (1917, p. 15) and graphic section (1917, pl. 3). Lower member tentatively correlated with combined tongues Cliff House and Pictured Cliff sandstones; upper bentonitic unit may be equivalent of Fruitland formation and possibly part of Kirtland formation.

H. E. Wright, Jr., 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1827–1834. Tohatchi shale was named by Gregory for many colored shales and some sandstones at southern end of Chuska Mountains. He stated that it unconformably overlies Cretaceous rocks and is overlain in turn by Chuska sandstone. Both the Tohatchi and Chuska were placed in Tertiary, and an unconformity between them was mentioned at one locality. Independent field work done in area by Allen and the writer [Wright] revealed only one unconformity. This lies between tilted Cretaceous rocks and flat-lying Tertiary rocks. Shales beneath this unconformity resemble those described by Gregory as Tohatchi shale, and Allen has assigned Tohatchi formation to Mesaverde group. The Tohatchi, as thus defined, has maximum thickness of 1,350 feet and rests conformably on the Menefee. Above the unconformity, the sands, minor shale, and basal conglomerate cannot be Gregory's Tertiary Tohatchi shale because there is no room anywhere in area for more than 250 feet of the stated 200 to 1,000 feet of Tohatchi shale between the unconformity and typical Chuska sandstone caprock. The 250 feet of sands, minor shale, and basal conglomerate must therefore have been included by Gregory as part of Chuska sandstone. They are herein described as Deza formation which grades upward into crossbedded eolian Chuska sandstone.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2160–2161. Nomenclature of Mesaverde group, in San Juan basin, revised. Tohatchi formation as redefined by Allen and Balk accepted for uppermost unit in group, but Gregory's original spelling retained.

Named for exposures near Tohachi Indian School, McKinley County, N. Mex.

Tohatchi Formation

*See* **Tohachi Formation.**

Tok Sandstone

Tertiary(?): Eastern Alaska.

Original reference: A. H. Brooks, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 473, 483.

Exposed a few miles below Tok River.

**Tokio Formation**[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas and southeastern Oklahoma.

Original reference: H. D. Miser and A. H. Purdue, 1918, U.S. Geol. Survey Bull. 690, p. 19, 24.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 42–46. Formation, in McCurtain County, includes strata formerly assigned to upper part of Bingen formation and was originally described as Tokio sand member of that formation. Name Bingen has been dropped. Tokio as defined has gravel at base and is separated from underlying Woodbine formation by unconformity. Formation thickens southeastward from featheredge in outcrop to more than 595 feet in subsurface in southern part of county. Underlies Ozan and Brownstown formations undifferentiated.

First described in vicinity of Tokio, Hempstead County, Ark.

Tokopah Porphyritic Granodiorite

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 11–12, pl. 1. Notably porphyritic with stubby to equant subhedral to euhedral pink to gray microcline phenocrysts as large as 25 mm across, set in medium-grained groundmass averaging 3 to 5 mm; some of the plagioclase also present as phenocrysts as large as 15 mm in length. Relation to other named plutonic rocks in area not determined.

Named from exposures in upper Tokopah Valley in eastern part of area, Sequoia National Park.

**Tokun Formation**[1]

Eocene and Oligocene: Southeastern Alaska.

Original reference: G. C. Martin, 1908, U.S. Geol. Survey Bull. 335, p. 24, 35.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Name appears on map legend under Eocene rocks.

Crops out on both shores of Lake Tokun, Controller Bay region.

Tolay Volcanics[1]

Pliocene, middle(?): Central western California (surface and subsurface).

Original reference: R. R. Morse and T. L. Bailey, 1935, Geol. Soc. America Bull., v. 46, no. 10, p. 1437–1455.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 118. Patches of lava exposed west of Tolay Creek near Lakeville School and regarded as outcrops of Tolay volcanics are herein mapped as part of Sonoma volcanics.

G. T. Cardwell, 1958, U.S. Geol. Survey Water-Supply Paper 1427, p. 27 (table 6), 32. This report [Santa Rosa and Petaluma Valleys] follows Weaver (1949) and maps the Tolay volcanics of Morse and Bailey as part of Sonoma volcanics. Morse and Bailey considered Tolay volcanics to be of early Pliocene age. Inasmuch as uppermost strata of the Tolay are interbedded with lowermost beds of Petaluma, now believed to be of middle or late Pliocene age, the Tolay volcanics are probably of middle Pliocene age. Thickness in wells is more than 4,000 feet.

Exposed at surface in small area west of Tolay Creek, near Lakeville School, Petaluma quadrangle.

Tolchaco Gravels

Quaternary: Central northern Arizona.

Parry Reiche, 1937, Am. Jour. Sci., 5th ser., v. 34, no. 200, p. 130–134, pl. 1. Alluvial terrace deposits. Include two members related to previous channels of Little Colorado River and one or more members related to its present position. Upper member lies at elevations about 220 feet above the river grade and rests on Shinarump sandstones at three localities near Tappan Wash. Consists of loose massive to vaguely bedded sandy pebble and cobble gravel. Medium member, Cameron beds (new), lies at elevations about 170 feet above river profile. Lowest members, exposed at and across river from Cameron, consist of terraces formed at earlier stages of Little Colorado River, after it had attained its present location—these members have not been studied.

In Little Colorado River valley above Cameron. Named from the Navajo term for the Little Colorado River.

Tolchico shale[1]

Lower Triassic: Northeastern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 250, 338.

Well developed around mouth of Canyon Diablo. Probably named for Tolchico Settlement, The Crossing, Little Colorado River, Coconino County.

**Toledo Formation**[1]

Eocene, upper, to Oligocene, middle: Northwestern Oregon.

Original reference: Harrison and Eaton (Consulting Petroleum Geologists), 1920, Mineral Resources of Oregon: Oregon Bur. Mines and Geology, v. 3, no. 1, p. 3–40.

H. E. Vokes, Hans Norbisrath, and P. D. Snavely, Jr., 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 88. Consists of two members: Moody shale at base and unnamed upper member. Thickness 2,500 to 3,000 feet. Underlies Yaquina sandstone; overlies Burpee formation. Present study establishes upper Eocene age for Moody member and middle Oligocene age for greater part of upper member; future work may raise Moody member to rank of formation and permit restricting of name Toledo to strata of upper member.

Type locality: Along banks of Yaquina River, 3 miles south of Toledo, Lincoln County.

Tolenas Marble[1]

Tertiary, upper (?), or Quaternary: Western California.

Original reference: W. L. Watts, 1890, California State Mining Bur. 10th Ann. Rept., p. 668–669.

Quarried at Tolenas Springs, Solano County.

Toll Pit Beds[1]

Silurian: Southeastern Michigan.

Original reference: W. H. Sherzer and A. W. Grabau, 1910, Michigan Geol. Survey Pub. 2, geol. ser. 1, p. 47.

Occurs at Toll Pit quarry, near Scofield, Monroe County.

Tolman Formation

Eocene: Northern California.

C. A. Hall, 1956, Dissert. Abs., v. 16, no. 12, p. 2426. Incidental mention as containing fossil algae; overlies Del Valle formation (new).

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 14–15, fig. 2, geol. map. At type section, consists of bioclastic deposits; grades laterally from fine- to coarse-grained sandstone, and near Niles passes into a conglomerate; bioclastic deposits consist largely of fragments of calcareous algae and other organic material in finer grained quartz sand matrix. Rocks are dirty gray or brown and weather to lighter brown. Total thickness may be 900 feet or more; minimum thickness of 470 feet measured at type locality; beds are overturned and faulted. Overlies Sobrante sandstone; overlies (but not in direct superposition) Del Valle formation.

Type locality: Tolman Peak, north of town of Niles, Alameda County. Tolman Peak is herein named; it is located at intersection of lat 37°38′8″ N. and long 121°53′49″ W. Formation has general trend of N. 42° W., and is well exposed 1 mile north of Niles Canyon-Highway 9 intersection, and also approximately 2.7 miles N. 25° W. from intersection.

**Tolovana Limestone**[1]

Silurian: Northeastern Alaska.

Original reference: J. B. Mertie, Jr., 1936, U.S. Geol. Survey Bull. 872.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Mapped in Yukon-Tanana region.

In Preacher, Tolovana, and Hot Springs districts.

Toltec Andesite Member (of Treasure Mountain Rhyolite)

Miocene, upper: Northwestern New Mexico.

W. R. Muehlberger and others, 1960, New Mexico Geol. Soc. Guidebook 11th Field Conf., p. 100. Chiefly black perlitic vitric porphyritic andesite. Lowermost member; fills valleys cut into underlying Conejos quartz latite. Thickness 0 to 50 feet. Underlies Lagunitas clastic member (new). Name credited to E. L. Trice, (unpub. thesis).

Northeastern part Brazos Peak quadrangle.

**Toluca Quartz Monzonite**

Ordovician: Western North Carolina and western South Carolina.

W. R. Griffitts and W. C. Overstreet, 1952, Am. Jour. Sci., v. 250, no. 11, p. 779–783, 787, 788 (table 1). Monazite-bearing granitic rock, typically medium gray, moderately to strongly gneissic. Unit was included in Whiteside granite as mapped by Keith and Sterrett (1931, U.S. Geol. Survey Bull. 660–D, p. 130–132); hence, Whiteside granite is herein restricted to area of its type locality. Considered older than Cherryville quartz monzonite (new). May be Carboniferous(?) or pre-Carboniferous(?).

W. C. Overstreet and W. R. Griffitts, 1955, Geol. Soc. America Guidebook for 1955 Ann. Mtg. Age determinations on zircon and monazite from granitic rocks, from associated bodies of pegmatites and quartz veins, and from enclosing schists and gneisses gave consistent early Ordovician (about 400 million years) for zircon and monazite from Toluca quartz monzonite and enclosing metamorphosed sediments.

J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Mapped as Paleozoic.

Named for exposures near Toluca, Lincoln County, N.C.

Tomah Member (of Franconia Formation)

Upper Cambrian: Southwestern Wisconsin.

R. R. Berg, 1951, Minnesota Geologist, v. 8, no. 4, p. 2; 1953, Jour. Paleontology, v. 27, no. 4, p. 554–555 (fig. 2); 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 863–864, measured sections. Consists of thinly interbedded sandstone and shale; sandstone is yellow to gray, fine grained to silty, and laminated; shale consists of equal amounts of silt and illite clay; locally contains thin beds of wormstone. Thickness at type locality is 28 feet. Underlies Reno sandstone member (new); overlies Birkmose sandstone member (new).

Type locality: Roadcuts on U.S. Highway 16, 6 miles west of Tomah, NW¼ sec. 22, T. 17 N., R. 2 W., Monroe County.

**Tomahawk Amygdaloid**[1] (in Central Mine Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Keweenaw Point.

Tomales Formation[1]

Pleistocene, upper: Western California.

Original reference: R. E. Dickerson, 1922, California Acad. Sci. Proc., 4th ser., v. 11, no. 19, maps.

Named for occurrence on northeast side of Tomales Bay, Marin and Sonoma Counties.

Tomales Bay deposits[1]

Pleistocene: Western California.

Original reference: V. C. Osmont, 1904, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 76.

Form series of low broad hills, extending along middle of valley near Olema, and occurring at intervals on both shores of Tomales Bay, Marin County. West of main ridge, occur in occasional patches around flanks of hills at head of Drake's Estero and north of Abbott's Lagoon.

†Tombigbee[1]

Eocene: Alabama.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog, 1884–1888, geog. map of Alabama.

†Tombigbee Chalk[1]

Upper Cretaceous: Southwestern Alabama and northeastern Mississippi.

Original references: W. J. McGee, 1890, Am. Jour. Sci., 3d, v. 40, p. 25, 30, 31; 1891, U.S. Geol. Survey 12th Ann. Rept., pt. 1, p. 419, 475.

Probably named for development on both sides of Tombigbee River in Greene, Hale, Sumter, and Marengo Counties, Ala., and near Tombigbee River, in northeast Mississippi.

**Tombigbee Sand Member** (of Eutaw Formation)[1]

Upper Cretaceous: Northeastern Mississippi, southern Alabama, western Georgia, and western Tennessee.

Original reference: E. W. Hilgard, 1860, Mississippi Geol. and Agric. Rept., p. 3, 61, 68–75.

W. H. Monroe and D. H. Eargle, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 50. In Aubrey, Aliceville, Mantua, and Eutaw quadrangles, Alabama, member underlies Mooreville chalk of Selma group. Thickness about 25 feet.

W. S. Parks, 1960, Mississippi Geol. Survey Bull. 87, p. 22 (table 2), 26, 36–40, pl. 1. In this report, Tombigbee sand refers to strata between lower typical Eutaw beds and Coffee formation above. In Prentiss County, member consists of 70 to 85 feet of massive, very glauconitic, in part agrillaceous, somewhat calcareous, and fossiliferous sand.

Named for exposures on Tombigbee River near Aberdeen, Monroe County, and at Plymouth Bluff, Lowndes County, Miss.

Tombstone Sandstone[1]

Upper Cretaceous: Central southern Montana.

Original reference: W. H. Weed, 1893, U.S. Geol. Survey Bull. 105, p. 16, 18.

Occurs at Cokedale, 10 miles west of Livingston, Park County.

Tombstonian series

Paleozoic [Upper Devonian]: Arizona.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228 (table). Includes (ascending) Patagonia limestone (new)—thickness 250 feet and Espinal limestone (new)—150 feet. Older than Jeromian series (new); younger than Rockfordian series.

Southeastern Arizona.

Tomera Formation (in Ely Group)

Middle Pennsylvanian (Atokan-Desmoinesian): Northeastern Nevada.

R. H. Dott, Jr., 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 11, p. 2243–2248, figs. 2, 5. Chert-pebble conglomerates and interbedded limestones, with numerous brachiopod coquinites. Individual brown-weathering conglomerate units rarely more than 30 to 50 feet thick. Interbedded limestone comprises about half of formation. Quartz arenite and siltstone associated with conglomerate as matrix and interbeds. Conglomerate units generally very thin to thick bedded, with flaggy to blocky split. Thicker conglomerate units commonly rather massive. Subangular to subround, poorly to moderately sorted granules and pebbles of dense chert with varying hues of gray, green, red, and brown; average size about 10 to 20 mm. Finer detrital beds weather grayish yellow or grayish orange, and light and moderate brown. Associated limestones consist principally of crinoidal and fossil hash calcarenite and calcirudite, and brachiopod coquinites. Complete section is composite of parts of several fault blocks. Lower 1,400 feet present in Tomera Ridge; at least 300 feet of higher strata present at lower South Fork Canyon making total thickness of 1,700 to 2,000 feet. Unconformably underlies Strathearn formation (new), overlapped by Humboldt formation; overlies Moleen formation (new). Moleen and Tomera formations are practically equivalent to Ely limestone of east-central Nevada. Proposed to raise Ely to rank of group in Elko and north Diamond Ranges to include Moleen and Tomera.

Type section: At north end of lower parallel ridge east of Grindstone Mountain, here called Tomera Ridge (east-central sec. 34 and west-central sec. 35, T. 33 N., R. 54 E.), and at west side of head of lower canyon of South Fork of Humboldt River (SW¼ sec. 19, T. 33 N., R. 55 E.). Also exposed north of Highway 40 from east end of Carlin Canyon northeast toward Tomera Ranch and Moleen, and in low ridge southeast of canyon. Named for Tomera Ranch, northwest of Grindstone Mountain on south side of Humboldt River, just east of Carlin Canyon along Western Pacific Railroad (NE¼NW¼ sec. 25, T. 33 N., R. 33 E.).

†Tomichi Limestone[1]

Lower, Middle, and Upper Ordovician: Central Colorado.

Original reference: R. D. Crawford, 1913, Colorado Geol. Survey Bull. 4, p. 56.

J. H. Johnson, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 322. Fremont limestone as differentiated in this report includes beds previously called by many names. It forms upper part of Tomichi limestone of Crawford (1913) in Monarch and Tomichi districts.

Named for Tomichi, Gunnison County.

Tomil Agglomerate

Tomil Volcanics

Oligocene or Miocene: Caroline Islands (Yap and Map)

Risaburo Tayama, 1935, Topography, geology, and coral reefs of the Yap Islands: Tohoku Univ. Inst. Geology and Paleontology Contr. in Japanese Language, no. 19, p. 29–30 [English translation in library of U.S. Geol. Survey, p. 26–27]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 62–63 [English translation in library of U.S. Geol. Survey, p. 73–74]. Consists of augite-andesite, agglomerate, and tuff; andesite commonly amygdaloidal. Contains deposits of bauxite. Unconformably overlies Map beds. Believed to be overlapped by Garim limestone, but contact not observed. Oligocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 62–63. Miocene.

W. S. Cole, Ruth Todd, and C. G. Johnson, 1960, Bulls. Am. Paleontology, v. 41, no. 186, p. 78. Referred to as Tomil volcanics. Unconformably overlies both Map and Yap formations.

Typically exposed on Tomil Plateau, Tomil Island, Yap group.

Tomlinson Shale[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Named for Tomlinson, Scott County, Ark.

†Tomlinson Stage[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: H. M. Chance, 1896, New York Acad. Sci. Trans., v. 15, p. 52.

Occur along Choctaw, Oklahoma & Gulf Railway, Okla. Probably named for Tomlinson, Scott County, Ark.

Tom Sauk Limestone Member (of Bonneterre Formation)

Cambrian: Southeastern Missouri.

G. F. Brightman, 1937, (abs.) Missouri Acad. Sci. Proc., v. 3, no. 4, p. 120. Pure fine-grained sublithographic limestone which occurs in Bonneterre formation only in St. Francois Mountains.

G. F. Brightman, 1938, Jour. Geology, v. 46, no. 3, pt. 1, p. 248–267. Limestone is irregular in distribution, thickness, and stratigraphic position.

Maximum thickness at outcrop 30 feet; in drill holes as much as 225 feet. Underlies bulk of Bonneterre formation. Type locality designated.

Type locality: Outcrop on south side of Little Tom Sauk Creek, on boundary between Iron and Reynolds Counties.

**Tomstown Dolomite**[1]

Tomstown Formation

Lower Cambrian: Central southern Pennsylvania, western Maryland, and northern Virginia.

Original reference: G. W. Stose, 1906, Jour. Geology, v. 14, p. 208.

B. L. Miller, D. M. Fraser, and R. D. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–48, p. 223–229. Formation, in Northampton County, overlies Hardyston formation and underlies Allentown formation. Contact with Hardyston not observed. Replaces name Leithsville in this area.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 70–72. Tomstown dolomite directly overlies Antietam quartzite and makes curving band, about 1 mile wide, around outcrop of the quartzite on plunging end of main South Mountain anticline in Cumberland County. Makes lowland between foot of steep slope of South Mountain and line of low hills composed of overlying Waynesboro formation to northeast. Offset 1½ miles southward by Reading Banks fault and makes wide lowland west of this fault. Dolomite is cut off 1 mile north of Dillsburg by eastern part of Dogwood Run fault and is here offset southwestward. Thickness estimated between 1,000 and 1,500 feet.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 40. Name Shady used in this report [Appalachian Valley] in preference to Tomstown.

B. L. Miller and others, 1941, Pennsylvania Geol. Survey Bull. C–39, p. 180–186. Described in Lehigh County where it is about 1,000 feet thick. Overlies Hardyston quartzite; underlies Allentown formation. Replaces term Leithsville in this area.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Mineral Resources [Rept. 12] Carroll and Frederick Counties, p. 42–43. Narrow belt of Tomstown dolomite extends along east foot of Catoctin Mountain west and southwest of Frederick. Lies between ridge of Antietam quartzite and Triassic border fault. Thickness about 200 feet.

H. P. Woodward, 1949, West Virginia Geol. Survey, v. 20, p. 124–139. Crops out only in Jefferson County. Outcrop is extended belt slightly more than 1 mile in width that enters county in vicinity of Antietam, Washington County, Md., and strikes southwestward along meander belt of Shenandoah River into Clark County. Estimated thickness between 1,200 and 1,500 feet. Overlies Antietam quartzite; underlies Waynesboro formation.

P. B. King, 1950, U.S. Geol. Survey Prov. Paper 230, p. 24–30, pl. 1. Described in Elkton area, Virginia, where it is about 1,000 feet thick. Overlies Antietam quartzite of Chilhowee group; underlies Waynesboro formation. Closely resembles in character and stratigraphic position Shady dolomite, whose type locality is in northeastern Tennessee. Name Tomstown is now used in Virginia as far south as Roanoke, beyond which name Shady dolomite is used for same unit. At some future time, name Tomstown may well be dropped as synonym, and Shady substituted for it.

Bradford Willard and others, 1959. Pennsylvania Geol. Survey, 4th ser., Bull. C–9, p. 10, 28–31, pl. 2. Mapped as Tomstown dolomite (Leithsville limestone) in Bucks County. Crops out in two narrow east-west strips. Overlies Hardyston quartzite. Difficult to distinguish from Triassic limestone conglomerate. Also difficult to distinguish from overlying Conococheague (Limeport) limestone.

Named for exposures at Tomstown, Franklin County, Pa.

**Tom Thumb Tuff Member** (of Klondike Mountain Formation)

Oligocene: Northern Washington.

Hunting Geophysical Services Inc., 1960, Washington Div. Mines and Geology Rept. Inv. 20, p. 6. At base of formation. Umpleby (1910, Washington Geol. Survey Bull. 1) referred to unit as Lake beds. Contains flora considered to be Oligocene in age. Not present in Curlew quadrangle. Republic quadrangle and part of Aeneas quadrangle mapped by Siegfried Muessig and J. J. Quinlan (1959, U.S. Geol. Survey Open-File Map).

Report discusses parts of Okanogan and Ferry Counties.

Tonawandan Stage

Middle Silurian (Niagaran) : North America.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser., no. 1. Niagaran series divided into four stages (ascending): Lewiston(ian), Ontario(an), Tonawanda(n), and Lockport(ian). Tonawanda stage includes upper Clinton strata. Thickness at type section 90 feet; 115 feet in Genesee Gorge; 210 feet in central New York; 180 feet near Oneida Lake; 105 feet at Clinton (Rome quadrangle).

Type section: Niagara Gorge. Named from good exposures in Tonawanda quadrangle, New York.

Tonga Formation (in Easton Group)

Paleocene or older: Northwestern Washington.

R. S. Yeats, 1958, Dissert. Abs., v. 19, no. 4, p. 775. Relict graded bedding, poor sorting, flat-pebble conglomerates, and load casts suggest turbidity current origin. Intruded by Beckler quartz diorite (new).

Between central and eastern part of Skykomish area in northwestern Cascade Mountains, 45 miles east of Seattle.

**Tonganoxie Sandstone[1] Member** (of Stranger Formation)

Pennsylvanian (Virgil Series) : Eastern Kansas and northwestern Missouri.

Original references: R. C. Moore, M. K. Ellias, N. D. Newell, 1934, Stratigraphic sections of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc: Wichita, Kans. [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]; J. M. Jewett and C. C. Williams, May 1, 1935, Kansas Acad. Sci. Trans., v. 38, p. 191–198.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 15. In Missouri underlies Vinland shale member.

T. W. Lins, 1950, Kansas Geol. Survey Bull. 86, pt. 5, p. 108–140. Basal member of Stranger formation. Represents filling of large southwest-trending valley, major feature of regional disconformity which separates Pedee group or older beds (Missourian) from overlying Douglas group

(Virgilian). Tonganoxie contains four lithologic units (ascending): conglomerate, sandstone, shale, and coal. Thickness 4 to 100 feet, no complete sections exposed and thickness determined from composite sections. Underlies Westphalia limestone member.

Type locality: Area east of Tonganoxie, Leavenworth County, Kans. Well exposed along U.S. Highway 40 in secs. 26 and 35, T. 11 S., R. 21 E., about 7 miles east of Tonganoxie and on Stranger Creek and its tributaries north of Linwood, Kans.

**Tongue River Member** (of Fort Union Formation)[1]

Tongue River Formation (in Fort Union Group)

Paleocene: Northeastern Wyoming, eastern Montana, southwestern North Dakota, and South Dakota.

Original reference: J. A. Taff, 1909, U.S. Geol. Survey Bull. 341, p. 129–130.

W. M. Laird and R. H. Mitchell, 1942, North Dakota Geol. Survey Bull. 14, p. 21–23. Described in southern Morton County where it is considered formation in Fort Union group. Thickness 180 feet. Overlies Cannonball formation. Paleocene.

R. V. Hennen, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 12, p. 1573 (fig. 1), 1580. In Morton County, N. Dak., Almont sandstone (new) lies approximately 35 feet above base of Tongue River member of Fort Union.

W. E. Benson, 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1873. Tongue River member of Fort Union formation conformably underlies Golden Valley formation.

S. P. Fisher, 1953, North Dakota Geol. Survey Rept. Inv. 11. Formation, as now recognized, includes all strata above Ludlow-Cannonball formation below Golden Valley beds. Includes Sentinel Butte shale facies in upper part. Thickness within map area [McKenzie County] 745 to 1,010 feet; average 800 feet.

P. R. May, 1954, U.S. Geol. Survey Bull. 995–G, p. 268. Tongue River member, which is exposed over nearly all Wibaux area [Montana and North Dakota], is composed of light-yellow, tan, and gray sandstones and shales; thin lenses of limestone; and numerous beds of lignite, the thicker margins of which are commonly marked by fringes of clinker. Thickness about 1,200 feet in Sidney lignite area; about 600 feet in Marmarth field. Overlies Ludlow member; underlies Sentinel Butte member. In older reports, term Fort Union formation is restricted to yellow strata herein referred to as Tongue River member. Paleocene.

B. M. Hanson, 1955, North Dakota Geol. Survey Rept. Inv. 18. Upper 350 feet of Tongue River formation well exposed in bluffs bordering Little Missouri River along its entire course through Elkhorn ranch area. Lower 750 feet of formation exposed between mapped area and Marmarth, 36 miles to south. At latter locality, the Tongue River conformably overlies Ludlow formation. Total thickness of Tongue River, including Sentinel Butte member, about 1,600 feet.

B. C. Petsch, 1956, Areal geology of the Ladner quadrangle (1:62,500) South Dakota Geol. Survey. Formation geographically extended into Ladner quadrangle, South Dakota, where it is dominantly massive sandstone that forms prominent cliffs. Thickness 35 to 200 feet. On North Cave Hills, composed of upper and lower sandstone separated by gray clay-shale, peat clay, and lignite seam ("E" bed of U.S. Geological Survey and Atomic Energy Commission), and Lodgepole facies which is commonly radioactive. Top of section; overlies Ludlow formation.

W. J. Mapel, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 220 (fig. 2), 221. Tongue River member is at least 2,000 feet thick in southern Rosebud County, Mont., 800 feet near Sheridan; and about 600 feet near Gillette, Wyo. Overlies Lebo shale member; underlies Wasatch formation.

Named for exposures along Tongue River, northeastern Wyoming and southeastern Montana.

Tonica cyclothem (in Spoon-Carbondale Formations)

Pennsylvanian: Northern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 53 (table 2), pl. 1. Proposed for strata previously referred to Liverpool cyclothem. Occurs above Abingdon cyclothem and below Lowell cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Along Vermilion River one-half mile west of Lowell, LaSalle County. Name derived from Tonica, 3 miles southeast of type section.

Tonka Formation

Mississippian and Pennsylvanian (Meramecian-Springeran): Northeastern Nevada.

R. H. Dott, Jr., 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 11, p. 2222–2233, figs. 2, 5. Brown weathering chert-pebble conglomerate with quartzite and fossiliferous calcareous interbeds. Coarse conglomerates and quartzites crop out as series of bold dark-brown or reddish-brown cliffs and ledges with intervening poorly exposed limestones and siltstones. Pebbles of conglomerate of varying hues of gray, brown, black, and especially grayish green. Sandstone and siltstone comprise less than one-third of formation. Calcareous interbeds are light gray, pinkish, grayish yellow, or light brown. Thickness at least 2,000 feet in type section; at least 3,000 feet in Carlin Canyon. Conformably overlies and grades eastward into White Pine? shale; conformably underlies Moleen formation (new).

Standard [type] section: Begins in ridge directly southeast of Tonka and extends three-quarters mile eastward. Two supplementary sections are: lower west side of Grindstone Mountain, 5 miles east, and Spring Canyon Mountain, 5 miles south of Tonka. Named for Tonka Siding on Western Pacific Railroad at east end of railroad tunnel in central Carlin Canyon (NE¼SE¼ sec. 28, T. 33 N., R. 53 E.).

**Tonnie Siltstone Member** (of Chinitna Formation)

Tonnie Sandstone Member (of Tuxedni Formation)

Tonnie Siltstone Member (of Tuxedni Formation)

Upper Jurassic: Central southern Alaska.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1). Series of alternating sandstones, shales, and coarse conglomerates with numerous fossil-bearing horizons. Thickness 1,200 feet. Uppermost member of Tuxedni formation; underlies Shelikof formation.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Youngest member of Tuxedni formation on Iniskin Peninsula. Consists of 900 feet of siltstone capped by approximately 200 feet of sandstone on Tonnie Peak. Siltstone is dark gray and weathers light brown; thick bedded and calcareous in part. Beds at top of member range from 1 to 10 feet thick and are composed of fine- to medium-grained sandstone. Overlies Bowser member (new); underlies Chinitna siltstone. Geographic distribution given.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 979; 1953, U.S. Geol. Survey Prof. Paper 249–B, p. 49, 51. Massive sandstone capping Tonnie Peak disappears to south, and in most places the siltstones assigned to the Tonnie cannot be separated from the overlying siltstones of Chinitna formation. Therefore, Tonnie member placed in Chinitna, forming roughly lower third of formation.

Crops out in trough of Tonnie syncline and in long, narrow belt that extends from Chinitna Bay to Iniskin Bay along west face of coastal ridge on Iniskin Peninsula. Best exposures in vicinity of Tonnie Peak.

**Tonoloway Limestone** (in Cayuga Group)[1]

Upper Silurian: West Virginia, Maryland, Pennsylvania, and Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 28.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 75–76, 79, 84. In Pennsylvania, underlies Keyser limestone. Some beds formerly included in Tonoloway are placed in Keyser of this report.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 8, 207–257, measured sections. Described in West Virginia where it is 100 to 600 feet thick. Overlies Wills Creek formation; underlies Keyser limestone. This is "Bossardville limestone" of earlier reports. States type locality. Cayugan series, Upper Silurian.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept. 14] Washington County, p. 79–80. In Maryland, overlies Wills Creek formation and underlies Keyser limestone member of Helderberg. Thickness about 600 feet. Includes Indian Spring sandstone and Indian Spring red beds.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 5, 20. Thickness of formation 400 to 600 feet in central Pennsylvania. Overlies Wills Creek formation; underlies Keyser formation. Silurian.

Type locality: East flank of Tonoloway Ridge, along Cacapon near Rock Ford, Morgan County, W. Va.

**Tonopah Formation**[1]

Tertiary: Central Nevada.

Original reference: J. E. Spurr, 1905, U.S. Geol. Survey Prof. Paper 42, p. 41, map.

Well exposed in westerly workings of Tonopah Extension mine. Tonopah district.

Tonosí Limestone

Oligocene, middle: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, pt. 4a, no. 29, p. 134 (chart). Named on correlation chart. Occurs above Bucaro formation and below unnamed upper Oligocene unit.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4, p. 234 (chart). Name Tonosí limestone appears on correlation chart. Occurs below upper Oligocene Santiago formation and above unnamed lower Oligocene unit.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 347. An undefined name for strata of Oligocene age in Tonsí area.

Los Santos Province.

**Tonto Group**[1]

Lower and Middle Cambrian: Central and northwestern Arizona.

Original references: G. K. Gilbert, 1864, Phil. Soc. Washington Bull., v. 1, p. 109; 1875, U.S Geog. and Geol. Survey W. 100th Mer., v. 3, p. 60, 171–186, fig. 82.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 3, p. 237–239. Location of original outcrop of Tonto formation was Tonto Creek, from which title of formation was derived in vicinity of Fort Apache nearly 200 miles southeast from Grand Canyon station and not in Grand Canyon section which has come to be regarded by many geologists as type locality. Tonto group holds precedence over name Apache group of Precambrian age and has surprisingly limited areal expanse—not to include Grand Canyon section with which it was erroneously correlated.

Alexander Stoyanow, 1942, Geol. Soc. America Bull., v. 53, no. 9, p. 1270–1271. Since Gilbert originally referred to "Tonto group" as being located in headwaters of Verde and Tonto Creeks and because western tributaries in headwaters of Tonto Creek cut through Diamond Mesa and other mesas in which Tapeats sandstone (basal member of Tonto group) is well exposed, presence of this basal sandstone member of Tonto group in the true Tonto basin (Gilbert's type locality, 1875, p. 60) of western Gila County is beyond question. Type locality not in vicinity of Fort Apache as indicated by Keyes. Tonto confused with Apache beds.

T. F. Stipp and H. M. Beikman, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–201. Includes rocks of Lower and Middle Cambrian age in northwestern and central Arizona where it underlies Temple Butte limestone.

Type locality: Tonto basin, western Gila County. Group floors the valleys that contain headwaters of Big Williams Fork of Colorado River and of Verde and Tonto Creeks, tributaries of Salt River.

†Tonto Sandstone[1]

Middle Cambrian: Arizona.

Original reference: G. K. Gilbert, 1875, U.S. Geog. and Geol. Survey W. 100th Mer., v. 3, p. 60, 171–186, fig. 82.

†Tonto Shale[1]

Middle Cambrian: Arizona.

Original reference: G. K. Gilbert, 1875, U.S. Geog. and Geol. Survey W. 100th Mer., v. 3, p. 60, 171–186, fig. 82.

**Tonzona Group**[1]

Silurian, Devonian, and Carboniferous: Central southern Alaska.

Original reference: A. H. Brooks, 1911, U.S. Geol. Survey Prof. Paper 70, p. 55, 66, 73, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Name appears on map legend under both Silurian and Devonian rocks.

Named for Tonzona River, in whose basin these rocks typically occur, Tonzona district, Kuskokwim region.

**Topache Limestone**[1]

Devonian(?) and Mississippian: Southwestern Utah.

Original reference: B. S. Butler, 1913, U.S. Geol. Survey Prof. Paper 80.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 135, pl. 2 (column 29). Name appears on Mississippian correlation chart. Parts of fauna typically of Madison limestone; others may be slightly younger.

Grant Steele, 1960, Dissert Abs., v. 20, no. 12, p. 4635. Three facies of lower part of Pennsylvanian system (Springeran to Des Moinesian) in eastern Great Basin are clearly defined by their proximity to tectonically active lands formed by Antler orogeny in late Mississippian to earliest Pennsylvanian time. Sediments characterizing eastern and southern facies (Ely, Oquirrh, Bird Spring, Callville, and Topache formations) being less affected by the Antler positives, were deposited in a limestone, dolomite, and silt province.

Type locality: Topache Peak, southeast of Frisco district.

**Topagoruk Formation**

Topagoruk Member (of Umiat Formation)

Lower Cretaceous: Northern Alaska (subsurface and surface).

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 162–163, fig. 2. Top 1,000 feet of member include nonmarine units of Niakogon tongue (new) of Chandler formation (new) and consists of coal, shale, sandstone, and minor amounts of ironstone. Bottom 2,100 feet entirely marine clay shale, silt shale, silt, and sandstone. Thickens southward and intertongues with Hatbox and Niakogon tongues (new) of Chandler formation. Overlies Tuktu member (new); underlies Seabee member (new) of Schrader Bluff formation (new). Lower(?) Cretaceous.

F. M. Robinson, F. P. Rucker, and H. R. Berquist, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 229–232. Most exact type locality data given. Redescribed in subsurface as formation to include major part of previously described member. Original member extended from 50 feet to 3,100 feet in test well, whereas formation as now defined extends from 1,350 feet to 3,900 feet in same well. Formation primarily of medium- to medium-dark-gray clay shale, with thin beds and laminae of medium-gray siltstone, although upper 800 feet also contain some thin beds of very argillaceous, very fine-grained sandstone. Dominantly of fine marine clastics in contrast to overlying sandstone of Grandstand formation. Unconformably overlies Oumalik formation (new) in type well; formations have gradational contact in Oumalik type area.

F. M. Robinson, 1959, U.S. Geol. Survey Prof. Paper 305–J, p. 527–528, fig. 46. Age of formation given as Early Cretaceous.

Named from section from 50 to about 3,100 feet in Topagoruk test well No. 1, a dry hole located on coastal plain of northern Alaska, at lat 70°37′30″ N., long 155°33′36″ W., approximately 72 miles S. 14° E. of

Point Barrow. Type section [as redescribed] in this well between 1,350 and 3,900 feet.

**Topango Formation**[1]

Miocene, middle: Southern California.

Original reference: W. S. W. Kew, 1923, Am. Assoc. Petroleum Geologists Bull., v. 7, p. 411–420.

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists, v. 30, no. 4, p. 515–520. In Puente and San Jose Hills area. subdivided to include Buzzard Peak conglomerate member (new) near top. Here underlies Puente formation and overlies [Glendora volcanics]. Thickness 3,000 feet.

Takeo Susuki, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1345. At type locality, consists of more than 8,000 feet of conglomerates, sandstones, and shales with intercalated basalts; disconformably overlies Oligocene Sespe and underlies Upper Miocene Modelo shales with marked angular unconformity.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 6 (table 1), 20–23. In Griffith Park area, Los Angeles County, composed of three unnamed members each separated by unconformities; aggregate thickness 4,900 feet. Underlies Hollycrest formation (new); unconformably overlies Cahuenga beds (new).

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–154. Mentioned in Santa Ana Mountains area where it underlies La Vida member (new) of Puente formation.

J. G. Vedder, R. F. Yerkes, and J. E. Schoellhamer, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–193. In Orange County, subdivided into three members (ascending): Bommer, Los Trancos, and Paularino.

Type locality: Topanga Canyon, 10 miles northwest of Santa Monica, Los Angeles County.

†Topatopa Formation[1]

Eocene: Southern California.

Original reference: G. H. Eldridge, 1907, U.S. Geol. Survey Bull. 309.

Crops out in mountains north of Santa Clara Valley, Ventura County.

**Topeka Limestone** (in Shawnee Group)[1]

Topeka Limestone Member (of Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original references: E. Haworth, 1895, Kansas Univ. Quart., v. 3, pl. opposite p. 290; 1895, Am. Jour. Sci., 3d, v. 50, pl. opposite p. 466.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 160–165. Uppermost formation in Shawnee group. Thickness in Kansas 33 to 55 feet. Comprises (ascending) Hartford limestone, Iowa Point shale, Curzon limestone, Jones Point shale, Sheldon limestone, Turner Creek shale, DuBois limestone, Holt shale, and Coal Creek limestone members. Overlies Calhoun shale; underlies Severy shale of Wabaunsee group.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 20–21. Thickness of formation in Nebraska about 36 feet. Includes nine members [see above annotation]. Condra and Reed (1937), being uncertain regarding relation of the Hartford of southern Kansas to lower member of Topeka in northeastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa, proposed name Wolf River for basal member of Topeka in this area. Nebraska Survey will drop name Wolf River if it proves correlative with the Hartford. Underlies Severy shale; overlies Calhoun formation. Shawnee group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii (fig. 3), 16, 18. As defined in Missouri, it is uppermost formation in Shawnee group. Jones Point shale, Sheldon limestone, and Iowa Point shale formerly included in underlying Calhoun shale are here classed as members of the Topeka. Hence the Topeka consists of nine members [see annotation Moore, 1949, above]. Overlies Calhoun shale; underlies Severy shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 15–17, fig. 5. In Iowa, thickness is variable largely as result of thinning and thickening of shale members. Thickness 13 feet in north at Macedonia; 35 feet northeast of Greenfield. Comprises nine members [see annotation Moore 1949, above]. Overlies Calhoun shale; underlies Severy shale of Wabaunsee group.

Type locality at Topeka, Shawnee County, Kans.

Tophet Limestone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 356.

Type locality: On hill road toward Lick Creek, 0.2 mile north of Tophet, Summers County.

Tophet Sandstone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 357.

Type locality: On hill road toward Lick Creek, 0.2 mile north of Tophet, Summers County.

Tophet Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 356–358.

Type locality: In vicinity of Tophet, Summers County.

Top Hill Sandstone[1]

Pennsylvanian: Western central Kentucky.

Original reference: D. D. Owen, 1856, Kentucky Geol. Survey, v. 1, pl.

Hancock, Breckinridge, and Meade Counties.

**Toqua Sandstone Member** (of Blockhouse Shale)

Middle Ordovician: Eastern Tennessee.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 150–151, pl. 28. Light-gray fine- to coarse-grained calcareous sandstone. Finer grained sandstone well laminated, crossbedded, and in beds 4 to 12 inches thick separated by thinner beds of dark-gray shale. Coarser grained rock poorly laminated and in beds 10 to 20 inches thick set apart by poorly defined bedding plane partings. Weathers greenish brown or olive; its saprolite is yellow brown to ochrous. Thickness at type section about 400 feet. Overlies Whitesburg limestone member; underlies dark shale member.

Type section: Measured 1.15 miles southeast of Toqua Church, Vonore quadrangle, Monroe County, near southeast bank of Tellico River, along and near a wagon road. Name taken from Toqua Church.

**Toquima Formation**[1]

Lower, Middle, and Upper(?) Ordovician: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

C. E. Decker, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 1, p. 107. Mentioned in discussion of significance of graptolites of Athens shale.

Present over considerable part of Toquima Range.

Tor Formation

Devonian: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). Named on cross section and structure section in report on Paleozoic continental margin in central Nevada. Overlies Antelope Valley formation.

Toquima Range, Nye County.

**Torcer Formation**[1]

Lower Cretaceous(?): Western Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 254–257, 286.

C. C. Albritton, Jr., 1937, Jour. Paleontology, v. 11, no. 1, p. 19; 1937, Field and Laboratory, v. 5, no. 2, p. 50. Redefined to include only the Lower Cretaceous fraction of original Malone. Embraces minimum thickness of 400 feet of limestone, sandstone, and shale, with persistent basal chert-pebble conglomerate and quartzitic sandstone resting conformably on the Malone. Basal member contains diagnostic *Neocomites cf. indicus* Waagen along with foraminifers *Guembelina paucistriata* Albritton and *Anomalina torcerensis* Albritton; *Ammobaculites subcretaceous* Cushman and Alexander occurs higher in section. Top not exposed in Malone Mountains.

C. C. Albritton, Jr., 1938, Geol. Soc. America Bull., v. 49, p. 1754 (fig. 2), 1764–1767, strat. sections. Section used for defining formation shows duplication of beds. Pelecypods thought to be characteristic of formation actually occur in Malone and, hence, are Jurassic rather than Cretaceous. On basis of paleontological evidence, it can be shown that approximately the upper 400 feet of sedimentary column in Malone Mountains is Lower Cretaceous. For these strata, name Torcer is retained.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 996–997, 998 (fig. 3). Formation, which crops out only in northwestern part of northern Quitman Mountains area, is composed of two distinct lithologic units: a quartz- and chert-pebble conglomerate at the base that grades upward into a quartzitic sandstone. Torcer proper is predominantly impure black limestone and sandstone with abundant thin shale layers. Basal quartzite member thins to south and is only about 10 feet thick in Third Hill. Thickness of upper member about 300 feet. Conformably overlies Malone formation; contact is a narrow gradational zone.

Contact with overlying Yucca formation not exposed. Believed to be lowermost Cretaceous.

Type locality: In Malone Mountain. Named from exposures at and near Torcer (formerly Malone) Station, on Southern Pacific Railway, west of Sierra Blanca, Hudspeth County.

**Torch Lake Amygdaloid**[1] (in Central Mine Group)

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Keweenaw Point.

**Torch Lake Flow**[1] (in Central Mine Group)

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Keweenaw Point.

**Torchlight Sandstone Member** (of Frontier Formation)[1]

Upper Cretaceous: Northern Wyoming and southern Montana.

Original reference: F. F. Hintze, Jr., 1915, Wyoming Geol. Survey Bull. 10, p. 23.

J. H. Heathman, 1939, Wyoming Geol. Survey Bull. 28, p. 7 (table 2), 13. On south and east sides of Bighorn basin consists of massive sandstone about 75 feet thick at top of Frontier formation. Underlies Niobrara.

Exposed in Torchlight dome, Basin oil field, Wyoming.

Torcido member (of Serpiente Sandstone)

*See* Serpiente Sandstone.

Tordilla sandstone bed (in Dubose Member of Whitsett Formation)

Eocene, upper: South-central Texas.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2633. Local name applied to a 30-foot silicified fine-grained sandstone bed in Dubose member of the Whitsett.

Exposed in Tordilla Hill, western tip of Karnes County.

**Tordrillo Formation**[1]

Middle Jurassic: Central southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey Ann. Rept., pt. 7, p. 153–155.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500.000) : U.S. Geol. Survey. Appears on map legend.

On Tordrillo Mountains, Cook Inlet region.

Toreo Limestone

Eocene(?) : Panamá.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 239.

A. A. Olsson, 1942, 8th Am. Sci. Cong. Proc., v. 4; p. 242. Upper Eocene Torio limestone is unconformable below Montijo formation.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 348. Poorly defined name. Eocene(?). Correct spelling Toreo.

On west side of Azuero Peninsula. Along Río Toreo, Veraguas Province.

**Toreva Formation** (in Mesaverde Group)

Upper Cretaceous: Northeastern Arizona.

G. A. Kiersch, 1955, Mineral Resources Navajo-Hopi Indian Reservations, Arizona-Utah, v. 2: Tucson, Ariz., Univ. Arizona Press, p. 4 (fig. 1), 7. Comprises lower sandstone member, medial carbonaceous member, and upper sandstone member. Underlies Wepo formation (new); overlies Mancos shale. Name credited to Repenning and Page.

C. A. Repenning and H. G. Page, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 271–277. Lower member is light-brown to pale-yellowish-gray fine- to medium-grained quartz sandstone, forms vertical blocky cliffs 128 feet high. Middle member, in gradational contact with lower member, has extremely varied lithologic character from place to place; in general consists of alternation of flat and thinly bedded carbonaceous mudstone, varicolored siltstone units with coal, and thick lenses of yellowish-gray fine- to coarse-grained poorly sorted quartz sandstone; thickness 106 feet. Upper member is yellowish-gray to grayish-orange-pink sandstone; upper part commonly conglomeratic in southern part of Black Mesa; thickness 79 feet both upper and lower contacts of formation gradational.

Type locality: In Cliffs of Black Mesa 1.3 miles northwest of small settlement of Toreva, from which unit is named, in Hopi Indian Reservation, Navajo County. Traceable by nearly continuous outcrops about entire margin of Black Mesa.

Torio Limestone[1]

*See* Toreo Limestone, correct spelling.

†Tornado Limestone[1]

Lower Mississippian and Lower Pennsylvanian: Central Arizona.

Original reference: F. L. Ransome, 1915, Washington Acad. Sci. Jour., v. 5, p. 380–385.

N. P. Peterson, C. M. Gilbert, and G. L. Quick, 1951, U.S. Geol. Survey Bull. 971, p. 20, 21. Rocks previously included in Tornado limestone in Castle Dome area mapped as Escabrosa limestone (Mississippian) and Naco limestone (Pennsylvanian).

E. D. Wilson, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 52, 53. In general, the Mississippian beds are crystalline and relatively pure, whereas Pennsylvanian tend to be dense, impure, and cherty.

Named for Tornado Peak, Dripping Spring Range, Ray quadrangle.

**Tornillo Clay**[1]

Upper Cretaceous (Gulf Series): Western Texas.

Original reference: J. A. Udden, 1907, Texas Univ. Bull. 93, p. 17, 54–60.

J. A. Wilson and others, 1952, Texas Univ. Bur. Econ. Geology Rept. Inv. 14, p. 7. On basis of vertebrate faunas, it is believed that part of strata formerly included in Tornillo are Paleocene and lower Eocene.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol. Survey Prof. Paper 312, p. 16, pl. 1. Described in Terlingua district where it is exposed only in extreme southeastern part of area. Thickness 600 to 1,000 feet. Overlies Aguja formation; underlies Chisos volcanics.

Named for exposures along Tornillo Creek, Brewster County, in Chisos Mountains quadrangle.

†Toro Formation[1]

Lower Cretaceous: Western California.

Original reference: H. W. Fairbanks, 1904, U.S. Geol. Survey Geol. Atlas, Folio 101.

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 459. Original Toro included both the restricted Knoxville (Upper Jurassic) and Paskenta stage of Lower Cretaceous; the two are separated by an unconformity. Knoxville part of Toro contains pillow basalts and intruded by basic and ultrabasic igneous rocks; Lower Cretaceous part contains no igneous material except as debris in conglomerates. Name Marmolejo formation proposed for Lower Cretaceous of Santa Lucia Range.

Named for exposures along Toro Creek, San Luis Obispo County.

**Toro Limestone Member** (of Chagres Sandstone)

Toro Limestone[1]

Pliocene, lower: Panamá and Costa Rica.

Original reference: D. F. MacDonald, 1915, U.S. Bur. Mines Bull. 86, p. 26.

[T. F. Thompson], 1943, Panama Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 21–22, fig. 3–2. Names Toro limestone and Caribbean limestone have been used to describe deposits of shell breccia or cemented coquina that overlie Gatún sandstone in region between Lemon Bay and Chagres River. The formation [Toro] has been assigned to upper Miocene.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 244, 246 (fig. 2). Rank reduced to member status in Chagres sandstone. Chiefly a lime-cemented coquina made up of barnacle and shell fragments; lenses of medium- to coarse-grained sandstone interbedded with the calcareous beds. Variable thickness; maximum 125 feet. Overlies Gatún formation. Late Miocene.

W. P. Woodring, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–1; 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 47–50, 51 (fig. 4), pl. 1. Lower Pliocene

Type locality: Toro Point, C.Z.

**Torok Formation**

Lower Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160, 161, fig. 2. Comprises 2,000 feet of dark silt and clay shale with limestone concretions in lower part and about 8,500 feet of dark shale and marine conglomerate and sandstone of graywacke type in upper part at Castle Mountain. Consists of 4,500 feet of dark clay and silt shale in upper part which includes 500 feet of sandstone and some conglomerate, and 1,500 feet of dark silt and clay shale in lower part in vicinity of Tuktu Bluff about 11 miles north of Castle Mountain. Total thickness at Tuktu Bluff 6,000 feet; at Castle Mountain 10,500 feet.

Unconformably overlies Okpikruak formation (new) at most places. Underlies Nanushuk group.

W. W. Patton, Jr., 1956, *in* George Gryc and others, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 219, 222–223, fig. 5. Redefined to exclude sandstone, conglomerate, and intercalated shale sequence that overlies Okpikruak formation and crops out along east-trending belt near southern margin of Arctic Foothills province. These beds now included in Fortress Mountain formation (new). Restricted to northern predominantly shale facies. Type section only about 50 percent exposed. Bulk of formation, as redefined, composed of gray silt and clay shale interbedded with subordinate amounts of green to gray siltstone. Specific type section given. Type section approximately 6,000 feet thick.

E. G. Sable, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2637, fig. 3. Underlies and intertongues with Kukpowruk formation (new) as traced southwestward.

R. M. Chapman and E. G. Sable, 1960, U.S. Geol. Survey Prof. Paper 303–C, p. 73–83, pls. Thickness about 6,458 feet in Utukok-Corwin region. Overlies Fortress Mountain formation and may be in part equivalent to it; underlies Kukpowruk formation with contact gradational and intertonguing.

Type locality: Torok Creek, a tributary to Chandler River in vicinity of Castle Mountain, and on Chandler River between mouth of Torok Creek and mouth of Kiruktagiak River. Type section along Chandler River and Torok Creek between lat 68°40′ N. and lat 68°43′45″ N.

**Toronto Limestone[1] Member** (of Oread Limestone)

Pennsylvanian (Virgil Series): Southeastern Kansas, southwestern Iowa, and western Missouri.

Original reference: E. Haworth and W. H. H. Piatt, 1894, Kansas Univ. Quart., v. 2, p. 117.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5). Basal member of Oread formation; underlies Snyderville shale member; overlies Lawrence formation. This is classification agreed upon by Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 26. Persistent in central and southern Kansas and correlated by Kansas Survey with Weeping Water limestone of Nebraska; if this correlation is correct, the occurrence is in Iowa, Nebraska, Missouri, and through Kansas into Oklahoma. Name Toronto has priority over Weeping Water limestone of Nebraska, although Nebraska uses term Weeping Water.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 38, pl. 1. Member, in Douglas County, is typically light yellow brown or light gray when fresh; weathers deep yellow brown. Average thickness about 10 feet.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 23, fig. 5. Nodular sandy limestone occurring about 8 feet beneath Leavenworth limestone in Adair County is tentatively identified as Toronto. A similar limestone is known from well records in Cass and Montgomery Counties. Data are not available to preclude possibility that this bed represents the Amazonia, Haskell, or Iatan limestones of the Lawrence-Stranger formations.

Type locality: Toronto, Woodson County, Kans.

**Toroweap Formation** (in Aubrey Group)

Permian: Northwestern Arizona, southeastern Nevada, and southwestern Utah.

E. D. McKee, 1937, Carnegie Inst. Washington Year Book 36, p. 341–343. Unconformity occurs at top of middle red-bed member of Kaibab. Proposed to restrict Kaibab to units above unconformity and to apply name Toroweap to units below unconformity.

E. D. McKee, 1938, Carnegie Inst. Washington Pub. 492, p. 12–28, geol. sections. In type locality, consists of two red-bed series separated by massive limestone unit. Complete lithological change occurs within distance of few miles laterally between distinctive western and eastern types (referred to as phases); western phase is larger in geographical extent and includes type locality. Western phase divided into three members, $\alpha$, $\beta$, and $\gamma$, representing, respectively, the upper red member or time of receding sea, the limestone member or time of extended sea, and lower red member or time of advancing sea. Thickness at type locality about 325 feet. Conformably overlies Coconino sandstone; underlies Kaibab formation (name used in restricted sense).

R. E. Lehner, 1958, U.S. Geol. Survey Bull. 1021–N, p. 543–545. Described in Clarkdale quadrangle, Arizona, where it is 150 to 165 feet thick, conformably overlies Coconino sandstone and underlies Kaibab limestone. Lithology indicates that in this area it is part of transitional phase where members of western phase are partly formed and intertongue with sandstone of eastern phase. Can be subdivided into three main units (ascending): red to buff sandstone; calcareous sandstone and arenaceous limestone; and alternating red and buff sandstone, siltstone, and some shale including a few white fine-grained pure sandstone beds intercalated. These units may be the easternmost, recognizable equivalents of McKee's three units. In area of present report, the middle unit is most prominent unit of formation.

T. F. Stipp and H. M. Beikman, 1959, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map OM–201. Included in Aubrey group.

Type section: Eastern wall of Toroweap Valley in Grand Canyon National Monument, Ariz. Section is about 8 miles north of Colorado River.

**Torpedo Sandstone Member** (of Wann Formation)

Torpedo Sandstone (in Ochelata Group)

Torpedo Sandstone Member (of Ochelata Formation)[1]

Pennsylvanian (Missouri Series): Central northern Oklahoma.

Original reference: O. B. Hopkins, 1918, U.S. Geol. Survey Bull. 686–H, p. 76–77, pl. 12.

M. C. Oakes, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 720 (table 1), 727–728; 1940, Oklahoma Geol. Survey Bull. 62, p. 81–86. Included in Ochelata group. Overlies Wann formation (revived, restricted, and redefined); underlies unnamed shale below Birch Creek limestone, locally in contact with Birch Creek. At northern and southern extremities, cut off by unconformity at base of Birch Creek. Thickness as much as 60 feet. Type locality stated.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 34, 37. Oakes (1940) revived, restricted, and redefined term Wann formation to apply to all strata between top of Iola formation below and base of Torpedo sandstone above or base of Birch Creek limestone where Torpedo sandstone is absent. Oakes (1951, Tulsa Geol. Soc. Digest, v. 19) included Birch Creek limestone in Barnsdall formation as basal member in northern Oklahoma. Torpedo sandstone and the shale above the Torpedo and beneath Birch Creek limestone crop out only in Washington County and eastern Osage County. This situation led Miser (1954, Geologic map of Oklahoma) to place top of Wann formation at base of Barnsdall formation throughout, and to include Torpedo sandstone and the shale above it in Wann formation. This amounts to minor change in definition of the Wann, but it is significant for northern Oklahoma only. This report follows Miser's interpretation of the Wann. Thickness of Torpedo 2 feet at Kansas-Oklahoma line; 30 feet 3 miles farther south. Unit does not appear to extend into Kansas.

Type locality: In hills, 1 mile northwest of Torpedo, on north side of Creek. Torpedo switch is on Atchison, Topeka, and Santa Fe Railroad, in SW¼ sec. 17, T. 26 N., R. 12 E., Osage County.

Torrance shale[1]

Permian (?): Central-northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 3, 11.

In Manzano Mountains. Derivation of name not given.

**Torrejon Formation** (in Nacimiento Group)[1]

Paleocene: Northwestern New Mexico.

Original reference: J. L. Wortman, 1897, as reported by G. N. Calkins, secy. of Biology section, A. A. A. S., in Sci., new ser., v. 6, p. 852.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 33, pl. 1. Underlies Canyon Largo group (resurrected); overlies Puerco formation. Paleocene (Torrejonian).

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 272–273. On east side of San Juan Basin, Puerco and Torrejon are not recognizable lithologic units. Seems practical to consider this part of stratigraphic sequence as single formation, the Nacimiento, containing Puerco and Torrejon faunas.

Extends from Arroyo Torrejon in Sandoval County across southern and western parts of San Juan Basin almost to Colorado-New Mexico boundary.

Torrejonian Age

Paleocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 9, pl. 1. Provincial time term, based on Torrejon formation of San Juan Basin, New Mexico, type locality, the heads of Arroyo Torrejon. Covers interval between Paleocene Dragonian (older) and Tiffanian ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

Typical area: From [Arroyo Torrejon] northwest to Ojo Alamo, with additional poorer localities scattered to the north almost to Colorado line.

**Torres Member** (of Yeso Formation)

Permian (Leonard) : Central New Mexico.

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 61. Comprises bulk of Yeso formation. Alternating beds of orange-red and buff sandstone and siltstone, gray limestone, and gypsum. Thickness ranges from 350 to 600 feet. Underlies Canas gypsum member; overlies Meseta Blanca sandstone member. Type section shown on graphic section 4.

Type locality: Outcrops in tributary of Agua Torres Canyon, after which it is named, on Sevilleta Grant, 7 miles due south of Black Butte, Socorro County.

Torrey Sand[1]

Torrey Sand Member (of La Jolla Formation)

Eocene, middle: Southern California.

Original reference: M. A. Hanna, 1926, California Univ. Pub., Dept. Geol. Sci. Bull., v. 16, no. 7, p. 187–246.

L. G. Hertlein and U.S. Grant 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 66. Sand member of La Jolla. Maximum exposed thickness about 200 feet. Underlies Rose Canyon shale member; overlies Delmar sand member with gradational contact; in eastern part of La Jolla quadrangle, unconformably overlies Black Mountain volcanics.

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Shown on chart as sand member of La Jolla. Middle Eocene.

G. B. Oakeshott, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 254 (table). Table lists Torrey sand (formation). Underlies Rose Canyon shale; overlies Delmar sand.

Typically exposed on Torrey Pines grade, where highway climbs from Soledad Valley, San Deigo County.

Torrington Member (of Lance Formation)[1]

Upper Cretaceous: Southeastern Wyoming.

Original reference: E. M. Schlaikjer, 1935, Harvard Coll. Mus. Comp. Zoology Bull., v. 76, no. 2, p. 31–54, 65.

Named for proximity to town of Torrington, on North Platte River, north of typical exposures on Horse Creek, Goshen County.

**Tortugas Andesite**

Upper Cretaceous: Puerto Rico.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (chart), 9 (fig. 3), 10 (fig. 4), 13–15, pl. 2. Nonpersistent horizon of flow rock, breccia, and in places conglomerate—all of a characteristic augite-andesite composition—lying between Guaynabo formation (redefined) and Frailes formation (new). Varies in thickness rapidly, as for example at El Laberinto where probably over 1,300 feet of volcanic rocks of the Tortugas disappear almost abruptly along strike and suggests a local vent accumulation at this place. Unit was not recognized by Meyerhoff and Smith (1931). Its outcrop in vicinity of La Muda and Trujillo Alto is included in their Guaynabo, Luquillo, and Fajardo formations.

Named for exposures at Barrio Tortugas, north and east of La Muda, San Juan district.

**Tosi Chert Member** or **Tongue** (of Phosphoria Formation)

Permian: Western Wyoming, eastern Idaho, southwestern Montana, and eastern Utah.

R. P. Sheldon *in* V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2830 (fig. 2), 2832 (fig. 3), 2836 (fig. 4), 2851–2852; 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 30–31, pls. 2, 3. Thin dark- to light-colored chert beds that lie above Retort phosphatic shale member (new) of the Phosphoria in Wyoming, Montana, and in limited areas in Idaho and Utah, are here designated Tosi chert member of Phosphoria formation. At type locality, composed of lower brownish-gray-black chert unit, 25 feet thick, that contains abundant columns of chert several inches in diameter and 1 to 2 feet long, oriented obliquely to bedding, and an upper light-gray sandy chert unit, 8 feet thick. Contact with underlying Retort gradational through zone consisting of interbedded fissile mudstone and thin-bedded chert. Tosi is prominent member of Phosphoria in southeastern Montana and northwestern Wyoming, where in recent reports it has been included in E unit or member; most extensive tongue of Phosphoria into Park City formation in central Wyoming and into Shedhorn sandstone (new) in Wyoming and Montana. North of type locality, thickens to about 40 feet in Yellowstone Park and 145 feet in Beaverhead County, Mont.; 70 feet in Wind River Mountains; 15 feet in Owl Creek Mountains, Wyo., about 40 feet at Brazer Canyon, Rich County, Utah. Lower part of Tosi grades from Retort member; contact progressively falls to lower horizons north and east of Tosi Creek, and in vicinity of Yellowstone Park the Tosi is separated from lower member of Shedhorn sandstone by a phosphorite 0.5 foot thick. Overlain by Dinwoody formation in Wyoming Range and in western Beaverhead County; in Brazer Canyon, underlies thin tongue of the Franson; east and north of these areas, Tosi is overlain by units of Shedhorn and Park City formations; in Owl Creek and Wind River Ranges and Conant Creek anticline, Tosi is overlain by Ervay member of Park City.

Type locality: Tosi Creek in SE¼ sec. 17, T. 39 N., R. 110 W., Sublette County, Wyo., 8½ miles ENE of Tosi Peak on east nose of small anticline.

†Toston Beds[1]

Oligocene, upper: Western central Montana.

Original reference: E. Douglass, 1902, Am. Phil. Soc. Trans., v. 20, new ser., pt. 3, p. 237–245.

M. R. Thorpe, 1937, Am. Jour. Sci., v. 33, 5th ser., no. 198, p. 427. Upper Oligocene.

Northeast of Toston near Cottonwood Creek, in Helena-Big Belt region, Broadwater County.

**Totatlanika Schist**[1]

Mississippian(?): Central Alaska.

Original reference: S. R. Capps, 1912, U.S. Geol. Survey Bull. 501, p. 22, map.

Clyde Wahrhaftig, 1958, U.S. Geol. Survey Prof. Paper 293–A, p. 12, pls. 1, 2, 5. Assigned Mississippian(?) age based on fossils recovered in Nenana River valley region. Probably underlies Nenana gravel from Slate Creek to northern edge of gravel.

Named for exposures in canyon of Totatlanika River, 15 miles east of Nenana River, Bonnifield region. Forms belt 5 to 20 miles wide that extends along north edge of Alaska, to Little Delta River, 60 miles east of Nenana River.

†Totsen Series[1] or Group[1]

Early Paleozoic(?) : Northern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 239.

Named for Totsenbetna, a name formerly applied by the natives to Wild Creek.

Touchet Beds

Pleistocene: Eastern Washington.

R. L. Flint, 1938, Geol. Soc. America Bull., v. 49, no. 3, p. 493–495. Name applied to deposit of buff- to cream-colored silt and fine sand containing erratic stones. Younger than Palouse soil; grades stratigraphically and topographically into scabland fill. Thickness ranges from thin veneer up to more than 100 feet in single exposures.

Occurs in Pasco basin and in Columbia basin downstream as far as gorge through Cascade Mountains. Well exposed in vicinity of Touchet, Walla Walla County.

†Toughkenamon rock[1]

Precambrian: Southeastern Pennsylvania.

Original reference: F. Frazer, 1883, Pennsylvania 2d Geol. Survey Rept. $C_4$, p. 307–308, 319, 321.

Named for development near Toughkenamon Station, Chester County.

Tough Mountain Quartzite

*See* Tough Nut Quartzite.

Tough Nut Quartzite

Lower Cambrian: Southern California.

J. C. Hazzard, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 241. Listed as underlying Kelso shale and unconformably overlying Archean gneiss. Thickness 1,085 feet.

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, p. 32 (table 1). Name preoccupied. Unit termed Prospect Mountain quartzite. Underlies Latham shale (new) which replaces preoccupied term Kelso.

Area is in Providence Mountains, San Bernardino County.

Toughnut Series[1]

Lower Cretaceous(?) : Southeastern Arizona.

Original reference: W. P. Blake, 1902, Tombstone and its mines.

In Tombstone district.

**Toutle Formation**

Eocene, upper, and Oligocene, lower: Southwestern Washington.

M. H. Pease, Jr., and Linn Hoover, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–188. Named on correlation chart. Younger than Hatchet Mountain formation (new). Name credited to A. E. Roberts (in press).

A. E. Roberts, 1958, U.S. Geol. Survey Bull. 1062, p. 12 (chart), 24–31, pl. 1. Consists of about 570 feet of basaltic conglomerate, sandstone, siltstone, clay, and associated beds of lignite; locally interbedded basalt flows. In type area, unconformably overlies Hatchet Mountain formation; overlies Cowlitz formation in northern half of sec. 26, T. 11 N., R. 2 W. Unconformably underlies middle(?) Miocene volcanic sequence.

Type area: Along banks of Toutle River, from its tributary, Cline Creek, east to Coalbank Rapids, and north along Cedar Creek to Windom, Toledo-Castle Rock district.

Toutle River Mud Flow

Recent: Western Washington.

Don Mullineaux, 1960, Geol. Soc. Oregon Country Newsletter, v. 26, no. 5, p. 40. Flow came down North Fork of Toutle River, traversed length of main stream valley, and debouched into Cowlitz River valley; total length exceeds 40 miles. Flow almost completely filled Toutle River valley and created Silver Lake.

Flow issued from Mount St. Helens.

**Towanda Limestone Member** (of Doyle Shale)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: R. C. Moore, 1920, Kansas Geol. Survey Bull. 6, pt. 2, p. 61.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44. Consists of limestone, light bluish gray to yellow slabby and platy in middle and lower parts; brecciated in upper; fossils rare. Thickness commonly 5 to 10 feet; in Geary County, Kans., about 15 feet. Underlies Gage shale member; overlies Holmesville shale member.

Named from exposures near Towanda, Butler County, Kans.

†Towanda Sandstone (in Chemung Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: A. Sherwood, 1878, Pennsylvania 2d Geol. Survey Rept. G., p. 38–39.

Crops out in Wysox Township, opposite and a little above Towanda, Bradford County.

**Tow Creek Sandstone Member** (of Iles Formation)

Tow Creek Sandstone (in Mesaverde Formation)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: K. M. Willson, 1920, Colorado Geol. Survey Bull. 23, p. 30–39.

N. W. Bass, J. B. Eby, and M. R. Campbell, 1955, U.S. Geol. Survey Bull. 1027–D, p. 155–156. Reallocated to member status in Iles formation. Thickness 35 to 125 feet. Not everywhere a single massive bed; in some areas, consists of two or more beds separated by units of shale and sandy shale. Becomes shaly and loses identity in vicinity of Oak Creek. Underlies unnamed units of formation; overlies Mancos shale.

R. E. Kucera, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 41, 43, fig. 3. Basal member of Iles formation. Consists of

33 feet of light-brown to light-gray medium-grained crossbedded and massive sandstone in Yampa district. Overlies Mancos shale.

Forms top of ridges on both sides of Tow Creek, Routt County.

†Tower Group[1]

Precambrian: Northeastern Minnesota.

Original reference: A. Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept., p. 330–367.

Mapped at Tower, St. Louis County.

†Tower Sandstone Lentil (of Green River Formation)[1]

†Tower Sandstone Lentil (in Laney Shale Member of Green River Formation)

Eocene: Southwestern Wyoming.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Unita Mountains, p. 40, 45.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1074. Redefined as lentil in lower part of Laney shale member of Green River; only in few places does it coincide with base of member. A crystal tuff, not fluviatile deposit, made up of clastic sand grains; uniformly fine grained—not coarse grained as it has been described many times.

Forms top of weathered rocks known as The Towers, in vicinity of Green River, Sweetwater County.

**Tower Creek Conglomerate**[1]

Pliocene: Yellowstone National Park.

Original reference: A. Hague and others, 1904, U.S. Geol. Survey Yellowstone Nat. Park Atlas, geol. maps to accompany U.S. Geol. Survey Mon. 32.

Well exposed in northwest corner of Gallatin quadrangle. Named for exposure on Yellowstone River, opposite mouth of Tower Creek, Canyon quadrangle.

Tower Peak Porphyritic Syenite

Age not stated: Central Montana.

R. N. Miller, 1959, Montana Bur. Mines and Geology Mem. 37, p. 21–23. Name applied to porphyritic syenite which characterizes Tower Peak. Rocks of this type are light orange to brown or dark brown on weathered surface. Freshly broken surface shows dense, glassy-appearing, moderate-grayish-brown matrix with abundant phenocrysts of dark-greenish-black ferromagnesian mineral, and two kinds of feldspar, one grayish pink and the other light gray.

Named for occurrence on Tower Peak in South Moccasin Mountains, Fergus County.

**Towle Shale**[1] **Member** (of Onaga Shale)

Towle Shale (in Admire Group)

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: R. C. Moore and G. E. Condra, Oct. 1932, Revised classification chart of Pennsylvanian rocks of Kansas and Nebraska.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 170. Includes Indian Cave sandstone member which is present only locally and fills channels as deep as 120 feet. Wolfcamp series.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Rank reduced to member status in Onaga shale. Locally contains Indian Cave channel sandstone bed. Underlies Aspinwall limestone member; overlies Brownville limestone member of Wood Siding formation.

Type locality: Towle Farm, 2 miles south and 3 miles west of Falls City, SW¼ sec. 20, T. 1 N., R. 16 E., Richardson County, Nebr.

Towner Greenstone[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 615, 622.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included in Snowy Range series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consist of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

Exposed along road between Brooklyn Lodge and Towner Lake, Medicine Bow Mountains.

Townline Lake Granodiorite

Precambrian (Laurentian): Northeastern Minnesota.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1033. Name applied to granodiorite cutting Ely greenstone. May be offshoot of Saganaga granite.

Occurs as small mass on Townline Lake portage NW¼ sec. 18, T. 65 N., R. 5 W., in Vermilion district.

Town Mountain Granite[1]

Precambrian: Central Texas.

Original reference: H. B. Stenzel, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 144.

Virgil Barnes, Frederick Romberg, and W. A. Anderson, 1954, Internat. Geol. Cong., 19th, Algiers 1952, Comptes rendus, sec. 9, pt. 9, p. 153. Town Mountain granite invaded the already deformed metasediments [Valley Spring gneiss and Packsaddle schist] and was followed by Oatman Creek granite, Sixmile granite, and Llanite, the latter being the youngest.

Occurs on Llano uplift in Llano, Mason, Burnet, and Gillespie Counties.

Townsend Shale

Oligocene, lower: Northwestern Washington.

J. W. Durham, 1942, Jour. Paleontology, v. 16, no. 1, p. 86. Name proposed for a gray-black shale, 60 to 65 feet thick, that overlies the Lyre conglomerates, contact irregular, and unconformably underlies Quimper sandstone (new). Shale is well bedded and includes occasional nodular calcareous beds 6 to 12 inches thick.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 596, chart 11. Overlies Lyre conglomerate; unconformably underlies Quimper sandstone.

Type locality: North of Woodmans Wharf (now called Romana Beach), 8 miles southeast of Port Townsend, Jefferson County.

**Towow Formation**[1]

Pennsylvanian(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 199.

Occurs only in Lebanon Township. Name derived from original name of first settlement in town of Lebanon, York County.

**Towsley Formation**

Miocene, upper, and Pliocene, lower: Southern California.

E. L. Winterer and D. L. Durham, 1954, California Div. Mines Bull. 170, map sheet 5; 1958, U.S. Geol. Survey Oil and Gas Inv. Map OM-196. Sequence of lenticular units of light-colored conglomerate and sandstone interbedded with units of brown-weathering mudstone. Thickness as much as 4,000 feet; attains its maximum thickness along north slope of Santa Susana Mountains where it overlies and interfingers with Modelo formation; thins eastward to about 1,500 feet and near Newhall is overlapped by Pico formation.

Area of report is part of eastern Ventura Basin, Los Angeles County.

**Toyabe Quartz Latite**

Pliocene(?): South-central Nevada.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ-40. Thick sequence of flows of very uniform composition. Flow breccias in places. Locally thin tuff layers between flows. Total thickness may exceed 1,500 feet, with individual flows averaging between 50 and 100 feet in thickness. Unconformable contacts with Gilbert andesite below and Pleistocene(?) basalt above.

Type locality: Crest and west flank of Toyabe [Toiyabe] Range.

**Trabuco Formation**[1]

Cretaceous: Southern California.

Original reference: E. L. Packard, 1916, California Univ. Pub., Dept. Geol. Bull., v. 9, p. 140-141.

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166-170. Described in Santa Ana Mountains, Orange County, as soft red friable deeply weathered boulder conglomerate with some interbedded thin lenses of red crossbedded sandstone; unfossiliferous; thickness more than 300 feet. Forms base of unmetamorphosed sedimentary section. Unconformably overlies basement complex; underlies Baker Canyon member of Ladd formation. Cretaceous(?).

Named for Trabuco Canyon, Santa Ana Mountains.

Tracian Stage

Late Cretaceous: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 987-989, 1005-1006. One of six stages, based on foraminiferal assemblages, in Upper Cretaceous column between top of Moreno and base of Panoche, as defined by Anderson and Pack (1915). Includes interval between Ingramian stage (new) above and Weldonian stage (new).

Occurs in Great Valley in both surface and subsurface. Named from Amerada Petroleum Corp. F. D. L. Well 1, sec. 15, T. 2 S., R. 5 E., near town of Tracy, San Joaquin County.

†Tracy City measures[1]

Pennsylvanian: Southeastern Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 104, 148–153, 167, 169.

Named for Tracy City, Grundy County.

**Tracy Creek Quartz Latite**

Tracy Creek Andesite[1]

Miocene(?): Southwestern Colorado.

Original reference: Whitman Cross and E. S. Larsen, 1935, U.S. Geol. Survey Bull. 843, p. 64–65, pl. 1.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 86–87, pl. 1. Redescribed as quartz latite. Irregularly overlies Beidell quartz latite; underlies dark quartz latites of Conejos age.

Makes up much of drainage of Tracy Creek, for which it is named, Saguache quadrangle, Saguache County. Occurs chiefly in extreme southern part of Saguache quadrangle and extends into Del Norte quadrangle.

**Traders Iron-Bearing Member** (of Vulcan Iron-Formation)[1]

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1900, U.S. Geol. Survey Geol. Atlas, Folio 62.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Basal member of Vulcan iron-formation. Underlies Brier slate member; overlies Felch formation.

Named for Traders mine, north of Lake Antoine, Menominee district, [Dickinson County].

**Tradewater Formation**

Tradewater Formation (in Pottsville Group)[1]

Tradewater Group

Middle Pennsylvanian: Western Kentucky.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 27.

R. M. Kosanke, 1950, Illinois Geol. Survey Bull. 74, p. 63–70. Tradewater group, formerly called upper Pottsville, is known from outcrops in southern, western, and northern Illinois. Top of group in southern and western Illinois is placed at base of Palzo and Isabel sandstones. Base in southern Illinois is at base of Grindstaff sandstone. Beds from the Tarter to base of Carbondale have been placed in Tradewater group. Maximum thickness 445 feet, southern Illinois; 100 feet, western Illinois; possibly as much as 600 feet in central Illinois. Group includes a number of sandstones, shales, coal beds, and two marine limestones, the Stonefort and Curlew, in southern Illinois, and Seville and Seahorne limestones in western Illinois. Overlies Caseyville group; underlies Carbondale group.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 64–82, geol. sections. Tradewater group in Beardstown, Glasford, Havana, and Vermont quadrangles, is divided into pre-Babylon strata (at base) and the Babylon, Tarter, Pope Creek, Lower DeLong, Middle DeLong, Upper Delong, Seahorne, Wiley, and Greenbush cyclothems. Underlies Carbondale group. Pre-Babylon strata conform in position to knobs or other projections of the Mississippian surface and locally may fill solution cavities.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1). Name discontinued in Illinois. Lower part of Tradewater included in McCormick group (new) and upper part in Kewanee group (new).

U.S. Geological Survey uses the term Tradewater Formation in Kentucky, but has discontinued use of the term Pottsville Group in Kentucky.

Named for exposures along Tradewater River east of Battery Rock.

Trafalgar Formation

Pleistocene: Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 19 (fig. 3). Named on diagram showing formations of Pleistocene age in Indiana. Name appears above Jessup formation and below Lagro formation (both new). Name credited to W. J. Wayne (in preparation).

Type locality and derivation of name not given.

**Trail Formation**[1]

Upper Triassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–175, table 2. Shown on paleotectonic map as Lower Jurassic; underlies Hardgrave sandstone.

K. B. Ketner, 1959, *in* E. D. McKee and others, U.S. Geol. Survey Misc. Geol. Inv. Map I–300, p. 17. Diller (1892) listed as Upper Triassic (ascending) the Swearinger slate, Hosselkus limestone, Trail formation, and Foreman formation, but he expressed doubt as to stratigraphic position of Trail formation. Diller (1908, U.S. Geol. Survey Bull. 353) assigned the Foreman and Trail to the Jurassic, and stratigraphic positions of Hosselkus and Swearinger slate were reversed. Order of Hosselkus and Swearinger was again reversed in interpretation by Silberling (*in* Reeside and others, 1957, Geol. Soc. America Bull., v. 66, no. 11) based on data of McMath, and Trail formation was returned to the Triassic stratigraphically below the Hosselkus and Swearinger. Sequence, as interpreted by Silberling and accepted for this folio, is (ascending) Trail formation, Swearinger slate, and Hosselkus. Footnote states that McMath (1958, unpub. thesis) now doubts validity of data given to Silberling.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California, Westwood sheet (1:250,000): California Div. Mines. Mapped with Upper Jurassic marine sedimentary and metasedimentary rocks.

Named for exposures along Hosselkus Creek on the trail, Plumas County.

**Trail City Member** (of Fox Hills Formation)

Upper Cretaceous: North-central South Dakota and southern North Dakota.

R. E. Morgan and B. C. Petsch, 1945, South Dakota Geol. Survey Rept. Inv. 49, p. 13–14, fig. 4. Commonly brown or buff sandy shale, becoming more sandy toward top; contains three to five locally persistent zones of fossiliferous concretions, Thickness 50 to 90 feet. Underlies Timber Lake member (new); overlies Pierre formation.

S. P. Fisher, 1952, North Dakota Geol. Survey Bull. 26, p. 10–11, 37. Geographically extended into Emmons County, N. Dak., where it is 50 to 75 feet thick and consists of brown to gray sandy shales which pass upward into brown and green-gray sands. Thins eastward. Underlies Timber Lake member.

Named for exposures in area around Trail City, Corson County, S. Dak. Recognized at least 12 miles north of Trail City along edge of breaks of Grand River and also about 50 miles southwest from city along edge of breaks of Moreau River.

**Trail Creek Formation**[1]

Silurian: Central Idaho.

Original reference: L. G. Westgate and C. P. Ross, 1930, U.S. Geol. Survey Bull. 814, p. 10, 23.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 8. Silurian rocks are relatively scarce in Idaho. Sequence includes Laketown dolomite which locally attains thickness of 2,000 feet, and shale and sandstone of Trail Creek formation.

Exposures confined to west side of Trail Creek, in its upper part, Hailey quadrangle.

**Trail Crossing Basalt**[1]

Eocene(?): Central northern Oregon.

Original reference: H. T. Stearns, 1931, U.S. Geol. Survey Water-Supply Paper 637, p. 134.

Exposed on both banks of Crooked River at Trail Crossing and extend northeast across Haystack Butte country in belt about 1 mile wide, in Deschutes Basin.

Trail Hill Sandstone (in Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 22–23, pl. 2. Brownish- to brick-red shales and interbedded fine- to medium-grained sandstones. Lenses of pebble conglomerates as much as 1 foot thick, crossbedding, and minor ripple marks characterize parts of unit. Sandstones, friable and brick-red, locally with white mottling or white banding. White to grayish-white siliceous limestone from 6 inches to 1½ feet in thickness at top of ledge sandstone. Red medium-grained friable sandstone with minor interbedded brick-red shales above siliceous limestone. Green to gray shales, locally bluish green, above pink to red sandstones; thickness 25 feet. Bed of jasper 2 to 6 inches thick occurs 8 feet below upper contact of shale. Overlies Fire Clay Hill bentonitic shale (new); underlies Leeds sandstone (new) with local unconformity.

In Silver Reef (Harrisburg) Mining District, Washington County.

**Training School Volcanics**[1] **(in Honolulu Volcanic Series)**

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 132–133. Cone of bedded cinders and associated lava flow of melilite-nepheline basalt. Flow at least 50 feet thick. Flow rests unconformably on sandstone and conglomerate terrace graded to the plus 95 foot (Kaena) stand of the sea and was cliffed by the sea during the plus 25 foot (Waimanalo) stand.

Named for Maunawili Training School for Girls, near which it occurs. Flow is 1½ miles long and three-fourths mile wide, on northeast side of Koolau Range about 8½ miles northwest of Makapuu Head.

†Trampan Formation[1]

Miocene, upper: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pub., Dept. Geol. Bull., v. 2, p. 447–448.

Named for exposures along Las Trampas Creek, Contra Costa County.

Tranquilla Shale

Eocene, upper: Panamá.

H. N. Coryell and J. R. Embich, 1937, Jour. Paleontology, v. 11, no. 4, p. 289–291. Name proposed for basal Tertiary beds that have been included in Bohío formation. Bohio is restricted to include only Oligocene sediments which overlie Tranquilla. Greenish-gray shale that contains well-preserved foraminiferal fauna. On basis of fauna, regarded as Jackson (late Eocene).

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 227; W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 13. Name Tranquilla has priority over Gatuncillo formation, but name Tranquilla was defined inadequately. Type locality is now flooded by Madden Lake.

Type locality: Near town of Tranquilla, 79°13′ [33′] W., 10°15′ N., in upper Chagres River valley.

Tranquillon Volcanics

Miocene, lower (Saucesian): Southern California.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 33–34, pls. 1, 2. Defined as local phase of Obispo tuff of San Luis Obispo County; composed of as much as 1,200 feet of rhyolite, agglomerate, and ash. Where exposed on Tranquillon Mountain ridge, the volcanic series lies conformably below Monterey shale and unconformably above Rincon and older formations.

Type locality: Ridge west of Canada del Rodeo, Santa Barbara County.

Traveller Rhyolite[1]

Devonian: North-central Maine.

Original reference: F. W. Toppan, 1932, Geology of Maine, Dept. Geology Union College, Schenectady, N.Y., p. 69–70.

D. W. Rankin, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1632. At least 8,500 feet of felsitic flows, tuffs, and welded tuffs. Overlies marine subgraywacke of Oriskany age.

Forms mass of Traveller Mountains, a group of peaks north of Katahdin, Piscataquis County.

**Traverse Group**

Traverse Formation[1]

Middle and Upper Devonian: Southern Michigan.

Original reference: A. Winchell, 1871, Michigan Geol. Survey Rept. Prog., p. 26–33.

G. M. Ehlers and R. E. Radabaugh, 1937, Michigan Acad. Sci., Arts, and Letters Sec. Geology and Mineralogy [Guidebook] 7th Ann. Field Excursion, [p. 8–9]; 1938, Michigan Acad. Sci., Arts, and Letters, Papers, v.

23, p. 441–445. Belle shale formation of Traverse group overlies Rogers City formation (new).

B. F. Hake and J. B. Maebius, 1938, Michigan Acad. Sci., Arts, and Letters, Papers, v. 23, p. 447–461. Term group is used to designate the series of beds which underlie all gray and black shales near base of Antrim formation and which overlie massive buff to brown relatively unfossiliferous limestones and dolomites belonging to Dundee and older formations. Group, in central Michigan, comprises (ascending) Bell shale, Rockport limestone, middle shale and limestone unit, middle massive limestone unit, upper shale unit, and Squaw Bay limestone.

G. A. Stewart, 1938, Geol. Soc. America Spec. Paper 8, p. 6–7. Stauffer (1909, Ohio Geol. Survey, 4th ser., Bull. 10) applied Michigan term Traverse to upper Middle Devonian rocks in northwestern Ohio, on assumption that they were continuation of formation of that name in Michigan. However, faunal correlation was only approximate, and some have questioned whether term should be used for northwestern Ohio, especially as limits of unit have never been definitely fixed in Michigan, and it has not been possible to correlate it with formations elsewhere. Seems best to discontinue use of term Traverse for upper Middle Devonian units of northwestern Ohio between Columbus limestone and Ohio shale. Terms Blue limestone, Silica shale, and Tenmile Creek dolomite are herein used for units of this interval.

L. L. Sloss, 1939, Jour. Paleontology, v. 13, no. 1, p. 52–73. Three-fold division of Middle Devonian Traverse beds of Lower Peninsula of Michigan is suggested. Pohl (1930) divided Traverse into Gravel Point stage at base, Charlevoix stage in middle, and Petoskey formation at top. Present writer [Sloss] was unable to locate prominent angular unconformity at top of Charlevoix stage mentioned by Pohl and believes that Pohl was confused by unusually high initial dips prevailing in area due to proximity of large bioherms. Term formation not applicable to beds involved; for purposes of this paper, all three divisions are considered as faunal zones. Rugose corals indicate Traverse beds are contemporaneous with Hamilton group of New York and Cedar Valley formation of Iowa.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 571–595. First locality name for rocks now termed Traverse group was that given by Douglass in 1841 (Fourth Ann. Rept. of the State Geologist for 1840, Michigan Legis. Doc., v. 1, no. 11, p. 550). This name was "Little Traverse Bay limestones," changed to "Little Traverse Bay group" by Winchell (1871). [Winchell used Little Traverse Group.] Lane (1893, Michigan Geol. Survey Rept. State Board 1891–1892) introduced present usage by referring to Traverse group. Subdivisions of Traverse group in Thunder Bay region [this report] have been assigned to stage, series, or formation rank by different authors. Thunder Bay series, Alpena limestone, Lower Traverse series with Long Lake limestone and shale, and Bell shale (Grabau, 1902, Michigan Geol. Survey Rept. State Board, 1901); Thunder Bay series, Alpena limestone series, and Presque Isle series (Grabau and Shimer, 1910, North American Index Fossils, v. 2); Thunder Bay series, Alpena limestone, Long Lake series (Ver Wiebe, 1927, Michigan Acad. Sci., Arts, and Letters, Papers, v. 7); Thunder Bay stage, Alpena stage, Presque Isle stage with Long Lake member, Grand Lake member, and Bell shale member (Pohl, 1930, U.S. Natl. Mus. Proc., v. 76, art. 14). In present report, group is subdivided into formations based on combination of lithological and paleontological criteria. In this classification, term Thunder Bay is used in conformity with original definition of Douglass (1839?). Limits of Alpena limestone are redefined. Term Presque Isle series or stage, with its synonym, Long Lake series, are abandoned. Name Rockport Quarry limestone replaces preoccupied term Rockport limestone. Group, in Thunder Bay region, comprises (ascending) Bell shale, Rockport Quarry limestone, Newton Creek limestone, Alpena limestone, Four Mile Dam formation, Norway Point formation, Potter Farm formation, Thunder Bay limestone, and Squaw Bay limestone. Overlies Rogers City limestone, erosional unconformity. Top of group is usually recognized as top of highest Devonian limestone in Michigan. This would exclude from group "overlying transition zone" of shale referred to by some authors. Middle and Upper Devonian.

W. A. Kelly and G. W. Smith, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 3, p. 447–469. Group described in Afton-Onaway area, Michigan. Comprises (ascending) Belle shale (recognized in wells), Rockport Quarry limestone, Ferron Point shale, Genshaw formation, Koehler limestone (new), Gravel Point formation, and Beebe School formation (new). Beebe School formation underlies Antrim shale.

Name derived from Little Traverse Bay and Grand Traverse Bay, Southern Peninsula.

Traverse Volcanics (in Salt Lake Group)

Oligocene and Miocene, lower: North-central Utah.

L. W. Slentz, 1955, Utah Geol. Soc. Guidebook 10, p. 23, 24 (fig. 6). Salt Lake group, in Lower Jordan Valley, is divided into (ascending) Traverse volcanics, Jordan Narrows unit, Camp Williams unit, Harkers fanglomerate, and Travertine unit. Figure 6 shows Traverse volcanics interfingering with Jordan Narrows unit. Thickness 1,000 to 3,000 feet.

Lower Jordan Valley is defined as that part of Jordan Valley northward from Traverse Mountains to Great Salt Lake.

Travertine unit (in Salt Lake Group)

*See* Camp Williams unit, Jordan Narrows unit, and Harkers Fanglomerate.

Travesser Formation (in Dockum Group)

Triassic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 35 (table 2), 38, pls. 1–a, 2. Consists largely of clayey silt and fine-grained sandstone. Sandstone beds, as much as 20 feet thick, in measured section, range from massive to thin bedded and from parallel bedded to cross laminated. Conglomeratic lenses common; some fissile clay present. Commonly medium red brown; some orange sandstone and some dark-red-brown beds. Thickness 245 feet at type section; thickens eastward to as much as 550 feet in northeast Union County. Overlies Baldy Hill formation (new), possible angular unconformity; underlies Sloan Canyon formation.

Type section: Two miles south of Baldy Hill in sec. 12, T. 31 N., R. 32 Union County. Named for exposures near Travesser Creek, Underlies slope wash and alluvium from Tollgate eastward to Oklahoma State line.

Travester shale[1]

Middle Jurassic: Northeastern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 3, 12.

Well exposed in Travester Canyon.

**Travis Peak Formation** (in Trinity Group)[1]

Lower Cretaceous (Comanche Series): Southern and eastern Texas.

Original reference: R. T. Hill, 1890, Texas Geol. Survey 1st Ann. Rept., p. 118–119, 133.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 28. Subsurface Hosston formation (new) replaces name Travis Peak, as applied to beds older than real Travis Peak of Texas. Stratigraphic equivalents of Travis Peak formation of Texas are present in Pine Island field of northwestern Louisiana in lower part of Pine Island formation which lies about 250 feet above Hosston formation. This correlation is based on occurrence of ammonites, *Dufrenoya* and *Prochelonicera*s which mark Travis Peak formation of Texas and upper Aptian stage of European section.

R. W. Imlay, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 10, p. 1416–1469. Discussion of subsurface Lower Cretaceous formations of south Texas. Evidence presented to show that Travis Peak formation of outcrop area is represented in subsurface by shaly sequence, herein named Pearsall formation which includes basally Pine Island shale member, medially Cow Creek limestone member, and at top Hensell shale member. Recommended that term Travis Peak formation be used hereafter only for outcrops.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 318–319 [1946]. Rocks of Lower Cretaceous age outcropping in Johnson City area are given conventionally as follows: Travis Peak formation with Sycamore sand, Cow Creek limestone, and Hensell sand member; and Glen Rose limestone. Mapping in Johnson City area and to west shows that the so-called Hensell sand member of Travis Peak is more really a shoreward facies of Glen Rose limestone, but present report uses conventional terminology.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 5–8. Proposed to remove Hensell sand from Travis Peak formation and place it in Shingle Hills formation (new). As restricted, Travis Peak contains two members: Sycamore sand and Cow Creek limestone. Underlies Shingle Hills formation.

F. E. Lozo and F. L. Stricklin, Jr., 1956, Gulf Coast Assoc., Geol. Soc. Trans., v. 6, p. 67–68. Type "Travis Peak formation" restudied. Data indicate that recognition of Travis Peak "formation," as originally defined and long accepted, should be deleted from modern stratigraphic terminology. Intra-Travis Peak disconformities at boundaries of original members (top of Cow Creek and top of Sycamore) effectively eliminate any implication of unity within "formation." At same time, with recognition of proposed new unit (Hammett shale, previously unrecognized in Cow Creek "beds" or included with the Sycamore), the remaining terminology of the historical cartographic lithic units can be retained in original or long used sense. Four other reasons given for discontinuing use of name "Travis Peak formation." Phrase "Travis Peak sand" is common synonym of "basal Trinity sand" and is applied to any sand locally at base of the Trinity, thus it spans entire Trinity division. Statements of "Travis Peak equivalence" mean only Trinity when based on member name-correlations. Faunal reports of "Travis Peak age" are based on comparison with middle member only; no diagnostic fauna is known from the Sycamore or Hensel [herein considered correct spelling]. Fossiliferous Cow Creek is known to be Aptian and entire "Travis Peak" is commonly identified as Aptian.

Named for Travis Peak post office, Burnet County.

Travis Peak Limestone (in Travis Peak Formation)[1]

Lower Cretaceous (Comanche Series) : Northeastern Texas.

Original reference: W. M. Winton, 1925, Texas Univ. Bull. 2544.

In Denton County.

**Treadwell Slate**[1] or **Formation**

Jurassic(?) to Lower Cretaceous(?) : Southeastern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 255–256, 270, chart opp. p. 247.

Fred Barker, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–100. Black graphitic slate and interlayered gray to green fine-grained poorly schistose to massive plagioclase-quartz-sericite-chlorite graywacke form bulk of formation in Juneau (B–3) quadrangle. Thickness probably at least several thousand feet. On northeast limb of Shelter syncline. Jurassic(?) to Early Cretaceous(?).

On Treadwall Island, Juneau region.

**Treasure Mountain Rhyolite** (in Potosi Volcanic Group)

Treasure Mountain Quartz Latite (in Potosi Volcanic Series)[1]

Treasure Mountain Welded Tuff

Tertiary, middle or upper: Southern Colorado and northern New Mexico.

Original reference: H. B. Patton, Colorado Geol. Survey Bull. 13, p. 20, 33–35.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13, 93 (table 18), 117–124. Described in San Juan region as Treasure Mountain rhyolite. Made up in most places of a series of alternating flows, welded tuffs, and tuff beds of rhyolite and rhyolitic quartz latite. Generally, flows and welded tuffs are 100 feet or less in thickness, but some are as much as 200 or 300 feet, and tuff layers are locally somewhat thicker. Present in three domes; thickness in central part of domes are: Conejos quadrangle, 1,500 feet; San Cristobal quadrangle, 1,200 feet; and Saguache quadrangle, 300 feet. Underlies Sheep Mountain quartz latite; overlies Conejos quartz latite; locally underlies Alboroto rhyolite or later formations of Potosi series; where directly overlain by Hinsdale formation, the two are separated by interval long enough to develop San Juan peneplain.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 38–42, pl. 1. A. P. Butler (1946, unpub. thesis) extended Treasure Mountain formation southward from Colorado to area of Tusas Valley. Only mappable unit of this formation in Las Tablas quadrangle is the bipartite layer of welded tuff; hence in this report it is termed Treasure Mountain welded tuff. Thickness 3 to 15 feet. Butler reported 100 feet.

W. R. Muehlberger and others, 1960, New Mexico Geol. Soc. Guidebook 11th Ann. Field Conf., p. 100–101. Trice (1957, unpub. thesis) subdivided Treasure Mountain rhyolite in Brazos Peak quadrangle into (ascending)

Toltec andesite, Lagunitas clastic member, and Osier Mountain welded tuff. Upper two members crop out in Chamo quadrangle [this report].

U.S. Geological Survey currently designates the age of the Treasure Mountain Rhyolite as middle or late Tertiary on the basis of an age change of Potosi Volcanic Group.

Named for exposures on Treasure Mountain in northwestern part of Summitville quadrangle, Colorado.

Treat Limestone[1]

Upper Ordovician (Richmond) : Northeastern Illinois.

Original reference: J. R. C. Evans, 1926, Chicago Univ., Abs. Theses, Sci. ser., v. 2, p. 199–200.

Type locality not stated.

†Trego zone (in Niobrara Formation)[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 51.

Named for Trego County.

Tremaines Bridge Beds[1]

Upper Ordovician: Northern New York.

Original reference: R. Ruedemann, 1925, New York State Mus. Bull. 258, p. 137, 141, 149, 154.

Observed only at head of "gulf" just above bridge leading to Tremaines and below Pulaski.

**Trempealeau Formation**[1]

Upper Cambrian: Southern Wisconsin, northern Illinois, northeastern Iowa, and southeastern Minnesota.

Original reference: F. T. Thwaites, 1923, Jour. Geology, v. 31, no. 7, p. 547.

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935, Geol. Soc. America Bull., v. 46, no. 11, p. 1705–1714, geol. sections. Formation subdivided into five members (ascending) basal conglomerate and greensand, St. Lawrence dolomite, Lodi "shale" (siltstone), Jordan sandstone, and Madison sandstone. Overlies Franconia formation.

Josiah Bridge, 1937, U.S. Geol. Survey Prof. Paper 186–L, p. 234 (table 1) Table shows Trempealeau formation comprises (ascending) St. Lawrence dolomite, Lodi shale and siltstone, Jordan sandstone, and Madison sandstone members. This is Kansas Geological Society Conference classification (1935).

C. R. Stauffer, G. M. Swartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1237–1238. In proposed St. Croixian classification for Minnesota, term Trempealeau of the "Conference classification" is replaced by terms St. Lawrence and Jordan formations.

G. O. Raasch, 1939, Geol. Soc. America Spec. Paper 19, p. 97–113, 114 (fig. 14). Trempealeau formation restricted at top to exclude Madison which is restored to formation rank.

G. O. Raasch, 1951, Illinois Acad. Sci. Trans., v. 44, p. 147–150. Formation includes (ascending) Arcadia (new), St. Lawrence, Lodi, and Jordan members. Overlies Bad Axe member of Franconia; underlies Sunset Point formation (new name to replace term Madison).

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 170–171. Discussion of upper Croixan stratigraphy of upper Mississippi Valley.

Recommended that term Trempealeau, previously used as a formation name to include St. Lawrence and Jordan formations and also as a stage name, be restricted to Trempealeauan stage.

Well exposed in Trempealeau Bluff on Mississippi River at Trempealeau, Trempealeau County, Wis.

Trempealeauan Stage

Upper Cambrian: North America.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Upper Cambrian comprises three stages (ascending): Dresbachian, Franconian, and Trempealeauan. The Trempealeauan includes four faunal zones: *Platycolpus-Scaevogyra*, upper *Dikelocephalus*, *Saukiella-Calvinella*, and *Plethopeltis*.

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 170–171. Discussion of upper Croixan stratigraphy of upper Mississippi Valley. Recommended that term Trempealeau, previously used as a formation name to include St. Lawrence and Jordan formations and also as a stage name, be restricted to Trempealeauan stage.

W. C. Bell, R. R. Berg, and C. A. Nelson, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 441. Authors [Bell, Berg, and Nelson] of present report concur with Nelson's (1956) recommendation that name Trempealeau be reserved only as a stage name. Consensus among Cambrian workers at present time is that Trempealeauan stage be equated to Saukia zone of Raasch (1951, Illinois Acad. Sci. Trans., v. 44), which means in terms of Cambrian correlation chart (Howell and others, 1944), it would encompass zones of *Dikelocephalus postrectus* through *Plethopeltis*, inclusive. Further investigations in other parts of North America may demonstrate useful faunal subdivisions of significant geographic extent, but at present the interval correlations with type Trempealeauan are far from precise.

**Trent Marl**[1]

Miocene, lower: Southern North Carolina.

Original reference: B. L. Miller, 1910, Geol. Soc. America Bull., v. 20, p. 674–675.

H. E. LeGrand and P. M. Brown, 1955, Carolina Geol. Soc. Guidebook of Excursion in Coastal Plain of North Carolina, Oct. 8–9, p. 30. Kellum (1926, U.S. Geol. Survey Prof. Paper 143) concluded that the Trent was of early Miocene age, separated from underlying Castle Hayne limestone of Jackson age by erosional unconformity. Most of Kellum's Trent species came from vicinity of Silverdale, a locality not mentioned by Miller and which is about 17 miles from type locality along Trent River. Recent work has shown that Kellum's Trent (lower Miocene) is nonexistent and that units designated by Kellum as lower Miocene are in part of Castle Hayne age and in part of Yorktown age. Original Trent of Miller is here moved from middle Eocene to upper Eocene and included within the Castle Hayne although considered a distinctive facies of it.

Named for exposures along Trent River from vicinity of Trenton, Jones County, to near Junction of Trent and Neuse Rivers.

Trenton Clays[1]

Upper Cretaceous: Western New Jersey.

Original reference: H. B. Kummel and G. N. Knapp, 1904, New Jersey Geol. Survey, v. 6, p. 197.

Occur in a number of pits along Pond Run, 2 miles east of Trenton, Mercer County.

†Trenton Gravel[1]

Pleistocene: Western New Jersey and southeastern Pennsylvania.

Original reference: H. C. Lewis, 1881, Philadelphia Acad. Nat. Sci. Proc. 1880, v. 32, p. 296–309.

Covers flat ground of Camden, N.J., and lower part of Philadelphia, and forms islands in river. Part of city of Trenton, Mercer County, N.J., is built on terrace covered with this gravel.

**Trenton Limestone[1] or Group[1]**

Trenton Member (of Martinsburg Formation)

Middle Ordovician: New York, Georgia, Michigan, northern Ohio, Pennsylvania, Vermont, and western Virginia.

Original reference: L. Vanuxem, 1838, New York Geol. Survey 2d Rept., p. 257, 276, 283.

R. L. Bates, 1936, Virginia Geol. Survey Bull. 46–M, p. 184–185. Member of Martinsburg formation in Big A Mountain area. Trenton member is Upper Mohawkian in age, and remainder of formation is Cincinnatian. In some regions, Trenton is removed from Martinsburg and given formational status; as such, it is known from Pennsylvania to Alabama. With Trenton removed, the remaining shales are known as Reedsville formation which extends from Pennsylvania to Tennessee.

G. M. Kay, 1937, Geol. Soc. America Proc. 1936, p. 82. Stratigraphy of Trenton group in New York and Ontario reveals influence of regional structural development of distribution, lithology, and fauna of sediments. In early Trenton, Rockland and Hull stages, limestone-depositing seas advanced on lands retaining characteristics inherited from earlier Ordovician; boreal faunas invaded in Rockland. In middle Trenton Sherman Fall stage, Vermontian disturbance produced geanticline that became important source of detrital sediments east of region; also some synchronous elevation of Adirondack arch. In later Trenton Cobourg stage, the arch continued to rise, and trough on east was restricted by incursion of sediments on its eastern side; boreal faunas invaded northern part of region. In latest Trenton Collingwood and Gloucester stages, shale-forming fine-grained clastics spread far eastward.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 233–302. Discussion of stratigraphy of Trenton group (Mohawkian series). Standard section of group comprises (ascending) Rockland limestone with Selby and Napanee members (both new); Hull formation, Sherman Fall formation with Shoreham and Denmark (new) members; Cobourg formation with Hallowell and Hillier members (both new), Collingwood shale; and Gloucester shale. Overlies Black River group. Formations of Rockland age include Rockland limestone, Coboconk limestone (Ontario), Cloche Island limestone (Ontario), Amsterdam limestone and Isle La Motte limestone. Formations of Hull age include Hull limestone and Larrabee member of Glens Falls formation (upper Glens Falls is of Sherman Fall age). Formations of Sherman Fall age include Sherman Fall limestone, Canajoharie shale, Snake Hill formation, Schenectady formation, Cumberland Head formation, Stony Point formation, Lacolle conglomerate (Quebec), and Rysedorph conglomerate. Formations of Cobourg age include Cobourg limestone, Liskeard formation (Ontario), and Utica shale.

Late Trenton shale formations include Collingwood shale (Ontario), Blue Mountain shale (Ontario), Atwater Creek shale, and Holland Patent formation. Within some part of its distribution, each formation and member is believed to be lithologically distinct; traced laterally, the differences may become obscure and faunal evidence may be useful basis of recognition. Lateral changes alter rank of certain synchronous units from one part of region to another; units have been given rank that seems most useful within each area of outcrop. Throughout New York-Ontario region, where sediments of post-Trenton age are preserved, they are of lower Cincinnatian Eden age and of clastic character. They comprise lower Lorraine sandy shales in New York and eastern Ontario, lower Dundas shales in central Ontario, and Sheguiandah shale of Manitoulin. Cincinnatian sediments lie with essential conformity on youngest Trenton shales in each area except lower Mohawk Valley, where Indian Ladder shale of Eden age lies disconformably on Schenectady formation of middle Trenton (Sherman Fall) age. Report discusses Trenton history and refers to Rockland, Hull, Sherman Fall, Cobourg, Collingwood, and Gloucester stages.

John Rodgers, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1579–1580. Discussion of Whitehall quadrangle, New York-Vermont. For mapping purposes, Trenton formation was divided into limestone part and shale part. Limestone part was mapped with Black River limestone. These are merely facies and as such can be compared with (not correlated with) rocks of similar facies in lower Mohawk Valley. Limestone part averages 100 feet and consists of thin-bedded shaly limestone, carrying characteristic Trenton fossils. At Crown Point, Amsterdam (Rockland), Larrabee (Hull), and Shoreham (lowermost Sherman Fall) formations have been recognized by Kay. Overlying limestone is at least 500 feet of shale. It is everywhere involved in minor thrust faults, being repeated by the slicing. Toward Taconic thrust on east, it is metamorphosed into low-grade slate and underlies large areas as near Benson. In some places in slate areas are outcrops of quartzitic slate, derived from sandy shale. Presumably they lie at top of section and represent an upper sandy facies of the Trenton. They would thus correspond in facies to Schenectady beds of lower Mohawk Valley. This facies has not hitherto been recognized in Champlain Valley.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 213–216. In type region, the Trenton rests either upon Lowville or upper Black River limestone. In Lee County, Va., along northwest base of Wallen Ridge, the Trenton lies upon the Eggleston or upper Black River limestone. In type region, the Trenton is succeeded by Utica shale and the Utica by Lorraine shale. The Trenton in Lee County and adjacent areas is succeeded by Reedsville shale which corresponds approximately to the Lorraine. Trenton as distinct lithologic unit occurs only in Wise and Lee Counties; in other areas, not differentiated from Martinsburg shale.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Group, west of Adirondack axis, central Pennsylvania, includes basal Reedsville black shale (upper Utica); Coburn limestone, 175 feet at Salona (Whitcomb) (Cobourg); Salona limestone, 339 feet at Salona (Whitcomb) (Denmark and Shoreham); and Nealmont limestone, 65 to 135 feet, including type Rodman, Lemont, Center [Centre] Hall (Hull and Rockland). Overlies Black River group. Mohawkian series.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 1–23; no. 2, p. 97–116. Group in central Pennsylvania includes (ascending) Nealmont, Salona, Coburn, and Antes (new) formations. Overlies Curtin limestone of Black River group; underlies Cincinnatian Reedsville formation.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 555–561. Group in west-central Vermont includes Orwell limestone (new), Glens Falls limestone, and Hortonville slate.

C. W. Wilson, Jr., 1948, Tennessee Div. Geology Bull. 53, p. 11. Safford's Nashville group redéfined to include strata of Hermitage, Bigby, Cannon, and Catheys formations and to exclude strata of the Leipers, Arnheim, and Fernvale formations which were included in Safford's original definition. Thus, name Nashville group will replace name Trenton group of New York, which has been in general use for these formations. Believed best to drop all New York names that have been used for the Ordovician of Tennessee.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 32. Trenton limestone is about 150 feet thick in northwest Georgia where it is well exposed in Lookout Valley.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 31–37, pl. 1. Group, in Castleton area, comprises (ascending) Orwell limestone, Whipple marble, and Hortonville slate. Appears to be depositional hiatus between uppermost Middlebury strata (Chazy) and the Trenton.

V. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 248, no. 11, p. 785–814. Evidence presented to substantitate radical change in interpretation of Paleozoic stratigraphy of Saratoga Springs region, New York. Previously accepted sequence of beds (Potsdam sandstone, Theresa formation, Hoyt limestone, Little Falls dolomite, Amsterdam limestone, Trenton limestone, Canajoharie shale) is revised to read Potsdam sandstone, Galway formation, Hoyt limestone, Ritchie limestone (new), Mosherville sandstone (new), Gailor dolomite (new), Lowville limestone, Amsterdam limestone, Trenton limestone (Rockland?, Hull, Sherman Fall representatives), and Canajoharie shale. Thickness of Trenton in Saratoga area about 50 feet.

R. C. Hussey, 1952, Michigan Dept. Conserv., Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14. Trenton formation subdivided into Chandler Falls, Groos Quarry, and Haymeadow Creek members (all new). Overlies Bony Falls member (new) of Black River formation; underlies Bills Creek member of Richmond formation.

C. G. Winder, 1953, (abs.) Geol. Soc. America Bull., v. 64, no. 12, pt. 2, p. 1493; 1955, Western Ontario Univ. Dept. Geology Contr. No. 9, p. 1–11. Middle Ordovician (Mohawkian) sediments in New York, Ontario, and Ottawa-St. Lawrence Lowlands have been interpreted for about 100 years as a sequence of successively younger formations, and all have been named as such. Reconstruction of paleoecological conditions indicates that Black River and Trenton groups were deposited contemporaneously. Each "formation" is a phase of deposition, of which the lithology and fauna reflect the environment. Black River sediments are near-shore equivalents of Trenton sediments. The Mohawkian was deposited in a transgressive sea, whereas the repetition of Mohawkian phases in the Cincinnatian in reverse order indicates a regressive sea. Terms Black

River and Trenton refer to rocks deposited contemporaneously and have no time significance.

W. H. Twenhofel and others, 1954, Geol Soc. America Bull., v. 65, no. 3, p. 247–298, chart 2. Terms Chazyan, Black River, and Trentonian used for stages of Middle Ordovician on correlation chart. Term Trenton limestone used in parts of Ontario, New York, Virginia, Tennessee, and Georgia.

R. L. Miller and W. P. Brosge, 1954, U.S. Geol. Survey Bull. 990, p. 67–70, pls. In most of the Appalachian Valley of Virginia, beds of Trenton, Eden, and Maysville age are predominantly shale and have been grouped together in one formation, Martinsburg shale. In westernmost belts of exposure in extreme southwest Virginia and adjacent Tennessee, beds of Trenton age are predominantly limestone and have been called Trenton limestone, and overlying shales of Eden and Maysville age have been called Reedsville shale. Application of name Trenton to the limestone beds is confusing inasmuch as underlying Eggleston limestone is believed to be of early Trenton age, and the still older beds here referred to Hardy Creek and Ben Hur limestones are believed to be of earliest Trenton age. Hence, limestones (post-Eggleston) of Trenton age in Powell and Wallen Valleys of southwest Virginia and adjacent Tennessee should be given a new formation name. However, old name Trenton limestone is retained for purposes of this report [Jonesville district, Virginia]. Formation consists predominantly of brown and dark-gray limestone; three bentonite beds present. Average thickness about 560 feet.

Named for exposures at Trenton Falls on West Canada Creek, Herkimer and Oneida Counties, N.Y.

Trenton Stage

Trentonian[1] Series or Epoch

Middle Ordovician: North America.

Original reference: A. W. Grabau, 1909, Science, new ser., v. 29, p. 351–356.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1401, 1411–1415. Mohawkian series divided into Bolarian below and Trentonian series. Term Bolarian preferred to series name Black Riverian. Original Trenton had practically content of present usage, though subsequently the name was applied to a period including the "Chazy," "Birdseye," "Black River," and "Trenton" epochs, and later "Trenton," "Utica," and "Hudson" epochs. Term Trentonian series was applied by Grabau (1909) containing essentially the rocks of original usage. Lower Trentonian formations of northwestern New York and eastern Ontario, the Rockland and Kirkfield or Hull limestones, disconformably overlap Black River rocks, lying locally on Canadian and Cambrian along Mohawk River, and on Precambrian in Ontario; Rocklandian and Kirkfieldian are considered stages. In central Pennsylvania, Nealmont formation is equivalent, and subseries in Appalachians is referred to as Nealmontian, extending from base of Trentonian. Maximum lower Trentonian thickness is about 150 feet in New York and Ontario. Dimunition westward and eastward is partly by overlap; there are intervals of no deposition within the subseries as it approaches its disappearance at Canjoharie on Adirondack line at Mohawk River. Generally, there is southward divergence along axis of maximum thickness. In Pennsylvania, there is similar overlap on regional unconformity toward the southeast to minimum at Adirondack line in Path Valley northwest of Chambersburg, and divergence in Chambersburg limestone beyond. In Bellefonte district there are abrupt variations because of overlap on unconformity of local relief of tens of feet. Within area of outcrop of this region, there is isopachous trough that may be filling of a subsequent valley within cuesta of Curtin limestone, rather than continuation of Rideauan overlap southward in argillaceous facies in southwestern Virginia. Middle Trentonian includes rocks equivalent to Shoreham and Denmark limestones of New York or undivided Sherman Fall limestone. Middle Trentonian includes Shorehamian and Denmarkian stages. Upper Trentonian includes Cobourg limestone and disconformably overlying Holland Patent shale in northwestern New York, the latter passing into Collingwoodian calcareous shale and Gloucesterian black shale, mapped also as Billings and Eastview formations in Ontario. The Cobourg and Holland Patent become Utica black shale eastward, the change in facies and nature of stratigraphic change being abrupt but somewhat obscure. Only area on the southwest where there has been any separation of these higher units is in north-central Pennsylvania, where 700 feet of Coburn limestone and Antes black shale have been correlated. Holland Patent and Antes are commonly called "Utica" but represent only upper third of true Utica, most of which is Cobourgian.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 84–99. Middle Ordovician limestones of Chazyan, Bolarian, and Trentonian series are exposed in western anticlines in Appalachian Mountains of West Virginia and Virginia northeast of New River. Trentonian rocks lie with disconformity on the Bolarian. In the southwest, the lower Trentonian is dominantly Moccasin argillite; northwestward, it changes into fossiliferous Nealmont limestone facies like that of Pennsylvania. In the southwest, Eggleston shale has basal quartz sandstone, and in the northwest it passes into Onego argillaceous limestone which resembles Oranda limestone of Appalachian Valley. Younger Trentonian has not been successfully divided and traced and is called the "Martinsburg," though in northeastern exposures it is essentially like Salona limestone of Pennsylvania. Base of Nealmont is judged to be basal Trentonian. In New York, and Ontario, Canada, Selby member of Rockland formation forms base of Trentonian.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 9, chart 1. In this report, term Trenton is used as a stage name. Occurs above Wilderness stage (new) of Mohawkian series. Stage is modified by removal of the Rockland which has mostly fossils derived from underlying Black River and Witten. Deposition of the Sherman Fall is thought to inaugurate Trenton stage.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, p. 90, 91, 94 (table 3). Trentonian series has its base at contact of Selby member of Rockland formation on Chaumont limestone of Black River group in northwestern New York and eastern Ontario, Canada. Trentonian extends from top of Black River in northwestern New York to top of Utica. To the southwest, there is disagreement whether base of Trentonian is within upper Witten formation or at top. Cooper (1956) placed lowest Trentonian as well as Black River equivalents in his Wilderness stage. Trentonian series includes Rocklandian stage.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–33. North American Ordovician comprises Canadian, Chazyan, Blackriverian, Trentonian, and Cincinnatian series. Trenton group was divided by Raymond (1916, Harvard Coll. Mus. Comp. Zoology Bull., v. 56) into succession of faunal zones that he thought time-stratigraphic, but which he called formations. In time these became the stages of Kay (1937; 1943; 1948): Rocklandian, Kirkfieldian, Shorehamian, Denmarkian, Cobourgian, Collingwoodian, and Gloucesterian. The lithic units are also time-stratigraphic, lithic differences reflecting physical conditions that are in turn recognizable in the successive faunas; also there are progressive changes in fauna that have time value. Probably term stages too high an order for named divisions of Trentonian; they can be considered substages of smaller number of stages. Suggested that Nealmontian be applied to Rocklandian and Kirkfieldian substages and that Shermanian be applied to Shorehamian and Denmarkian. Cobourg-Collingwood-Gloucester seems time-equivalent to Utica group, but name Utica is stongly associated with black shale facies. Hence, uppermost Trentonian stage is designated Pictonian stage originally given in more restricted sense by Raymond (1911 [1914, Canada Geol. Survey Rept. 1912]) and abandoned by him in 1921 (Geol. Soc. Canada Mus. Bull. 31); Pictonian contains Utica group of formations (Kay, 1943, Am. Jour. Sci., v. 241, no. 10; 1953, New York State Mus. Bull. 347). Boundary between Trentonian and Cincinnatian series has been defined variably because of selection of differing horizons in known successions, and varying correlations between type sections in separated areas. Boundary in North America is taken invariably as separating "Middle" and "Upper" Ordovician, although in European terms, assuming the Caradocian to be "Middle," the American boundary lies within the Cincinnatian under any definition of that series.

Trenton Falls series[1]

Ordovician: New York.

Original reference: T. A. Conrad, 1837, New York Geol. Survey 1st Ann. Rept., p. 165.

Salmon River.

**Tres Hermanos Sandstone Member** (of Mancos Shale)[1]

Upper Cretaceous: Central northern New Mexico.

Original references: C. L. Herrick, 1900, Am. Geologist, v. 25, p. 331–346; C. L. Herrick and D. W. Johnson, 1900, New Mexico Univ. Bull., v. 2, pt. 1, p. 3–63; pt. 2, p. 1–17.

C. B. Hunt, 1936, U.S. Geol. Survey Bull. 860–B, p. 41–43. East of Mount Taylor coal field, northwestern New Mexico, are three prominent sandstones in lower 350 feet of Mancos shale to which name Tres Hermanos sandstone has been applied in previous reports. Name was first used by Herrick and Johnson (1900), though without recording type locality. Sandstone No. 2 of present report is 75 feet thick and is most persistent of the three sandstones. It crops out as prominent capping of mesa or ridges over most of area east of Mount Taylor.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 32, 36, 65, 93. Discussion of intertonguing between marine Mancos and nonmarine Mesaverde strata in New Mexico, Arizona, and southwestern Colorado. One or more sandstones near base of Mancos at various localities in New Mexico have been called Tres Hermanos. Herrick and Johnson, who first applied term, did not give type locality. Original type locality is probably east of Tres Hermanos Buttes, three volcanic necks in Alamosa Creek valley, in sec.

26, T. 3 N., R. 7 W., where sandstones occur in similar stratigraphic position. Invasion of Upper Cretaceous sea in New Mexico is divided into at least two parts; minor regressions are recorded in Tres Hermanos sandstones. This is based on the probability that the Tres Hermanos is a tongue of the Dakota (?) and joins with it in a landward direction.

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 19, 20, 21 (fig. 6), pls. Discussion of Mancos shale and Mesaverde group in Puertecito quadrangle. Mancos shale is restricted to strata below Tres Hermanos(?) sandstone. Tres Hermanos(?) sandstone is tentatively assigned to Mesaverde group, but it may be more closely related to Dakota(?) sandstone. Tres Hermanos(?) conformably underlies La Cruz Peak formation (new) of Mesaverde group. Tres Hermanos(?) apparently pinches out to south in secs. 4 and 8, T. 2 N., R. 5 W.

D. B. Givens, 1957, New Mexico Bur. Mines Mineral Resources Bull. 58, p. 7–8, pl. 1. In Dog Springs quadrangle, Tres Hermanos member of Mancos is well-layered quartzose sandstone about 25 feet thick. Probably pinches out near west boundary of quadrangle.

C. H. Dane, 1959, New Mexico Geol. Soc. Guidebook 10th Field Conf., p. 85–91. Discussion of historical background of type locality of Tres Hermanos sandstone member of Mancos shale. Derivation and definition of name Tres Hermanos sandstone has been subject of confusion in the literature for many years. Herrick's original report is herein reviewed. It is clear from this report that Herrick applied name Tres Hermanos to three dark igneous plugs in north part of sec. 26, T. 3 N., R. 7 W., still known by that name, and that he described the mountain now known as D–Cross Mountain as Turtle Mountain. It is also clear that sandstone to which name Tres Hermanos was applied by Herrick also cropped out east of his Tres Hermanos Buttes and was "a band of sandstone with enormous concretions." Herrick gives thickness of this sandstone as 75 feet. Hunt's (1936) description of "sandstone No. 2" is comparable to sandstone described by Herrick and Johnson (1900). Although Lee (1917, U.S. Geol. Survey Prof. Paper 101) used name Tres Hermanos for zone of sandstones 150 feet thick, presumably including Hunt's three sandstones and intervening shale, it now seems best to restrict use of name to the single sandstone to which Herrick originally applied it (Hunt's sandstone No. 2 in Puerco Valley) and to those sandstones that can be correlated with it.

Type locality (Dane): North part of sec. 26, T. 3 N., R. 7 W., Socorro County. Name derived from Tres Hermanos Buttes.

Tresner Limestone

Pennsylvanian: Central eastern Illinois.

E. F. Taylor and G. H. Cady, 1944, Illinois Geol. Survey Rept. Inv. 93, p. 22–23. Name applied to limestone that lies about 175 feet above No. 7 coal bed.

Exposed in S½SE¼NE¼ sec. 10, T. 14 N., R. 11 W., near Tresner, Edgar County.

Tres Peidras Granite

Precambrian: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 59–62, pl. 1. Unit, as exposed in type locality and along Tusas Canyon, is pink, flesh-colored, or reddish-orange faintly to well-foliated fine- to medium-grained quartz-microcline-albite-biotite-muscovite granite. Crude laminae and flattened knots of the two micas commonly well developed. Appears to have intruded Petaca schist and Mopping metavolcanic series (new). Formerly included in Tusas granite.

Exposed along lower Rio Tusas and in and around town of Tres Piedras. Other masses of this granite found east of Hopewell in sec. 33, T. 29 N., R. 7 E., and on lower east slope of Jawbone Mountain. Dikes of it near Hopewell.

Tres Pinos Sandstone[1]

Eocene, middle: Southern California.

Original reference: P. F. Kerr and H. G. Schenck, 1925, Geol. Soc. America Bull., v. 36, p. 470, 475.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 206–207, pl. 3. Described in San Benito quadrangle where it conformably overlies Los Muertos Creek formation (new). Exposed thickness about 900 feet; top of formation concealed by overlapping terrace deposits to southwest and San Benito gravels to southeast.

Probably named for exposures at or near Tres Pinos or Tres Pinos Creek, San Benito County.

**Tribes Hill Limestone** (in Beekmantown Group)[1]

Lower Ordovician: Central, eastern, and northern New York.

Original references: E. O. Ulrich and H. P. Cushing, 1910, Geol. Soc. America Bull., v. 21, p. 780–781; 1910, New York State Mus. Bull. 140.

R. R. Wheeler, 1941, (abs) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939; 1942, Am. Jour. Sci., v. 240, no. 7, p. 518–524. Cambro-Ordovician correlation revised in Champlain, Hudson, Mohawk, and St. Lawrence valleys. Lower "typical" Theresa is physically and faunally differentiated from "Upper Theresa" (now Heuvelton member of Tribes Hill); two marine cycles, represented by Tribes Hill formation (containing the Norton-Heuvelton, Fort Ann-Bucks Bridge, Benson-Ogdensburg members) and Cassin formation, constitute Beekmantown series.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 808. In Saratoga region proper, rocks of Tribes Hill age are lacking due to offlap, removal by post-Canadian erosion or by facies change into Gailor dolomite (new). Thin representation of Tribes Hill sandy limestone is present to southwest in Amsterdam and Broadalbin quadrangles where it overlies Gailor dolomite.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 71–96. Name Tribes Hill restricted to limestone phase of Lower Canadian. Subdivided into (ascending) Fort Johnson, Palatine Bridge, Wolf Hollow, and Fonda members. Thickness about 145 feet. Underlies Chuctanunda Creek (new) formation. Wheeler separated Tribes Hill in Champlain Valley into Norton limestone, Fort Ann limestone, and Benson dolomite. Wheeler's subdivisions are poorly defined; he gives no type localities or sections, and application to Lower Ordovician of Mohawk Valley is untenable. New names for Mohawk Valley Canadian are necessary.

Named for exposures at Tribes Hill, Montgomery County.

†Tribune Limestone (in Chester Group)[1]

Mississippian: Western Kentucky and southeastern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, v. 2, 2d ser., p. 109.

Named for Tribune, Crittenden County, Ky.

†Trickham Bed (in Graham Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 402.

Wallace Lee *in* Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 120–121. Wayland shale member was called "Trickham shale" by Drake for Coleman County type locality, and "Wayland shale" by Plummer and Moore (1921) for locality in Stephens County. Although name "Trickham" has priority, name "Wayland" has been adopted because it has had much wider usage and is better established.

Named for Trickham, Coleman County.

Trident[1] (Formation)

Lower Mississippian: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Derivation of name not stated.

**Trimble Granite**[1]

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 131.

Occurs in large area surrounding Trimble Pass, La Plata County.

**Trimmers Rock Sandstone**[1] (in Susquehanna Group)

Trimmers Rock Member (of Fort Littleton Formation)

Upper Devonian: Central southern Pennsylvania.

Original reference: B. Willard, 1935, Geol. Soc. America Proc. 1934, p. 123.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 15–16. Member of Fort Littleton formation. Overlies Losh Run shale member; underlies Parkhead sandstone member.

U.S. Geological Survey currently classifies the Trimmers Rock as a formation in Susquehanna Group on the basis of a study now in progress.

Named for Trimmers Rock, a hill 1½ miles east of Newport, Perry County.

Trincheras division[1]

Tertiary, late: Southeastern Arizona, and Sonora, Mexico.

Original references: E. T. Dumble, 1900, Am. Inst. Mining Engrs. Trans., v. 29; 1902, Am. Inst. Mining Engrs. Trans., v. 31.

In Cochise County, Ariz., and Sonora, Mex. Derivation of name not stated.

Trinidad lignitic group[1]

Cretaceous: Colorado.

Original reference: F. V. Hayden, 1875, U.S. Geol. and Geog. Survey Terr., Bull. 1, p. 402.

Typically developed at Trinidad, Las Animas County.

**Trinidad Sandstone**[1] (in Montana Group)

Upper Cretaceous: Southeastern Colorado and northeastern New Mexico.

Original reference: R. C. Hills, 1899, U.S. Geol. Survey Geol. Atlas, Folio 58.

R. L. Griggs, 1948, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 1, p. 33–34; G. H. Wood, Jr., S. A. Northrop, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM-141. In Colfax County, N. Mex., conformably overlies and interfingers with Pierre shale; conformably underlies and interfingers with Vermejo formation. Massive to thin-bedded, light-gray to light-buff, somewhat feldspathic sandstone. Thickness approximately 100 feet.

R. B. Johnson and G. H. Wood, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 709 (fig. 2), 710–712. In Raton basin, intertongues with underlying Pierre shale; tongues of Pierre wedge out in westerly direction, and tongues of Trinidad wedge out laterally in northerly and easterly directions. Conformably underlies Vermejo formation; tongues of Vermejo wedge out in easterly and northeasterly directions, and tongues of Trinidad wedge out west and northwest. Composed of buff to gray, slightly arkosic sandstone and thin interbeds of light tan to gray silty shale. Formation is absent in vicinity of Ute Park, N. Mex., and from this point northward it increases in thickness to 300 feet northwest of Walsenburg, Colo.

Named for exposures at Trinidad, Las Animas County, Colo.

†Trinity Formation[1]

Pre-Cretaceous: California.

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 226.

In Klamath Mountain region.

**Trinity Group[1] or Sand[1]**

Trinity division

Lower Cretaceous (Comanche Series): Texas, southwestern Arkansas, northwestern Louisiana, and central southern and southeastern Oklahoma.

Original reference: R. T. Hill, 1888, Science, v. 11, p. 21.

C. P. Ross, 1943, U.S. Geol. Survey Bull. 928–B, p. 53 (table), 66–83. Group, in Shafter region, Presidio County, comprises (ascending) Presidio and Shafter formations. Overlies Permian Cibolo formation; underlies Fredericksburg group.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. In outcrops in southern Arkansas, group comprises (ascending) Pike gravel, Delight sand (new), Dierks limestone, Holly Creek formation, De Queen limestone, and Paluxy sand. In subsurface of Arkansas, Louisiana, and east Texas, comprises (ascending) Pine Island shale, James limestone, Rodessa formation, Ferry Lake anhydrite, Mooringsport formation, and Paluxy formation. In subsurface of south Texas comprises (ascending) Pearsall formation and Glen Rose limestone. In outcrops in central mineral region comprises (ascending) Travis Peak formation and Glen Rose limestone. Outcrops in north-central Texas comprise (ascending) basal sand, Glen Rose limestone, and Paluxy sand.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 5–12. Trinity group revised for central Texas as follows: Travis Peak formation with Sycamore sand and Cow Creek limestone members and Shingle Hills formation (new) with Hensell sand and Glen Rose limestone members.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, pl. 1. As shown on map legend, Trinity group, in Eagle Mountains, Tex., comprises (ascending) Yucca formation, Bluff Mesa formation, and Cox sandstone.

F. E. Lozo and F. L. Stricklin, Jr., 1956, Gulf Coast Geol. Assoc., Geol. Soc. Trans., v. 6, p. 67–68. Outcrop basal Cretaceous of central Texas assigned to Trinity "group" has been historically divided into two lithofacies, an upper sequence of alternating shales and limestones called Glen Rose limestone or formation and a lower predominantly arenaceous clastic interval originally called Travis Peak sands. Evaluation of rock unit boundaries within Trinity division has revealed datum planes and disconformities that permit regrouping of lithic units on basis of cyclic repetitions of systematic deviations in type of sedimentation. With this concept of tectonic—sedimentary lithogenetic entities, Trinity stratal interval is divisible into three subdivisions herein referred to as lower, middle, and upper. These lithogenetic units, with limits at least in part at variance with boundaries of previously accepted formations or members, provide nonoverlapping subdivisions of section and are thus more significant for historical stratigraphic analysis. In gross sense, each unit may be considered a couplet consisting of basal terrigenous detritus phase, quartzose or argillaceous succeeded by carbonate phase often with evidence of extremely shallow turbulent terminal depositional conditions. Data indicate that recognition of Travis Peak "formation," as originally defined and long accepted, should be deleted from modern stratigraphic terminology. Advances in knowledge of physical relations of basal Cretaceous lithic units evolved from Paleozoic mapping by Barnes. Discoveries of localities where Cow Creek limestone was in direct contact with Paleozoic eliminated notion that the Sycamore passed imperceptibly into the Hensel [herein considered correct spelling]: as basal transgressive clastic. Barnes (1948) emended Travis Peak formation to include only Sycamore and Cow Creek. He proposed Shingle Hills formation as new upper Trinity combination to include Hensel and Glen Rose. These proposals parallel questionable practice increasingly prevalent in subsurface stratigraphic terminology to have "formations" represent restricted "time" intervals. Despite certain advantages in considering some cyclic subdivisions (for example those in Trinity) as "formations" and the phases as "members," the burden of more new names and predictable usage of these names in sense of paleontologically determined zones or sub-stages weigh against the practice. Reference outcrop section designated for Trinity division. Here Trinity division comprises (ascending) Sycamore sand (lower Trinity); Hammet shale (new), and Cow Creek limestone (middle Trinity); Hensel sand, Glen Rose limestone (lower), *Corbula* bed, and Glen Rose limestone (upper).

J. M. Forgotson, Jr., 1956, Gulf Coast Assoc., Geol. Soc. Trans., v. 6, p. 91–108; 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2328–2363. Purpose of report is to present correlation of formations within Trinity group (Comanchean Cretaceous) of Gulf Coastal Plain and to interpret tectonic frame work and paleogeography existing during Trinity deposition. Each correlation is based on time-stratigraphic unit defined by recognized formation boundaries in type area. Each unit is extended geographically by correlation of electrical log markers that are assumed to represent contemporaneously deposited beds. Trinity time-stratigraphic unit (group throughout most of area) represents interval below top of Glen Rose formation (as recognized near Austin, Tex.) or its time-stratigraphic equivalent and above top of Sligo formation (as recognized in subsurface of northern Louisiana) or its time-stratigraphic equivalent. Trinity unit subdivided into (ascending) Pearsall time-stratigraphic unit, Rodessa time-stratigraphic unit, Ferry Lake time-stratigraphic equivalent, Rusk time-stratigraphic unit (Rusk is new in this report) and, in areas where Ferry Lake is not recognizable, the undifferentiated Glen Rose (interval between top of Trinity unit and base of Rodessa unit). Term Paluxy formation used for sand unit which is time-stratigraphic equivalent of part of Walnut and Fredericksburg groups.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 20–26. Group, in McCurtain County, comprises (ascending) Holly Creek formation, De Queen limestone, and Paluxy sand. Basal division of Cretaceous rocks in county. Unconformably underlies Fredericksburg group.

Reference section (Trinity division): Hayes-Travis County area, Texas. Measured at localities in order of geologic sequence (ascending) Hammet Crossing section, Hamilton Pool, Craft Ranch, Murrah Ranch, and Shingle Hills. Named for exposures on Trinity Rivers of Texas.

Trinityan series[1]

Lower Cretaceous (Comanche): Arizona.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 64, no. 2, p. 128, 129, 139.

Triphammer Shale (in Ithaca Shale)

Triphammer shale member (of Ithaca facies subgroup)

Upper Devonian: South-central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 202.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4. Shale is upper unit in Ithaca shale. Underlies Enfield shale in Skaneateles and Cayuga Lakes area.

Occurs in Ithaca region.

**Trippe Limestone**[1]

Middle Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

Named for exposures in Trippe Gulch, on south side of North Pass Canyon, Gold Hill district.

Triumph Conglomerate[1]

Pennsylvanian: Pennsylvania.

Original reference: J. F. Carll, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 38–40.

Exposed in hilltops at Triumph, Warren County.

Trivoli cyclothem[1] (in McLeansboro Group)

Trivoli cyclothem (in Modesto Formation)

Pennsylvanian: Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

J. M. Weller and W. A. Newton, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 11. In sequence, occurs above Gimlet cyclothem and below Collinsville cyclothem (new). Thickness about 30 feet.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 121–122, 193. Highest Pennsylvanian unit in western Illinois. Maximum thickness 37 feet at type exposure, top eroded. Overlies Exline cyclothem. Includes Trivoli sandstone and Trivoli limestone. Derivation of name and type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Modesto formation (new). In northern, western, southeastern, and eastern areas occurs above Gimlet cyclothem; in northern and western areas occurs below Hicks cyclothem; in southwestern area occurs below Carlinville cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Ravine draining northeast and north, near Trivoli, SW¼ sec. 3, T. 8 N., R. 5 E., Glasford quadrangle, Peoria County.

Trivoli Limestone (in McLeansboro Group)

Pennsylvanian: Central western Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 104. Marine limestone in lower McLeansboro.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 123, geol. sections 8, 9. Light-gray fossiliferous buff-weathering limestone that occurs in massive bed. At type exposure of Trivoli cyclothem is 8 to 10 inches thick. Occurs near top of cyclothem above Trivoli (No. 8) coal.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38, 56 (table 3). Replaced by Cramer limestone member of Modesto formation (both new).

Type exposure (of cyclothem): Ravine draining northeast and north, SW¼ sec. 3, T. 8 N., R. 5 E., near Trivoli, Glasford quadrangle, Peoria County.

Trivoli Sandstone Member (of Modesto Formation)

Trivoli Sandstone (in McLeansboro Group)

Pennsylvanian: Southeastern, southwestern, western, and northern Illinois.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 121, geol. sections 8, 9. Commonly light gray or blue gray, has rusty spots, and is medium to fine grained, thin to medium bedded, and micaceous. Commonly grades without break into underlying Gimlet gray shale, but locally cuts down through shale to rest on black limestone; in such places sandstone is somewhat more massive and resembles other channel sandstones of area. Thickness at type exposure of Trivoli cyclothem 15 feet.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 38, 49 (table 1), 69, pl. 1. Rank reduced to member status in Modesto formation (new). In southeastern area, occurs above West Franklin limestone member and below Chapel (No. 8) coal member; in southwestern area, occurs above Scottville limestone member and below Chapel (No. 8) coal member; western and northern area occurs above Exline limestone member and below Chapel (No. 8) coal member. Thickness 12 to 38 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type exposure: Ravine draining northeast and north, SW¼ sec. 3, T. 8 N., R. 5 E., near Trivoli, Glasford quadrangle, Peoria County.

**Tropic Shale[1] or Formation**

Upper Cretaceous: Central southern Utah.

Original reference: H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51, 102–105, 129–130, pl. 5. Formation described in Zion Park region where it is 400 to 1,250 feet thick; unconformably underlies Straight Cliffs sandstone and overlies Dakota(?) sandstone. Drab, sandy, argillaceous; many beds of sandstone, more abundant in lower part; beds of coal; marine, brackish-water, and fresh-water fossils. Exposed continuously across Kolob Terrace from Kanarra Mountain to Orderville and eastward across Skutumpah Terrace to Paria River.

Named for exposures at and around village of Tropic, Garfield County.

**Tropico Group**

Miocene(?) and Pliocene(?): Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 135–139. Name applied to sequence of nonmarine sedimentary, pyroclastic, and volcanic rocks exposed in Rosamond Hills and originally described as Rosamond series by Hershey (1902), together with similar and probable correlative rocks of Tertiary age exposed in vicinities of Kramer borate area and in Kramer Hills in western Mojave Desert. Rocks of group are moderately deformed and rest on deeply eroded surface of pre-Tertiary granitic and metamorphic rocks that form crystalline basement complex of region, and are overlain unconformably by Quaternary alluvial sediments. Maximum exposed thickness about 2,800 feet. Group is divided into several lithologic units of local extent. In most sections lower unit is pyroclastic formation, with associated rhyolitic intrusions and flow breccias; upper unit is either fanglomerate or sequence of carbonate rocks, clays, and sandstones of lacustrine and fluviatile origin; basalt flows occur locally, mostly in middle part. Group is nonfossiliferous except at one locality where diatom remains in upper part suggest early Pliocene age. Lower unit is tentatively correlated with lithologically similar formations of known Miocene age in areas west and northwest. Formations that are locally distinct are: Gem Hill formation, Fiss fanglomerate, Bissel formation, Saddleback basalt, and Red Buttes quartz basalt.

Type section: In Rosamond Hills one-half mile west of Mojave-Tropico Road 1 to 2 miles north of Tropico mines, Rosamond quadrangle, in NE¼ sec. 2, T. 9 N., R. 13 W., San Bernardino Base and Meridian, Kern County. Most complete sections are at Antelope Buttes, Rosamond Hills, hills north of Bissell, at and near Castle Butte,. and in Kramer Hills; incomplete sections are at Soledad Mountain and Kramer borate area.

Troublesome Formation

Oligocene: Northwestern Colorado.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 41. Name applied by A. H. Richards (unpub. thesis) to several hundred feet of light-gray to light-tan tuffaceous sands and clays in valley of Troublesome Creek. Contains both Oligocene and late Miocene or early Pliocene fossils.

J. D. Schlottman and L. E. Smith, 1954, U.S. Atomic Energy Comm. [Pub.] RME–1042, p. 8–9. Youngest Tertiary sediments in Middle Park Basin; lies unconformably on all older formations. Maximum thickness 960 feet, measured along Troublesome Creek north of U.S. Highway 40. Upper 800 feet consists of volcanic ash in beds as much as 30 feet thick, interbedded with clays and fluvial sands. Deposited during Oligocene time and reworked during Miocene and Pliocene.

Named for occurrence in valley of Troublesome Creek, near Kremmling in Middle Park, Grand County. Covers about 160 square miles.

Troublesome Creek Sandstone Member (of Jelm Formation)

Upper Triassic: Southeastern Wyoming.

R. G. Hubbell, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2744–2748. Light gray to light buff fine-grained strongly crossbedded massive sandstone containing numerous large varicolored rounded frosted quartz and chert grains. Maximum observed thickness along southwestern flanks of Freezeout Hills 167 feet. Unconformably underlies Sundance formation.

Type section: Sec. 26, T. 24 N., R. 80 W., Carbon County in southwest Freezeout Hills, where it is well exposed.

**Trough Creek Limestone Member** (of Mauch Chunk Formation)[1]

Mississippian: Central Pennsylvania.

Original reference: I. C. White, 1885, Pennsylvania 2d Geol. Survey Rept. $T_3$, p. 73–76, 85.

J. M. Weller, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 2 (column 102). Included in Chesterian series on correlation chart.

On south bank of Trough Creek in Huntingdon County three-fourths mile below Todd (Brick) mills, on Mr. Taylor's land.

Trousdale Shale[1] or Formation

Upper Devonian: Central Tennessee and Kentucky.

Original references: E. R. Pohl, 1930, Tennessee Acad. Sci. Jour., v. 5, no. 2, p. 56–63; 1930, Am. Jour. Sci., 5th, v. 20, p. 151–152.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 857, 859, 860, 861, 866–868, 883. Basal bed of New Albany shale in Kentucky contains abundant *Schizobolus concentricus* Vanuxem through its entire thickness and is without *Leiorhynchus* assemblage that occurs above *Schizobolus* in Indiana. This change in faunal content becomes evident just south of Ohio River; *Schizobolus* shale prevails in Kentucky and Tennessee where it was described and named Trousdale shale by Pohl (1930). Since there is no apparent difference in this layer in this area, bed in Kentucky is identified as Trousdale. The Trousdale extends around Cincinnati arch to Olympian Springs where it pinches out and extends south into Tennessee. Has uniform thickness of about 10 feet. Overlies Portwood formation (new), where Portwood is present, and Hamilton limestone elsewhere. Overlain everywhere by Blackiston formation (new), and where contact is within the black shale of the two formations, the boundary can be approximately located by fossils in the Trousdale and can be determined definitely when joints in the two strata are exposed. From Estill County, Ky., north, the Olentangy shale, basal member of Blackiston, rests on Trousdale. In Tennessee, Trousdale lies below Dowelltown formation (new) of Chattanooga.

Derivation of name not stated. Map shows two towns named Trousdale, one in Sumner County Tenn., and one in Warren County.

Trout Creek Formation[1]

Miocene, upper: Southeastern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

H. D. MacGinitie, 1933, Carnegie Inst. Washington Pub. 416, p. 45. Plant fossils indicate upper Miocene age.

Type locality: Trout Creek on east side of Alvord Valley, southeastern part of Harney County.

**Trout Creek Sandstone Member** (of Iles Formation)[1]

Trout Creek Sandstone[1] (in Mesaverde Group)

Upper Cretaceous: Northwestern Colorado.

Original reference: N. M. Fenneman and H. S. Gale, 1906, U.S. Geol. Survey Bull. 297, p. 26.

N. W. Bass, J. B. Eby, and M. R. Campbell, 1955, U.S. Geol. Survey Bull. 1027–D, p. 157, pl. 19. Member consists of fine-grained massive cliff-forming sandstone about 100 feet thick. Occurs at top of formation above unnamed sandstone sequence containing coal beds. Conformably underlies Williams Fork formation.

Named for Trout Creek, on northeastern side of Twentymile Park, about 10 miles northwest of Yampa, Routt County. Typically exposed on north side of U.S. Highway 40 at Bear River, on both sides of road in Hayden Gulch.

Trout Creek Schists

Precambrian: Eastern Nevada and western Utah.

R. B. Nelson, 1959, Dissert. Abs., v. 20, no. 3, p. 997. Name appears only in stratigraphic section. Thickness 2,900 feet. Older than Cherry Canyon schists (new); younger than unnamed tectonitic dolomitic marble.

Stratigraphic section covers northern Snake Range and Kern Mountains in eastern Nevada and southern Deep Creek Range in western Utah.

**Troutdale Formation**[1]

Pliocene, lower: Northwestern Oregon and Washington.

Original reference: E. T. Hodge, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 157.

R. W. Chaney, 1944, Carnegie Inst. Washington Pub. 553, p. 323–351. Lower Pliocene, on basis of flora.

R. C. Treasher, 1942, Geologic map of Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. In Portland area, overlies Columbia River lava and unconformably underlies Boring lava.

W. D. Wilkinson, W. D. Lowry, and E. M. Baldwin, 1946, Oregon Dept. Geology and Mineral Industries Bull. 31, p. 24–28. Described in St. Helens quadrangle, Oregon and Washington. Troutdale sediments traced from near Camas, Wash., across Columbia River from Troutdale, northwesterly into St. Helens quadrangle. As much as 600 feet of relatively unconsolidated conglomerate, sandstone, and silt, tentatively assigned to upper part of Troutdale, cover parts of quadrangle.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 7–14. Includes Portland Hills silt member (new) in upper part.

Lower part consists of sands, silts, and quartzite-bearing gravels. Also includes basaltic interbed referred to as Crown Point lava member. Although Pliocene sediments can be traced southward from Troutdale formation (as mapped by Treasher, 1942) into coalescing Molalla formation, it is desirable to retain Hodge's definition of Troutdale because not only have other names (Molalla formation and Fern Ridge tuffs farther south) been introduced but also composition of part of Troutdale is different, in that it contains quartzite pebbles. Troutdale sand and gravels are restricted to valley of lower Columbia River, but the somewhat younger Portland Hills silt is not and covers much of adjacent land. Williams (1916, Oregon Bur. Mines and Geology Mineral Resources, v. 2, no. 3) referred the sands and gravels to Satsop formation.

D. E. Trimble, 1955, (abs.) Geol. Soc. America Bull., v. 66, no. 12, pt. 2, p. 1667. Overlies Rhododendron formation of Hodge.

D. E. Trimble, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–104. In Portland quadrangle, formation consists of conglomerate, sandstone, shale, and mudstone; tuffaceous in part. Thickness more than 1,100 feet. Overlies Columbia River basalt; underlies Boring lava. Lower Pliocene.

Named for gravels and sands deposited by ancestral Columbia River, which are well displayed near Troutdale, Multnomah County, Oreg.

Troutdale Granite[1]

Precambrian(?): Central northern Colorado.

Original references: J. Underhill, 1906, Colorado Univ. Studies, v. 3, no. 4, p. 272; 1906, Colorado Sci. Soc. Proc., v. 8, p. 103–122.

Named for town in Evergreen, Denver Mountain Parks quadrangle, Jefferson County.

Trout Pond Limestone[1]

Precambrian: Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199, p. 112, 114, fig. 25.

Occurs on George W. Smith property, south of Clintonville, Clinton County.

Trowbridge Coal Member (of Mattoon Formation)

Pennsylvanian: Central and southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 51 (table 1), pl. 1. Assigned member status in Mattoon formation (new). Occurs below Calhoun coal member (new) and above Opdyke coal member. Coal named by Cady (1948 Illinois Geol. Survey Bull. 62). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: About center of south line sec. 11, T. 10 N., R. 6 E., Shelby County.

Trowbridge Shale

Upper Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 263–265. Consists of black shale with large concretions. Thickness about 4,000 feet. Underlies Lonesome formation (new); overlies Snowshoe formation (new); base difficult to determine.

Type area: Trends northeast across South Fork Valley along Mowich anticline where beds dip steeply to southeast. Named for H. H. Trowbridge Ranch, at mouth of Rosebud Creek, in South Fork Valley, Crook County.

Troy Granite[1]

Precambrian: Central southern Oklahoma.

Original reference: C. H. Taylor, 1915, Oklahoma Geol. Survey Bull. 20.

Occurs along Rock Creek near town of Troy, Johnston County.

**Troy Quartzite**[1]

Precambrian: Central Arizona.

Original reference: F. L. Ransome, 1915, Washington Acad. Sci. Jour., v. 5, p. 380–385.

A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 474–475, 477 (table 1). Troy is differentiated from Apache group, not only because it overlaps Mescal limestone but because it carries Cambrian fossils and conformably underlies younger Middle Cambrian strata. Thickness 350 feet in Peppersauce Canyon where it underlies Santa Catalina formation and is disconformable above unnamed sandstone of Apache group.

N. E. A. Hinds, 1936, Carnegie Inst. Washington Pub. 463, p. 32. South of Roosevelt Dam, the Troy rests either on Roosevelt member (new) of Apache group or on unnamed basalt member that overlies Mescal limestone.

N. P. Peterson, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–41. Mapped in Globe quadrangle. Underlies Martin limestone and overlies Mescal limestone of Apache group with disconformable contacts.

U.S. Geological Survey currently designates the age of the Troy Quartzite as Precambrian on the basis of a study now in progress.

Named for exposures on Troy Mountain, Ray quadrangle.

Troy Shales[1]

Troy Shale and Limestone Member (of Schodack Formation)

Lower Cambrian: Eastern New York.

Original reference: R. Ruedemann, 1914, New York State Mus. Bull. 169, p. 67–70.

Rudolf Ruedemann, 1942, New York State Mus. Bull. 331, p. 64, Term Schodack formation, in Catskill quadrangle, is extended to include as members beds that occur associated or even interbedded with it such as Zion Hill quartzite, Burden conglomerate, and Troy shale and limestone, which is for most part a mass of greenish, reddish-purplish shale in places with small beds of more or less calcareous quartzite.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 64. In Troy and Cohoes quadrangles, Schodack formation includes (ascending) Bomoseen grit, Diamond Rock quartzite, Troy shale and limestone, and Schodack shale and limestone.

Exposed at Troy, N.Y., at dam in Poesten Kill, and other localities.

Truchas slate[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 12.

Occurs at Picuris, north of Santa Fe, Santa Fe County. Derivation of name not stated.

**Truckee Formation**[1]

Pliocene: Northern and central western Nevada, eastern California, and southeastern Oregon.

Original reference: C. King, 1876, U.S. Geol. Expl. 40th Par. Atlas, map 5; 1878, U.S. Geol. Expl. 40th Par. Rept., v. 1, p. 412.

Age considered Pliocene on basis of study of molluscan fauna. Teng-Chien Yen, 1950, Am. Jour. Sci., v. 248, no. 3, p. 180–193.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 55–56, pl. 3. Formation described Virginia City quadrangle, Nevada, where it is composed of stream and lake deposits which occur in many disconnected areas; beds of diatomite common. Thickness uncertain; may be 3,000 feet or more in Chalk Hills but much less elsewhere. Underlies Lousetown formation; base intertongues with lower part of Kate Peak formation. Early Pliocene.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 99–102, 141–142. Type area restudied. Here formation is represented by three unnamed members: lower, basalt tuff (palagonite) as much as 80 feet thick; middle, nearly pure diatomite, about 1,500 feet thick; upper, slabby gray limestones which range in thickness from 1 or 2 inches up to several feet, with some beds 20 to 30 feet, approximately 850 feet of section exposed. Underlies Lake Lahontan deposits; overlies Desert Peak formation (new). Pliocene; lower member late Clarendonian; middle, Hemphillian; upper, higher parts of which may be as young as Blancan. Misunderstanding of nature of formation in its type area has resulted in including in Truckee rocks in western area near California-Nevada border that represent a distinct formation.

Type section: Northeastern corner Hot Springs Range, 70 miles northeast of town of Truckee and 18 miles from Truckee River at its nearest point.

Truckhaven Rhyolite

Pliocene: Southern California.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 23 (fig. 2), 24, pl. 2. A lens of varicolored felsitic rock that was extruded along an adjacent east-west fault. Maximum thickness 100 feet. Wedges out southward into Canebrake conglomerate (new).

Crops out near Truckhaven, west of Salton Sea, Imperial County.

Trujillo Formation[1]

Cretaceous: Puerto Rico.

*See* **Trujillo Alto Limestone.**

**Trujillo Formation** (in Dockum Group)[1]

Upper Triassic: Northeastern Texas.

Original reference: C. N. Gould, 1907, U.S. Geol. Survey Water-Supply Paper 191, p. 20–29.

G. Maxwell, 1954, Panhandle Geol. Soc. [Guidebook] Spring Field Trips April 24 and May 1, p. 15. Thickness 20 to 25 feet in Potter County. Consists of one to five or more sandstones or conglomerates with interbedded red and gray shales. Overlies Tecovas formation.

Name for exposures on Trujillo Creek, Oldham County.

**Trujillo Alto Limestone**[1]

Upper Cretaceous: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 21, 61.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47, 48 (table 4). Thickness 200 feet. Overlies Luquillo formation; underlies Figuera formation. Upper Cretaceous.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 9 (fig. 8), 20–22, pl. 2. Fossiliferous medium-bedded to massive limestone. Maximum thickness about 900 feet. Overlies Monacillo formation (new); underlies Figuera volcanics.

Named for outcrops in vicinity north of Trujillo Alto.

Trumbull facies (of Cleveland Shale)

*See* **Cleveland Shale.**

Trumbull Gneiss[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199, p. 45, 127.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs at base of sequence and below Hague gneiss.

Named from Trumbull Mountain, Essex County.

Trump Conglomerate

Pliocene(?): Central Colorado.

J. H. Johnson, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 77. A series of gravels and poorly consolidated conglomerates. Overlies Wagontongue formation (new). Late Pliocene.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 34 (table 7). 70–72, pl. 1. Estimated maximum thickness 500 feet. Pliocene(?).

Widespread along extreme southern end of South Park. Well exposed along pediments sloping up to Coffman Ridge in T. 14 S., R. 76 W., and along divide between Agate Creek and Badger Creek in secs. 14 and 23 in same township. Named from settlement of Trump, Park County.

Truro Limestone[1]

Pennsylvanian: Central southern Iowa.

Original reference: J. L. Tilton, 1897, Iowa Acad. Sci. Proc., v. 4, p. 52, 54.

Named for Truro, Madison County.

†Truro Series[1]

Pleistocene: Southeastern Massachusetts.

Original reference: N. S. Shaler, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 541–593.

Named for occurrence in Truro, Barnstable County.

Truxton limestones[1]

Carbonic (Mississippian Series): Northwestern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 243, 251, 338.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart). In Mississippian series. Underlies Elden limestones; overlies Simon limestones. Of Carbonic age.

Exposed in Grand Wash Cliffs and Yampai Cliffs overlooking Truxton Plateau, Mohave County.

Tryon Peak flows

Late Tertiary: Central eastern California.

H. G. Wilshire, 1957, California Univ. Dept. Geol. Sci. Bull., v. 32, no. 4, fig. 1. Named on map legend of Ebbetts Pass region. Younger than Silver Peak andesites and Raymond Peak andesites (both new).

Ebbetts Pass region is in Alpine County.

**Tsadaka Formation**

Eocene(?) and Oligocene: South-central Alaska.

F. F. Barnes and T. G. Payne, 1956, U.S. Geol. Survey Bull. 1016, p. 13, 19–20, pls. 1, 2. Poorly indurated coarse conglomerate characterized by boulders and cobbles of granite and diorite in matrix of granitic debris. Consists of at least 700 feet of interbedded silty sandstone, siltstone, pebbly sandstone, and fine to coarse conglomerate in Tsadaka Canyon. Sandstone beds are arkosic. Youngest bedrock formation in district; underlies relatively thin veneer of unconsolidated material in area immediately south of Wishbone Lake; unconformably overlies Wishbone formation (new). Represents uppermost conglomeratic beds on Wishbone Hill, mapped as Eska conglomerate by Martin and Katz (1912).

U.S. Geological Survey currently designates the age of the Tsadaka Formation as Eocene(?) and Oligocene on the basis of a study now in progress.

In Tsadaka Canyon on Moose Creek below Premier mine, Wishbone Hill district, Matanuska coal field; also on Wishbone Hill.

Tsegi Formation

Quaternary, upper: Northeastern Arizona.

J. T. Hack, 1941, Geog. Review, v. 31, no. 2, p. 262–263; 1942, Harvard Univ. Peabody Mus. Am. Archeology and Ethnology Papers, v. 35, no. 1, p. 51–53, fig. 29. Clay beds and silt beds common, but in general, formation contains more numerous gravel lenses, as though in part deposited by more torrential streams. Not cemented in most places, but here and there, especially in center of valley, hard, sandy clay beds contain calcium carbonate cement. Gray to brown. No artifacts found in formation, but several pieces of charcoal found below ruin of Kawaika-a, probably indicating human occupation of region during deposition of formation. Deposited before 1100 A.D. Above Awatovi, where formation is thick, it consists of two members separated by erosional unconformity. Below end of Antelope Mesa, formation becomes thin, suggesting that streams must have deposited all of their load before reaching lower part of valley. Underlies Naha formation (new); overlies Jeddito formation (new).

Type locality: In Tsegi Canyon, western Navajo country.

Tualatin Gravels

Pleistocene: Northwestern Oregon.

R. C. Treasher, 1942, Geologic map of the Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. Consists of silt, grit, and gravel as much as 200 feet thick; represents piedmont fan deposition.

Form terraces along Tualatin River, Portland area.

Tub Springs Sandstone (in Cross Mountain Group)

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 11, 19, pl. 2. Sandstone, usually massive, about 20 to 50 feet thick. Overlies shale interval 110 to 200 feet thick which in turn overlies Low Gap sandstone (new) ; in Cross Mountain section, underlies 270 feet of shale containing minor amounts of sandstone.

Type locality: Same as Cross Mountain group, which is on road leading to top of Cross Mountain, Lake City quadrangle, Anderson County. Named from exposures near Tub Spring at top of Frozen Head Mountain above Petros, Fork Mountain quadrangle.

Tuckahoe Group (in Newark Group)[1]

Upper Triassic: Eastern Virginia.

Original reference: N. S. Shaler and J. B. Woodworth, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 423–435.

Exposed in shafts and mines bordering Tuckahoe Creek, Goochland County, in vicinity of Gayton, Henrico County.

Tuckahoe Marble[1]

Precambrian: Southeastern New York.

Original reference: C. P. Berkey and J. R. Healy, 1912, Columbia Univ. Contr., v. 20, p. 1907–1912.

In Westchester County.

†Tucquan Gneiss[1]

Precambrian: Southeastern Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 1, p. 128–129, 136, 203, 204.

Probably named for exposures in broad, flat anticlinal arch whose axis crosses Susquehanna River at mouth of Tocquan [Tucquan] Creek (McCalls Ferry).

Tucson Sandstone[1]

Upper Cretaceous (Benton) : Southern central New Mexico.

Original reference: G. H. Hansen, 1931, George Washington Univ. Bull., Summ. doctoral theses, 1925–1928, p. 84.

Well exposed on Tucson Mountain, Sierra Blanca region.

Tucson Mountain chaos

Tertiary, lower to middle(?) : Southeastern Arizona.

J. H. Courtright, 1958, Arizona Geol. Soc. Digest, p. 7, 8. Characterized principally by abundance of large angular blocks of limestone, arkose, andesite porphyry conglomerate, and other rocks. In exposure one-half mile due south of Gates Pass, chaos consists of erratically positioned large rock blocks enclosed in series of thin-bedded conglomerates and silts. Underlies Cat Mountain rhyolite formation; unconformably overlies arkosic beds of probable Cretaceous age. Name credited to J. E. Kinnison (unpub. thesis).

J. E. Kinnison, 1959, Arizona Geol. Soc. Guidebook 2, p. 48–57. Includes two members—lower conglomerate member with poorly consolidated well-rounded reddish-brown cobble conglomerate at its base and well consolidated conglomerate with more numerous boulders in upper part, thickness about 150 feet, apparently only a local feature; and upper chaos member, characterized by blocks 10 to more than 200 feet in maximum dimension, with angular limestone conglomerate bodies erratically distributed throughout member, thickness of member 185 feet. Chaos overlies Amole group. Tentatively considered to be of probable early to middle Tertiary age.

Crops out extensively in Tucson Mountains, from which it derives its name, Pima County.

**Tucumcari Shale**

†Tucumcari Beds[1]

Tucumcari Shale Member (of Purgatoire Formation)

Lower Cretaceous: Northeastern New Mexico.

Original reference: W. F. Cummins, 1892, Texas Geol. Survey 3d Ann. Rept., p. 201–209.

Ernest Dobrovolny and C. H. Summerson, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 62. Member consists of gray shale and buff calcareous sandstone that contains nodules of argillaceous limestone and has thin basal sandstone. Contained fauna indicates Kiamichi and Duck Creek age. Name Tucumcari beds was originally used for this interval, but term included overlying unit here named Mesa Rica sandstone member. Unconformably overlies Morrison, Wingate(?), or Chinle formations.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2005 (fig. 2), 2007. Rank raised to formation; term Purgatoire abandoned in Tucumcari-Sabinoso area. Thickness 0 to about 60 feet.

Named for Mount Tucumcari, northwestern Quay County.

Tucumcarian series

Mesozoic (Early Cretacic): New Mexico.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 2, p. 105 (chart), 153–154. Comprises (ascending) Redondo, Pyramid, Fredericksburg, and Washita terranes.

Tuerto Gravel

Quaternary: North-central New Mexico.

C. E. Stearns, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 476, 477, pl. 1. Thickness 5 to more than 150 (300?) feet. Interbedded with basalt flows tentatively correlated with Cuerbio basalt. Younger than Santa Fe formation.

Brewster Baldwin, 1956, New Mexico Geol. Soc. Guidebook 7th Field Conf., p. 118 (fig. 2), 119. Mentioned in discussion of upper unit of Santa Fe group. Puye gravel, Ancha formation, and Tuerto gravel all rest with angular unconformity on Tesuque formation. These gravel units are 500, 300, and 150 feet in maximum thickness. Early Pleistocene.

In Galisteo-Tonque area, Sandoval and Santa Fe Counties.

**Tufts Quartzite Member** (of Cambridge Slate)[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: M. Billings, 1929, Am. Jour. Sci., 5th, v. 18, p. 101, 102, 106, 107, 111, 112.

Exposed in athletic field of Tufts College, Medford, Boston region, Suffolk County.

Tuira Formation

Miocene: Panamá.

Karl Sapper, 1937, Mittelamerika, Handbuch der regionalen Geologie: Heidelberg, v. 8, Abt. 4a, no 29, p. 132, 134 (correlation chart). Underlies Pucro sandstone. Equivalent to lower Gatún formation. Middle Miocene.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 349. Not properly defined. Miocene.

In Darién area.

**Tuktu Formation** (in Nanushuk Group)

Tuktu Member (of Umiat Formation)

Lower Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 162, fig. 2. Member consists almost entirely of marine sandstone at type locality where it is about 1,000 feet thick and underlies Hatbox tongue (new) of Chandler formation (new). Northward, member thickens progressively to about 2,500 feet and includes part of marine equivalent of Hatbox tongue. Base of member coincides with base of Umiat formation (new) and base of Nanushuk group. Overlies Torok formation (new); underlies Topagoruk member (new) of Umiat formation.

R. L. Detterman *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 233–235, figs. 2, 5. Redefined as formation. Rocks form prominent south-facing escarpment along southern edge of Northern Foothills section. Northward across strike, formation grades abruptly into shale but is present 35 miles north of escarpment. More exact data on type locality given. Approximately 1,030 feet thick at type locality. Underlies Chandler and Grandstand (new) formations. Predominantly dirty-green to greenish-gray very fine- to fine-grained sandstone. Siltstone and silt shale form subordinate part of formation. Sandstone is commonly thin bedded, calcareous, highly argillaceous, and in places micaceous.

Type locality: On Chandler River where river cuts through Tuktu Bluff, a continuous south-facing escarpment that can be traced for many miles, lat 68°44′ N., long 152°18′ W.

**Tulare Formation**[1]

Pliocene and Pleistocene(?): Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 181.

W. P. Woodring, Ralph Steward, and R. W. Richards, 1940, U.S. Geol. Survey Prof. Paper 195, p. 13–22, pl. 3. Formation is nonmarine and consists principally of sandstone and conglomerate and toward base of fine-grained rocks in which fresh-water mollusks and fresh- and brackish-water diatoms are abundant. Exposed thickness 1,700 to 3,500 feet.

Underlies alluvium; overlies San Joaquin formation, base drawn just above youngest widespread marine deposits constituting upper *Mya* zone of San Joaquin. Youngest folded strata in Kettleman Hills. Named by Anderson (1905) but no type locality designated. Kettleman Hills have been regarded as type region (Arnold and Anderson, 1910, U.S. Geol. Survey Bull. 398) as exposures there were only ones described, and name was derived from Tulare Lake, shore of which at that time lay close to edge of North dome. Type section suggested.

F. F. Davis and D. W. Carlson, 1952, California Jour. Mines and Geology, v. 48, no. 3, p. 212, 221 (table). In Merced County, overlies Ora [Oro] Loma formation (new). Underlies upper Pleistocene lake beds called Peckham formation by Leith (1949).

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 12 (fig. 2), 48–49, pls. 1, 2, 3. Formation, in Ortigalita Peak quadrangle, consists of as much as 500 feet of gravel, sand, silt, and marly beds. Overlies Oro Loma formation. Lithologic similarity of Tulare to Oro Loma led Anderson and Pack (1915, U.S. Geol. Survey Bull. 603) to consider the formations as single unit, but separation can be made on lithology and structural characteristics. Oro Loma beds are folded with bedrock series, and Tulare strata extensively overlap all these units, including Franciscan formation. Formation postdates upper Pliocene orogeny and predates mid-Pleistocene orogeny, thus limiting time of deposition to Plio-Pleistocene.

Suggested type section: On La Ceja, one-fourth mile southeast of Avenal-Lenmoore Road, sec. 35, T. 21 S., R. 17 E., on east side of northern North dome. This is probably section studied by Anderson. Owing to overlap of alluvium, only lower part of formation is exposed. Name derived from Tulare Lake.

Tularosa Formation[1]

Tertiary or Quaternary(?): Southeastern New Mexico.

Original reference: C. L. Herrick, 1904, Am. Geologist, v. 34, p. 179, 187.

Derivation of name not stated.

Tularosa Malpais Lava

Recent: Central southern New Mexico.

L. R. Dice, 1940, Scientific Monthly, v. 50, p. 419–420. Large bed of black lava with total area of about 120 square miles. Thickness around edges usually about 10 to 20 feet, but in some places as much as 50 feet. In middle of its stream, lava must be thicker.

In Tularosa Basin, in belt roughly along line extending from Malpais Spring to Carrizozo.

**Tule Formation**[1]

Pleistocene: Northern Texas.

Original reference: W. F. Cummins, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 199–200, 203.

G. L. Evans and G. E. Meade, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 493–495. Formation consists mainly of well-bedded gray unconsolidated sands and greenish-tan bentonitic clays. Beds of unaltered volcanic ash present locally. Thickness as much as 114 feet. Vertebrate fauna indicates intermediate Pleistocene age.

J. C. Frye and A. B. Leonard, 1957, Texas Univ. Bur. Econ. Geology Rept. Inv. 32, p. 21–24, strat. sections. Discussion of Cenozoic geology along eastern margin of Texas High Plains, Armstrong to Howard Counties. Name Tule formation is used as regional unit to include all deposits of Kansan Cycle in area of study. It is thus applied not only to relatively slack water fills of broad valleys that crossed High Plains area but also to high terrace deposits of same age that flank some of major stream canyons and to terrace deposits of equivalent age that occur beyond escarpment of High Plains. Thickness in type area 27 to 55 feet.

Named for Tule Canyon, Swisher County.

Tule Mountain Trachyandesite

Tertiary: Southwestern Texas.

J. D. Martinez, Edwin H. Statham, and L. G. Howell, 1960, Texas Univ. Bur. Econ. Geology Pub. 6017, p. 37, 42 (fig. 36). Incidental mention in paleomagnetic study of Tertiary volcanics in Big Bend National Park.

**Tule Spring Limestone**[1]

Lower Mississippian and Pennsylvanian: Southeastern Arizona.

Original references: W. Lindgren, 1905, U.S. Geol. Survey Prof. Paper 43; 1905, U.S. Geol. Survey Geol. Atlas, Folio 129.

A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 511–512. Lower 200 feet of unit carries Lower Mississippian fauna and upper 300 feet contains characteristic Pennsylvanian fossils.

Named for exposures around Tule Springs, at head of Tule Creek, Clifton quadrangle.

†Tulik Basalt

Tertiary and Quaternary: Southwestern Alaska.

F. M. Byers, Jr., and others, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 3, p. 28, pl. 3. Composed principally of basalt porphyry flows 20 to 60 feet thick. Lavas vary in texture from finely granular to porphyritic and contain as much as 60 percent of phenocrysts, mainly bytownite feldspar with some olivine. Oldest lavas interfinger with late Crater Creek flows. Partly underlies veneer of Okmok ash (new).

F. M. Byers, Jr., 1959, U.S. Geol. Survey Bull. 1028–L, p. 308. Name Tulik abandoned. Replaced by informal name.

Makes up much of Mount Tulik, large slightly dissected parasitic cone on south flank of Okmok Volcano, on Umnak Island in eastern part of Aleutian Islands.

**Tulip Creek Formation**[1] (in Simpson Group)

Ordovician: Central southern Oklahoma.

Original references: F. C. Edson, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 7, p. 947; C. E. Decker, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 12, p. 1498–1505. Name credited to E. O. Ulrich.

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, p. 77–85, charts 1, 2, fig. 1. In chart (column 8, fig. 1) presented from manuscript before Geological Society of America at annual meeting in New York City in 1928, Ulrich introduced the Tulip Creek as a Simpson formation in stratigraphic interval between underlying McLish and overlying Criner formation. Decker (1930) published this chart. Ulrich (1929 [1930], U.S. Natl. Mus. Proc., v. 76, art. 21) published Simpson correlation chart showing Tulip Creek in stratigraphic position below the Criner, but overlying the

Falls, not McLish. He later (Edson, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 8) proposed Cool Creek formation in stratigraphic position between Tulip Creek and Criner formations. Decker and Merritt (1931, Oklahoma Geol. Survey Bull. 55) placed Tulip Creek in stratigraphic position between subjacent McLish and superjacent Bromide, and subsequent stratigraphers have thus adopted it. Subdivisible into two parts: basal sandstone ("Wilcox" of type Tulip Creek locality), and an overlying section of shales and thin-bedded limestones and a few thin sandstones. Thickness at type section 395 feet (subdivisible into 175-foot basal sand and 235 feet of overlying green shales with thin limestones and occasional thin sandstone). Disconformable relationships with both underlying McLish and overlying Bromide formations. Ostracodal fauna indicates Black River age.

Type section: Along Tulip Creek, on southern side of Arbuckle Mountains, adjacent west side of U.S. Highway 77, north of Springer, Carter County.

†Tullahoma Formation[1]

Mississippian: Tennessee and western Kentucky.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 104, 143, 144.

Named for Tullahoma, Coffee County, Tenn.

**Tullock Member** (of Fort Union Formation)

Tullock Formation[1]

Paleocene: Eastern Montana, South Dakota, and Wyoming.

Original reference: G. S. Rogers and Wallace Lee, 1923, U.S. Geol. Survey Bull. 749, p. 29.

A. J. Collier and M. M. Knechtel, 1939, U.S. Geol. Survey Bull. 905, p. 10–11, pl. 3. Lance formation in McCone County, Mont., comprises two members—a lower Hell Creek, and an upper, Tullock. Footnote, page 10, states that since present report was written, Hell Creek and Tullock members have been raised to rank of formation in official classification of Geological Survey, Hell Creek being assigned to Cretaceous and Tullock to Cretaceous or Eocene.

Erling Dorf, 1940, Geol. Soc. America Bull., v. 51, no. 2, p. 230 (table 5). Discussion of relationship between floras of type Lance and Fort Union formations. In proposed revision of nomenclature, Tullock formation (equivalent to Ludlow formation and Cannonball marine member) is placed at base of Fort Union group. Eocene or Upper Cretaceous.

Erling Dorf, 1942, Carnegie Inst. Washington Pub. 508, p. 95–97. Deposits above Lance formation have been generally referred to Fort Union formation on basis of stratigraphic position, lithology, absence of dinosaurs, and presence of typical lower Eocene (Paleocene) flora. Contact between typical Lance and lowest unit of Fort Union group is traceable northward into Gillette coal field region, where it coincides with contact between Hell Creek and Tullock formations. Tullock formation was regarded by Dobbin and Barnett (1927, U.S. Geol. Survey Bull. 796–A), as elsewhere by others, as upper member of Lance. In Gillette coal field, as well as at its type locality and elsewhere, the Tullock is now known to contain plant remains of typical Paleocene Fort Union aspect. This conclusion is substantiated by southward extension of the Tullock of Gillette coal field into Fort Union beds above top of Lance formation, as defined in Lance Creek area. Lower unit of Fort Union group of Lance Creek area is equivalent to Tullock formation, which is traceable from its type locality in eastern Montana into area of Gillette coal field. Thickness of Tullock in Lance Creek area about 400 feet. Units above Tullock in Lance Creek area not studied.

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, pl. 7. Plate 7 shows that Livingston formation intertongues with Claggett, Judith River, Bearpaw, Lennep, Hell Creek, Tullock, and Lebo formations.

C. E. Dobbin, W. B. Kramer, and G. H. Horn, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–185. Thickness of Tullock member, 1,110 feet, in southeastern part of Powder River Basin, Wyoming. Underlies unnamed unit in upper part of formation; overlies Lance formation.

W. J. Mapel, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 200–201. Discussion of Powder River Basin. Fort Union formation as used herein comprises (ascending) Tullock, Lebo, and Tongue River members. Tullock has maximum thickness of about 1,100 feet in southern part of basin; thins northward to about 500 feet at Montana-Wyoming border, and to about 200 to 250 feet in northern Powder River and southern Rosebud Counties, Mont. Overlies Upper Cretaceous Hell Creek or Lance formation.

Named for exposures in valley of Tullock Creek, Treasure County, Mont.

Tullos Clay Member (of Yazoo Clay)

Eocene (Jackson): Central Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 78 (fig. 6), 98–99. Series of clays ranging in thickness from 75 to 175 feet; on fresh exposure clays are deep blue gray but weather to drab yellow, or light gray. Grades into overlying Verda member (new) through sandy concretionary transition phase herein named Union Church; overlies Moodys Branch marl.

Well exposed in grade cuts of Missouri Pacific Railroad, half a mile southwest of Tullos station, La Salle Parish.

**Tully Limestone**[1]

Tully Limestone (in Susquehanna Group)

Middle Devonian: New York and Pennsylvania.

Original reference: L. Vanuxem, 1839, New York Geol. Survey 3d Rept., p. 278.

G. A. Cooper and J. S. Williams, 1935, Geol. Soc. America Bull., v. 46, no. 5, p. 781–868. Divided into several members in different areas: Apulia, Laurens, New Lisbon (new), Tinkers Falls (new), and West Brook (new).

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1786–1788, chart 4. On basis of new information, it seems best to regard Tully as Middle Devonian, and to make a stage, the Taghanic, to include it and its correlatives in the Midwest and the overlying Geneseo shale.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2816–2818. Tully limestone underlies Geneseo shale member of Genesee formation. Lenses of fossiliferous pyrite and marcasite as much as 7 inches thick and 1 inch to 10 feet long separate Genesee formation from underlying Moscow shale in most outcrops between Canandaigua Lake and Lake Erie. These lenses were named Tully pyrite by Loomis (1903, New York State Mus. Bull. 69) and Leicester marcasite member of Moscow formation by Sutton (1951). Although Tully limestone and Tully pyrite of Loomis had not been found in same outcrop, the pyrite and marcasite were considered to be older than, or equivalent in age to, the Tully limestone. Recently pyrite and marcasite lenses have been found at base of Geneseo shale overlying nodules of Tully limestone in Gage Gully on east side of Canandaigua Lake. Relation of rocks in this outcrop indicates that Tully pyrite of Loomis is younger than Tully limestone and appears to be part of Genesee formation.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook for Field Trips Pittsburgh Mtg., p. 3. At base of Susquehanna group.

Well exposed in town of Tully, Onondaga County, N.Y.

†Tulsa Group[1]

Pennsylvanian: Northeastern and central northern Oklahoma.

Original reference: C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910, Oklahoma State Univ. Research Bull. 3, p. 6, 10.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey. Name applied to strata of Marmaton group.

Named for Tulsa County.

†Tuluga Member (of Schrader Bluff Formation)

Upper Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 166, figs. 2, 3. Distinguished by abundant bentonite and tuff interbedded with light-colored sandstone and shale. In Fish Creek test well No. 1, member almost entirely marine except for one thin coal bed and associated sandstone. Maximum thickness estimated to be 2,200 feet in outcrop belt, but this thickness includes minor units of Tuluvak tongue (new) of Prince Creek formation (new). Underlies Sentinel Hill member (new); overlies Seabee member (new), both of Schrader Bluff formation.

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 246. Rocks formerly included in Tuluga member placed in Seabee formation and newly defined Rogers Creek and Barrow Trail members of Schrader Bluff formation and name Tuluga member is abandoned.

Type locality: Schrader Bluff, which is best exposure of this member. Named from Tuluga River, which enters Anaktuvuk River at north end of Schrader Bluff. Also well exposed on Chandler River near confluence with Ayiyak River and on Colville River in Umiat area.

**Tuluvak Tongue** (of Prince Creek Formation)

Upper Cretaceous: Northern Alaska (surface and subsurface).

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 166, figs. 2, 3. Lower part of (nonmarine) formation. Thickness 1,200 feet in Tuluvak Bluffs. Overlies Seabee member (new) of marine Schrader Bluff formation (new). Intertongues with Tuluga tongue (new) of Schrader Bluff formation.

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 252–253, fig. 4. Nonmarine tongue is a wedge dividing marine rocks of Colville group into two easily recognizable formations—Seabee formation (redefined) below and Schrader Bluff formation (redefined) above.

Best exposed in Tuluvak Bluffs on Chandler River.

Tumbez Limestone

Middle Ordovician: Southwestern Virginia.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66, p. 133–134, 156, pl. 23. Proposed for limestone equivalent to the typical Blackford in Russell County. The Blackford undergoes a distinct facies change along Clinch Mountain belt; shaly dolomitic beds are supplanted by predominantly coarse-grained limestone. In type section of the Tumbez, interbedding of coarse-grained limestones with the typical Blackford is well shown. Thickness at type section about 120 feet. Underlies Elway limestone; overlies "Knox" dolomite.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. In Duffield quadrangle, included in Blackford formation.

Type section: South of Tumbez, Russell County.

Tumbledown Gneiss

Age not stated: West-central Maine.

Kern Jackson, 1953, Maine State Geologist Rept. 1951–1952, p. 53, 66. Described as very coarse banded metasedimentary gneiss. Composed of alternate bands of micaceous quartzite and muscovite schist. Basic dikes cut across the gneissic structure.

Makes up bulk of Tumbledown and Jackson Mountains, Rumford quadrangle.

**Tumbling Run Member** (of Pottsville Formation)

Tumbling Run Formation (in Pottsville Group)

Lower Pennsylvanian: Eastern Pennsylvania.

G. H. Wood, Jr., and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2673–2675, 2680–2683; 1957, U.S. Geol. Survey Coal Inv. Map C–43, sheet 1. Predominantly conglomerate and sandstone with less quantities of conglomeratic sandstone, siltstone, shale, and coal; conglomerate beds are coarser and less well sorted in lower part of member and proportion of sandstone, conglomeratic sandstone, siltstone, shale, and coal beds somewhat greater in upper part. Comprises basal 535 feet of formation at reference section herein designated. Underlies Schuylkill member (new). Conformably overlies Mauch Chunk formation; contact arbitrarily placed at top of uppermost sandstone, siltstone, or shale; at reference section of Pottsville, uppermost red shale, unit 0 (fig. 3), of Mauch Chunk lies directly below gray shale of unit 1 (fig. 3), basal bed of Pottsville and Tumbling Run member. Most geologists consider contact at type and reference sections to be local time boundary between Mississippian and Pennsylvanian systems. Regional stratigraphic studies indicate that there may be considerable intertonguing of facies between Tumbling Run member of Pottsville formation and Mauch Chunk formation; therefore it is possible that the time boundary, as recognized in type and reference sections, is in rocks of Mauch Chunk formation at some localities and in rocks of Pottsville formation at other places.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation in Pottsville group in anthracite region.

Type section: Basal part of Pottsville formation reference section, which is in road cut on east side of U.S. Highway 122, about 150 feet farther east than original type section of Pottsville which is on eastern side of Pennsylvania Railroad cut through water gap south of Pottsville, Schuylkill County.

Tumco Formation

Paleozoic or older: Southern California.

P. C. Henshaw, 1942, California Jour. Mines and Geology, v. 38, no. 2, p. 155–157, pl. 2. Fine-grained gray to pinkish-gray massive arkosite.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 489, table 4. Older Precambrian(?).

Occurs in Tumco Valley in Cargo Muchacho Mountains, Imperial County.

Tumey Formation[1]

Tumey Sandstone Lentil (in Kreyenhagen Formation)

Oligocene: Southern California.

Original reference: E. R. Atwill, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 8, p. 1192–1204.

John Zimmerman, Jr., 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 7, p. 953–976. In Ciervo Hills, Fresno County, the Kreyenhagen in outcrop contains three members: lower Kreyenhagen shale, Tumey sandstone lentil, and Tumey or upper Kreyenhagen shale. Sandstone crops out as lens about 9 miles long and up to one-half mile wide in shales of the Kreyenhagen.

J. E. Schoellhamer and D. M. Kinney, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–128. In this report, all strata between Domengine sandstone and overlapping Temblor formation are included in Kreyenhagen shale. Atwill's sandstone unit of Tumey formation is here called sandstone member of Kreyenhagen. Area of report is Tumey and the Panoche Hills, Fresno County.

Type locality: In S½ sec. 16, T. 16 S., R. 13 E., Fresno County. Name derived from nearby Tumey Gulch.

†Tunangwant Conglomerate[1]

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: J. F. Carll, 1880, Pennsylvania 2d Geol. Survey Rept. $I_3$, p. 79.

G. A. Cooper and others, 1944, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1742. Upper Devonian.

Named for exposures in New York along Tunangwant Creek, which flows north through Bradford, Pa., into New York. Exposed in hills bordering Tunangwant Creek, between Carrollton, N.Y., and Bradford, Pa.

Tunbridge Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Probably named for Tunbridge Township, Orange County, or some of villages of that name within township.

Tunitas Sandstone Member (of Purisima Formation)

Pliocene: Northern California.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1326. Maximum thickness 400 feet. Top member of formation; overlies Lobitos mudstone member (new).

Area of report is in Santa Cruz Mountains, 30 to 40 miles south of San Francisco.

Tunnel Creek Glacial Stage

Tunnel Creek Till

Pleistocene (Wisconsin): Northwestern Oregon.

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 20, 24–25. Defined as time during which Tunnel Creek till was deposited. Till is composed largely of angular blocks which bear few facets or striae.

Exposed in North Santiam River valley near Tunnel Creek [Marion County].

Tunnel Hill zone[1]

Precambrian: Northwestern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 6, 8, 12.

Named for exposures at Tunnel Hill, Oconee County.

Tunnel Peak Breccia, Dacite

Tertiary: Central California.

R. L. Rose, 1960, California Div. Mines Spec. Rept. 60, p. 15 (fig. 3), 16–17. Volcanic complex that consists of hornblende dacite surrounded by tuff breccia. Contact of breccia with Mehrten formation is nearly vertical and apparently breccia intrudes Mehrten. Tunnel Peak vent breccia shown on geologic map.

Complex, about 2,000 feet in diameter, makes up topographic prominence known locally as Tunnel Peak, Golden Gate Hill area, Calaveras County.

**Tunnel Point Sandstone**

Tunnel Point Beds[1]

Tunnel Point Formation

Oligocene, middle: Southwestern Oregon.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 336–343.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 590, chart 11. Tunnel Point sandstone, 350 feet thick where exposed in sea cliffs north of Tunnel Point, is probably conformable on Bassendorf shale but is unconformable beneath Empire formation.

C. E. Weaver, 1945, Washington [State] Univ. Pubs. in Geology, v. 6, no. 2, p. 50–52. Type section of formation consists of 760 feet of concretionary and nodular sandstone, thickly bedded stratified sandstones, medium-grained sandstones and beds of interstratified sandstones, and shaly sandstones. Overlies Bassendorf formation; underlies Empire formation.

Type section (Weaver, 1944). In west limb of syncline at Coos Bay, Coos County.

†Tununk Sandstone Member (of Mancos Shale)[1]

Upper Cretaceous: Central southern Utah.

Original reference: G. K. Gilbert, 1877, Geology of the Henry Mountains: U.S. Geog. and Geol. Survey of the Rocky Mountain region, p. 4 [2d ed. 1880].

C. R. Longwell and others, 1923, U.S. Geol. Survey Prof. Paper 132–A, p. 3–4 (table), 15, 21–22. Discussion of rock formations in Colorado Plateau of Utah and Arizona. To rocks above Dakota(?) sandstone in Henry Mountains, Gilbert (1877) applied local names (ascending) Tununk shale, Tununk sandstone, Blue Gate shale, Blue Gate sandstone, Masuk shale, and Masuk sandstone. Only Gilbert's names for the sandstones have been adopted by U.S. Geological Survey and in present report his names for the shales are used in quotation marks because of doubt regarding relations of this whole succession of sandstone and shale to named units to north and east. R. C. Moore tentatively correlates "Tununk shale," Tununk sandstone, and "Blue Gate shale" with Mancos shale of southwestern Colorado and east-central Utah; Blue Gate sandstone he tentatively correlates with Mesaverde formation, "Masuk shale" with Lewis shale, and Masuk sandstone with so-called Laramie sandstone of southwestern Colorado. Some geologists, however, believe entire succession corresponds to Mancos shale. Tununk sandstone is yellowish-brown medium- to massive-bedded sandstone. Thickness 50 to 75 feet in section measured across Waterpocket fold near SW cor. T. 32 S., R. 8 E., at Bitter Creek divide, head of Halls Creek.

H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164, p. 108. Discussion of Kaiparowits region, Garfield and Kane Counties, Utah. Measured section, east side of Circle Cliffs, Garfield County, shows Tununk sandstone member of Mancos shale above "Tununk shale" of Gilbert and below "Blue Gate shale" of Gilbert. Thickness 65 feet.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 80. Replaced by Ferron sandstone member of Mancos.

In Tununk Plateau, Henry Mountains region.

**Tununk Shale Member** (of Mancos Shale)

†Tununk Shale (in Mancos Shale)[1]

Upper Cretaceous: Central southern Utah.

Original reference: G. K. Gilbert, 1877, Geology of the Henry Mountains: U.S. Geog. and Geol. Survey of the Rocky Mountain region, p. 4 [2d. ed. 1880].

C. R. Longwell and others, 1923, U.S. Geol. Survey Prof. Paper 132–A, p. 3–4 (table), 15, 21–22. Discussion of rock formations in Colorado Plateau of Utah and Arizona. To rocks above Dakota(?) sandstone in Henry Mountains, Gilbert (1877) applied local names (ascending) Tununk shale, Tununk sandstone, Blue Gate shale, Blue Gate sandstone, Masuk shale, and Masuk sandstone. Only Gilbert's names for the sandstones have been adopted by U.S. Geological Survey, and in present report his names for the shales are used in quotation marks because of doubt regarding the relations of this whole succession of sandstone and shale to named units to north and east. R. C. Moore tentatively correlates "Tununk shale," Tununk sandstone, and "Blue Gate shale" with Mancos shale of southwestern Colorado and east-central Utah; Blue Gate sandstone he tentatively correlates with Mesaverde formation, "Masuk shale" with Lewis shale, and Masuk sandstone with so-called "Laramie sandstone" of southwestern Colorado. Some geologists, however, believe entire succession corresponds to Mancos shale. "Tununk shale" consists of bluish-drab sandy shale grading to fossiliferous sandstone at base. Thickness 975 feet, measured section across Waterpocket fold near SW cor. T. 32 S., R. 8 E., at Bitter Creek divide, head of Halls Creek.

E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, no. 3, p. 437. Discussion of Mancos shale in Wasatch Plateau. Mancos is divided into five members. Lower shale member, unnamed, is equivalent to "Tununk shale" of Gilbert's section in Henry Mountains and to Graneros and Greenhorn formations east of the Rockies. Underlies Ferron sandstone member which is faunal equivalent of Tununk sandstone of Gilbert's section in Henry Mountains.

C. B. Hunt and R. L. Miller, 1946, Utah Geol. Soc. Guidebook 1, p. 8 (table). Generalized section of exposed sedimentary rocks in Henry Mountains structural basin shows Tununk shale member of Mancos shale underlies and grades into Ferron sandstone member; overlies Dakota sandstone. Thickness 550 feet.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 37 (table), 79–80, pl. 1. Basal member of Mancos in Henry Mountains region; underlies Ferron sandstone member; overlies Dakota sandstone. Consists of dark-gray fissile shale containing a few thin beds of bentonite near base and top, and few thin, calcareous and shaly sandstone layers near middle; at top is series of interbedded sandstone and shale beds where member is transitional into overlying Ferron. Thickness 525 to 650 feet. Ferron sandstone of present report is Gilbert's (1877) Tununk sandstone.

Probably named for occurrences on Tununk Plateau, Henry Mountains.

Tununkian series[1]

Upper Cretaceous: Utah.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 43, p. 295.

†Tuolumne Group[1]

Triassic(?) and Jurassic(?): East-central California.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 233–234.

N. L. Taliaferro, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 89. Amador group substituted for preoccupied name Tuolumne.

Named for Tuolumne County, in which group is well exposed.

**Tuolumne Intrusive Series**[1]

Cretaceous: Yosemite National Park.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 121, map.

Includes named units (ascending) Sentinel Granodiorite, Half Dome Quartz Monzonite, Cathedral Peak Granite, and Johnson Granite Porphyry.

Named for exposures along Tuolumne River, Yosemite National Park.

**Tupelo Tongue** (of Coffee Sand)[1]

Upper Cretaceous: Northeastern Mississippi.

Original reference: L. W. Stephenson, 1917, Washington Acad. Sci. Jour., v. 7, p. 243–250.

L. W. Stephenson and W. H. Monroe, 1940, Mississippi Geol. Survey Bull. 40, p. 150–151. Thickness at type exposure 80 feet. Lower 50 feet consists of massive gray more or less calcareous, glauconitic sand with several widely separated ledges of calcareous sandstone; upper 30 feet is massive reddish ferruginous marine sand, grading downward into yellowish-green massive slightly glauconitic sand.

Type locality: Abandoned cut of Fulton Road on westward-facing slope of Old Town Creek Valley, sec. 33, T. 9 S., R. 6 E., 1½ miles east of Tupelo, Lee County.

**Tupper Complex**

Tupper Syenite[1]

Precambrian: Northern New York.

Original reference: H. P. Cushing, 1907, New York State Mus. 60th Ann. Rept., pt. 2, p. 476–482, 515, map.

U.S. Geological Survey has modified the name to Tupper Complex on the basis of a study now in progress.

Exposed about Tupper Lake, Franklin County.

Turkey Creek Beds (in Yegua Formation)[1]

Eocene: Eastern Texas.

Original reference: L. C. Reed and O. M. Longnecker, Jr., 1929, Texas Univ. Bull. 2901, p. 163–174.

Exposed on upper part of Turkey Creek and tributaries; also in North Turkey Creek, Brazos County.

**Turkey Creek Sandstone Member** (of Mineral Wells Formation)[1]

Turkey Creek Sandstone Member (of Keechi Creek Formation)

Middle Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 77–88, charts; 1922, Jour. Geology, v. 30, p. 25, 31.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 87, 88. Reallocated to member status in Keechi Creek formation. Basal member of formation; underlies unnamed limestones; overlies unnamed sandstones and limestone that overlie Dog Bend limestone member of Salesville formation. Name Mineral Wells dropped in this report.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 25, fig. 3, pl. 1. Sandstone forms continuous trace from Parker County line to main east fork of Rock Creek and marks base of Keechi Creek formation. Thin to massive bedded, with faint evidences of crossbedding; no conglomerate observed in Parker County. Thickness 10 to 12 feet. Underlies unnamed shale and sandstone member; overlies unnamed shale member of Salesville formation.

Type locality: On Turkey Road, 2¼ miles northwest of Mineral Wells, Palo Pinto County.

Turkey Mountain Andesite

Quaternary: Northeastern New Mexico.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1033. Rock is gray-green fine-grained porphyritic andesite with ferromagnesian phenocrysts up to 10 mm. long forming 50 percent of rock. Not known whether hornblende andesite is dominant rock or a differentiation fraction.

At head of Slagle Canyon in sec. 16, T. 27 N., R. 25 E., 8 miles northwest of Chico in eastern Colfax County.

Turkey Mountain Flows (of Chico Phonolites)

Quaternary: Northeastern New Mexico.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1036. Gray-green fine-grained porphyritic phonolites with much local variation in size of orthoclase phenocrysts. Top surfaces of flows undulate gently and are covered with thin soil and phonolite joint blocks.

Comprise four flow areas around Turkey Mountain, 9 miles northwest of Temples Peak, Colfax County.

Turkey Mountain Member (of Hoosac Formation)

Cambrian or Lower Ordovician: Eastern Vermont.

J. B. Thompson, Jr., *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., 1952, Geol. Soc. America Guidebook for Field Trips in New England, p. 41. Consists of amygdaloidal greenstone and greenstone schist, metamorphosed locally to epidote-amphibolite. Thickness 0 to 1,000 feet. Overlies Bull Hill member (new). At approximate position of Plymouth member (new) in Chester dome and on east limb of Green Mountain anticlinorium from Jamaica south. Not present at Ludlow.

Type locality and derivation of name not stated.

Turkey Ridge Sandstone Member[1] (of Marcellus Formation)

Middle Devonian: Central Pennsylvania.

Original reference: Bradford Willard, 1935, Geol. Soc. America Bull., v. 46, no. 2, p. 202–203.

H. H. Arndt, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 4, 27. In Juniata, Mifflin, and Perry Counties, the Marcellus is subdivided into three members (ascending): Shamokin shale, Turkey Ridge sandstone, and Mahanoy shale. Thickness 103 feet in East Waterford section if the shaly beds exposed in syncline axis represent Mahanoy member. Northeast along strike, the Turkey Ridge member is persistent for 25 miles to type locality. East and southeast, it is included in base of Montebello formation.

Named for Turkey Ridge which separates Juniata and Perry Counties.

**Turkey Run Limestone Member** (of Pawhuska Formation)

†Turkey Run Limestone Member (of Buck Creek Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: K. C. Heald and K. F. Mather, 1919, U.S. Geol. Survey Bull. 686–M, p. 150, 153.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 49. In northern Osage County, the Pawhuska contains six limestone members (ascending) : Lecompton, Plummer, Deer Creek, Little Hominy, Pearsonia (new), and Turkey Run.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 25, 41–44. In Pawnee County, the Turkey Run is a single bed of dense gray fossiliferous limestone. Thickness 1½ to 3 feet. Overlies Lecompton limestone member; underlies Severy shale of Wabaunsee group.

Named for exposures near head of Turkey Run, in secs. 9, 16, and 17, T. 24 N., R. 8 E., Osage County.

Turkey Track limestone layer (in Richmond Group)[1]

Upper Ordovician: Southwestern Ohio.

Original reference: J. J. Wolford, 1930, Ohio Jour. Sci., v. 30, no. 5, p. 304.

Turlock Lake Formation

Pliocene, upper, and Pleistocene, lower: Central California.

S. N. Davis and F. R. Hall, 1959, Stanford Univ. Pub. Geol. Sci., v. 6, no. 1, p. 12, 13–16, pls. 2, 3. Name applied to oldest post-Mehrten formation in area (eastern Stanislaus and northern Merced Counties). Consists of sand, gravel, and silt. Thickness at type locality 51 feet; however, thickness is not definitely known due to difficulties in picking upper contact in subsurface; probable thickness shown on geologic cross section (pl. 3) ranges from 300 to 850 feet. Conformably overlies Mehrten formation; in some areas contact is sharp but in many places there is a transitional zone of decreasing andesitic material and increasing amounts of quartz, feldspars, and biotite. Crops out east of younger Riverbank formation (new); probably continuous with Laguna formation of Mokelumne area.

Type section: NW¼SE¼, SW¼SE¼, SE¼SW¼, NE¼SW¼ sec. 31, T. 3 S., R. 13 E., Cooperstown quadrangle; section consists of series of exposures on hill in Turlock Lake State Park, eastern Stanislaus County. Crops out in northwest-southeast trending belt of variable width.

Turnbull Conglomerate

Miocene and Pliocene: Southern California.

G. J. Bellemin, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 652 (fig. 1), 655–656. Named as one of five conglomerates interbedded in Miocene and Pliocene shales of Puente Hills, Los Angeles County.

Named for its occurrence on north slope of Turnbull Canyon.

Turner cyclothem (in McLeansboro Group)

Pennsylvanian: Northern Illinois.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 12, 16 (fig. 2). Pennsylvanian succession between Gimlet and La Salle cyclothems, exposed in upper Illinois valley, contains several prominent, but thin limestones which are basis for recognition of incomplete cyclothems to which names (ascending), Turner, Hicks, and Hall, have been applied by H. B. Willman.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. Includes Turner limestone. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 56 (table 3). Replaced by Trivoli cyclothem.

Type locality: NW¼NE¼ sec. 29, T. 33 N., R. 1 W., Putnam County.

Turner Limestone (in McLeansboro Formation)

Turner Limestone (in McLeansboro Group)

Pennsylvanian: Northern Illinois.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 29). Shown on correlation chart as limestone in McLeansboro formation. Occurs below Hicks limestone (new) and above Lonsdale limestone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. Shown on correlation chart as limestone in McLeansboro group. Included in Turner cyclothem. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38, 56 (table 3). Replaced by Cramer limestone member of Modesto formation (both new).

Type locality: NW¼NE¼ sec. 29, T. 33 N., R. 1 W., Putnam County.

**Turner Sandy Member** (of Carlile Shale)[1]

Upper Cretaceous: Northeastern Wyoming, southeastern Montana, and northwestern South Dakota.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2187–2189. Consists of 185 to 260 feet of dark-gray noncalcareous shale with many lighter gray sandy shale partings that contain thin lenses of fine- to very fine-grained sandstone. Underlies Sage Breaks member; overlies unnamed member. Well exposed 6 miles north of Belle Fourche, Butte County, S. Dak.

Named for exposures along Turner Creek in Tps. 46 and 47 N., R. 64 W., Weston County, Wyo.

**Turner Creek Shale Member** (of Topeka Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 42, 52, 53.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 164; G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 21; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Turner Creek shale member of Topeka formation; underlies Du Bois limestone member; overlies Sheldon limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 16 (fig. 5). Largely light- to bluish-gray massive shale that is in part calcareous with some interbedded lime nodules. Thickness 3½ feet, Fremont County; 6.1 feet in Pottawattamie County. Underlies Du Bois limestone member; where Du Bois is absent, underlies Holt shale member; overlies Sheldon limestone member.

Named for exposures on Turner Creek, southeast of Du Bois, Pawnee County, Nebr.

**Turners Falls Sandstone**

Triassic: Central Massachusetts.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Name proposed for thinly bedded shaly red sandstone, locally micaceous. Near Bull Hill at south end of Mount Toby highland, brick-red sandstone and fine conglomerate occur. Thicker parts to north are finer grained, contain ripple marks, dinosaur tracks, and fossil fish. Unconformably underlies Mount Toby conglomerate; overlies Deerfield diabase. Most northern exposures in Mount Toby quadrangle and those in Greenfield quadrangle were mapped as Longmeadow sandstone by Emerson (1898, U.S. Geol. Survey Geol. Atlas, Folio 50) and as Chicopee shale by Emerson (1917, U.S. Geol. Survey Bull. 599). Southern continuations were previously included in Mount Toby conglomerate.

M. E. Willard, 1952, Bedrock geology of the Greenfield quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–20]. Includes gray to black thin-bedded sandy shale and grayish-red sandstone interbedded with sandy limestone in Greenfield quadrangle. Thickness 400 to 600 feet in central part of quadrangle. Continental origin.

Type locality: Vicinity of town of Turners Falls near northern boundary of Greenfield quadrangle. Well exposed along Massachusetts State Highway between Turners Falls and French King Bridge in Millers Falls quadrangle.

Turnley Hornstone[1] or Shale[1]

Precambrian (Belt Series) : Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, map.

Occurs only on slopes above Turnley placer, in southwestern part of Elkhorn mining district, Elkhorn region.

Turpin Sandstone Member (of Grassy Creek Shale)

Upper Devonian: Northeastern Missouri.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 84–85. Name applied to sandstone at base of Grassy Creek shale. Sandstone commonly pale buff that becomes various shades of brown and reddish brown upon weathering. Physical properties vary considerably from place to place. Thickness 1 inch to as much as 15 inches or more. Conodont fauna indicates upper Devonian age comparable to that of the Hardin of Tennessee.

Type locality: At spring near roadside in NW¼SW¼NE¼ sec. 3, T. 52 N., R. 1 E., about 2½ miles northeast of community of Turpin, Pike County.

**Turquoise Granite**

Triassic or Jurassic: Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 65–67, pl. 5. Highly sericitic, silicified granite. Extremely altered. Poorly exposed; hence, its relations to adjacent formations can only locally be unequivocally determined. Exposures north and south of Brown's Peak clearly indicate that it intrudes Bolsa quartzite and Pinal schist. Boundaries with Gleeson quartz monzonite and Copper Belle monzonite porphyry (both new) are faults, and none of these three rocks show facies changes that are noticeably related to the contacts. Known to be of post-Cambrian age and is probably post-Paleozoic, but is older than period of thrust faulting that has affected region, as shown not only by the faults referred to but also by flat fault contact beneath block of Escabrosa limestone resting on it on south wall of Arroyo that divides Brown's Peak from Gleeson Hill. Relations with Sugarloaf quartz latite (new) uncertain, owing to intense sericitization that both rocks have undergone along their mutual contacts. Assigned to early Mesozoic.

Named for Turquoise Ridge, west of Courtland, in secs. 17, 20, and 23, T. 19 S., R. 25 E., on west slope of which it is widely exposed, central Cochise County.

Turtleback Complex[1]

Pre-Devonian-Late Mesozoic(?) : Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington Univ. Pub. in Geology, v. 2, p. 142–154.

W. R. Danner, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 2056. Turtleback complex, described as a variety of intrusive rocks, offshoots of a late Jurassic batholith located on Vancouver Island, is now known to include many areas of an amphibolite gneiss complex intruded by diorite rocks of pre-Devonian. Granitic rocks thought to be early Mesozoic or later age also present. In addition are volcanic and sedimentary rocks of Devonian, early Permian, and middle and late Permian age.

Well exposed on Turtleback Mountain, San Juan Islands.

Tusas Granite

Precambrian (Proterozoic) : Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 44–46, pl. 3. Varies greatly in composition and texture. In general, composed of medium-sized grains and is nonporphyritic. With exception of large dike north of Kiawa Mountains, granite south of Tusas Mountain is pink and noticeably lacking in ferromagnesian minerals. In dike and north of Tusas Mountain, rock is gray, contains a good deal of biotite, and varies from monzonite to quartz monzonite in composition. Probably intruded during Pueblo revolution. Intrudes all older Proterozoic rocks in area which are considerably altered.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 59. Replaced by Maquinita granodiorite and Tres Piedras granite.

Part of large intrusive mass that is irregularly exposed along east side of Petaca area from Jawbone Mountain to Servilleta Plaza and in scattered inliers near Tres Piedras. Also outcrops at Ojo Caliente Mountain and in some of adjacent hills. In dike between Tusas and Kiawa Mountains, Rio Arriba County.

Tusayan series[1]

Carbonic: Northern Arizona.

Original reference: Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart).

In Grand Canyon region.

†Tuscahoma Marl[1]

Eocene, lower: Southwestern Alabama.

Original reference: E. A. Smith and L. C. Johnson, 1887, U.S. Geol. Survey Bull. 43, p. 50.

Named for exposures at Tuscahoma, on Tombigbee River, in Choctaw County.

**Tuscahoma Sand**[1] **or Formation** (in Wilcox Group)

Eocene, lower: Southern Alabama, Georgia, and eastern Mississippi.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–88, geographic map of Alabama.

L. D. Toulmin, Jr., 1944, Southeastern Geol. Soc. [Guidebook] 1st Field Trip, p. 9. Extends entirely across state of Alabama and consists of about 200 feet of unfossiliferous crossbedded sand and stratified sandy clay. In central and western Alabama, contains two fossiliferous marl beds, Greggs Landing marl and Bells Landing marl. Formation is here considered to include all the strata up to the base of the Bashi marl; it is thus extended to include the 3-foot lignite bed and overlying crossbedded sand and sandy clay strata, about 70 feet thick, that have been included heretofore in Bashi formation. Overlies Nanafalia formation.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart of outcropping Tertiary formations of eastern Gulf region shows Tuscahoma sand present in Georgia.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 166–177, pls. 1, 5. Tuscahoma sand described in Kemper County, Miss., where it is as much as 300 feet thick. Overlies Nanafalia formation; underlies Bashi marl member of Hatchetigbee formation. Wilcox group.

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 22, 124–141. Tuscahoma sand described in Wilcox County, Ala., where it includes all strata from top of Nanafalia formation to base of Bashi member of Hatchetigbee formation. Includes Greggs Landing marl member below and Bells Landing marl member above. Thickness about 275 feet.

Named for exposures at Tuscahoma, on Tombigbee River, in Choctaw County, Ala.

**Tuscaloosa Formation,**[1] **Gravel,** or **Group**

Upper Cretaceous: Coastal Plain from western Tennessee, northeastern Mississippi, and northwestern Alabama, across Alabama, Georgia, South Carolina, and North Carolina.

Original reference: E. A. Smith and L. C. Johnson, 1887, U.S. Geol. Survey Bull. 43, p. 18, 95–117, 136–138, pl. 11.

C. W. Cooke, 1936, U.S. Geol. Survey Bull. 867, p. 17–25. Formation is thought to include all strata of Upper Cretaceous age exposed at surface in South Carolina below Black Creek formation, but it is possible that beds older than the Tuscaloosa may some day be differentiated from these deposits in North Carolina and South Carolina. Term Tuscaloosa is herein substituted for name Middendorf formation as used by Cooke (1926, U.S. Geol. Survey Prof. Paper 140–E). Sand and gravel like those of Tuscaloosa formation and doubtless of same age make up at least the greater part of Cape Fear formation of North Carolina, which is now designated "Tuscaloosa," although it is possible that beds older than typical Tuscaloosa may be included in it. In South Carolina, the Tuscaloosa rests directly on crystalline rocks of the Piedmont without interposition of older Cretaceous deposits. Time interval represented by this unconformity includes all of Triassic, Jurassic, and Lower Cretaceous time, probably much of Paleozoic time, and perhaps early part of Upper Cretaceous.

Tom McGlothlin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 1, p. 40–43. Series of beds now called "Tuscaloosa formation" can be subdivided into two formations. In this report [Mississippi] these beds are referred to as lower Tuscaloosa and upper Tuscaloosa. There appears to be major unconformity between the two, with lower wedging out updip and being overlapped by upper. It would probably be logical to restrict term "Tuscaloosa" to those beds that are here assigned to upper Tuscaloosa, and give new name to lower beds, but name is not proposed in this report.

L. C. Conant and W. H. Monroe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 37; W. H. Monroe, L. C. Conant, and D. H. Eargle, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 187–212. Rank raised to group to include (ascending) Cottondale, Eoline, Coker, and Gordo formations (all new). Overlies undifferentiated Paleozoic rocks; underlies McShan formation.

W. E. Belt, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Formation, undifferentiated, mapped in Mississippi.

Erling Dorf, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 11, p. 2161–2184. An analysis of Cretaceous stratigraphy and paleobotany of Atlantic Coastal Plain. In South Carolina, plant-bearing beds of upper part of Cooke's (1936) Tuscaloosa formation are reassigned to Middendorf member of Black Creek formation, and are shown to be equivalent in age to lower Black Creek formation of North Carolina. Name "Tuscaloosa" is abandoned for beds in both North and South Carolina which are here referred to "Lower Cretaceous? (undifferentiated)".

C. W. Drennen, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 3, p. 522–538. Group contains only two units of formational rank—lower unit, Coker formation, which is redefined to include all beds of pre-Gordo Tuscaloosa age, and upper unit, Gordo formation. Name Cottondale abandoned; Eoline reduced in rank to member of Coker formation.

D. H. Eargle, 1955, U.S. Geol. Survey Bull. 1014, p. 8–23, pls. 1, 2. Formation described in report on outcropping Cretaceous rocks of Georgia. Consists generally of coarse to gravelly and arkosic sand, and of subordinate beds of mottled clay and silt. Average thickness 250 feet. Overlies crystalline rocks; underlies Eutaw formation. Formation crops out in gradually narrowing east-northeastward-trending belt from Chattahoochee River near Columbus to Ocmulgee River near Macon; belt is about 11 miles wide in Chattahoochee River valley, 6 miles wide in Flint River valley, and 5 miles wide at Ocmulgee River.

R. G. Stearns, 1957, Geol. Soc. America Bull., v. 68, no. 9, p. 1077, 1093 (fig. 13). Subsurface data show that in northern Mississippi Embayment Cretaceous, Paleocene, and lower Eocene deposition occurred in single sedimentary cycle. Cycle began with Cretaceous deposition of nonmarine Tuscaloosa gravel, restricted in area.

G. E. Siple, 1957, Carolina Geol. Soc. Guidebook for the South Carolina Coastal Plain Field Trip Nov. 16–17, p. 3–5, geol. map. Formation in South Carolina consists typically of light-gray, white, or buff arkosic sand gravel interbedded with white, pink, brown, or purple clay. Formation broken by many local unconformities. Thickness 0 to 800 feet. Crops out in belt gradually widening from 10 to 40 miles, extending in northeasterly direction from Aiken County to Marlboro County. Map shows Tuscaloosa underlies Black Creek formation.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 43–44; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Described and mapped in North Carolina where it is oldest recognized formation exposed at surface in Coastal Plain. Underlies Black Creek formation; in some areas, covered by younger sediments of unknown age. Main outcrop lies along western part of Coastal Plain and extends southwest from Neuse River.

Named for Tuscaloosa, Tuscaloosa County, Ala., and Tuscaloosa (Black Warrior) River at Steele's Bluff and White's Bluff, Hale County, Ala.

**Tuscan Formation**

Tuscan Tuff[1]

Pliocene: Northern California.

Original reference: J. S. Diller, 1895, U.S. Geol. Survey Geol. Atlas, Folio 15.

C. A. Anderson and R. D. Russell, 1939, California Jour. Mines and Geology, v. 35, no. 3, p. 231–232, pl. 3. Formation consists of series of volcanic breccias, tuffs, volcanic gravels and sands, and tuffaceous clays. Maximum thickness about 1,000 feet. Greatest thickness occurs along eastern edge of formation, where only breccias are found. Thins in direction of Sacramento Valley, where gravels, sands, silts and clays are interbedded with the breccias. Contemporaneous with and interfingers with Tehama formation in their zone of junction. Nomlaki tuff member interbedded in both formations.

R. C. Treasher, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1257. In Tehama and Tuscan Buttes quadrangles, subdivided into five members (ascending): Supan tuff and sand, Bald Hill agglomerate, Seven-Mile tuff and sand, Iron Canyon agglomerate, and Sacramento tuff and sand.

Named for exposures at or near Tuscan Springs, Lassen Peak quadrangle.

**Tuscarora Sandstone[1] or Quartzite[1]**

Tuscarora Formation

Lower Silurian: Central southern and eastern Pennsylvania, western Maryland, western Virginia, and eastern West Virginia.

Original reference: N. H. Darton, 1896, U.S. Geol. Survey Geol. Atlas, Folio 28.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Tuscarora (Clinch) sandstone in Albion series. Underlies Clinton group. Underlies Castanea sandstone in northern Pennsylvania.

F. M. Swartz, 1948, Pennsylvania Geologists Guidebook 14th Ann. Field Conf., supp., diagram (following p. 4), fig. 3. In Lewiston region, Pennsylvania, overlies Run Gap sandstone (new).

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 6, pl. 1. In central Pennsylvania, Tuscarora formation (the White Medina of Pennsylvania Second Geologic Survey) is gradational with overlying Rose Hill formation and transitional with underlying Juniata formation. Thickness 350 to 750 feet.

Named for Tuscarora Mountain which extends along border line of Juniata and Perry Counties, Pa.

**Tuscher Formation**[1] (in Mesaverde Group)

Tuscher Formation (in Wasatch Group)

Upper Cretaceous: Central eastern Utah.

Original reference: D. J. Fisher, 1936, U.S. Geol. Survey Bull. 852.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 140, 142. Measured section of post-Castlegate rocks on Green River between Desolation Canyon and Range Creek, Utah, shows Tuscher(?) formation, 215 feet thick, disconformable above Price River formation and below North Horn formation. This unit is almost certainly Tuscher formation of Fisher's (1936) section in eastern Book Cliffs. The place of the Tuscher in Price River-North Horn succession of the western Book Cliffs, however, is not settled. Stratigraphic evidence on Green River, as well as that observed by Fisher in the Book Cliffs, suggests alliance of the Tuscher with the overlying rather than the underlying strata. Present conclusion is that the Tuscher is a coarse basal phase of North Horn formation. This still leaves question concerning relationships to west. Along Green River, the Tuscher is disconformable on underlying Price River formation and contrastively different, whereas in western part of Book Cliffs there is no apparent break between the Price River and North Horn formations. Throughout eastern Book Cliffs, base of Tuscher marks first strong change in Cretaceous section above Mancos shale, and it would seem to signify break of regional importance.

M. D. Williams, 1950, Utah Geol. Soc. Guidebook 5, p. 104, 105. Assigned to Wasatch group (redefined).

J. D. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 11 (table), 18–19, 60, 62–63. Little direct evidence of age of Tuscher is available; since it seems to be essentially equivalent to Hunter Canyon formation and appears to be older than undifferentiated North Horn and Flagstaff formations, it is here assigned to Mesaverde group and arbitrarily considered of Late Cretaceous age. Overlies Farrer formation. Thickness on Green River 215 feet; east of Green River 267 to 600 feet.

Named after canyon in T. 20 S., R. 17 E., Grand County. Makes continuous unit in Book Cliffs of Utah east of Green River.

**Tuscumbia Limestone**[1]

Upper Mississippian: Northern Alabama.

Original reference: E. A. Smith, 1894, Alabama Geol. Survey Geol. map of Alabama.

P. E. LaMoreaux, G. W. Swindel, Jr., and C. R. Lanphere, 1950, Alabama Geol. Survey Bull. 62, p. 24 (table 1), 26–27. Limestone units of Warsaw and St. Louis age are herein considered as a unit, for which name Tuscumbia limestone is applied. Thickness about 200 feet. Overlies Fort Payne chert; underlies Ste. Genevieve limestone.

G. W. Stose, 1952, Washington Acad. Sci. Jour., v. 42, no. 8, In Murphree Valley anticline, underlies Bangor limestone and overlies Fort Payne chert. Contains many lentils and thick beds of sandstone.

G. T. Malmberg and H. T. Downing, 1957, Alabama Geol. Survey County Rept. 3, p. 40–43. Described in Madison County where it is composed of about 150 to 200 feet of thin- to thick-bedded, gray, fine to coarsely crystalline, highly fossiliferous limestone with small amounts of gray to white chert occurring as irregular lenses and nodules. Includes rocks between Fort Payne chert and Ste. Genevieve limestone and is equivalent to St. Louis and Warsaw limestones of Mississippi Valley region.

Named for exposures at Tuscumbia, Colbert County.

Tushar Conglomerate

Cretaceous(?): Southwestern Utah.

R. R. Kennedy, 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 4, p. 26, 27, geol. map. Limestone conglomerate, light to dark gray, pebble-size to smaller, well cemented. Thickness 65 feet. Overlies Winsor formation, marked unconformity. Unconformable below Sevier River formation.

Measured section is in eastern Tushar Range, on north side of Tenmile Creek, sec. 36, T. 28 S., R. 4 W., 7 miles southwest of Marysvale, Piute County.

Tuskahoma Siliceous Shale Member (of Stanley Shale)

Tuskahoma Siliceous Shale Member (of Tenmile Creek Formation)

Mississippian: Southeastern Oklahoma.

August Goldstein, Jr., and T. A. Hendricks, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 431. Stanley shale is divided into four siliceous shale members (ascending): Basal Ten Mile Creek, Tuskahoma siliceous shale, Middle Ten Mile Creek, and Moyers. The Tuskahoma is typically carbonaceous and pyritiferous. With exception of the Tuskahoma, the names used in describing these beds are those originated by Harlton (1938), but they have been restricted to apply to the siliceous shale beds in instances where Harlton applied the name to the siliceous shale and the overlying sandstone and shale beds.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 25 (table 2), 30. Reallocated to member status in Tenmile Creek formation.

Type locality: Center of west side of sec. 22, T. 2 N., R. 20 E., Pushmataha County, approximately 4½ miles east of Tuskahoma on U.S. Highway 271. Crops out near Potato Hills.

Tusonimo Limestone (in Pàcheta Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12. Gray weak arenaceous limestone, in places pinkish and earthy. Thickness 8 feet. Underlies Cienda limestone (new); overlies unnamed sandstone.

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

**Tusquitee Quartzite[1]**

Lower Cambrian: Western North Carolina, central northern Georgia, and eastern Tennessee.

Original reference: A. Keith, 1907, U.S. Geol. Survey Geol. Atlas, Folio 143, p. 4.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60 no. 2, p. 284–285. In Murphy syncline, Keith (1907) and La Forge and Phalen (1913, U.S. Geol. Survey Geol. Atlas, Folio 187) mapped a white quartzite—the Tusquitee—which overlies Nantahala slate and underlies Brasstown schist and Valleytown formation. At most places, Keith mapped the quartzite in two parallel lenticular bands with anticlines of Nantahala slate between. These white quartzites are herein correlated with Big Butt quartzite, and the intervening slaty beds are regarded not as Nantahala slate but as part of the Big Butt quartzite equivalent to the fine-grained arkosic quartzite and argillite that separate the two quartzite beds of the Big Butt on Bald Mountain.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27. Included in Talladega series believed to be Precambrian. Thickness 500 to 600 feet in Georgia.

Named for exposures in Tusquitee Mountains, Clay County, N.C.

Tusseyville Limestone

[Ordovician]: Central Pennsylvania.

R. R. Conlin and others, 1957, Geol. Soc. America Guidebook Ann. Mtg., Field Trips, p. [279] (pl. 3). Incidental mention in structure section. Underlies Bellefonte dolomite; overlies Salona limestone.

In section from Tyrone Gap to Birmingham.

Tuttle Sandstone Member (of Manning Formation)

Eocene (Jackson): East-central Texas.

W. L. Russell, 1955, Gulf Coast Assoc. Geol. Soc. Trans., v. 5, p. 166–171. Name applied to sandstone, 5 to 50 feet thick, in Manning formation about 75 feet above Goodbread sandstone [member] (new). Separated from overlying Yuma sandstone member by shaly zone 30 to 60 feet thick. Renick (1936, Texas Univ. Bull. 3619) called unit Dilworth on assumption that it was equivalent to Dilworth sandstone of Gonzales County.

Type locality: In abandoned Southern Pacific right-of-way 1½ miles north of Piedmont, Grimes County.

Tutu Formation (in Virgin Island Group)

Upper Cretaceous: Virgin Islands.

T. W. Donnelly, 1960, Dissert. Abs., v. 20, no. 7, p. 2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. Relatively coarse volcanic wacke, composed almost entirely of unweathered Louisenhoj debris, with minor admixed limestone debris. Includes Coki Point megabreccia lithofacies (new). Congo Cay limestone member (new) present near top. Exposed thickness 6,000 feet. Overlies Outer Brass formation (new). May be older than or equivalent to Hans Lollik formation (new). Virgin Island group considered of Cenomanian age.

Report discusses geology of St. Thomas and St. John Islands.

**Tuxedni Group**

Tuxedni Sandstone[1] or Formation

Middle and Upper Jurassic: Central southern Alaska.

Original reference: G. C. Martin and F. J. Katz, 1912, U.S. Geol. Survey Bull. 485, p. 59, map, chart facing p. 30.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1), 207, 209. Formation comprises (ascending) sandy shale with numerous stringers of shaly sandstone, 1,250 feet thick; Cynthia Falls member (new), 800 feet; sandy shale with stringers of shaly sandstone, 950 feet; and Tonnie sandstone member (new), 1,200 feet. Total thickness 4,000 feet. Overlies Kialagvik formation. Underlies Chinitna shale member of Shelikof formation on Iniskin-Chinitna Peninsula.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Formation includes (ascending) lower siltstone member, Cynthia Falls sandstone member, Bowser member (new), and Tonnie siltstone member. Underlies Chinitna siltstone. Middle and Upper Jurassic.

R. W. Imlay, 1953, U.S. Geol. Survey Prof. Paper 249–B, p. 49, 51, table 5 facing p. 60. In most places, siltstones assigned to Tonnie member cannot be separated from overlying siltstones of Chinitna formation. Therefore, Tonnie reassigned to Chinitna. Age of formation given as Middle Jurassic.

U.S. Geological Survey currently classifies the Tuxedni as a group on the basis of work now in progress.

Type section: On south shore of Tuxedni Bay, Cook Inlet region.

Twelvemile Beds[1]

Tertiary: Southwestern Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3.

Exposed at junction of Twelvemile Creek and Mission Creek, Yukon gold district.

**Twelvemile Canyon Member** (of Arapien Shale)

Upper Jurassic: Central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 125. Shale, gray in lower part, with prominent red blotches in main part, deep-red and salt-bearing member in upper 500 feet; beds of sandstone and gypsum in middle. Thickness about 7,000 feet. Basal member of Arapien; underlies Twist Gulch member (new). Base of Arapien not located in entire region south of Wasatch Mountains.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., no. 8, p. 10–15. Term Arapien shale restricted to Twelvemile Canyon member, and term Twist Gulch member raised to formational rank. Change credited to Hardy and Spieker (in preparation).

Named for outcrops in Twelvemile Creek west of Arapien Valley, Sanpete County.

**Twentymile Sandstone Member** (of William Fork Formation)[1]

Twentymile Sandstone[1] (in Mesaverde Group)

Upper Cretaceous: Northwestern Colorado.

Original reference: N. M. Fenneman and H. S. Gale, 1906, U.S. Geol. Survey Bull. 297, p. 27.

N. W. Bass, J. B. Eby, and M. R. Campbell, 1955, U.S. Geol. Survey Bull. 1027–D, p. 158, pl. 19. Member is commonly massive white ledge-forming sandstone about 100 to 200 feet thick. Occurs above lower unnamed member, about 1,000 feet thick, consisting of shale, sandstone, and coal beds and below upper unnamed member, about 200 feet thick, consisting of sandstone, sandy shale, shale, and coal.

Named for Twentymile Park, about 10 miles northwest of Yampa, Routt County.

**Twiggs Clay Member** (of Barnwell Formation)[1]

Eocene, upper: Eastern Georgia.

Original references: C. W. Cooke and H. K. Shearer, 1917, Georgia Geol. Survey Bull. 31, p. 14, 158–173; 1918, U.S. Geol. Survey Prof. Paper 120–C, p. 51–56.

P. E. LaMoreaux, 1946, Georgia Geol. Survey Bull. 50, pt. 1, p. 11–17. In northern Washington and southern Jones, Baldwin, and Hancock Counties, consists of about 25 feet of pale-green hackly fuller's earth clay; to south and southwest in western Washington and Wilkinson Counties, thickens gradually and locally includes 20 to 40 feet of green hackly clay which grades down into 10 feet of gray marl, which in turn grades at some localities into 15 feet of calcareous sand at base of member. Near type locality, attains maximum thickness of 80 feet. In western and northern part of Twiggs County, interfingers with Ocala limestone (Tivola tongue). Conformably underlies Irwinton sand member (new). Type locality stated.

J. F. L. Connell, 1958, Southwestern Louisiana Jour., v. 2, no. 4, p. 321, 325, 328. Basal part of Barnwell. Conformably underlies Irwinton sand member.

Type locality: At Pikes Peak Station on Macon, Dublin, and Savannah Railroad, Twiggs County.

**Twilight Granite**[1]

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 131.

F. H. T. Rhodes and J. H. Fisher, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 11, p. 2514, 2518. Granite in most areas of its occurrence is light in color and intrudes schist; in localities where it underlies Ignacio quartzite, it is dark colored and contains abundant biotite which is oriented to give distinct foliation. Most contacts with Ignacio unconformable.

Composes Twilight Peak in Needle Mountains quadrangle.

Twilight Park Conglomerate

Upper Devonian: New York.

C. S. Prosser, 1899, New York State Geologist 17th Ann. Rept., p. 283–284. Incidental mention.

G. H. Chadwick, 1940, New York State Geol. Assoc. 16th Ann. Mtg. Field Guide Leaflets, p. 2. In list of formations in Catskill region below Onteora redbeds and above Kaaterskill sandstone. Cobbly puddingstone 40 feet thick.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 126, 130. Conglomerates at base of Onteora redbeds are Twilight Peak conglomerate of Prosser 1899.

Exposed in Twilight Park, one-half mile southeast of Haines' corners, Greene County.

Twin Bridges Limestone

[Eocene(?)] to Miocene: Central southern Idaho and northeastern Nevada.

F. B. Van Houten, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2816 (fig. 6). Name appears only on stratigraphic chart.

Twin Buttes Member (of Bridger Formation)[1]

Eocene: Southwestern Wyoming.

Original reference: H. E. Wood 2d, 1934, Am. Mus. Nat. History Bull., v. 67, art. 5, p. 241–242.

H. E. Wood 2d, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 34, pl. 1. Bridgerian. Overlies Blacks Fork member.

Type locality: Henrys Fork Table and Twin Buttes. Name is taken from Twin Buttes, west of Green River and east of Henrys Fork Table, Sweetwater County.

**Twin Creek Limestone[1] or Formation**

Middle and Upper Jurassic: Southwestern Wyoming, southeastern Idaho, and northeastern Utah.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56, p. 56, chart opposite p. 50, map.

R. W. Imlay, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 1020 (table 1), 1021, 1022. On basis of ammonite studies Twin Creek limestone, in Freedom quadrangle, southeastern Idaho, is assigned to Middle and Upper Jurassic.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, pt. 1, p. 1275–1277. In western Uinta Range, Twin Creek limestone overlies Nugget sandstone and underlies Preuss redbeds. Along Weber River, consists of 1,351 feet of light-gray limestone, sandy limestone, and calcareous shale. Thins eastward and in Lake Fork and Whiterocks Canyon area is replaced by Carmel redbeds.

Helen Foster, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1565–1566. In Teton County, Wyo., limestone is about 475 feet thick; overlies Nugget sandstone and underlies Stump formation; the Preuss, which overlies Twin Creek farther west, not recognized in this area.

R. W. Imlay, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 37–45. Described in mountains along west side of Green River basin. Overlies Nugget and underlies Preuss. Mainly medium-light-gray limestone with two persistent red members in its lower third. Comprises seven mappable members (A–G); member A is equivalent to Gypsum Spring formation (Love and others, 1945) and could properly be called Gypsum Spring member of Twin Creek. Thickens westward from about 800 to 3,000 feet. Term Twin Creek limestone should not be extended east of Darby-Absaroka line of thrusting because equivalent beds east of faulted area, such as exposed at Lower Slide Lake on Gros Ventre River, are much thinner, much less calcareous, and much more fossiliferous than the Twin Creek, and may more properly be classified according to terminology used in southern Montana or central Wyoming. This restriction does not apply to Nugget or Stump sandstones.

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 579 (fig. 2), 597–598. Described in Strawberry Valley quadrangle, Utah. Equivalent in part to Carmel limestone, and name Carmel has been applied to it by some geologists. Thickness along West Fork of Duchesne River 950 feet. Overlies Navajo; underlies Entrada. Middle and Upper Jurassic.

R. W. Imlay, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 54–62. Report includes summary of lithologic and stratigraphic characteristics of the seven members of the Twin Creek, descriptions of some typical sections in western Wyoming and southeastern Idaho, and three lines of columnar sections.

E. R. Cressman, 1957, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–118. As mapped in Snowdrift Mountain quadrangle, Caribou County, Idaho, consists of seven unnamed members with aggregate thickness of 2,510 feet. Overlies Nugget sandstone and underlies Preuss sandstone.

Named for exposures on Twin Creek between Sage and Fossil, Lincoln County, Wyo.

Twin Lakes Andesites[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 223–230, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 686. Cenozoic.

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, p. 77 (table 2). Listed on table.

Twin Lakes are in Lassen Volcanic National Park.

Twin Lakes Formation

Pleistocene (Iowan-Tazewell) : Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene, Rocky Mountain Sec., 2d Ann. Field Trip, Oct. 4–5, correlation chart, geol. map. Consists of lower and upper member. Underlies Lake Creek formation (new).

Twin Lakes region, Lake County.

Twin Lakes Glacial Substage

Pleistocene (Wisconsin) : Southern Rocky Mountains.

L. L. Ray, 1939, (abs.), Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 2007; 1940, Geol. Soc. America Bull., v. 12, pt. 1, p. 1857–1858. Earliest of five substages of Wisconsin glaciation in southern Rocky Mountains. Followed by Home substage. Terminal moraines rare; evidence of ice advance based on patches of weathered till on valley walls above till of second substage.

Named for moraine at Twin Lakes in upper Arkansas Valley.

Twin Lakes Quartz Monzonite Porphyry[1]

Tertiary: Central Colorado.

Original reference: J. V. Howell, 1919, Colorado Geol. Survey Bull. 17.

Occurs on both sides of valley of Lake Creek below Everett and in vicinity of Twin Lakes, Lake County.

Twin Mountain Basalt

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 132, pl. 15. Mentioned in discussion of Capulin basalts in Des Moines quadrangle. [Most of discussion refers to flows and basalts from Twin Mountain.]

Twin Mountains is elongate center cone that lies 3 miles southeast of Folsom, Union County.

**Twin River Formation**[1]

Eocene, upper, to Oligocene, upper: Northwestern Washington.

Original reference: R. Arnold and H. Hannibal, 1913, Am. Philos. Soc. Proc., v. 52, p. 579, 584, 604.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 117. Stratigraphic position of beds at Twin Rivers in upper part of Clallam County section of Oligocene and prevailing character of its molluscan fauna permit approximate correlation with Blakeley formation and elimination of newer term, Twin River formation.

J. W. Durham, 1944, California Univ. Dept. Geol. Sci. Bull., v. 27, no. 5, p. 113. Faunal studies indicate upper part of Twin River formation is younger than fossiliferous type Blakeley formation.

R. D. Brown, Jr., and H. D. Gower, 1948, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2492–2512. Redefined to include mappable sequence of predominantly argillaceous sedimentary rocks exposed in northern Olympic Peninsula. Three mappable sequences recognized: lower member consisting of thin-bedded sandstone and siltstone, middle member of massive siltstone that grades westward into bedded siltstone and sandstone, and upper member composed chiefly of massive mudstone. Lenses of conglomerate present in places. Maximum thickness 17,500 feet, south limb of Clallam syncline. Overlies Lyre formation; underlies Clallam formation as used by Weaver. Mollusks and Foraminifera indicate an age range of late Eocene to early Miocene. Redefinition of Twin River, rather than Blakeley, is preferred because Blakeley has been used as lithologic term as well as faunal stage and has become so well entrenched in literature that any change in its stratigraphic and biostratigraphic connotation seems inadvisable. Some of rocks here included in Twin River have been described by Weaver (1937) as Lyre formation and Lincoln formation. Type locality, type section, and reference sections of redefined formation designated.

Type locality (Brown and Gower): Along Deep Creek, a north-flowing stream which enters Strait of Juan de Fuca at point about 3.4 miles west of mouth of West Twin River. Type section in Deep Creek is exposed from point 3,600 feet S. 41° W., from U.S. Forest Service road bridge across Deep Creek, northward to point on axis of local east-trending syncline, 700 feet east, 4,350 feet north of SW cor. sec. 20, T. 31 N., R. 10 W., Clallam County. Reference section: In stream bed and canyon of Lyre River, about 10 miles east of type locality on Deep Creek. In Lyre River, formation is exposed from point 950 feet south, 3,690 feet west of NE cor. sec. 10, T. 30 N., R. 9 W., to point 400 feet north, 1,050 feet west of SE cor. sec. 28, T. 31 N., R. 9 W.

Twin Sisters Dunite

Tertiary: Northwestern Washington.

Peter Misch, 1952, The Mountaineer, v. 45, no. 13, p. 4 (geol. map). An ultrabasic intrusive.

Twin Sisters Mountain is in Whatcom County.

Twisselmann Sandstone Member (of Monterey Formation)

Miocene, middle and upper: Southern California.

H. H. Heikkila and G. M. MacLeod, 1951, California Div. Mines Spec. Rept. 6, p. 4 (table 1), 5 (table 2), 11, 12–13, pl. 1. Name proposed for large sandstone lens occupying stratigraphic position equivalent in part to lower McDonald shale member and upper Gould-Devilwater shale member. Consists of friable silty to medium-grained sandstone, generally gray but locally rust mottled to tan; includes two shale beds in upper half and bioclastic reef 30- to 50-feet thick at base. In type area, has maximum thickness of 2,200 feet, conformably underlies McDonald shale member and unconformably overlies undifferentiated Cretaceous deposits; basal contact is marked locally by discontinuous massive bioclastic reef.

Type locality: Vicinity of C. Twisselman's deserted ranch building in NW cor. NE¼ sec. 14, T. 27 S., R. 18 E., Kern County.

**Twist Gulch Member** (of Arapien Shale)

Twist Gulch Formation

Upper Jurassic: Central Utah.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 124, 125. Upper member of Arapien. Overlies Twelvemile Canyon member (new); underlies Morrison(?) formation. Siltstone and shale, red, in thin-bedded succession, with many thin beds of green-gray to white siltstone. Thickness 3,000 feet.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., no. 8, p. 10–15. Rank raised to formation.

Named for exposures on north side Salina Canyon above Twist Gulch, Sevier County.

Twobar Shale Member (of San Lorenzo Formation)

Eocene (Narizian): Western California.

E. E. Brabb, 1960, Dissert. Abs., v. 21, no. 5, p. 1163. Named as lower member of formation. Underlies Rices mudstone member (new).

Type section: Along Kings Creek, Big Basin area, Santa Cruz Mountains. Derivation of name not stated.

**Two Creeks Interstade**

Twocreekan Substage

Two Creeks Forest Bed

Two Creeks Intraglacial Substage

Pleistocene (Wisconsin): Eastern Wisconsin.

J. W. Goldthwait, 1907, Wisconsin Geol. Nat. History Survey Bull. 17, p. 61–62. Two Creeks forest bed may record an interval between early and late Wisconsin time; or it may mark interval between Calumet stage and readvance of ice sheet to Manistee moraine.

L. R. Wilson, 1932, Wisconsin Acad. Sci., Arts, and Letters, Trans., v. 27, p. 31–46. Bed is several inches thick and approximately 100 feet long. Lies between varved clays deposited during retreat of middle Wisconsin or "gray ice" and till of late Wisconsin or "red ice".

F. T. Thwaites, 1946, Outline of glacial geology: Ann Arbor, Mich., Edwards Bros., Inc., p. 75, 86. Referred to as Two Creeks interstadial between Valders glaciation and Cary glaciation.

R. V. Ruhe, Meyer Rubin, and W. H. Scholtes, 1957, Am. Jour. Sci., v. 255, no. 10, p. 671–689. New radiocarbon dates in Iowa permit grouping of age values and raise new problems in stratigraphic correlation of late Pleistocene deposits in Iowa and adjacent regions. Older group of ages greater than 29,000 years dates Iowan substage and pre-Iowan deposits.

Old group of ages of 22,900 to 25,100 years dates Farmdale substage. Intermediate group of ages ranges 14,000 to 17,000 years. Parts of Des Moines lobe previously classified as Mankato are dated at 11,600 and 11,800 years, and antedate Two Creeks interstadial dated at 11,400 years B. P.

R. J. Mason, 1958, Michigan Univ. Mus. Anthropology, Anthropol. Paper 11, p. 23. Two Creeks interstadial represents period between end of Mankato retreat and next and last glacial advance. Probably began about 12,000 years ago and lasted until about 11,000 B. P.; radiocarbon age determination.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 2 (fig. 1), 8–9. In classification proposed herein, Twocreekan is substage next younger than Woodfordian substage (new) and older than Valderan substage. It is based on Two Creeks forest bed of Wisconsin (Thwaites and Bertrand, 1957) and contains time of very short-lived retreat of glacier ice in Lake Michigan lobe. Has time span of no more than 1,500 radiocarbon years.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529–552. Presentation of classification of Wisconsin glacial stage of north-central United States. Two Creeks intraglacial substage separates older Mankato glacial substage from younger Valders glacial substage.

Exposed on shore of Lake Michigan, 2 miles east of Two Creeks, in secs. 11 and 13, T. 21 N., R. 25 E., Manitowoc County.

**Two Medicine Formation** (in Montana Group)[1]

Upper Cretaceous: Northwestern Montana.

Original reference: E. Stebinger, 1914, U.S. Geol. Survey Prof. Paper 90, p. 62–68.

J. B. Lyons, 1944, Geol. Soc. America Bull., v. 55, no. 4, p. 449 (fig. 2), 451–452. Formation, in northern end of Big Belt Mountains, is 1,000 feet thick; overlies Eagle sandstone and unconformably underlies Adel Mountain volcanics (new). Upper Cretaceous.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 115–116. Underlies Bearpaw shale; overlies Virgelle sandstone. Crops out on west flank of Sweetgrass arch. Thickness north of Dupuyer 2,125 feet. Almost entirely nonmarine and is largely mudstone that weathers pale greenish gray or gray.

G. W. Viele, 1960, Dissert. Abs., v. 21, no. 4, p. 853. In Flat Creek area, Lewis and Clark County, name Hogan formation is given to 2,477 feet of andesitic to latitic volcanic-rich sedimentary rocks which are stratigraphically equivalent to middle and upper Two Medicine formation. Hogan rests disconformably on lower fossiliferous Two Medicine.

Well exposed on Two Medicine River, between its mouth and Family post office, Glacier County.

Twomile Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: I. C. White, 1885, The Virginias, v. 6, p. 8, 9.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 12). Twomile limestone shown on correlation chart below Morgantown sandstone and above Bakerstown coal. Conemaugh series.

Named for exposure on Twomile Run, below Charleston, Kanawha County.

Two Mile Member (of Crockett Formation)

Eocene (Claiborne) : Central Texas.

G. D. Harris, 1941, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 33, p. 13, 14, 15–19. Crockett as exposed in Lee County divided into (ascending) Stone City, Wheelock, Two Mile (new), and Tabor (new) members. Two Mile is sequence of sand and clay with minor amounts of limestone and gypsum. Thickness as much as 19 feet. Name is from manuscript of H. B. Stenzel.

Exposed in Elm Creek valley for entire length of stream. Type locality and derivation of name not stated.

Twowells Sandstone Lentil (of Mancos Shale)

Upper Cretaceous : Northwestern New Mexico.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 22, 35–36. Hard massive tan to pinkish sandstone. Thickness from fraction of a foot to 35 feet. Within lower part of Mancos shale, 30 to 75 feet above its base.

Named from typical exposures near Two Wells in T. 12 N., R. 19 W., McKinley County.

**Tybo Shale**[1]

Cambrian : Central Nevada.

Original reference: H. G. Ferguson, 1933, Nevada Univ. Bull. v. 27, no. 3, p. 13–25.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 148. Listed with names not included on chart of recommended revision of stratigraphic units in Great Basin. Reasons for omission usually are that names are incapable of being interpreted or are rejected synonyms. [Hales limestone and Swarbrick formation, noted by Ferguson, 1933, as overlying and underlying the Tybo are also omitted from chart.]

Exposed in Tybo Canyon, near Camp Tybo, Tybo district.

Tye Formation (in Clear Fork Group)[1]

Permian : Central and central northern Texas.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull. 1, pl. opposite p. 96.

Probably named for Tye, Taylor County.

Tye Granite[1]

Jurassic : Central Washington.

Original references: W. S. Smith, 1915, School of Mines Quart., v. 36, p. 157 ; 1916, Jour. Geology, v. 24, p. 560.

Named for Tye River in Skykomish Basin.

**Tyee Sandstone**[1] or **Formation**

Eocene, middle : Western Oregon.

Original reference: J. S. Diller, 1898, U.S. Geol. Survey Geol. Atlas, Folio 49.

H. E. Vokes, P. D. Snavely, Jr., and D. A. Myers, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–110. Described in Eugene area as Tyee formation since here beds include substantial proportion of mudstone. Thickness about 5,000 feet; base not exposed. Unconformably underlies Lorane shale member of Spencer formation (restricted).

H. E. Vokes, D. A. Myers, and Linn Hoover, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–150. Described in Corvallis area where it overlies Kings Valley siltstone member of Siletz River volcanic series and underlies Spencer formation. Mapping in Corvallis-Monroe area indicates that Lorane shale member is more closely related to Tyee formation than to Spencer formation. Correlation is suggested between siltstone in upper part of Tyee in Monroe and Albany quadrangles and Lorane shale member of Spencer formation.

E. W. Baldwin, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–162. Described in Marys Peak and Alsea quadrangles where it overlies Siletz River volcanic series, where it consists of thick series of rhythmically bedded sandstone and intercalated siltstone. This same sequence of sedimentary rocks is exposed along Yaquina River in Toledo quadrangle and was named Burpee formation by Schenck (1927). Recent mapping has shown that Burpee formation is equivalent at least in part, to Tyee formation. Inasmuch as name Tyee has priority, it is used in this report.

E. M. Baldwin, 1959, Geology of Oregon: Ann Arbor, Mich., Edwards Bros., Inc., p. 13. Near Lukiamute River appears to interfinger with Yamhill formation.

U.S. Geological Survey restricts the use of the term Burpee to its type locality. Elsewhere the term Tyee is used.

Type locality: Douglas County. Forms prominent escarpment from Tyee Mountain to Camas Valley.

Tyende sandstone[1]

Jurassic: Northwestern Arizona and southwestern Colorado.

Original reference: C. R. Keyes, 1936, Pan-Am. Geologist, v. 66, no. 1, p. 71–72.

Named for Tyende Arroyo, tributary of Rio San Juan, passing by north point of Black Mesa, near Kayenta settlement, Navajo County, Ariz.

**Tygee Sandstone** (in Gannett Group)[1]

Cretaceous: Southeastern Idaho and southwestern Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 76, 83.

V. R. D. Kirkham, 1924, Idaho Bur. Mines and Geology Bull. 8, p. 26–28. Section measured on Fall Creek, Fall Creek quadrangle, gives thickness of Tygee as 1,020 feet. Overlies Draney limestone; underlies Wayan formation. Thickness at type locality about 100 feet.

C. A. Moritz, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 68. In Fall Creek area, Bonneville County, Idaho, about 980 feet of Tygee beds are assigned to Bear River formation; section not complete.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 53, 56–57, pl. 21. Geographically extended into Wyoming where it forms uppermost beds of Gannett group. Overlies Draney limestone. Underlies Bear River formation. Units referred to as members of Gannett group. Lower Cretaceous.

R. B. Boeckerman and A. J. Eardley, 1956, Wyoming Geol. Soc. Assoc. Guidebook 11th Ann. Field Conf., p. 198. In Jackson Hole country, uppermost member of Gannett group. Consists of brownish-gray siltstone and rust-stained shale. Contains one or more reddish sandstone beds. Thickness 198 feet. Overlies Draney limestone member; unconformably underlies Bear River formation. Lower Cretaceous.

J. D. Vine, 1959, U.S. Geol. Survey Bull. 1055–I, p. 259 (table), 261–262. In Bonneville County, Idaho, Tygee sandstone conformably overlies Draney limestone and conformably underlies Bear River formation. Thickness 285 feet where measured on Skyline Ridge. Formation consists of interbedded red shale and gray to brown sandstone. Strata in Skyline Ridge section are overturned and dip 85° NE. The intense deformation may have caused formation to be thinner here than in a normal section. Limits of formation differ greatly from limits described by Kirkham (1924), who included beds in Tygee that are here called Bear River formation. Apparently Kirkham measured his section east of Fall Creek Ranger Station, where faulting has duplicated strata.

Named for Tygee Creek [Idaho], east of which, in T. 8 S., R. 46 E., it is well exposed.

Tyger zone[1]

Precambrian: Northwestern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 6, 7, 12.

Named for exposures on Tyger River.

Tyler Formation

Tyler Sandstone Member (of Heath Formation)

Tyler Sandstone Member (of Quadrant Formation)[1]

Mississippian or Pennsylvanian: Central northern Montana.

Original reference: O. W. Freeman, 1922, Eng. and Min. Jour.-Press, v. 113, no. 19, p. 827.

H. D. Hadley, P. J. Lewis, and R. B. Larsen, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 142. Referred to as member of Heath formation. Thickness 5 to 100 feet. Mississippian.

P. A. Mundt, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1920–1925; 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 46–47. Redefined as formation. Freeman used term primarily with reference to massive sands; as redefined, the Tyler also includes black, gray, and reddish shales within which the sandstone bodies occur; also includes marine limestone tongue locally present near top. Thickness where typically exposed in secs. 21, 22, and 27, T. 14 N., R. 21 E., Fergus County, 382 feet. Underlies Alaska Bench formation; unconformably overlies Heath formation. Unit has been referred to as Amsden, Heath, Heath-Amsden transition zone, nonmarine Heath and so forth. Mississippian. Uncertainty exists as to exact geographic position of Freeman's type locality. No Tyler rocks outcrop a mile west of present site of Tyler; nearest exposures are more than 3 miles south of Tyler School and outcrop at Durfee Creek dome which cannot be considered part of Middle Bench as mentioned by Freeman. Type section restated.

G. H. Norton, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 58, 62, figs. 5, 6, 7. Formation includes East Buffalo Creek limestone member and Bear Gulch limestone member of lentil (both new).

R. P. Willis, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1948–1962. Formation in Montana area is limited in occurrence to central Montana trough and overlaps locally underlying Heath formation. Isopach pattern shows abrupt thinning toward north along Cat Creek trend, which may indicate truncation. Suggested that formation be divided into two members: lower characterized by predominantly dark-colored slightly calcareous shale, and upper containing predominantly red and maroon calcareous shales with abundant marine fauna. Division is made at base of the "A" zone, at which point the Tyler takes on more marine characteristics, and a trend change from east-west to southwest-northeast. Name Cameron Creek applied to upper member. The "A" zone denotes both the sand facies and its limestone equivalent; the limestone has been referred to as Bear Gulch member or tongue. This subdivision of Tyler is not everywhere applicable. Pennsylvanian (Morrow).

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 335–337. Name Tyler formation not used in revision of Big Snowy group because, as expressed by Scott (1935, Jour. Geology, v. 43), the sands are neither a lithologic, paleontologic, or mappable unit over broad areas. Also name is twice preoccupied. Its type section as given by Mundt (1956) is a section of Heath and Cameron Creek formations made anomalous by local appearance of about 150 feet of gray to white sandstone bedded in black shale of the Heath and overlain by red shale of Cameron Creek formation. In this study, no regional unconformity was found within Big Snowy sequence. Erosional unconformity at base of Mundt's Tyler is believed to be widely spaced local channel cuts, each of which can be traced for a few hundred yards or a few miles, depending on the angle at which present outcrop cuts ancient channel before it dies out in normal sequence of marine shale and limestone.

Type section: Section mentioned by Freeman as exposed at east end of Middle Bench. This section is about 5 miles west of Tyler School (also site of old Tyler post office), at southeast end of Middle Bench, in S½ sec. 5, T. 12 N., R. 21 E., Fergus County.

Tyler Greensand Member (of Sparta Sand)[1]

Eocene, middle: Eastern Texas.

Original reference: E. A. Wendlandt and G. M. Knebel, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 1359–1360.

Well exposed throughout city of Tyler, and west and northwest of Swan, Smith County.

Tyler Red Beds (in Monongahela Formation)[1]

Tyler redbed member

Pennsylvanian: Northern West Virginia and eastern Ohio.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 30, 44.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 177. Member of Benwood cyclothem in report on Athens County. Average thickness about 31 feet. Unit variable; grades laterally into either sandstone or shale, and fresh-water limestone and redbeds may be interbedded with either Sewickley sandstone or Benwood limestone. Monongahela series.

Named for prominence in area around Tyler County, W. Va.

**Tyler Slate**[1]

Precambrian (Animikie Series): Northwestern Wisconsin and northwestern Michigan.

Original reference: C. R. Van Hise, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 338.

W. O. Hotchkiss, 1919, Eng. and Min. Jour., v. 108, p. 501, 506. Includes Pabst member.

U.S. Geological Survey currently considers the Tyler Slate a part of the Animikee Series.

Named for exposures at Tylers Fork, [Iron County, Wis.]

**Tymochtee Formation**

Tymochtee Shale[1] (in Bass Islands Group)

Upper Silurian: Western Ohio and southeastern Michigan, and southern Ontario, Canada.

Original reference: N. H. Winchell, 1873, Ohio Geol. Survey, v. 1, p. 633.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3 (column 17). Correlation chart shows Tymochtee shale present in southern Ontario.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 124–125, chart facing p. 108. Dolomite, thin- to massive-bedded, gray to brown. Thickness indefinite approximately 125 to 175 feet. Overlies Greenfield formation; underlies Put-in-Bay dolomite. In Bass Island[s] group.

Named for exposures on Tymochtee Creek at Crawford, Wyandot County, Ohio.

**Tyner Formation**[1]

Middle and Upper Ordovician: Eastern Oklahoma.

Original reference: J. A. Taff, 1905, U.S. Geol. Survey Geol. Atlas, Folio 122.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 16 (fig. 3), 22–24, pls. 2, 3, 4. Described on southwestern flank of Ozark uplift. Cram's (1930, Oklahoma Geol. Survey Bull. 40QQ) subdivisions of lower dolomite and green shale, middle green shale, and upper cherty dolomite limestone can be recognized throughout much of area. Exposed thicknesses vary from 8 feet near Blackgum to over 90 feet on Cornshell Mountain, sec. 25, T. 16 N., R. 22 E.; 79 feet near Qualls; both contacts exposed; thins northward by truncation and overlap of Chattanooga. Conformably overlies Burgen sandstone; conformably underlies Fite limestone in southern exposures, and near contact buff, dolomitic limestone alternates with white, lithographic limestone of Fite to form narrow transition zone. Precise age and correlation questionable; fossil evidence suggests that upper part of Tyner is equivalent in part at least with units which have been classed as Black River. Figure 2 shows unit in Champlainian series.

Named for exposures along Tyner Creek, a tributary of Barren Fork in northern Adair County, near town of Proctor.

**Tyonek Formation**[1]

Eocene: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 171–172, 184.

Exposed along shore of Cook Inlet southwest of Tyonek.

†Tyringham Gneiss[1]

Precambrian: Western Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18.

Named for occurrence in Tyringham Township, Berkshire County.

†Tyrone Conglomerate[1]

Upper Ordovician: Central Pennsylvania.

Original reference: A. W. Grabau, 1909, Science, new ser., v. 29, p. 353, 355.

Typically exposed at Tyrone, Blair County.

**Tyrone Limestone**[1] (in High Bridge Group)

Tyrone Limestone Member (of High Bridge Limestone)

Middle Ordovician: Central Kentucky and western Virginia.

Original reference: A. M. Miller, 1905, Kentucky Geol. Survey Bull. 2, p. 9, 14.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 12–13; D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 40–41. Uppermost formation in High Bridge (Highbridge) group. Overlies Oregon limestone; underlies Curdsville limestone in Lexington group. Very pure limestone of birdseye or, in places, lithographic type; contains three bentonite beds. Thickness approximately 90 feet. May be wholly or in part Trenton in age.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 46. Kentucky name Tyrone should not be used in central Tennessee; name Carters has priority.

J. L. Rich, 1951, Geol. Soc. America Bull., v. 61, no. 1, p. 18. Referred to as member of High Bridge limestone.

M. H. Ross and W. E. Moore, 1952, (abs.) Virginia Jour. Sci., v. 3, new ser., no. 4, p. 333–334. Geographically extended into Lee County, Va. Contains bryozoan fauna. Beds have previously been referred to Eggleston formation.

Named for Tyrone, Anderson County, Ky.

Tyson Formation

Tyson Member (of Monastery Formation)

Cambro-Ordovician: West-central Vermont.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 42, 43, 44. Basal conglomerate and schistose sandstone member of Lower Cambrian Monastery formation (new). Thickness varies from featheredge to 600 feet. Underlies Battell member (new) of Monastery formation; overlies Mount Holly complex. Name attributed to Thompson (unpub. thesis, 1950).

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 45–47. Rank raised to formation in Rutland area. Thickness as much as 600 feet. Underlies Grahamville formation (new); overlies Precambrian(?) Saltash formation (new) or Mount Holly complex.

Largest belt of exposures in valley of West Branch, 1 mile east of Bingo Camp in Rochester-East Middlebury area.

774–954—vol. 3—66——71

Tyus Member (of Weches Formation)

Eocene, middle (Claiborne) : Eastern Texas.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 97, 100–104 [1939]. Gray powdery slightly glauconitic sparingly fossiliferous calcareous marl with numerous small irregular white to gray lime nodules, which unite in some places to form thin layers; includes gray limestone bench or limestone concretions; lime in form of limestone or nodules is outstanding component of member. Thickness 2 to 15 feet; average 9 feet; thickness increases along strike from southwest to northeast. Underlies Viesca member (new), boundary transitional; disconformable above Queen City sand.

Type locality: Cut of abandoned Houston & Texas Central Railroad, 0.4 mile north of Robbins crossroads, R. M. Tyus Survey, Leon County.

U Bar Formation

Lower Cretaceous: Southwestern New Mexico.

R. A. Zeller, Jr., 1958, Roswell Geol. Soc. Guidebook 11th Field Conf., p. 10 (chart). Name appears only on chart. Consists of massive- and thin-bedded limestone. Thickness approximately 2,000 feet. Underlies Mojado formation (new) ; overlies Hell-To-Finish formation (new).

Big Hatchet Peak quadrangle, Hidalgo County.

**Ucross Formation**

Recent(?) : Eastern Wyoming.

L. B. Leopold and J. P. Miller, 1954, U.S. Geol. Survey Water-Supply Paper 1261, p. 10. Consists of fresh rounded gravel including variety of rocks, mostly igneous and metamorphic. Pebbles average 1 to 2 inches in diameter. Formation contains occasional deeply weathered yellow- and red-stained pebbles. Upper few feet locally composed of silt and may contain lenses of clay. Upper 2 to 3 feet characteristically impregnated with large amounts of calcium carbonate and gypsum in form of strong white mottlings, concentrically-filled tubules, and hard nodules ⅛ to 1 inch in diameter. Underlies newly named Kaycee formation and disconformably overlies Arvada formation (new).

Type locality : In Clear Creek Valley, 1 mile south of Ucross.

Udall Limestone Lentil (in Geuda Springs Shale Member of Wellington Formation)

Permian: Southeastern Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 13. Limestone several feet thick that occurs in Geuda Springs about 160 feet below Prairie Creek limestone lentil (new).

Well exposed near Udall in Maple Township, T. 30 S., R. 3 E., Cowley County.

**Uffington Shale Member** (of Conemaugh Formation)[1]

Uffington Shale (in Conemaugh Group)

Upper Pennsylvanian : Northern West Virginia and western Pennsylvania.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 323.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 78, 88, fig. 21. Lowest member of Conemaugh group.

Underlies Lower Mahoning sandstone; overlies Upper Freeport coal. Thickness as much as 20 feet in Fayette County.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 22 (table 4). Listed in summary of stratigraphic section of Conemaugh formation in Harrison County.

Named for exposures at Uffington, Monongalia County, W. Va.

Uhalde Sandstone and Shale (in Panoche Group)

Upper Cretaceous: Central California.

M. B. Page, 1960, Soc. Econ. Paleontologists and Mineralogists, Pacific Sec., Guidebook Spring Field Trip, p. 5 (fig. 3), 6 (fig. 4), 7 (fig. 5), 13 (fig. 6). Equal amounts of gray-brown shale and interbedded sandstone. Thickness 3,370 feet. Overlies Television sandstone (new); underlies Dosados sandstone and shale member of Moreno shale. Name credited to D. W. Sutton (unpub. thesis).

Type locality: Moreno Gulch, Fresno County. Name derived from Uhalde Canyon, secs. 4 and 9, T. 14 S., R. 11 E., and secs. 33 and 34, T. 13 S., R. 11 E.

**Uinta Formation**[1]

Eocene, upper: Northeastern Utah and Colorado.

Original reference: O. C. Marsh, 1871, Am. Jour. Sci., 3d, v. 1, p. 196.

H. E. Wood 2d, 1934, Am. Mus. Nat. History Bull., v. 67, art. 5, p. 241–242. Includes Wagonhound member below and Myton member above.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 97 (table 1), 99 (table 2), 121–122. Central part of Uinta basin, just south of synclinal axis, is occupied by outcrops of Uinta formation. Consists of variegated shale interbedded with gray and buff sandstone. Thickness 1,648 to 1,800 feet. Conformably overlies Green River shale; conformably underlies Duchesne River formation.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 405–425. Discussion of stratigraphic and facies relationships of upper part of Green River formation and lower part of Uinta formation in Duchesne, Uintah, and Wasatch Counties, Utah. Uinta formation comprises thick sequence of chiefly fluviatile beds but includes varying amount of lacustrine beds. Westward from Colorado State line to the Green River, where formation has been most studied, it contains three vertebrate faunal zones of middle to late Eocene age, and surface exposures indicate thickness of 1,500 to 2,000 feet. This sequence conformably overlies Green River formation and was formerly divided by U.S. Geological Survey into Bridger formation, consisting approximately of horizons A and B of Osborn and Peterson (1895, Am. Mus. Nat. History, v. 7) and Uinta formation, which was horizon C of Osborn and Peterson (1895). More general and recent usage has been to refer entire sequence to Uinta formation, which usage is followed in present report. Lowest part of sequence of fluviatile beds consists of a brown massive cross-bedded medium- to coarse-grained sandstone unit that overlies Green River formation for many square miles in vicinity of Evacuation Creek and White River north of Watson, Utah, in eastern part of Uinta basin. This sandstone unit, about 800 feet thick, contains some hard greenish-gray sandy mudstone interbedded with the sandstone and is lower unit of Bridger formation of Bradley (1931, U.S. Geol. Survey Prof. Paper 168).

Lower part of this sandstone unit, about 500 feet thick, contains few fossils, but according to Peterson (Riggs, quoting Peterson, 1912, Field Mus. Nat. History Pub. 159, Geol. Ser., v. 4), specimens of *Metarhinus* and *Sphenocoelus* were found near base; upper part is more fossiliferous and the two fossiliferous parts represent closely horizon A, lowest vertebrate faunal zone of the three recognized by Osborn and Peterson. There has been some uncertainty as to whether lowest part of Osborn and Peterson's horizon A should be placed in Uinta or underlying Green River. Despite this uncertainty, the unit has generally not been included in the Green River. An indefinite lower part of horizon A beds (lower beds of Bridger formation of Bradley) has been casually referred to as Wagonhound buff sandstones, but name Wagonhound member was proposed by Wood (1934) for lower part of Uinta formation (horizons A and B of Osborn and Peterson). Top of Evacuation Creek member of Green River is regarded as base of Uinta formation. This formation boundary rises stratigraphically toward center of basin. Much of lower part of fluviatile beds of the Uinta as exposed along Colorado-Utah line grades westward into beds that are in considerable part of lacustrine, playa, and mud-flat origin in an area of which Indian Canyon is the center. These beds, formerly considered saline facies of Green River formation, are here included as part of Uinta formation.

W. B. Cashion and J. H. Brown, Jr., 1956, U.S. Geol. Survey Oil and Gas Inv. Map OM–153. Thickness about 1,500 feet in Bonanza-Dragon area, Uintah County, Utah, and Rio Blanco County, Colo. Overlies Evacuation Creek member of Green River formation; underlies Duchesne River formation.

First described in Uinta Basin, Utah.

†Uinta Glacial Epoch[1]

Pleistocene (Wisconsin): Colorado.

Original references: W. W. Atwood and K. F. Mather, 1912, Science, new ser., v. 35, p. 315; 1912, Jour. Geology, v. 20, p. 388; 1912, Geol. Soc. America Bull., v. 23, p. 732.

Name derived from Uinta Mountains, Utah.

†Uinta Quartzite,[1] Sandstone,[1] or Group[1]

Precambrian: Northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 42, 61, 70, 138, 139, 141–145.

Forms crest and core of main axis of Uinta Mountains and extends east into Colorado, nearly as far as junction of Little Snake and Yampa Rivers.

**Uinta Mountain Group[1]**

Precambrian: Northeastern Utah and northwestern Colorado.

Original reference: T. S. Lovering and others, 1935, Geologic map of Colorado.

G. E. Untermann and B. R. Untermann, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 5, p. 685, 689 (table 1). In Green and Yampa River Canyons, group unconformably underlies Lodore formation. Thickness about 12,000 feet.

N. C. Williams, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2737–2738. Group, in western Uinta Mountains, divided into (ascending) Mutual quartzite and Red Pine shale (new). Underlies Tintic quartzite (Pine Valley of previous reports).

W. R. Hansen, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 25–27, pl. 1. Described in area between Clay Basin and Browns Park in Utah and Colorado. Consists predominantly of dark-red medium- to coarse-grained massive- to crossbedded siliceous sandstone and quartzite with considerable amounts of shale and conglomerate. Approximate thickness 20,600 feet; section is on west end of Cold Spring Mountain between Uinta fault on north and Browns Park on south, section incomplete. Overlies Red Creek quartzite with angular unconformity.

H. R. Ritzma, 1959, Utah Geol. and Mineralog. Survey Bull. 66, p. 18–19, 20. Core of Uinta Range exposes more than 20,000 feet of Precambrian quartzitic sandstone and argillite, the Uinta Mountain group. Proposed that older Precambrian rocks of previous studies, the Red Creek quartzite (or complex), are metamorphosed equivalents of Uinta Mountain group sediments. Group rests with apparent unconformity on contorted and faulted Red Creek complex. Unconformably underlies Lodore formation. Area of report, Daggett County.

Most widely exposed unit in Uinta Mountain area. Crops out in almost continuous exposures from one end of range to the other, a distance west to east of about 140 miles, in a belt 15 or 20 miles or more wide. Forms main divide and major peaks of range proper as well as greater part of chain of hills north of Green River between Flaming Gorge and Vermilion Creek, including Goslin, O-Wi-Yu-Kuts, and Cold Spring Mountains.

Uintan Age

Eocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 10, pl. 1. Provincial time term, based on Uinta formation of northern Utah, that is, time of deposition of Uinta A–C, inclusive (pl. 1), with included faunas. Covers interval between Bridgerian and Duchesnean ages. Report defines 18 provincial time terms based on mammal-bearing units for North American continental Tertiary. [For sequence see under Puercan.]

Ulatisian Stage

Eocene, middle: California.

V. S. Mallory, 1953, (abs.) Jour. Paleontology, v. 27, no. 6, p. 903. Named as one of six stages, based on foraminiferal assemblages, in lower Tertiary of California. Includes interval between Narizian stage above and Juniperan [Juniperian] stage.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 40–44, 76–78, 96–98, fig. 7, tables. Spans interval between Penutian stage (name proposed to replace Juniperian stage) below and Narizian stage above. Includes two zones, *Vaginulinopsis mexicana* below and *Amphimorphina californica* above. Interval is essentially represented by most of Laiming's (1939, 6th Pacific Sci. Cong. Proc., v. 2) "B-Zones". At base is the megafossiliferous "Domengine" and at top is the "Transition Zone" of molluscan terminology.

Type is in strata mapped by Boyd (1949, unpub. thesis) as Vacaville shale in vicinity of Dunn's Peak along Ulatis Creek, Vaca Valley quadrangle, Solano County.

Ulm coal group (in Wasatch Formation)[1]

Eocene: Eastern Wyoming and southeastern Montana.

Original reference: J. A. Taff, 1909, U.S. Geol. Survey Bull. 341, p. 123–150.

Named because of their best known occurrence in vicinity of Ulm, on Burlington Railroad in Sheridan County, Wyo.

Ulm Formation[1]

Eocene: Eastern Wyoming and southeastern Montana.

Original reference: R. L. Nace, 1936, Wyoming Geol. Survey Bull. 26, p. 104.

Named for Ulm, Sheridan County, Wyo.

Ulsterian Group[1]

Ulsterian Series

Ulsterian Stage

Lower and Lower or Middle Devonian: North America.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 131 (footnote). Term Ulsterian stage in New York includes the Onondaga and Schoharie, but not the Esopus which is classed with the Oriskany. If used here [Pennsylvania], it would embrace Onondaga group which includes the so-called Esopus of eastern Pennsylvania. No Schoharie is recognized in the State. Such usage being inapplicable, term Stroudsburgian stage is introduced from Stroudsburg, Monroe County, where the group may be observed at its best, for eastern Pennsylvania.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. As shown on correlation chart, Devonian comprises (ascending) Ulsterian, Erian, Senecan, Chautauquan, and Bradfordian (in part) series. Ulsterian comprises (ascending) Helderberg, Deerpark (new), and Onesquethaw (new) stages. Lower and Lower or Middle Devonian.

Named for Ulster County, N.Y.

**Ultima Thule Gravel Member** (of Holly Creek Formation)

†Ultima Thule Gravel Lentil (of Trinity Formation)[1]

Lower Cretaceous (Comanche Series): Southwestern Arkansas.

Original reference: H. D. Miser and A. H. Purdue, 1918, U.S. Geol. Survey Bull. 690–B.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Referred to as Ultima Thule gravel member of Holly Creek formation. Subsurface equivalents discussed.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2333 (fig. 2), 2339. Ultima Thule gravel lentil represents surface equivalent of lower part of Rodessa formation.

Exposed near Ultima Thule, De Queen quadrangle, Sevier County.

**Ulupau Tuff**[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 85–90.

G. A. Macdonald and G. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 133. Gray to brown partly palagonitized tuff forming Ulupau Cone. Contains fragments of reef limestone. Thickness more than 500 feet. Cut by nepheline basalt dike. Unconformably underlies Kii Point limestone and beach deposits of plus 25-foot (Waimanalo) stand of sea. Has been referred to as Ulupau Head tuff (Winchell, 1947, Geol. Soc. America Bull., v. 58, no. 1).

Named for Ulupau Head, tuff cone at north end of Mokapu Peninsula. Covers about 0.3 square mile on northeast coast of Oahu, about 12 miles northwest of Makapuu Head.

**Umatac Formation**

Umatac Andesite

Miocene, lower: Mariana Islands (Guam).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 48, table 4 [English translation in library of U.S. Geol. Survey, p. 57–58]. Basal rock of island. Typically pillow lava with amygdaloidal structures and intercalated green tuffs and agglomerates. Cut by dikes. Underlies Bolanos (Balanos) beds. Thick stratum of Santa Rosa beds intercalated between Umatac and Bolanos beds. Eocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 64. Aquitanian.

U.S. Geological Survey currently classifies the Umatac as a formation and designates its age as lower Miocene on the basis of a study now in progress.

Typically exposed at Umatac coast, Guam.

**Umbrella Hill Formation**

Middle Ordovician: North-central Vermont.

A. L. Albee, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–102. Quartz- and slate-pebble conglomerate. Friable calcareous gray slate separates conglomerate bands at top and bottom. Underlies Moretown formation with apparent conformity; overlies Stowe formation unconformably.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, pl. 3. Middle Ordovician.

Typically exposed on and near Umbrella Hill along east-central border of Hyde Park quadrangle. Also exposed in Hardwick quadrangle to the east.

†Umiat Formation (in Nanushuk Group)

Lower and Upper Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160 (table 1), 162–164. Inshore facies of the marine formation consists of relatively clean sandstone that grades northeast through argillaceous sandstone into shale of offshore facies. Thickness about 5,000 feet. Lower part is marine shale similar to shale of Torok formation (new) which it overlies. Underlies Schrader Bluff formation (new). Tongues into nonmarine Chandler formation (new) to the south. Divided into two new members, Tuktu below and Topagoruk above. Lower part is Lower Cretaceous; upper part probably also Lower Cretaceous.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, chart (facing p. 246). Age shown on chart as Lower and Upper Cretaceous.

George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 211, 233. Name abandoned.

Named from marine part of section below 750 feet in Umiat test well No. 1, in vicinity of Umiat, Colville River region.

**Umpqua Formation**[1]

Eocene, lower to middle: Southwestern Oregon and northern California.

Original reference: J. S. Diller, 1898, U.S. Geol. Survey Geol. Atlas, Folio 49.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 589, chart 11. Correlation chart shows Umpqua formation below Tyee formation in Roseburg and Comstock areas, Oregon. States type section.

J. E. Allen and E. M. Baldwin, 1944, Oregon Dept. Geology and Mineral Industries Bull. 27, p. 13, 19, pls. 1, 5. In Coos Bay quadrangle, formation consists of more than 1,800 feet of tuffaceous sandstone and shale with thick lenticular basalts and pyroclastic. Overlies sediments, schists, and volcanics tentatively correlated with Franciscan-Knoxville group of California. Underlies Tyee sandstone in northeastern part of quadrangle. In some areas, underlies Coaledo formation. Middle Eocene.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 18, pl. 1. Mapped in Macdoel quadrangle, California.

F. G. Wells, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–89. Described in Medford quadrangle, Oregon-California. Forms floor of most of Bear Creek valley from Siskiyou, where it is faulted against volcanic rocks of Western Cascades, north to Rogue River. Western boundary follows trend of foothills of Cascade Range. Maximum thickness about 8,000 feet. Predominantly medium-grained sandstone with some shaly and conglomerate layers. Disconformably overlies Hornbrook formation; in northern part of area, grades into overlying Colestin and Roxy formations (both new) but to south is separated from them by angular discordance. Eocene.

U.S. Geological Survey currently considers the Umpqua Formation lower Eocene in age.

Type section: Along north Umpqua River about 17 miles northeast of Roseburg, Douglas County, Oreg.

Umpqua Group[1]

Eocene: Southwestern Oregon.

Original reference: T. Condon, 1902, The Two Islands: Portland, Oreg., The J. K. Gill Co.

Named for association with Umpqua Valley, Douglas County.

Unadilla Formation[1]

Upper Devonian: East-central New York.

Original reference: C. S. Prosser, 1903, Am. Geologist, v. 32, p. 380–384.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Unadilla shale and sandstone. Underlies Oneonta redbeds; overlies Gilboa sandstone. Genesee group.

Bradford Willard and R. E. Stevenson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2274. Onteora redbeds grade laterally westward into Unadilla marine sandstones and sandy shales. Unadilla listed under Portage group.

Named for Unadilla River below New Berlin village, Chenango County.

Uncas Shale[1]

Permian: Central northern Oklahoma.

Original reference: D. W. Ohern and R. E. Garrett, 1912, Oklahoma Geol. Survey Bull. 16, p. 10.

Named for exposures in vicinity of Uncas, Kay County.

Uncle Israels Granite

Age not stated: Southeastern Maine.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 172. Name proposed for white granite with cataclastic texture. Occurs as sills.

Occurs on Mount Desert Island and Bartlett Island, Hancock County.

**Uncle Sam Porphyry**

Eocene(?) to lower Pliocene(?): Southeastern Arizona.

B. S. Butler, E. D. Wilson, and C. A. Rasor, 1938, Arizona Bur. Mines Bull. 143, Geol. Ser. 10, p. 24–25, pl. 3. Rock designated as quartzite latite porphyry. Buff or rusty brown where weathered but dark gray on fresh fractures. Characteristic feature of rock is blotchiness or unevenness of texture due to variations in crystallinity of groundmass. Intrusive into sandstone and shale of Bisbee group west of Ajax Hill, and intrudes volcanic breccias and flows southwest toward Charleston.

James Gilluly, 1945, Am. Jour. Sci., v. 243, no. 12, p. 647–651. Intrusive into Bronco volcanics (new), Bisbee formation, and locally, into Naco limestone. At Bronco Hill and point about 1½ miles to the southeast, it is cut by Schieffelin granodiorite. Probably early Tertiary age.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 94–99, pl. 5. Mapped in central Cochise County as Tertiary—Eocene(?) to lower Pliocene(?). Locally invades Colina limestone and Epitaph dolomite.

Forms Uncle Sam Hills 2½ miles southwest of Tombstone and the Three Brothers, and is general country rock of State of Maine, Merrimac, San Pedro, and Montezuma mines. Occupies extensive area in western part of Tombstone district and extends westward toward Charleston, Cochise County.

Uncompahgran Quartzite

*See* **Uncompahgre Formation.**

Uncompahgran System

Precambrian: Western United States.

N. E. A. Hinds, 1936, Carnegie Inst. Washington Pub. 463, p. 58, 134. Strata in western United States formerly classed as Algonkian are divisible into two groups (Uncompahgran and Beltian) separated by considerable time interval during which orogenic deformation, intrusion of granite, and deep erosion occurred. The older group, for which periodic and system term Uncompahgran is suggested, includes the Needle Mountains group of San Juan Mountains, southwestern Colorado; Mazatzal quartzite of central Arizona; and Cottonwood series of Wasatch, Uinta, Oquirrh, and other ranges of northern Utah. Uncompahgran formations are chiefly quartzite, with subordinate amounts of quartzitic conglomerate and slate.

Named from fine exposures of rocks of this type in Uncompahgre Canyon, San Juan Mountains, Colo.

**Uncompahgre Formation** (in Needle Mountains Group)[1]

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 120.

N. E. A. Hinds, 1940, 6th Pacific Sci. Cong. Proc., p. 290 (table). Cited as Uncompahgran quartzite.

W. S. Burbank and C. T. Pierson, 1953, U.S. Geol. Survey Circ. 236, p. 3. In Uncompahgre Canyon on western flank of San Juan Mountains, formation consists of alternate layers of quartzite and black slate from 50 to several thousand feet in thickness. Neither bottom nor top of series exposed.

Well exposed in Uncompahgre Canyon, Silverton and Ouray quadrangles.

†Uncompahgre Interglacial Interval[1]

Pleistocene: Southwestern Colorado.

Original reference: W. W. Atwood and K. F. Mather, 1912, Jour. Geology, v. 20, p. 392–409.

Underwood Formation (in New Albany Shale)

Underwood Shale Member (of New Albany Shale)

Mississippian (Kinderhookian): Southeastern Indiana and northern Kentucky.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 835, 840 (fig. 3), 849–851, 858. Underwood formation lies between Falling Run member of Sanderson formation (both new) and Henryville shale (new). At type locality, consists of soft greenish 6-inch fossiliferous shale with layer of phosphatic nodules at top.

H. H. Murray and others, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 43, pl. 1. Mississippian part of New Albany has been divided into (ascending) Sanderson, Underwood, and Henryville "formations." Indiana Geological Survey uses these terms with rank of member.

Type locality: On south Ester Farm, in SE¼ sec. 21, T. 2 N., R. 8 E., 2 miles east of Underwood, Clark County, Ind. Noted at Pine Lick, 1 mile northwest of Loretto, Marion County, Ky.

Underwood Lava[1]

Tertiary(?): Southern Washington.

Original reference: I. A. Williams, 1916, Oregon Bur. Mines and Geol., Min. Res. Oreg., v. 2, no. 3, p. 108, 115–117.

In vicinity of Underwood, Skamania County.

Underwood Mountain Lava

Pliocene: Northwestern Oregon and southwestern Washington.

W. D. Lowry and E. M. Baldwin, 1952, Geol. Soc. America Bull., v. 63, no. 1, pl. 2. Name appears on chart only. Younger than Hood River conglomerate.

Underwood Mountain located on north side of Columbia River in Washington, near Hood River, Oreg.

**Unga Conglomerate**[1]

Miocene: Southwestern Alaska.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 234.

P. S. Smith, 1936, U.S. Geol. Survey Prof. Paper 182, p. 27. Section about 200 feet thick was measured by Dall in 1872 on Unga Island, where series consisted largely of conglomerates with some shales and sandstones containing in places abundant marine fossils. Also recognized at other places in same general region as on shores of Balboa and Herendeen Bays and Port Moller. At Port Moller, beds attain thickness of at least 1,000 feet. In type area, Unga conglomerate appears to rest conformably on highest recognized Eocene stratum but this is not believed to be normal relation, as beds usually show much less deformation than the Eocene deposits.

Type area: Unga Island.

**Ungalik Conglomerate**[1]

Lower Cretaceous: Central western and central Alaska.

Original reference: P. S. Smith and H. M. Eakin, 1911, U.S. Geol. Survey Bull. 449, p. 55.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, pl. 1 (facing p. 246). Age given as Lower Cretaceous on correlation chart.

Exposed on steep-faced cliffs along Ungalik River and forms most of prominent range of hills between river and coastal plain from Bonanza Creek north to about 1 mile below Camp A17; Nulato-Norton Bay district, Lower Yukon River region.

Unibon Shale[1]

Upper Cretaceous: Puerto Rico.

Original reference: D. R. Semmes, 1919, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, p. 69, 74.

J. D. Weaver, 1956, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2b, p. 345. Upper Cretaceous. Light porous shale, with foraminifera. Exact stratigraphical position and distribution not known.

Type locality: At junction of Morovis trail and Unibon River in northern part of island.

**Unicoi Formation**[1] (in Chilhowee Group)

Lower Cambrian(?): Eastern Tennessee, northwestern North Carolina, and southwestern Virginia.

Original reference: M. R. Campbell, 1899, U.S. Geol. Survey Geol. Atlas, Folio 59, p. 3.

P. B. King and others, 1944, Tennessee Div. Geology Bull. 52, p. 27–28, 37–41. In this report [northeastern Tennessee], basal clastic group of Lower Cambrian series is divided into Unicoi, Hampton, and Erwin formations. Other formation names have been used in region, and various names have been given to group as a whole. Terms Unicoi formation, Hampton shale, and Erwin quartzite were originally applied by Keith (1903, U.S. Geol. Survey Geol. Atlas, Folio 90; 1905, Folio 118; 1907, Folio 151) to broad lithologic units; Unicoi consisting dominantly of arkose and conglomerate, Hampton of shale, and Erwin of quartzite. However, formation boundaries, when based on lithologic character alone, are not of same age from place to place; also, the different rock types are so interbedded that none of the formations consists of a single rock type. In this report, boundaries of the formations are placed at top or bottom of widely traceable beds in such manner that formations are convenient units of mapping. Lithologic titles of formations are abandoned, although their gross character corresponds approximately to Keith's original intention. Top of Unicoi is placed at top of thick unit of arkosic and vitreous quartzite which lies at rather constant interval of 2,500 to 3,000 feet below base of Shady dolomite. Upper surface of arkosic and vitreous quartzite is easily recognized and is persistent horizon that is probably of same age everywhere.

G. W. Stose and A. J. Stose, 1944, Am. Jour. Sci., v. 242, no. 7, p. 389. Discussion of Chilhowee group and Ocoee series of southern Appalachians. With present knowledge, it is not possible to decide which formation, if any, in Chilhowee type section represents Unicoi formation, but it is evident that lower part of that formation which contains the basalt flows is not present because neither Hayes (1895, U.S. Geol. Survey Geol. Atlas, Folio 20) nor Keith (1895, U.S. Geol. Survey Geol. Atlas, Folio 16; 1896, Folio 25) describe such flows in the section.

P. B. King, 1949, Am. Jour. Sci., v. 247, no. 8, p. 519 (table 1), 521. Basal formation of Chilhowee group in northeastern Tennessee and southwest Virginia. Underlies Hampton shale; overlies volcanics of Mount Rogers area.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 12, 13. 18–20, pl. 1. Rocks mapped by Keith (1904, U.S. Geol. Survey Geol. Atlas, Folio 116) as quartzite lentil and lower part of Nichols slate and as Cochran conglomerate are all included in Unicoi formation of present report [Hot Springs Window]. Top is placed above thick-bedded to massive vitreous and coarsely feldspathic quartzites that underlie lower shale member of Hampton formation; boundary is sharp and distinct. Lower contact is here defined as base of lowermost conglomeratic bed above the Sandsuck. Boundary difficult to recognize because slates are interbedded with Unicoi conglomerates and there are lenses of coarse conglomerate in upper part of Sandsuck. Formation thickens southwestward, from 1,400 feet on south side of Lovers Leap Ridge to 2,600 feet along East Fork Shut-in Creek; 2,250 feet along Spring Creek. Northwest of window and in overlying thrust sheet are rocks which are herein assigned to Unicoi as Keith did in his Asheville folio (1904); Stose and Stose (1947) assign these rocks to Great Smoky quartzite of Ocoee series, or Snowbird as mapped by Keith. Two sets of formation names for Lower Cambrian clastic rocks are in current usage in eastern Tennessee and western North Carolina. Northeast Tennessee names, Unicoi, Hampton, and Erwin, are used here for same rocks which Keith (1904) and Stose and Stose (1947, Am. Jour. Sci., v. 245, no. 10) named Cochran, Nichols, Nebo, Murray, and Hesse, all defined by Keith (1895) in Chilhowee Mountain area, Blount and Sevier Counties, Tenn.

H. W. Ferguson and W. B. Jewell, 1951, Tennessee Div. Geology Bull. 57, p. 11 (table 1), 12 (table 2), 21–28, pl. 1. Described in Del Rio district, Cocke County, where it is 1,825 feet thick in Stone Mountain thrust block and about 5,000 feet thick in Meadow Creek Mountain thrust block. Overlies Sandsuck formation; underlies Hampton formation. In all but Stone Mountain and Neddy Mountain thrust blocks of Del Rio thrust sheet that contain Unicoi sediments, a bed of coarse-grained quartzite about 50 feet thick occurs about 1,000 feet or more from top of formation. This unit is here named Moccasin Gap member. In several blocks of Del Rio thrust sheet, the Unicoi above the Moccasin Gap quartzite can be separated into upper shale member and upper quartzite member. In this report, Unicoi, Hampton, and Erwin formations are referred to as clastic group of Lower Cambrian age. The Unicoi represents about same stratigraphic interval as the Cochran as mapped by Keith (1904, U.S. Geol. Survey Geol. Atlas, Folio 116).

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 34–38; pt. 1, pls. Described and mapped in eastern Tennessee where it is basal formation of northeastern sequence of Chilhowee group. Keith was not consistent in his mapping of Unicoi. In Asheville Folio (1904, U.S. Geol. Survey Geol. Atlas, Folio 116), he mapped beds now assigned to Unicoi as quartzite lentil in Nichols slate or even as Nebo quartzite. In Roan Mountain Folio (1907, U.S. Geol. Survey, Geol. Atlas, Folio 151), he mapped much of Unicoi as Hiwassee slate and Snowbird formation. Safford (1869, Geology of Tennessee) varied his usage, placing the beds in the Ocoee where they are obviously conglomeratic but retaining them in the Chilhowee where they are more quartzitic. In present usage, top of formation is taken at top of conglomeratic beds, whether quartzitic or not, beneath fairly persistent layer of argillaceous shale that has been recognized in most areas. Underlies Hampton formation. Thickness ranges from 2,000 to 5,000 feet; variation in thickness probably result of deposition on uneven floor.

R. O. Bloomer and H. J. Werner, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 594–595, pl. 1. Described in Blue Ridge region of central Virginia where it is as much as 500 feet thick and consists of volcanics and intergradational conglomeratic graywackes, subgraywackes, pebbly arkoses, and pebbly quartzites. Conformably underlies Harpers formation; owing to overlap overlies Late Precambrian and basement complex formations. Chilhowee group.

A. J. Stose and G. W. Stose, 1957, Virginia Geol. Survey Bull. 72, p. 78–98, pl. 1. Described in Gossan lead district where it is at base of Cambrian. Thickness about 1,700 feet. Underlies Hampton shale; unconformably overlies Precambrian rocks described as injection complex, and Mount Rogers volcanic series.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 38–39; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Formation in North Carolina is predominantly sandstone, quartzite, and conglomerate with interbedded shale and slate. Thickness 1,400 to 2,600 feet. Basal formation of Chilhowee group; underlies Hampton formation.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28, 36–40, pls. 1, 12. Described in northeasternmost Tennessee where it underlies Hampton formation and overlies units of Mount Rogers volcanic group. Formation is mass of arkosic coarse-grained and conglomeratic sandstone, with some beds of vitreous quartzite and shale, as well as amygdaloidal basalt. Thickness as much as 5,000 feet. At type section, herein designated, formation is about 2,000 feet thick and consists mostly of thick-bedded arkosic sandstone and quartzite but includes two basalt layers. Above the upper basalt are several beds of massive vitreous quartzite and two of sedimentary greenstone. Lower part of section contains coarse conglomerate.

Type locality: On Nolichucky River, southeast of Unaka Springs, Unicoi County, Tenn.

Union Formation[1]

Pleistocene: Western Kentucky.

Original reference: L. C. Glenn, 1912. Kentucky Geol. Survey Rept. Prog. 1910–1911, p. 26.

Named for Union County.

Union Limestone[1]

Pennsylvanian: Southeastern Nebraska.

Original reference: G. E. Condra and N. A. Bengston, 1915, Nebraska Acad. Sci. Pub., v. 9, no. 2, p. 7, 13, 37.

Exposed in old quarry at Union, Cass County, in valley side in NW¼ sec. 22, T. 10 N., R. 13 E., and 1½ miles southwest of Union, in secs. 33 and 28, T. 10 N., R. 13 E.

Union Limestone (in Greenbrier Limestone[1] or Series)

Mississippian (Meramecian): Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 450, 467.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 272; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 98, 99). Limestone in Greenbrier series. Underlies Greenville shale; overlies Pickaway limestone.

D. B. Reger, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 9, p. 1911. In southern West Virginia counties and southwestern Virginia, intermediate sandstone and shale between the Gasper and Fredonia largely disappear; hence, term "Union" limestone was applied to both of these calcareous units.

Type locality: At west edge of Union, Monroe County, W. Va.

Union Shale[1]

Upper Devonian: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, 438, map.

Occurs in Queen Gulch, also near Union mine, at head of Alpreston Gulch, Elkhorn region.

Union Church transition phase (of Tullos Member of Yazoo Clay)

Eocene (Jackson): Central Louisiana.

N. H. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 78 (fig. 6), 99–100. Alternating thin beds of sandy silts and clays which in upper 20 feet of section contain large light-brown concretions or slabs of fossils cemented by limonite. Occurs between Tullos member and overlying Verda member.

Well exposed at Union Church, in center of sec. 30, T. 10 N., R. 2 E., La Salle Parish.

Union Corners Granite[1]

Precambrian: Southeastern New York.

Original reference: W. J. McGee, 1894, Geologic map of New York prepared under direction of James Hall.

In Bronxville, New York City.

Union Dairy member (of Hoxbar Formation)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 15.

Named for Union Dairy Hill, in NE¼ sec. 7, T. 5 S., R. 2 E., Carter County.

Union Mountain Member (of Nevada Formation)

Devonian: Northeastern Nevada.

Donald Carlisle and others, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2178 (fig. 2), 2181, 2182–2183. Diverse unit characterized by abundant quartz sand either in sandy dolomite or as vitreous siliceous quartz arenite or quartzite, but also including white crystalline dolomite and dark crinoidal dolomite. Thickness approximately 700 to 800 feet in southern part of area; 830 feet at type section; nearly 1,200 feet in northern part of Pinyon Range. Overlies McColley Canyon member (new); underlies Telegraph Canyon member (new).

Type locality: Crest of Union Mountain, in Pinyon Range, northeastern part of Mineral Hill quadrangle.

Union Peak Lavas

Pliocene to Pleistocene, lower: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 22–25, 130, pl. 3. Lavas from Union Peak, volcano which became extinct either before Mount Mazama began to develop or shortly thereafter. Toward the north and east, Union Peak lavas pass beneath Mount Mazama; in other directions, they merge into identical lavas from other sources. Huckleberry lavas at Huckleberry Mountain may have issued from fissures at base of Union Peak volcano. [Diller and Patton, 1902, U.S. Geol. Survey Prof. Paper 3, described Union Peak andesite area.]

Union Peak is south and west of Crater Lake.

**Union Springs Member** (of Marcellus Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 132, 218, 219.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1745, chart 4. Bakoven shale represents easternmost known facies of Union Springs shale. In Cayuga Lake region, the Union Springs is black limestone, but in eastern central New York it is sooty-black shale. In Catskill region, the Union Springs is dark sandy shale with *Paracardium* and *Buchiola*. Basal member of Marcellus; underlies Cherry Valley limestone member; overlies Onondaga.

Type section: Upper part of Woods quarry, 1 mile south of Union Springs, Cayuga County.

Union Station Shale Member (of Chanute Formation)

Pennsylvanian (Missouri Series): Northwestern Missouri.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Red, green, gray clayey shale, sandy at top. Thickness 8 to 25 feet in Jackson County; 10 to 24 feet in Cass County. Underlies Paola limestone member; overlies Cement City limestone member.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2032. Settlement of the "Iola problem" has led to a number of changes in Missouri Survey's classification of middle and upper Kansas City beds so as to bring interstate agreement in nomenclature. Union Station shale member of Chanute formation is suppressed because it is a synonym of Chanute as a whole.

Type locality and derivation of name not given.

Uniontown cyclothem

Pennsylvanian (Monongahela Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 182–185. Embraces interval between Lower Uniontown cyclothem (new) below and Little Waynesburg cyclothem (new) above. Normal succession includes six members (ascending) : Lower Uniontown shale and sandstone, Uniontown redbed, Uniontown limestone, Uniontown underclay, Uniontown (No. 10) coal, and Uniontown roof shale. In Athens County, Uniontown commonly rests on Arnoldsburg coal and roof shale and extends uninterrupted to top of Uniontown roof shale. Where Lower Uniontown cyclothem is developed, base of Uniontown is considered to overlie Lower Uniontown coal. Arnoldsburg sandstone and Ritchie redbed members of Lower Uniontown cyclothem are continuous laterally, irrespective of presence or absence of Lower Uniontown coal horizon, and these names are carried in the Uniontown wherever its boundary is placed over Arnoldsburg coal horizon. Thickness of Uniontown varies with position of its lower boundary; average thickness where boundary is placed at Arnoldsburg coal zone 33 feet; 15 feet wherever Lower Uniontown cyclothem occurs. In area of this report, Monongahela series is discussed on cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Present in Athens County.

Uniontown Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 97.

Derivation of name not stated.

**Uniontown Limestone Member** (of Monongahela Formation)[1]

Uniontown Limestone (in Monongahela Group)

Uniontown limestone and shale member

Upper Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

Original reference: F. Platt and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$, p. 55–104, 286, 292.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 100, 123, 124 (fig. 29). Overlies Arnoldsburg sandstone; underlies Uniontown coal which in turn underlies Uniontown sandstone. Included in Monongahela group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 82–83, geol. map. In Morgan County, Uniontown limestone and shale member (Monongahela series) consists of limestone and calcareous shale or calcareous shale with limestone layers. Average thickness 4 feet. Underlies Arnoldsburg sandstone and shale member; separated from underlying Uniontown sandstone and shale member by Uniontown (No. 10) coal.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 184. Limestone member of Uniontown cyclothem in report on Athens County. Term in its present usage indicates fresh-water limestone between Arnoldsburg sandstone and Uniontown coal bed, for this lithology is not present in Lower Uniontown-Uniontown coal bed interval. Limestone is closely associated with underlying Ritchie redbed as it frequently interbeds with or grades laterally into them. Thickness varies from few inches to 20 feet, but in places member is totally absent and its position occupied by redbeds. Monongahela series.

Named for exposures at Uniontown, Fayette County, Pa.

Uniontown Member (of Monongahela Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

Name derived from occurrence near Uniontown, Fayette County.

Uniontown redbed member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 148 (table 13), 184. Member of Uniontown cyclothem in report on Athens County. Name is intended to apply to this lithology only where it is underlain by Lower Uniontown coal bed. Where Lower Uniontown coal bed is absent, this member is coalesced with Ritchie redbed of Lower Uniontown cyclothem. Thickness 14 feet.

Name derived from cyclothem.

Uniontown roof shale member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 185. Member of Uniontown cyclothem in report on Athens County. Thickness a few inches to a little more than 1 foot. Wherever present, member is clay shale, laminated or massive, that grades vertically into shale. Overlies Uniontown (No. 10) coal member. Uppermost member of cyclothem.

**Uniontown Sandstone Member** (of Monongahela Formation)[1]

Uniontown Sandstone (in Monongahela Group)

Uniontown sandstone and shale member

Upper Pennsylvanian: Southwestern Pennsylvania, eastern Ohio, western Maryland, and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 58–59.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 100, 124 (fig. 29), 125. Underlies Lower Waynesburg limestone; separated from Uniontown limestone by Uniontown coal. Included in Monongahela group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 84, geol. map. In Ohio, Uniontown sandstone and shale member (Monongahela series) occupies interval between Uniontown (No. 10) coal below and Waynesburg limestone and shale member above. In Morgan County, consists of 20 to 40 feet of sandstones, sandy shales, and red shales.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 184. Member of Little Waynesburg cyclothem in report on Athens

County. White (1891) proposed this name for sandstone that occurs 60 to 70 feet below Waynesburg coal bed, because of its relation to underlying Uniontown coal. In West Virginia, a shale facies at this position has been designated Annabelle shale by Hennen and Reger (1913). In Athens County, member is highly variable in thickness, rock type, and prominence. Invariably member rests directly on or is separated from Uniontown coal bed by only a few inches of shale. It is most resistant unit between Sewickley sandstone and Little Waynesburg coal bed. Average thickness 21½ feet. Monongahela series.

Named for association with Uniontown coal, although it is not prominent at Uniontown, Fayette County, Pa.

Uniontown underclay member

*See* Uniontown cyclothem.

Union Valley Formation (in Springer Group)

Union Valley Sandstone Member (of Wapanucka Formation)[1]

Pennsylvanian: East-central Oklahoma.

Original reference: R. V. Hollingsworth, 1934, Geol. Soc. America Proc. 1933, p. 364.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 889–895. Formation (in Springer group) includes Stapp conglomerate member (new) at base. Thickness about 360 feet. At typical exposure in Ouachitas, consists of gray to dark-gray shale and intercalated massive and thin-bedded greenish-yellow fine to medium subangular sandstone. Underlies Round Prairie formation (new); overlies Wesley shale (new) in Jackfork group. Union Valley was initial deposit of Morrow time; unconformity at base of Union Valley, which in Ouachitas is marked by Stapp conglomerate, is proper horizon to draw base of Morrow.

J. C. Barker, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 180–183. Formation described in Lawrence uplift where it is about 30 feet thick. Overlies "Springer" shale; underlies Wapanucka formation.

L. M. Cline, 1956, Tulsa Geol. Soc. Digest, v. 24, p. 103. Overlying Wesley siliceous shale and underlying Johns Valley shale in Ouachitas is persistent fossiliferous sandstone containing fragments of crinoid columnals, brachiopods and bryzoans, and plant fragments. Harlton (1938) correlated this sandstone with Union Valley sandstone which, at its type locality east of Ada, contains goniatite fauna of basal Morrow age. Inasmuch as overlying Johns Valley shale contains Caney goniatite fauna of Mississippian age, this fossiliferous sandstone must be older than type Union Valley.

B. H. Harlton, 1959, *in* The geology of the Ouachita Mountains—a symposium: Dallas, Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 132. Unit termed Union Valley sandstone by Harlton (1938) is here renamed Game Refuge formation.

Type locality: Outcrops near Union Valley Schoolhouse, Pontotoc County.

**Unionville Granodiorite**

Upper Cretaceous: Southwestern Montana.

Adolph Knopf, 1957, Am. Jour. Sci., v. 255, no. 2, p. 81, 90–91, map facing p. 88. Hypersthene-bearing augite-hornblende (basic) granodiorite that is dark and heavy and resembles diorite. Represents earliest intrusion of Boulder bathylith.

Well exposed south and southeast of Helena. Named for small village south of Helena, Lewis and Clark County.

Unionville Sandstone[1]

Pennsylvanian: Northwestern Illinois.

Original reference: J. Shaw, 1873, Illinois Geol. Survey, v. 5, p. 147–149.

Named for outcrop at Unionville, Whiteside County.

United Verde Diorite[1]

Precambrian: Central Arizona.

Original references: L. E. Reber, Jr., 1920, Am. Inst. Mining Engrs.; 1922, Am. Inst. Mining Metall. Engrs. Trans., v. 66, p. 3–26, map.

L. E. Reber, Jr., 1938, Arizona Bur. Mines Bull. 145, Geol. Ser. 12, p. 59. Mentioned in report on mineralization in Jerome district.

Probably named for United Verde mine, Jerome district.

Unity Group

Upper(?) Devonian: Southwestern New Hampshire.

C. A. Chapman, 1942, Geol. Soc. America Bull., v. 53, no. 6, p. 897, 898, 902. Name proposed for plutonic rocks of Oliverian magma series in the Unity dome. Similar to Croydon group which consists of fine- to medium-grained biotite gneiss. Quartz diorite is most common rock type.

Composes core of Unity dome in southeastern part of Claremont quadrangle.

**Universal Limestone Member** (of Dugger Formation)

Middle Pennsylvanian: Southwestern Indiana.

C. E. Wier, 1951, U.S. Geol. Survey Coal Inv. Map C–9. About 3 feet thick; commonly in two benches separated by few inches of shale; both benches arenaceous and locally grade into calcareous sandstone. Occurs between Coals VI and VII in Sullivan and Greene Counties and between Coals Vb and VII in Vermillion and Vigo Counties.

Type locality: Half mile south of Universal, small town in southern Vermillion County, in NW¼SW¼ sec. 31, T. 4 N., R. 9 W.

University Beds[1]

Quaternary: Central northern New Mexico.

Original reference: K. Bryan, 1909, New Mexico Univ. Bull., Geol. Ser., v. 3, no. 1.

Form considerable part of Sandia Mesa, extending from Menaul School south to mouth of Power House Arroyo and to east in wedge shape to eastern limit of area in Albuquerque region.

University Mesa Marl (in Fredericksburg Group)[1]

Lower Cretaceous (Comanche Series): Western Texas.

Original reference: W. S. Adkins, 1933, Texas Univ. Bull. 3232, p. 271, 328, 339, 347.

L. W. Stephenson, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. University Mesa clay shown on correlation chart above Comanche Peak limestone and below Kiamichi clay.

Pecos County.

**Unkar Group**[1]

Unkar Series

Precambrian (Grand Canyon Series) : Northern Arizona.

Original reference: C. D. Walcott, 1894, U.S. Geol. Survey 14th Ann. Rept., pt. 2, pl. 60.

J. F. Mason, 1948, Geol. Soc. America Bull., v. 59, no. 4, p. 350. Incidental mention of Unkar series.

C. E. Van Gundy, 1959, Geol. Soc. America Bull., v. 62, no. 8, p. 953, 954, pl. 1. Lower group of Grand Canyon series. Stratigraphically restricted, upper part reassigned to Nankoweap group. Thickness in Basalt Canyon, 5,684 to 6,138 feet. Disconformably underlies Nankoweap group.

Named for outcrops in Unkar Valley, Grand Canyon region.

**Unkpapa Sandstone**[1]

Upper Jurassic: Western South Dakota.

Original reference: N. H. Darton, 1899, Geol. Soc. America Bull., v. 10, p. 393.

1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 144. Generalized columnar section of Black Hills shows Unkpapa sandstone overlying Sundance formation and underlying Morrison and where Morrison pinches Lakota. Soft massive fine-grained sandstone 0 to 225 feet thick.

W. J. Mapel and G. B. Gott, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–218. Maximum thickness about 250 feet in Angostura Reservoir and Cascade Springs quadrangles, South Dakota. Thins westward and in Flint Hill and Minnekahta quadrangles pinches out under Morrison formation. Underlies Lakota formation.

Named for Unkpapa Peak, at head of Calico Canyon, northwest of Buffalo Gap, Custer County.

**Upham Member** (of Montoya Dolomite)

Upham Dolomite or Limestone (in Montoya Group)

Upham Member (of Second Value Formation)

Upper Ordovician: Southwestern New Mexico and western Texas.

V. C. Kelley and Caswell Silver, 1952, New Mexico Pubs. in Geology 4, p. 11, 31 (table), 51–59–60, fig. 4. Massive-bedded medium-gray- to brownish-gray-weathering dolomite. Microcrystalline to coarsely crystalline and medium to dark gray on fresh exposure. Detrital quartz grains present as scattered grains, thin lentils, and irregular vertical streaks. Where present, chert occurs as scattered nodules of irregular shape. Thickness 20 to 80 feet. Underlies Aleman formation (new) ; overlies Cable Canyon sandstone (new) with gradational contact. Montoya group.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 7, 23–25. Upham dolomite described in San Andres Mountains where it is 115 feet thick in Rhodes Canyon, 77 feet in Hembrillo Canyon, and 104 feet in Ash Canyon. Overlies Cable Canyon sandstone; underlies Aleman dolomite. Montoya group.

R. H. Flower, 1958, Roswell Geol. Soc. Guidebook 11th Field Conf., p. 70. Rank reduced to member of Second Value formation.

H. J. Howe, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 10, p. 2285–2332. Montoya group described in Trans-Pecos region, Texas.

Upham formation (limestone or dolomite) constitutes basal formation of group in areas where Cable Canyon sandstone is missing. Along southeast-facing escarpment of Baylor Mountains, a 116-foot interval composed of fine-grained sandstones and argillaceous dolomites (probably Simpson) is present between Lower Ordovician El Paso dolomite and upper Trentonian(?) Upham limestone.

Type locality: Cable Canyon section opposite Sierrite mine in NW¼ sec. 10, T. 16 S., R. 4 W., Caballo Mountains.

†Upland Formation[1]

Pleistocene: Southern and eastern Nebraska.

Original reference: A. L. Lugn and G. E. Condra, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 190.

G. E. Condra, E. C. Reed, and E. D. Gordon, 1950, Nebraska Geol. Survey Bull. 15–A, p. 22; J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 87; D. R. Hill and J. M. Tompkin, 1953, U.S. Geol. Survey Bull. 1001, p. 25. Replaced by Sappa formation (new).

Named for outcrops along West Branch of Thompson Creek, about 2½ miles west of Upland, Franklin County.

Upper Bakerstown cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 123–129. Embraces interval between Anderson cyclothem below and Harlem cyclothem above. Normal succession includes four members (ascending): Cow Run sandstone, Ewing limestone, Upper Bakerstown underclay and coal. Thickness about 30 feet. Only the two basal members are present in Athens County. In Ohio, coal from which this cyclothem is named has heretofore been called Barton coal; Flint (1951) used name Barton for cyclothem under discussion. Waagé (1950, Maryland Dept. Geology, Mines and Water Resources Bull. 9) stated that Barton coal is equivalent to Upper Bakerstown coal of Maryland and that true Barton coal is above Ames limestone, which is contrary to Condit's (1912, Ohio Geol. Survey Bull. 17, 4th ser.) interpretation. Name Upper Bakerstown is used here since Condit's correlation is in error. In area of this report. Conemaugh series is discussed on cyclothemic basis; 15 cyclothems are named. [For sequence see Mahoning cyclothem.]

Present in Athens County.

Upper Brush Creek cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 111 (map 12), 112–113. I. C. White (1878) applied name Brush Creek to marine shale and limestone at position of Lower(?) Brush Creek limestone. Brush Creek is now applied to series of different beds comprising two more or less complete cyclothems which are now designated Lower Brush Creek and Upper Brush Creek. Upper Brush Creek embraces interval between Lower Brush Creek cyclothem below and Wilgus cyclothem above. Normal succession includes four members (ascending): Upper Brush Creek shale and (or) sandstone, Upper Brush Creek underclay, Upper Brush Creek coal, and Upper Brush Creek limestone. Thickness 27 feet. Heretofore, Upper Brush Creek members have been discussed in reports along with Lower Brush Creek members.

Little attention has been given to nonmarine members of Upper Brush Creek cyclothem, although double nature of Brush Creek limestone had long been recognized. In area of this report, Conemaugh series is discussed on cyclothemic basis; 15 cyclothems are named. [For sequence see Mahoning cyclothem.]

Present in Athens County.

Upper Brush Creek limestone member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 113. Member of Upper Brush Creek cyclothem in report on Athens County. Average thickness 2 feet.

Upper Brush Creek shale and (or) sandstone member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 112. Member of Upper Brush Creek cyclothem in report on Athens County. Thicknesses of nonmarine shale and sandstone lying between Brush Creek limestones vary from 5 to 40 feet; average thickness 22 feet.

Upper Brush Creek underclay member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 12. Member of Upper Brush Creek cyclothem in report on Athens County. Thickness 8 inches to more than 4 feet.

†Upper Freeport Clay (in Allegheny Formation)[1]

Upper Freeport clay or underclay member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1878, Pennsylvania 2d Geol. Survey Rept. $K_3$.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 55–56, table 1, strat. sections. Included in Upper Freeport cyclothem (new) in Perry County, Ohio. Thickness ranges from less than 6 inches to 14 feet and averages 5 feet. Overlies Upper Freeport limestone; underlies Upper Freeport coal. In Allegheny series where limestone is missing and clay at this horizon is as thick as 14 feet, the Upper Freeport is probably in contact with Bolivar clay.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 22–23. Upper Freeport clay measured in sections 23 and 34, T. 14 N., R. 14 W., in western York Township, Morgan County. In section 34, Upper Freeport (No. 7) coal is underlain by 4 feet of poorly exposed gray to dark-gray clay shale with some sandy material near base. In northwestern corner of section 23, the coal is underlain by about 6 inches of dark-gray clay and by 1½ feet of crossbedded sandstone, which may be top part of Upper Freeport sandstone, or may represent more sandy phase of Upper Freeport clay member. Upper Freeport limestone not recognized definitely in Morgan County. Allegheny series. Cyclothemic classification not used in this report.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 90. Upper Freeport underclay present in Athens County.

Name derived from town of Freeport, Armstrong County, Pa.

Upper Freeport cyclothem

Pennsylvanian (Allegheny Series) : Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 12, 16. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 55–57, table 1, geol. map. Includes (ascending) Freeport limestone, 2 feet; Upper Freeport clay, 5 feet; Upper Freeport (No. 7) coal; and unnamed shale. Occurs above Bolivar cyclothem and below Mahoning cyclothem of Conemaugh series. In area of this report, Allegheny series is described on cyclothemic basis; nine cyclothems are named. [For sequence see Brookville cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 88–92. Topmost cyclothem in Allegheny series in Athens County. Occurs above Bolivar cyclothem. Comprises (ascending) Upper Freeport shale and (or) sandstone, Upper Freeport limestone, Upper Freeport underclay, and Upper Freeport (No. 7) coal members. Uffington shale member not known in Athens County but is considered topmost member of cyclothem and, for purposes of description, topmost member of Allegheny series. In this report, Allegheny series comprises 13 cyclothems. [For complete sequence see Brookville cyclothem.]

Name derived from town of Freeport, Armstrong County, Pa.

†Upper Freeport Limestone Member (of Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: F. Platt and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. $H_3$ p. 316.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 27–28. Discussion of limestones of eastern Ohio. From 3 to 12 feet below base of Upper Freeport coal is an irregular bed of limestone which Rogers (1855, Geology of Pennsylvania, v. 2) called Freeport limestone in northwestern Pennsylvania and which Newberry apparently described as White limestone in Mahoning County, Ohio (1878, Ohio Geol. Survey v. 3). In his report on Lawrence County, Pa., White (1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$), renamed Butler limestone, which underlies Lower Freeport coal and which was not recognized by Rogers, the Lower Freeport and the Freeport limestone of Rogers, the Upper Freeport. This terminology has been generally accepted in reports dealing with geology of coal measures in Pennsylvania, West Virginia, and Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 90. Upper Freeport limestone included in Upper Freeport cyclothem. In this report [Athens County], Upper Freeport limestone is limited to fresh-water limestone at or near base or within Upper Freeport underclay. Average thickness 1¼ feet. Separated from base of Upper Freeport coal by 2 to 4 feet of underclay. Allegheny series.

Name derived from town of Freeport, Armstrong County, Pa.

†Upper Freeport Sandstone[1]

Pennsylvanian: Western Pennsylvania.

Original reference (Butler—Upper Freeport sandstone) : I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 40–71, 130.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 20–21. U.S. Geological Survey and Pennsylvania Geological Survey have adopted name Butler for unit herein termed Upper Freeport sandstone and shale member. In Ohio, term Upper Freeport sandstone and shale has been used and is established firmly in the literature. Thickness about 28 feet in Morgan County [this report]. Below Bolivar clay member and above Lower Freeport (No. 6–a) coal member. Allegheny series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 88. Interval between Bolivar underclay and Upper Freeport limestone and underclay is occupied by Upper Freeport shale and (or) sandstone member [of Upper Freeport cyclothem]. Thickness 5 to 28 feet. Allegheny series. Area of report, Athens County.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 22 (table 5). Upper Freeport sandstone listed in table of recognizable named members of Allegheny formation in Harrison County.

Name derived from town of Freeport, Armstrong County, Pa.

†Upper Kittanning Clay[1]

Upper Kittanning underclay member

Pennsylvanian: Pennsylvania, Ohio, and West Virginia.

[Original reference]: M. G. Wilmarth, 1938, U.S. Geol. Survey Bull. 896, p. 2221.

J. B. McCue and others, 1948, West Virginia Geol. Survey, v. 18, p. 16. Upper Kittanning underclay lies immediately beneath Upper Kittanning coal. Thickness 3 to 9 feet. Occurs a few feet above Hardman clay. Allegheny series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 78. Upper Kittanning underclay included in Upper Kittanning cyclothem. Light to dark-gray thin impure clay. Thickness 2 to 18 inches. Occurs above Upper Kittaning shale and (or) sandstone member and below Upper Kittanning coal member.

Upper Kittanning cyclothem

Pennsylvanian (Allegheny Series): Eastern Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 51. Consists of Upper Kittanning coal and underlying shale or sandstone. An uncertain unit in Ohio column. No evidence is found for its presence in area of this report [Perry County].

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 76–78. Embraces interval between Middle Kittanning cyclothem below and Lower Freeport cyclothem above. Incomplete. Includes (ascending) Upper Kittanning shale and (or) sandstone, Upper Kittanning underclay, and Upper Kittanning coal members. Thickness about 14 feet. In area of this report [Athens County], Allegheny series is discussed on cyclothemic basis; 13 cyclothems are named. [For sequence see Brookville cyclothem.]

Type area (Upper Kittanning coal): Vicinity of Kittanning, on Allegheny River, in Armstrong County, Pa. Coal is also present in Maryland.

Upper Kittanning Limestone (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania and northern West Virginia.

Original reference: J. J. Stevenson, 1878, Pennsylvania 2d Geol. Survey Rept. $K_3$.

Fayette and Westmoreland Counties, Pa.

Upper Kittanning Marine Shale

*See* Kittanning Formation.

Upper Kittanning shale and (or) sandstone member

Pennsylvanian (Allegheny Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 78. Upper Kittanning shale and (or) sandstone member included in Upper Kittanning cyclothem in report on Athens County. Average thickness 12½ feet. In absence of Upper Kittanning coal and underclay, it is impossible to distinguish this member from overlying shale and sandstone, and it is treated as part of Lower Freeport cyclothem in this report.

Upper Little Pittsburgh cyclothem

Pennsylvanian (Conemaugh Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 155 (map 19), 156–157. Uppermost cyclothem recognized. Occurs above Lower Little Pittsburgh cyclothem (new). Normal succession includes five members (ascending) : Upper Little Pittsburgh sandstone, Upper Little Pittsburgh redbed, Upper Little Pittsburgh limestone, Upper Little Pittsburgh underclay, and Upper Little Pittsburgh coal. Thickness about 33 feet. Two Little Pittsburgh cyclothems underlie Pittsburgh (No. 8) coal in parts of northern Appalachian coal basin. In general, these cycles are irregular and uncertain in development, and at many places, most or even all members of one or both cyclothems seem to be missing. Hence, correlation of Little Pittsburgh members is often uncertain. In area of this report, Conemaugh series is discussed on cyclothemic basis; 15 cyclothems are named. [For sequence see Mahoning cyclothem.]

Present in Alexander, Ames, Athens, Bern, Canaan, and Rome Townships, Athens County.

Upper Little Pittsburgh Limestone[1]

Upper Little Pittsburgh limestone member

Pennsylvanian (Conemaugh Series) : Western Pennsylvania and eastern Ohio.

Original reference: J. P. Leslie, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 305–308.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 157. Limestone associated with Upper Little Pittsburgh coal, here called Upper Little Pittsburgh limestone, is poorly developed in Athens County. Average thickness 2½ feet. Upper Little Pittsburgh cyclothem. Conemaugh series.

Upper Little Pittsburgh redbed member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 157. Redbed phase of Upper Little Pittsburgh cyclothem is designated Upper Little Pittsburgh redbed member in this report [Athens County]. Overlies Upper Little Pittsburgh sandstone member and separated from Upper Little Pittsburgh coal by that coal's associated limestone and underclay where these are present. Average thickness about 11 feet. Conemaugh series.

Upper Little Pittsburgh sandstone member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 156–157. Basal member of Upper Little Pittsburgh cyclothem. Average thickness 18 feet. Underlies Upper Little Pittsburgh member of cyclothem. Condit (1912) named a sandstone closely underlying the Pittsburgh coal, the Bellaire for town of Bellaire, Ohio. He stated that it [the sandstone] "is prominent in Pennsylvania where it has been called Lower Pittsburgh sandstone." Stout (in Bownocker and Dean, 1929 [1930], Ohio Geol. Survey, 4th ser., Bull. 34) placed Bellaire sandstone in Upper Little Pittsburgh cyclothem rather than in its correct position as correlative of Lower Pittsburgh sandstone, that is, as basal member of Pittsburgh cyclothem. Unless it can be demonstrated that Lower Pittsburgh sandstone is absent in type area of the Bellaire, then Stout's correlation of Bellaire sandstone is in error.

Upper Little Pittsburgh underclay member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 157. Gray to dark-gray silty micaceous clay about 1 foot thick. Underlies Little Pittsburgh coal. Upper Little Pittsburgh cyclothem. Conemaugh series.

Upper Little River Limestone[1]

Lower Cretaceous (Comanche Series) : Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 111, 188.

Named for exposures on Little River at Oklahoma State line.

Upper Mahoning redbed member

*See* Mahoning Red Bed (in Conemaugh Formation) and Mason cyclothem.

†Upper Mahoning Sandstone (in Conemaugh Formation)[1]

Upper Mahoning Sandstone (in Conemaugh Group)

Upper Mahoning sandstone and shale member

Pennsylvanian: Western Pennsylvania, Maryland, eastern Ohio, and northern West Virginia.

Original reference: F. Platt, 1876, Pennsylvania 2d Geol. Survey Rept. L.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 91, fig. 21. Upper Mahoning sandstone lies above Mahoning coals and below Brush Creek strata. Shale replaces sandstone in many areas. Conemaugh group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 29–30. In Ohio, Upper Mahoning sandstone and shale member occupies interval between Mahoning coal and Mason clay or coal. Average thickness about 28 feet in Morgan County [this report]. Allegheny series. Cyclothemic classification not used.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 104–106. Upper Mahoning shale and (or) sandstone member included in Mason cyclothem in report on Athens County. Average thickness of interval 30 feet. Lowermost member of cyclothem. Occurs below

Upper Mahoning redbed member. Occurs above Lower Mahoning coal member of Lower Mahoning cyclothem. Allegheny series.

Name taken from Mahoning Creek(s) in Indiana and Jefferson Counties, Pa.

Upper Mercer cyclothem

Pennsylvanian (Pottsville Series) : Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 36. Includes (ascending) Upper Mercer shale and (or) sandstone (contains Little Red Block ironstone) ; Upper Mercer clay ; and Upper Mercer (No. 3a) coal. Occurs above Middle Mercer cyclothem and below Bedford cyclothem.

Generally inconspicuous throughout Ohio and not recognized in area of this report, Perry County.

Upper Mercer flint and limestone member

*See* Bedford cyclothem.

Upper Mercer Iron Shales (in Pottsville Formation)[1]

Pennsylvanian : Western Pennsylvania and eastern Ohio.

Original reference: I. C. White, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$.

Upper Mercer Limestone (in Pottsville Formation)[1]

Pennsylvanian : Western Pennsylvania and eastern Ohio.

Original reference: I. C. White, 1879, Pennsylvania 2d Geol. Survey Rept. $Q_2$.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser. Bull. 49, p. 24. White (1879) discarded term Mahoning of Rogers (1858, Geology of Pennsylvania, v. 2, pt. 1) and renamed unit Upper Mercer. Orton (1884, Ohio Geol. Survey, v. 5) accepted White's usage of this term for Ohio although he had previously referred in reports to the Upper Mercer as Gore limestone. Member is composed of hard compact dense-textured limestone of dark-bluish-gray to gray-black color with varying amounts of black flint. Thickness varies from a few inches to nearly 10 feet; average thickness a little in excess of 1 foot. Occurs from 15 to 40 feet above Lower Mercer limestone. Pottsville series.

Named for Mercer, Mercer County, Pa.

Upper Mesa Formation or Gravels

Pleistocene : Southwestern Idaho and southeastern Oregon.

V. R. D. Kirkham, 1931, Jour. Geology, v. 39, fig. 1 (p. 202), fig. 12 (p. 211), fig. 13 facing p. 212. Overlies Idaho formation. Name appears only on geologic map and on geologic cross sections.

Mapped in Ada, Canyon, Owyhee, and Payette Counties, Idaho, and Malheur County, Oreg.

Upper Pittsburgh cyclothem

Pennsylvanian (Monongahela Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 166–167, 168 (map 21). Embraces interval between Pittsburgh cyclothem (new) below and Redstone cyclothem (new) above. Thickness about 12 feet. Includes Upper Pittsburgh coal member, occurrence of which breaks normal cyclical sequence of strata that extend from roof shale of Pittsburgh coal bed to roof shale of Redstone coal bed into two cyclothems, Upper Pittsburgh and Redstone. In area of this report, Monongahela series is discussed on cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburgh cyclothem.]

Present in Athens County. Occurrences sparse.

**Upper Pittsburgh Limestone Member** (of Conemaugh Formation)[1]

Upper Pittsburgh limestone member

Upper Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 63–65, geol. map. In Morgan County, Upper Pittsburgh limestone member (Conemaugh series) is immediately subjacent to Pittsburgh (No. 8) coal or separated from it by a few inches or feet of Pittsburgh clay; overlies Bellaire sandstone and shale member or separated from it by Upper Little Pittsburgh clay shale member. Thickness as much as 40 feet; commonly 15 to 20 feet.

M. T. Sturgeon, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 161–163. Rogers (1858, Geology of Pennsylvania, v. 2, pt. 1) used name Pittsburgh for limestone immediately below Pittsburgh coal. It is thought that Rogers' original definition included Little Pittsburgh limestones as well. This limestone in Pittsburgh cyclothem is now generally called Upper Pittsburgh limestone, and is so called in this report [Athens County]. Average thickness 11 feet. In Pittsburgh cyclothem, Upper Pittsburgh limestone member occurs above Lower Pittsburgh redbed member and below Pittsburgh underclay and coal member. Monongahela series.

Named for its occurrence with Pittsburgh coal in western Pennsylvania.

Upper Pittsburgh Sandstone[1]

*See* **Pittsburgh Sandstone Member** (of Monongahela Formation) and Upper Pittsburgh shale and sandstone member.

Upper Pittsburgh shale and sandstone member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 159 (table 13), 167–169. Rogers (1858, Geology of Pennsylvania, v. 2) designated conspicuous sandstone strata that occur between Pittsburgh and Redstone coal beds along Conemaugh and Loyalhanna streams in Pennsylvania as Upper Pittsburgh sandstone. Coarse clastic material at this position has been similarly designated by Ohio and West Virginia Geological Surveys. In Ohio, this member is commonly represented by sandy shale containing sandstone interbeds with local variations of prominent sandstone. In Athens County, this unit is predominantly shale and siltstone. Average thickness 19 feet. Basal member of Redstone cyclothem. Underlies Redstone redbed member. Monongahela series.

Upper Sewickley Sandstone

Upper Sewickley sandstone and shale member

Pennsylvanian (Monongahela Series): West Virginia and eastern Ohio.

R. V. Hennen, 1912, West Virginia Geol. Survey [Rept.] Doddridge and Harrison Counties, p. 199–200. Sewickley sandstone (White, 1891) is herein renamed Upper Sewickley sandstone in contradistinction to Lower Sewickley ledge belonging immediately under Sewickley coal.' Massive arenaceous sandstone 40 to 60 feet thick. In Marion and Monongalia Counties. Overlies Sewickley coal.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 77–78. Upper Sewickley sandstone and shale member (Monongahela series) in Ohio overlies Meigs Creek coal and underlies Benwood limestone and shale member. As described by White (1891, U.S. Geol. Survey Bull. 65), this is unit accepted as Sewickley sandstone by U.S. Geological Survey. U.S. Geological Survey does not recognize the term Lower Sewickley, and inasmuch as that term is used in Ohio to designate sandstone and shale subjacent to Meigs Creek coal, it follows that the term Upper is necessary to designate the sandstone superjacent to that coal. Upper Sewickley member is present in only part of Morgan County [this report]. Thickness 4 to 34 feet. Monongahela series.

**Upper Washington Limestone Member** (of Washington Formation)[1]

Upper Washington Limestone

Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K, p. 45–47.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 39, 40. In Ohio, Upper Washington limestone is recognized only over small areas in Belmont and Monroe Counties; elsewhere its horizon is occupied by sandstones and shales. Thickness ranges from a few inches to 23 feet. Closely overlain by Jollytown "A" coal, basal member of Greene series. In Belmont County, lies about 100 feet above Washington coal. Included in Washington series which, in Ohio, consists of the following limestones (ascending): Elm Grove, Mount Morris, Lower Washington, Middle Washington, and Upper Washington.

Named for exposures near Washington, Washington County, Pa.

**Upshur Sandstone**[1]

Middle Pennsylvanian: Northeastern West Virginia.

Original reference: J. A. Taff and A. H. Brooks, 1896, U.S. Geol. Survey Geol. Atlas, Folio 34.

Covers large part of Upshur County.

**Upson Clay**[1]

Upper Cretaceous (Gulf Series): Southern Texas.

Original reference: E. T. Dumble, 1892, Geol. Soc. America Bull., v. 3, p. 224–230.

L. W. Stephenson, 1937, U.S. Geol. Survey Prof. Paper 186–G, p. 135 (fig. 7). As shown on correlation chart of exposed sediments of Austin and lower Taylor age in Gulf Coastal Plain, Upson clay occurs above Austin chalk and below San Miguel formation; interfingers with Anacacho limestone.

Named for Upson, Maverick County.

Upton Sandstone Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 139 (fig. 2), 140, 142, 143 (fig. 2), 145 (fig. 3). Where well exposed, consists of light-yellowish- to bluish-gray fine-grained calcareous well-bedded sandstone 450 feet thick. Uppermost member of formation; overlies Judd shale member (new); underlies Henefer formation. Name credited to D. W. Trexler (unpub. thesis).

Named for exposures near settlement of Upton, 7 miles east of Coalville, Summit County.

**Urbana Phyllite**

Lower Paleozoic(?) (Glenarm Series): Western Maryland.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 346. Green ferruginous quartzose chlorite phyllite with green slaty layers, and is probably pyroclastic facies of associated metabasalt; contains many sericitic quartzite layers, some thin calcareous layers, and infolded quartzite similar to that associated with Ijamsville phyllite (new). Underlies Sugarloaf Mountain quartzite (new). Precambrian(?).

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12] Carroll and Frederick Counties, p. 69–71, 121–126. Overlies Sams Creek metabasalt (new) in southern part of Frederick County. North of U.S. Highway 40, from point 1½ miles east of New Market westward to point 1 mile east of Bartonsville, phyllite is in narrow infolds in metabasalt. South of highway it extends southward in three parallel belts to Frederick-Montgomery County line. Western of these belts is widest and contains synclinal mass of Sugarloaf Mountain quartzite which overlies Urbana phyllite. On west side of main belt, the Urbana is in contact with Ijamsville phyllite; from a point 2 miles south of Park Mills to Frederick County line, Triassic sedimentary rocks overlie the phyllite on its western border. On the east side, the Urbana lies adjacent to the Ijamsville. North of U.S. Highway 40, the Urbana grades northward into the Ijamsville. Sugarloaf Mountain syncline encloses Ijamsville and Urbana phyllites and associated quartzites, and Sugarloaf Mountain quartzite. Syncline is overturned to northwest and beds dip southeast.

D. M. Scotford, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 49. Phyllites of Sugarloaf area, which have been considered volcanic members of Glenarm series (Stose and Stose, 1946) are Harpers phyllite. Stose and Stose divided this phyllite into the Ijamsville and Urbana. Although this division may be valid, it is difficult to map contacts accurately, and they are here considered to be part of the Harpers. Area is interpreted as anticlinal dome.

A. J. Stose and G. W. Stose, 1951, Geol. Soc. America Bull., v. 62, no. 6. p. 697–699. Discussion of article by Scotford. Stose and Stose interpret area as synclinal.

U.S. Geological Survey currently considers the age of the Glenarm series to be Lower Paleozoic(?).

Named from Urbana, Frederick County, Md. Mapped in a belt 4 miles wide, adjacent to Sugarloaf Mountain; has been traced a maximum of 12 miles northeastward to narrow tongues, where it apparently interfingers with the metabasalt.

Utah Metals Limestone[1]

Pennsylvanian: Utah.

Original reference: O. P. Peterson, 1924, Am. Inst. Mining Metall. Engineers Trans., v. 70, p. 908–926.

Probably named for mine in Bingham district.

**Ute Limestone**[1]

Middle Cambrian: Northeastern Utah and southeastern Idaho.

Original reference: C. King, 1876, Am. Jour. Sci., 3d, v. 11, p. 477.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1113–1114, 1116, 1117 (fig. 4), 1120–1121. Walcott's (1908, Smithsonian Misc. Colln., v. 53, no. 1804) Blacksmith Fork section emended. Thickness 685 feet. Shale at base of formation cannot be correlated with Spence shale of Idaho. Overlies Langston limestone; underlies Blacksmith dolomite (emended).

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 9–10, pls. 1, 6. Described in Randolph quadrangle, Utah, where it is 480 to 585 feet thick and considered to include Spence shale member. Overlies Langston limestone and underlies Blacksmith limestone.

J. S. Williams and G. B. Maxey, 1941, Am. Jour. Sci., v. 239, no. 4, p. 280, 281; J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1133. Restricted to exclude Spence shale member, which is herein reallocated to Langston formation.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 653–654, 670 (fig. 2), 671–672, 673 (fig. 3). Maximum thickness is 745 feet at High Creek, Utah; estimated thickness 790 feet at Promontory Point, Utah.

Type locality: Slopes of Ute Peak, near forks of East Fork, east of Paradise, Cache County, Utah.

**Ute Canyon Tongue** (of Cliff House Sandstone)

Upper Cretaceous: Northwestern New Mexico.

P. T. Hays and A. D. Zapp, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–144, sheet 1. In central part of Barker dome-Fruitland area, the Cliff House sandstone consists of two massive sandstone bodies separated by approximately 350 feet of shaly sandstone. Upper sandstone thins northeastward and in northeastern part of area is represented by thin sandy stratum not differentiated from enclosing Lewis shale. This wedge is called Ute Canyon tongue.

Stratigraphic relations of this sandstone wedge well displayed in exposures in Ute Canyon in southeastern part of Ute Mountain Indian Reservation, San Juan County.

†Ute Pass Dolomite

Upper Cambrian(?): Central Colorado.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 39. Name applied to dolomite unit which rests with gradational contact on Sawatch sandstone and underlies Manitou limestone (as restricted in this report). Thicknesses of 8½ to 16 feet measured in Gove Canyon, Williams Canyon, and Missouri Gulch. There is little difference in lithologic character of formation at these localities. Red glauconitic coarsely crystalline dolomite predominates although a few feet of pinkish-buff coarsely crystalline dolomite is present at top in Williams Canyon exposure. Amount of sand in dolomite beds appears to increase to north because outcrop in Gove Canyon is very sandy and that in Williams Canyon only slightly sandy. In Missouri Gulch section, formation consists of sandy micaceous dolomite beds in lower part, separated by 6 inches of brown platy shale from nonsandy dolomite beds in upper part. Paper-thin green shale partings present near middle of formation in Williams Canyon.

R. R. Berg and R. J. Ross, Jr., 1959, Jour. Paleontology, v. 33, no. 1, p. 106–108. Term abandoned. On basis of faunal correlations, unit formerly called Ute Pass at Williams Canyon is reassigned to lower part of Manitou formation. On basis of lithology and stratigraphic position, Ute Pass of Missouri Gulch is correlated with Peerless formation.

Type section: In Williams Canyon, NW¼ sec. 32, T. 13 S., R. 67 W., Ute Pass area, El Paso County.

Utica Clay (in Carbondale Formation)

Pennsylvanian: Northern Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 25, 106. Fire clay in lower part of Carbondale formation. Extends from La Salle Third vein (Colchester No. 2) coal down to base of Pennsylvanian.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 56 (table 3). Term discontinued.

Occurs near Utica, La Salle County.

†Utica Limestone[1]

Silurian: Southeastern Indiana.

Original reference: W. W. Borden, 1874, Indiana Geol. Survey 5th Ann. Rept., p. 143, 172.

Quarried at Utica, on Ohio River, in Clark County.

Utica Quartz Monzonite Porphyry[1]

Tertiary: Central northern Colorado.

Original reference: F. G. Worcester, 1921, Colorado Geol. Survey Bull. 21, p. 31–32.

Occurs as dike extending for about one-half mile southeast from Utica mine in Boulder County.

**Utica Shale**[1]

Upper Ordovician: New York and Michigan, and Ontario, Canada.

Original reference: E. Emmons, 1842, Geology of New York, pt. 2, div. 4, geol. 2d dist., p. 116–118, 183, 278, 319, 397, 429.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 233–302. Nomenclature of Utica shales is complex and confusing. At type locality, the Utica is probably wholly upper Utica, but, in sections a few miles east of city, the formation is separable into three faunal divisions. Lower two are probably of Cobourg age, but upper seems equivalent to Deer River and Atwater Creek shales of northwestern New York and to Collingwood and Gloucester formations of Ontario. Thus, a single member of the Utica, when traced laterally, becomes equivalent to two formations. It is confusing to consider the zones of the Utica as members of the formation. Nowadaga member has been defined as "lower Utica or zone of *Climacograptus typicalis*" (Hall). Loyal Creek member has been defined as "middle Utica, or zone of *Dicranograptus nicholsoni*" Hopkinson. Holland Patent member is "upper Utica, or zone of *Climacograptus pygmeus*" and *Glossograptus quadrimucronatus timidus* of Ruedemann. Overlies Canajoharie.

Marshall Kay, 1960, Internat. Geol. Cong. 21st, Copenhagen, pt. 7, p. 31. Pictonian stage of Trentonian series contains Utica group of formations.

Named for exposures at Utica, Oneida County, N.Y.

Utley Metarhyolite[1]

Precambrian: Central southern Wisconsin.

Original reference: S. Weidman, 1898, Wisconsin Geol. Nat. Hist. Survey Bull. 3, Sci. ser. 2, p. 4–31.

O. E. Gram, 1947, Jour. Geology, v. 55, no. 5, p. 427–438. Porphyritic meta-rhyolite. Phenocrysts of quartz and feldspar range from less than one-sixteenth to three-eighths inch in diameter. Groundmass uniformly aphanitic and almost glassy in hand specimen, and of very dark to black color.

Consists of rounded knoblike area more than 100 feet high at Utley, Green Lake County.

**Utopia Limestone[1] Member** (of Howard Limestone)

Pennsylvanian (Virgil Series): Eastern Kansas, Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 21, 94, 96.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 209. Uppermost member of Howard limestone. Underlies White Cloud shale; overlies Winzeler shale member of Howard limestone. Type locality designated.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 19. Mentioned as occurring in Iowa.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 57 (fig. 22), 61–63. Gray to brown limestone and sandy limestone resembling coquina in many outcrops. Consists of two or more limestones and ostracode-bearing shale in parts of the State. Thickness ranges from less than 1 foot to maximum of about 16 feet.

F. C. Greene and W. V. Searight, 1959, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 20. Church, Winzeler, and Utopia members distinguishable in Missouri.

Type locality: Just east of village of Utopia, sec. 5, T. 25 S., R. 11 E., Greenwood County, Kans.

Utuado Complex

Post-Lower Cretaceous, pre-lower Miocene: Puerto Rico.

R. C. Mitchell, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2972. Incidental mention.

**Uvalde Gravel[1]**

Uvalde Formation

Pliocene(?): Southern Texas.

Original reference: R. T. Hill, 1891, Am. Geologist, v. 7, p. 368.

R. W. Mathis, 1944, Jour. Sed. Petrology, v. 14, no. 2, p. 87. Formation near Austin consists almost wholly of rounded flint cobbles and boulders and occasional limestone pebbles. Accumulations of this material are extensive coastward from Balcones fault. In vicinity of Austin, accumulations are on hilltops at elevations up to 320 feet above river level; they are not at definite level and do not form continuous deposit. Delaney gravel (new) tops hill 245 feet above river level on Delaney Ranch; this is lower than Uvalde formation.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1703 (fig. 8), 1704–1707. Uvalde gravels discussed with Quaternary deposits of Texas Coastal Plain. Uvalde is restricted to deposits herein described, though it is possible that Uvalde of other geologists perhaps included writer's [Weeks] Uvalde as well as remnants of older terrace deposits which are no longer in place and which have come down from higher levels as erosion progressed. Writer [Weeks] does not agree with Mathis' (1944) views on Uvalde formation or Delaney gravel; Delaney gravel may have come down from higher levels as erosion progressed and therefore may not be in place. Uvalde occurs between terrace deposits termed Bastrop Park and Asylum. Pleistocene.

H. R. Blank and others, 1952, Texas Univ. Bur. Econ. Geology Rept. Inv. 12, p. 10 (table 1), 16. Upland gravel (Uvalde formation), as much as 1 foot thick, unconformably overlies Pecan Gap formation and unconformably underlies Brazos River terraces near Waco. Pliocene(?).

Named for occurrences in vicinity of Uvalde, Uvalde County.

Uvalde Phonolite[1]

Eocene(?): Southern Texas.

Original reference: T. W. Vaughan, 1900, U.S. Geol. Survey Geol. Atlas, Folio 64, p. 4, maps.

Occurs at Inge Mountain. Named for Uvalde, Uvalde County.

Uvas Basalt or Basaltic Andesite

Miocene: Southwestern New Mexico.

F. E. Kottlowski, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 32 (map), 40, 144, 145, 148 (chart). Dark-gray glassy rock. Interbedded with scoria and basaltic tuffs, as much as 145 feet thick near Las Cruces. Underlies Santa Fe group; overlies Bell Top formation (new).

In Las Cruces region of Rio Grande Valley.

Uvas Conglomerate Member (of Tejon Formation)

Eocene: Southern California.

J. G. Marks, 1941, (abs.) Geol. Soc. America Bull., v. 12, pt. 2, p. 1922; 1943, California Div. Mines Bull. 118, pt. 3, p. 535, 536 (fig. 232), 537 (fig. 233). Listed as basal member of Tejon formation in type area of Tejon. Thickness 110 feet. Conformably underlies Liveoak member (new); unconformably overlies basement complex.

Type locality: Grapevine Canyon, Tehachapi Mountains, Kern County.

**Uwekahuna Ash** (in Puna Volcanic Series)

Pleistocene or Recent: Hawaii Island, Hawaii.

J. B. Stone, 1926, Bernice P. Bishop Mus. Bull. 33, p. 27–28. Ash bed in wall of Kilauea caldera. Thickness 1 inch to 7 feet. At northeast end of exposure, bed is 3 feet thick and consists of gravel and a few lava-coated bombs; beneath Uwekahuna intrusive body is 6½ feet of ash having basal layer of medium-coarse black ash overlain by a second gravel stratum, and at top about 8 inches of yellow ash; at southwest end of exposure, ash bed lies on surface of unconformity in the lavas.

G. A. Macdonald, 1949, U.S. Geol. Survey Prof. Paper 214–D, p. 65, 67–68. Included in Puna volcanic series. Recent.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 134. Pleistocene or Recent.

Type locality: West wall of Kileau caldera at Uwekahuna Bluff.

Vaca Triste Sandstone Member (of Salado Formation)

Permian (Ochoa): Subsurface in southeastern New Mexico and western Texas.

J. E. Adams, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 11, p. 1600 (fig. 2), 1610. Fine-grained orange-red sand about 10 feet thick. Occurs between 1,555 and 1,565 feet in type well.

Type well: Continental's King well 1, sec. 26, T. 25 S., R. 32 E., Lea County, N. Mex. Name derived from Vaca Triste Draw.

Vacaville Shale

Eocene, lower or middle: Northern California.

C. W. Merriam and F. E. Turner, 1937, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 24, no. 6, p. 95 (fig. 1), 98 (table 1). Named on correlation chart. Occurs below unit termed Domengine (?). Middle Eocene.

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 129 (table), 133. Vacaville shales considered equivalent to Capay formation in age (lower Eocene).

Named for occurrence at Vacaville, Solano County.

Vadito Formation

Precambrian: Central northern New Mexico.

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 8 (fig. 2), 21–31, pl. 1. In general it comprises lower conglomerate member—thickness about 2,000 feet, and upper schist member—thickness about 2,500 feet. Lower member consists of quartzite and conglomerate interlayered with flows and sills. Upper schist member consists of quartz schists, phyllites, and granulites interlayered with thick flows and sills of various kinds of amphibolite. Younger than Ortega formation in Picuris area. Intruded by Embudo granite (new).

Named after village of Vadito, located near southeastern corner of Picuris range, and several miles south of excellent outcrops of rocks of this formation. Occurs in southern third of Picuris range, Taos County. Best exposures within 1-mile radius of Harding mine.

Valcour Limestone[1] or Formation

Ordovician (Chazyan): Western Vermont and eastern New York.

Original reference: H. P. Cushing, 1905, New York State Mus. Bull. 95.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 817–853. Formation included in Valcourian stage (new), Shazyan series. Thickness about 250 feet. Includes Hero member below and Beech member above (both new). Overlies Crown Point formation; underlies "Lowville" limestone. Reference section designated.

Reference section: Exposures on hill 0.6 mile southwest of Rutland Railroad Station of South Hero Vt. Forms northern and southeastern shores of Valcour Island.

Valcourian Stage

Ordovician (Chazyan): North America.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 91, 94 (table 2). Chazy has long been divided into three lithologic and faunal zones (Brainerd and Seely, 1888, Am. Geologist, v. 2) which were given "substage" names Day Point, Crown Point, and Valcour (Cushing, 1905, New York State Mus. Bull. 95). As stages, these have been called Dayan, Crownian, and Valcourian by Oxley (unpub. ms.).

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 833–838. In Champlain Valley, Chazy series is separable into Dayan, Crownian, and Valcourian stages, distinguished by faunal criteria. Each stage has several lithologic facies. Reefs are prevalent.

**Valders Stade**

Valderan Substage

Valders Glacial Substage

Pleistocene (Wisconsin): Northeastern Wisconsin.

F. T. Thwaites, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 121, 136–141. Wisconsin drift is divisible into deposits of Cary below and Valders substages. Name Valders proposed because of uncertainty of former correlations across brush- and forest-covered region around Lake Superior. Drift of Valders age is distinguished from Cary till by its red color and higher clay content; this lithologic criterion is not easily applicable in the northern part of district.

F. T. Thwaites, 1946, Outline of glacial geology, Ann Arbor, Mich., Edwards Bros., Inc., p. 75. Valders and Cary glaciations separated by Two Creeks interstadial.

M. M. Leighton, 1957, Jour. Geology, v. 65, no. 1, p. 108–109. Valders considered a substage of the Wisconsin succeeding the Mankato substage.

R. J. Mason, 1958, Michigan Univ. Mus. Anthropology, Anthropol. Paper 11, p. 22 (map 4), 23–25. Radiocarbon age determination places Valders maximum around 10,700 B. P. (before present); correlated with red drift in Wisconsin and Michigan. Two Creeks interstadial placed between Mankato and Valders substages.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 2 (fig. 1), 9. In classification proposed herein, Valderan substage is defined as youngest time-stratigraphic subdivision of Wisconsinan stage in Lake Michigan lobe. Base is defined as base of Valders till (Thwaites, 1946; Thwaites and Bertrand, 1957 Geol. Soc. America Bull., v. 68, no. 7) of eastern Wisconsin that overlies Two Creeks forest bed. Substage terminated with final dissipation of Wisconsinan continental glacier, even though glacial till representative of entire time span does not occur in Lake Michigan basin. Substage includes alluvial deposits made during time of rising sea level that is thought to have reached its present position of equilibrium about 5,000 years ago. Deposits of glacial till or of loess of Valderan age not known to occur in Illinois.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529, 549. Mankato-Valders intraglacial substage is herein named Two Creeks.

Name amended to Valders Stade to comply with Stratigraphic Code adopted 1961.

Name based on exposure in quarry at Valders, Manitowoc County.

**Valdez Group**[1]

Upper Mesozoic(?) : Central southern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 408–410, 413.

F. H. Moffit, 1954, U.S. Geol. Survey Bull. 989–E, p. 236, 242–247, 275, pl. 8. Workers who have studied sedimentary deposits of Prince William Sound region have accepted rocks around Port Valdez as typical of Valdez group and have agreed in assigning basaltic flows and intrusives, or greenstones as they are commonly called and massive conglomerate beds of Ellamar district to Orca group. Aside from these points held in common, there is no generally accepted definition of what constitutes Valdez and Orca groups, what are their limits, and what are stratigraphic and structural relations of the beds included in them. Valdez dominantly graywacke, argillite, and slate. Measured in thousands of feet. Part of the rocks assigned to Valdez group, in mountains north of Prince William Sound, not older than Late Cretaceous.

Typified by sedimentary rocks exposed about Port Valdez, Prince William Sound region.

**Vale Formation** (in Clear Fork Group)[1]

Lower Permian : Central and central northern Texas.

Original reference: J. W. Beede and V .V. Waite, 1918, Texas Univ. Bull. 1816, p. 47.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 42. Consists of Bullwagon dolomite at top and about 350 feet of red shale below; grades westward in subsurface as a unit so that thickness of basal red shale becomes less and less as amount of dolomite, gray shale, and anhydrite increases, although formation maintains its thickness of about 390 feet.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Underlies Choza formation; overlies Arroyo formation. Includes Bullwagon dolomite member at top. Leonard series.

Named for old post office on Ballinger-Maverick Road, on east side of Valley Creek, Runnels County.

Valencian series[1]

Precambrian: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico : Des Moines, Robert Henderson, State Printer, p. 4, 12.

Valentine Formation[1]

Valentine Member (of Curtin Formation)

Middle Ordovician : Central and central southern Pennsylvania.

Original reference: R. M. Field, 1919, Am. Jour. Sci., 4th ser., v. 48, p. 404, 414–417, 422.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 194 (table 2), 197. Rank reduced to member status in upper part of Curtin limestone (new). Overlies Valley View member (new). Underlies Nealmont limestone. Thickness at Bell Mine. Bellefonte, about 91 feet. Contains thin yellow clay—

metabentonite "A" at base; about 25 feet of very light-gray white-weathering dense laminated limestone; and about 66 feet of very light white-weathering dense heavy-ledged massive limestone ("Bellefonte Ledge") at top. Restricted to outcrop belts northwest of line from east of Lock Haven and Rebersburg to north of Millheim, Spring Mills, Lemont, and Stormstown, in Clinton and Centre Counties. Regional unconformity at base of overlying Nealmont gradually reduces unit toward line of extinction. Black River group.

Named for small hamlet and forge near Bellefonte, Centre County.

Valentine Formation (in Ogallala Group)

Valentine Member (of Ogallala Formation)

Valentine Beds[1]

Pliocene: Northwestern Nebraska, western Kansas, and southwestern South Dakota.

Original reference: E. H. Barbour and H. J. Cook, 1917, Nebraska Geol. Survey, v. 7, pt. 19, p. 173.

R. A. Stirton and P. O. McGrew, 1935, Am. Jour. Sci., 5th ser., v. 29, no. 170, p. 125–132. Three late Tertiary faunas representing two epochs were found in one formation near Valentine, Nebr., and following faunal names have been applied: Niobrara River, upper Miocene; Burge, lower Pliocene; and Valentine, transitional from lower to middle Pliocene.

F. W. Johnson, 1936, Am. Jour. Sci., 5th ser., v. 31, no. 186, p. 467–475. Paper reestablishes original and proper usage of name Valentine beds as designating lower part of Ogallala formation of Valentine area, northern Nebraska. Vertebrate fauna from these beds is known as Valentine fauna. Fine-grained sands and clays of Valentine beds are overlain by Burge sands, a name proposed for the fine- to coarse-grained sands and gravels in which Burge fauna typically occurs. Overlying the Burge is the cap rock bed that lithogically resembles typical Ogallala of southwestern Nebraska. Valentine beds are 175 to 225 feet thick and unconformably overlie Brule(?) clay of Oligocene(?) age. Lower part of Valentine beds is composed of loose channel sands, and it is in these beds that Valentine fauna occurs at type locality. In most places, the loose sand is overlain by beds of greenish-gray massive sandstones (upper Valentine beds). These massive sands are not very fossiliferous in Valentine area. The beds were called Fort Niobrara formation by Osborn (1918), but Valentine was used by Thorpe (1922, Am. Jour. Sci., 5th ser., v. 3) and other writers. Simpson (1933, Am. Mus. Nat. History Bull., v. 57, art. 3) recognized Valentine as having priority over Fort Niobrara and more firmly established the name in its correct usage. Name Valentine was first used erroneously when it was applied to upper fauna in area by Cook (1933, Nebraska Geol. Survey Paper 5). Stirton (1933, Am. Jour. Sci., ser. 5, v. 26, no. 156) assigned name Valentine to upper fauna in region and substituted term Niobrara River fauna for fauna from lower beds (Valentine beds). Usage of term Valentine when applied to upper fauna of area is incorrect. Term Valentine should be used to designate lower beds of area and their included fauna. Type locality designated.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, no. 213, p. 220–227. Discussion of Valentine problem and presentation of table of Tertiary stratigraphic divisions acceptable in Nebraska and Kansas. Tertiary is divisible into four lithologic groups (ascending): White River, Arikaree (redefined). Hemingford (new), and Ogallala redefined to include (ascending) Valentine, Ash Hollow, Sidney, and Kimball formations. Valentine formation, in Nebraska, includes *Stipidium* fossil seed zone; Burge channel member, and "Burge" fauna at top; the true Valentine fauna occurs well down in the formation. Thickness 175 to 225 feet. Overlies Hemingford group which includes Sheep Creek formation at top. Pliocene.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 134–139. Lower formation in Ogallala group. In type area, formation is composed largely of unconsolidated layers of greenish silty marl sand and sandy silt and very few local lenses of diatomaceous marl and light bluish-gray volcanic ash. Lowermost described occurrence of mammalian fauna is at so-called Railroad quarries on south side of Niobrara River south of Valentine, Nebr. This is Niobrara River fauna of Stirton and McGrew (1935). Channel sands from which this fauna has been collected are herein designated Niobrara River channel. Arboreous floral described by Chaney and Elias (1936, Carnegie Inst. Washington Pub. 476) from lower part of Valentine formation of White Bluff locality occurs in bed of diatomaceous marl herein designated Brown County bed. Highest known fauna in Valentine comes from Burge channel quarries. Seems best not to consider the Burge a channel member of the Valentine, but merely a channel within the undivided Valentine. Underlies Ash Hollow formation.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 20. Uppermost member of Ogallala formation in Kansas. Underlies Ash Hollow member. Maximum thickness 140 feet. Early Pliocene and possibly late Miocene. Major unconformity marks base of Tertiary rocks. They are known to rest on all subdivisions of Comanchean series (Cretaceous) and on Permian redbeds.

S. G. Collins, 1960, Geology of the Patricia quadrangle (1:62,500): South Dakota Geol. Survey. Lower formation in Ogallala group. Consists mostly of light-gray and light-olive-greenish, fine to medium, very poorly consolidated feldspathic or arkosic sand. Estimated thickness at least 175 feet. Grades upward into conformably overlying Ash Hollow formation. Underlies Harrison formation of Arikaree group.

Type locality: On south side of drainage cut between old and new railroad grades in NE¼ sec. 17, T. 33 N., R. 27 W., Cherry County, Nebr. Named for town of Valentine in Cherry County.

**Valentine Limestone** or **Dolomite Member** (of Sultan Limestone)[1]

Middle and Upper Devonian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 14.

J. C. Hazzard, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881, 884 (fig. 3). Geographically extended into Nopah Range, Inyo County, Calif., where it is 690 feet thick, overlies Ironside(?) member and underlies Crystal Pass limestone member. Suggested that name Stewart Valley limestone be abandoned and that Devonian beds ascribed to it be assigned to Crystal Pass and Valentine members of Sultan.

U.S. Geological Survey currently designates the age of the Sultan Limestone and its members as Middle and Upper Devonian.

Well exposed east of Valentine mine in sec. 23, T. 25 S., R. 58 E., Clark County, Nev.

**Valera Shale Member** (of Belle Plains Formation)[1]

Valera Shale and Anhydrite (in Belle Plains Group)

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 426.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Belle Plains here given group status.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Member of Belle Plains formation. An unfossiliferous dark-blue clay shale unit, 25 to 50 feet thick, that occurs next above Jagger Bend limestone member. Well expressed topographically along most of its outcrop, but near Colorado River upper boundary of unit is ill. defined. Underlies Bead Mountain limestone member.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 274. Valera shale member is 65 to 180 feet thick in Brazos River valley. Overlies Jagger Bend limestone member; underlies Bead Mountain limestone member.

Named from town of Valera, west-central Coleman County.

Vallecito Basalt

Quaternary: North-central New Mexico.

H. T. U. Smith, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 103. Named as third in series of seven Quaternary formations in area. Younger than Canones andesite; older than Black Mesa basalt.

Occurs in Abiquiu quadrangle, Rio Arriba County.

**Vallecito Conglomerate** (in Needle Mountains Group)[1]

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 131.

N. E. A. Hinds, 1939, 6th Pacific Sci. Cong. Proc., v. 1, p. 290. Mentioned in discussion of Precambrian formations of western North America. Thickness 2,000 feet; underlies Uncompahgran quartzite.

Named for exposures on both sides of Vallecito Creek for about 1 mile north from south boundary of Needle Mountains quadrangle.

Vallecitos Rhyolites

Precambrian (Proterozoic): Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 13 (table 1), 44, pl. 3. A number of rhyolite and trachyte flows, contained in Hopewell series and Ortega quartzite. Trachyte subordinate to rhyolite in amount. In some places, flows are somewhat schistose, but characteristically their original textures (aphanitic ground masses with distinct phenocrysts up to a quarter inch in diameter) have been well preserved and flow banding is well developed. Range in color from deep pink to brick red. Flows are as much as three-fourths mile thick. Thicknesses presumably represent aggregates of flows rather than single flows.

Exposed in mountainous area between towns of Petaca and Vallecitos, Rio Arriba County.

Vallejo Formation

Eocene or Oligocene: Central southern Colorado.

J. E. Upson, 1941, Am. Jour. Sci., v. 239, no. 8, p. 577–589. Consists of fine-grained unconsolidated but compact silt and clay with thin lenses of cemented sand and fine gravel, and thick layers of coarse gravel containing rounded cobbles. Whole formation stained dark-red in marked contrast to other beds of region. Thickness from 0 to 500 feet. Rests on Precambrian basement rocks; in some places, it underlies unnamed volcanics believed to be mid-Tertiary in age, in other localities, it unconformably underlies Hinsdale beds.

Named from Vallejo Creek in whose valley characteristics of the beds are well displayed. Apparently restricted to the Culebra Re-entrant along west flank of Culebra Range.

**Vallenar Formation**[1]

Middle Devonian: Southeastern Alaska.

Original reference: A. H. Brooks, 1902, U.S. Geol. Survey Prof. Paper 1, p. 40–52, map.

Mapped as broad belt on west side of Gravina Island, but was positively identified only at Vallenar Bay, Ketchikan region.

†Valley Limestone[1]

Cambrian and Ordovician: Eastern Pennsylvania to northern Virginia.

Original reference: P. Frazer, Jr., 1883, Pennsylvania 2d Geol. Survey Rept. $C_4$, p. 99–100, 112–144.

Named for Great Valley of Appalachian region, of which Shenandoah Valley is a part.

†Valley Forge Quartzite[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: F. Bascom, 1904, Am. Jour. Sci., 4th, v. 17, p. 143.

Philadelphia region.

Valley Head Sandstone[1]

Upper Devonian: Eastern West Virginia.

Original reference: D. B. Reger, 1928, Am. Jour. Sci., 5th, v. 15, p. 50–57.

G. A. Cooper, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart above Elkins sandstone and below Hendricks sandstone.

Well exposed at village of Valley Head, Randolph County.

Valley Heads Drift

Valley Heads Substage

Pleistocene (Wisconsin): Southwestern New York.

Paul MacClintock and E. T. Apfel, 1944, Geol. Soc. America Bull., v. 55, no. 10, p. 1145 (fig. 1), 1159–1161, pl. 1. Based primarily on lithologic differences, three Wisconsin drift sheets are recognized (ascending): Olean, Binghamton, and Valley Heads, Valley Heads drift covers inner, or north edge of Binghamton drift in area of this report [southwestern New York].

L. C. Peltier, 1949, Pennsylvania Geol. Survey, 4th ser., Bull. G–23, p. 4 (table 1), 16 (fig. 5). Referred to as Valley Heads substage in discussion of glacial geology of Susquehanna River terraces.

Derivation of name not given. Valley Heads moraine enters New York from west and is continuation of Lake Escarpment morainic system (Leverett, 1902, U.S. Geol. Survey Mon. 41).

Valley Mountain facies (of Flagstaff Formation)

Paleocene, upper: Central Utah.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., no. 8, p. 26–28, pl. 11. In general, Flagstaff formation in Valley Mountains grades from dominantly yellow and gray with some red dense lacustrine limestone in northern area to dominantly red and pink, partly arenaceous limestone with some sandstone and conglomerate in southern area. Southern type of lithology continues into Pavant Plateau and becomes more clastic. Formation thickens southward from over 1,100 feet in Hayes Canyon to about 1,400 feet in southern Valley Mountains. Divisible into five lithologic units, three of which may be coincident with faunal zones—units A and B tend to thin southward, whereas C and E thicken in the same direction. Unit D is missing in southern Valley Mountains. Overlies North Horn formation; underlies Colton formation.

In Valley Mountains, Gunnison quadrangle, Sevier and Sanpete Counties. All five (A–E) lithologic units clearly exposed in Picket Canyon.

**Valley Spring Gneiss**[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey Ann. Rept., p. lvi, 274, pl. 3.

V. E. Barnes, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 56 [1945]. Intruded by Big Branch Gneiss.

Virgil Barnes, Frederick Romberg, and W. A. Anderson, 1954, Internat. Geol. Cong., 19th, Algiers 1952, Comptes rendus, sec. 9, pt. 9, p. 152–153. Oldest Precambrian rocks in Llano uplift are mostly light-colored, highly feldspathic metasediments named Valley Spring gneiss, followed by dark-colored metasediments, including amphibolite, mica schist, graphite schist, and some marble, all of which are included in Packsaddle schist. These rocks are highly folded, and during folding it is believed the igneous rocks were intruded which were metamorphosed into Red Mountain gneiss and dioritic Big Branch gneiss. Date of intrusion of perioditic rocks, now serpentized into Coal Creek serpentine, in relation to Big Branch gneiss not satisfactorily determined. Town Mountain granite invaded the already deformed metasediments and was followed by Oatman Creek granite, Sixmile granite, and Llanite, the latter being the youngest.

Named for Valley Spring, Llano County.

**Valley Springs Formation**[1]

Miocene, upper(?): Northern California.

Original reference: A. M. Piper and others, 1939, U.S. Geol. Survey Water-Supply Paper 780, p. 34 (table), 71–80, pl. 1.

J. H. Eric, A. A. Stromquist, and C. M. Swinney, 1955, California Div. Mines Spec. Rept. 41, p. 16–18, pls. 1, 3. Described in Angels Camp quadrangle as interbedded white to light-gray rhyolite tuff and gravel containing pebbles and cobbles of rocks of pre-Tertiary age. Maximum thickness about 200 feet. Unconformably underlies Mehrten formation; unconformably overlies auriferous river gravel of Eocene(?) age. Miocene(?).

Type section: West slope of Valley Springs Peak, 1½ miles northwest of Valley Springs, near center sec. 11, T. 4 N., R. 10 E., Calaveras County.

**Valleytown Formation**[1]

Lower Cambrian: Western North Carolina, central northern Georgia, and eastern Tennessee.

Original reference: A. Keith, 1907, U.S. Geol. Survey Geol. Atlas, Folio 143, p. 4.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 285. Green phyllite, slate, and ottrelite-mica schist overlie Big Butt (Tusquitee) quartzite in Murphy syncline. Keith (1907) separated these rocks into Brasstown schist and Valleytown formation. Only locally is there lithologic criteria for separating these rocks into two formations. The phyllites and schists for the most part are closely folded and have prominently developed schistosity which obscures the bedding so that, on stratigraphic evidence available, they are not readily divisible. In this report, these two formations are treated as Valleytown formation, the more widely used name.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27. Included in Talladega series believed to be Precambrian.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 48–51. In Mineral Bluff quadrangle, Ga., Keith's (1907) sequence is not entirely applicable. Rocks mapped by LaForge and Phalen (1913, U.S. Geol. Survey Geol. Atlas, Folio 187) as Valleytown formation belong to four formations: Brasstown, Andrews schist, Nottely quartzite, and Mineral Bluff (new). As originally defined, the Valleytown is without definite lower boundary and is lithologically indistinguishable from underlying beds, therefore name Valleytown is not retained. Rocks between Tusquitee quartzite and Murphy marble all conform to Keith's description of the Brasstown and they are renamed Brasstown formation.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 32; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Lower Cambrian(?).

Named for exposures in vicinity of Valleytown, Cherokee County, N.C.

Valley View Member (of Curtin Limestone)

Middle Ordovician (Trentonian): Central Pennsylvania.

G. M. Kay, 1943, Econ. Geology, v. 48, no. 3, p. 194, 197–200. Lower member of Curtin limestone (new). An impure cherty fine- to medium-textured heavy ledge, in part, gray limestone with argillaceous partings and interbeds. Contains four metabentonites (B–E); top of member is at base of metabentonite A. Thickness 52 feet in type section. Remarkably constant in character and thickness from Nippenose Valley, south of Jersey Shore, to Pleasant Gap and western end of Bellefonte district. Underlies redefined Valentine member in type section; also underlies Nealmont limestone. Overlies Stover member of Benner limestone. Persists to limit of distribution of Curtin, though bevelled by unconformably overlying Nealmont near limit.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 20–21. Beds between metabentonites E and D have been termed "Lemont member of Carlim". Upper part of unit has been classified as "Lowville." It is preferable to use a local name since precise correlation with Lowville of New York uncertain. Unit has also been included in an expanded "Valentine formation".

Type section: In quarry wall south of headframe of Bell mine of American Lime and Stone Company at Bellefonte, Centre County. Named from hamlet 2 miles southwest of Bell mine.

Valmeyer Series[1]

Mississippian: Mississippi Valley.

Original reference: R. C. Moore, 1933, Historical geology; New York, McGraw-Hill Book Co., p. 261–264.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 132. Series is sequence of dominantly limestone strata, which succeed each other conformably except upon flank of Ozark area where several unconformities have been recognized. Overlies Kinderhook series unconformably in Mississippi Valley and overlaps those beds onto strata as old as Ordovician. Includes Osage and Meramec groups.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 12. Illinois Geological Survey accepts the name Valmeyer series to include Osage and Meramec groups.

Name derived from southern Illinois where rocks of series are well exposed.

Valmont Dolomite

Upper Ordovician: South-central New Mexico.

L. C. Pray, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1897 (fig. 2), 1899 (fig. 4), 1900 (fig. 5), 1902, 1906–1911. Name proposed for strata consisting predominantly of light-gray-weathering thin- to medium-bedded sublithographic dolomite lying between underlying cherty member of Montoya formation and generally massive darker and more coarsely crystalline dolomite termed "upper member of Fusselman limestone" by Darton (1917, U.S. Geol. Survey Prof. Paper 108–C). Thickness 150 to 225 feet. A few feet of argillaceous dolomite from 40 to 70 feet above base divides formation into two members. Fossils from lower member are upper Ordovician, those from upper member are indeterminate as Upper Ordovician or Silurian. Underlies Fusselman (?) formation.

L. C. Pray, 1958, West Texas Geol. Soc. Guidebook Field Trip Nov. 6, 7, 8, p. 35. Valmont dolomite is equivalent to Cutter dolomite of Caballo Mountains, and latter term has priority on basis of date of publication.

Type section: On northeast side of Alamo Canyon in SE¼SW¼SW¼ sec. 6, T. 17 S., R. 11 E., Sacramento Mountains, Otero County. Name derived from station of Valmont on Southern Pacific Railroad in sec. 14, T. 18 S., R. 9 E., about 10 miles south of Alamogordo.

**Valmonte Diatomite Member** (of Monterey Shale)[1]

Miocene, upper: Southern California.

Original reference: W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 2, p. 143.

W. P. Woodring, M. N. Bramlette, and W. S. W. Kew, 1946, U.S. Geol. Survey Prof. Paper 207, p. 11 (fig. 3), 14 (table), 15 (fig. 4), 33–35, pl. 1. Relatively pure diatomaceous strata. Diatomite occurs as layers of laminae of varying thickness; in some areas, thinly laminated diatomite forms units several feet thick alternating with massive diatomaceous mudstone; in other areas, entire exposed thickness consists of laminated diatomite and diatomaceous shale containing varying proportions of diatoms. Thickness 300 to 500 feet. Underlies Malaga mudstone member; overlies Altamira shale member.

Type region: Along lower course of Agua Negra Canyon, southeast of Valmonte residential district, where diatomite is quarried and processed. Palos Verdes Hills area, Los Angeles County.

**Valmy Formation**

Lower, Middle, and Upper Ordovician: North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler Peak quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-10]. Interbedded quartzite, chert, argillite, slate, and a little intercalated greenstone (altered andesitic lava). Quartzites thick-bedded to massive, medium to coarse grained. Chert is gray, green, brown, and black with argillite interbeds and partings. Intercalated greenstones include pillow lavas. Thickness estimated at more than 3,000 feet, may be as much as 5,000 feet. In thrust contact with Comus formation (new). Middle(?) Ordovician.

H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-15]. Type locality designated.

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2823 (fig. 5), 2832-2833. Lower, Middle, and Upper Ordovician.

Type locality: North Peak, 8 miles south of Valmy, a station on the Southern Pacific Railway, Golconda quadrangle.

Valparaiso Till or Drift

Pleistocene (Wisconsin): Northeastern Illinois.

J. H. Bretz, 1939, Illinois Geol. Survey Bull. 65, pt. 1, p. 52, 53, 55. A till about 10 feet thick; overlies Lemont drift (new).

Leland Horberg and P. E. Potter, 1955, Illinois Geol. Survey Rept. Inv. 185, p. 9 (fig. 2), 10, 12. Differentiated from overlying Tinley drift primarily on basis of morphology and areal relations; in a few places, such as Worth gravel pit [near Chicago], the two tills occur together stratigraphically; here they are differentiated by unconformity with basal gravel and greater abundance of Devonian shale pebbles in Tinley.

Named for town of Valparaiso, Ind., which is situated on Valparaiso moraine.

Valverde flags[1]

Upper Cretaceous (Gulf Series): Southern Texas.

Original reference: E. T. Dumble, 1892, Geol. Soc. America Bull., v. 3, p. 221, 229, 230.

Named for Val Verde County.

Val Verde Tonalite

Jurassic(?): Southern California.

R. W. Wilson, 1937, Am. Mineralogist, v. 22, no. 2, p. 122-130. Coarse-grained rock, medium dark in color, and varying only slightly in composition throughout district. Constant feature is presence of abundant dark fine-grained rounded inclusions that vary from a few inches to several feet in diameter. In some places inclusions occur in swarms making up 50 percent or more of rock.

E. F. Osborn, 1939, Geol. Soc. America Bull., v. 50, no. 6, p. 921–950. Discussion of structural petrology of Val Verde tonalite. Name credited to F. L. Ransome (1932, unpub. rept.). Footnote states that Val Verde tonalite is same as Perris quartz diorite of Dudley (1935).

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 481, table 4. Plutonic sequence lists Perris and Estelle quartz diorite (Val Verde tonalite) as older than Lakeview quartz monzonite and younger than Virginia quartz norite. Late Mesozoic.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 58. In this report, name Bonsall tonalite replaces name Val Verde tonalite as used by Osborn (1939).

Crops out in Val Verde district, a part of the Perris fault block in Riverside County. Probably named for railroad station of Val Verde.

**Vamoosa Formation**[1]

Pennsylvanian (Virgil Series) : Central Oklahoma.

Original reference: G. D. Morgan, 1924, Bur. Geol. [Oklahoma] Bull. 2, p. 125–128, pls. 3, 27, map.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 119 (fig. 1), 121 (fig. 2), 122. Unconformably overlies Tallant formation (new). Includes Cheshewalla sandstone at base.

W. F. Tanner, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 2046–2050. Unconformably overlies Hilltop formation (new).

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 80–84, pl. 1. In type area, Vamoosa conformably overlies Belle City limestone and is overlapped by overlying Ada so that only lower shale and about 30 feet of clastic part of formation are exposed near town of Byng. In Okfuskee County, the Vamoosa strike-overlaps Tallant and Barnsdall formations and is conformably overlain by "Pawhuska" formation. Discovery of unconformity at base of lowermost conglomerate of Vamoosa necessitates redefinition of formation. Vamoosa (as used by Morgan) is herein redefined and restricted so that its lower boundary is extended upward to unconformity at base of lowermost conglomerate (Boley conglomerate member, new) in formation. Thickness 650 to 690 feet in Okfuskee County. This unconformity makes it possible to establish a natural boundary for base of formation and also establishes natural Missouri-Virgil series boundary.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 89–98, pls. 1, 2. Described in Seminole County where it consists of a sequence of shales, sandstones, and chert conglomerates, thinning southward as result of numerous periods of erosion. Coarsest conglomerates are in middle and lower parts of formation. Three highest members of formation have been mapped across northern and central parts of county as Pawhuska or Lecompton limestone by some geologists. This report does not so consider them; they, like the overlying Pawhuska of Okfuskee County, are truncated by overlying Ada formation at more or less regular intervals. Thickness 125 to 550 feet. Includes Boley conglomerate member at base. Unconformably overlies Hilltop formation.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 39–54, pl. 1. Lower part of Vamoosa formation described in Osage County where it consists of gray-green, blue-green, and maroon shale, sandstone and siltstone, and thin limestones. Thickness 250 to 310 feet. Named and mapped members include (ascending) Cheshewalla sandstone, Bowring limestone (new), Kiheki sandstone (new), Labadie sandstone, Cochahee sandstone, Bowhan sandstone, Jonesburg sandstone, Wynona sandstone, and Oread limestone. Overlies Tallant formation.

K. E. Masters, 1957, Shale Shaker, v. 7, no. 5, p. 8, 10. Bird Creek limestone considered upper bed of Vamoosa in Prague area, Lincoln and Pottawatomie Counties, Okla.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 43–47, pls. 1, 2. In present usage, base of Vamoosa is at base of lowest conglomerate of Morgan's Vamoosa in Stonewall quadrangle and at base of similarly situated conglomerate and sandstone northward to Kansas-Oklahoma line. Top of formation from Kansas-Oklahoma line to North Canadian River, is at base of Lecompton limestone member of Pawhuska formation. South of North Canadian River, top of formation is at base of Ada formation. Thickness in Creek County 220 to 400 feet. Unconformably overlies Tallant formation; conformably underlies Pawhuska. South of Canadian River, unconformably overlain by Ada formation. Not known that unconformity at base of Ada extends north of North Canadian River but, if it does so, it is in rocks younger than Vamoosa formation, in rocks of Vanoss formation of this report.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 25 (table 2), 26 (fig. 6), 27–37, pls. 1, 2, 3. Formation in Pawnee County extends upward from Missouri-Virgil unconformity to base of Lecompton limestone member of Pawhuska. Thickness about 400 feet. Contains no conglomerate or coarse clastic beds. Many thick sandstone members present in southern part of county wedge out northward in width of one township. Others can be traced completely across county and continue into Osage County and southern Kansas with little change in thickness; still others thicken northward from little or no representation in Pawnee County to prominent sandstones in central and northern Osage County. Table 2 lists (ascending) Cheshewalla sandstone, Kiheki sandstone, Cochahee sandstone. Wynona sandstone, Oread limestone, and Kanawaka shale members. Of these only Kanawaka and Wynona can be positively identified. Formation included in Douglas-Shawnee group, Virgil series.

Named for exposures about one-half mile east of village of Vamoosa, Seminole County.

Vamos Vamos Beds[1]

Eocene or Oligocene: Panamá.

Original reference (Vamos Á Vamos): R. T. Hill, 1898, Harvard Coll. Mus. Comp. Zoology Bull., v. 28, no. 5, p. 179–180, 206–207.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 22–23; *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 349. Vamos Á Vamos beds are now interpreted as marine deposits in lower part of Bohio formation. Name should be Vamos Vamos.

Vamos Vamos is now submerged locality on French Canal, C.Z. Site is off northeast coast of present Barro Colorado Island.

Vanar Hills Volcanics

Tertiary: Southeastern Arizona.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 69–70, table 1, pl. 1. Flows, vitric tuffs, crystal tuffs, and pitchstone;

pinkish-gray latitic rocks, with phenocrysts of feldspar and biotite in an aphanitic hypocrystalline groundmass. Rock is similar, except for texture, to latite porphyry dikes and sills which intrude most of the rocks in the area. Probably middle or late Tertiary. Younger than Steins Mountain quartz latite porphyry (new) ; believed to be older than Weatherby Canyon ignimbrite (new).

Crop out in Vanar Hills, north of Arizona State Highway 68, in northwest corner of mapped area in central part of Peloncillo Mountains, Cochise County. Extend northward for undetermined distance.

**Van Bibber Shale Member** (of South Platte Formation)

Lower Cretaceous : North-central Colorado.

K. M. Waagé, 1955, U.S. Geol. Survey Prof. Paper 274–B, p. 31–33, figs. 10, 17, 19. Dark-gray refractory shale and silty shale with interbeds of fine-grained sandstone. Persistent kaolinitic marker at base of main refractory shale bed. Thickness at type section is 50 feet which is thickest of the many sections measured; more commonly member ranges from 35 to 45 feet thick. Unconformably underlies unnamed first sandstone subunit of South Platte formation (new) ; overlies Kassler sandstone member (new) of South Platte formation.

Type section: Composite of adjacent exposures on scarp of hogback, between 200 and 500 yards north of Van Bibber Creek; southernmost of these exposures, showing the main clay bed, is in airhole of Golden Fire Brick Co. mine. Named for exposures in vicinity of Van Bibber Creek, Golden quadrangle, Jefferson County.

**Van Buren Formation**[1]

Van Buren Member (of Gasconade Dolomite)

Lower Ordovician : Southeastern Missouri.

Original reference: H. S. McQueen, 1930, Insoluble residues as a guide in stratigraphic studies: Missouri Bur. Geology and Mines, separate.

O. R. Grawe, 1945, Missouri Geol. Survey and Water Resources, 2d ser., v. 30, p. 55–56. Basal zone of Gasconade is the Gunter. It is overlain by 80 to 125 feet of thin- to medium-bedded cherty dolomite which, in some Missouri Survey reports, is referred to as Van Buren formation, and this in turn is overlain by massively bedded, cherty dolomite 140 to 200 feet thick. In reports in which term Van Buren is used, term Gasconade is restricted to the upper cherty dolomite. In this report, Gasconade is used in unrestricted sense to include all strata between Eminence and Roubidoux.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 52). Shown on correlation chart as member of Gasconade dolomite.

R. D. Knight, 1954, Kansas Geol. Soc. Guidebook 17th Ann. Field Conf., p. 57. [Reprinted as Missouri Geol. Survey and Water Resources Rept. Inv. 17.] Gunter sandstone is considered member at base of Gasconade. Term Van Buren not used in Missouri.

Name derived from town of Van Buren, Carter County. Well exposed along U.S. Highway 60 west of Van Buren.

Vanceburg Black Shale[1]

Mississippian : Northeastern Kentucky.

Original reference: E. Orton, 1880, Review of strat. geology of eastern Ohio, p. 21, table.

Probably named for Vanceburg, Lewis County.

Vanceburg facies (of New Providence Formation)

Vanceburg sandstone facies[1] (of Cuyahoga Formation)

Vanceburg sandstone facies (of Logan Formation)

Lower Mississippian: Northern Kentucky and southern Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 657, 758–763.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 134, pl. 6. Vanceburg facies is northeasternmost one of New Providence formation in Kentucky; limited on outcrop to west-central and northern Lewis County. Thickness in vicinity of Vanceburg about 275 feet. Includes (ascending) Henley shale, Buena Vista siltstone, Rarden shale, Vanceburg siltstone, and Churn Creek shale members of formation. Considered Lower Mississippian.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 53, 54 (fig. 3), 62–64. In Ohio, considered facies of Logan formation. Includes Buena Vista sandstone, Rarden shale, Vanceburg siltstone, Churn Creek, and Vinton sandstone members. Lies to west of Scioto Valley shale facies.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 3 (table 1), 25. Here considered facies of Cuyahoga formation. Editor's note states that Hyde (1921, Ohio Geol. Survey Bull. 23) correlated Buena Vista sandstone with Berne and lower part of Byer in discussing geology of Camp Sherman quadrangle; such a correlation would necessitate placing Rarden, Vanceburg, Churn Creek and most of Portsmouth shale in Logan formation.

Well developed in vicinity of Vanceburg, Ky., and Buena Vista Ohio.

Vanceburg Sandstone Member (of Cuyahoga Formation)[1]

Vanceburg Siltstone Member (of Logan Formation)

Vanceburg Siltstone Member (of New Providence Formation)

Lower Mississippian: Northern Kentucky and southern Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 665. 758, 763, 768.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 134, pl. 6. Hyde's "Vanceburg member" is retained for the series of even-bedded siltstones constituting bulk of New Providence formation in area of Vanceburg facies. Just how much of the column should be included in this member and where stratigraphic limits should be placed are subject to question. Overlies Rarden shale member; underlies Churn Creek shale member. Considered Lower Mississippian.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 2), 62–63. Vanceburg siltstone member included in Vanceburg facies of Logan formation in Ohio. Thickness 80 to 150 feet. Overlies Rarden shale member; underlies Churn Creek member, no dependable horizon separates the two, the distinction being made on the basis of the larger sandstone content of Vanceburg.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 3 (table 1), 25. Here considered member of Cuyahoga formation in area of Vanceburg facies.

Editor's note states that Hyde (1921, Ohio Geol. Survey Bull. 23) correlated Buena Vista sandstone with Berne and lower part of Byer in discussing geology of Camp Sherman quadrangle; such correlation would necessitate placing Rarden, Vanceburg, Churn Creek, and most of Portsmouth shale in Logan formation.

Well developed in vicinity of Vanceburg, Ky., and Buena Vista, Ohio.

Van Cleve Flow (of Capulin Basalt)

Van Cleve Flow (of Clayton Basalt)

Quaternary: Northeastern New Mexico.

R. F. Collins, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1031. Dark-gray fine-grained vesicular olivine basalt.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 133, 137, 144. East of type locality, Clayton basalt consists of many long tongues. The basalt flows have been named, from south to north, Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that give rise to these basalts are unknown.

Nineteen mile flow from northeast flank of Sierra Grande east and northeast to Van Cleve, sec. 7, T. 29 N., R. 32 E, Union County.

†Vancouver Group[1]

Upper Cretaceous: Southwestern British Columbia, Canada, and northwestern Washington.

Original reference: C. A. White, 1889, U.S. Geol. Survey Bull. 51, p. 33.

Probably named for Vancouver Island, B.C.

Vanderburg Sandstone (in Dixon Formation)

Vanderburg Sandstone (in Henshaw Formation)[1]

Pennsylvanian: Western Kentucky.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 26.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 106. A division of Dixon formation, between Mount Gilead shale above and Bald Hill shale. [Apparently so designated by Glenn, 1922, Kentucky Geol. Survey, 6th ser., p. 5.]

Named for Vanderburg, Webster County.

**Vandever Member** (of Crab Orchard Mountains Formation)

**Vandever Shale** (in Lee Group)[1]

Vandever Formation (in Crab Orchard Mountains Group).

Vandever Member (of Lee Formation)

Lower Pennsylvanian: Eastern Tennessee and northern Georgia.

Original reference: Charles Butts, 1916, Tennessee Geol. Survey Resources of Tennessee, v. 6, p. 107–110.

H. R. Wanless, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1941. Listed as member of Lee formation.

V. H. Johnson, 1946, Coal deposits of Sand and Lookout Mountains, Dade and Walker Counties, Georgia: U.S. Geol. Survey Prelim. Map Geographically extended into northern Georgia where it is 150 to 200 feet thick; overlies Bon Air sandstone and underlies Rockcastle sandstone.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4, 19, pls. 2, 3, 4. Originally named Vandever shale, but presence of large amounts of sandstone in unit along eastern edge of Walden Ridge makes term formation more applicable. Over most of Walden Ridge, consists of three units: lower shaly part, prominent middle sandstone or conglomerate, and upper shaly part. Thickness less than 100 to more than 400 feet: near Vandever, where exposed along axis of an anticline, about 250 feet. Includes Lantana coal near base and Morgan Springs coal near top. Included in Crab Orchard Mountains group (new); underlies Rockcastle conglomerate; overlies Newton sandstone.

U.S. Geological Survey currently classifies the Vandever as a member of Crab Orchard Mountains Formation on the basis of a study now in progress.

Named for exposures at Vandever, Cumberland County, Tenn.

Vandusen cyclothem

Pennsylvanian (Pottsville Series): Southeastern Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 29, table 1, geol. map. Includes (ascending) Vandusen shale and (or) sandstone, 10 feet thick, clay, coal, and Lowellville or Poverty Run limestone (absent in Perry County). Occurs above Bear Run cyclothem and below Lower Mercer cyclothem. In area of this report, Pottsville series is described on cyclothemic basis; 10 cyclothems are named; [For sequence see Anthony cyclothem.]

Exposed in southeastern Perry County.

Vandusen Shales

Pennsylvanian (Pottsville Series): Eastern Ohio.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 67 (chart), 88–99. Vandusen shale horizon extends from top of Vandusen coal to base of Lower Mercer coal. Sandstones locally present. Average thickness about 24 feet.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 29. Vandusen shale and (or) sandstone included in Vandusen cyclothem.

Type locality and derivation of name not given.

Van Etten[1] zone

Upper Devonian: South-central New York.

Original reference: H. S. Williams, 1907, Jour. Geology, v. 15, p. 97, 108, 109.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Van Etten zone in Enfield formation. Occurs above Juliand zone.

Exposed along railroad cuts at Van Etten, Chemung County.

**Vanhem Formation** (in Sanborn Group)

Pleistocene and Recent: Southwestern Kansas.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no. 4, p. 69 (fig. 1), 84–87. Proposed for sediments laid down during cycle of deposition which followed entrenchment of streams into Kingsdown and older formations. Includes following lithologic units (ascending): (1) sand and gravel; (2) silt, (3) silt to clayey silt, and (4) loess. Thickness at type section 68 feet. Type section of the Vanhem is the section given by Smith (1940) as a typical section of the Kingsdown. Most exposures previously referred to or mapped as Kingsdown silt are of deposits younger than the Kingsdown formation and are part of the Vanhem.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Upper formation in Sanborn group in southwestern Kansas.

Type locality: In N½ sec. 13, and S½ sec. 12, T. 30 S., R. 23 W., Pyle Ranch, on north side of Bluff Creek, Clark County; type section is along west bluff of a small tributary of Bluff Creek in secs. 12 and 13, T. 30 S., R. 23 W.

**Van Horn Sandstone**[1]

Precambrian (?) : Western Texas.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 28.

P. B. King, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 145 (table), 152–153. Van Horn sandstone, as defined by Richardson, included red arkosic sandstones below and white quartzose sandstones above; the two parts were supposed to be conformable. Subsequent work has shown that the two parts of original formation are separated by well-marked unconformity. Proposed here to restrict name Van Horn to lower red arkosic part of original formation. Upper part included in Bliss sandstone. Maximum thickness of restricted Van Horn about 700 feet. Rests on truncated edges of Allamoore (new) and Hazel formations. Cambrian and Precambrian.

P. B. King and P. T. Flawn, 1953, Texas Univ. Bur. Econ. Geology Pub. 5301, p. 21 (table 1), 24, 25, 90–97. Precambrian (?).

Named for Van Horn, El Paso County.

Vanhornsville Sandstone[1]

Silurian (Niagaran) : Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Exposed at Vanhornsville, Herkimer County.

Vann Quartzite (in Chilhowee Group)

Lower Cambrian : Northwestern North Carolina.

G. W. Stose and A. J. Stose, 1947, Am. Jour. Sci., v. 245, no. 10, p. 626, 627, 629. Thick-bedded arkosic quartzite, shale, and hard feldspathic light-gray quartzite 1,200 to 1,400 feet thick. Underlies Sandsuck shale; unconformable above Precambrian granite gneiss, Keith [1904, U.S. Geol. Survey Geol. Atlas, Folio 116] used name Snowbird formation in this area.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 13 (table 3), 26. Vann quartzite is included in Snowbird formation in this report.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 300 (table 4). Table 4 lists Vann quartzite as late Precambrian.

Named from exposure at Vann Cliff on Spring Creek, near Hot Springs, Madison County.

†Van Nest Gap Gneiss[1]

Precambrian : Northern New Jersey.

Original reference: N. E. A. Hinds, 1921, Am. Jour. Sci., 5th, v. 1, p. 355–364.

Occurs at Van Nest Gap, near Oxford Furnace, Warren County.

Van Oser Member (of Jordan Sandstone)

Van Oser Submember (of Jordan Member of Trempealeau Formation)

Upper Cambrian (St. Croixian) : Southeastern Minnesota and southwestern Wisconsin.

C. R. Stauffer, G. M. Schwartz, and G. M. Thiel, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, p. 1902; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1238 (table 2), 1240. Coarse massive gray to white sandstone. Overlies Norwalk member. Forms uppermost division of St. Croixian series in Minnesota. Commonly overlain by Oneota dolomite. Has been referred to as *Tellerina-Saukiella* zone in Minnesota classification.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 48–49. Thickness about 40 feet at type locality of Jordan sandstone. Overlies Norwalk member.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 45, p. 93. In Stoddard quadrangle, Wisconsin, considered submember of Jordan member of Trempealeau formation.

Probably named for exposures on Van Oser Creek, Scott County, Minn.

**Vanoss Formation** (in Pontotoc Group)[1]

Pennsylvanian (Virgil Series) : Central southern Oklahoma.

Original reference: G. D. Morgan, 1924, Bur. Geology [Oklahoma] Bull. 2, p. 133–137, pls. 3, 27, map.

W. E. Ham, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2040–2044. The four principal conglomerates in the Arbuckle Mountains region are divisible into two general groups, older consisting of "Franks" and Deese, and younger consisting of Collings Ranch (new) and Vanoss. Each group is characterized by rocks of which the pebbles and cobbles in the conglomerates are composed. The Vanoss (youngest) contains granite feldspar, and vein quartz from Precambrian rocks that were exposed only after the highest uplift and deepest erosion of the Arbuckles. Formation consists of lower conglomerate member and an upper shale member. Combined maximum thickness about 1,550 feet. Conglomerate member has maximum thickness of 650 feet and is restricted to northern edge of mountains in area between Sulphur and Hennepin. Northward from Sulphur, the conglomerate member disappears by interfingering into shale member whereas, westward and southward around Arbuckle anticline it is overlapped by shale member. In area south of Sulphur, the Vanoss overlies Deese conglomerate. At most places, the rocks have gentle dips and are nonfaulted, although in a few areas they dip as much as 40° and are cut by small faults whose displacement dies out upward in conglomerate sequence. Collings Ranch and Vanoss conglomerates rest with pronounced angular unconformity on older rocks that were steeply folded during culmination of Arbuckle orogeny.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 103–108, pl. 1. Described in Seminole County where it overlies Ada formation or completely cuts out the Ada and rests on Arbuckle group. Underlies Permian

Konawa formation, locally unconformable. Consists of shales and sandstones, and in southern part of county, limy arkosic sandstones and conglomerates. Thickness 140 to 550 feet, thickening southward.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 51–52, pl. 1. In this report [Creek County], term "Vanoss" applies to all rocks from top of Lecompton limestone member of Pawhuska formation up to top of Pennsylvanian system, which, in northern Oklahoma and southern Kansas, is top of Brownville limestone. Term as so applied probably includes not only Morgan's (1924) Vanoss but also his Ada formation and lower part of his Konawa formation. Rocks to which term "Vanoss" is here applied crop out in a band 6 to 12 miles wide from North Canadian River, in northeastern Pottawatomie County and southwestern Okfuskee County, northeastward to Kansas-Oklahoma line in north-central Osage County. Maximum thickness in county about 300 feet. Intergrades laterally with Pawhuska formation and contains and interfingers with units named in northern Oklahoma and in Kansas, notably the Bird Creek and Wakrusa limestones.

Named for exposures in Vanoss, T. 3 N., R. 4 E., Pontotoc County.

Vanport flint, limestone, or shale member

*See* **Vanport Limestone** (in Allegheny Group) and Scrubgrass cyclothem.

**Vanport Limestone** (in Allegheny Group)

**Vanport Limestone Member** (in Allegheny Formation)[1]

Vanport Limestone Member (of Clarion Formation)

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 60–66.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 44–45, table 1. Vanport member of Scrubgrass cyclothem in report on Perry County. Composed of either milky-colored flint or chert, crystalline limestone, sandy limestone, calcareous limestone, or very fossiliferous shale. Flint facies dominates all others whereas limestone facies is more localized than any other. Thickness 4 inches to 2½ feet. Overlies Scrubgrass coal. Underlies Ferriferous member, Allegheny series.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 22 (table 5). Vanport limestone listed with recognizable members of Allegheny formation in Harrison County.

G. C. Williams, 1960, Jour. Paleontology, v. 34, no. 5, p. 910 (fig. 2). Member of Clarion formation. Above Clarion sandstone member and below Lower Kittanning sandstone. Allegheny group.

Named for exposures at Vanport, Beaver County, Pa.

Van Schaick[1] zone

Middle Ordovician: Eastern New York.

Original reference: R. Ruedemann and G. H. Chadwick, 1935, Science, new ser., v. 81, p. 400.

In Mohawk Valley.

Van Vacter Gypsum Member (of Blaine Formation)

Permian: Southwestern Oklahoma.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 17 (fig. 3), 26–28, pl. 1. Name applied to gypsum bed at top of Blaine formation (redefined). In type area, Van Vacter consists of lower and upper division of massive white and pink granular gypsum, respectively 14 and 18 feet thick, separated by 4 feet of red shale. Maximum thickness about 50 feet. Overlies Mangum dolomite member; underlies Dog Creek shale.

Type area: Along west branch of Boggy Creek, center E½ sec. 10 and center W½ sec. 11, T. 8 N., R. 22 W., about 2 miles northwest of Van Vacter ranchhouse, Beckham County.

Van Valkenurg Beds

[Recent?]: Central eastern Florida.

E. H. Sellards, 1940, Geol. Soc. America Bull., v. 51, no. 3, p. 381–385. Proposed for deposit of sand and muck that overlies Melbourne bone bed; contact erosional unconformity. Contains vertebrate fossils, human remains, and pottery. Thickness as much as 7 feet.

Irving Rouse, 1950, New York Acad. Sci. Trans., ser. 2, v. 12, no. 7, p. 220–222. Article correlates cultural periods with geologic intervals. The Valkenburg includes Malabar I (in part), Malabar II, St. Augustine, and Seminole. Malabar I may be dated between 750 and 1150 A.D.

Van Vleck Sands

Oligocene: Southern Texas (subsurface)

Alexander Deussen and K. D. Owen, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1617, 1630 (fig. 5), 1631 (fig. 6), 1634. Name suggested for thick body of sands, now commonly called the "Frio" in subsurface, that lie below a marine Oligocene shale wedge and above the Vicksburg. Approximately 2,900 feet thick; occupies interval between 8,100 and 11,000 feet below sea level in type well.

Typically displayed in well No. 21 (Skelly Oil Co., Cobb No. 14–B), at Van Vleck, Matagorda County.

**Vaqueros Sandstone**[1] or **Formation**

Vaqueros Stage

Oliogcene(?) and Miocene, lower: Southern California.

Original reference: H. Hamlin, 1904, U.S. Geol. Survey Water-Supply Paper 89.

Thomas Clements, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 2, p. 215, 216, (fig. 1). Formation, in Tejon quadrangle, overlies Sespe formation and underlies Temblor formation, marked angular unconformity.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 7–9, fig. 4. Vaqueros formation rests directly on quartz diorites of Santa Lucia Range; apparently attains thickness of about 4,000 feet; neither top nor bottom of formation at type locality has as yet been exactly defined. Underlies Monterey shale. Zemorrian and lower Saucesian.

J. E. Eaton, U. S. Grant, H. B. Allen, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 195–199, 204–205 (fig. 3), 212–213, 216–224, fig. 8. Discussion of Miocene of Caliente Range and environs. Marine Miocene of California is transgressive series, essentially conformable basinward, but revealing strandward two oscillations which respectively inaugurate and divide its upper third. It comprises three nearly equal natural divisions—Vaqueros, Temblor, and Monterey stages—which approximate lower, middle, and upper Miocene. Each of these has a more or less distinctive epeirogenic history, fauna, and average physical aspect. Vaqueros stage is divisible into a lower and an upper substage by minor but usually perceptible change in fauna that coincided with an acceleration of transgression about the middle of Vaqueros time. At Caliente Mountain, a homoclinal section exposes about 1,100 feet of upper Oligocene(?), 4,500 feet of Vaqueros, 4,700 feet of Temblor, and 4,600 feet of Monterey strata.

R. R. Thorup, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1957–1958; 1943, California Div. Mines Bull. 118, pt. 3, p. 463–466. Type Vaqueros formation restricted and five new formations named in Vaqueros Valley. Formation below restricted Vaqueros are (ascending) Junipero sandstone, Lucia shale, The Rocks sandstone, and Berry conglomerate. Restricted Vaqueros consists of about 2,000 feet of marine sandstone and interbedded siltstone containing "Vaqueros" fossils. Subdivided into six members (A to F); upper member considered to be of lower Saucesian age and lower members Zemorrian. Separated from overlying Monterey by Sandholdt formation (new).

J. E. Allen, 1946, California Div. Mines Bull. 133, p. 18 (fig. 2), 26–30. Vaqueros group, in San Juan Bautista quadrangle, consists of fossiliferous sandstones and red beds as much as 1,800 feet thick (commonly less) which form highest points of rolling hills near town of San Juan Bautista. Conformably overlies Pinecate formation, contact determined only by lowest horizon containing Vaqueros fossils; unconformably underlies lavas and agglomerates.

C. J. Leith, 1949, California Div. Mines Bull. 147, p. 12 (fig. 2), 21, pl. 1. In Hollister quadrangle, which borders Quien Sabe quadrangle on west, Taliaferro (unpub. ms.) reports maximum of 225 feet of sandstone, gravel, and limestone containing upper Vaqueros fossils; these [sediments] rest on Cretaceous and are overlain by Quien Sabe volcanics. These sediments thin eastward and, at boundary of Hollister and Quien Sabe quadrangles, the Vaqueros in this area gives new evidence on extent of lower Miocene sea and provides definite evidence for delineating lower limit of age of overlying volcanics.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 31–32, pls. 1, 3. Formation, in southwestern Santa Barbara County, is as much as 900 feet thick. Underlies Rincon shale; overlies Sespe formation, and in some areas, Alegria formation (new), a marine facies of continental Sespe.

J. E. Upson, 1951, U.S. Geol. Survey Water-Supply Paper 1108, p. 13–14, table facing p. 12, pls. 1, 2. Exposed low on south flank of Santa Ynez Mountains and crops out in small bodies southwest of Santa Barbara and near coast of Summerland. Average thickness about 350 feet. Overlies Sespe formation; underlies Rincon shale. Lower Miocene.

M. L. Hill, S. A. Carlson, and T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12 p. 2982 (fig. 5), 2983–2988. Discussion of Cuyama Valley-Caliente Range area. Lower Miocene marine sandstone and shale formation lying above Simmler (new) or older formations and conformably underlying Monterey shale or its time equivalent, is mapped as Vaqueros formation. Along northeast flank of La Panza Range, formation is composed almost entirely of standstone and averages about 500 feet in thickness. In Caliente Range, from Caliente Mountain northward, formation thickens to more than 7,000 feet and is made up of two members, here named Soda Lake shale below and Painted Rock sandstone above. Southeast of Caliente Mountain, consists of (ascending) Soda Lake sandstone, Soda Lake shale, and Painted Rock sandstone members. At southeastern end of the range and in Cuyama Badlands, the Vaqueros is about 700 feet thick and almost all sandstone. Thinning in this direction is in part the result of gradation of upper beds into overlying continental Caliente formation (new). In Salisbury Canyon, a sandstone 1,200 feet thick was mapped as Vaqueros by English (1916, U.S. Geol. Survey Bull. 621–M) ; it is here included in younger Branch Canyon formation (new).

U.S. Geological Survey currently designates the age of the Vaqueros as Oligocene(?) and lower Miocene on the basis of a study now in progress.

Type area: T. 20, T. 6 E., M. D. M., Junipero Serra quadrangle, Monterey County. Named for exposures on Los Vaqueros Creek.

**Vashon Stade**

**Vashon Drift**[1]

Vashon glacial epoch[1] or glaciation

Pleistocene (Wisconsin) : Western Washington.

Original reference: B. Willis, 1898, Geol. Soc. America Bull., v. 9, p. 111.

R. C. Newcomb, 1952, U.S. Geol. Survey Water-Supply Paper 1135, p. 18–26, 39–44, pls. 1, 2. Pleistocene deposits, in Snohomish County, consists, above sea level, of about 200 feet of Admiralty clay and as much as 1,000 feet of deposits of Vashon glaciation. The latter include as much as 300 feet of either clay or sand units of advance outwash, as much as 150 feet of till, and variable thicknesses of outwash-terrace and train material. Vashon drift includes Pilchuck clay and Esperance sand members (both new).

J. E. Sceva, 1957, U.S. Geol. Survey Water-Supply Paper 1413, p. 20–26, pls. 1, 3. Vashon drift, in Kitsap County, consists of advance outwash, till, and recessional outwash. Overlies Puyallup sand.

P. D. Snavely, Jr., and others, 1958, U.S. Geol. Survey Bull. 1053, p. 74–77, pl. 1. Vashon drift, consisting of outwash sand, gravel, and marginal terrace deposits, occurs above Logan Hill formation in Centralia-Chehalis district.

D. R. Crandell, D. R. Mullineaux, and H. H. Waldron, 1958, Am. Jour. Sci., v. 256, no. 6, p. 384–397. Pleistocene succession in Puget Sound Lowland is (ascending) Orting glaciation, Alderton nonglacial interval, Stuck glaciation (new), Puyallup nonglacial interval, Salmon Springs glaciation (new), erosion interval, and Vashon glaciation. According to Willis (1898) deposits of Vashon age include Vashon drift, Osceola tills, Oceola clays, and Douty gravels. Osceola till of Willis is now known to be a postglacial volcanic mudflow deposit from Mount Rainier. The Osceola clays and Douty gravels of Willis are glacial drift of Vashon age, and the two names are abandoned.

Named for occurrence on Vashon Island, Puget Sound region.

**Vasquez Formation**

Vasquez Series[1]

Oligocene and Miocene, lower(?): Southern California.

Original reference: R. P. Sharp, 1935, Pan-Am. Geologist, v. 63, no. 4, p. 314.

R. H. Jahns, 1939, Am. Jour. Sci., v. 237, no. 11, p. 820. In Mint Canyon-Bouquet Canyon area, Vasquez series underlies Tick Canyon formation (new).

L. F. Noble, 1953, Geology of the Pearland quadrangle, California: U.S. Geol. Survey Geol. Quad. Map [GQ–24]. Described as formation consisting of sedimentary and volcanic rocks, mostly well indurated and forming bold outcrops on mountain slopes south of San Andreas fault zone. Sediments lie at base of formation at one place but are absent elsewhere; they are well-bedded red sandstone, shale, and conglomerate composed mostly of granitic material but containing a few rhyolite cobbles. Volcanics constitute most of the formation and include lava flows of pyroxene basalt, andesite, dacite, and rhyolite and some interbedded tuff, ash, and breccia. Thickness more than 500 feet. Unconformably underlies Punchbowl formation (new); unconformably overlies basement rocks. Oligocene and lower Miocene(?).

G. B. Oakeshott, 1958, California Div. Mines Bull. 172, p. 23 (fig. 3), 59–62, pl. 1. Present north of San Gabriel fault. Formation distributed over several square miles of northeastern part of Soledad basin almost completely across northern part of San Fernando quadrangle. Occupies faulted structural basin plunging 25° to 40° toward the southwest from the northeastern corner of quadrangle. In upper Vasquez Canyon-Tick Canyon area, continuity of formation across quadrangle is interruped by exposure of gneissoid biotite-muscovite granite 1¼ miles wide between Mint Canyon fault and pre-Tick Canyon formation fault in Vasquez Canyon. Most complete and continuous section is in Escondido Canyon. Consists of total thickness of about 8,800 feet, comprised of 500 feet of basal conglomerate and sandstone lying on quartz-augite syenite at head of north branch of Escondido Canyon, 3,800 feet of basaltic volcanic rocks, and 4,500 feet of sandstone, shale, and conglomeraate, overlain unconformably by Mint Canyon formation at Agua Dulce Canyon. Also unconformably overlain by Tick Canyon formation, marked angular unconformity. In most places, it is in fault contact with granitic rocks; in several places, in northeastern corner of quadrangle, it lies unconformably on syenite and related hornblende diorite, both of probable Upper Jurassic or Lower Cretaceous age.

Named for outcrops at Vasquez Rock, in upper Agua Dulce Canyon, San Fernando quadrangle, Los Angeles County.

Vassalboro Sandstone[1] or Formation

Silurian(?): Southwestern Maine.

Original reference: E. H. Perkins and E. S. C. Smith, 1925, Am. Jour. Sci., 5th ser., v. 9, p. 204–228.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 124–125, table 1 facing p. 112. Termed a formation. Consists of massive bluish-gray sandstone, calcareous mica phyllite, biotite phyllite, and limestone and calcareous sandstone. Traced into Androscoggin formation near Litchfield. Silurian(?).

A. R. Cariani, 1959, Dissert, Abs., v. 19, no. 10, p. 2577. Correlates with Anson formation (new) on basis of similar lithology.

Well exposed in town of Vassalboro, Kennebec County.

Vatia Trachyte

Pleistocene(?): Samoa Island (Tutuila).

R. A. Daly, 1924, Carnegie Inst. Washington Pub. 340, p. 108–110, 129–130. Trachyte plug. Cuts older basalt flows. Pioarhyolite, Matafao, Papatele, Afono, and Vatia trachytes were erupted contemporaneously or nearly so.

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285–1286 (table 1), 1304–1305. Vatia trachyte plug associated with Pago volcanics (new). Pliocene and early Pleistocene(?).

G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, P. 223. Pleistocene(?).

Crops out on Pola Island at northwest side of Vatia Anchorage. Total length about 3 kilometers; maximum width about 500 meters.

Vaucluse zone[1]

Precambrian: Northwestern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in Catalogue of mineral localities of South Carolina, South Carolina Geol. Survey, ser. 4, Bull. 2: 1907, Summary of mineral resources of South Carolina, p. 6, 9, 12.

Named for exposures at Vaucluse, Aiken County.

**Vaughn Member** (of Blackleaf Formation)

Lower Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2790–2791, 2792 (fig. 3); 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 90. Characterized by light-colored highly bentonitic clay and sandstone of nonmarine origin. Mineral heulandite occurs as minute crystals, earthy masses, and short irregular veinlets throughout much of member and gives red color to so-called red speck zone. Basal part chiefly arkosic sandstone containing abundant petrified wood. Black carbonaceous shale forms top of member north of Great Falls. Thickness at type section 97 feet; thins eastward and thickens westward. Underlies Bootlegger member (new); overlies Taft Hill glauconitic member (new).

Type section: About 3½ miles northeast of Vaughn in low south-facing bluffs in NE¼ sec. 6, T. 21 N., R. 2 E., and SE¼ sec. 31, T. 22 N., R. 1 E. Named from village of Vaughn in sec. 24, T. 21 N., R. 1 E., Cascade County.

**Vaughn Hills Member** (of Worcester Formation)

Carboniferous: Eastern Massachusetts.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 1, 23–25, pl. 1. Proposed for those predominantly quartzitic rocks, previously undifferentiated, that lie at base of mica schist facies of Worcester formation in Harvard and Bolton area. The Vaughn Hills feathers out to north and northeast. Overlies Harvard conglomerate lentil.

Best exposed on southern of the two Vaughn Hills (locality from which it is named) in town of Bolton, Worcester County.

Veazie Formation

Age not stated: South-central Maine.

L. A. Wing, 1957, Maine Geol. Survey GP. and G. Survey 1, sheet 1. Bucksport formation (new) appears to be overlain by interbedded quartzites and slates which are referred to informally as Veazie formation by workers in area. Within this formation is a thin band of iron and manganese slate which closely resembles some of deposits in Aroostook County described by Miller (1947, Maine Geol. Survey Bull. 4). He described the majority of these deposits as of Silurian age and suggested that they may correlate with the Clinton.

Report covers parts of Hancock and Penobscot Counties.

Vecol limestone

[Upper Devonian] (Jeromian): Arizona.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228 (table). Lower part of Jeromian series (new). Thickness 250 feet. Underlies Sycamore sandstone; younger than Espinal limestone (new). Lower part of Jerome formation (of Stoyanow).

In Jerome region.

Vedder Greenstone[1]

Carboniferous: Southwestern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 16, 17.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 16–17. Associated with rocks of Chilliwack series are greatly altered gabbroid masses which have been termed Vedder formation. Carboniferous.

Mapped on Vedder Mountain, British Columbia.

Veleno Member (of Cook Mountain Formation)

Eocene (Claiborne): Tamaulipas, Mexico, and western Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 262–263. Name proposed for middle member of formation. Consists of alternating beds of shale and sandstone as differentiated from the practically solid sandstone members above and below. Sandstones are calcareous, fossiliferous, concretionary, and in many places glauconitic; shales are mainly carbonaceous, fossiliferous, and weather to characteristic chocolate color. Thickness 700 to 800 feet. Underlies Falcon sandstone member (new); overlies Garceno sandstone member (new).

Named for Arroyo Veleno (misspelled Boleno on topographic map), Zapata quadrangle. Member is exposed on Mexico side of the Rio Grande in vicinity of Zapata.

Velpen Limestone (in Carbondale Group)

Pennsylvanian: Southern Indiana.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1942, Illinois Geol. Survey Bull. 67, p. 32 (chart); C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2). Shown on correlation chart at base of Carbondale group; stratigraphically below Houchin Creek [limestone].

Locality not given but may be in vicinity of Velpen, Pike County.

Venado Formation

Upper Cretaceous (Chico Series): Northern California.

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 287–289, 291, 293. Predominantly sandstone with minor amounts of siltstone and shale; conglomerate layers particularly at or near base. Thickness 1,890 to 3,440 feet. Underlies Yolo formation (new); overlies Shasta series. Replaces preoccupied name Golden Gate formation (Kirby, 1942).

Type locality: In sec. 9, T. 17 N., R. 4 W., Colusa County. Named from village of Venado.

Venango Formation[1] (in Conewango Group)

Upper Devonian: Northern Pennsylvania and southern New York.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 2, p. 1405–1406, 1438–1440, 1500–1506.

Bradford Willard, 1939. Pennsylvania Geol. Survey, 4th ser., Bull. C–19, p. 14, 243, 253. Formation in Conewango group comprises (ascending) Panama conglomerate, Amity shale, Bimber Run conglomerate, North Warren shale, Pope Hollow conglomerate, Saegerstown shale, Tuna-Kilbuck conglomerate lens, and Woodcock sandstone member. Underlies Riceville formation. Overlies Chadakoin formation of Conneaut group.

I. H. Tesmer, 1954, Dissert. Abs., v. 14, no. 12, p. 2317, 2318. Term Cherry Creek member proposed for succession of gray siltstones and shales which overlie Panama conglomerate member of Venango in Cherry Creek quadrangle, New York.

Name derived from Venango County, Pa.

Venango Group,[1] Stage,[1] monothem[1]

Devonian: Northwestern Pennsylvania.

Original reference: J. F. Carll, 1880, Pennsylvania 2d Geol. Survey Rept. $I_3$, Atlas, pl. 11.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Prog. Rept. 126, p. 9–11. Devonian comprises Chautauquan and Conewango series. Conewango series includes Venango and Riceville stages. Venango stage includes Sandstone B which will probably be named Youghiogheny sandstone and Shale C which will probably be named Watering Trough shale.

Named for Venango County.

Venice Member (of Columbus Limestone)[1]

Middle Devonian: Northeastern and central Ohio.

Original reference: C. K. Swartz, 1907, Johns Hopkins Univ. Circ. 7, p. 62.

J. W. Wells, 1944, Geol. Soc. America Bull., v. 55, no. 3, p. 276 (fig. 1). Upper member of formation; overlies Marblehead member.

Named for Venice, Erie County.

Ventana sandstones[1]

Upper Triassic: Arizona, Colorado, and Utah.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 250, 338.

Charles Keyes, 1936, Pan-Am. Geologist, v. 65, no. 1, p. 63 (table). Overlies Leroux limestones. Name spelled Vantana.

Named for Ventana Mesa, near Chinle, Apache County, northeastern Arizona.

Venteran Substage

Pennsylvanian (Desmoinesian): Missouri, Iowa, Kansas, Nebraska, and Oklahoma.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1), 2749. Named on northern Midcontinent composite stratigraphic column. Venteran substage together with overlying Cygnian substage (new) make up Desmoinesian stage. Comprises Seville limestone and lower "Cherokee" beds [Krebs group].

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv., 20, p. 10. Type locality and derivation of name.

Type locality: Venter Bluff on U.S. Highway 54, Cedar County, Mo.

Ventioner Beds (in Brad Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: G. Scott and J. M. Armstrong, 1932, Texas Univ. Bull. 3224, p. 35.

Occurs on west side of Trinity River, upstream from mouth of Ventioner Creek, and exposed 1 mile west of Ventioner Creek bridge.

Ventura Formation[1]

Triassic(?): Central northern Washington.

Original reference: I. C. Russell, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 2, p. 100–137, map.

J. D. Barksdale, 1948, Northwest Science, v. 22, no. 4, p. 174. Red tuffaceous sandstones and shales named Ventura formation by Russell (1900) are included at base of newly defined Upper Cretaceous Midnight Peak formation.

Named for mining camp in mountains bordering Methow Valley, Okanogan County.

Ventura Sands[1]

Pliocene and Pleistocene: Southern California.

Original reference: C. M. Carson, 1925, Pan-Am. Geologist, v. 43, p. 265–270.

Well exposed in foothills between Ventura and Santa Paula, in Las Posas Hills, near Camarillo, on south and west flanks of South Mountain and in Simi Valley, Ventura County.

Venturian Stage

Pliocene: Southern California.

Manley Natland, 1953, Pacific Petroleum Geologist, v. 7, no. 2, p. 2. One of four stages, based on foraminiferal assemblages, in the Pliocene and Pleistocene of southern California. Includes interval between Wheelerian above and Repettian, below (both new). Venturian is equivalent to lower Pico as used by many geologists.

Venus formation

Precambrian (Chuaran series): Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 112. Dark brown and green shales. Thickness 600 feet. Underlies Marble limestone (new); overlies Oso beds (new).

Named from butte known as Venus Temple, Grand Canyon region.

†Vera Cruz Graphite Schist[1]

Precambrian: Southern Pennsylvania.

Original reference: B. L. Miller, 1911, Pennsylvania Topog. and Geol. Survey Rept. 4, p. 16.

Easton-Reading district.

Veraguas Crystalline Series[1]

Cretaceous(?): Panama.

Original reference: O. H. Hershey, 1901, California Univ. Dept. Geol. Bull., v. 2, p. 247.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 349. Volcanic and intrusive rocks. Cretaceous(?).

Present in range forming continental divide in Veraguas Province.

Verda Member (of Yazoo Clay)

Eocene (Jackson): Central Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 100–102. A series of sparingly fossiliferous brackish-water lignitic clays, and interbedded silty sands, with intercalated lenticular marine sandstones, freshwater leaf-bearing silts, and marine clays. Aggregate average thickness 200 feet. Includes, in lower part, Saddle Bayou lentil (new) and in upper part Mossy Ridge and Zenoria lentils (both new) which occupy about same stratigraphic horizon. Grades into underlying Tullos member (new) through transitional phase herein named Union Church; gradationally underlies Danville Landing beds.

J. Huner, Jr., 1939, Louisiana Dept. Conserv. Geol. Bull. 15, p. 149 (fig. 7), 159–163. In Caldwell Parish, includes Myatt lentil (new) and Bayou Calamus lentil (new), both near middle of member.

Well exposed in vicinity of Verda and New Verda, Grant Parish.

**Verde Formation**[1]

Pliocene(?) or Pleistocene: Central Arizona.

Original reference: L. E. Reber, 1922, Am. Inst. Mining and Metall. Engineers Trans., v. 66, p. 3–26.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 59–61, fig. 2. Age shown on map as Pliocene(?) or Pleistocene. Unconformably overlies Hickey formation (new) in Jerome area. Derivation of name given.

R. E. Lehner, 1958, U.S. Geol. Survey Bull. 1021–N, p. 557–563, pls. 45, 46, 47. Mutual relationship of Verde with Perkinsville formation (new) not demonstrated in Clarkdale quadrangle but they are tentatively correlated. Thickness as much as 2,000 feet.

Named from occurrence in Verde Valley in region about Clarkdale and Camp Verde, Yavapai County.

**Verden Sandstone Member** (of Marlow Formation)

Verden Sandstone[1]

Permian: Central southern and southwestern Oklahoma.

Original reference: N. Meland and R. D. Reed, 1924, Jour. Geology, v. 32, no. 2, p. 150–167.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Shown on correlation chart as member of Marlow formation.

L. V. Davis, 1955, Oklahoma Geol. Survey Bull. 73, p. 65, fig. 4 (chart). Crossbedded dolomitic sandstone about 10 feet thick. Occurs near middle of formation.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000) : U.S. Geol. Survey. As mapped, Marlow formation includes Doe Creek sandstone member in northwestern Oklahoma and Verden sandstone member in southwestern Oklahoma.

Named for exposures on buttes a few miles northwest of village of Verden, Grady County.

Verdi Beds (in St. Louis Limestone)[1]

Verdi Member (of St. Louis Limestone)

Mississippian (Meramec) : Southeastern Iowa.

Original reference: H. F. Bain, 1895, Am. Geologist, v. 15, p. 319.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 813, 815. The St. Louis is divided into two members, Croton below and Verdi above. Verdi consists of dense gray limestone which grades locally into fine sandstone. Maximum thickness 35 feet. Unconformably overlain by Pella beds.

Named for exposures in old railroad quarry near Verdi Station, Washington County.

**Verdigris Limestone Member** (of Cabaniss Formation or Senora Formation)

Verdigris Formation (in Cabaniss Group or Cherokee Group)

Verdigris Limestone (in Cherokee Formation)[1]

Pennsylvanian (Des Moines Series) : Oklahoma, Kansas, and Missouri.

Original reference: C. D. Smith, 1928, Oklahoma Geol. Survey Bull. 40–U, map.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Verdigris formation in Cabaniss group shown on composite stratigraphic column of Desmoinesian rocks in northern midcontinent. Overlies Croweburg formation; underlies Bevier formation.

W. V. Searight *in* W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. On generalized section of strata exposed in Carroll and Livingston Counties, Mo., Verdigris formation underlies Wheeler formation (new) and overlies Croweburg formation. Cabaniss group.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 9, 13, 16 (fig. 2). Member of Senora formation in Oklahoma. Thickness 5 to 11 feet.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 5. Listed as Verdigris coal cycle in Senora formation in Oklahoma. Includes shale, limestone, Verdigris black shale, Verdigris limestone, and Wheeler coal. Occurs above Croweburg coal cycle and below Bevier coal cycle.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 72–78 (measured sections). Formation includes beds above Croweburg coal and extending to top of Wheeler coal. Underlies Bevier formation; overlies Croweburg formation. Takes its name from widespread Verdigris ("Ardmore") limestone which is its most prominent member. In northern Missouri, formation includes the following members (ascending): thinly laminated light-gray clay shale, black fissile shale, Verdigris limestone, underclay, and Wheeler coal. In western Missouri and in Cherokee and Crawford Counties, Kans., underclay of Bevier coal lies directly on Verdigris limestone, and the Verdigris becomes uppermost member of formation in these areas. In eastern Labette County, Kans., and in northern Oklahoma, a succession of shale and sandstone beds occurs between Verdigris limestone and Bevier coal. Thickness as much as 53 feet. Cabaniss subgroup of Cherokee group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Verdigris limestone member of Cabaniss formation shown on correlation chart.

Name derived from Verdigris River in southern Rogers County, Okla.

**Verdos Alluvium**

Pleistocene (Kansan or Yarmouth): Northeastern Colorado.

G. R. Scott, 1960, Geol. Soc. America Bull., v. 71, no. 10, p. 1541–1542. Name applied to alluvial deposit lying 100 feet below older alluvium (Rocky Flats, new), and 100 feet above next younger alluvium (Slocum, new). Where typically exposed, it is a sheet, 16 to 35 feet, of brown well-stratified coarse sand containing some larger stones and volcanic ash bed. Unconformably overlies Mesozoic bedrock. Volcanic ash considered to be correlative with Pearlette ash.

Typically exposed in an outcrop on slope of pediment on Verdos Ranch, in NE¼NW¼SE¼ sec. 22, T. 6 S, R. 69 W., Littleton quadrangle.

Veredas Group

Pennsylvanian (Missouri Series): Central and southern New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull., 17, p. 27 (table 2), 57–60. Term proposed for (ascending) Coane formation, Adobe formation, and Council Spring limestone (all new). Stratigraphic limits of group at type locality are top of Bolander group (new) of Des Moines series below and base of Hansonburg group (new) of upper part of Missouri series. Thickness about 125 feet at type locality.

Type locality: Northwest side of Oscura Mountains on west slope of range in eastern part of SE¼ sec. 36, T. 5 S., R. 5 E., Socorro County. Name derived from Canyon de las Veredas, in central part of Oscura Mountains.

**Verendrye Member** (of Pierre Shale)

Verendrye Beds or zone (in Sully Member of Pierre Shale)

Upper Cretaceous: Central South Dakota.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 25–26, 31, pls. 2, 3. Zone, or beds, at top of Sully member (new) of Pierre formation. Consists of clay and shale beds underlying Virgin Creek member (new) and overlying manganiferous Oacoma zone of Sully. Thickness 170 to 180 feet.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 1), 2343, 2345. Rank raised to member of Pierre shale. Underlies Virgin Creek member; overlies DeGrey member (new).

Named from exposures under and above Verendrye monument, at Fort Pierre, Stanley County.

**Vergennes Sandstone Member** (of Spoon Formation)

Vergennes Sandstone Member (of Carbondale Formation)[1]

Middle Pennsylvanian: Southwestern and central western Illinois.

Original reference: E. W. Shaw and T. E. Savage, 1912, U.S. Geol. Survey Geol. Atlas, Folio 185.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 50 (table 1). Reallocated to member status in Spoon formation (new). In lower part of formation below Seahorne limestone member.

Type locality: N¼ sec. 11, T. 7 S., R. 3 W., Jackson County. Named for Vergennes.

†Verkin Shales[1]

Lower Triassic: Southwestern Utah.

Original reference: E. Huntington and J. W. Goldthwait, 1903, Jour. Geology, v. 11, p. 46–63.

Name probably derived from Verkin Creek, Washington County.

**Vermejo Formation**[1]

Upper Cretaceous: Northeastern New Mexico and southeastern Colorado.

Original reference: W. T. Lee, 1913, Am. Jour. Sci., 4th, v. 35, p. 531.

W. T. Lee, 1917, U.S. Geol. Survey Prof. Paper 101, p. 163–169. In Fremont County, Colo., includes Rockvale sandstone member.

W. T. Lee, 1924, U.S. Geol. Survey Bull. 752. In Raton coal field, New Mexico, includes Rail Canyon sandstone member.

R. L. Griggs, 1948, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 1, p. 33; G. H. Wood, Jr., S. A. Northrup, and R. L. Griggs, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–141. In Colfax County, N. Mex., conformably overlies and interfingers with Trinidad sandstone; unconformably overlies Raton formation. Consists of interbedded coal, shale, siltstone, and sandstone. Maximum thickness about 85 feet.

R. B. Johnson and G. H. Wood, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 709 (fig. 2), 712. Formation rests conformably on Trinidad sandstone over most of Raton basin region. Tongues of Vermejo strata wedge out in easterly and northeasterly directions, and tongues of Trinidad wedge out west and northwest. Underlies Raton formation. Vermejo rocks consist of buff, gray, and dark-gray siltstone; buff, gray, and gray-green slightly arkosic sandstone; nearly black carbonaceous coaly and silty shale; and numerous coal beds. Thickness as much as 550 feet near East Spanish Peak. Formation absent near Raton, Van Houten, and Ute Park, N. Mex. Montana age.

Type locality: At southeastern extremity of Vermejo Park, N. Mex.

Vermilion facies (of Cleveland Shale)

*See* **Cleveland Shale.**

**Vermilion Granite**[1]

Precambrian: Northeastern Minnesota.

Original reference: F. F. Grout, 1923, Econ. Geology, v. 18, p. 253–269.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1036. Presumably contemporaneous with Kekequabic granites. Algoman(?).

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1040. Intrudes Knife Lake series at hundreds of places and is clearly younger, but how much is not clear. Nowhere in contact with Animikie sediments to prove that it is older than Animikie. Magnetite associated with Vermilion granite pegmatites gives tentative age (Hurley, 1943, Geol. Soc. America Bull., v. 54, no. 3) of 750 million years.

Named for exposures on Vermilion Lake and along Vermilion River, northern St. Louis County.

†Vermilion Series,[1] Schists,[1] or Group[1]

Precambrian (Keewatin) : Northeastern Minnesota.

Original reference: N. H. Winchell and A. Winchell, 1887, Minnesota Geol. Nat. History Survey 15th Ann. Rept., p. 4, 192, 355–357.

Occur at northwestern extremity of Vermilion Lake and extend east from Vermilion Lake to Basswood Lake, Vermilion district.

†Vermilion Cliff Group[1]

Upper Triassic: Southwestern to northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 52–54, 151.

Named for Vermilion Cliffs, to south of White Cliffs, near Paria, a little town on Paria River, Kane County, Utah.

†Vermilion Creek Group[1]

Eocene: Northwestern Colorado, northeastern Utah, and southwestern Wyoming.

Original reference: C. King, 1876, U.S. Geol. Expl. 40th Par., Atlas, maps 1, 2.

†Vermilion Lake Iron-Bearing Series[1]

Precambrian (Huronian) : Minnesota.

Original references: R. D. Irving, 1883, U.S. Geol. Survey 3d Ann. Rept., pl. 3, map; 1888, U.S. Geol. Survey 7th Ann. Rept., p. 440–441.

Vermilion Lake region.

**Vermilionville Sandstone Lentil** (in Carbondale Formation)[1]

Vermilionville Sandstone (in Carbondale Group)

Vermilionville Sandstone Member (of Carbondale Formation)

Middle Pennsylvanian: Northern and southern Illinois.

Original reference: G. H. Cady, 1919, Illinois Geol. Survey Bull. 37, p. 31, 56–58.

H. B. Willman and J. N. Payne, 1942, Illinois Geol. Survey Bull. 66, p. 123 (fig. 66), 127–128. Described in Marseilles, Ottawa, and Streator quadrangles as a sandstone in Carbondale group. Thickness 15 to 75 feet; variations in thickness result partly from the sandstone filling channels in underlying Canton shale and partly from the channellike depressions in top of sandstone. Included in Brereton cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 10. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 48 (table 1). Member of Carbondale formation (redefined).

Name is extended from northern Illinois to equivalent sandstone in southern Illinois for which name Cuba sandstone has been used. Name Cuba preempted.

Type locality: SE part sec. 9, T. 32 N., R. 2 E., La Salle County. Named for outcrops along Vermilion River near Vermilionville.

†Vermont Formation[1] or Quartzite[1]

Lower Cambrian: Southwestern Vermont and western Massachusetts.

Original reference: J. D. Dana, 1873, Am. Jour. Sci., 3d, v. 6, p. 272–278.

Derivation of name not stated, but probably named for development in southern Vermont.

Vermont Quartz Diorite

Pre-Cretaceous(?): Southern California.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 3, 7 (table 1), 10–11, pl. 1. A medium-grained quartz diorite in Vermont pluton. Present only in northern half of Mount Hollywood fault block, where it intruded and metamorphosed a complex of basalt, diabase, and gabbro. Suggested sequence of intrusion in area is Vermont quartz diorite, Lar quartz diorite (new) and Feliz granodiorite (new).

Occurs in Griffith Park area, city of Los Angeles. [Name probably derived from fact that it is near Vermont Ave., Los Angeles.]

Vernal[1] (shale)

Upper Jurassic: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Derivation of name not stated.

**Vernal Mesa Quartz Monzonite**

Vernal Mesa Granite[1]

Precambrian: Central western Colorado.

Original reference: J. F. Hunter, 1925, U.S. Geol. Survey Bull. 777.

Occurs near northwest end of Vernal Mesa and walls adjacent to part of Black Canyon, in Gunnison River region.

Verne cyclothem (in Saginaw Group)

Pennsylvanian: Southern Michigan.

W. A. Kelly, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 159, 166, 177, 183, 190. Cyclical formation in Saginaw group. Contains Verne shaly limestone.

Named for Verne mine, sec. 23, T. 10 N., R. 4 E., Saginaw County.

Verne Shaly Limesone Member (of Saginaw Formation)

Pennsylvanian: Southern Michigan.

W. A. Kelly, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 159, 166, 177, 183, 190. Verne shaly limestone member of Verne cyclothem. Limestone is persistent and makes it possible to divide Saginaw into pre- and post-Verne cyclical formations.

Michigan Geol. Soc., 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 28. Referred to as limestone member of Saginaw formation. Consists of a few feet of black highly argillaceous limestone that grades upward into a calcareous shale. Limestone is late

Pottsvillian in age and its fauna is more closely related to fauna of the Pottsville in Illinois than to fauna of same age in Ohio.

Type locality (cyclical formation): Verne mine, sec. 23, T. 10 N., R. 4 E., Saginaw County.

†Vernon Gneiss[1]

Upper Carboniferous or post-Carboniferous: Southeastern Vermont and western central Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 17, pl. 34.

Named for occurrence in Vernon Township, Vt.

Vernon Limestone[1]

Devonian: Southeastern Vermont and western central Massachusetts.

Original reference: B. K. Emerson, 1890, Am. Jour. Sci., 3d, v. 40, p. 365.

Occurs in Vernon Township, Vt.

**Vernon Shale** (in Salina Group)

Vernon Shale Member (of Salina Formation)[1]

Upper Silurian: Western to east-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 18–19, chart.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as shale in Salina group, Cayugan series. Overlies Pittsford shale; underlies Syracuse salt.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 10, fig. 1. Discussion of age of Brayman shale. The Brayman lies first upon Ordovician strata in type area and at Sharon Springs. West of Cherry Valley, it lies upon progressively younger strata of Middle and Upper Silurian. At western border of Richfield Springs quadrangle, the Lockport, Vernon, Camillus, and Bertie have all appeared in the section. Figure 1 shows the Vernon underlying the Camillus and overlying the Herkimer.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7. Salina formation, in central New York, consists of two facies, Vernon red shales near base, and above, Camillus gray calcareous shales and dolomites with salt and gypsum beds.

W. P. Leutze, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 7, p. 1693, 1694 (fig. 1). Underlies Syracuse formation where that formation outcrops in Onondaga and Madison Counties. Thickness about 300 feet. Salina group.

W. L. Kreidler, 1957, New York State Mus. Bull. 361, p. 6. Underlies Syracuse salt member of Camillus.

D. W. Fisher, 1957, New York State Mus. Bull. 364, p. 3–30. Discussion of Vernon shale in type area; reference section designated. The Vernon has been variously treated as a distinct formation or as a member of Salina formation and commonly considered to be 150 feet thick in type area. At least five distinct rock types are represented in strata classed as Vernon, but they are so interrelated that further differentiation into smaller units is not warranted from cartographic standpoint. The Vernon is here regarded as a phase of sedimentation (magnafacies) capable of geologic mapping; hence, it can properly be termed a formation.

Name "Pittsford shale" is suppressed and the discontinuous occurrence of greenish-black shale above Lockport dolomite is included in Vernon formation. Thickness at reference section 270 feet; contact with underlying Lockport not exposed, and section does not extend up to contact with overlying Camillus. Total estimated thickness of Vernon in type area 400 feet. Within New York, the Vernon is considered correlative of High Falls shale of Orange and Ulster Counties. Upper Silurian.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Included in Canastota(n) stage (new), Cayugan series.

Type locality: Vernon Township, Oneida County. Reference section: Downing Brook, which enters Oneida Creek from east 1.3 miles south of part of Sherrill known as Kenwood and 0.6 miles north of southern boundary of Oneida County. This is 2.3 miles south of intersection of New York Highway 5 and Kenwood-Sherrill Road.

Versailles Bed (in Richmond Group)[1]

Upper Ordovician: Southeastern Indiana and north-central Kentucky.

Original reference: A. F. Foerste, 1905, Science, new ser., v. 22, p. 150.

Named for Versailles, Ripley County, Ind.

**Vershire Schist**[1]

Ordovician: Northeastern Vermont.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept., p. 115.

Probably named for exposures in or near Vershire village or elsewhere in Vershire Township, Stafford quadrangle, in Orange County.

Vestal Limestone[1]

Ordovician (Chazyan): Central Tennessee.

Original reference: C. H. Gordon, 1924, Tennessee Dept. Ed., Div. Geol. Bull. 28, p. 35, 40.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 94. A marble about 150 to 200 feet thick near base of Sevier formation on south side of Knoxville. Has about same position as Meadow marble.

Named for exposures in town of Vestal, Knox County.

Veta Pass Limestone Member[1] (of Sangre de Cristo Conglomerate)

Pennsylvanian: South-central Colorado.

Original reference: F. A. Melton, 1925, Jour. Geology, v. 33, p. 812.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 811 (fig. 1), 829. If, in its type section, top of member were drawn at Whiskey Creek Pass limestone (new), 3,138 feet would be more nearly correct for thickness of member than 2,100 feet as cited by Melton.

D. W. Bolyard, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1911. Madera formation as used in this report replaces Veta Pass limestone member of Sangre de Cristo conglomerate of Melton (1925).

Type section: Along Placer Creek north of Russell post office, near La Veta Pass, Sangre de Cristo Range.

**Vick Formation**

Lower(?) Cretaceous: Central Alabama.

L. C. Conant, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 5, p. 711–715. Semi-indurated sandstone and mottled brick-red and gray sandy clay unlike and apparently older than anything known in Tuscaloosa but younger than near-by Paleozoic rocks. Proposed that strata represented by these outcrops be tentatively designated Vick formation, of either Jurassic or Lower Cretaceous age. Several outcrops have between 20 and 50 feet of beds; composite section shows total thickness of about 100 feet represented. In some areas, unconformably overlain by coarse conglomeratic sandstone believed to be base of Eoline formation.

C. W. Drennan, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 3, p. 536. Coker formation is extended to include all outcropping pre-Gordo sediments of Tuscaloosa group except those designated Vick formation by Conant (1946), which may be Tuscaloosa in age.

Type locality: Series of exposures along old Centerville-Randolph Road in SE¼SW¼ and SW¼SE¼ sec. 27, T. 23 N., R. 10 E., together with exposures in wall of 60-foot sink hole a quarter mile southwest of road exposures, in vicinity of Vick, Bibb County.

**Vicksburg Group**[1]

Vicksburg Formation

Oligocene: Gulf Coastal Plain.

Original reference: T. A. Conrad, 1848, Acad. Nat. Sci. Philadelphia Proc., v. 3, p. 280–299.

W. D. Chawner, 1936. Louisiana Dept. Conserv. Geol. Bull. 9, p. 94–110. Group exposed in northwestern Catahoula Parish in broad outcrop. Overlies Danville Landing zone of Jackson group. Contact is not distinct lithologic break, and contact line as mapped is based on uppermost appearance of Danville Landing fossils in various sections. Upper part of Vicksburg section unconformably overlain by Cassel Hill member of Catahoula.

A. N. Fisk, 1938, Louisiana Dept. Conserv., Geol. Bull. 10, p. 124–141. Outcrop of Vicksburg follows outcrop of Catahoula formation as narrow band from Rosefield, Catahoula Parish, to region north of Summerfield, Grant Parish. In the field, no definite contact can be drawn separating the Vicksburg from overlying continental siltstone of Catahoula or from underlying marine Jackson beds. Nor can any hard or fast line be drawn between similar beds within the Vicksburg sediments. However, beds can be separated into two interrelated members of sedimentation, a lower gypsiferous member and an upper sandy clay member with microfaunas characteristic of both Byram marl and Mint Spring marl.

F. F. Miller, 1940, Mississippi Geol. Survey Bull. 39, p. 12 (table), 23–24. Rank reduced to formation. Comprises Mint Spring facies, Glendon and Byram members. Overlies Jackson formation with disconformity; underlies Citronelle formation with disconformity.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1313–1354. Vicksburg group is restricted to middle part of the Oligocene, namely Marianna limestone (with Mint Spring marl member) and Byram formation (with Bucatunna clay and Glendon limestone members). Excluded from group are the three youngest Oligocene formations—Chickasawhay limestone, Suwannee limestone, and Flint River formation—and basal Oligocene formations—Forest Hill sand, and Red Bluff clay. Thus, the Vicksburg includes only beds for which name was intended, the fossiliferous Oligocene of Warren County, Miss. This restriction is not a new idea. Various geologists have suggested that the top, or bottom, or both, of the Oligocene be removed from the Vicksburg, some have suggested that the upper part is Miocene, and others that the lower part is Eocene.

C. W. Stuckey, Jr., 1953, Am. Assoc. Petroleum Geologists Guidebook Field Trips Houston Mtg., p. 25–27. Vicksburg group, overlying the Jackson, is accepted as lower part of Oligocene. There is disagreement as to upper boundary of Oligocene. The Vicksburg does not appear on surface in Texas because of overlap by Miocene beds. In subsurface of Texas, consists of about 500 feet of gray calcareous shales containing local sand lenses. Distinctive microfauna. Top is picked on *Textularia warreni*. Section overlying Vicksburg in subsurface is referred to as Frio.

Named from exposures at Vicksburg, Miss.

†Vicksburg (fossiliferous) Loam[1]

Recent(?) : Mississippi.

Original reference: T. A. Conrad, 1846, Am. Jour. Sci., 2d, v. 2, p. 212.

Vicksburg Stage, Age

Oligocene: Gulf Coastal Plain.

G. E. Murray, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 700–707. Since Vicksburg, in its present broad application, has no real lithologic unity and is applied in essentially a time-rock (time-stratigraphic) sense, it is proposed to recognize it as a stage, even though its exact isochronous boundaries are unknown and, except at its type locality, may never be precisely determined. Vicksburg stage and its corollary, Vicksburg age, should contain sediments deposited during stand of sea in Gulf and Atlantic coastal region as represented by type section of Vicksburg deposits at and in vicinity of Vicksburg, Miss., and their equivalents. Name Mosley Hill formation proposed for sediments at Sabine River equivalent to type Vicksburg. Harris (1902, Louisiana State Expt. Sta. Geol. Agr. Louisiana, pt. 6, Spec. Rept. 1) applied Vicksburg stage to sediments exposed in and around Rosefield, Catahoula Parish, La., and used term stage in essentially the modern concept.

E. C. Tonti, 1955, Dissert. Abs., v. 15, no. 8, p. 1372. Two sedimentary cycles identified in Vicksburg stage. Distinct disconformity marks upper and lower boundary of each unit. Lowermost cycle extends from disconformity at base of Mint Springs-Marianna formation to similar break at top of Byram formation as defined in this report. Uppermost cycle contains Bucatunna marl and clay facies extending to disconformity at base of overlying Catahoula and Chickasawhay formations. In each case, cycle contains a lower transgressive and an upper regressive unit. Term Vicksburg stage suggested to include at least those deposits mentioned and whatever variable, but equivalent facies might be determined elsewhere.

A. D. Warren, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 221–237. In Louisiana, the subsurface stratigraphic section between Anahuac stage and Vicksburg stage is named Frio stage.

Victor Andesite[1]

Tertiary: Nevada.

Original reference: T. B. Nolan, 1930, Nevada Univ. Bull., v. 24, no. 4, p. 16.

In Tonopah Extension mine, Tonopah district.

**Victor Formation**[1]

Pleistocene: Central California.

A. M. Piper and others, 1939, U.S. Geol. Survey Water-Supply Paper 780, p. 33 (table), 38–49, pl. 1. Fluviatile sand, silt, and gravel, in small part well sorted and well stratified. Thickness as much as 125 feet. Underlies Recent alluvium; overlies Arroyo Seco gravel (new); locally overlies Mehrten formation (new).

Type section: Pit in SW¼NE¼ sec. 3, T. 3 N., R. 7 E., 190 feet north of Southern Pacific Railroad at east edge of Bruella Road, Mokelumne area.

†Victoria Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Victoria mine, Ontonagon County.

†Victoria Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Victoria mine, Ontonagon County.

**Victoria Formation**

Victoria Quartzite[1]

Upper Devonian: Central northern Utah.

Original reference: C. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 11 (fig. 3), 12–13. As currently defined by U.S. Geological Survey, formation includes all Victoria quartzite as originally defined, plus 70 to 80 feet of mottled coarse-grained dolomite, now known to be of Devonian age, that was formerly placed in lower part of Loughlin's Gardner dolomite. Thickness 250 to 300 feet. Overlies Bluebell dolomite; underlies Pinyon Peak limestone. Upper boundary of Victoria is placed at top of uppermost dolomite bed that underlies thin-bedded shaly limestones of the Pinyon Peak. This contact marks disconformity that is unimportant in East Tintic Mountains, but corresponds to major pre-late Late Devonian unconformity that is recognized in Stansbury Mountains, Oquirrh, central Wasatch, and eastern Uinta Ranges.

Named for Victoria mine, three-fourths mile south-southeast of Eureka.

†Victoria Formation, Clays,[1] or Shale[1]

Upper Cretaceous: Central Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 50.

Named for exposures at Victoria, Ellis County.

Victoria Peak Massive Member (of Bone Spring Limestone)[1]

*See* **Victorio Peak** correct spelling.

**Victorio Peak Limestone**

Victorio Peak Gray Member (of Bone Spring Limestone)

Permian (Leonard Series): Western Texas and southeastern New Mexico.

Original reference: P. B. King and R. E. King, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 921, 922, 925.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 569, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 16–17, pl. 3. Referred to as Victorio Peak gray member. Consists of gray, calcitic limestone in thick, fairly even beds, 500 to more than 1,000 feet thick. Overlies unnamed black limestones in lower part of formation; underlies Cutoff shaly member (new).

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Formation described in Wylie Mountains and vicinity. Composed dominantly of dolomite. Mapped in four units: basal thin-bedded marly limestone; limestone member; marl member; dolomite member. Thickness 1,600 feet. Overlies Hueco limestone; underlies Seven Rivers limestone. Leonard-Guadalupe.

D. W. Boyd, 1958, New Mexico Bur. Mines Mineral Resources Bull. 49, p. 12–13, 62–63, pl. 1, strat. sections. Victorio Peak gray member mapped and described in Otero County, N. Mex.

Named for exposures on Victorio Peak, promontory of Sierra Diablo scarp, Texas.

Victorville Quartz Monzonite

Upper Jurassic: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 40, no. 1, p. 105–106. Typically very light gray, massive, medium grained, and almost totally devoid of dark minerals. Dikes of the quartz monzonite cut Oro Grande metasediments.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 504. Cuts Bell Mountain quartz diorite (new).

Named for exposures north and northeast of Victorville, Barstow quadrangle, San Bernardino County.

Victory Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., fig. 3. Shown on columnar section as underlying Forreston member (new) and overlying Eldena member (new) of Nachusa formation (new).

Occurs in Dixon-Oregon area.

Victory Junction Shale Member[1] (of Stanton Limestone)

Pennsylvanian (Missouri Series): Central eastern and northeastern Kansas.

Original references: R. C. Moore, M. K. Elias, and N. D. Newell, 1934, Stratigraphic sections of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita, Kans., [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]; N. D. Newell, 1935, Kansas Geol. Survey Bull. 21, pt. 1, p. 76–79.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 51. Rock Lake shale was named in Nebraska by Condra (1927) but was named Victory Junction shale by Newell (1935) for occurrences in Kaw Valley area, Kansas. On the basis of subsequent studies, it is agreed that original name is valid.

Named for Victory Junction in western part of Wyandotte County.

Vidae Flows, Lavas

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 37. Probably first dacites erupted by Mount Mazama were those forming Grayback Ridge and those making up southern end of Vidae Ridge. They date back to time preceding maximum glaciation of Mount Mazama and are older than lavas of Llao Rock, Cleetwood Cove, Grouse Hill, and Redcloud Cliff. Vidae lavas thickens southward from probable vent to as much as 500 to 600 feet.

Vidae Ridge is on south side of Crater Lake.

**Vidrio Limestone Member** (of Word Formation)

Vidrio Massive Member (of Capitan Limestone)[1]

Permian (Guadalupe Series): Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 52.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 655–656, pl. 2. Restricted to that part of former Vidrio member which is believed to be middle Guadalupe in age, and classed as member of Word formation. Capitan is restricted to that part of former Vidrio member or reef facies that is upper Guadalupe (post-Word) in age. Overlies and (or) interfingers with unnamed limestones or formation; underlies Capitan limestone in western part of Glass Mountains and Gilliam limestone in eastern part.

Unit is conspicuous part of Glass Mountains. Vidrio is Spanish word for glass and is often used among local Mexican population as a name for the mountains.

Vieja Group

Vieja Series[1]

Tertiary: Southwestern Texas.

Original reference: T. W. Vaughan, 1900, U.S. Geol. Survey Bull. 164, p. 78–81.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 15 (fig. 3). Redefined as Vieja group; stratigraphically extended upward; subdivided. Vieja series of Vaughan is subdivided into five formations (descending): Chambers tuff, Buckshot ignimbrite, Colmena tuff, Gill breccia (all new), and Jeff conglomerate. Expanded upward to include four newly defined formations (ascending) Bracks rhyolite, Capote Mountain tuff, Brite ignimbrite, and Petan basalt. Group unconformably overlies Upper Cretaceous rocks; in many places contact is concordant, but in others Cretaceous rocks were folded or thrust-faulted prior to Vieja deposition.

Named for exposures in Vieja Mountains, Presidio County.

Viejas Gabbro-Diorite[1]

Upper Jurassic or Lower Cretaceous: Southern California.

Original reference: W. J. Miller, 1935, California Jour. Mines and Geology, v. 31, no. 2, p. 115–141, map.

Type occurrence: In Viejas Mountains, southern Peninsular Ranges, San Diego and Imperial Counties.

**Vienna Limestone**[1]

Vienna Limestone (in Elvira Group)

Upper Mississippian (Chester Series): Southern Illinois, southern Indiana, western Kentucky, and southeastern Missouri.

Original references: S. Weller, 1920, Jour. Geol., v. 28, no. 4, p. 281-290; no. 5, p. 395–416.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 136; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 836. Assigned to Elvira group (new). In standard Mississippian section, underlies Waltersburg sandstone and overlies Tar Springs sandstone. Youngest Chester formation recognized in Missouri where it is represented by thick residual chert on a few hilltops in southeastern Perry County.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7. Name Vienna limestone extended into Indiana and applied to shale and limestone interval underlying Waltersburg sandstone and overlying Tar Springs sandstone.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, pl. 1. Vienna limestone shown on stratigraphic column of upper Chester rocks in Indiana as dark- to olive-green shale; locally contains dark-gray or brown thin beds of crystalline limestone. Thickness 5 to 15 feet. Term Elvira group not used in Indiana.

Named for exposures at Vienna, Johnson County, Ill., where it is exposed in some streets and in an old quarry just west of town.

Viesca Member (of Weches Formation)

Eocene, middle: Eastern Texas.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 97, 104–107. Composed of poorly bedded fossiliferous argillaceous and calcareous glauconite rock where fresh and of red and brown clays and clay-ironstones with fossil casts where weathered. Thickness varies from 5½ to a little more than 38 feet, average 26 feet. Underlies Therrill member (new) with boundary transitional; overlies Tyus member (new) with boundary transitional.

Type locality: Lee's Waterfall in Jose Maria Viesca survey, Leon County.

**Vigo Limestone Member** (of Shelburn Formation)

Upper Pennsylvanian: Southwestern Indiana.

C. E. Wier, 1952, Indiana Geol. Survey Prelim. Coal Map 1. Shown on columnar section as limestone near top of Shelburn formation. Occurs above Vigo coal.

Courtney Waddell, 1954, U.S. Geol. Survey Coal Inv. Map C–17. Limestone bed 1½ to 2½ feet thick near top of formation. Where weathered, limestone is dull gray and appears argillaceous; on fresh surface, appears to be made up of small aggregates of brown crystalline calcite in argillaceous matrix. Underlies a black fissile shale 8 to 10 inches thick. Separated from underlying Maria Creek member by a unit of thin-bedded gray-green nonfossiliferous sandy shale about 110 feet thick that contains a few thin local bands of iron concretions and several thin discontinuous coal beds, less than 1 foot thick. Derivation of name given.

D. J. McGregor, 1958, Indiana Geol. Survey Bull. 15, p. 46 (table 8). Stratigraphically below Murphys Bluff sandstone member.

Name from exposures along Prairie Creek near Vigo, center NW½NW¼ sec. 28, T. 10 N., R. 10 W., Sullivan County.

**Vilas Shale (in Lansing Group)**[1]

Vilas Shale Member (of Lansing Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 51, 103.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Shale in Lansing group. Overlies Plattsburg formation; underlies Stanton formation. This is classification agreed upon by Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 33. Thickness about 8 feet in Cass and Sarpy Counties, Nebr. Lansing group.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 419. In Madison and Adair Counties, Iowa, formation is 10 to 12 feet thick. Overlies Plattsburg formation; underlies Stanton formation(?).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 24, fig. 5. Exposed only in Adair and Madison Counties where it is a 12-foot sequence of gray unfossiliferous shale overlying a maroon shale. Underlies Stanton limestone; overlies Plattsburg limestone. Lansing group.

Named for exposures in vicinity of Vilas, Wilson County, Kans.

Village Bend Limestone (in Mineral Wells Formation)[1]

Village Bend Member (of East Mountain Shale)

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1929, Texas Bur. Econ. Geology, geol. map of Palo Pinto County.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in East Mountain shale. Uppermost member of formation; overlies Capps limestone member; underlies Lake Pinto sandstone member of Salesville formation. Strawn-Canyon boundary placed at top of Village Bend limestone. Name Mineral Wells dropped in this report.

J. W. Shelton, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1515–1524. Discussion of Strawn-Canyon boundary. In eastern Palo Pinto County, boundary is placed at base of Lake Pinto sandstone which overlies Village Bend limestone.

L. F. Brown, Jr., 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2866–2871. Discussion of problems of stratigraphic nomenclature and classification, Upper Pennsylvanian, north-central Texas—erecting series from groups, suppression of formations, redefining and raising rank of rock-stratigraphic units, and time-stratigraphic boundaries versus lithologic contacts.

Type locality: Exposure near west end of Village Bend of Brazos River 2¾ miles in direct line southeast of Palo Pinto, Palo Pinto County.

Villa Nueva Sandstone Member (of Fayette Formation)[1]

Eocene, upper: Tamaulipas, Mexico, and southern Texas.

Original reference: W. G. Kane and G. B. Gierhart, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 9, p. 1387.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 270. In Texas, overlies Agua Verde shale member (new). Exposures limited. Thickness probably more than 100 feet in Starr County. Appears to be overlapped by Frio south of Zapata County line.

Derivation of name not stated.

**Vinalhaven Rhyolite**[1]

Vinalhaven Granite

Upper Silurian: South-central Maine.

Original reference: G. O. Smith, 1896, Geology of the Fox Islands, Maine, p. 12, 46–55.

H. W. Fairbairn and P. M. Hurley, 1957, Am. Geophys. Union Trans., v. 38, no. 1, p. 104 (table 7), 106 (table 9). Referred to as granite.

Occurs in northwestern part of Vinalhaven Island, Knox County.

**Vincentown Formation** (in Rancocas Group)

Vincentown Sand (in Rancocas Group)[1]

Paleocene: New Jersey.

Original reference: W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897, Geol. Soc. America Bull., v. 8, p. 316–338.

A. R. Loeblich, Jr., and Helen Tappan, 1957, Jour. Paleontology, v. 31, no. 6, p. 1113 (fig. 2), 1128 (fig. 5), 1129–1132. Age of formation given as Paleocene (Landenian). Determination made on basis of foraminiferal studies. Report summarizes opinions of several workers and cites bibliography.

H. G. Richards, J. J. Groot, and R. M. Germeroth, 1957, Geol. Soc. America Guidebook Field Trips Atlantic City Mtg., p. 184 (table 2), 186 (table 3), 199–200, 201 (table 4). Marl (formation) underlies Manasquan marl; overlies Hornerstown marl and occurs in belt immediately to southeast of it. Consists of calcareous phase and quartz phase with varying amounts of glauconite; the two phases are probably not traceable over great distances. Thickness at outcrop 25 to 100 feet; average dip 27 feet per mile. Opinion as to age is now divided between Paleocene (Midway) and Lower Eocene (Wilcox); general opinion now favors Paleocene dating.

S. K. Fox, Jr., and R. K. Olsson, [abs.] 1955, Jour. Paleontology, v. 29, no. 4, p. 736. Comparison of type Vincentown microfauna with Hornerstown and basal Vincentown assemblages reveals that type Vincentown is Eocene in age. It contains no diagnostic Paleocene forms.

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184. Rancocas group includes (ascending) Hornerstown sand, Vincentown formation, and Manasquan formation.

Named for Vincentown, Burlington County.

**Vindicator Rhyolite**[1]

Tertiary: Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 37.

Well exposed on flanks of Vindicator Mountain, Goldfield district.

Vine Hill Sandstone

Paleocene: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 21–30, pls. 4B, 4C. Name applied to Paleocene rocks of Martinez area. Consists of massive medium- to coarse grained brown to reddish-brown glauconitic sandstone and minor amounts of interbedded silty shale formerly considered by several writers as Lower Martinez. Thickness at type section approximately 1,225 feet; beds dip from 70° to vertical toward southwest. Base of section [type section] as exposed in cuts along Santa Fe Railway does not represent lowermost part of Vine Hill. Basal beds, which occur farther to southeast in low hills are about 425 feet thick and consist of poorly exposed dark-brown gritty sandstone with interbedded layers of silty shale. Underlies Las Juntas shale (new); contact with underlying Cretaceous Chico not established. Vine Hill sandstone together with Las Juntas shale were mapped and described in San Francisco folio (Lawson, 1914) as Martinez group. At type section, Vine Hill sandstone is equivalent to basal sandstone part of Martinez group as that term was used by early investigators.

B. Y. Smith, 1957, California Univ. Pub. Geol. Sci., v. 32, no. 3, p. 143–144. Since Pacheco syncline is generally accepted as type area for the Martinez, it is particularly difficult to follow Weaver's (1953) omission of that term as an appropriate designation for lower part of sequence, and it seems desirable that Weaver's new units, Vine Hill, Las Juntas, and Muir, be included either as members within Martinez formation or as formations within Martinez group. Foraminifera described.

Type section: In east limb of Pacheco syncline in cuts along Santa Fe Railway immediately east of Pacheco Road, near Martinez, Contra Costa County. Exposed in limbs of northwest trending folds in hills between Southampton and Franklin faults from Franklin Ridge southeast to town of Walnut Creek. On west limb of syncline, concealed beneath surface along Southampton fault.

**Vineyard Formation**[1]

**Vineyard Interglaciation**

Vineyard interglacial stage[1]

Pleistocene: Southeastern Massachusetts and southeastern New York.

Original reference: J. B. Woodworth, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 1, p. 975–988.

C. W. Cooke and others, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Correlation chart shows Vineyard formation younger than Manhassett formation. Wisconsin.

Name amended to Vineyard Interglaciation in compliance with Code of Stratigraphic Nomenclature (1960), article 40.

Named for occurrence on Martha's Vineyard.

Vineyard Series[1]

Upper Cretaceous to Pliocene: Southeastern Massachusetts.

Original reference: N. S. Shaler, 1888, U.S. Geol. Survey 7th Ann. Rept., p. 303–363, map.

Well exposed at both extremities of Marthas Vineyard.

**Vinini Formation**

Lower and Middle Ordovician: Central Nevada.

C. W. Merriam and C. A. Anderson, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1953; 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1693–1698. Quartzites, calcareous sandstones, cherty shales, cherts, and andesite flows and tuffs. Present in low-angle thrust plate above Pogonip limestone, Eureka quartzite, and Hanson Creek limestone in Roberts Mountains area. Vinini embraces at least two and possibly three formational divisions; for purposes of this report, divided into lower and upper divisions. Age established on the basis of graptolites.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 34–36. Discussed in stratigraphic section in vicinity of Eureka. Formation has been folded and cut by local minor thrust faults; both folds and thrust faults seem to be transgressed by unconformity at base of overlying Permian sequence.

Named from exposures along Vinini Creek, eastern slope of Roberts Creek Mountain, 25 miles northwest of Eureka, Roberts Mountains quadrangle.

Vinita Beds[1] or Sandstones (in Chesterfield Group)

Upper Triassic: Eastern Virginia.

Original reference: N. S. Shaler and J. B. Woodworth, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 435.

C. B. Brown, 1937, Virginia Geol. Survey Bull. 48, p. 16. Incidental mention in discussion of Triassic rocks in Goochland County.

Occur in James River bluff west of Vinita Station on Tomahawk Creek and crop out on east slope of Goat Hill near Vinita, Goochland County.

†Vinita Formation[1]

Pennsylvanian: Northeastern Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 12.

Named for Vinita, Craig County.

**Vinland Shale[1] Member** (of Stranger Formation)

Vinland Shale Member (of Plattford Formation)

Pennsylvanian (Virgil Series): Eastern Kansas and northwestern Missouri.

Original references: R. C. Moore, M. K. Elias, and N. D. Newell, 1934, Stratigraphic sections of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc.: Wichita, Kans., [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23]; N. D. Newell, 1935, Kansas Geol. Survey Bull. 21, p. 82.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 72–73. Member of Stranger formation. Gray clayey, calcareous and sandy shale, and locally some sandstone underlying Haskell limestone member; locally in Woodson County, Kans., dark-green layer occurs in middle part; north of Anderson and Coffey Counties, Kans., where Westphalia limestone member is absent, top of Upper Sibley coal is regarded as marking base of Vinland shale. Disconformity beneath sandstone at base of Vinland cuts out the Westphalia limestone locally in Coffey County. Thickness 9 to 50 feet.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 30 In Nebraska, uppermost member of Plattford formation. Thickness 6 to 14 feet in outcrop area in Cass County where it rests unconformably on Stanton formation.

Type locality: About 2 miles northeast of Vinland, Douglas County, Kans.

**Vintage Dolomite**[1]

Lower Cambrian: Southeastern Pennsylvania and northern Virginia.

Original reference: G. W. Stose and A. I. Jonas, 1922, Washington Acad. Sci. Jour., v. 12, p. 359, 362, 363.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51–A, p. 19, 20, 21. Proposed to extend names Vintage dolomite, Kinzers formation, and Ledger dolomite to comparable Lower Cambrian formations in area southeast of Austinville, Va. Section near Austinville shows Vintage dolomite overlying Erwin quartzite.

Well exposed in cut of Pennsylvania Railroad at Vintage, 15 miles east of Lancaster, Lancaster County, Pa.

Vinton Member[1] (of Logan Formation)

Lower Mississippian: Central Ohio.

Original reference: J. E. Hyde, 1912, History of Fairfield County and representative citizens, by C. C. Miller, p. 206–212.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172–173; 1942, Jour. Geology, v. 50, no. 1, p. 41 (table 1), 59, 62, 64. Included in Pretty Run sandstone facies, Scioto Valley shale facies, and Vanceburg siltstone facies (all new) of Logan formation. In Pretty Run facies, overlies Allensville conglomerate member and underlies Rushville shale member; in Scioto Valley facies, overlies Portsmouth shale member; in Vanceburg facies, overlies Churn Creek siltstone. Lower Mississippian.

Named for Vinton County.

Vinton phase (of Otis Limestone)[1]

Middle Devonian: Central eastern Iowa.

Original reference: W. H. Norton, 1921?, Iowa Geol. Survey, v. 27, p. 377.

M. A. Stainbrook, 1944, Illinois Geol. Survey Bull. 68, p. 182, 185. "Vinton phase" is shown by its fossils to belong to Cedar Valley formation.

Exposed in quarries north of Vinton, Benton County, along Cedar River.

**Viola Limestone**[1]

Viola Limestone (in Patterson Ranch Group)

Middle and Upper Ordovician: Central southern and southwestern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

C. E. Decker, 1942, Oklahoma Acad. Sci. Proc., v. 22, p. 153, 154 (table 1). Basal formation in Patterson Ranch group (new). Overlies Bromide formation; underlies Fernvale.

C. E. Decker, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 1, p. 101–102, 135 (table 5). Discussion of Athens graptolites in Viola limestone. Viola extends east of Arbuckle Mountains to northwest edge of Ouachita Mountains where it has been more complexly folded and more highly metamorphosed, part of the limestones having been silicified. From east edge of Arbuckle Mountains, Viola thickens from 200 to 500 feet and westward to more than 900 feet. Overlies Bromide formation. Of the 59 graptolites identified from the Viola, 48 are found in Athens. *Nemagraptus* present. Trentonian.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (columns 54, 55). As shown on correlation chart overlies Bromide formation (limestone) in Arbuckle and Wichita Mountains. Black River-Trentonian.

W. E. Ham, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2038–2039. Collings Ranch conglomerate (new) rests with marked angular unconformity on steeply dipping rocks of Arbuckle anticline. Viola limestone is listed among units exposed beneath the conglomerate.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in central southern and southwestern Oklahoma.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 123–125. Information on Viola formation is relevant to the discussion of brachiopods forming subject of this monograph because of Decker's (1952) correlations of Athens shale of Virginia with part of Viola limestone of Oklahoma. Report of *Nemagraptus* in Viola is disturbing because it leads to correlation that is in distinct conflict with that indicated by other groups of animals. On the basis of brachiopods, lower Viola would be placed at the lowest with about middle Trenton. Decker makes same age assignment for the Viola, but this is inconsistent with his reported discovery of *Nemagraptus* fauna in lower part of Viola.

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, p. 100. Disconformably overlies Corbin Ranch formation (new).

Named for former village of Viola, near Bromide, Johnston County, which was located near outcrop of formation.

Violin Breccia (in Ridge Basin Group)

Miocene to Pliocene: Southern California.

J. C. Crowell, 1954, California Div. Mines Bull. 170, map sheet 7. Consists of rubble of gneiss blocks as much as 6 feet in diameter in muddy matrix, accumulated as talus or alluvial debris at base of San Gabriel fault scarp. Thickness 27,000 feet; extends along strike for maximum distance of 4,000 feet. Grades abruptly into finer grained Ridge Basin rocks on east. Underlies Hungry Valley formation; overlies Castaic formation (new).

Named for exposures on divide between Violin and Palomas Canyons, Ridge Basin area, Los Angeles and Ventura Counties.

Vipont Limestone

Carboniferous(?): Northwestern Utah.

V. E. Peterson, 1942, Econ. Geology, v. 37, no. 6, p. 471 (table 1). Consists of fine-grained crystalline blue-gray limestone, locally containing numerous small calcite stringers. Thickness 50 to 100 feet. Underlies newly named Wardlaw shale and overlies newly named Sentinell limestone.

In Ashbrook mining district on west side of Goose Creek Range.

Virden Formation

Upper Cretaceous: Northwestern New Mexico.

W. E. Elston, 1960, New Mexico Bur. Mines and Mineral Resources Geol. Map 15. Fanglomerate, fluvial conglomerate, tuffaceous sandstone, and gray shale. Contains plant fossils tentatively dated as late Cretaceous. Maximum thickness 4,000 feet. Stratigraphically above Colorado shale and below Datil formation.

Type locality: Sec. 16, T. 18 S., R. 20 W., Hidalgo County, Virden quadrangle.

**Virgelle Sandstone** (in Montana Group)[1]

**Virgelle Sandstone Member** (of Eagle Sandstone)[1]

Upper Cretaceous: Northwestern, central northern, and central southern Montana.

Original reference: E. Stebinger, 1914, U.S. Geol. Survey Prof. Paper 90, p. 62–68.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 108 (fig. 1), 114, 115. On northwest flank of Sweetgrass arch, Virgelle is considered of formation rank. Here it is a cliff-forming formation with average thickness of about 160 feet. Underlies Two Medicine formation; overlies Telegraph Creek formation. On northeast flank of Sweetgrass arch, considered member of Eagle sandstone. Thickness 95 to 210 feet. Underlies unnamed upper member; overlies Telegraph Creek formation.

Well exposed along Missouri River from town of Virgelle, a few miles below Fort Benton, Chouteau County, eastward.

Virgen [Virgin] series[1]

Tertiary, late: Southeastern California and southwestern Nevada. .

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 61.

Occurs in Virgen Valley and in Furnace Canyon, Inyo County, Calif.

**Virgil Series**[1]

Upper Pennsylvanian: Kansas, Arkansas, Iowa, Missouri, Nebraska, and Oklahoma.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. Guidebook 5th Ann. Field Conf. correlation chart.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 657–706, chart 6. In upward order, midcontinent time-rock divisions of Pennsylvanian are designated as Morrowan, Lampasan, Desmoinesian, Missourian, and Virgilian.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2020–2022. Uppermost Pennsylvanian rocks, lying between post-Missourian disconformity and similar break occurring above horizon of Brownville limestone, which in northern midcontinent area is recognized to define Pennsylvanian-Permian boundary, are classified as Virgilian series. They are characterized by invertebrate faunas of intermediate nature between those of the Missourian and Lower Permian and are classed as composing upper part of zone of *Triticites*. As recognized by State Geological Surveys of northern midcontinent area, series comprises (ascending) Douglas, Shawnee, and Wabaunsee groups.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 297. Approximately upper one-third of Pennsylvanian system belongs to Kawvian series (new). Kawvian rocks are divided into Missourian stage below and Virgilian stage above.

W. H. Bradley, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2284–2285. In midcontinent region (including Arkansas, Iowa, Kansas, Missouri, Nebraska, and Oklahoma), U.S. Geological Survey uses following series subdivision of the Pennsylvanian: Morrow, Atoka, Des Moines, Missouri, and Virgil. Virgil is late Pennsylvanian.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 23. In Iowa it is not possible to locate accurately unconformity separating Pedee group of Missouri series from Douglas group of Virgil series. If break in sedimentation exists, it may be above, within, or below sediments lying between Oread limestone of Shawnee group (Virgil series) and Stanton limestone of Lansing group (Missouri series).

Named for town in eastern part of Greenwood County, Kans.

Virgilian Series or Stage

*See* **Virgil Series.**

Virgilina Greenstone[1]

Virgilina Group[1] or Volcanic Group[1]

Precambrian: Central northern North Carolina and central southern Virginia.

Original reference: T. L. Watson, 1916, Virginia Geol. Survey geol. map of Virginia.

J. P. Meador, 1949, (abs.) Virginia Acad Sci. Proc. 1948–1949, p. 137. In eastern Lunenburg County, Va., Flat Rock Creek granite (new) lies between Virgilina greenstone and injected gneisses.

Rocks form Virgilina Ridge and are typically developed in and near town of Virgilina, Halifax County, Va.

**Virgin Limestone Member** (of Moenkopi Formation)[1]

Virgin Formation (in Moenkopi Group)

Lower Triassic: Southwestern Utah and northwestern Arizona.

Original reference: H. Bassler and J. B. Reeside, Jr., 1921, U.S. Geol. Survey Bull. 726–C, p. 90–92.

H. E. Gregory, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 226; 1950, U.S. Geol. Survey Prof. Paper 220, p. 48 (fig. 24), 52 (table), 60. Separated from underlying Timpoweap member (new) by unnamed lower red member about 200 feet thick. Thickness 8 to 116 feet.

S. J. Poborski, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1342; 1953, Plateau, v. 25, no. 4, p. 69–79; 1954, Geol. Soc. America Bull., v. 65, no. 10, p. 971–1006. Rank raised to formation in Moenkopi group herein rank raised. Boundary of formation is placed at base of lowest limestone layer; this limestone rests disconformably on either "lower red member" of Moenkopi or upon alpha member of Kaibab. Thickness as much as 213 feet..

Named for Virgin City [now Virgin], Washington County, Utah.

**Virgin Creek Member** (of Pierre Shale)

Upper Cretaceous: Central and southeastern South Dakota.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 35–43, pl. 3. Includes all beds between Sully member (new) below and Mobridge member (new) above. Consists of gumbo-forming shale; zone of limestone concretions near top; many thin bentonites in lower part. Thickness 55 to 224 feet.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 1). Overlies Verendrye member (new); underlies Mobridge member.

H. E. Simpson, 1960, U.S. Geol. Survey Prof. Paper 328, p. 12 (table 1), 38–39. Thickness about 25 feet in Yankton area. Overlies Verendrye member; underlies Mobridge member.

Named from exposure in valley wall of Virgin Creek and in flats and hills above it, 1½ miles south of Promise, northeastern Dewey County.

Virginia Limestone Member (of Moenkopi Formation)[1]

*See* **Virgin Limestone Member** (of Moenkopi Formation)

Virginia Quartz Hypersthene Norite[1]

Late Mesozoic: Southern California.

Original reference: P. H. Dudley, 1935, California Jour. Mines and Geology, v. 31, no. 4, p. 491, 501.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 481, table 4. In succession of intrusives Virginia quartz norite is older than Perris and Estelle quartz diorite (Val Verde tonalite) and younger than Gavilan Peak gabbro. Late Mesozoic.

Occurs in Perris fault block, Riverside County.

**Virginia Slate**[1] (in Animikie Group)

Precambrian: Northeastern Minnesota.

Original reference: C. R. Van Hise and C. K. Leith, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 353, 360.

G. M. Schwartz, 1951, Geology of the Cuyuna Range: Minnesota Univ. Center for Continuation Study, Mining [Geology] Symposium [No. 2], p. 3. For most part, the Deerwood iron formation and Cuyuna slates have been considered to belong to the Virginia. This correlation has very little evidence to support it.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1047–1050. Included in Animikie group. Unit is an argillite and graywacke; lacks slaty cleavage and is not dynamically metamorphosed; much of it is thin bedded, but graywacke is thick bedded. Thickness estimated to be 2,000 to 3,000 feet in Cook County, but on western Mesabi may be much greater. Data on unit based largely on drill-core information. Overlies Biwabik iron-formation; contact may or may not be conformable.

F. F. Grout and J. F. Wolff, 1955, Minnesota Geol. Survey Bull. 36, p. 3, 4, 7, 56, pl. 6. In Cuyuna district, includes South Range member (new).

Named Virginia slate because in its typical form it has been found in numerous test pits and drill holes west of town of Virginia, St. Louis County. Recently has been exposed on south side of Embarrass Lake mine near Aurora.

Virginia Blue Ridge Complex

Precambrian: South-central Virginia.

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 7–9, 48, pl. 1. Complex of schistose, gneissose, granitoid, and migmatitic rocks, which is older than Lynchburg and Swift Run formations. Comprises inner or core portion of Blue Ridge structural province in Virginia referred to variously as "injection complex," "granitized complex," and "basement complex." Principal units included are: Pedlar formation, Marshall gneiss, Lovingston gneiss and granite, Roseland anorthosite, and Moneta gneiss (with Reusens migmatite facies).

In Catoctin-Blue Ridge anticlinorium of Lynchburg quadrangle.

Virginia Creek Member (of Pierre Shale)

Probably lapsus for **Virgin Creek Member** (of Pierre Shale).

†Virginian[1]

Miocene: Maryland and Virginia.

Original references: A. Heilprin, 1883, Philadelphia Acad. Nat. Sci. Proc. 1882, p. 183–184; 1884, Philadelphia Acad. Nat. Sci. Jour. 2d ser., v. 9, pt. 1, p. 120.

Virginian Ridge Formation

Lower and Middle Cretaceous(?): Northwestern Washington.

J. D. Barksdale, 1948, Northwest Sci., v. 22, no. 4, p. 165, 169–171. Black siltstones, graywackes, and silica pebble conglomerates. Bulk of formation composed of spheroidally weathering black to dark-greenish siltstone occasionally interbedded with dark graywacke. Contains at least five beds of well-sorted pebble conglomerate from 10 to 30 feet thick. Complete absence of granitic debris characterizes conglomerates made up of well-rounded gray to black chert and white vein quartz pebbles. Basal conglomerate in some places several hundred feet thick. Approximately 12,000 feet of section above basal conglomerate. Rests unconformably on Newby formation (new) and grades into overlying Winthrop sandstone.

Type locality: In Wolf Creek and along Virginian Ridge between Wolf Creek and the west fork of Methow River in northwestern part of Methow quadrangle. Basal conglomerate best exposed along Twisp River 3½ miles west of Twisp.

Virgin Island Group

Upper Cretaceous: Virgin Islands.

T. W. Donnelly, 1960, Dissert. Abs., v. 20, no. 7, p. 2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. Overlies Water Island formation (new), slight angular unconformity. Includes (ascending) Louisenhoj formation, Outer Brass limestone, Tutu formation, and Hans Lollik formation. Considered of Cenomanian age.

Report discusses geology of St. Thomas and St. John Islands.

Virgin Spring phase (of Amargosa chaos)

Post-Miocene(?): Southern California.

L. F. Noble, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1936. Listed as phase of Amargosa chaos, an assemblage of blocks on overthrust plate of Amargosa thrust.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 965–968, pl. 3. Mosaic of fault blocks composed mostly of dolomite, limestone, sandstone, quartzite, shale, and slate; prevailingly dark shades of brown and gray; consists essentially of later Precambrian and Cambrian formations but contains a few blocks of Tertiary volcanic rocks. Average thickness about 600 feet; maximum thickness more than 1,000 feet. Lies everywhere directly on the Amargosa thrust. Underlies Calico phase with which it is folded just as if the two units were beds in sedimentary series.

Occurs in Virgin Spring area near Death Valley. Name is derived from Virgin Spring, in Virgin Spring Canyon. Phase covers about 20 square miles in area mapped.

Virgin Valley Beds[1]

Virgin Valley Formation

Miocene: Northwestern Nevada and southeastern Oregon.

Original references: J. C. Merriam, 1907, Science, new ser., v. 26, p. 380–382; 1910, California Univ. Dept. Geology Bull., v. 6, no. 2, p. 33–36.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 35, pl. 1. Virgin Valley formation, late Hemingfordian or early Barstovian.

D. O. Cochran, 1959, Oregon Dept. Geology and Mineral Industries Bull. 50, p. 10 (chart), 14. Correlation chart shows Virgin Valley formation in Steens-Pueblo Mountain area, Oregon. Upper zone white to buff beds; ash and diatomaceous beds. Middle zone gray to yellow and brown shales and clays; carbonaceous shales, lignites, diatomaceous beds. Lower zone white to green, purple, and red clays and ash. Thickness 1,000 to 2,000 feet. Overlies Canyon rhyolite; underlies Danforth(?) formation. Miocene, Barstovian.

Virgin Creek drains valley in which beds occur in Nevada.

**Vishnu Schist[1]**

Vishnu Series

Precambrian: Northern Arizona.

Original reference: C. D. Walcott, 1889, Geol. Soc. America Bull., v. 1, p. 50.

Ian Campbell and J. H. Maxson, 1938, Carnegie Inst. Washington Year Book 37, p. 361–362. Vishnu series proposed for the 25,000 feet or more of metasediments, a usage which will restrict term "Vishnu schist," originally proposed by Walcott for entire Archean terrane. Type locality indicated.

C. A. Anderson, 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1333–1334. No name was given by Campbell and Maxson for metavolcanic rocks in Grand Canyon and until they complete their studies, it is desirable to retain Vishnu schist for all metasediments and metavolcanics older than Grand Canyon series.

Type locality: In lower canyon of Vishnu Creek, Grand Canyon region.

Vista Member (of White River Formation)

Oligocene (Whitneyan): Northeastern Colorado.

E. C. Galbreath, 1953, Kansas Univ. Paleont. Contr. 13, Vertebrata, art. 4, p. 15 (fig. 5), 16–18, 25. Beds composed of massive, tan silt with highly calcareous zone (the "white marker") at bottom; erosional disconformity at top. Thickness at type locality about 97 feet. Overlies Cedar Creek member (new); underlies Pawnee Creek formation.

Type locality: NE½ sec. 17, T. 11 N., R. 53 W., Logan County. Name derived from Vista triangulation station, SW¼ sec. 1, T. 11 N., R. 54 W., which is almost at center of Vista member exposures.

Vista Monzonite or Granodiorite Porphyry

Tertiary(?): Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 39, pl. 1. Gray-green granodiorite or monzonite intrusive of unknown age.

In sec. 21, T. 19 S., R. 9 W., in northern Cooks Range, near Vista fluorite mine, Dwyer quadrangle.

Vitrefrax Formation

Paleozoic or older: Southern California.

P. C. Henshaw, 1942, California Jour. Mines and Geology, v. 38, no. 2, p. 153–155, pl. 2. Comprises several indefinitely bounded lithologic units —quartz, kyanite schist, sericite schist.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 489, table 4. Older Precambrian(?).

Occurs in Cargo Muchacho Mountains, Imperial County. Named for its best developed exposure in Bluebird quarry on Vitrefrax Hill.

Vivian Sandstone (in Pocohontas Group)

Vivian Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 232.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 107. Sandstone in Pocahontas group.

Has been quarried east of East Vivian railway station, McDowell County.

Volcano Bay Basalt Flow (in Mount Hague Volcanics)

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, p. 15, pl. 2 (geol. map). Believed to be at most only a few hundreds of years old, because of its fresh blocky surface and lack of dissection. May have had its source on southeast flank of Mount Hague. Flow believed to have moved southwestward until it reached heads of two narrow southeastward-trending valleys carved in older Dushkin and Arch Point flows (new). Lava followed these two valleys until it flowed out on low plain at valley mouths where the two lava streams fanned out and coalesced. Much of flow has been capped by younger flow from Cone G.

Covers much of lowlands north of Dushkin and Long John Lagoons in vicinity of Pavlof Volcano, near end of Alaska Peninsula.

Volga shales[1]

Upper Ordovician: Iowa.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 55, p. 217–222.

Volta Formation (in Orestimba Group)

Upper Cretaceous: Central California.

R. D. Reed, 1943, California Div. Mines Bull. 118, pt. 2, p. 109 (table 6) [preprint 1941]. Listed on table as uppermost formation of Orestimba group. Name credited to F. M. Anderson.

Occurs in San Joaquin Valley.

Volusia Shale[1]

Upper Devonian: Western New York.

Original reference: G. H. Chadwick, 1923, Geol. Soc. America Bull., v. 34, p. 69.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 14. Volusia shale (Chadwick, 1923) bearing *Pugnoides duplicatus*, is here included in Dexterville member of Chadakoin formation.

Named for occurrence near Volusia, Chautauqua County.

**Voss Shale Member** (of Belle Plains Formation)

Permian: West-central Texas.

R. C. Moore, 1948, *in* M. G. Cheney, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, sheets 3, 4. Shown on columnar section. Underlies Jagger Bend limestone member; overlies Elm Creek limestone member.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheets 1, 2. Thickness 10 to 50 feet. No complete outcrop found; partial exposures indicate that member consists mainly of yellowish and blue clay shale.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 273. Thickness 20 to 85 feet in Brazos River area. Overlies Elm Creek limestone member; underlies Jagger Bend limestone member.

Name derived from village of Voss, southwestern Coleman County, 9 miles south and 1 mile west of Valera.

Vowell Mountain Group

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 11, 19, pls. 2, 3, 4, 6, 8. Includes all strata between top of Redoak Mountain group (new) below and base of Cross Mountain group (new) above that is between top of Pewee coal and top of Frozen Head sandstone. Thickness 230 to 390 feet. Includes (ascending) shale interval, Pilot Mountain sandstone, shale interval, and Frozen Head sandstone.

Type locality: Cross Mountain, Lake City quadrangle, Anderson County. Name derived from Vowell Mountain, a spur on east side of Cross Mountain. Group is preserved only on higher mountains and, hence, has more restricted outcrop area than older groups.

**Vulcan Iron-Formation**[1] (in Menominee Group)

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 16; Mon. 36, p. xxv, xxvi.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 35. Upper formation in newly defined Menominee group. Includes (ascending) Traders iron-bearing member, Brier slate member, Curry iron-bearing member, and Loretto slate member. Overlies Felch formation; underlies Goodrich quartzite of Baraga group (new).

Named for exposures in vicinity of West Vulcan, Menominee district, [Dickinson County].

**Waawaa Volcanics** (in Hualalai Volcanic Series)

Waawaa pyroclastic materials

Pleistocene(?): Hawaii Island, Hawaii.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 86–87, 145. Pumiceous and dense, trachytic lapilli and ash in Puu Waawaa cone referred to as Waawaa pyroclastic materials.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 138 (table), 143–148; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6 Océanie, fasc. 2, p. 134–135. Waawaa volcanics considered member of Hualalai volcanic series (new). Consist of trachyte flow and its source cone. Flow made up of several units 250 to 500 feet thick; exposed thickness 900 feet; base not exposed. Older than at least part of Pahala ash. Pleistocene(?).

Type locality: Puu Waawaa. Covers about 3 square miles on northern slope of Hualalai.

Wabash Formation[1]

Pennsylvanian: Southwestern Indiana.

Original reference: M. L. Fuller and F. G. Clapp, 1904, U.S. Geol. Survey Geol. Atlas, Folio 105.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 25). Shown on correlation chart as comprising (ascending) Parker limestone, Buffkin limestone, Graysville limestone, and Livingston limestone. Occurs above Inglefield sandstone and below Merom sandstone.

Named for exposures in bluff of Wabash River in Patoka quadrangle.

†Wabash Group[1]

Pennsylvanian: Indiana.

Original reference: G. H. Ashley, 1902, U.S. Geol. Survey 22d Ann. Rept., pt. 3, p. 273.

D. W. Franklin, 1944, Illinois Acad. Sci. Trans., v. 37, p. 86 (table 1). Shown on table as a group 250 to 300 feet thick above the Merom group.

Named for Wabash River, which cuts through the various formations.

†Wabash Stage[1] or Beds[1]

Pleistocene: Central Indiana.

Original reference: O. P. Hay, 1912, Smithsonian Misc. Colln., v. 59, no. 20, p. 13.

Type locality: About 4 miles east of Fairmount, Grant County. Named for Wabash River, where it is well developed in valley of river and its tributaries.

**Wabaunsee Group[1]**

Wabaunsee Formation[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, southeastern Nebraska, and northern Oklahoma.

Original reference: C. S. Prosser, 1895, Jour. Geology, v. 3, p. 688–697.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 165–196. Uppermost major division of Virgilian strata. As adopted by interstate conference of Geological Surveys, includes (ascending) Severy shale, Howard formation, White Cloud shale, Happy Hollow limestone, Cedar Vale shale, Rulo limestone, Silver Lake shale, Reading limestone, Harveyville shale, Elmont limestone, Willard shale, Tarkio limestone, Wamego shale, Maple Hill limestone, Langdon shale, Dover limestone, Dry shale, Grandhaven limestone, Friedrich shale, Jim Creek limestone, French Creek shale, Caneyville limestone, Pony Creek shale, and Brownville limestone. Overlies Shawnee group. Top drawn at prominent disconformity just above Brownville limestone. Comprises Sacfox, Nemaha, and Richardson subgroups. Agreed that nomenclature in the several States may be required to deviate from this standard section by combination or omission of terms where certain named rock units are not recognizable.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. viii, 19–21. As redefined for Missouri, includes beds from top of Topeka formation to top of Pennsylvanian in Missouri, which is top of French Creek shale. Grandhaven limestone has not been identified in Missouri, and shale between Dover limestone and Jim Creek limestone is called Dry-Friedrich shale. Lower limestone of Tarkio has been considered base of Wabaunsee and lower limestone (Elmont) and Willard shale included in Shawnee group.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 12–20. Nebraska follows interstate agreement on classification of Wabaunsee except in use of Pierson Point for Wamego, Morton formation for Grandhaven interval, and Wood Siding formation between French Creek formation and Brownville limestone. Thickness of group in Nebraska about 396 feet.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2271–2278. Redefined. Includes ascending [Severy shale, Howard limestone], Scranton shale, Bern limestone (new), Auburn shale, Emporia limestone, Willard shale, Zeandale limestone (new), Pillsbury shale (new), Stotler limestone (new), Root shale (new), and Wood Siding formation.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 25 (table 2), 44–71. Uppermost group of Virgilian series. Currently group includes beds upward from top of Topeka (Turkey Run limestone) to top of Brownville limestone. In Kansas, Wabaunsee deposits are cyclic and similar to those of underlying Shawnee group. Southward these deposits lose much of their cyclic character, and although alternating marine and nonmarine beds are present in Pawnee County section, the rhythmic pattern of cyclic deposition is obscure. Key beds in group in Pawnee County are traceable northward into Kansas, and names of these beds are generally taken from Kansas section. When it comes to naming shale-sandstone sequences between key limestones of Pawnee County, modification of Kansas nomenclature is necessary. Most of limestones on which subdivision of Kansas section is based pinch out southward; hence, beds between any two key units of Pawnee County may represent several formations in Kansas section. Moore (1936, Kansas Geol. Survey Bull. 22) suggested that this situation be dealt with by applying hyphenated names in areas where missing key units make standard Kansas section inapplicable. Branson (1956, Oklahoma Geology Notes, v. 16, no. 11) proposed alternate solution to problem by giving names to each of shale-sandstone units between most extensive limestones of upper Pennsylvanian in north-central Oklahoma. Stratigraphic sequence to which each name applies becomes progressively greater southward as recognizable Kansas units disappear from section. Branson's revised nomenclature is followed in this report. Key beds of group in north-central Oklahoma are (ascending) Bird Creek, Wakarusa, Reading, Elmont, Grayhorse, and Brownville limestones. Names used in this report are (ascending) Severy shale, Bird Creek limestone, Hallett shale, Wakarusa limestone, Auburn shale, Emporia limestone with Reading limestone, Harveyville shale, and Elmont limestone members, Gano shale, Wood Siding formation with "Grayhorse" limestone, Pony

Creek shale, and Brownville limestone members. Wabaunsee outcrops cover most of central part of Pawnee County, forming belt up to 8 miles wide that strikes north-south across county.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 10–14, fig. 5. Present only in Adams, Montgomery, Taylor, Page, and Fremont Counties. Group is predominantly shale with limestone, siltstone, minor sandstone units, and thin coal seams. The subgroups, Richardson, Nemaha, and Sac-Fox, are not well defined in Iowa and are not identified in this report, nor are major units broken down into members as they are in other groups of the Pennsylvanian. Because of predominance of shale within the group, exposures soon become slumped and overgrown; for this reason, some sections described by early workers have since become obscured. For example, youngest rocks to be described in Iowa was exposure on Mill Creek, south of Riverton (Smith, 1908, Iowa Geol. Survey, v. 19). Here French Creek shale, Jim Creek limestone, and Friedrich-Dry shale were exposed but are no longer visible. Younger rocks may be present beneath the drift between Hamburg and Thurman and east of Hamburg, but they are not exposed and have not been reported in drilling records. There is little to distinguish units as seen, and many correlations are necessarily on basis of sequence and not lithologic or paleontologic distinction. Strata are believed to thin considerably to northwest. Group includes (ascending) Severy shale, Howard limestone, White Cloud shale, Happy Hollow limestone, Cedar Vale shale, Silver Lake shale, Burlingame limestone. Soldier Creek shale. Wakarusa limestone, Auburn shale, Reading limestone, Elmont limestone, Willard shale, Tarkio limestone, Pierson Point shale, Table Creek shale, Dover limestone, Dry shale, Grandhaven limestone, Friedrich shale, Jim Creek limestone, and French Creek shale.

Named for exposures in Wabaunsee County, Kans.

**Waccamaw Formation**[1]

Pliocene, lower: Southern and eastern South Carolina and southern North Carolina.

Original reference: W. H. Dall, 1892, Wagner Free Inst. Sci. Trans., v. 3, pt. 2, p. 209–213.

H. E. LeGrand and P. M. Brown, 1955, Carolina Geol. Soc. Guidebook of Excursion in coastal plain of North Carolina Oct. 8–9, p. 11–12. In this report, Waccamaw is considered contemporaneous with Duplin marl and placed in Yorktown formation which is geographically extended into North Carolina. This reclassification made on the basis of the fact that 15 species of Ostracoda known to occur in Duplin marl occur in Waccamaw formation, and, in addition, no ostracod species have been found in the Waccamaw that do not occur in the Duplin. Yorktown is considered upper Miocene.

G. E. Siple, 1957, Carolina Geol. Soc. Guidebook for South Carolina Coastal Plain Field Trip No. 16–17, p. 20–22. Although age of the Waccamaw could be either latest Miocene or Pliocene, it is here included in the Pliocene until more conclusive evidence is found to the contrary.

Named for exposures along Waccamaw River, Horry County, S.C.

**Wachsmuth Limestone** (in Lisburne Group)

Lower Mississippian: Northern Alaska.

A. L. Bowsher and J. T. Dutro, Jr., 1957, U.S. Geol. Survey Prof. Paper 303–A, p. 4, 6, 17–24, figs. 2–4, pl. 2. Comprises four unnamed members at type locality (ascending): shaly limestone, 18 feet thick; crinoidal limestone, 179 feet; dolomite, 564 feet; and banded chert-limestone, 429 feet. Total thickness 1,230 feet. Underlies Alapah limestone (new) and overlies Kayak shale (new) both disconformably.

Type locality: On south slope of Mount Wachsmuth, from which limestone takes its name, Shainin Lake area, central Brooks Range.

†Wachusett Gneiss[1]

Upper Carboniferous or post-Carboniferous: Central northern Massachusetts.

Original reference: L. S. Burbank, 1876, Rept. on geol. map of Massachusetts, by W. O. Crosby, p. 43–52.

Wachusett Range in Worcester County region.

Waco Limestone[1]

Silurian (Niagaran): East-central Kentucky.

Original references: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145; 1906, Kentucky Geol. Survey Bull. 7, p. 10, 52.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Waco limestone stratigraphically below Dayton limestone and above Lulbegrud conglomerate.

Named for Waco, Madison County.

Waddell Sandstone (in Simpson Group)

Middle Ordovician: Western Texas (subsurface).

Taylor Cole, C. D. Cordry, and H. A. Hemphill, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 280 (fig. 1), 281–282. Proposed for lower sandstone bed in Simpson group. Lies between depths of 6,143 and 6,231 feet in type well. Top occurs 280 feet below top of McKee sand (new) and about 355 feet above top of Ellenburger; these intervals vary somewhat in a widespread area.

Type well: Gulf Oil Corp. W. N. Waddell et al No. 1, sec. 4, Block B–27, PSL Survey, Crane County.

**Wading Branch Formation** (in Snowbird Group)

Precambrian (Ocoee Series): Western North Carolina.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 954, 955 (table 1), 956 (fig. 3). Consists of medium-bedded dark clastic rocks, including sandy argillaceous rocks, siltstone, and coarse pebbly feldspathic sandstone; coarser rocks are poorly sorted, have a dark micaceous matrix, and are somewhat graded; a basal unit generally less than 100 feet thick, representing residual reworked clay, is present throughout much of the formation. Basal formation of group; underlies Longarm quartzite (new); contact gradational over several tens of feet; unconformably overlies earlier Precambrian granitic and gneissic rocks (Max Patch granite of Keith).

Type section: Along Pigeon River, 4½ miles southeast of Waterville. Named for Wading Branch Ridge west of Pigeon River about 5 miles southeast of Waterville, Haywood County. Traceable southwestward through several belts of outcrop as far as Cherokee.

†Wadmalaw Shell Marl[1] or phase[1]

Pleistocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 20–21.

Exposed south of Bees Ferry, at the Faber place, and along northerly shore of Stono and Wadmalaw inland waterway, at Cherokee, Bolton, and St. Andrews phosphate mines, and at base of Simmons Bluff, Charleston County.

**Wagnon Member** (of Pride Mountain Formation)

Upper Mississippian: Northern Alabama.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Series of limestones and shales. Includes lower part of strata referred to by Butts (1926) as Gasper formation. Thickness ranges from 70 feet at south Tuscumbia to 30 feet near Pride and averages about 50 feet. Underlies Southward Spring sandstone member and overlies Tanyard Branch member (new); both contacts sharp and conformable. At type locality of the Pride Mountain, where Southward Spring sandstone member is absent, underlies Sandfall member (new).

Named for exposure along road up Wagnon Mountain about 5 miles south of Pride, in south-central sec. 6, T. 5 S., R. 12 W., Colbert County.

Wagonhound Member[1] (of Uinta Formation)

Eocene: Northeastern Utah and southwestern Wyoming.

Original reference: H. E. Wood 2d, 1934, Am. Mus. Nat. History Bull., v. 67, art. 5, May 26, p. 241–242.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 417. Mentioned in discussion of Uinta formation.

Name derived from Wagonhound Canyon which opens into White River, Utah.

Wagontire Formation[1]

Eocene(?): Central southern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Type locality: Wagontire Mountain, northeastern part of Lake County.

Wagontongue Formation

Miocene(?): Central Colorado.

J. H. Johnson, 1937, (abs.) Colorado Univ. Studies, v. 25, no. 1, p. 77; J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 34 (table 7), 68–69, 173, pl. 1. Series of coarse sandstones, sandy clays, and conglomerates made up largely of reworked volcanic materials. Contains beds of volcanic ash. Thickness 110 to 500 feet. Underlies Trump conglomerate (new); overlies Antero formation (new).

Well exposed in two northward-facing cuts in secs. 29 and 30, T. 14 S., R. 75 W. Many good outcrops along Wagontongue Creek, from which unit takes its name, and small tributaries leading into it, especially in NE¼ sec. 6, T. 15 S., R. 75 W., Park County.

Wagonwheel Formation[1]

Oligocene or Oligocene(?): Southern California.

Original reference: H. R. Johnson, 1909, Science, new ser., v. 30, p. 63–64.

H. P. Smith, 1956, California Univ. Pubs. Geol. Sci., v. 32, no. 2, p. 65–108. Consists of three unnamed members, a lower sandstone, a middle argillaceous siltstone, and an upper glauconitic siltstone. Thickness about 470 feet. Unconformably underlies basal shale of Temblor; conformably overlies Welcome member of Kreyenhagen. Oligocene. Entire area of outcrop not more than 2¼ miles long and one-quarter mile wide.

Occurs in Devil's Den district, approximately 25 miles southeast of Avenal and 50 miles northwest of Taft, northwestern Kern County.

Wagon Yard Gypsum[1]

Wagon Yard Gypsum Member (of Dog Creek Formation)

Permian (Guadalupe): Western Texas.

Original reference: L. W. Storm, 1929, Texas Econ. Geol. Survey map of Stonewall County.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of west Texas: West Texas Geol. Soc., p. 30, fig. 9. Shown on chart as top member of Dog Creek formation. Overlies Guthrie dolomite member; underlies Childress formation.

First used in Stonewall County.

Wahkiakum Formation[1]

Miocene, lower: Southwestern Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 15, p. 10–12.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 100. Name abandoned. Unit considered part of Blakeley formation.

Occurs near head of Alockaman River, Wahkiakum County.

Wahluke Formation

Pleistocene: Central Washington.

G. F. Beck, 1936, Mineralogist, v. 4, no. 11, p. 12–14. Name applied to thin layer of sediments lying above a white lime-rock layer that lies within Columbia basalts, Ellensburg sediments, Wenas basalts, or Ringold sediments—whichever of these was exposed or truncated by post-Ringold surface. Wahluke sediments are fossiliferous, poorly cemented, flat lying, and crossbedded; locally contains lenses and horizons of sand. Includes Tiflis member (new) at top.

Named for typical exposure above undoubted Ringold at head of Beverly highway grade, about 1 mile south of Wahluke, Grant County.

Wahs Creek Shale (in Moran Formation)[1]

Permian: Central northern Texas.

Original reference: O. F. Hedrick, E. Owens, and P. A. Meyers, 1929, Texas Bur. Econ. Geology, geol. map of Shackelford County.

In Shackelford County.

Wahwah Limestone (in Pogonip Group)

Lower Ordovician (Canadian): Western Utah and east-central Nevada.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 16–17, 51. Ledge-forming quartz silty calcisiltite. Thickness at type section

227 feet. Overlies Fillmore limestone (new); underlies Juab limestone (new).

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 72–73, pl. 1. Described in Sheeprock Mountains where it is 456 to 476 feet thick; conformably overlies Fillmore limestone and conformably underlies Juab limestone. Included in Pogonip group.

Type section: Ibex, Millard County, Utah. Name derived from Wahwah (also spelled Wah Wah) Valley. Unit extends into east-central Nevada.

Wah Wah Springs Tuff Member (of Needles Range Formation)

Eocene(?) or Oligocene, lower(?): Southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 92 (fig. 2), 99. Shows complete gradation upward from black vitrophyre at base to light-gray nonwelded ashy top. Thickness 700 to 800 feet. Basal member of formation; underlies Minersville tuff mmeber (new).

Named for occurrence south of Wah Wah Springs, 15 miles west of abandoned mining town of Frisco, Iron Springs district.

**Wahweap Sandstone**[1]

Upper Cretaceous: Central southern Utah.

Original reference: H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 200, p. 51 (table), 107–109, pls. 2, 4, 5. Described in Zion Park region where it overlies Straight Cliffs sandstone and underlies Kaiparowits formation. Most common beds of Wahweap are sandstones 5 to 10 feet thick, irregularly laminated and lenticularly stratified with highly arenaceous shale; some beds of considerable length are thick, uniformly massive, crossbedded, and consist of coarse and fine rounded grains of quartz; others combine to make series of thin evenly or roughly stratified beds; many sandstones change along strike from solid beds of uniform composition and texture to beds that include shalelike and iron concretions and into series of platy beds of various dimensions. Absence of continuous guide beds and scarcity of fossils in Wahweap and upper Straight Cliffs make it impracticable to draw definite division line between the two formations. Thickness of the two formations 600 to 1,200 feet.

Upper part of Wahweap Creek, Kane County, is cut in the formation.

**Waiaaka Basaltic Andesite** (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 230 (table), 243–244, pl. 1. A persistent thin lava flow overlying Makapipi basalts (new); clinker layers interbedded in the lava may indicate two or more flows. Predominantly aa except in extreme southwestern part where it is pahoehoe. Prominent platy jointing parallel to flow planes. Average thickness 30 feet; 120 feet in test hole 47. Where Makapipi basalts have been removed by erosion, Waiaaka rests on gravel above Kula basaltic andesite (new). Locally overlain by Mossman basalt (new). Each member in series is underlain by local erosional unconformity.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 135. Pleistocene(?).

Named for occurrence along Waiaaka Gulch. Best exposed in Hanawi Gulch north of highway.

## Waianae Volcanic Series[1]

Pliocene(?) : Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 135–136. Divided into lower, middle, and upper members. Lower predominantly olivine basalt, in thin flows of both aa and pahoehoe; middle consists of same rock types but in thick massive flows ponded in the caldera; upper predominantly basaltic andesite, with some flows of basalt and olivine basalt near base. Total thickness above sea level 4,025 feet; series presumably extends down to level of surrounding ocean, about 12,000 feet below sea level. On east side, overlapped with erosional unconformity by lavas of Koolau series. Pliocene(?).

No single type locality designated. Lower member well exposed in cliffs along lower Nanakuli and Lualualai Valleys and in Puu Heleakala; middle member exposed continuously from head of Nanakuli Valley around head of Lualualai and Waianae Valleys and in Keaau-Makaha Ridge overlaps lower member with erosional unconformity; upper member veneers most of eastern slope of Waianae Range. Crops out over area of about 100 square miles comprising most of Waianae Range on western side of island.

## Waiau Formation

Pleistocene to Recent: Hawaii Island, Hawaii.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 36, 57–86. Consists both of central cinder cone phase and yellow tuff phase of pyroclastic materials produced by explosive eruptions from numerous vents in Mauna Kea summit area. Overlies Waimea formation (new).

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 136. Cinder cone and fresh ash phase now largely included in Laupahoehoe volcanic series and partly in Hamakua volcanic series; yellow tuff phase now considered part of Pahala ash. Pleistocene to Recent.

Slopes of Mauna Kea.

## Waihu Fanglomerate

Pleistocene: Hawaii Island, Hawaii.

H. T. Stearns, 1945, Geol. Soc. America Bull., v. 56, no. 3, p. 269, 270–273. Described by Wentworth and Powers (1939, 1941) as Waihu drift. It is here interpreted as laid down by floods caused by eruptions melting ice cap of Mauna Kea in early Wisconsin time. Well indurated, distinctly bedded and crossbedded. Forms fans 100 feet thick between altitudes 9,000 and 9,750 feet between Waikahalulu and Pohakuloa Gulches. Thins down slope and below 6,900 feet is only a few feet thick Stratigraphically lower than Makanaka drift and outwash.

Probably named from Waihu Springs, west of Pohakuloa Gulch. Exposed over area of about one-half square mile on south slope of Mauna Kea.

Waihu Stage and Drift

Pleistocene: Hawaii Island, Hawaii.

C. K. Wentworth and W. E. Powers, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1942; 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1207. Four stages of glaciation, presumably correlative with Ice Age elsewhere, occurred on Mauna Kea. These are (beginning with latest) Makanaka, Waihu, Pohakuloa, and pre-Pohakuloa stages. Drift 25 to 30 feet thick.

H. T. Stearns, 1945, Geol. Soc. America Bull., v. 56, no. 3, p. 269. Of glacial deposits described by Wentworth and Powers, only Makanaka deposits can be accepted as definitely glacial. Waihu drift redefined as fanglomerate.

Drift occurs in vicinity of Waihu Springs, at 9,700 feet altitude west of Pohakula Gulch.

Wailuanui Basalt (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 94, 95 (table). Dark-gray olivine pahoehoe basalt. Older than Ohia lava (new) but time relationship to Pauwalu lava (new), oldest basalt in series in Keanae Valley, not known. Each formation of series underlain by local erosional unconformity.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 137. Pleistocene(?).

A narrow flow that descended west fork of Wailuanui Valley, in Keanae area.

Wailuku Volcanic Series

Pliocene(?): Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 65 (table), 159 (table), 160–172, pl. 1. Primitive olivine basalts, at type locality composed of thin-bedded pahoehoe and aa dipping 15° E. Aa is mostly highly vesicular and lies in jointed beds 2 to 10 feet thick, underlain, overlain, and in places mixed with clinker beds 6 inches to 4 feet thick. In cliffs, thin beds weather to dark gray, red, red violet, and brown in contrast to overlying Honolua lavas (new) which weather to light gray and white. In some areas, apparently never covered by Honolua lavas. Separated from Lahaina lavas (new) by erosional unconformity.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 314–320. Petrography discussed.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 138. Pliocene(?).

Type locality: The 3,500-foot south wall of Iao Valley behind Wailuku. Exposed at surface on most of West Maui and in all deep canyons.

Waimea Agglomerate or Formation

Pleistocene: Hawaii Island, Hawaii.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 38–39. Hummocky accumulations of agglomerate, 15 to 20 feet thick in places, underlying tuff of Waiau formation.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 138. Now known to be fragmental tops of aa lava flows of Hamakua and Laupahoehoe volcanic series. Pleistocene.

Occurs on slopes of Mauna Kea from several miles southeast of Laupahoehoe to Waimea.

Waimea Conglomerate

Pliocene(?): Kauai Island, Hawaii.

N. E. A. Hinds, 1930, Bernice P. Bishop Mus. Bull. 71, p. 56, 65, 76. Coarse conglomerate 75 to 100 feet thick. Overlies lower Kauai lavas and underlies upper Kauai lavas.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 138–139. Equivalent to part of Mokuone member of Makaweli formation. Pliocene(?).

Type locality: Bottom of Waimea Canyon between Waialae and Poomau Streams.

Waimea Volcanic Series

Pliocene and older: Kauai Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 83 (fig. 22), 85–86. Forms main mass of Kauai; subdivided into extra-caldera, or lower member, and caldera filling, or upper member. Lower member composed of more than 3,500 feet of thin-bedded primitive-type olivine basalts dipping 5° to 20° away from ancient caldera; upper member composed of 4,000 feet of chiefly horizontal and massive olivine basalts laid down in summit caldera. Members separated by partly exhumed fault scarps more than 3,000 feet high and talus breccia. Waimea and Haupu volcanic series are separated by deep zone of weathering and angular erosional unconformity from Kolea series.

G. A. Macdonald, 1949, Geol. Soc. America Bull., v. 60, no. 10, p. 1555, 1557. Preoccupied name Waimea replaced by Waimea Canyon volcanic series.

Exposed in walls of Waimea Canyon.

**Waimea Canyon Volcanic Series**

Pliocene(?): Kauai Island, Hawaii.

G. A. Macdonald, 1949, Geol. Soc. America Bull., v. 60, no. 10, p. 1555, 1557. Proposed to replace preoccupied term Waimea volcanic series. Unconformable below Koloa volcanic series.

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1954, Volcano Letter 526, p. 2; G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 118. Includes Napali, Olokele, Haupu, and Makaweli formations.

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1960, Hawaii Div. Hydrography Bull. 13, p. 21–52, table facing p. 20, pl. 1. Consists almost entirely of olivine basalt, with less abundant basalt poor in olivine, and picrite-basalt rich in olivine. All formations cut by small dikes. Exposed thickness about 8,650 feet. Comprises Napali, Olokele, Haupu, and Makaweli formations. Underlies Koloa volcanic series with profound erosional unconformity. Age not accurately known; contains no fossils; age determinations on basis of uranium-lead ratios, or similar methods, available. Latest lavas of series believed to be about 4 million years old; this places their extrusion in Pliocene. Stratigraphic table shows age Pliocene; map legend (p. 18) shows Pliocene(?); map legend (pl. 1) shows later Tertiary.

Type locality: In walls of Waimea Canyon. Exposed over most of island.

**Waiokamilo Basalt** (in Hana Volcanic Series)

Pleistocene(?): East Maui, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 95 (table), 96. Dark-gray olivine basalt, with some phenocrysts of plagioclase in dense fine-grained mass.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 139. Pleistocene(?).

Lava followed valley of Waiokamilo Stream, and cascaded down cliff at eastern edge of Keanae Valley, building small lava fan.

Waiokawa Flow

Recent: Maui Island, Hawaii.

Grote Reber, 1959, Geol. Soc. America Bull., v. 70, no. 9, p. 1246 (fig. 1). A very recent flow.

On southwest side of Haleakala.

Wait Member (of Day Point Formation)

Ordovician (Chazyan): Northwestern Vermont and northeastern New York.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 824 (fig. 3), 825 (fig. 4), 826 (fig. 5), 827, 845, geol. sections. Defined as 5 feet of medium to dark-gray finely laminated dense calcareous fine quartz sandstone to siltstone overlying Scott member (new) in cove at north end of Scott Point, Isle La Motte; underlies Fleury member (new). Member is irregularly divided by disconformity, blocks of lower beds forming pebbles in conglomerate above. The typical gray dense fine quartz sandstone grades eastward to dark quartz-silty shaly argillite with thin quartz sandy lenses. Thickens from type section to 15 feet on east shore of Isle La Motte; westward in New York, it is 5 feet at Wool Point and 3 feet southwest of Chazy; increases southward to about 28 feet on southern Valcour Island and 38 feet on South Hero.

Type locality: In Cove at Scott Point, Isle La Motte, Vt. Name derived from Wait Bay.

**Waits River Formation**

Waits River Limestone[1]

Waits River Limestone Member (of Memphremagog Formation)

Silurian and Devonian: East-central and northeastern Vermont and northwestern New Hampshire.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept., p. 79–115.

L. S. Currier and R. H. Jahns, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1491, 1492, 1506. Formation is largely the Waits River limestone of earlier reports. Includes prominent beds of phyllite and quartzite. Ordovician(?).

C. G. Doll, 1945, Vermont State Geologist 24th Rept., p. 16, pl. 4. Rank reduced to member of Memphremagog formation in northeastern Vermont. Middle Silurian or Lower Devonian.

G. E. Moore, Jr., 1949, Geol. Soc. America Bull., v. 60, no. 10, p. 1618–1619, pl. 1. In Keene-Brattleboro area, New Hampshire-Vermont, Waits River formation crops out in north-south band along extreme western edge of area. Thickness 4,000 to 5,000 feet. Orfordville formation crops out in north-south belt between Northey Hill thrust on east and Waits River formation on west.

W. S. White and R. H. Jahns, 1950, Jour. Geology, v. 58, no. 3, p. 187–189, 192, fig. 2. Standing Pond amphibolite member is tentatively included in uppermost part of formation. In southern part of Strafford quadrangle, Standing Pond marks boundary between Gile Mountain and Waits River formations; farther north, occurs beneath calcareous beds in the Waits River.

C. G. Doll, 1951, Vermont Geol. Survey Bull. 3, p. 22. Name not used in northeastern Vermont because too comprehensive; in its place, three new names used: Ayers Cliff, Barton River, and Westmore formations.

M. P. Billings, 1956, The geology of New Hampshire, pt. 2, bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 6–8. Geographically extended to New Hampshire. Middle Ordovician(?); possibly Silurian and (or) Lower Devonian.

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 16–19, 25, 26–28. Summary of earlier uses of name. Contains Ayers Cliff member and Barton River member in northeastern Vermont.

W. M. Cady, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–79. Age designated Silurian(?) and Devonian(?).

V. R. Murthy, 1957, Vermont Geol. Survey Bull. 10, p. 20, 23 (table 1), 24, 35–38, pls. Metasedimentary rocks of East Barre quadrangle divided into four mappable units. Previously, the western three units were included in one formation, the Waits River (Currier and Jahns, 1941). On basis of present study it is proposed that term Waits River formation be redefined and stratigraphic sequence modified as follows (ascending): Northfield slate (exposed in Barre quadrangle), Barton River formation (partly exposed in area), Westmore formation (type locality—Memphremagog quadrangle), Waits River formation (as newly restricted—type locality in this area), and Gile Mountain formation (type locality—Strafford quadrangle). If structural interpretation offered in this report is accepted, Westmore formation may be correlated with Gile Mountain and stratigraphic column modified as follows: Northfield slate, Barton River formation, Gile Mountain formation (equivalent to Westmore) and Waits River (as here restricted). Waits River is restricted in this area to essentially calcareous rocks in central and eastern parts of quadrangle. Stratigraphically younger than Westmore and Gile Mountain formations. Thickness 4,750 to 6,500 feet. Age may be Lower Devonian(?).

V. R. Murthy, 1958, Jour. Geology, v. 66, no. 3, p. 276–287. Rocks between Northfield slate and Gile Mountain formation in east-central Vermont can be divided into three mappable units. Western two units are continuous with Barton River and Westmore formations as defined in Memphremagog quadrangle to north. These units have been included in Waits River formation, a thick sequence of calcareous and noncalcareous rocks in Barre and East Barre quadrangles. Analysis of structural relations in area indicates possibility of correlating Westmore formation and Gile Mountain formation across limbs of major syncline, trough of which is occupied by calcareous unit in central part of East Barre quadrangle. If correct, this interpretation makes this calcareous unit the youngest in Paleozoic sequence in Vermont and calls for revision of stratigraphic sequence. Proposed that name Waits River formation be restricted to this youngest calcareous unit. Also that total section of rocks included under Waits River formation of Currier and Jahns (1941) be redefined as Barre group composed of Barton River, Westmore, and present Waits River.

L. M. Hall, 1959, Vermont Geol. Survey Bull. 13, p. 15, 19–28, 36–41, pls. 1–4. Formation present in two regions in St. Johnsbury quadrangle where it occupies more surface area than any other formation. Largest area is belt 4 to 9 miles wide that trends northeastward through quadrangle. Small area located in northwest portion. Includes Crow Hill member (new) and Standing Pond amphibolite member. Total thickness not known because lower contact is not exposed. Age not certain. Present information favors Waits River as being older than Gile Mountain formation.

Type locality: Waits River town, Orange County, Vt.

**Wakarusa Limestone Member** (of Bern Limestone)

Wakarusa Limestone (in Shawnee Group)

Wakarusa Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 30.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 32). Correlation chart shows Wakarusa limestone in Shawnee group in Missouri.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 20. Assigned to Wabaunsee group when that group was redefined for Missouri.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273 (fig. 1), 2277. Rank reduced to member status in Bern limestone (new). Overlies Soldier Creek shale member; underlies Auburn shale.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 53–54. As now defined, name Wakarusa is applied to first resistant limestone unit above Burlingame limestone in Kansas section. Fusulinid-bearing phase of Wakarusa extends into Oklahoma, where, in earlier reports, it was referred to as *Cryptozoon* limestone. Thickness in Pawnee County 2 to 9½ feet. Overlies Hallett shale; underlies Auburn shale. Wabaunsee group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 13, fig. 5. Consists of two blocky bluish-gray fine-grained limestone beds separated by thin gray crinoidal shale. Underlies Auburn shale; overlies Soldier Creek shale. Wabaunsee group.

Named for exposures along Wakarusa Creek immediately south of Auburn, Shawnee County, Kans. Well exposed on Kansas Highway 10, west of Topeka, in sec. 35, T. 11 S., R. 13 E., and along creek north of highway.

**Wakefield Marble**

Lower Paleozoic(?) (Glenarm Series): Western Maryland and southeastern Pennsylvania.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 346. Name applied to white finely crystalline marble which underlies and is interbedded with volcanic flows in western Piedmont of Maryland and York County, Pa.; in part of area it is beneath and infolded with albite-chlorite schist facies of Wissahickon formation. Occurs on northwestern side of Peach Bottom syncline; the Cockeysville marble underlies the Wissahickon on southeastern side of the syncline but, since equivalency of the two marbles is not established, name Wakefield is proposed. In some areas, grades into Silver Run limestone (new). Precambrian(?).

A. J. Stose and G. W. Stose, 1944, U.S. Geol. Survey Prof. Paper 204, p. 38–39, pl. 1. Described in Hanover-York district, Pennsylvania, where it is apparently oldest formation in region and underlies the albite-chlorite schist facies of Wissahickon. Estimated thickness in southern Pennsylvania and adjacent Maryland 100 feet.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties [Rept. 12], p. 58–62. Described in Carroll and Frederick Counties. Underlies Libertytown metarhyolite (new). No complete section of the Wakefield found; estimated thickness near Union Bridge 150 feet.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 43 (table 7). Late Precambrian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Probably Lower Paleozoic.

Named from Wakefield, Carroll County, Md.

†Wakulla Formation[1]

Miocene, lower: Northern Florida.

Original reference: L. C. Johnson, 1892, Geol. Soc. America Bull., v. 3, p. 128–132.

Exposed in vicinity of Wakulla Springs in Wakulla County.

**Walcott Tuff**

Pliocene, middle: Southern Idaho.

H. T. Stearns and Andrei Isotoff, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 23. Name proposed for unit that was formerly called Eagle Rock tuff (Stearns and others, 1938). Eagle Rock was used as locality name at the time but, because a basaltic tuff originated at Eagle Rock vent, confusion can be avoided in present report by renaming the tuff from Walcott Lake. Four phases recognized: dark-red brittle pitchstone, fine-grained pink and gray rock rock honeycombed with lithophysae, hard obsidian containing spherulites, and well-bedded glass shard tuff and loose white and gray ash. Thickness 50 to 70 feet.

Named from Lake Walcott, where an excellent section is exposed in east bank in SE¼ sec 29, T. 8 S., R. 30 E., Power County.

Walden Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southeastern Tennessee, northeastern Alabama, and northwestern Georgia.

Original reference: C. W. Hayes, 1892, Alabama Geol. Survey Bull. 4, p. 49–51.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 8, 9, 10, 45, 152. Includes Whitwell, Herbert, Eastland, Newton, Vandever, and Rockcastle formations of present Tennessee classification.

Named for exposures on Walden Ridge, Chattanooga, Pikeville, and Kingston quadrangles, southeastern Tennessee.

**Walden Creek Group**

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 953 (fig. 2), 955 (table 1), 961–962. Forms northern sequence of Ocoee series. A varied assemblage of argillaceous and silty rocks and quartz-pebble conglomerate, with locally prominent quartzite, limestone, and dolomite. Best defined sequence is south of English Mountain in eastern part of foothills, where rocks form a broad pattern of northeast-plunging folds that expose a section about 8,000 feet thick. Formations of group defined in this area are (ascending) Licklog (new), Shields (new), Wilhite, and Sandsuck. Overlain by Chilhowee group of Cambrian and Precambrian(?) age; in fault contact with Snowbird group on southeast; not in contact with Great Smoky group; northeast of Great Smoky Mountains, the Walden Creek is reported to overlie Snowbird group as part of a sedimentary sequence from basement rocks upward through Chilhowee group into the overlying Paleozoic. Group corresponds approximately to Wilhite slate, Citico conglomerate, and Pigeon slate as mapped by Keith (1895) and to his more inclusive Hiwasse slate of his later terminology (1904).

Named for Walden Creek, Sevier County, a western tributary of the West Fork of the Little Pigeon River, which drains southeast slope of Chilhowee Mountain and northern foothill belt, an area underlain by rocks of the group. Crops out in a belt a few miles to 8 miles wide in northwesternmost foothills of Great Smoky Mountains and extends along strike for many miles northeast and southwest.

Walden Hollow Glacial Stage

Pleistocene: North-central Colorado.

R. L. Ives, 1942, Geog. Review, v. 32, no. 3, p. 450 (table 1). Name appears only on table giving late Pleistocene chronology of the Monarch Valley. Younger than Hell Inlet glacial stage (new); older than Stillwater glacial stage.

Monarch Valley, Grand County.

†Waldo Formation[1]

Miocene, lower: Northern Florida.

Original reference: L. C. Johnson, 1888, Am. Jour. Sci., 3d, v. 36, p. 230–236.

Occurs near Waldo, Alachua County, at old Fort Harlee.

Waldo Granite

Devonian(?) or Carboniferous(?): South-central Maine.

J. M. Trefethen, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 2020. Medium-textured porphyritic biotite granite.

Occurs in central part of Bucksport quadrangle.

†Waldrip division[1]

Pennsylvanian: Central Texas.

Original reference: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxvii, pl. 3.

Named for Waldrip, McCulloch County.

**Waldrip Shale Member** (of Pueblo Formation)

Waldrip Bed or Formation (in Cisco Group)[1]

Waldrip Limestone Member (of Harpersville Formation)[1]

Permian (Wolfcamp Series): Central Texas.

Original references: N. F. Drake, 1893, Texas Univ. Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 412; F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Reallocated to member status in Pueblo formation. Age designated as Permian. This reallocation made on basis of change of Pennsylvanian-Permian boundary. Top of Pennsylvanian is drawn in middle part of Cisco group and within sequence of rocks formerly designated as Harpersville formation. Use of Harpersville is suppressed, lower part of Harpersville being added to underlying Thirfty formation, which is classed as Pennsylvanian, and upper part being added to Pueblo, which is classed as Permian. In Colorado River valley, Waldrip consists of prominent red shale, yellowish to gray shale, light-gray to tan sandstone, and thin beds of hard blue-gray limestone. Thickness 40 to 55 feet. Lies 20 to 25 feet below Saddle Creek limestone member.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58 (table 1), 75–76, pl. 27. Waldrip shale member of Pueblo was described by Drake (1893), who called it Waldrip bed, as consisting of blue clay, sandstone, coal, carbonaceous shale, and limestone. The beds of sandstone are mostly near the base of unit and are quite irregular in thickness. Three limestone beds near top of Waldrip, Drake designated by numbers 1, 2, and 3 beginning with lowest. Plummer and Moore (1921, Texas Univ. Bull. 2132) included in their Harpersville formation the beds later called Waldrip shale by Moore (1949), together with Saddle Creek limestone member. Bullard and Cuyler (1935, Texas Univ. Bull. 3501) restricted term Waldrip to about 115 feet of beds from base of No. 1 limestone to base of Saddle Creek limestone. Lower part of the unit to top of Chaffin limestone member of Thirty formation (their Breckenridge limestone) they found to be about 90 feet in thickness, and they called this part Lower Harpersville beds. Nickell (1938, Texas Univ. Bur. Econ. Geology Pub. 3801) found Waldrip beds of Drake to be 238 feet thick. Cheney (1940) placed upper boundary of Cisco series at unconformity in Harpersville formation above Waldrip-Newcastle coal zone and below *Schwagerina*-bearing Waldrip limestone No. 3. The beds underlying this systemic boundary and overlying his Chaffin formation he termed Obregon formation. Moore (1949) placed Permian-Pennsylvanian boundary 40 to 55 feet below top of Waldrip shale member, between limestones 1 and 2 of Drake. In survey for present report [Brown and Coleman Counties], no traceable horizon was found which could be considered boundary between Pennsylvanian and Permian. For purposes of this report, whole interval that Drake called Waldrip beds is considered Waldrip shale member of Pueblo. Underlies Saddle

Creek limestone member; overlies Chaffin limestone member of Thrifty formation.

Named for Waldrip, McCulloch County.

**Waldron Clay Member** (of Wayne Formation)[1]

**Waldron Shale**[1]

Middle Silurian: Southern Indiana, west-central Kentucky, and central Tennessee.

Original reference: M. N. Elrod, 1883, Indiana Dept. Geology and Nat. History 12th Ann. Rept., p. 106–111.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 249–251. Waldron shale included in Wayne group. A gray or greenish-gray calcareous shale with occasional thin beds of limestone or argillaceous shale. Southward along Tennessee River, thins and changes character from place to place; at many localities it is tripartite, consisting of upper foot or so of red or gray shale or red or gray calcareous mudstone, middle thin bed of gray limestone, and lower thin zone of white clay-shale; south of Saltillo, consists of 18 inches of red earthy limestone or red calcareous mudstone; at Cerro Gordo and Swallow Bluff, consists of 1 foot of gray shale. Thickness between 2 and 5 feet; average 3 feet. Overlies Laurel limestone; underlies Lego limestone; where Lego is absent, unconformably underlies Chattanooga shale.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. In Indiana, Waldron formation overlies Laurel formation and underlies Louisville formation. Consists of shale, blue gray, knotty, calcareous, locally fossiliferous. Thickness 0 to 10 feet. In Clinton group.

Named for Waldron, Shelby County, Ind.

†Waldron Sandstone (in Douglas Formation)[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 52.

Named for exposures at Waldron, Platte County.

**Wales Group**[1]

Pre-Ordovician to Devonian: Southeastern Alaska.

Original reference: A. H. Brooks, 1902, U.S. Geol. Survey Prof. Paper 1, p. 40–52, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Name appears on map legend under undifferentiated Paleozoic metamorphic rocks.

Occupies large area on Prince of Wales Island.

Walgreen Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 15A. Shown on columnar section as underlying Stillman member (new) and overlying Dement member (new). Thickness about 6½ feet.

Occurs in Dixon-Oregon area.

Walhalla formation (in Kwaguntan series)

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 114. Black shales having a thickness of about 200 feet. Underlies Nunkoweap sandstone (new); overlies Echo limestone (new).

Shales crop out under Walhalla Plateau from which they take their name; Grand Canyon region.

†Walker Beds[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 359.

Named for Walker's Draw, a well-known branch of Medicine Lodge River south of Belvidere, Kiowa County.

Walker Conglomerate and Sandstone[1]

Pennsylvanian: Western Missouri.

Original reference: F. C. Greene and W. F. Pond, 1926, Missouri, Bur. Geology and Mines, v. 19, 2d ser., p. 62–65.

Occurs only on crest of ridge which extends to northwest on Walker Mound, sec. 8, T. 36 N., R. 30 W., Vernon County.

Walker Formation[1]

Oligocene: Southern California (subsurface and surface).

Original reference: V. H. Wilhelm and L. W. Saunders, 1927, California State Mining Bur., v. 12, no. 7, p. 9, pl. 1.

T. W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 12 (fig. 2), 33–35, pls. 1, 2, 3. Described in surface section. Consists of granitic sandstone, conglomerate, siltstone, and tuff breccia. Thickness at type section herein designated, 2,000 feet; thickens southwestward along strike to 2,950 feet and grades into Bealville fanglomerate (new) facies; thins northwestward, and in Cottonwood Canyon consists of about 200 feet of sand and gravel. At type section, overlies (Jurassic) quartz diorite conformably underlies Ilmon basalt (new); in Cottonwood Canyon (outside mapped area), conformably underlies Freeman-Jewett shale. Oligocene.

Otto Hackel and K. F. Krammes, 1958, San Joaquin Geol. Soc. [Guidebook] Spring Field Trip May 17, p. 10. Walker formation overlies basement complex in outcrop. To the west, subsurface Eocene rocks rest on basement, and it is apparent that Walker is land-laid equivalent of marine rocks of lower Miocene through upper Eocene.

Type section: Along southeast bank of Walker Basin Creek, 1 to 2 miles northeast of Bena, Breckenridge Mountain quadrangle, Kern County.

Walker Shale[1]

Upper Devonian: Southwestern Virginia.

Original reference: M. R. Campbell, 1894, Geol. Soc. America Bull., v. 5, p. 171, 177, pl. 4.

In Wythe, Montgomery, and Pulaski Counties. Named for Walker Mountain, Giles County.

Walker Mountain Sandstone Member (of Moccasin Formation)

Ordovician: Southwestern Virginia.

Charles Butts and R. S. Edmundson, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1678. Name proposed for upper of two sandstones in formation. Thick-bedded gray quartzose rock 8 to 12 feet thick. Underlies Martinsburg formation.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 95. Butts and Edmundson did not designate type section. Exposure noted herein.

Named for exposures in southwestern end of Walker Mountain, Washington County. Well exposed along Keywood Branch Road about one-half mile north of Seven Springs and along Virginia Highway 91, about 1 mile northwest of McCall Gap, Washington County.

Walker Plain Basalt

Miocene: Northern California.

Anna Hietanen, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 586, 587. Youngest rock in area; hence, younger than Merrimac granodiorite, Bucks granodiorite, and Bald Rock granite (all new).

Occurs on both sides of old Quincy-Oroville Road extending south from Four Trees Junction, Merrimac area, Plumas National Forest.

Walker Ridge Sandstones[1]

Post-Franciscan and pre-upper Miocene: Northern California.

Original reference: W. Stalder, 1915, California State Mining Bur. Bull. 69, p. 447–449.

D. L. Everhart, 1950, California Jour. Mines and Geology, v. 46, no. 3, p. 388. Incidental mention in report on quicksilver mine in Sonoma County.

Named for exposures on Walker Ridge, Humboldt County.

Walker Ridge Shales[1]

Post-Franciscan and pre-upper Miocene: Northern California.

Original reference: W. Stalder, 1915, California State Mining Bur. Bull. 69, p. 447–449.

Named for Walker Ridge, Humboldt County.

Walkup Clay[1]

Eocene: Northern California.

Original reference: V. T. Allen, 1929, California Univ. Pub., Dept. Geol. Sci. Bull., v. 18, no. 14, p. 364, 403.

Occurs at Walkup pit, less than one-half mile east of Gladding McBean pit in Chico quadrangle.

Wall Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 24, figs. 3, 12. Dolomite, argillaceous in upper part, with bentonite 3 feet above base. Thickness about 9 feet. Shown on columnar section as underlying Wyota member (new) and overlying Sherwood member (new).

Occurs in Dixon-Oregon area.

**Wallace Formation**[1] (in Piegan Group)

Precambrian (Belt Series): Northeastern Idaho and western Montana.

Original reference: F. L. Ransome, 1905, U.S. Geol. Survey Bull. 260, p. 277–285.

F. L. Ransome and F. C. Calkins, 1908, U.S. Geol. Survey Prof. Paper 62, p. 39–44, pl. 11. Thin-bedded bluish and greenish more or less calcareous shales, underlain by rapidly alternating thin beds of argillite, calcareous sandstone, impure limestone: these in turn underlain by gray-green siliceous argillites. Ripple marks, sun cracks, and so on, throughout. Thickness about 4,000 feet. Overlies St. Regis formation; underlies Striped Peak formation.

Russell Gibson, 1948, U.S. Geol. Survey Bull. 956, p. 13–16, pl. 1. Thickness as much as 17,000 feet in Libby quadrangle, Montana. Overlies Ravalli formation; underlies Striped Peak formation.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 112–113. Principal component of Piegan group has been variously called Siyeh, Newland, and Wallace limestone or formation, and these names are retained locally. In and near Coeur d'Alene region, the Wallace is the only representative of the group.

R. E. Wallace and J. W. Hosterman, 1956, U.S. Geol. Survey Bull. 1027–M, p. 584–585, pl. 48. Crops out over large part of Mineral County, Mont. Thickest section, about 6,500 feet, is exposed at head of Savenac Creek near Mount Bushnell on north flank of Savenac syncline; base of section here is fault contact. Commonly overlies St. Regis formation with contact transitional. Predominantly argillite.

A. B. Campbell, 1960, U.S. Geol. Survey Bull. 1082–I, p. 557–560, pl. 28. In St. Regis-Superior area, Montana, conformably underlies Spruce formation (new) of Missoula group; overlies St. Regis formation.

Well exposed at town Wallace, Coeur d'Alene district, Idaho.

Wallace shale

Cretaceous (Mid-Cretacic): Northwestern Kansas.

C. R. Keyes, 1941, Pan-Am. Geologist, v. 76, no. 4, p. 304 (chart). Name applied to upper formation in Buckskinian series. Consists of shales about 300 feet thick. Overlies Gove chalk; underlies unnamed interval below Arickaree formation of Rawlinsian series.

C. R. Keyes, 1941, Pan-Am. Geologist, v. 76, no. 5, p. 374, 376. Proposed for so-called Pierre shales of Kansas. Derivation of name given.

Name derived from Wallace County.

Wallace Creek Formation[1]

Lower Ordovician: Northwestern Vermont, and southeastern Quebec, Canada.

Original reference: H. W. McGerrigle, [1931], Vermont State Geologist 17th Rept., p. 182, 184, 185.

J. A. Dresser and T. C. Denis, 1944, Quebec Dept. Mines Geol. Rept. 20, v. 2, p. 396, 397. Consists of thin-bedded dark-gray to black limestones, with interbedded shale. Thickness about 250 feet. Overlies Strites Pond limestone; overlies Morgan Corners dolomite.

Exposed from northern part of St. Albans quadrangle, Vermont, across the international border for about 20 miles into Quebec.

Wallace Ledge Formation

Lower Cambrian: West-central Vermont.

E. P. Kaiser, 1945, Geol. Soc. America Bull., v. 56, no. 12, pt. 1, p. 1089, pl. 1. Gritty purplish slate in lower part and soft green slate with some purple slate above. Thickness about 100 feet. Underlies Zion Hill quartzite; overlies Schodack formation.

Named for exposure on western side of Wallace Ledge, Castleton Township, Rutland County. Occurs in northern end of Taconic Range.

†Wallala Beds[1] or Group[1]

*See* Gualala Group accepted spelling.

**Wall Creek Sandstone Member** (of Frontier Formation)[1]

Wall Creek facies (of Carlile Formation)

Wall Creek Member (of Carlile Formation)

Upper Cretaceous: Eastern Wyoming and western South Dakota.

Original reference: C. H. Wegemann, 1911, U.S. Geol. Survey Bull. 452, p. 43, 45.

E. P. Rothrock, 1949, South Dakota Geol. Survey Rept. Inv. 62, p. 17–19, fig. facing p. 4. Wall Creek member lies about 250 feet above base of Carlile in Fall River County. Where typically exposed, appears to consists of beds about one-fourth inch thick of alternating sand and black shale or carbonaceous matter. Thickness about 20 feet.

R. E. Stevenson, 1952, South Dakota Geol. Survey Rept. Inv. 69, p. 13, fig. 1. Facies of Carlile formation in southwestern Butte County. Facies (which is unit 1 of Turner member—Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10), lies about 86 to 126 feet above base of Carlile. Thickness 20 to 60 feet, thickens westward.

J. D. Haun, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 85. In Powder River basin, top of Frontier is placed at top of Wall Creek sandstone member.

Named for exposures in escarpment 12 miles west of Salt Creek, which rims Powder River dome, forming lofty escarpment known locally as "The Wall." Also well exposed above Wall Creek stream, eastern Wyoming.

**Wallingford Dolomite**[1]

Wallingford Member (of Danby Formation)

Lower Cambrian: West-central Vermont.

Original reference: A. D. Hager, 1861, Rept. Geol. Vt., v. 2.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 525, 535–536. Rank reduced to member at top of Danby formation. Upper Cambrian.

Type locality: Wallingford Township, Rutland County.

Wallington Limestone (in Clinton Group)

Middle Silurian (Ontarian): Western New York.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser., no. 1. Name suggested for limestone formerly regarded as Reynales at Rochester and eastward. Thickness at type section 15 feet. Younger than type Reynales of Niagara and Orleans Counties and separated stratigraphically from it by Furnaceville hematite. Underlies lower Sodus shale.

Type section: Along east branch of Salmon Creek at Wallington, Wayne County.

†Wallkill Limestone[1]

Upper Cambrian and Lower Ordovician: Northern New Jersey.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 443–454.

In vicinity of Franklin Furnace and Hamburg; also in Wallkill Valley, south of Franklin Furnace, Sussex County.

**Walloomsac Slate**[1]

Middle Ordovician: Southwestern Vermont, northwestern Massachusetts, and eastern New York.

Original reference: L. M. Pringle and E. B. Knopf, 1932, Am. Jour. Sci., 5th, v. 24, p. 268–269 (map), 274–275.

R. V. Cushman, 1950, New York State Water Power and Control Comm. Bull. GW–21, p. 9 (table 2), 11, pl. 2. In Rensselaer County, Walloomsac slate underlies broad areas in Hoosick-Berlin Valley and is everywhere separated from adjacent Lower Cambrian shale and grit by thrust faults. It lies in elongated belt east and southeast of Rensselaer Plateau where it forms most of Kinderhook Creek valley southward from Berlin to Columbia County boundary. Also underlies area that reaches from Eagle Bridge to Hoosick and extends eastward to Vermont boundary. Appears to rest conformably on uppermost blue phase of Stockbridge limestone. Thickness unknown. Stratigraphic position of the Walloomsac and fossils found in it indicate age that is probably equivalent to that of upper Normanskill shale of Hudson Valley.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Correlation chart for Vermont shows Walloomsac slate overlies Stockbridge limestone. Middle Ordovician.

R. V. Cushman, 1953, New York State Water Power and Control Comm. GW–33, p. 10 (table 3), 15, pl. 2. In southeastern part of Washington County, there is an extensive massive known as Walloomsac slate. Massif consists of green to black smooth shale, schist, and soft slate. Included fossils indicate age equivalent to upper Normanskill. Thickness unknown. Probably separated from other Taconic rocks by thrust fault. Table 3 lists Walloomsac slate below Snake Hill formation.

J. A. MacFayden, Jr., 1956, Vermont Geol. Survey Bull. 7, p. 27–28, p. 16. In Bennington area, overlies Mount Anthony formation (new). Contact with underlying Canadian limestone appears to be locally conformable but over large area it marks major unconformity. Along eastern flank of Taconic Range lies in apparent normal stratigraphic succession on limestone section; southeastward, just north of Mason Hill, it overlies Upper Cambrian Clarendon Springs; on western flank of The Dome, a small remnant of the phyllite with one of the characteristic limestone lenses lies on Lower Cambrian Dunham dolomite. Middle Ordovician.

Named for extensive distribution in valley of Walloomsac River, west and northwest of Bennington, Vt., in both Bennington County, Vt., and Rensselaer County, N.Y.

**Walnut Clay** (in Fredericksburg Group)[1]

**Walnut Shaly Member** (of Goodland Limestone)[1]

Walnut Marl (in Fredericksburg Group)

Lower Cretaceous (Comanche Series): Northeastern Texas and southern Oklahoma.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504, 512.

L. W. Stephenson and others, 1942, Geol. Soc. America Bull., v. 53, no. 3, chart 9. Walnut shaly member in lower part of Goodland shown on correlation chart.

W. O. George, 1952, U.S. Geol. Survey Water-Supply Paper 1138, p. 14 (table 7), 21–22. Walnut clay described in Comal County, Tex., where it is lowest formation of Fredericksburg group. Conformably overlies Glen

Rose limestone; conformably underlies Comanche Peak limestone. In most places, represented by bed of sandy marl 3 to 5 feet thick.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Walnut clay in Fredericksburg group, mapped in southeastern Oklahoma.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 21–22. Foraminifera of Walnut clay described. Basal formation of Fredericksburg group. Underlies Goodland limestone. The Walnut is time-transgressing formation, laterally equivalent to Comanche Peak formation and in part to Edwards limestone.

V. E. Barnes, 1958, Texas Univ. Bur. Econ Geology Guidebook 1, p. 34. In Travis and Williamson Counties, includes Cedar Park limestone member.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 11–15, pls. 1, 2. In this report [Fort Worth-Weatherford area], term Walnut marl is used for yellow and gray shell-bed-bearing marls delimited below by Paluxy sand and above by basal blue marl of Goodland formation. Consists of beds of shells of *Gryphaea mucronata* Gabb and *Exogyra texana* Roemer alternating with thin marl units. Thickness about 25 feet. Previous writers have placed upper and lower contacts of Walnut formation at various stratigraphic levels; as a result, reports of thickness of formation have ranged from 27 to 170 feet. Taff (1893 Texas Geol. Survey Ann. Rept. 4, pt. 1) assigned 170 feet to the formation (Texana limestone) and included about 15 feet of arenaceous marl that in this report is considered Paluxy and about 130 feet of limestone and marly limestone that in this report is considered Goodland. Hill (1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7) assigned 130 feet to the formation and included 3 feet of sand herein considered Paluxy and more than 90 feet of marly limestone herein considered Goodland. Winton and Adkins (1920 [1919], Texas Univ. Bull. 1931) placed upper contact of Walnut at top of uppermost massive *Gryphaea mucronata* ledge, as is done in this report, but included in formation 100 feet of marl, sand, and shell ledges considered Paluxy in this report. Scott and Hawley (*in* Adkins, 1933 (Texas Univ. Bull. 3232) and Hawley and Smith (1933, Texas Univ. Bull. 3201) applied name Walnut in area west and northwest of Fort Worth to calcareous sediments including *Gryphaea marcouri* [*G. mucronata*] shell banks. This application was followed by Lozo (1944, Am. Midland Naturalist, v. 31, no. 3). Thompson (1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 10) included in his definition of Walnut, arenaceous marls presently assigned to Goodland formation.

Named for Walnut (also called Walnut Springs), Bosque County, Tex.

†Walnut Shale[1]

Pennsylvanian: Eastern Kansas and northeastern Oklahoma.

Original reference: E. Haworth and J. Bennett, 1908, Kansas Acad. Sci. Trans., v. 21, pt. 1, p. 74.

Named for Walnut, Crawford County, Kans.

Walnut Wells Monzonite

[Tertiary]: Southwestern New Mexico.

A. M. Alper and Arie Poldervaart, 1957, Econ. Geology, v. 52, no. 8, p. 953, 954, 963, 965. Believed to be penecontemporaneous and derived from same magma as quartz monzonite-porphyry of Animas intrusive.

Occurs in vent 6 miles south of Animas stock, Walnut Wells quadrangle, Hidalgo County.

**Walston Silt**

Pleistocene (Yarmouth): Southeastern Maryland (subsurface and surface).

W. C. Rasmussen and T. H. Slaughter, 1955, Maryland Dept. Geology, Mines and Water Resources Bull. 16, p. 115 (table 17), 116–117. Lenticular unit of sand, silty sand, sandy silt, silt, clayey silt, silty clay, and clay, with organic material. Thickness from a fraction of a foot to as much as 57 feet at reference locality. Underlies unconformably Parsonsburg sand (new) and overlies unconformably Beaverdam sand (new).

Reference locality is a test hole, Wi–Cg 40, 2 miles north of Parsonsburg. Crops out in banks of Walston Branch, from which it takes its name, a tributary to Beaverdam Creek, Wicomico County.

Walter Johnson Sandstone Member (of Nowata Shale)

Pennsylvanian (Des Moines Series): Eastern Kansas, western Missouri, and northeastern Oklahoma.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 292, 335. Name applied to lenticular sandstone in Nowata.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 96. Thin-bedded to massive sandstone in lower and middle part of Nowata. Thickness commonly 4 to 10 feet.

W. B. Howe, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 9, p. 9, 22. Name Walter Johnson applied to sandstone and siltstone, about 6 feet thick, in Nowata shale, in LaFayette County.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 3. Stratigraphic column in northeastern Oklahoma includes Nowata shale with Walter Johnson sandstone member.

Named from Walter Johnson School in sec. 10, T. 35, S., R. 17 E., Montgomery County, Kans.

**Waltersburg Sandstone**[1] or **Formation**

Waltersburg Sandstone (in Elvira Group)

Upper Mississippian (Chester Series): Southern Illinois, southern Indiana, and western Kentucky.

Original references: S. Weller, 1920, Jour. Geology, v. 28, no. 4, p. 281–290; no. 5, p. 395–416; 1920, Illinois Geol. Survey Bull. 4.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 136; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 837. Assigned to Elvira group (new). In standard Mississippian section, underlies Menard limestone and overlies Vienna limestone.

C. A. Malott, 1942, Stratigraphy of Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7. Name Waltersburg sandstone extended into Indiana where it replaces Wickliff sandstone. Local Indiana names of upper Chester are dropped, and formations are given names of standard Chester column.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, pl. 1. Waltersburg sandstone shown on stratigraphic column of upper Chester rocks in Indiana as gray to brown sandstone and gray to green-gray shale and silty shale. Thickness 30 to 60 feet. Term Elvira group not used in Indiana.

Named for exposures at Waltersburg, Pope County, Ill.

**Waltham Gneiss**[1]

Precambrian: Eastern Massachusetts.

Original reference: L. LaForge, 1932, U.S. Geol. Survey Bull. 839.

Occupies much of northern Waltham, southeast Lexington and Burlington, and northwest Woburn, in Middlesex County. Extends northeast into Lawrence and Salem quadrangles and southwest into Framingham and Franklin quadrangles.

Waltham Shale (in Panoche Formation or Group)

Upper Cretaceous: Central western California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2), 993. Panoche group (or formation) is subdivided into 10 units. Waltham shale is divided into lower unit and upper unit separated by Juniper Ridge sandstone (new). Upper Waltham may belong to Cachenian stage (new) and lower Waltham may belong to Delevanian stage (new). Name credited to J. Q. Anderson.

Occurs in Alcalde Hills, Coalinga-Ortigalito area, San Joaquin Valley.

**Wamego Shale Member** (of Zeandale Limestone)

Wamego Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Eastern Kansas and southeastern Nebraska.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 42–43. Name applied to shale between Maple Hill limestone above and Tarkio limestone below. Thickness at type locality 15 to 18 feet. Replaces Pierson Point shale of Condra (1927). [See explanation under Pierson Point.]

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 15. Reference made to Pierson Point shale by Condra and Reed (1943) is in error; name Pierson Point retained and Wamego dropped.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276. Rank reduced to member status in Zeandale limestone (new).

Type locality: In bluffs north of U.S. Highway 40, about 4 miles west of Wamego, Pottawatomie County, Kans.

**Wamsutta Formation**[1]

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134, 141–158, pl. 17.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 5b). Age of lowermost part of formation shown as Mississippian; remainder is Pennsylvanian.

A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Pennsylvanian. Appears to interfinger with both Rhode Island formation and Pondville conglomerate in southern part of Pawtucket quadrangle.

A. W. Quinn, 1952, Bedrock geology of the East Greenwich quadrangle, Rhode Island: U.S. Geol. Survey Geol. Quad Map [GQ–17]. Not recognized south of Greenwich Bay, R.I., where unit as mapped by Emerson (1917, U.S. Geol. Survey Bull. 597) is assigned to Rhode Island formation.

Wamsutta was name proposed but not actually adopted for North Attleboro, Mass., where Wamsutta Mills are located.

†Wamsutta Volcanics[1]

Carboniferous: Massachusetts.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 155–156.

**Wanakah Formation** (in San Rafael Group)

Wanakah Marl Member (of Morrison Formation)

Wanakah Member (of Morrison Formation)[1]

Upper Jurassic: Southwestern Colorado and northwestern New Mexico.

Original reference: W. S. Burbank, 1930, Colorado Sci. Soc. Proc., v. 12, no. 6, p. 172.

M. I. Goldman and A. C. Spencer, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1748 (fig. 2), 1749, 1952 (fig. 3), 1753 (table 1), 1754 (fig. 4), 1756 (fig. 5), 1762 (fig. 7). Restricted and termed marl member of Morrison. Consists of succession, 50 to 150 feet thick, of hard, calcareous, concretionary, sandy, red, argillaceous beds with some thin sandstones. Overlies Bilk Creek sandstone member (new); underlies Junction Creek sandstone member (new). [See La Plata sandstone.]

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1668. Inasmuch as upper limit of beds that may be properly assignable to San Rafael group, rather than Morrison formation, is not yet definitely known in New Mexico, it seems desirable to extend into New Mexico and adjacent parts of northeastern Arizona, for these upper beds of San Rafael group, use of term Wanakah formation, which has been sharply discriminated from overlying Morrison in San Juan Mountain region of southwestern Colorado. Todilto limestone and gypsum, where present, are thus members of Wanakah formation.

E. B. Eckel, 1949, U.S. Geol. Survey Prof. Paper 219, p. 27 (table), 28–29. Term Wanakah formation is here applied to beds between Entrada and Junction Creek sandstones. Formation is equivalent to La Plata limestone and La Plata shale, as these terms are applied by miners, and to middle part of La Plata sandstone as defined in La Plata folio (no. 60) and other early reports on parts of southwestern Colorado. In La Plata district and elsewhere, rocks here placed in the Wanakah were formerly regarded as part of Morrison formation. As redefined, consists of (ascending) Pony Express limestone member, Bilk Creek sandstone member, and unnamed marl member. Thickness 25 to 150 feet. Overlies Entrada sandstone; underlies Junction Creek sandstone.

L. C. Craig and C. N. Holmes, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 94. Redefined to include Junction Creek sandstone member, which has been treated as member of Morrison formation and as separate formation.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. In Mora County, N. Mex., conformably overlies Ocate sandstone (new); conformably underlies Morrison formation. Average thickness 25 feet.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 39. In this report [Navajo country], unit herein assigned to Summerville formation, together with Todilto limestone, has been assigned to Wanakah formation by other workers.

R. L. Griggs and C. B. Read, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 2006. Name Bell Ranch formation applied to sequence of beds in Tucumcari-Sabinoso area believed by Wood, Northrop, and Griggs (1953, U.S. Geol. Survey Oil and Gas Inv. Map OM-141) to be equivalent of Wanakah formation.

Named for exposures in Wanakah mine, Ouray district, Colo.

Wanakah Member (of Ludlowville Shale)

Wanakah Shale[1] or Formation

Middle Devonian: Western and central New York.

Original reference: A. W. Grabau, 1917, Jour. Geology, v. 25, p. 338 (footnote).

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, no. 5-6, p. 364-369, pl. 1. In Batavia quadrangle, Wanakah and Ledyard members of Ludlowville were not separated as defined by Cooper (1930, Am. Jour. Sci., 5th ser., v. 19). Ledyard-Wanakah member overlies Centerfield limestone member and underlies Tichenor limestone member.

T. B. Coley, 1954, Jour. Paleontology, v. 28, no. 4, p. 453, 454, 455 (fig. 2). Referred to as formation. Thickness 48 feet at Jacox Run near Geneseo. Overlies Ledyard formation; underlies Tichenor formation. Ostracodes discussed.

R. S. Boardman, 1960, U.S. Geol. Survey Prof. Paper 340, p. 4 (fig. 2), 5-6. Trepostomatous Bryozoa discussed.

Type section: In Wanakah and Lakewood Beach Cliffs along Lake Erie.

†Wando Clays and Sands[1]

Pleistocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies, published in 1908 in South Carolina Geol. Survey, ser. 4, Bull. 2, p. 484; 1907, Summary of mineral resources of South Carolina, p. 12 (table).

Named for exposures along Wando River, between Charleston and Berkeley Counties.

Wanette division

Permian: Oklahoma.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1518-1521. Named as lowermost of three time divisions of Permian of Oklahoma. Followed by the Minco division and Upper Red-Beds division. In central Oklahoma, the Wanette includes sediments from top of Brownville limestone to top of Stratford shale.

J. E. Adams and others, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1677. Recommended that in Oklahoma term Wanette be dropped in favor of Wolfcamp series which in northern Oklahoma, Kansas, and Nebraska includes beds from disconformity immediately above Brownville limestone up to horizon near top of Herington limestone.

Reference locality, town of Wanette, Pottawatomie County.

**Wann Formation**[1] (in Ochelata Group)

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: D. W. Ohern, 1910, Oklahoma State Univ. Research Bull. 4, p. 28.

M. C. Oakes, 1939, Oklahoma Acad. Sci. Proc., v. 20, p. 105, 106 (fig. 2). Restricted and redefined to apply to all strata between top of Iola formation below and base of Torpedo sandstone above or base of Birch Creek limestone in areas where Torpedo sandstone was removed by pre-Birch erosion.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 119–122. Underlies Barnsdall formation (new).

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 83–88. Described in Tulsa County where it is about 225 feet thick along north side of area and thickens southward uniformly to about 265 feet at southside of area. Progressive southward truncation at top, by Pre-Barnsdall erosion, and interfingering of lower part into Avant limestone member of Iola formation are offset by progressive southward increase in thickness of remaining parts of formation. Northward from area of this report, the Wann has been subdivided into four lithologic zones (ascending): basal shale; shale and thin platy limestones; limestone and calcareous, fossiliferous shale; and sandstone and shale. Upper limit of zone 3 is base of Clem Creek sandstone of Emery (1918); zone 2 includes sandstone locally known as Washington Irving.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 34–36, pls. 1, 2. Oakes (1951) included Birch Creek limestone in his Barnsdall formation as basal member, in northern Oklahoma. Torpedo sandstone and shale above the Torpedo and beneath Birch Creek limestone crop out only in Washington County and eastern Osage County. This situation led Miser (1954, Geologic map of Oklahoma) to place top of Wann at base of Barnsdall formation throughout and to include Torpedo sandstone and shale above it in Wann formation. This amounts to minor change in definition of Wann, but it is significant for northern Oklahoma only. In this report [Creek County], Miser's definition is followed and term Wann formation is applied to rocks that crop out above Iola formation and below Barnsdall formation. Thickness 40 to 180 feet in Creek County.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 14–18, pls. 1, 2, 3, 4. Only upper part of formation crops out in Pawnee County. Thickness 142 feet at most complete section. Includes both Clem Creek and Washington Irving sandstones.

Named for Wann, Nowata County.

Wanrhodes Volcanics

Oligocene: Northern Utah.

Frank Neighbor, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 179. Series of water-laid tuffs. Light gray, medium to conglomeratic and fairly well bedded. Overlie Unita formation.

Crop out on northwest flank of Diamond Fork anticline, Utah County. Type locality and derivation of name not stated.

Wanship Formation

Upper Cretaceous and Paleocene: Northeastern Utah.

A. J. Eardley, 1952, Utah Geol. Soc Guidebook 8, p. 53–54. Unconformably overlies Frontier formation in Coalville anticline. In Wasatch hinterland may unconformably underlie Almy conglomerate. Name credited to N. C. Williams.

R. H. Peterson, D. J. Gauger, and R. R. Lankford, 1953, Utah Geol. and Mineralog. Survey Bull. 47, p. 13. Term first used in reference to 2,117 feet of strata outcropping in Cherry Canyon, east of Wanship. Composed of medium-bedded to massive ridge-forming sandstone beds separated by soft friable sandstone and siltstone and soft light- to dark-gray shale beds; intercalated lenticular seams of coal. Basal 170 feet consist of three thick beds of coarse conglomerate separated by two horizons of medium- to coarse-grained brown sandstone.

D. J. Jones, M. D. Picard, and J. C. Wyeth, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2221 (table). Wanship formation shown on correlation table of Cenozoic formations of Utah and parts of adjacent states. Underlies Almy formation; overlies Henefer formation in north-central Wasatch Mountains. Upper Cretaceous.

N. C. Williams, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 127–129. Sequence of sandstones and shales, largely marine but partly of brackish water and continental origin. Fossil evidence indicates deposition of Wanship continued without interruption from Montanan time into early Paleocene. Locally truncates Frontier and older formations; underlies Almy conglomerate, in some areas gradational, in others, unconformable.

N. C. Williams and J. H. Marsden, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 122–123. In Coalville area, Utah, formation is about 4,950 feet thick. Unconformably overlies Frontier formation; underlies Echo Canyon conglomerate (new). Unit has been considered part of Frontier formation which is herein restricted to exclude unit termed Wanship.

Named for occurrence near Wanship, Summit County.

**Wapanucka Limestone**[1]

Pennsylvanian: Central southern and southeastern Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 858, 902–908. Harlton (1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 8) proposed to subdivide Wapanucka into basal, middle, and upper units. It is now proposed to apply names Primrose and Limestone Gap (new) formations to unit heretofore designated as basal Wapanucka. Name Wapanucka is restricted and applied to middle unit (or main lower massive limestone as Taff undoubtedly intended the usage); to upper unit, name Barnett Hill formation is applied. Wapanucka formation has been defined in various ways by different authors. Differences of opinion respecting age arose largely from the fact that Taff did not describe or designate a type locality. Hence it has been customary to accept exposures at town of Wapanucka as type. Section at this locality is not complete and units above Wapanucka have been included at other exposures. Original description by Taff appears to have included chiefly or entirely the lower limestone series, and same limits are observed in this paper. In extreme northwestrn Ouachitas, this formation, together with the Barnett Hill, as well as the Primrose, was erroneously designated by Taff (1902, U.S. Geol. Survey Geol. Atlas, Folio 79) as Chickachoc chert lentils. Recommended that Chickachoc be abandoned. Thickness of Wapanucka at Taff's possible type locality, 1 mile west of Wapanucka, about 220 feet. At Limestone Gap, near center of E½ sec. 31, T. 2 N., R. 13 E., thickness is 198 feet. Here Wapanucka overlies Limestone Gap shale and underlies Barnett Hill formation. Wapanucka is included in Morrow series of Bendian period.

H. D. Miser and others, 1944, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Pennsylvanian. Chickachoc chert equals Wapanucka.

R. B. Laudon, 1958, Oklahoma Geol. Survey Circ. 46, p. 10 (fig. 3), 19–20. Chart shows Wapanucka underlies Atoka formation in McAlester Basin and Ouachita Front. Overlies Bloyd formation in McAlester Basin and Caney shale and Union Valley [sandstone] in Ouachita Front. Subsequent workers have not separated Harlton's (1938) Barnett Hill from the Atoka.

Named for Wapanucka, Johnston County.

Wapellan series[1]

Pleistocene (pre-Wisconsin): Iowa.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 56, p. 349.

†Wappinger Limestone[1] or Marble

†Wappinger Valley Limestone[1]

Lower Cambrian to Middle Ordovician: Southeastern New York.

Original reference: W. W. Mather, 1838, New York Geol. Survey 2d Rept., p. 168–169.

Robert Balk, 1936, Geol. Soc. America Bull., v. 47, no. 5, pl. 1. Wappinger limestone shown on geologic map of vicinity of Dutchess County; crystalline marble east of Poughquag.

P. H. Bird, 1941, New York Acad. Sci. Trans., 2d ser., v. 3, no. 5, p. 107, 108. Wappinger limestone (formation) of Cambro-Ordovician age conformably overlies Poughquag sandstone and underlies Hudson River formation. Thickness about 1,000 feet.

K. E. Lowe, 1947, Geol. Rev., v. 7, no. 1, p. 10. Wappinger limestone crops out near Tomkins Cove. Both Wappinger limestone and associated Annsville phyllite (new) trend southwest representing continuation of Cambro-Ordovician belt of sediments in Sprouts Brook (Peekskill) across Hudson River to northeast.

F. M. Swartz, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1521–1522. *Olenellus* fauna of Lower Cambrian has been discovered in median to southern parts of Hudson River valley of New York in Poughquag quartzite and Wappinger limestone. Wappinger mass is a complex that is much deformed and poorly exposed. Discovery of *Olenellus* fauna in some layers of the Wappinger in Poughkeepsie quadrangle shows that these particular layers are Lower Cambrian in age, if it may be assumed that the specimens were not carried in by reworking; other parts of the Wappinger according to their faunas represent Potsdam, Beekmantown, and Trenton formations. Total thickness of Wappinger sequence about 1,000 feet.

Sidney Paige, 1956, Geol. Soc. America Bull., v. 67, no. 3, p. 391–394. Stratigraphic sequence, recognized and accepted as Paleozoic (Cambro-Ordovician) by workers in region, consists of three formations: Poughquag quartzite at base (about 200 feet), Wappinger limestone (about 2,000 feet), and Hudson River phyllite and shale (thickness unknown?) at top. These beds have been mapped both east and west of Hudson River (1) in northeast-trending strip about 1 mile north of Peekskill and east of the river, and (2) at Tomkins Cove, west of river. A second (shown on West Point quadrangle) stratigraphic sequence, "Inwood" limestone and "Manhattan" schist, has been mapped east of river, in city of Peekskill and to the southeast and southwest. Concluded that in Peekskill region stratigraphic units mapped as Cambro-Ordovician north of Peekskill and at Tomkins Cove, west of Hudson River, are identical with stratigraphic units in and south of Peekskill, mapped as "Inwood" limestone and "Manhattan" schist of "doubtful" age and referred to by Berkey and Rice (1921, New York State Mus. Bulls. 225–226) as of late Grenville age.

J. W. Clarke, 1958, Connecticut Geol. Nat. History Survey Quad. Rept. 7, p. 18. In this report [Danbury quadrangle], term Inwood marble is used in preference to term Wappinger marble (Balk, 1936) because unit is nearly physically continuous with Inwood of type locality (Inwood district of New York City).

S. Schaffel, 1958, New York Geol. Assoc. Guidebook 30th Ann. Mtg., p. 1–5. Conformably overlies Poughquag quartzite; conformably underlies Annsville phyllite (Hudson River pelite group). True thickness about 1,000 feet. Cambro-Ordovician. Discussion of controversies regarding age of stratigraphic units in area.

Named for Wappinger Creek, Dutchess County.

**Wapsipinicon Limestone**[1]

Middle Devonian: Eastern Iowa and southwestern Illinois.

Original reference: W. H. Norton, 1895, Iowa Geol. Survey, v. 4, p. 127, 155–166.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1788. Referred to Taghanic stage (new).

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 66. Formation comprises (ascending) Coggon, Otis, Kenwood, Spring Grove, and Davenport members. Studies indicate that, normally, Independence shale lies immediately below Cedar Valley limestone and above Wapsipinicon formation.

Named for Wapsipinicon River, between Troy Mills, Linn County, and Central City, Linn County, Iowa.

Waramaug Formation

Precambrian(?) or pre-Triassic: Northwestern Connecticut.

R. M. Gates *in* R. M. Gates and W. C. Bradley, 1952, Connecticut Geol. Nat. History Survey Misc. Ser. 5, p. 7, 8–14. Name proposed for those rocks previously termed Berkshire formation in this area. Includes two important rock types: coarse mica-quartz gneiss and gray mica quartzite with streaks of biotite. Weathering of gneiss member causes rough corrugated surface. Foliation locally significant. All rock types are injected and intruded by granites, pegmatites and granitic materials. Precambrian(?).

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Pre-Triassic.

Typical occurrence around Lake Waramaug, Kent and New Preston quadrangles.

Ward Gypsum[1]

Permian: Central northern Texas.

Original reference: L. W. Storm, 1929, Geologic map of Stonewall County: Texas Bur. Econ. Geology.

Stonewall County.

Ward Limestone[1] Member (of Cannon Limestone)

Middle Ordovician: Central Tennessee.

Original reference: P. M. Jones, 1892, Geology of Nashville and immediate vicinity: Univ. Press, p. 36–38.

C. W. Wilson, Jr., 1948, Tennessee Div. Geology Bull. 53, p. 24, 27–29, geol. map. Averages 25 feet thick in Nashville area; consists of massively bedded very coarse-grained gray to bluish-gray limestone, locally extensively crossbedded or irregularly bedded. Overlain and underlain by units termed upper dove-colored member and lower dove-colored member.

Named for exposures in Mrs. Ward's quarry, near the Hudson place on Addison Ave., and Pearl St., Nashville, Davidson County.

Ward Cove Limestone

Ward Cove Limestone Member (of Cliffield Formation)

Middle Ordovician: Southwestern Virginia.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 827–832, 863, 884 (fig. 3). In Tazewell County, strata embraced by Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Ward Cove limestone member of Cliffield formation is applied to first coarse-grained limestone (zone 6) and overlying *Nidulites* beds (zone 7). Thickness 225 feet. Underlies Lincolnshire member (new); overlies Peery limestone member (new). First coarse-graind limestone is Butts' Holston of some areas; *Nidulites* beds constitute a part of Butts' lower Ottosee.

B. N. Cooper, 1945, Virginia Geol. Survey Bull. 66. p. 46–49. Rank raised to formation.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1152, 1157–1159. Restricted to *Nidulites* beds (zone 7); zone 6 is herein named Thompson Valley limestone. Thickens southwest from about 150 feet, near New Castle, to over 350 feet at Mechanicsburg, and over 550 feet near Sharon Springs.

Well exposed along State Highway 91 south of junction with County Road 604 and opposite Al Gillespie Farm. Takes its name from a breached plunging anticline in Tazewell County.

Wardell Formation

Middle Ordovician: Southwestern Virginia and northeastern Tennessee.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 838–840, 873–875, 884 (fig. 3), pl. 5. In Tazewell County, strata embraced by Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones.

Name Wardell formation is applied to *Stromatocerium* beds (zone 16), *Receptaculites biconstrictus* beds (zone 17), third coarse-grained limestone (zone 18), and overlying buff shale (zone 19). Thickness more than 200 feet south of Wardell; thins gradually to the northeast and pinches out a short distance east of Tazewell; 35 feet at Marys Chapel, about 60 feet at North Tazewell, and 45 feet in west end of Burkes Garden. In type section and in southeastern end of Thompson Valley, overlies Burkes Garden member of Benbolt formation (both new); toward Tazewell from Russell-Tazewell County line, Gratton limestone (new) appears between the two formations and thickens at expense of the Wardell; in western part of the county, the Wardell is overlain by a sandstone that pinches out northeast of Russell-Tazewell County line; east of Liberty the sandstone that pinches out northeast of Russell-Tazewell County line; east of Liberty, the sandstone is absent and Wardell is overlain by red mudrock tongue of Bowen formation (new); in other words, the Wardell overlaps successively younger beds northeastward and is overlapped in the same direction by successively younger beds. Wardell includes beds which Butts considered characteristic limestone of Ottosee in Russell County.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1166–1171. Northeast of Clinch Mountain, the Wardell occurs throughout entire Copper Creek belt from Pearisburg, Va., where it is only about 10 feet thick, to Knoxville region, where it is several hundred feet thick.

G. A. Cooper, 1957, Smithsonian Misc. Colln., v. 127, pt. 1, p. 96–97. Where Gratton limestone is not present, as at Rye Cove, it is difficult to separate the Wardell from the Benbolt, and the two combined are known as Dryden formation (new).

Type section: About 150 feet east of County Road 610 about 1 mile north of ford across Little River, Tazewell County, Va. Name derived from settlement near Tazewell-Russell County line.

Wardlaw Shale

Carboniferous(?): Northwestern Utah.

V. E. Peterson, 1942, Econ. Geology, v. 37, no. 6, p. 471 (table 1). Consists of black to gray thin to massive bedded pyritic shale, locally containing lenses of gray dolomitic limestone. Thickness 400 feet. Underlies newly named Phelan limestone and overlies newly named Vipont limestone.

In Ashbrook mining district on west side of Goose Creek Range.

War Eagle Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 216.

H. R. Wanless, 1939, Geol. Soc. America Special Paper 17, p. 93. Massive sandstone in Kanawha group.

Named for association with War Eagle coal [Mingo County].

War Eagle Underclay (in Kanawha Group)

Pennsylvanian (Pottsville): Eastern West Virginia.

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 18. Varies from light to dark gray, and from plastic to hard. Average thickness 7.2 feet. Occurs below War Eagle coal, and about 1,400 feet below top of Pottsville series.

Present in Nicholas and Webster Counties.

Ware Schist[1]

Carboniferous: Central Massachusetts.

Original reference: E. Callaghan, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 230.

Occurs along Ware River near village of Coldbrook, Worcester County.

**Warley Hill Marl**[1]

Warley Hill Formation

†Warley Hill phase[1]

Eocene, middle: Western and central South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 16.

C. W. Cooke and F. S. MacNeil, 1952, U.S. Geol. Survey Prof. Paper 243–B, p. 20 (fig. 2), 23. "Warley Hill phase," described by Sloan, was included in the McBean formation by Cooke (1936, U.S. Geol. Survey Bull. 867). Name Warley Hill marl is here revived in restricted sense to include dominantly glauconitic beds that intervene between Congaree formation (rank raised) and *Ostrea sellaeformis* zone, or restricted McBean. As restricted, the Warley Hill includes beds 9 and 10 of section described by Cooke (1936, p. 71); this is considered type locality and thickness here is 16 feet.

G. E. Siple, 1957, Carolina Geol. Soc. Guidebook Nov. 16–17, p. 11, 12. Referred to as Warley Hill formation.

Type locality: On abandoned road west of State Highway 267 and south of Warley Creek 3 miles north-northwest of Lone Star, Elloree quadrangle, Calhoun County. Phase and marl were named for exposures at Warley Hill, in eastern part of Orangeburg County.

Warm[1] (formation)

Lower Cretaceous: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Derivation of name not stated.

Warman Quartz Monzonite

Precambrian (late Algoman): Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1002, 1009, 1011, pl. 1. White to very light gray; may be weathered to pink, red, or yellow; medium granitoid with poikilitic orthoclase phenocrysts 1 to 3 centimeters long; massive except locally where there is slight primary foliation. Cut by basalt dikes; contains inclusions and roof pendants of Thomson formation. One of five major instrusives in late Algoman; these cannot be shown to be members of single magma series; age relations of named intrusives, St. Cloud gray granodiorite, Hillman tonalite, and the Warman are indeterminate as no contacts are exposed.

Exposed along the Snake River in T. 42 N., and T. 43 N., in vicinity of Ann River, and in quarries at Warman, Isle, and Pierz, in Pine, Kanabec, Mille Lacs, and Morrison Counties.

**Warm Creek Shale** (in Colorado Group)[1]

Upper Cretaceous: Central northern Montana.

Original reference: A. J. Collier and S. H. Cathcart, 1922, U.S. Geol. Survey Bull. 736–F, p. 172.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. As shown on correlation chart, Colorado group in central Montana, comprises Mowry shale below and Warm Creek shale, which underlies Telegraph Creek formation.

J. P. Gries, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 449. Colorado group, which formerly included all of Graneros formation around Black Hills, has been restricted to Upper Cretaceous (Cobban and Reeside, 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10–b) and includes Belle Fourche shale, together with overlying Greenhorn, Carlile, and Niobrara formations. Term Bell Fourche shale is now used in Williston basin wherever underlying Mowry can be differentiated, except in Little Rocky Mountains where name lower Warm Creek shale is applied.

Named for exposures along Big Warm and Little Warm Creeks, Little Rocky Mountain region.

Warmington Limestone Member (of Elephant Butte Formation)

Pennsylvanian (Des Moines Series) : Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 47, 49. Named proposed for basal 22 feet of Elephant Butte formation (new). Member consists of medium- to light-gray dense and cherty limestone. Overlies Cuchillo Negro formation (new).

Type locality: Western end of Whiskey Canyon, in northern part of Mud Springs Mountains, sec. 1, T. 13 S., R. 5 W., Sierra County.

Warm Spring Formation

Lower (?) Triassic: Southeastern California.

B. K. Johnson, 1957, California Univ. Pub. Geol. Sci., v. 30, no. 5, p. 384, 385–388, figs. 1, 3. Consists of two unnamed members, an upper, 10 to 100 feet thick, that is a limestone breccia or pépérite; and a lower, more than 4,000 feet thick, of andesite flows. Upper limit of formation is marked at some places by bodies of Jurassic(?) quartz monzonite that intruded the andesite and at other places by extrusive Tertiary rocks that conceal the andesites; thus, total thickness of the formation is unknown. Due to eastward overlap of Triassic rocks, the Warm Spring rests on Triassic Butte Valley formation (new) east of Striped Butte and on Permian Anvil Spring formation (new) near eastern edge of quadrangle.

Named for exposures at head of Warm Spring Canyon in eastern part of Manly Peak quadrangle, Inyo County.

Warm Springs Formation (in Colpitts Group)

Middle Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229–249. Sandstone, shale, and mudstone gradation in upper part of Colpitts group (new). Thickness 100 to 300 feet. Unconformably underlies Hyde formation (new); overlies Weberg formation (new) with contact not sharply defined.

W. R. Dickinson, 1960, Dissert. Abs., 20, no. 11, p. 4367 Weberg, Warm Springs, and Basey (new) formations are lateral equivalents of Snowshoe formation.

Type area: On east side of Warm Springs Creek valley in secs. 19, 20, 29, and 30, T. 18 S., R. 26 E. Named for Warm Springs Creek, Crook County.

Warner Basalt[1]

Pliocene, upper: Northeastern California.

Original reference: R. J. Russell, 1928, California Univ. Pub., Dept. Geol. Sci. Bull., v. 17, no. 11, p. 416–425, map.

R. S. LaMotte, 1936, Carnegie Inst. Washington Pub. 455, p. 65. Geologic section exposed at Rattlesnake Butte, Modoc County, shows Warner basalt overlying Alturas formation.

T. E. Gay, Jr., and Q. A. Aune, 1958, Geologic map of California (1:250000) Alturas Sheet: California Div. Mines. Mapped with Pliocene volcanic rocks. Warner basalt of Russell (1928) includes lithologically similar basalts ranging in age from post middle Miocene through Pleistocene; subdivided on this map sheet into Pleistocene, Pliocene, and Miocene units.

Cordell Durrell, 1959, California Univ. Pubs., Geol. Sci., v. 34, no. 3, p. 165 (fig. 1), 178–180. In Blairsden quadrangle, overlies Penman formation. Thickness 350 to 1,300 feet. The Warner was last formation to be deposited as sheet over area. Older than Mohawk lake beds. Upper Pliocene.

Named for exposures on sides of Warner Valley and for widespread distribution in Warner Lakes Range and Warner Range.

**Warner Sandstone Member** (of McAlester Formation)[1]

Warner Formation (in Cherokee Group or Krebs Group)

Warner Sandstone Member (of Krebs Formation)

Pennsylvanian (Des Moines Series): Eastern Oklahoma, southeastern Kansas, and southwestern Missouri.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 37–41. Member of McAlester formation. Generally consists of massive buff calcareous and hard sandstone 5 to 30 feet thick. In Tps. 12, 13, and 14 N., a thin-bedded sandstone as much as 10 feet thick occurs a few feet above scarp forming sandstone of Warner and a thin coal bed occurs in the intervening 5-foot shale. The two sandstones and intervening shale and coal were included by Wilson in the Warner. Term Warner is here restricted to the scarp-forming massive lower sandstone. Overlies McCurtain shale member; underlies unnamed shale below Lequire sandstone member. Reconnaissance mapping northward from Wagoner indicates that Warner sandstone is continuous with Little Cabin sandstone of northeastern Oklahoma. From Wagoner northward, Warner (Little Cabin) sandstone gradually converges with top of Mississippian rocks unitil it rests directly on Mississippian in southeastern Kansas.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 32–35. Member of McAlester. Described in Haskell County. Type locality stated.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Warner formation in Krebs group. Overlies Riverton formation; underlies Rowe formation (new). Includes beds up to and including Neutral coal. A lower coal above Warner is present in Oklahoma and its horizon is identifiable in Kansas.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 9 (fig. 1), 11 (fig. 3), 18 (fig. 7), 19, 41. Formation, in Jasper County, Mo., is about 25 feet thick and consists of a sequence of shale and sandstone. Overlies Riverton formation. Thickness 31 feet in Vernon County. Name has priority over Little Cabin sandstone. Krebs group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 32–35. Warner formation, in Krebs sub-group of Cherokee, includes beds above Riverton coal extending upward to top of Neutral coal bed. Succession includes prominent and wide-spread Warner (Little Cabin) sandstone from which it takes its name. Thickens southward in outcrop area in southeastern Kansas; generally less than 50 feet thick in Vernon and Barton Counties, Mo.; 50 to 100 feet in Cherokee County, Kans.

D. T. Russell, 1960, Oklahoma Geol. Survey Circ. 50, p. 14–17, pl. 1. Member of McAlester. Described in Latimer County where it is 77 feet thick; overlies McCurtain shale member, and underlies unnamed shale below Cameron sandstone member. Lequire sandstone member not recognized in area of this report.

Type locality (Oakes and Knechtel): About one-fourth mile east of NW cor. sec. 21, T. 12 N., R. 19 E., 1 mile north of Warner, Okla.

†Warren Beds (in Richmond Group)[1]

Upper Ordovician: Southwestern Ohio, southeastern Indiana, west-central Kentucky, and west-central Tennessee.

Original reference: J. M. Nickles, 1902, Cincinnati Soc. Nat. History Jour., v. 20, p. 86.

Named for Warren County, Ohio.

Warren Sandstone[1]

Mississippian: Northeastern Ohio.

Original reference: H. P. Cushing, 1888, Am. Assoc. Adv. Sci. Proc., v. 36, p. 214–215.

Named for Warren, Trumbull County.

†Warrendale Formation[1]

Oligocene or Miocene, lower: North-central Oregon.

Original references: W. D. Smith and E. L. Packard, 1919, Oregon Univ. Bull., v. 16, no. 7, p. 97–99; 1919, Jour. Geology, v. 27, p. 97–98.

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull., v. 15, p. 7. Mehama volcanics are comparable in age to Warrendale or Eagle Creek formation in Columbia River Gorge. Oligocene.

E. T. Hodge, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2025. Referred to as lower Miocene pyroclastics.

Named for town of Warrendale, near Eagle Creek, Multnomah County.

**Warren Point Sandstone Member** (of Gizzard Formation)[1]

Warren Point Sandstone (in Gizzard Group)

Warren Point Sandstone (in Lee Formation)

Lower Pennsylvanian: Eastern Tennessee and Georgia.

Original reference: W. N. Nelson, 1925, Tennessee Div. Geology Bull. 33–a, p. 43, 44, 148–149, 184.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 18). Shown on correlation chart for northern Tennessee as sandstone in Lee formation.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p.

1, 4, 19, pls. 3, 4, 12–D. Rank raised to formation in Gizzard group (herein rank raised). Attains its maximum thickness—a little more than 200 feet—in vicinity of Signal and Lookout Mountains near Chattanooga, where it is conglomeratic. The Warren Point of this area may be composite sandstone, with true Warren Point sandstone resting unconformably on one or more sandstones of Raccoon Mountain formation (new); from Chattanooga northeastward to Sale Creek-Soddy mining district, the Warren Point thins gradually and splits into several nonconglomeratic sandstones; this change makes identification difficult; farther northeast, in Roddy quadrangle, it is again a single massive conglomeratic sandstone. Underlies Signal Point shale (new); overlies Raccoon Mountain formation. Pottsville series. Type locality stated.

Type locality: Warren Point, just north of Monteagle, Grundy County, Tenn.

Warren Ranch conglomerate facies (of Deese Group)

Pennsylvanian (Desmoinesian): Southern Oklahoma.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Petroleum geology of southern Oklahoma, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 33–35. Series of boulder conglomerates, totaling about 100 feet in aggregate thickness and distributed through about 1,000 feet of other sediments, chiefly gray and red shales. Lowest conglomerate lies about 900 feet above Rocky Point member; upper conglomerates lie within West Arm formation (new).

Occurs in an area of 2 or 3 square miles in sec. 14, S½ sec. 11, W½W½ sec. 23, E½E½ secs. 22 and 27, T. 3 S., R. 2 E., west of Ardmore Air Force Base, Carter County. Name taken from ranch which occupies much of outcrop area.

**Warrensburg Channel Sandstone**[1]

Warrensburg Sandstone (in Labette Shale)

Warrensburg Sandstone Member (of Nowata Formation)

Pennsylvanian: Central western Missouri.

Original reference: A. Winslow, 1892, Missouri Geol. Survey Sheet Rept. 1, (v. 9), p. 22, 45–54.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. v (fig. 1), 8–9. Shown on stratigraphic section as Warrensburg sandstone member of Nowata formation. Name is retained in Missouri for sandstones occupying the Warrensburg and Moberly channels. Name has also been applied by Missouri geologists to sandstone now known to lie between the Altamont and Sni Mills limestones in Jackson County. Howe (unpub. thesis) restricted position of subsurface Warrensburg when he tentatively correlated a thin limestone overlying it with Norfleet limestone or lower Lenapah. These subsurface sandstones thus lie within the Nowata interval and occupy the approximate position of Walter Johnson sandstone of Kansas Geological Survey. Because of priority in usage, name Warrensburg will continue to be used in Missouri to include post-Altamont, pre-Lenapah sandstones of Marmaton age, and channels sands of the Warrensburg and Moberly channels.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 97. Englevale sandstone member is one of several bodies of sandstone collectively referred to as Warrensburg sandstone, lying in middle and lower parts of Labette shale.

Named for exposures at Warrensburg, Johnson County.

†Warrensburg Group[1]

Pennsylvanian: Central western Missouri.

Original reference: G. C. Broadhead, 1873, Missouri Geol. Survey Prelim. Rept. on Iron Ores, pt. 2, p. 169, 182.

Named for exposures at Warrensburg, Johnson County.

Warrens Ranch Latite

Tertiary: Southeastern Arizona.

W. H. Brown, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 742. Quartz-bearing latite porphyry. Constitutes a sill at extreme eastern end of Silver Lily dike system. Rests on narrow belt of Safford tuff (new) on the south and apparently in fault contact with Cat Mountain rhyolite (new) on the north.

Outcrops over an elliptical area 1½ miles by one-half mile in extent; approximately 1 mile north of Twin Hills, Tucson Mountains, Pima County.

Warrenton Agglomerate Member (of Catoctin Series)

Precambrian: Northeastern Virginia.

A. S. Furcron, 1939, Virginia Geol. Survey Bull. 54, p. 20–22, pl. 1. Composed of boulders, cobbles, and pebbles of greenstone imbedded in finer matrix of similar material. Largest boulders several feet in diameter. In some places, agglomerate composed almost entirely of greenstone fragments; in other places, greenstone fragments sparingly scattered through a fine matrix. Fragmental character best criterion for identification of rock in field. Most fragments of epidosite. Thickness variable; at Shiloh School and in Piney Mountain at least 1,500 to 2,000 feet; in southwestern corner of Warrenton quadrangle, it is thin. At or near base of greenstone making up series. Overlies Fauquier formation (new).

Widespread in Warrenton area, Warrenton quadrangle, Culpeper and Fauquier Counties.

**Warrior Limestone**[1]

Upper Cambrian: Central Pennsylvania.

Original reference: Charles Butts. 1918, Am. Jour. Sci., 4th v. 46, p. 528, 534, 537.

Charles Butts, 1939, Pennsylvania Geol. Survey, 4th ser., Topo. and Geol. Atlas 96, p. 9–10. Described in Tyrone quadrangle. Composed of interbedded limestone and dolomite, with thin layers of siliceous shale or shaly sandstone. Thickness about 1,200 feet. Overlies Pleasant Hill limestone; underlies Gatesburg dolomite.

J. L. Wilson, 1952, Geol. Soc. America Bull., v. 63, no. 3, p. 278–281, pl. 1. Described in Nittany Arch belt. Thickness at Williamsburg 1,340 feet. Overlies Pleasant Hill formation; underlies Stacy member of Gatesburg formation.

Named for exposures on Warrior Run, along river bluff 1 mile west of Williamsburg, Blair County, and on Warrior Creek, east of Warriorsmark in northern part of Huntingdon County.

**Warsaw Shale, Limestone, or Formation**

Warsaw Formation (in Osage Group)

Warsaw Shale or Limestone (in Meramec Group)[1]

Upper Mississippian (Meramec Series): Illinois, northern Alabama, Indiana, Iowa, Kentucky, northeastern Mississippi, eastern Missouri, and Tennessee.

Original references: J. Hall, 1857, Am. Assoc. Adv. Sci. Proc., v. 10, pt. 2, p. 54–56; 1858, Iowa Geol. Survey Rept., v. 1.

Charles Butts, 1922, Kentucky Geol. Survey, 6th ser. [Geol. Repts.], v. 7, p. 89–120, 121, 122, 123, 124. Formation in Meramec group. Warsaw succeeds rocks or Keokuk age. Lower limit in Jefferson County, Ky., is placed at top of Holtsclaw sandstone, whereas, in southern Kentucky. where Holtsclaw is absent, lower limit is determined by differences in lithology and fossils. In Kentucky, includes (ascending) Wildie sandstone, Somerset shale, and Garrett Mill sandstone members. Limestone of the Warsaw throughout Kentucky and Tennessee is practically identical in lithologic character with "Harrodsburg" limestone, of Warsaw age, at its type locality, Harrodsburg, Ind. Thicknesses; about 240 feet between Colesburg and Tunnel Hill, Hardin County; about 200 feet in Ohio River bluff in Indiana opposite West Point, Ky.; less than 100 feet at Edwardsville, Ind.; 80 to 100 feet in southern counties of central Kentucky and in northern middle Tennessee. In part of Kentucky and Tennessee, underlies St. Louis limestone. In south-central Indiana, particularly in Monroe, Lawrence, and Washington Counties, the limestone between the same upper and lower limits as the Warsaw of Kentucky, as herein interpreted, is divided into two formations, Warsaw ("Harrodsburg") limestone below and Spergen limestone above, the Spergen being called Salem limestone by Indiana geologists.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 14, 15, 16, 17, 35, 41, 44, 49, 54, 57, 216, 222, 229. Discussion of Lower Mississippian of east-central interior. Lower Mississippian as used here includes Kinderhook and Osage divisions of standard Mississippian time scale. Warsaw is uppermost subdivision of the Osage and not the Meramec. Papers by Butts discussed, especially (1922). Some strata regarded by Butts (1922) as Warsaw are not so regarded in present study. Lower Harrodsburg (Keokuk age) is removed from Warsaw and placed at top of Muldraugh formation (new), uppermost formation of Borden group. Upper Harrodsburg (Harrodsburg, restricted) contains distinctive Warsaw fauna and consitutes definite bounding unit at top of lower Mississippian rocks studied in this report. Wildie sandstone member (Butts, 1922) is reallocated to Muldraugh formation; Somerset shale member (Butts, 1922) is interpreted as basal phase of Salem limestone at top of Harrodsburg (restricted). So-called Warsaw of Tennessee not studied for this report, but question arises as to correctness of classification and correlation of "Warsaw" in Tennessee. This involves "Garrett Mill" sandstone member of Warsaw (Butts, 1922).

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 802–805. Uppermost formation of Osage group, Iowa series. This classification follows Illinois Geological Survey. Name Warsaw was originally given to 18 feet of thin-bedded bluish-gray limestone with interbedded calcareous shale which crops out at Warsaw, Hancock County, Ill. Hall (1858) expanded the Warsaw to include about 50 feet of strata lying between the geode beds and St. Louis limestone.

Subsequently, 8 feet of crossbedded yellowish-weathering limestone grading locally into calcareous sandstone which occurs immediately below St. Louis limestone was removed from Warsaw at its type locality and assigned to Salem limestone (Weller, 1908, Illinois Geol. Survey Bull. 8), and the geode beds, which had formerly been included in the Keokuk, were transferred to Warsaw formation (Butts, 1915, Kentucky Geol. Survey, ser. 4, v. 3, pt. 2; Tuyl, 1925, Iowa Geol. Survey, v. 30). The Warsaw, as thus defined, was considered exact equivalent of Harrodsburg limestone of Indiana (Butts, 1915; Cumings, 1922, Indiana Dept. Conserv. Pub. 21), and latter name was abandoned because Warsaw had priority. Lower division of Warsaw, which at type locality is about 36 feet thick and has been termed "geode beds," consists of massive fine-grained earthy geode-bearing limestone below, thin bed of locally brownish dolomitic cherty limestone in middle, and bluish-gray slightly calcareuos geode-bearing shale above. Upper part of Warsaw has not been distinguished from overlying Salem everywhere in western Illinois and adjacent parts of Missouri. Upper division of Warsaw, at Warsaw, consists of about 40 feet of bluish-gray shale with thin interbedded layers of argillaceous limestone, a few thin beds of fine-grained bluish-gray sandstone, and several massive bluish-gray dense to finely crystalline limestone strata which locally are irregularly and incompletely dolomitized. It thins northward and disappears from section a little north of Keokuk. South of Warsaw this part of formation becomes increasingly calcareous and has probably been included in Salem or Spergen formation. In Ste. Genevieve County, Mo., and Monroe County, Ill., the upper Warsaw consists of about 60 feet of gray to buff fine-grained more or less earthy and locally dolomitic limestone. Warsaw and Salem limestones have not been separated in southern Illinois and western Kentucky where they attain maximum combined thickness of 200 to 250 feet. In northern Hardin County, Ky., the Warsaw, including the few feet of limestone above Somerset shale that may be equivalent to the Salem, is about 220 feet thick. Because Edwardsville formation of Borden group has commonly been included in Warsaw formation in Jefferson, Hardin, and adjoining counties, Kentucky, its reported thicknesses there may be too great by 50 feet or more. In Indiana, the Warsaw crops out continuously from Montgomery County to Ohio River with thickness of 60 to 90 feet. Divisible into two parts: upper, massive limestone 30 to 50 feet thick, and lower, divided into (ascending) Ramp Creek, Leesville, and Guthrie Creek. Conformably overlies Edwardsville formation in Indiana.

L. R. Laudon, 1948, Jour. Geology, v. 56, no. 3, p. 289–290. Discussion of Warsaw problem and Osage-Meramec contact. Warsaw formation has been classified with beds of Meramec age or with beds of Osage age. Type section of Warsaw restudied. At type section, slightly more than 118 feet of strata occur between last crystalline crinoidal beds of Keokuk formation and contact of St. Louis limestone. No beds of Salem age recognized in area. No evidence found at type section for separating some 10 feet of crossbedded calcareous sandstone, which lies immediately beneath St. Louis limestone in the area, from the Warsaw. This sandstone has been considered to represent Salem formation (Weller, 1908). No evidence of disconformity found between rocks of Keokuk age and Warsaw beds at type section or at several other sections studied in area. No evidence of physical break found within Warsaw. Contact with overlying St. Louis remarkably conformable. All previously published lists of faunas disregarded and new collections made. Thirty species of abundant Warsaw forms identified and 27 of them were found in Keokuk rocks. Comparison of Warsaw fauna with 20 abundant species from type area of Salem formation shows almost no affinities at all. This observation contrasts strongly with general opinion regarding relationships of Warsaw-Salem faunas (Weller and Sutton, 1940). The Warsaw resembles clastic facies of older Osage formations farther east but does not resemble typical Meramec rocks. In present report, Salem is considered as base of Meramec series in upper Mississippi Valley area. If Salem is calcareous facies development within Warsaw formation, as suggested by Weller and Sutton (1940), this classification will need serious revision.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 99–100, chart 5. Shown on standard Mississippian section as basal formation in Meramecian series. Occurs below Salem limestone and above Keokuk limestone of Osagean series. Disagreement regarding boundary between Meramecian and Osagean series has been widespread and prolonged and has been concerned principally with proper placement of Warsaw formation. Current usage is not consistent.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 45–47. Formation in Osage group, Valmeyer series. Oldest outcropping formation in area of this report [Beardstown, Glasford, Havana, and Vermont quadrangles]. Thickness 50 to 75 feet. Underlies Salem limestone.

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 2 (table 1), 4. Underlies Kidd member (new) of Salem limestone.

Typical exposure: Along creek known as Soap Factory Hollow, which joins the Mississippi from the east about one-half mile south of Lower Warsaw, Ill. Named from exposures at Warsaw, Hancock County, Ill.

**Wartburg Sandstone**[1]

Wartburg Sandstone (in Crooked Fork Group)

Pennsylvanian: Northeastern Tennessee.

Original reference: Arthur Keith, 1896, U.S. Geol. Survey Geol. Atlas, Folio 33.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau, Tennessee: Tennessee Div. Geology [Folio], p. 5 (pl. 4), 6. Reallocated to Crooked Fork group (new). Overlies Glenmary shale (new); underlies Poplar Creek coal at top of group.

Named for Wartburg, Morgan County.

Wartburg Sandstone Member[1] (of Briceville Formation)

Pennsylvanian: Northeastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33B, p. 311.

Occurs in town of Wartburg, Morgan County.

Warwick Limestone[1]

Lower Ordovician: New York.

Original reference: W. W. Mather, 1843, Geology New York, v. 1, p. 367.

**Wasatch Formation**[1]

Wasatch Group[1]

Paleocene and Eocene: Utah, western Colorado, central southern and southeastern Montana, northwestern New Mexico, southwestern North Dakota, and western Wyoming.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Terr. 3d Ann. Rept., p. 191 of 1873 ed.

Walter Granger, 1914, Am. Mus. Nat. History Bull., v. 33, p. 205–207. Estimated thickness of Wasatch beds in New Mexico is about 1,000 feet. Mammalian fossils occur throughout greater part of vertical range. Lower two-thirds of Wasatch, referred to as Almagre beds (new) and upper horizon, comprising remaining third, the Largo beds (new). Overlies Torrejon formation.

E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, no. 3, p. 448–451. Formation, as recognized in Wasatch Plateau, consists of three members— lower member of sandstone, varicolored shale, conglomerate and small amounts of fresh-water limestone; middle member of fresh-water limestone, here called Flagstaff member; and an upper member of varicolored shale and sandstone. East of Wasatch Plateau, in Book Cliffs—Uinta Basin region—the three divisions lose their distinctness through wedging out, in many tongues, of the Flagstaff limestone.

W. T. Nightingale, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 8, p. 1019–1040. Includes Hiawatha member (new).

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 35–36, pl. 1. Term Wasatch is properly a group, though usually called a formation, in southwestern Wyoming, especially Uinta County. Early Eocene and (?) Paleocene. By unjustified extensions, term has come to include a wide variety of continental deposits of variegated colors in western North America, of uncertain age, presumed to be early Tertiary, as well as numerous actually dated deposits of Wasatchian age. In spite of its wide use in literature, it is an unfortunate term because the standard "Wasatch faunas" (those of the Bighorn and San Juan Basins) occur in formations which are merely called "Wasatch" and the Wasatch group proper is almost without fossil vertebrates. In the Wasatch proper, the La Barge local fauna is equivalent to that of the Lost Cabin, and the Knight fauna to that of the Lysite. Thus, the fossiliferous Wasatch is exactly equivalent, faunally, to the fossiliferous Wind River which, according to most text books and standard manuals, is supposed to overlie it. The exceedingly tentative determinations of the Fowkes as late Paleocene, the Almy as mid-Paleocene, and underlying Evanston as early Paleocene, do not rest on satisfactory evidence. When the "Wasatch fauna" is spoken of, it means in practice one of two things: (1) lower Eocene or Wasatchian of this report or (2) Gray Bull. The latter is difficult to justify because no fauna of Gray Bull age has been found in type Wasatch so that it is not certain that beds of that age are present. Term Canyon Largo group is here resurrected to replace term "San Juan Wasatch" (Holmes, 1877, U.S. Geol. and Geog. Survey Terr. 9th Ann. Rept. for 1875).

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 32–34, pls. 1, 8. Formation described in Randolph quadrangle, Utah-Wyoming, where it forms a belt across central part of the area, capping most of Bear River Plateau and extending westward over summit of part of Bear River Range. Composed of varicolored and varitextured continental deposits consisting principally of conglomerate and sandstone with subordinate amounts of sandy and clay shale, limestone, and tuff. Prevailing color red. Approximate thickness 1,000 feet. Not subdivided in this area. Overlies Bear River formation; near northern boundary of quadrangle, overlies tilted Twin Creek limestone. Eocene.

A. J. Eardley, 1944, (abs.) Utah Acad. Sci. Proc., v. 19, p. 19; 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1). Group comprises (ascending) Almy conglomerate (with Pulpit and Saw Mill conglomerates, both new), Fowkes(?), and Knight(?) formations. Overlies Henefer formation (new); underlies Norwood tuff (new). Middle Paleocene(?), upper Paleocene(?), and lower Eocene.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 114. In Uinta Basin, unconformably overlies Williams Fork formation.

H. E. Gregory, 1944, Am. Jour. Sci., v. 242, no. 11, p. 589–591, 601, 602. Formation, in upper Sevier River valley, Utah, underlies Brian Head formation (new). Thickness about 520 feet.

C. H. Dane, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 24. Overlying the Nacimiento formation in southern part of San Juan Basin, and Animas formation in northern part, is series of gray, tan, and copper-colored conglomerates and sandstones and red and gray clays that, in San Juan Basin, for many years has been referred to Wasatch formation. For convenience this usage is continued in present report, with understanding that age limits of beds included in formation are not thereby implied to be same as those included in Wasatch at type locality. Formation occupies all of central part of basin. In part of T. 23 N., R. 1 W., about 1,000 feet stratigraphically above base of formation, is an escarpment capped by a higher horizon of sandstones and conglomerates. Between these higher resistant beds and basal sandstones the lower 1,000 feet of formation consists in large part of soft red and gray clays. Upper part of clays contains the lower faunule division of the Wasatch as recognized by Granger (1914), the Almagre beds. Thickness not less than 2,000 feet. Lower part of formation in northeastern part of basin contains beds of Paleocene age.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 121, 122 (fig. 15). Discussion of late Mesozoic and early Cenozoic history in central Utah. Discovery of dinosaur bones in strata of central Utah formerly assigned to Wasatch formation, together with other findings, notably recognition of thick section of conglomerates as Colorado in age, has made possible an outline of late Mesozoic and early Cretaceous history considerably different from scheme hitherto used. Important changes are recognition of orogenic epoch in eastern part of Great Basin early in Upper Cretaceous time and placing of main Laramide folding of central Utah between middle and late Montana time instead of end of Cretaceous. Present report presents data bearing on these conclusions, together with many other stratigraphic and structural determinations that bear on history and paleogeography of region, and discusses certain problems involved. Main points of revision of stratigraphic nomencalture involved are as follows: (1) abandonment of classification as Wasatch of the three units, Lower member. Flagstaff limestone member, and Upper member, formerly designated as members of that formation; (2) recognition of basal conglomerate of former lower member as equivalent to original Price River formation, and distinction of overlying part of lower member as North Horn formation; (3) establishment of Flagstaff limestone as independent formation; (4) adoption of name Colton for upper member of Wasatch formation as originally defined; (5) naming of unit beneath the Price River in western districts the Indianola group, subdivided where feasible and undifferentiated where not; and (6) assignment to Cretaceous of all beds up to and including highest dinosaur zone, and assignment to Paleocene of overlying part of North Horn formation. Wasatch problem discussed and history of usage of term reviewed. Believed name should not be abandoned without more thorough study of type area than has yet been done.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 5, p. 257–282; no. 6, p. 363–385. Term San Jose formation proposed for "Wasatch" of authors in San Juan basin.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1130 (table), 1144–1147, pl. 1. Group, in Logan quadrangle, Utah, includes Cowley Canyon member (new) at base. Thickness 0 to 530 feet. Stratigraphically below Salt Lake group. Paleocene or lower Eocene.

M. D. Williams, 1950, Utah Geol. Soc. Guidebook 5, p. 102–106. Stratigraphic interval between Upper Cretaceous Mesaverde group and Green River formation in Uinta basin was originally referred to by early workers as Wasatch group but later came to be termed Wasatch formation. Spieker (1946) discusses Wasatch problem and in central Utah referred strata formerly assigned to Wasatch formation to North Horn, Flagstaff, and Colton formations. In a later publication, Spieker (1949, Utah Geol. Soc. Guidebook 4) does not use term Wasatch and apparently favors abandoning it, but without offering suitable substitute which can be used on regional basis. Top of Mesaverde group and base of Green River formation are usually readily recognizable horizons in regional mapping; intervening interval will here be designated as Wasatch group. Because lithologic boundaries and time limits do not always coincide, no definite age is assigned to the group other than "Cretaceous-Tertiary transition." As herein defined, Wasatch group may comprise North Horn, Flagstaff, and Colton formations; the 3,500 feet of strata containing the bituminous sandstone deposits at Sunnyside; the several thousand feet of strata assigned to the Wasatch in Piceance Creek basin and adjoining areas in western Colorado; the 780 feet of strata between the Mesaverde and Green River at Ravin Ridge; and Current Creek and Tuscher formations.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51 (table), 111–112, pls. 2, 4, 5. Generalized section of formations, in Zion Park region, shows Wasatch formation, about 400 feet thick unconformable above Kaiparowits formation. In topography, formation makes up the Pink Cliffs.

J. D. Love and J. L. Weitz, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–122. Formation, in Powder River basin, includes Kingsbury and Moncrief members. Overlies Fort Union formation; underlies White River formation. Base in some areas arbitrarily placed at top of Rowland coal. Eocene.

J. H. Donavan, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 62, 64. As exposed in south-central Sublette County, the upper Wasatch is divided into two units, Knight member below and New Fork tongue (new). The Knight is stratigraphically succeeded by Green River formation, basal part of which is herein designated Fontenelle formation.

J. R. Donnell, W. B. Cashion, and J. R. Brown, Jr., 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–134. Formation crops out in relatively broad belt in west-central part of Cathedral Bluffs area. As defined in this area by Gale (1910, U.S. Geol. Survey Bull. 415), the formation was believed to include, in its lower part, beds equivalent to Fort Union formation which is of Paleocene age. Paleontological evidence collected by several workers since this early report has demonstrated that lowermost part of formation is of Eocene age. Boundary between Paleocene and Eocene beds is indefinite in Cathedral Bluffs area. Along Cathedral Creek, formation consists mostly of beds of buff sandstone and small amounts of interbedded varicolored shale and clay; to the north, formation consists predominantly of varicolored shale and small amounts of brown sandstone and limestone in lenticular beds. Thickness as much as 371 feet. Contact between Wasatch and overlying Green River (Douglas Creek member) drawn at top of uppermost bed of red shale; near head of Cathedral Creek, boundary drawn directly above uppermost sequence of interbedded thin beds of coal, shale, and redbeds. Overlies Mesaverde formation.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 100–103. Formation, as mapped in this area [central part of Great Divide basin, Sweetwater County, Wyo.], is of early and middle Eocene age. Consists of rocks probably fluviatile and paludal in origin and intertongues throughout most of its vertical extent with rocks of Green River formation. Also intertongues with Battle Spring formation (new). Overlies Fort Union formation. Includes Red Desert and Niland tongues (both new) and Cathedral Bluffs tongue.

W. J. Morris, 1955, Dissert. Abs., v. 15, no. 3, p. 394. Use of term Wasatch for deposits in Washakie basin, Wyoming, is confusing. Name Knight extended from Bridger basin to include dominantly fluviatile Wasatchian deposits in Washakie basin. Knight formation includes Hiawatha member and Cathedral Bluffs tongue.

J. I. Tracey, Jr., and S. S. Oriel, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 128 (table 1), 129, 130. Formation, in Fossil Basin, Wyoming, overlies Evanston formation and underlies Green River formation. Confusion in original definition of Almy, Fowkes, and Knight formations as subdivisions of Wasatch group, and their areal distribution as mapped in much of Fossil Basin, had led to doubt as to validity of these names, especially Almy and Knight. These terms are not included in the Wasatch which is herein termed a formation.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 62–73. Formation described in Buffalo-Lake De Smet area, where it unconformably overlies Fort Union formation. Near Bighorn Mountains, comprises Kingsbury conglomerate and Moncrief members, which are separated by angular unconformity. Eastward, both members grade laterally into a conformable, nonconglomeratic sequence of sandstone, shale, and coal that makes up formation east of Buffalo and Lake De Smet. Eocene.

Type locality: Extends from Carter, Wyo., to the "Narrows on Weber," 7 miles below Echo City, Utah, and 10 to 15 miles east of crest of Wasatch Mountains. Name derived from Wasatch [Wahsatch] Station on Union Pacific Roalroad, Summit County, Utah.

†Wasatch Limestone[1]

Upper Ordovician, Silurian, Devonian, and Mississippian: Northeastern Utah.

Original reference: C. King, 1876, Am. Jour. Sci., 3d, v. 11, p. 477–479.

Northern Wasatch Mountains.

Wasatchian Age

Eocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc America Bull., v. 52, no. 1, p. 9, 10, pl. 1. Provincial time term, based on at least upper part of Wasatch group of southwestern Wyoming (modified to Wasatchian series by C. R. Keyes). Covers the time during which the faunas of the Sand Coulee, Gray Bull, Lysite, and Lost Cabin were deposited. As a functional term, the typical areas and faunas are those of the Bighorn and Wind River basins of Wyoming. Includes the interval between the Clarkforkian (Paleocene) and Bridgerian (Eocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for the North American continental Tertiary. [For sequence see under Puercan].

†Washakie Formation[1]

Eocene: Southwestern Wyoming.

Original reference: F. V. Hayden, 1869, U.S. Geol. Survey Terr. 3d Ann. Rept., p. 190 of 1873 ed; (1869 ed. not available).

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 36, pl. 1. Late Bridgerian and early Uintan.

W. J. Morris, 1955, Dissert. Abs., v. 15, no. 3, p. 394. Reinstated and applied to Bridgerian and Uintan strata lying above the Green River formation in Washakie Basin.

Named for exposures at Washaki Station between Creston and Bitter Creek on Union Pacific Railroad in Sweetwater Canyon, Wyo. (Washakie approved spelling).

Washburn Beds[1] (in Chequamegon Sandstone)

Precambrian (Keweenawan): Northeastern Wisconsin.

Original reference: F. T. Thwaites, 1912, Wisconsin Geol. Nat. History Survey Bull. 25, p. 34.

G. O. Raash, 1950, Illinois Acad. Sci. Trans., v. 43, p. 147. Discussion of Cambrian-Keweenawan boundary. Believed that Thwaites[1] Chequamegon brownstone formation is same as Port Wing brownstone member of Orienta formation repeated by faulting. Thwaites (1912) detailed description of the "Quarry" or "Brownstone beds" of the Chequamegon is essentially identical with that of the "Port Wing Brownstone" of the Orienta, whereas the upper or "Washburn beds" [upper part of Thwaites' Chequamegon] are described in much the same terms as his "upper member" of Orienta formation.

Named for exposures in shore cliffs south of Washburn, Bayfield County.

Washburn Sandstone[1]

Pennsylvanian: Western Arkansas and eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Probably named for Washburn, Sebastian County, Ark.

**Wash Creek Slate**[1]

Precambrian or Paleozoic: Central Alabama.

Charles Butts, 1940, U.S. Geol. Survey Geol. Atlas, Folio 226. Overlies Brewer phyllite; underlies Weisner formation. Thickness about 5,000 feet.

Named for exposures on Wash Creek, south of Sawyer Cove, Chilton County, in Columbiana quadrangle.

Washington cyclothem

Permian (Washington Series): Southeastern Ohio and western West Virginia.

A. T. Cross and M. P. Schemel, 1956, West Virginia Geol. Survey [Repts.], v. 22, pt. 1, p. 72 (fig. 1–61). Shown on geologic section below Winklers Mill cyclothem (new). Includes Washington coal at base and Washington "Rider B" No. 1 coal horizon at top.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 213–215. Embraces interval from base of Washington sandstone to top of roof shale of Washington coal. Occurs above Little Washington cyclothem (new). Thickness about 53 feet. Includes (ascending) Washington shale and sandstone, redbed, Bristol limestone, Washington fire clay shale, Washington (No. 12) coal, and Washington roof shale members. Where Little Washington coal is missing, lower boundary of cyclothem is placed at base of Mannington sandstone, hence, thickness of cyclothem is variable due to boundary differences in that absence or presence of Little Washington coal is controlling factor. In area of this report, Washington series is discussed on a cyclothemic basis; four cyclothems are named. [For sequence see Elm Grove cyclothem.]

Present in Parkersburg quadrangle, West Virginia, and in Athens County, Ohio.

Washington Fire Clay (in Washington Formation)[1]

Washington fire clay shale member

Permian: Northern West Virginia and eastern Ohio.

Original reference: C. E. Krebs, 1911, West Virginia Geol. Survey Rept. Jackson, Mason, and Putnam Counties, p. 117.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 215. Fire clay shale member of Washington cyclothem in report on Athens County. A yellowish-green, gray, or mottled maroon clay shale. Maximum thickness about 1 foot. Associated with Washington coal or at its horizon.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 18 (table 2). Washington fire-clay shale in Washington listed in summary of stratigraphic sections of Dunkard group in Harrison County.

Named for association with Washington coal.

**Washington Formation** (in Dunkard Group)[1]

Washington Group

Washington Series

Lower Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K, p. 44–46.

W. A. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 135–152. Washington group lies between Monongahela and Greene groups and, together with the latter, forms Dunkard series which was formerly called Upper Barren Coal Measures. Group consists of shale, sandstone, and limestone with several impure beds of coal. Base is taken at top of Waynesburg coal and at top of Upper Washington limestone. Named units listed.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 39. Rank raised to series. In Ohio, comprises lower part of Permian extending from top of Waynesburg coal to top of Upper Washington limestone. Four coal beds and five limestone horizons are present; remainder of series consists of sandstone and shale. Limestones, which are fresh-water type, are (ascending) Elm Grove, Mount Morris, Lower Washington, Middle Washington, and Upper Washington. Average thickness about 220 feet.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 89, geol. map. In Morgan County, series includes only lower part of strata, that is, from Cassville shale to within lower Marietta sandstone.

H. L. Berryhill *in* C. O. Dunbar and others, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, p. 1789–1790, chart 7 (column 80). Washington formation designated Pennsylvanian-Permian and Greene formation as Early Permian. There are neither lithologic nor faunal-floral bases for differentiating Washington and Greene formations anywhere in Dunkard Basin. Subdivision made by Stevenson (1876) has been handed down mainly through tradition. His Washington "group" is actually only a facies. Away from northern edge of basin, the Washington "group" has few of the lithologic characteristics of "type" area.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Formation mapped as Pennsylvanian and Permian. Consists of cyclic sequences of sandstone, shale, limestone, and coal; base at top of Waynesburg coal.

Named for exposures in highlands of Washington County, Pa.

**Washington Gneiss**[1]

Precambrian: Western Massachusetts and northern Connecticut.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 18, 20, 31–32, pl. 24.

Named for occurrence at Washington and Washington Center, Berkshire County, Mass.

†Washington Greensand[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept., 1888, v. 2, p. 72–75, 188.

Named for exposures in Town Creek Valley at Washington, Hempstead County.

†Washington Limestone[1]

Ordovician: Northeastern Vermont.

Original reference: C. H. Richardson, 1898, Am. Assoc. Adv. Sci. Proc., v. 47, p. 295–296.

In Orange, Washington, Windsor, Orleans, Essex, and Caledonia Counties.

†Washington reds (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: J. J. Stevenson, 1906. Geol. Soc. America Bull., v. 17, p. 65–216.

Washington roof shale member

*See* Washington cyclothem.

**Washington Sandstone Member** (of Washington Formation)[1]

Washington shale and sandstone member

Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876. Pennsylvania 2d Geol. Survey Rept. K.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 213. Shale and sandstone member of Washington cyclothem in report on Athens County. Can probably be more correctly identified stratigraphically with Mannington sandstone. In areas where Little Washington coal is absent and Waynesburg "A"—Washington coal interval is occupied by massive sandstone, this sandstone would then be equivalent to Mannington sandstone, but timewise the upper part of this sandstone may be equivalent to Washington sandstone. In areas where Waynesburg, Mannington, and Washington sandstones are separate entities, they could merely be channel deposits in tributaries of main "Hockingport" trunk channel which were migrating upward through time. Therefore, upper part of "Hockingport" sandstone could be equivalent to Washington sandstone.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 18 (table 2). Washington sandstone member of Washington formation listed in summary of stratigraphic sections of Dunkard group in Harrison County. Thickness about 10 feet.

Named for Washington County, Pa.

†Washington Shale and Sandstone[1]

Pennsylvanian: Northwestern Arkansas and eastern Oklahoma.

Original reference: F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. 26, 75–82.

Named for Washington Mountain, Washington County, Ark.

**Washington Hill Rhyolite**

Pliocene: Western Nevada.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 56–57, pl. 3. Light-gray highly flow-banded devitrified rhyolitic glass and perlite making up extrusive dome. Contains sparse phenocrysts of sodic plagioclase and biotite. Cuts through Kate Peak rocks and earlier beds of Truckee formation. Later beds of Truckee formation contains blocks of devitrified rhyolitic glass from the dome.

Name given to dome in and immediately southwest of Washington Hill, Virginia City quadrangle.

Washington Irving Sandstone (in Wann Formation)

Washington Irving Sandstone Member (of Wann Formation)

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 86. Name applied locally to sandstone in lower part of Wann formation, Tulsa County. In some area, it is a massive sandstone formed by coalescence of several thin sandstones, and in some areas consists of two sandstones with intervening shale.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 14 (table 1), 15 (fig. 3), 16–17. Washington Irving and Clem Creek sandstones both occur in Pawnee County where Washington Irving is lowest recognizable member of Wann. In SE¼ sec. 25, T. 20 N., R. 9 E., it is overlain by 38 feet of silty maroon shale capped by eroded remnant of Clem Creek sandstone. To the northwest, shale pinches out and Washington Irving-Clem Creek section is represented by 90 feet of massive to crossbedded sandstone.

Named because outcrop rims Washington Irving glen in NW cor. sec. 29, T. 20, N., R. 10 E., Tulsa County.

Washingtonville Member (of Allegheny Formation)[1]

Washingtonville shale member

Pennsylvanian (Allegheny Series): Eastern Ohio, western Pennsylvania, and northern West Virginia.

Original reference: W. Stout and R. E. Lamborn, 1924, Ohio Geol. Survey, 4th ser., Bull. 28, p. 175–181.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 49, table 1. Included in Middle Kittanning cyclothem, Allegheny series, Perry County.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 76. Shale member of Middle Kittanning cyclothem not recognized in area of this report [Athens County]. Nearest known exposure is near Lexington in Perry County. Member varies from 1 to 6 feet in thickness and normally rests directly upon or is separated from Middle Kittanning coal by several feet of unfossiliferous shale.

Named for exposures at Washingtonville, Green Township, Mahoning County, Ohio.

**Washita Group**[1]

Lower and Upper Cretaceous (Comanche Series): Southern Oklahoma, southwestern Arkansas, northwestern Louisiana, and Texas.

Original reference: R. T. Hill, 1887, Am. Jour. Sci., 3d, v. 33, p. 298.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Washita group, Lower and Upper Cretaceous (upper Albian-lower Cenomanian). In north-central Texas includes (ascending) Duck Creek limestone, Fort Worth limestone, Denton clay, Weno limestone, Pawpaw formation, Main Street limestone, Grayson shale, and Buda limestone; other Texas areas include (ascending) Georgetown limestone, Grayson shale, and Buda limestone.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, includes (ascending) Duck Creek formation, Fort Worth limestone, Denton clay, Weno clay, Pawpaw formation, Main Street limestone, and Grayson shale.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 23–31. In this report [Cretaceous Foraminifera of Texas], group includes (ascending) Duck Creek, Fort Worth, Denton, Weno, Pawpaw, Main Street, and Grayson formations, Buda limestone, and Maness shale (subsurface only). Overlies Kiamichi formation of Fredericksburg group; underlies Cretaceous Woodbine group.

N. M. Curtis, Jr., 1959, Oklahoma Geology Notes, v. 19, no. 12, p. 257–264. In Bryan County, group includes (ascending) Kiamichi clay, Caddo limestone, Bokchito formation, Bennington limestone, and Grayson marl.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 16 (table 2), 35–39, pl. 1. In McCurtain County, group is undifferentiated. Overlies Fredericksburg group; underlies Woodbine formation. As mapped, includes Kiamichi formation of Fredericksburg group.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 21–42, pls. 1, 2. Described in Fort Worth area where it comprises (ascending) Kiamichi formation, Duck Creek formation, Fort Worth limestone, Denison formation, and Buda limestone. Overlies Fredericksburg group; underlies Woodbine sandstone.

Named for old Fort Washita, T. 5 S., R. 7 E., about sec. 23, Bryan County, Okla.

†Washita Limestone[1]

Lower Cretaceous (Comanche Series): Southern Oklahoma and Texas.

**Original reference:** B. F. Shumard, 1860, St. Louis Acad. Sci. Trans., v. 1, p. 583, 586.

Named for old Fort Washita, T. 5 S., R. 7 E., about sec. 23, Bryan County, Okla .

**Wasson Formation** (in Little Butte Volcanic Series)

Oligocene, upper(?): Southwestern Oregon.

F. G. Wells, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–89. Name applied to sequence of tuff beds and flow breccias that form upper part of Little Butte volcanic series (new). Most conspicuous layer of sequence is chalky white tuff about 200 feet thick; below this tuff and separated from it by about 300 feet of platy andesite flows is a 300-foot bed of dirty-yellow tuff consisting of angular fragments in basaltic tuff matrix. Overlies Roxy formation (new); capped by Heppsie andesites (new).

Well exposed in Wasson Canyon and in amphitheater north of Brest Mountain, T. 38 S., R. 2 E., Jackson County.

Wassonville Limestone (in Osage Group)[1]

Wassonville Limestone Member (of Hampton Formation)

Mississippian (Kinderhook Series): Southeastern Iowa.

Original reference: H. F. Bain, 1895, Am. Geologist, v. 15, p. 322.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 69). Shown on correlation chart as upper member of Hampton formation; overlies North Hill beds member. Included in Kinderhook series.

Named for outcrops at old Wassonville Mill, Washington County.

Wassuk Group

Miocene, upper, to Pliocene, middle: Western Nevada.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 23, 61, 67–68, fig. 4. Made up of (ascending): Aldrich Station formation (new), thickness 4,050 feet; Coal Valley formation (new), thickness 3,325 feet; Morgan Ranch formation (new), thickness 700 feet. Aggregate thickness approximately 8,200 feet. Rests unconformably on biotite-hornblende andesite, or on granodiorite of Jurassic-Cretaceous(?) age. On page 67, age of Morgan Ranch formation is given as middle or upper Pliocene.

Exposed in Coal Valley-Mason Valley, Hawthorne quadrangle. Name derived from Wassuk Range.

Wassum Formation

Middle Ordovician (Mohawkian): Southwestern Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 97, chart 1 (facing p. 130). Calcarenites and buff crumbly shales. Composed principally of variegated marble or calcarenite in type locality. Total thickness 150 feet. Underlies Bays formation; overlies Chatham Hill formation (new). Name attributed to B. N. Cooper and G. A. Cooper.

Type locality: Four miles northwest of Marion, Marion quadrangle, Smyth County. Probably named for Wassum, Smyth County.

†Watauga Shale[1]

Lower Cambrian: Eastern Tennessee, northwestern Georgia, western North Carolina, and southwestern Virginia.

Original reference: A. Keith, 1903, U.S. Geol. Survey Geol. Atlas, Folio 90, p. 5.

Named for exposures in drainage area of Watauga River, Carter County, Tenn.

Watchman Flow, Andesite

Pleistocene: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 44–46. At least six of the Northern Arc of Vents on former Mount Mazama are visible on caldera walls of Crater Lake. In clockwise direction these are: vents of Watchman andesite, of the andesitic cone forming Hillman Peak, of Llao, Cleetwood, and Redcloud dacite flows, and Sentinel Rock andesite. Watchman flow is about 1¼ miles long with an average width of 2,000 feet. Average thickness between 400 and 500 feet. Watchman flow is one of youngest of pre-caldera andesites and probably coeval with andesite of Sentinel Rock. All but highest crags of Watchman flow have been overridden by ice. Watchman vent was active before the vents of the Llao, Cleetwood, and Redcloud dacite lavas. [Diller and Patton, 1902, U.S. Geol. Survey Prof. Paper 3, described Watchman andesite area.]

The Watchman is peak on western side of Crater Lake.

**Watchorn Formation** (in Meramec Group)

Upper Mississippian: Kansas (subsurface).

Wallace Lee, 1940, Kansas Geol. Survey Bull. 33, p. 84–89, pl. 2. Term applied in subsurface where subdivision of strata into Spergen, St. Louis, and possibly Ste. Genevieve limestones is impracticable. In Watchorn and Olson No. 1 Morrison, consists of three units: at base, a noncherty or sparsely cherty semigranular gray limestone 120 feet thick; in middle, a buff sucrose dolomite containing dull and semitranslucent gray chert, 25 feet thick; at top, semigranular gray and white limestone 545 feet thick. Overlies Warsaw limestone; unconformable below rocks of Batesville age.

First penetrated in Watchorn Oil and Gas Co. No. 2 Morrison well, in NE¼NW¼ sec. 20, T. 32 S., R. 21 W., Clark County. Thick sections occur in western Kansas; outliers of lower part present in eastern Kansas.

**Watchung Basalt**[1] or **Lava Flows** (in Newark Group)

Upper Triassic: Northern New Jersey and southeastern New York.

Original reference: N. H. Darton, 1889, Am. Jour. Sci., 3d, v. 38, p. 134–139; 1890, U.S. Geol. Survey Bull. 67.

Helgi Johnson *in* Erling Dorf, ed., 1957, Geol. Soc. America Guidebook Atlantic City Mtg., p. 112–113, 115. Termed basalts. Interbedded with sandstone and shales of upper Newark group. Only slight differences in composition of various sheets. Rocks generally fine granular to aphanitic except for vesicular zones which are glassy and filled with variety of secondary minerals. Visible phenocrysts in dense groundmass rarely found. Occasional beds of red-colored tuffs seen in drill cores. Geographically extended to New York.

E. D. McKee and others, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I-300. Listed as Watchung lava flows. Includes Hood Mountain flow.

Probably named for occurrence in Watchung Mountains of New Jersey.

**Waterboot Basalt**[1]

Miocene(?) or Pliocene(?): Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 55–56, pl. 1. Black porphyritic scoriaceous and vesicular olivine basalt. Groundmass predominantly ophitic, though locally trachitic. Cellular structure is recurrent feature that apparently marks tops of several successive and nearly horizontal lava flows, each a few feet thick. Total thickness probably not much more than 100 feet. Inferred that Waterboot basalt succeeds Holokuk basalt (new) in stratigraphic position. Gemuk group (new) probably forms footing of the basalt on eastern sides of mountain.

Type exposures: The nearly horizontal caprock of Flat Top Mountain, east of upper-middle course of Aniak River. Mountain lies between Atsaksovluk Creek, an easterly tributary of Aniak River, and Waterboot Creek (for which unit is named), which flows west at south foot of mountain, and then north into Atsaksovluk Creek; in central Kuskokwim region.

**Waterbury Gneiss**[1]

Precambrian(?): Central Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 86, 100, map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Complex of gneiss and schist of variable composition and texture. Schist mainly medium grained. Rusty-weathering gneiss typically strongly banded; quartz-feldspar bands alternate at inch or foot intervals with more micaceous bands that grade into schist. Small granitic and pegmatitic sills and dikes common in more contorted gneiss bodies. Mapped in Waterbury dome only. Pre-Triassic. Derivation of name stated.

Named for town of Waterbury, New Haven County.

**Water Canyon Formation**

Lower Devonian: Northern Utah and southeastern Idaho.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1138–1139, pl. 1. Consists of two unnamed members. Lower member essentially of compact thin-bedded silty and sandy dolomites that weather smoke gray (white) or buff. In upper member detrital content increases, and brown sandstone intraformational breccias and sandy shales are interbedded with dolomites, the only red beds in Paleozoic sequence in the quadrangle. Thickness of lower member estimated as much as 400 feet. Upper member 150 feet; missing northwest of Dry Lake. Disconformably underlies Hyrum member (new) of Jefferson formation; disconformably overlies Laketown dolomite.

H. W. Coulter, 1956, Idaho Bur. Mines and Geology Pamph. 107, p. 30–32, figs. 2, 3. Geographically extended to Preston quadrangle, Idaho.

Name taken from tributary of Green Canyon, Logan quadrangle, Utah, where, in sec. 4, T. 12 N., R. 3 E., it is well exposed.

**Waterford Slate**[1]

Ordovician(?): Northeastern Vermont.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept., p. 97.

In Waterford village or township, Caledonia County.

Watering Trough Shale

Upper Devonian (Conewango): Southwestern Pennsylvania.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Progress Rept. 126, p. 11. Name will probably be used, following more definitive study of area, for unit here termed Shale C and described as gray thin-bedded shales with interbedded gray limy brown-weathering sandstones and some clay-gall conglomerates. Sandstones lenticular and very local; may be channel fillings. Thickness 181 feet at type locality; varies from 137 to about 406 feet. Conformably underlies Sandstone D (Jumonville sandstone); overlies Sandstone B (Youghiogheny sandstone) with gradational contact.

Type section: Along National Pike about 2¼ miles east of town of Hopwood, Fayette County. Section best exposed in cuts above and below Watering Trough Inn and Spring.

Water Island Formation

Age not stated: Virgin Islands.

T. W. Donnelly, 1960, Dissert, Abs., v. 20, no. 7, p. 2755–2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. Chiefly keratophyre flows and tuffs with minor spilite flows and rare radiolarites. Terrigenous sediments absent. Exposed thickness 15,000 feet. Underlies Virgin Island group (new) with slight angular unconformity. Age not stated. Only fossils are radiolaria, *Stomiosphaera* cf. *moluccana* Wanner, which ranges from Tithonian to Turonian.

Report discusses geology of St. Thomas and St. John Islands.

**Waterloo Quartzite**[1]

Precambrian (Middle Huronian): Central southern Wisconsin.

Original reference: T. C. Chamberlin, 1877, Geology Wisconsin, v. 2, p. 252–256.

Exposed at foot of ridge on border of marsh in town of Waterloo, Jefferson County.

Waterman Gneiss

Precambrian(?) or Upper Paleozoic(?): Southern California.

O. E. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 16 (fig. 2), 17–23, pls. 1, 2, 3. Black hornblende-plagioclase-quartz-mica gneiss and local diorite and pegmatite. At least 4,000 feet thick at type section. Believed to be younger than Oro Grande series and intrusive into it.

T. W. Dibblee, Jr., 1960, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–233. Probably Precambrian, possibly Paleozoic. In vicinity of Hinckley Mound, was mapped by Bowen as Oro Grande series and gneissic hornblende diorite. Maximum exposed thickness about 10,000 feet.

Type section: In deeply eroded northeast-trending broad simple anticline south of Camp Irwin Road opposite Waterman silver mine, Barstow quadrangle, San Bernardino County. Unit covers about 3½ square miles in Barstow quadrangle and extends east into unmapped territory for undetermined distance.

Waterton Dolomite[1]

Waterton Member (of Altyn Formation)

Precambrian (Belt Series): Southern Alberta, Canada.

Original reference: R. A. Daly, 1913, Canada Dept. Int. Rept. Chief Ast. 1910, v. 2, p. 50, 178.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1882. Member of Altyn formation. Thickness about 280 feet, base not exposed. Grades upward in Hell Roaring member (new).

C. P. Ross, 1959, U.S. Geol. Survey Survey Prof. Paper 296, p. 19. Not known to crop out in United States.

Exposed in Waterton Lakes Park.

**Watertown Limestone** (in Black River Group)[1]

Watertown Member (of Chaumont Formation)

Middle Ordovician: Central New York.

Original reference: R. Ruedemann, 1910, New York State Mus. Bull. 138, p. 72.

G. M. Kay, 1929, Jour. Geology, v. 37, no. 7, p. 664. Chaumont formation (new) comprises (ascending) Leray, Glenburnie (new), and Watertown members.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 252, 253. Near Dexter, Jefferson County, Watertown member of Chaumont underlies Selby member (new) of Rockland formation. In earlier description of this section (Kay, 1931, Jour. Geology, v. 39, no. 4), the thin metabentonite that is 3 feet from base of Shelby member was mistakenly believed to separate Leray and Watertown members of Chaumont and to be same as persistent clay at that horizon in Glenburnie shale of Ontario. Type Hounsfield metabentonite is thus of Selby age. Hence, in revised section at Dexter, the Watertown underlies the Selby. Thickness at this section 5¾ feet.

G. M. Kay, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 599. Chaumont is separable into two members, Leray and Watertown limestones, only in limited area near Watertown.

Named for exposures at Watertown, Jefferson County.

Waterville Shale[1] or Slate

Silurian: South-central Maine.

Original reference: C. H. Hitchcock, 1861, Maine Bd. Agric. 6th Ann. Rept., p. 232.

Jacob Freedman, 1950, Geol. Soc. America Bull., v. 61, no. 5, p. 488. Middle Silurian.

Named for fine exposures at Waterville, Kennebec County.

Watson Limestone[1]

Lower Silurian: Northwestern Missouri.

Original reference: R. R. Rowley, 1916, Am. Jour. Sci., 4th, v. 41, p. 317–320.

Charles Schuchert, 1943, Stratigraphy of the eastern and central United States: New York, John Wiley and Sons, Inc., p. 671. Abandoned.

First described near Watson Station, Pike County.

†Watson Sandstone Member[1] (of Cattaraugus Formation)

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 203.

Watson Ledge Quartz Syenite

Carboniferous(?): East-central New Hampshire.

Alonzo Quinn, 1937, Geol. Soc. America Bull., v. 48, no. 3, p. 377, 388, 400. Grayish quartz syenite. Porphyritic along contact with syenite which it intrudes. Porphyritic phase contains inclusions of syenite and fine-grained basic rock. Contains many small coarse streaks of amphibole and large grains of quartz clustered together. Belongs to White Mountain magma series.

Forms prominent bluffs known as Watson Ledge on Red Hill, Carroll County.

Watson Ranch Tongue (of Swan Peak Quartzite)

Middle Ordovician: Western Utah and eastern Nevada.

G. W. Webb, 1956, Utah Geol. and Mineralog. Survey Bull. 58, p. 12, 13 (fig. 3), 35, 42–43 (fig. 11), 44; 1956, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2338. Thickness 243 feet at Smooth Canyon, near Ibex, Utah. Divided by numerous strongly developed bedding planes. In general, quartz arenite beds weather to an iron oxide-stained, reddish-brown-colored surface, although lower beds are light gray or yellow weathering. Underlies Crystal Peak dolomite (new).

Named for Jack Watson Ranch, Ibex, Millard County, Utah.

**Watts Creek Shale Member** (of Moran Formation)[1]

Permian: North-central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 419.

R. C. Moore, 1948, *in* M. G. Cheney, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, sheets 3, 4; R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Underlies Gouldbusk limestone member (new); overlies Camp Colorado limestone member of Pueblo formation.

Named for Watts Creek, Coleman County.

**Waubakee Dolomite**[1]

Upper Silurian: Southeastern Wisconsin.

Original reference: W. C. Alden, 1906, U.S. Geol. Survey Geol. Atlas Folio 140.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Waubakee limestone stratigraphically above Guelph dolomite.

First described near village of Waubakee, Ozaukee County.

Waucoba Lake Beds

Quaternary: Eastern California.

R. H. Hopper, 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 418. Name applied to lake beds in vicinity of Waucoba Canyon. Younger than Coso formation. Correlated with Sherwin glacial stage.

Vicinity of Waucoba Mountain, Inyo Range, Inyo County. [Walcott (1897, Jour. Geology, v. 5, no. 4) described these beds and referred to them informally as the lake beds of the Waucobi embayment.]

**Waucoban Series**[1]

Waucoban Epoch[1]

Lower Cambrian: North America.

Original reference: C. D. Walcott, 1912, Smithsonian Misc. Colln., v. 57, no. 10, p. 305–306.

A. B. Shaw, 1954, Geol. Soc. America Bull., v. 65, no. 11, p. 1046. Suggested that term Waucoban series be abandoned and term Georgian series be reinstated.

Name derived from Waucoba Springs, northeastern side of Saline Valley, Inyo County, Calif. Lower Cambrian strata are well exposed in this area and east into Nevada.

Waucoma Limestone[1] (Alexandrian Group)

Silurian (Albion Series): Northwestern Illinois and northeastern Iowa.

Original reference: T. E. Savage, 1914, Am. Jour. Sci., 4th, v. 38, p. 35–36.

E. H. Scobey, 1938, Jour. Geology, v. 46, no. 2, p. 213–214. Beds found at type section of Waucoma are placed in the Edgewood formation on the basis of paleontology, lithology, and normal stratigraphic sequence; beds contain no chert and, where observed in Iowa, the Kankakee normally carries some chert bands.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as overlying Winston limestone; placed in Albion series.

Named for Waucoma, Fayette County, Iowa.

Waukesha Limestone[1] or Formation (in Coe Group)

Middle Silurian: Eastern Wisconsin, northeastern and northwestern Illinois, and northeastern Iowa.

Original reference: I. A. Lapman, 1851, Rept. of J. W. Foster and J. D. Whitney on geology of Lake Superior district, pt. 2, S. Ex. Doc. 4, U.S. 32d Cong., spec. sess., p. 168–171.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 536, 547, chart 3. Waukesha limestone has been defined as underlying Racine dolomite, but its lower limit has been placed at various horizons from the base of Cordell to base of Byron. The term hence lacks precision and in Wisconsin has been replaced by names used here, Cordell dolomite and Schoolcraft dolomite. Savage proposed name Bellwood dolomite for beds formerly called Waukesha dolomite in northeastern

Illinois, and also proposes name Cordova dolomite for beds formerly called Waukesha in northwestern Illinois and Iowa.

H. B. Williams, 1943, Illinois Geol. Survey Rept. Inv. 90, p. 29. Term Bellwood as used by Savage (1942) includes strata herein considered Waukesha and Racine.

H. A. Lowenstam, 1949, Illinois Geol. Survey Rept. Inv. 145, p. 18. Included in Coe group. (new).

First described in Waukesha County, Wis.

Waukon sandstone[1]

Upper Cambrian: Northeastern Iowa.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 320–321, 326.

Named for exposures in vicinity of Waukon, Allamakee County.

Waupecan Sandstone[1]

Pennsylvanian: Northeastern Illinois.

Original reference: H. E. Culver, 1922, Illinois Geol. Survey, Extract from Bull. 43, 1923, p. 53–56.

Named for exposures along Waupecan Creek, Grundy County.

Wausau Granite[1]

Precambrian: Wisconsin.

Original reference: C. C. Wang, 1932, Geol. Soc. China Bull., v. 11, no. 4, p. 427.

Wausau Graywacke[1]

Precambrian (middle Huronian): Central northern Wisconsin.

Original reference: S. Weidman, 1907, Wisconsin Geol. Nat. History Survey Bull. 16, p. 55.

Occurs in isolated masses within a few miles northeast and northwest of Wausau, Marathon County.

**Wauseca Pyritic Member** (of Dunn Creek Slate)

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 38. Name applied to very fine-grained pyritic graphitic slate, typically containing 35 to 40 percent pyrite, that occurs in uppermost part of formation. Member is subdivided into two or three parts in detailed geologic mapping; one subunit is chaotic breccia that ranges from a foot or so to about 50 feet in thickness and is composed of small fragments of pyritic slate in matrix of same composition. True thickness probably 30 feet or less but commonly much greater or less due to squeezing and shearing.

Only exposure is roadcut south of Alpha, Iron County. Named for Wauseca mine at Iron River, in which unit is exposed in thousands of feet of mine workings.

Waushara Granite[1]

Precambrian (pre-Huronian?): Central southern Wisconsin.

Original reference: S. Weidman, 1898, Wisconsin Geol. Nat. History Survey Bull. 3, Sci. ser. 2, p. 47–64.

Crops out at several places in Marion and Warren Townships, Fox River district, southeastern part of Waushara County.

Wauswaugoning Quartzite[1]

Precambrian (Huronian): Northeastern Minnesota.

Original reference: N. H. Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept.

At head of Wauswaugoning Bay.

†Wautubbee Marl (in Claiborne Group)[1]

Wautubbee Member (of Lisbon Formation)

Eocene, middle: Mississippi.

Original reference: E. N. Lowe, 1919, Mississippi Geol. Survey Bull. 14. p. 78.

U. B. Hughes and others, 1940, Mississippi Geol. Soc. [Guidebook] Field Trip, Feb. 10, 11, columnar section. Uppermost member of Lisbon. Overlies Kosciusko sand member. Thickness 60 feet.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 47–68, pls. Term Wautubbee used in this report essentially as applied by Lowe. Includes all of marine section above Kosciusko and below Cockfield in eastern and central Mississippi and its nonmarine equivalent, Shipps Creek shale, in western Mississippi. In eastern part of State, includes (ascending) Archusa marl, Potterchitto, and Gordon Creek shale members (all new). This subdivision impractical in central Newton County, and formation is mapped as undifferentiated as far northwest as Yockahockany River in northwestern Leake County. In western Holmes and Carroll Counties, tongue of carbonaceous shale lying at stratigraphic horizon of marine Wautubbee is here named Shipps Creek member. Thickness 45 to 75 feet.

Named for exposures near Wautubbee, Clarke County, on Northeastern Railroad, in cut beneath highway bridge on Highway 11, sec. 10, T. 3 N., R. 14 E.

Wauwatosa Formation

Silurian: Southeastern Wisconsin.

F. B. Phleger, Jr., 1937, Harvard Coll. Mus. Comp. Zoology Bull., v. 80, no. 11, p. 420. Incidental mention only.

Wauwatosa, Milwaukee County.

†Waverly Conglomerate[1]

Mississippian: Ohio.

Original reference: E. B. Andrews, 1871, Ohio Geol. Survey Rept. Prog. 1870.

Named for occurrence within Waverly group.

†Waverly Group[1] or Series

Mississippian (Kinderhookian-Osagean): South-central Ohio and northern Kentucky.

Original references: W. W. Mather, 1838, Am. Jour. Sci., 1st, v. 34, p. 363; C. Briggs, Jr., 1838, Ohio Geol. Survey 1st Ann. Rept., pl. 1, p. 79.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 56. In Kentucky, includes (ascending) Bedford formation, Berea sandstone, and Sunbury shale.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 84). Age given on correlation chart as Kinderhookian and Osagean.

J. E. Hyde, 1953, Ohio Geol. Survey Bull. 51, p. 1–213. Name is applied to sandy and argillaceous series of rocks, 700 to 1,000 feet thick, which occupies interval between Ohio shale and the Coal Measures (excepting local Maxville limestone which intervenes between it and the Coal Measures). So delimited, series includes (ascending) Bedford shale, Berea grit, Sunbury shale, Cuyahoga shale, Black Hand formation, and Logan formation. Devonian-Mississippian contact and post-Waverlian disconformity in Ohio discussed.

Named for Waverly, Pike County, Ohio.

Waverlyan System[1]

Mississippian: North America.

Original references: E. O. Ulrich, 1905, U.S. Geol. Survey Prof. Paper 36, p. 24 (table); 1911, Geol. Soc. America Bull., v. 22, no. 3, p. 581–582.

R. C. Moore, 1948, Jour. Geology, v. 56, no. 4, p. 373. Lower Mississippian rocks of North America, comprising Kinderhookian and Osagean beds, which have been called "Waverlyan series," correspond to Tournaisian strata of Europe.

**Waxahatchee Slate**[1]

Precambrian or Paleozoic: Central Alabama.

Charles Butts, 1940, U.S. Geol. Survey Geol. Atlas, Folio 226, p. 3. Basal slate formation exposed in Montevalo-Columbiana quadrangles. Includes all slate below Brewer phyllite. Includes Sawyer limestone member near top. Thickness about 5,000 feet.

Named for exposures on Waxahatchee Creek, Shelby County, in Columbiana quadrangle.

**Wayan Formation**[1]

Lower(?) and Upper Cretaceous: Southeastern Idaho.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 83.

W. L. Stokes, 1953, Intermountain Assoc. Petroleum Geologists 4th Ann. Field Conf., p. 17–18. Continental sandstone, limestone, shale, and conglomerate, all showing rapid lateral facies changes. Passes eastward into Bear River and Aspen formations with complex facies relationships. Of Upper Cretaceous age.

J. D. Vine, 1959, U.S. Geol. Survey Bull. 1055–I, p. 259, 263–264, pl. 51. Mapped in Fall Creek area, Bonneville County, where it comprises about 3,000 to 4,000 feet of red and purple shale, and gray medium- to coarse-grained crossbedded friable sandstone. Overlies Bear River formation.

Named for settlement of Wayan, Bannock County, in northwestern part of Wayan quadrangle.

**Wayland Shale Member** (of Graham Formation)[1]

Wayland Shale (in Graham Group)

Upper Pennsylvanian: Central and central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132, p. 127–158; 1922, Jour. Geology, v. 30, p. 24, 31.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 698, chart 6 (column 38). Shown on correlation chart as formation in Graham group, Cisco series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 70. In Brown and Coleman Counties, Colorado River valley, Wayland shale member overlies Gunsight limestone member and underlies Ivan limestone member. Thickness about 100 feet along Colorado River. Plummer and Moore (1921) correlated their Wayland shale in Stephens County with Drake's (1893) Trickham bed in Coleman County. Most authors have followed Plummer and Moore in bringing term Wayland into Colorado River valley. Although term Trickham has priority, retention of name Wayland shale is recommended in Colorado River valley. Nickell (1938, Texas Univ. Bur. Econ. Geology Pub. 3801) extended term Avis sandstone into Colorado River valley and applied it to lenticular beds of sandstone at one or more positions below Ivan limestone member. Inasmuch as sandstone is present only locally and the sandstone lenses occupy several stratigraphic positions in the Wayland, name Avis member probably should not be brought into Colorado River valley.

Named for exposures at and near Wayland, Stephens County, Brazos River region.

**Wayne Formation**[1]

Wayne Group

Middle Silurian: Western Tennessee and northeastern Mississippi.

Original reference: N. F. Drake, 1914, Tennessee Geol. Survey Resources of Tennessee, v. 4, no. 3, p. 103.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 244. Wayne group includes the following formations (ascending): Osgood limestone, Laurel limestone, Waldron clay, Lego limestone, and Dixon limestone.

Named for Wayne County, Tenn., where all units are well developed.

**Waynesboro Formation**[1]

Lower Cambrian: Central and southern Pennsylvania, western Maryland, northern Virginia, and northern West Virginia.

Original reference: G. W. Stose, 1906, Jour. Geology, v. 14, p. 209.

C. E. Resser, 1938, Geol. Soc. America Spec. Paper 15, p. 4, 7. Name considered invalid. Rome was called Waynesboro by Stose (1906).

H. P. Woodward, 1949, West Virginia Geol. Survey, v. 20, p. 142–155. Described in West Virginia where it consists of a miscellaneous assortment of red, purple, and green shale, thin slabby limestone, impure sandstone, and dolomite. Estimated thickness about 1,000 feet. Main outcrop is in Jefferson County. Underlies Elbrook limestone; occurs above Tomstown dolomite which is present only in Jefferson County.

Philip King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 7 (table), 30–32, pl. 1. Described in Elkton area, Virginia, where it is about 1,700 feet thick, overlies Tomstown dolomite and underlies Elbrook dolomite. Consists of red and brown shale, calcareous shale and siltstone, and some limestone. Closely resembles Rome formation in character and stratigraphic position. Name Waynesboro is now used in Virginia as far south as Roanoke, beyond which name Rome is used for same unit.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 41–43. Overlies Tomstown dolomite; underlies Elbrook limestone. Many outcrops in Washington County, but complete sections are not known. Most complete section is east of Chewsville, where formation is about 875 feet thick.

Named for exposures in ridge just north of Waynesboro, Franklin County, Pa.

Waynesburg Clay[1] (in Monongahela Formation)

Waynesburg underclay member

Pennsylvanian (Monongahela Series) : Southwestern Pennsylvania, eastern Ohio, and northern West Virginia.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 189. Underclay member of Waynesburg cyclothem in report on Athens County. Less than 1 foot thick. What is frequently termed Waynesburg "horizon" is an underclay with carbonaceous matter rather than coal or coaly shale. Monongahela series.

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 10. Waynesburg underclay immediately underlies Waynesburg coal. Clay is light gray with iron-stained fractures. Average thickness of clay about 3½ feet.

Waynesburg cyclothem

Pennsylvanian (Monongahela Series) and Permian: Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 186–189. Youngest cyclothem in Pennsylvanian system in Appalachian region. Occurs above Little Waynesburg cyclothem (new). Includes (ascending) Gilboy sandstone, Waynesburg redbed, fresh water limestone, Waynesburg underclay, Waynesburg (No. 11) coal, and Cassville shale members. By drawing Pennsylvanian-Permian boundary at top of Waynesburg coal, Cassville shale becomes basal member of Permian system; hence, Waynesburg cyclothem transcends systemic boundary. Average thickness 20 feet; this interval is filled by Gilboy sandstone and the redbed member. Lateral continuity of the Waynesburg is broken wherever the Gilboy and Waynesburg sandstones are coalesced; also Little Waynesburg Rider cyclothem lies between the Little Waynesburg and Waynesburg coal beds. Although this cyclothem and identification of Waynesburg coal are critical to stratigrapher, they are not disctinctive in field, and a long measured section is necessary to determine intervals from other key horizons. In area of this report, Monongahela series is discussed on cyclothemic basis; 12 cyclothems are named. [For sequence see Pittsburg cyclothem.]

Confined to eastern third of Athens County, an area that includes eastern edge of Lodi Township; extensive parts of Bern, Carthage, and Rome Townships; and along Hocking River and its tributaries in Troy Township.

Waynesburg "A" cyclothem

Permian (Washington Series) : Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 204–210. Embraces interval between Elm Grove cyclothem (new) below and Little Washington cyclothem (new). Includes all strata from top of Cassville shale to base of Mannington sandstone. Thickness about 36½ feet. Includes (ascending) Waynesburg shale and sandstone, redbed, Mount Morris limestone, underclay, Waynesburg "A" (No. 11a) coal, and roof shale members. Variations in thickness and boundaries of cyclothem are due to lack of lateral persistence of Elm Grove and Lower Waynesburg "A" coal horizons or result of erosional downcutting and (or) coalescence of Waynesburg sandstone with the overlying and underlying sandstones. In area of this report, Washington series is discussed on cyclothemic basis; four cyclothems are named. [For sequence see Elm Grove cyclothem.]

Cyclothem, or parts of it, are present in Bern, Carthage, Lodi, Rome, and Troy Townships, Athens County.

Waynesburg Group[1]

Pennsylvanian: Pennsylvania.

Original reference: H. D. Rogers, 1858, Geology of Pennsylvania, v. 2, pt. 1, p. 474–477.

**Waynesburg Limestone Member** (of Monogahela Formation)[1]

Waynesburg Limestone (in Monongahela Group)

Waynesburg limestone and shale member

Upper Pennsylvanian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1877, Pennsylvania 2d Geol. Survey Rept. $K_2$.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 100, 124 (fig. 29), 125–126. Termed Waynesburg limestone in Monongahela group.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 84–85. In Ohio, Waynesburg limestone and shale member (Monongahela series) occurs between Uniontown sandstone and shale member and Little Waynesburg (No. 10–A) coal above. Average thickness about 10 feet. Poorly developed.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 186. Waynesburg limestone member of Little Waynesburg cyclothem in report on Athens County. Member was named by Stevenson (1876, Geology Pennsylvania, Rept. K, p. 62) for its association with Waynesburg coal bed which it underlies in its type area by 20 to 40 feet. Later another coal bed directly overlying the Waynesburg limestone was reported and named by Stevenson the Little Waynesburg coal. Although this member is not directly related to the coal bed from which its name was derived, name Waynesburg has been retained and is firmly entrenched in geologic literature. Thickness of member 2⅓ feet.

Named for Waynesburg, Greene County, Pa.

Waynesburg Member (of Monongahela Formation)[1]

Pennsylvanian: Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

Waynesburg redbed member

Pennsylvanian (Monongahela Series): Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 188. Member of Waynesburg cyclothem in report on Athens County. This member, together with underlying Gilboy sandstone member, accounts for virtually entire interval between Little Waynesburg and Waynesburg coal beds. Average thickness of member 9½ feet but, because of lateral gradation to sandstone, the range is from 3 to 20 feet. Monongahela series.

**Waynesburg Sandstone Member** (of Washington Formation)[1]

Waynesburg Sandstone (in Washington Group)

Waynesburg sandstone and shale member

Permian: Southwestern Pennsylvania, western Maryland, southeastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1873, Am. Philos. Soc. Trans., v. 15, new ser., p. 16.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 135, 146. In Fayette County, Waynesburg sandstone occurs 16 to 25 feet above base of Washington group. Lies between Mount Morris limestone above and Cassville shale below locally separated from latter by Elm Grove limestone. Thickness 10 to 45 feet.

W. D. Martin, 1955, Dissert. Abs., v. 15, no. 8, p. 1371. True Waynesburg sandstone is geographically restricted to southwestern Pennsylvania and northern West Virginia. Relatively local sandstone, which occurs in Washington, Athens, and Meigs Counties, Ohio, and adjacent part of West Virginia, and has previously been considered a part of the Waynesburg sandstone, is here named Hockingport sandstone.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 91–92, geol. map. Waynesburg sandstone and shale member (Washington series) includes interval between Elm Grove limestone below and Waynesburg "A" (No. 11–A) coal. In Morgan County, general absence of these latter units makes basal and upper boundaries of member indefinite. In thicker bodies, sandstone is gray to tan, fine to medium grained with zones of coarser material, and thin to platy bedded; commonly contains beds of sandy shale, and in many areas is an alternation of sandstones and shales. Thickness 28 to 37 feet. Locally coalesces with Gilboy sandstone, which occurs below Waynesburg (No. 11) coal, thus transgressing systemic boundary; in some areas, merges with stratigraphically higher Mannington sandstone.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 203 (table 14), 204–208. Waynesburg sandstone and shale member of Waynesburg "A" cyclothem in report on Athens County. Waynesburg sandstone is first major sandstone occurring in Washington series. Both top and bottom of this member have been used in the past as Pennsylvanian-Permian contact. Thickness 24½ feet.

Named for development on Tenmile Creek, east of Waynesburg, Greene County, Pa.

**Waynesville Shale[1] or Limestone** (in Richmond Group)

Waynesville Formation (in Richmond Group)

Upper Ordovician: Southwestern Ohio, southern Indiana, and north-central Kentucky.

Original reference: J. M. Nickles, 1903, Am. Geologist, v. 32, p. 205.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 110, chart facing p. 108. Shown on generalized section of Ohio as Waynesville formation. Thickness 95 feet. Includes (ascending) Fort Ancient, Clarksville, and Blanchester members. Underlies Liberty formation; overlies Arnheim formation.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (columns 44, 45). Correlation chart shows Waynesville shale and limestone underlying Liberty shale and limestone and overlying Arnheim shale and limestone.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030. Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations define Richmond stage of Cincinnatian series.

Named for Waynesville, Warren County, Ohio.

Wayside Sandstone Member (of Caseyville Formation)

Wayside Sandstone and Shale Member (of Pottsville formation)[1]

Pennsylvanian: Southwestern Illinois.

Original reference: J. E. Lamar, 1925, Illinois Geol. Survey Bull. 48, p. 23, 84–85, map.

J. M. Weller, 1939, Illinois Geol. Survey Rept. Inv. 60, p. 11. Reallocated to member status in Caseyville formation. Basal member of formation; underlies Lick Creek sandstone member.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 36. Strata formerly termed Wayside now included in Lusk formation (new).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 29, 30, 44 (table 1), pl. 1. Member of Caseyville formation (redefined). Occurs below Battery Rock sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: N½ sec. 30, T. 11 S., R. 2 E., Jackson County. Named for village of Wayside, a few miles northwest of type exposures.

**Wea Shale[1] Member** (of Cherryvale Shale or Formation)

Wea Shale Member (of Sarpy Formation)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 85, 91, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 95. Wea shale member of Cherryvale formation; underlies Westerville limestone member; overlies Block limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 38. In Nebraska, reallocated to member status in Sarpy formation (new). Thickness in eastern Kansas 10 to 30 feet; northwestern Missouri, 15 to 25 feet; Sarpy County, Nebr., 3½ feet; south-central Iowa, 5 feet.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Consists of two dark-gray shale units that are separated by hard black fissile shale. Thickness about 3 feet. Uppermost member of Cherryvale shale; overlies Block limestone member; underlies Westerville limestone.

Type locality: SE cor. sec. 31, T. 16 S., R. 24 E., and at center of east side sec. 12, T. 18 S., R. 22 E., Miami County, Kans. Named for Wea Creek in northeastern part of county.

**Wearyman Dolomite Member** (of Minturn Formation)

Pennsylvanian: Central Colorado.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 198–199. Prominent and persistent bed of light-gray to buff finely crystalline slightly siliceous reef dolomite that is pitted with small cavities elongated in plane of the bedding. Weathers to rounded forms but weathered surfaces rough and pitted. Dolomite probably largely of algal origin although at places it contains abundant remains of other fossils. Most organic structures almost obliterated by dolomitization and recrystallization. Thickness 15 to 75 feet. Underlies Hornsilver dolomite member (new).

Named for prominent exposures near Wearyman Creek, which lies in Minturn quadrangle just north of edge of Holy Cross quadrangle. Best exposed and thickest on ridge between Wearyman and Resolution Creeks, at northern edge of Holy Cross quadrangle.

Weatherby Canyon Ignimbrite

Tertiary: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 70–75, table 1, pl. 1. Rhyolite and some trachyte ignimbrite and thin interbeds of nonwelded tuff. Most of the ignimbrite is light-gray to red hard compact aphanitic-porphyritic rhyolite with phenocrysts of quartz, sanidine, and orthoclase in devitrified matrix of shards and glass shreds. Thickness at least 3,000 feet on 1117 Peak and ridges to the west. Younger than Vanar Hills volcanic rocks.

Named from exposures in Weatherby Canyon, near southern boundary of the mapped area of central part of Peloncillo Mountains, Hidalgo County. Particularly well exposed on 1117 Peak, south of Weatherby Canyon. Forms surface rock of most of the Peloncillo Mountains between Cowboy Pass and south boundary of area mapped, and extends southward at least additional 5 miles.

**Weatherford Member** (of Cloud Chief Formation)

Weatherford Dolomite[1]

Permian: Central-western Oklahoma.

Original reference: R. L. Six and others, 1930, Oklahoma Geol. Survey Bull. 40–UU, map.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Basal member of formation.

Present in Custer, Dewey, and Washita Counties. Probably named for Weatherford, Custer County.

**Weaver Rhyolite**[1] (in Koipato Group)

Permian(?) and Lower Triassic: Northwestern Nevada.

Original reference: A. Knopf, 1924, U.S. Geol. Survey Bull. 762.

R. E. Wallace and others, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–220. Upper formation in Kiopato group. In Buffalo Mountain quadrangle, comprises three units: (1) porphyritic rhyolite with phenocrysts of quartz and feldspar, white or light greenish gray; generally homogeneous with rare, poorly defined bedding; thickness probably more than 1,000 feet in vicinity of Fisher Canyon but appears to pinch out west of Buffalo Mountain; (2) clastics, including pebble conglomerate, sandstone, and thinly laminated dark-gray or brown tuffaceous argillite in variable proportions; well stratified; in places an upper and lower unit; impressions of ammonites of probable Early Triassic age present in argillite; maximum thickness more than 700 feet; and (3) rhyolitic felsite flows; estimated thickness 1,000 feet in Fisher

Canyon. Overlies Rochester trachyte; underlies Prida formation with angular unconformity. Permian(?) and Triassic.

Exposed at head of Weaver Canyon, Rochester district.

Weaver Lake Quartz Monzonite

Jurassic-Cretaceous: Central California.

D. C. Ross, 1958, California Div. Mines Spec. Rept. 53, p. 13, pl. 1. Notably light gray; distinguishing features are fine grain size and low color index; texture is xenomorphic granular and grains average 1 to 2 mm; biotite sprinkled through rock; hornblende rare. Relation to other named plutonic rocks in area not determined.

Named from exposures around Weaver Lake in northeast part of area, Sequoia National Park. Largest mass crops out over about 12 square miles, seven smaller masses, probably satellitic to large mass, are exposed around periphery of main mass.

**Weaverville Formation**[1]

Oligocene(?): Northern California.

Original reference: N. E. A. Hinds, 1933, California Jour. Mines and Geology, v. 29, nos. 1, 2, p. 79, 115.

W. P. Irwin, 1960, Sacramento Geol. Soc. [Guidebook] Ann. Field Trip, June, 3, 4, 5, p. 22. Mentioned in road log. Oligocene(?).

Named for exposures near Weaverville, Trinity County.

†Webb Bluff[1] (formation)

Eocene: Southern Texas.

Original reference: E. T. Dumble, 1892, Geol. Soc. America Bull., v. 3, p. 224, 228, 230.

Named for Webb Bluff, Webb County, 3 miles below Maverick County line.

**Webbers Falls Sandstone Member** (of Atoka Formation)[1]

Pennsylvanian (Atoka Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 24–33. Thickness 10 to 15 feet in Muskogee-Porum district. Separated from underlying Dirty Creek sandstone member and overlying Blackjack School sandstone member by unnamed shales.

Named for exposures in secs. 10 and 15, T. 15 N., R. 20 E., about 2 miles west of Webbers Falls, Muskogee County.

†Webberville Beds[1]

Upper Cretaceous (Gulf Series): Central Texas.

Original reference: R. T. Hill, 1899, Texas Geol. Survey Bull. 4, p. xiii, xxx.

Well exposed at blue bluffs of Colorado River, and at and near Webberville, Travis County.

Weber Conglomerate[1]

Lower Cretaceous: Northeastern Nevada.

Original references: Arnold Hague, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 28; 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253; 1892, U.S. Geol. Survey Mon. 20, p. 30, 91, 92.

Lore David, 1941, Jour. Paleontology, v. 15, no. 3, p. 318–321. On basis of discovery of fish and plant fossils, so-called Weber conglomerate, originally mapped as Upper Carboniferous, is considered to be Lower Cretaceous in age.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 68. Name Newark Canyon proposed for beds of Lower Cretaceous age that include almost all strata mapped as Weber conglomerate by Hague (1883; 1892).

Occurs in Eureka and other districts of Nevada.

†Weber Grits[1]

Pennsylvanian: Central Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1883, U.S. Geol. Survey.

Leadville and neighboring regions.

**Weber Quartzite[1] or Sandstone**

Weber Formation (in Durst Group)

Pennsylvanian and Permian: Northeastern Utah and western Colorado.

Original reference: C. King, 1876, Am. Jour. Sci., 3d, v. 11, p. 477–479.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1384–1385. Names Weber and Maroon abandoned in Gore area, Colorado; term Battle Mountain proposed for sequence of Pennsylvanian clastics. In earlier reports, sequence here assigned to Battle Mountain was divided into six formations (ascending): Weber (divided into Weber shale and Weber grit), Robinson limestone, White Quail limestone, Maroon, Jacque Mountain limestone, and Wyoming. Term Belden shale member of Battle Mountain is here proposed to replace Weber shale.

K. G. Brill, Jr., 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 633–635. Term Weber quartzite restricted in west-central Colorado to white sandstone overlying Maroon formation; in some areas, overlies Morgan formation. Underlies State Bridge formation, Phosphoria, or Dinwoody (Moenkopi) formations. Thicknesses: 880 feet, Disappointment Creek; 70 feet, Miller Creek section; 79 feet, Glenwood Springs section. Term Belden member raised to formation rank and is equivalent to "Weber shale" throughout region.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 833–834. At type section, herein described for first time, Weber quartzite is about 3,000 feet thick; overlies Morgan sandstone and underlies Park City formation. Lower sandstones, 730 feet thick, are overlain by 355 feet of limestone; remainder of unit is quartzite.

M. L. Thompson, 1945, Kansas Geol. Survey Bull. 60, pt. 2, p. 34, 39. Term Weber restricted in Uinta Mountains to the thick crossbedded to massive buff sandstones above the limestone-bearing part of the section. As thus restricted, overlies Youghall formation (new) and underlies Park City formation. Thickness about 1,000 feet in vicinity of Vernal, Utah; about 850 feet on north side of Uinta Mountains at Sheep Mountain Canyon. No fossils; age not determined.

J. W. Huddle and F. T. McCann, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 75. In Duchesne River area, 1,500 to 1,600 feet thick and consists mainly of very fine grained gray and white sandstone that weathers buff. Overlies Morgan formation; underlies Park City formation, contact not everywhere distinct.

K. G. Brill, Jr., 1953, Geol. Soc. America Bull., v. 63, no. 8, p. 811 (fig. 1), 823. In vicinity of Glenwood Springs and McCoy, Colo., Weber sandstone includes Schoolhouse tongue at top.

J. W. Vanderwilt, 1953, *in* Rocky Mountain Assoc. Geologists Guidebook Field Conf., May 14–16, p. 15, fig. facing p. 12. Maroon formation, in Glenwood Springs area, contains Glenwood tongue (new) of Weber sandstone. Tongue is 200 feet thick.

Walter Sadlick, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 58. Because of recent common usage, it is herein proposed that the Weber be henceforth known as Weber sandstone.

D. M. Kinney, 1955, U.S. Geol. Survey Bull. 1007, p. 45–48, pls. Originally defined as quartzite at type locality, the formation throughout Uinta Mountains and most of Wasatch Mountains is more correctly referred to as sandstone. Weber was defined as including strata that were later differentiated by Blackwelder (1910) as Morgan formation. In Uinta Mountains, geologists of Fortieth Parallel Survey mistakenly applied name to great thickness of Precambrian rocks, now known as Uinta Mountain group, instead of the less extensive sandstone of Pennsylvanian age. Powell (1876), in report on Uinta Mountains, named the massive sandstone of Pennsylvanian age the Yampa sandstone. Yampa sandstone was correlated by Schultz (1920, U.S. Geol. Survey Bull. 702) with more widely used Weber sandstone, and since that time Weber sandstone has been used in preference to Yampa. The Weber in Uinta River-Brush Creek area is uniform massive fine- to medium-grained light-gray slightly calcareous quartzose sandstone. Thickness 1,015 to 1,275 feet; thicker sections (in Ashley Creek and on Diamond Mountain) are adjacent and are located in area in which the upper 300 to 400 feet of Weber is particularly crossbedded. Overlies Morgan formation; underlies Phosphoria. No fossils; age open to question.

Walter Sadlick, 1957, Intermountain Assoc. Petroleum Geologists Guidebook 8th Ann. Field Conf., p. 70–71, 75–76. Weber formation included in Durst group (new).

H. J. Bissell and O. E. Childs, 1958, Rocky Mountain Assoc. Geologists Symposium on Pennsylvanian rocks of Colorado and adjacent areas, p. 27–30. Formation, as described in section that extends from type locality eastward to vicinity of Walcott, Colo., consists of western facies of orthoquartzites, shale, and limestone stringers that, in vicinity of Whiterock, Utah, interfingers with eolian and neritic sands. In western Colorado, includes Schoolhouse tongue at top and interfingers with Maroon formation. In vicinity of type locality, overlies Morgan and underlies Park City; eastward, underlies Phosphoria and between Meeker and Walcott, Colo., pinches out beneath State Bridge formation. Interpretation of fossil occurrences shows that Weber transcends Pennsylvanian-Permian time boundary, indicating that upper part of eolian Weber is Permian and that all of Schoolhouse tongue is Permian.

U.S. Geological Survey currently designates the age of the Weber Quartzite or Sandstone as Pennsylvanian and Permian on the basis of a study now in progress.

Type section: Upper Weber Canyon, east of Morgan, Morgan County, Utah.

†Weber Shales[1]

Pennsylvanian: Central Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1883, U.S. Geol. Survey Leadville Atlas; 1886, U.S. Geol. Survey Mon. 12.

Leadville and neighboring regions.

Weberg Formation (in Colpitts Group)

Middle Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 248. Consists mainly of gray granular limestone with calcareous sandstone, grit, and conglomerate; a thin basal conglomerate is present near Colpitts Ranch; elsewhere in type area, formation begins with limestone or coarse calcareous sandstone. Thickness 100 to 272 feet. Basal formation of group. Underlies Warm Springs formation (new); overlies Nicely shale (new).

W. R. Dickinson, 1960, Dissert. Abs., v. 20, no. 11, p. 4376. Weberg, Warm Springs, and Basey (new) formations are lateral equivalents of Snowshoe formation.

Type area: On east side of Warm Springs Creek valley in secs. 19, 20, 29, and 30, T. 18 S., R. 26 E. Named for Weberg Ranch, on lower Warm Springs Creek, in sec. 18, T. 18 S., R. 26 E., Crook County.

Webster Formation[1]

Ordovician: Oklahoma.

Original references: E. O. Ulrich, 1932, Unpublished chart exhibited at Geological Society of America meeting in December; F. C. Edson, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 8, p. 1122–1130.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 108. Abandoned by Oklahoma Geological Survey. An unpublished name for limestone now called Corbin Ranch.

Webster Group[1]

Devonian: Southwestern Missouri.

Original reference: E. M. Shepard, 1905, Drury Coll. Bradley Geol. Field Sta. Bull. 1, p. 57.

In Greene County. Derivation of name not stated.

Webster Springs Sandstone (in Bluefield Formation[1] or Group)

Mississippian: Southern West Virginia.

Original reference: D. B. Reger, 1920, West Virginia Geol. Survey Rept. Webster County, p. 214, 227–228.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 255, 264. In Greenbrier County, consists of 10 to 50 feet of shaly grayish-brown sandstone. Overlies Glenray limestone; separated from overlying Reynolds limestone by shale which may be equivalent of Bickett shale of Reger (1926). Mauch Chunk series.

Exposed on north side of Elk River at southeast edge of town of Webster Springs, Webster County.

**Weches Greensand Member** (of Mount Selman Formation)[1]

Weches Formation (in Claiborne Group)

Eocene, middle: Eastern Texas, and northwestern Louisiana.

Original reference: A. C. Ellisor, 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 1339–1346.

H. B. Stenzel, 1939, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 93–114. Rank raised to formation in Claiborne group. Thickness 25 to 45 feet. Subdivided into (ascending) Tyus, Viesca, and Therrill members (all new). Disconformably overlies Queen City sand; disconformably underlies Sparta formation (sand).

C. R. Smith, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2520. In Caddo Parish, La., formation overlies Mytis sand member (new) of Queen City formation; underlies Pleistocene(?) terrace deposits. Thickness about 14 feet.

Well exposed on Crockett Road 1½ miles southwest of Weches, Houston County, Tex.

**Wedington Sandstone Member** (of Fayetteville Shale)[1]

Upper Mississippian: Northern Arkansas and northeastern Oklahoma.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Prof. Paper 24, p. 27.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 65, 66). Shown on correlation chart about middle of Fayetteville shale.

Named for Wedington Mountain, Washington County, Ark.

**Wedowee Formation**[1]

Cambrian to Carboniferous: Eastern Alabama.

Original reference: G. I. Adams, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 36, map.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1379. Here regarded as part of Carolina series, age of which is given as Precambrian.

Named for exposures at and around Wedowee, Randolph County.

Weed Patch Member[1] (of Edwardsville Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 119, 189, 202, 280, 281.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 74; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 1. Included in Allens Creek facies of formation.

Name derived from Weed Patch Hill, 3 miles southeast of Nashville, Brown County.

**Weeks Limestone**[1]

Middle and Upper Cambrian: Western Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 9, 10.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1126, 1141 (fig. 5), 1147, 1166. Weeks formation, originally assigned to Middle Cambrian, contains *Cedaria?* and numerous *Tricrepicephalus* throughout thickness of more than 1,000 feet of strata and is Upper Cambrian (Dresbach) in age. Total thickness 1,940 feet (Walcott gave 1,390); hence, Upper-Middle Cambrian boundary is moved down from horizon given by Walcott. Overlies Marjum limestone (emended).

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 41, 42. Deiss (1938) placed Marjum-Weeks contact at estimated position of Middle-Upper Cambrian boundary. Therefore, as presently defined, these units are regarded invalid. Their present definition is comparable to the Cadiz formation of California and Comet shale in Nevada. Possible that part of lower Weeks may belong to Albertan series.

H. E. Wheeler and Grant Steele, 1951, Utah Geol. Soc. Guidebook 6, p. 30 (table 1), 32 (fig. 5), 34 (fig. 7), 36–37. Middle and Upper Cambrian. In this report, Weeks and Orr formations are described together because their similarity and intergradational character does not appear to justify distinction as separate formation. Total thickness 3,500 feet.

D. K. Powell, 1959, Brigham Young Univ. Research Studies, Geology Ser., v. 6, no. 1, p. 5 (chart), 12–15, geol. map. Weeks formation described and mapped in southern House Range (area of type locality for Weeks). Formation is 1,388-foot thick medium- to dark-gray fine-grained, thin- to thick-bedded argillaceous and arenaceous limestone; becomes more argillaceous toward top; color ranges from reddish brown to dark yellowish orange. Conformably overlies Marjum limestone; conformably underlies Orr formation. Complete section does not crop out in mapped area; much of unit has been intruded by Notch Peak intrusive and a large sill, or is metamorphosed. Albertan-Croxian.

U.S. Geological Survey currently designates the age of the Weeks as Middle and Upper Cambrian.

Type locality: North side Weeks Canyon, north of Orr Ridge, House Range, Millard County. Crops out on western slopes of Notch Peak, in Hansen Canyon, where it is terminated by fault, trends north to Notch Peak Canyon and continues to igneous intrusive.

Weeping Water Limestone Member (of Oread Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, northeastern Kansas, and northwestern Missouri.

Original reference: C. S. Prosser, 1897, Jour. Geology, v. 5, p. 154–172.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 26. Thickness 6 to 10 feet in Nebraska; thins to about 3 feet northwest of Leavenworth, Kans.; may be equivalent to part of Toronto limestone of southern Kansas. Nebraska Geological Survey uses name Weeping Water limestone, and Kansas Geological Survey uses name Toronto.

Type locality: West side North Branch Weeping Water Valley, about 1 mile northwest of Nehawka, Cass County, Nebr.

Weir Formation (in Cabaniss Group)

Weir Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series): Southeastern Kansas, southwestern Missouri, and northwestern Oklahoma.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 18, 20, 22; 1938, Kansas Acad. Sci. Trans., v. 41, p. 193, 195. Cherokee group is divided into 15 cyclic formational units. The Weir, sixth in sequence (ascending), occurs below the Pilot and above the Knifeton. Thickness about 36 feet. Includes a 3-foot coal bed known as Weir-Pittsburg. [For complete sequence see Cherokee group.]

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Shown on northern midcontinent composite stratigraphic section as Weir formation in Cabaniss group. Underlies Tebo formation; overlies Seville formation of Krebs group.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 6. Listed as coal cycle in Boggy formation, in Oklahoma.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 46–48. Formation in Cabaniss subgroup of Cherokee group. In Kansas, includes only Weir-Pittsburg coal and its underclay. Thickness averages about 12 feet in Cherokee and Crawford Counties.

Name derived from Weir-Pittsburg coal which is named for towns of Weir, Cherokee County, and Pittsburg, Crawford County, Kans.

Weisburg Member (of Whitewater Formation)

Ordovician (Richmond): Southwestern Ohio.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 110, 114, chart facing p. 108. Listed on page 110 as member of Whitewater; sequence (ascending) is Weisburg, Saluda, and Oxford. Stratigraphic chart and page 114 shows Whitewater sequence (ascending) as Lower Whitewater, Saluda, and Upper Whitewater.

Type locality and derivation of name not given.

**Weisner Quartzite[1] or Formation[1]**

Lower Cambrian: Northern central and northeastern Alabama and northwestern Georgia.

Original reference: E. A. Smith, 1890, Alabama Geol. Survey Rept. Cahaba coal field, p. 149.

T. L. Kesler, U.S. Geol. Survey Prof. Paper 224, p. 8–10, 30–33, pl. 1. Described in Cartersville district in Georgia where it consists principally of finely micaceous quartzite and, less commonly, beds of metaconglomerate, metasiltstone, and crystalline carbonate rocks; beds do not occur in any uniform stratigraphic order and are exposed in a belt of parallel ridges that trend northward through middle of district. Base of section not exposed, but thickness is more than 1,000 feet, probably more than 2,000 feet. As mapped, includes Pinelog conglomerate. Conformably underlies Shady formation.

Named for fact it forms Weisner Mountain, Cherokee County, Ala.

Weissport Member (of Tully Formation)

Upper Devonian: East-central Pennsylvania.

R. E. Stevenson and W. S. Skinner, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 30, 31, 32. Basal member of formation in Lehighton area. Consists of thin-bedded sandy shale. Thickness about 40 feet. Underlies Brodhead Creek member (new); overlies Moscow formation.

Type section: Roadcut 1.1 miles north of Weissport, Carbon County.

Weitchpec Schists[1]

Paleozoic or older: Northwestern California.

Original reference: O. H. Hershey, 1904, Am. Geologist, v. 33, p. 357.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, pt. 4, p. 686. Age given as Paleozoic or older.

Probably named for exposures near Weitchpec, Humboldt County.

**Welch Formation** (in Pottsville Group)[1]

Lower Pennsylvanian: Southern West Virginia and southwestern Virginia.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44.

Named for exposures at Welch, McDowell County, W. Va.

Welch Sandstone (in New River Group)

Welch Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 198.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 234. Commonly grayish white, medium to coarse grained, and lenticular. Thickness 20 to 45 feet. Occurs below unnamed shale; overlies unnamed shale above Welch coal. Apparently coalesces with Upper Raleigh sandstone. Included in New River group, Pottsville series.

Exposed at Welch, McDowell County.

Welcome Formation

Welcome Member (of Kreyenhagen Formation)

Eocene, upper: Central California.

Martin Van Couvering and H. B. Allen, 1943, California Div. Mines Bull. 118, pt. 3, p. 496–500. Siltstone and claystone 1,200 feet thick. Underlies Wagonwheel formation; overlies Point of Rocks formation.

H. P. Smith, 1956, California Univ. Pub. Geol. Sci., v. 32, no. 2, p. 67, 68 (fig. 2), geol. map. Rank reduced to member of Kreyenhagen formation. Map shows age as Eocene; stratigraphic column shows Eocene or Oligocene.

Occurs in Devils Den oil field district in northwestern Kern County, adjacent to Kings County line, about 40 miles from Paso Robles and about 60 miles northwest of Bakersfield.

**Welden Limestone**[1]

Mississippian: Central southern Oklahoma.

Original reference: C. L. Cooper, 1931, Oklahoma Geol. Survey Bull. 55, map.

C. L. Cooper, 1939, Jour. Paleontology, v. 13, no. 4, p. 381–382. Buff to blue-gray massive argillaceous limestone. Maximum thickness (type locality) 2 feet. Underlies Caney shale; overlies Bushberg-Hannibal strata. Lower Mississippian. Type locality designated.

M. K. Elias, 1956, *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 70 (table 2). In northern Arbuckles underlies Ahlosa member (new) of Caney shale.

Type locality: In railroad cut in sec. 27 , T. 3 N., R. 6 E., a few miles east of Ada, Pontotoc County. Name derived from Welden Creek which crosses outcrop in same section. Outcrops are some 20 miles in length.

Weldonian Stage

Late Cretaceous: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 989–991, 1006. One of six stages, based on foraminiferal assemblages, in Upper Cretaceous column between top of Moreno and base of Panoche, as defined by Anderson and Pack (1915). Surface equivalents are Joaquin Ridge sandstone in Alcalde Hills section. the Forbes, Guinda, and upper part of Funks formation in Putah Creek section, as classified by Kirby (1942). Includes interval between Tracian stage (new), above, and Cachenian stage (new).

Occurs in Great Valley in both surface and subsurface. Exposed along west side of San Joaquin Valley. Well represented in outcrops along Weldon Canyon.

**Welge Sandstone Member** (of Wilberns Formation)

Upper Cambrian: Central Texas.

Frederick Romberg and V. E. Barnes, 1944, Geophysics, v. 9, no. 1, p. 88, fig. 7 (geol. map). Brown sandstone that grades upward into Morgan Creek limestone member; overlies Lion Mountain sandstone member of Cap Mountain formation. Contact sharp. Name credited to Josiah Bridge and V. E. Barnes.

Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 114, pls. 1, 2, 4 (fig. 5). Brown mostly nonglauconitic sandstone. Average thickness 18 feet; at type locality 27 feet; thicker sections are along northern and western sides of Llano uplift. Overlies Lion Mountain sandstone here considered member of Riley formation; contact abrupt.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 155, 187, 225, 253, 310, [1946]. Local stratigraphy described.

Type section: Along Squaw Creek one-half mile north of Gillespie County line. Named from Welge land surveys between Threadgill and Squaw Creeks. Extends throughout Llano uplift.

**Wellborn Sandstone**[1] (in Jackson Group)

Eocene, upper: South-central Texas.

Original reference: W. Kennedy, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 39, 45.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626 (table 1), 2627–2628. In south-central Texas, Wellborn sandstone is considered a formation undivided, and is persistent unit chiefly of sandstone. Overlies Caddell formation; underlies McElroy formation (redefined). Ellisor (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11) applied name Wellborn sands to a member of McElroy formation, overlain by Manning beds and overlying, in east Texas, Wooleys Bluff clays, which she considered basal member of McElroy formation. West of Angelina County, she considered that the Wellborn overlaps Wooleys Bluff and lies directly on the Caddell. Renick (1936, Texas Univ. Bull. 3619) divided Wellborn into three members: Carlos sandstone at top; middle Wellborn, consisting of clay and soft lignitic sandstone; and Bedias sandstone at base. Exposures of Renick's members can be seen in vicinity of Wellborn. These exposures may be considered type locality.

Type locality (Eargle): In vicinity of Wellborn, about 7 miles south-southeast of College Station, Brazos County. On cuesta, one-fourth mile southeast of crossroads at Wellborn, contact of lower 4 feet of Carlos sandstone with brown clay of Renick's middle Wellborn is exposed in roadcuts in front of cemetery; 1¼ miles north of crossroad, cuts on road to College Station expose 5 feet of gray tuffaceous clayey siltstone of middle member grading down into 6 feet of gray silty very fine grained thin-bedded sandstone of Renick's Bedias sandstone; about 250 yards farther north basal 5 feet of Bedias sandstone, containing prints of pelecypods in lower 2 feet, lies on clay of Caddell formation.

Weller Sandstone[1] or horizon[1]

Miocene(?): Northwestern Colorado.

Original reference: O. A. Peterson, 1928, Carnegie Mus. Mem., v. 11, no. 2, p. 90–94.

Exposed at northern flanks of Douglas Mountain, on Weller Ranch, near Gray Stone post office, Moffat County.

Wellersburg Clay (in Conemaugh Formation)[1]

Pennsylvanian: Pennsylvania.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 65, 114, pl. 6.

Named for association with Wellersburg coal, which was named for occurrence at Wellersburg, Somerset County.

Wellersburg Limestone (in Conemaugh Formation[1] or Group)

Pennsylvanian: Southern Pennsylvania and western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, p. 65, 114, pl. 6.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 69 (fig. 4). Wellersburg limestone shown on generalized columnar section for Pennsylvanian of western Pennsylvania. Occurs above Barton (Elk Lick) coal and below Wellersburg coal. Conemaugh group.

Named for association with Wellersburg coal which was named for occurrence at Wellersburg, Somerset County, Pa.

**Wellesley Formation**[1]

Mississippian: Eastern Alaska.

Original reference: A. H. Brooks, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 470–472, 479, 483.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Composes Wellesley Mountain between Tanana and White Rivers.

**Wellington Formation** (in Sumner Group)[1]

Permian: Central and southern Kansas and northern Oklahoma.

Original reference: F. W. Cragin, 1885, Washburn Coll. Lab. Nat. History Bull., v. 1, no. 3, p. 85–86; Kansas City Review, 8, p. 678–682.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 3–17. Subdivided to include (ascending) Pearl shale, Hollenberg limestone, Geuda Springs shale (new), Annelly gypsum (new), Chisholm Creek shale (new), Carlton limestone, Highland shale (new), Slate Creek limestone (new), and Afton limestone (new) members.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1755–1758, 1762–1763 (fig. 2), 1764–1765 (fig. 3). Includes Milan limestone member (new) at top. Underlies Ninnescah shale (new) ; Big Blue series.

G. O. Raasch, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 2, pt. 2, p. 1928. Wellington in Oklahoma is limited to north-central section of State; southward it passes into Stillwater redbed complex. Thickness 820 feet. Subdivided into basal sequence, 18 feet; anhydrite sequence, 190 feet; Otoe redbed member (new), 115 feet; Midco (lacustrine) member (new), 255 feet; Billings member (new), 52 feet; Antelope Flats member (new), 195 feet. Upper 372 feet is continuously exposed and includes many key beds. Overlies Herington limestone; underlies Garber redbed complex.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 40–41. Basal formation of Sumner group. Thickness about 700 feet. Includes Milan limestone member at top; Hutchinson salt member in middle part but not exposed; Carlton limestone member below Hutchinson; Hollenburg limestone member near base. Underlies Ninnescah shale; overlies Herington limestone member of Nolans limestone.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, includes Fallis sandstone member in upper part.

Named for exposures at Wellington, Sumner County, Kans.

†Wells Chert[1]

Lower Ordovician (Beekmantown): North-central Tennessee.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, no. 3, p. 671, pl. 27.

E. O. Ulrich and G. A. Cooper, 1938, Geol. Soc. America Spec. Paper 13, p. 26. Upper Canadian (approximately Cotter).

In Wells Creek basin, Stewart and Houston Counties.

**Wells Formation[1]**

Pennsylvanian and Permian: Eastern Idaho, Montana, northeastern Utah, and southwestern Wyoming.

Original reference: R. W. Richards and G. R. Mansfield, 1912, Jour. Geology, v. 20, p. 683, 684, 689–693.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 24–25, pl. 6. Described in Randolph quadrangle, Utah-Wyoming, where it is about 1,000 feet thick; overlies Brazer limestone and underlies Phosphoria formation. Pennsylvanian.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2842. In southeastern Idaho and western Wyoming, upper siliceous limestone of Wells formation as used by Mansfield (1927, U.S. Geol. Survey Prof. Paper 153) is designated as lower tongue of Park City formation; the name Wells is thus restricted to underlying sandstones, redbeds, and carbonate rocks of Pennsylvanian age.

E. R. Cressman, 1957, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–118. Mapped in Snowdrift Mountain quadrangle, Caribou County, Idaho, where it overlies Brazer limestone and underlies Phosphoria formation. Consists of upper member, 1,000 to 1,300 feet thick, that contains 100-foot-thick cherty limestone tongue of Park City formation and lower member approximately 500 feet thick.

V. E. McKelvey and others, 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 15, 36 (footnote). Name Wells formation is retained for rocks in western Wyoming, eastern Idaho, and northern Utah, but is restricted to carbonate rock sandstone, sandstone, and red beds that lie below upper carbonate rock beds that are reassigned to newly named Grandeur member of Park City formation. Pennsylvanian and Permian.

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Suggested that Oquirrh formation be raised to group status and carried into Wells formation area and that the Wells be dropped or retained as formation within group.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). In Sublett Mountains, comprises (ascending) Calder Creek, Heglar Canyon, Sublett, and Indian Fork members (all new). Occurs above Milligen formation and below Grandeur member of Park City. Pennsylvanian-Permian (Springeran-Leonardian).

Name derived from Wells Canyon, in T. 10 S., R. 45 E., Bannock County, Idaho.

†Wells Limestone[1]

Middle Ordovician (Lowville): North-central Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 557, 705.

Named for Wells Creek Basin, Stewart and Houston Counties.

**Wellsburg Sandstone Member** (of Chemung Formation)[1]

Wellsburg Formation (in Chemung Group)

Upper Devonian: Central and west-central New York and northeastern Pennsylvania.

Original references: H. S. Williams, 1906, Science, new ser., v. 24, p. 365–372; 1907, Am. Assoc. Adv. Sci. Proc., v. 56, p. 265–267.

Bradford Willard, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 15 (table 4), 247. Chemung group in south-central New York and adjacent Pennsylvania consists of Cayuta formation and Wellsburg formation. Wellsburg consists of thin-bedded sandstone and shale to flaggy sandstone and coquinite lenses. Fall Creek conglomerate locally at top.

Named for outcrop at Wellsburg, Chemung County, N.Y.

**Wells Creek Dolomite**

Wells Creek Limestone[1]

Lower Ordovician: Central Tennessee and southwestern Kentucky.

Original reference: R. G. Lusk, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, no. 9, p. 908.

Ray Bentall and J. B. Collins, 1945, Tennessee Div. Geology Oil and Gas Inv. Prelim. Chart 4, sheet 1. Wells Creek dolomite is here applied to 432 feet of tan to gray-green silty to sandy argillaceous fine-grained dolomite interbedded with dark-brown to tan dense limestone occurring below Murfreesboro limestone and above rocks of Beekmantown age in Ada Belle Oil Co., Hillman No. 2–A (21–E–18E), Trigg County, Ky. Dolomite thins toward the south and east, is erratic in occurrence in easternmost part of area, and in places is absent. Where 30 to 70 feet thick it is very argillaceous silty and sandy fine-grained dolomite interbedded with thin green shales. These rocks are here considered to be Chazy(?), in age. Name was originally used by Lusk to designate about 350 feet of rocks in this stratigraphic position and said by him to be exposed only in Wells Creek basin in southeastern Stewart County, Tenn.

First mentioned in Stewart and Houston Counties, Tenn.

Wellsville Formation (in Chadakoin Group)

Wellsville Formation (in Conneaut Group)

Wellsville Member (of Chadakoin Formation)

Upper Devonian: Southwestern New York.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 17 (fig. 4), 31–33. Consists of thin sandstones or siltstone, ½ to 3 inches thick, interbedded with shales, for the greater part argillaceous but sometimes arenaceous; commonly olive green and gray. Thickness about 200 feet. Basal formation of Conneaut group; underlies Hinsdale formation; overlies Cuba formation.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 18. Rank reduced to member status in Chadakoin formation. Underlies Hinsdale member; overlies Cuba member of Canadaway formation.

L. V. Rickard, 1957, New York State Geol. Assoc. [Guidebook] 29th Ann. Mtg., p. 17 (table 2), 19. A formation in Chadakoin group. Inasmuch as Upper Devonian strata are still not thoroughly understood a more or less permanent classification satisfactory to a majority of workers may not be obtained for some time.

Well exposed near town of Wellsville but also present in nearly every locality of Wellsville quadrangle, Allegany County. [Tesmer and Rickard state that type locality is near Wellsville.]

Wemir Agglomerate

Miocene: Panamá Canal Zone.

[T. F. Thompson], 1943, Panama Canal Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 5, p. 37, figs. 5–54. Agglomerate is finer in texture than typical basaltic agglomerates in Pacific area; well bedded, with strata ranging from a few inches to several feet in thickness; commonly contains beds of soft shale of soapy fine-grained texture; contains water-sorted fragments and is believed to be phase of more massive land-laid deposits commonly present elsewhere. Age not stated.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 349. Now included in Pedro Miguel agglomerate member of Panamá formation. Miocene.

Occurs in West Miraflores Hill area.

**Wenas Basalt[1] Member** (of Yakima Basalt)

Pliocene, lower: Central Washington.

Original reference: G. O. Smith, 1903, U.S. Geol. Survey Prof. Paper 19; 1903, U.S. Geol. Survey Geol. Atlas, Folio 86.

R. C. Treasher, 1937, Geol. Soc. Oregon Country News Letter, v. 3, no. 20, p. 218–220. Underlies Snipes conglomerates (new).

A. C. Waters, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 671, 673, pl. 1. Described in Yakima East quadrangle as basalt flow interstratified in Ellensburg formation. Basalt is about 100 feet thick where it enters quadrangle, but thins rapidly to the east and ends about halfway across the quadrangle. Where lower sediments of Ellensburg are cut out, the Wenas basalt rests directly on Yakima flows; stratigraphically below Selah Butte flow (new). Map shows basalt flows in the Ellensburg as Miocene and Pliocene.

Type locality: Valley of Wenas Creek, Ellensburg region.

**Wendell Grade Basalt**[1]

Recent: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho, compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 29 (table), 84, pl. 4. Overlies Malad basalt and Hagerman lake beds. Thickness about 25 feet.

U.S. Geological Survey currently designates the age of the Wendell Grade Basalt as Recent on the basis of a study now in progress.

Type locality: Wendell grade in road in Gooding County, from which it takes its name. Northwest of town of Wendell.

Wendover Group

Pennsylvanian: Eastern Wyoming, northeastern Colorado, and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 3, 5, 22 (fig. 7), 23–24, 28 (fig. 10), 30, 45. Consists of limestones interbedded with sandstones, mudstones, and shales. At the base is a sandstone which probably marks an unconformity. Comprises upper part of Division II of Hartville "formation" (Condra and Reed, 1935, Nebraska Geol. Survey Paper 9). Thickness 104 feet. Underlies Broom Creek beds (new); overlies Meek group (new).

Type locality: Platte River valley in vicinity of Wendover, Platte County, Wyo.

**Weno Clay or Limestone** (in Washita Group)

Weno Clay Member (of Denison Formation)[1]

Weno Limestone Member (of Georgetown Limestone)

Weno Marly Limestone Member (of Denison Formation)

Lower Cretaceous (Comanche Series): Northeastern and central Texas and central southern Oklahoma.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 121, 247, 269–280.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Chart shows Weno limestone in Washita group. Occurs below Pawpaw formation and above Denton clay. [Denison formation abandoned.] Lower Cretaceous.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 27–28, table 4. Foraminifera of Weno formation described.

W. J. Fox and O. N. Hopkins, Jr., 1960, Baylor Geol. Soc. Guidebook 5th Field Trip, p. 88, 92. In central Texas, considered member of Georgetown limestone. Overlies Denton shale member; underlies Pawpaw shale member. Thickness 40 feet in McLennan County.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 31 (fig. 12), 32, 33 (fig. 13). Referred to as Weno marly limestone member of Denison formation. In Fort Worth area, consists largely of gray marl with several thick limestone beds in its uppermost and lowermost parts. Thickness about 50 feet. Overlies Denton marl member; underlies Pawpaw shale member.

Named for Weno, Grayson County, Tex.

†Weno Subgroup[1] (of Denison Beds)

Lower Cretaceous (Comanche Series): Northeastern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 121, 247, 269–280.

Named for Weno, Grayson County.

**Wenonah Formation** (in Matawan Group)

Wenonah Member (of Matawan Formation)

Wenonah Sand (in Matawan Group)[1]

Upper Cretaceous: New Jersey and Delaware.

Original reference: G. N. Knapp, as reported by R. D. Salisbury, 1899, New Jersey Geol. Survey Ann. Rept. State Geologist, 1898, p. 35, 36.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 32–36. Member of Matawan which is here reduced to formational rank. Conformably overlies Marshalltown member and underlies Mount Laurel member, both contacts conformable. Marine in origin and consists of fine micaceous sparingly glauconitic sand locally laminated with thin layers of clay. Thickness about 40 feet in Monmouth County, but thins to the south where it cannot be differentiated from overlying Mount Laurel. Can be followed in outcrop from Atlantic Highlands into Delaware where it is exposed in cuts of Chesapeake and Delaware Canal.

J. J. Groot, 1954, Delaware Geol. Survey Bull. 3, p. 25–26. Considered of formational rank in Matawan group. Where exposed in Chesapeake and Delaware Canal conformably overlies Merchantville and is gradational into it.

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184, B185. Formation in Matawan group. Overlies Marshalltown formation; underlies Mount Laurel sand of Monmouth group. Average dip SE. 35 feet per mile.

Named for occurrence at Wenonah, Gloucester County, N.J.

**Wepo Formation** (in Mesaverde Group)

Upper Cretaceous: Northeastern Arizona.

G. A. Kiersch, 1955, Mineral Resources Navajo-Hopi Indian Reservations, Arizona-Utah, v. 2: Tuscon, Ariz., Univ. Arizona Press, p. 4 (fig. 1). Includes widespread coal beds. Subdivided into lower, middle, and upper members. Overlies Toreva formation (new); underlies Yale Point sandstone (new). Name credited to Repenning and Page.

C. A. Repenning and H. G. Page, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 271, 277–279. Comprises thick series of intercalated siltstone, mudstone, sandstone, and coal. Siltstone and mudstone units vary from dark olive gray through light olive brown to medium light gray. Carbonaceous in many places, and contains sandy zones and sandstone lenses throughout area. Commonly thin and flat bedded. Above Wepo Wash at type section are 142 feet of cliff-forming

Toreva formation and 656 feet of slope- and ledge-forming Wepo formation, including upper tongue of Toreva, which occupies interval from 67 to 134 feet above base of Wepo. Thins northeast across Black Mesa as result of tonguing in that direction into underlying Toreva formation and into overlying Yale Point sandstone. Thickness of entire formation observable only in northern half of area, where formation ranges in thickness from 743 feet east of Cow Springs to 318 feet near Rough Rock. Type section, therefore, represents nearly maximum thickness of formation, if thickness of upper tongue of Toreva formation is included.

Type section: Seven miles northeast of town of Pinon on west side of Wepo Wash where entire Mesaverde group of Black Mesa is exposed. Wepo Wash is an ephemeral stream that runs in southwesterly direction across central part of Black Mesa and joins Polacca Wash between First and Second Mesas in Hopi villages area.

**Werner Formation**

Jurassic(?): Subsurface in southern Arkansas, northern Louisiana, and eastern Texas.

R. T. Hazzard, W. C. Spooner, and B. W. Blanpied, [1947], Shreveport Geol. Soc. 1945 Ref. Rept., v. 2, p. 483, 484, 486–487. In type well, consists of an anhydrite member 57 feet thick overlying a red bed and conglomerate member 55 feet thick. Total thickness of red bed member is as much as 110 feet. In type well, the conglomerate is in contact with folded Paleozoic rocks. In some wells, the Werner is in contact with Morehouse formation; in other wells it is inferred that the Werner is in contact with the Eagle Mills. Appears to be conformable with overlying Louann salt. Term "Louann tongue," as formerly used, is synonymous with Werner formation of this report. Permian.

F. M. Swain, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 7, p. 1207. Eagle Mills of this report includes (ascending) Werner formation, Louann salt, and Norphlet formation of Hazzard, Spooner, and Blanpied, who believe that type Eagle Mills is older than their Werner. Eagle Mills, including the salt, is assigned to Upper Jurassic; if the salt is Permian, an explanation of how it escaped extensive solution throughout Triassic time should be provided.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map I–175. Age shown as Jurassic. Position of lower boundary of Jurassic system is believed by some geologists to be above Louann and Werner formations, but by others to be beneath them, at top of Eagle Mills (restricted). Because Louann and Werner formations consist of unfossiliferous deposits of salt, anhydrite, and red beds, and because these formations have not been penetrated very far downdip, problem remains controversial. Base of Jurassic system is herein assumed to be at contact of Werner and Eagle Mills (restricted) formations.

Type well: Gulf Refining Co.'s No. 49 L Werner Saw Mill Co. well located in Louann district, Union County, Ark.

Weskan Shale Member (of Pierre Shale)[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 23. Consists of gray clayey shale; bentonite beds in lower part. Thickness 170 feet. Overlies Sharon Springs shale member; underlies Lake Creek shale member.

Type locality: Five miles north of town of Weskan, Wallace County.

**Weskeag Quartzite Member** (of Rockland Formation)[1]

Cambrian or Ordovician: South-central Maine.

Original reference: E. S. Bastin, 1908, U.S. Geol. Survey Geol. Atlas, Folio 158, p. 3–4.

H. W. Allen, 1951, Maine State Geologist Rept., 1949–1950, p. 79–80. Sequence of metamorphosed sedimentary rocks in Rockland quadrangle, Knox County, is (ascending) Isleboro formation, containing Coombs limestone member at top; Battie quartzite; Penobscot formation; and Rockland formation consisting of Weskeag quartzite member at base, siliceous limestone member above the quartzite, and Rockport limestone member at top.

Named for exposures on Weskeag River, Knox County.

Wesley Formation (in Jackfork Group)

Upper Mississippian: Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 857, 886–889. Proposed for uppermost formation in group. Consists of massive siliceous shale 100 to 500 feet thick. Underlies Union Valley sandstone; overlies Markham Mill formation (new); along Choctaw fault zone, shale of Wesley age is in normal contact with Caney shale of Chester age. Wesley shale is a correlative of most of the shale heretofore called "Pennsylvanian Caney," which in Arbuckle Mountains occurs between Union Valley sandstone and Chester Caney shale, and in Ardmore basin occurs between Rod Club sandstone and Chester Caney shale. Since this shale attains great thickness in Ardmore basin and is important lithologic and paleontologic unit of widespread distribution in Midcontinent, the name Wesley shale is proposed for it. Pushmataha series.

B. H. Harlton, 1959, *in* The geology of the Ouachita Mountains, a symposium: Dallas, Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 131 (fig. 1), 135. Underlies Game Refuge formation (new); overlies Markham Mill formation.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 43 (table 3), 55–57, pls. Described in Ouachita Mountains. Late Mississippian.

Type locality: Southwest of village of Wesley in E½SE¼NW¼ sec. 20, T. 1 N., R. 13 E., Atoka County.

Wesson Tongue (of Dorcheat Member of Schuler Formation)

Upper Jurassic: Subsurface in southern Arkansas, northern Louisiana, and eastern Texas.

F. M. Swain, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 5, p. 608–609. Dark-gray glauconitic fossiliferous shale near top of nearshore facies of Dorcheat member. Occurs between depths of 5,710 feet and 5,872 feet in type well.

Type well: Standard Oil Co. of Louisiana's D. A. Zimmerman No. 1, SE¼ SE¼ sec. 29, T. 18 S., R. 16 W., Union County, Ark.; Wildcat, Wesson area.

West Arm Formation (in Deese Group)

Pennsylvanian (Des Moines Series): Central southern Oklahoma.

C. W. Tomlinson and William McBee, Jr.. 1959, *in* Petroleum geology of southern Oklahoma, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 33. West Arm formation comprises upper part of Deese group. Includes Williams member at base and Natsy member near middle. Also includes upper members of Warren Ranch conglomerate facies (new). Name credited to B. H. Harlton (in preparation).

B. H. Harlton, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 213 (fig. 3), 220–221. Thickness approximately 900 feet. Includes Natsy member about 450 feet below top and Williams member at base. Underlies Confederate limestone of Hoxbar group. Type locality stated. Subsurface relationships discussed.

Type locality: West Arm of Lake Murray along west branch of Anadarche Creek, southeast of Ardmore, secs. 9, 16, 17, and 21, T. 5 S., R. 2 E., Carter County.

West Baden[1] Group

Mississippian, Chester Series): Indiana, Illinois, and Kentucky.

Original reference: E. R. Cumings, 1922, Indiana Dept. Conserv., Pub. 21, pt. 4, p. 514 (footnote).

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 44–48, pl. 1. Cumings (1922) suggested West Baden as group name to include (ascending) formations now known as Paoli limestone, Bethel formation, Beaver Bend limestone, Sample formation, Reelsville limestone, Elwren formation, and Beech Creek limestone. Name had little usage. Proposed here to revive Cuming's name West Baden and redefine it as comprising (ascending) Bethel formation, Beaver Bend limestone, Sample formation, Reelsville limestone, and Elwren formation. Thickness 105 to 135 feet. Overlies Blue River group (new); underlies Stephensport group (redefined).

Named for town of West Baden, Orange County, Ind.

West Bath Slate[1]

Pre-Silurian: Northwest New Hampshire.

Original reference: M. Billings, 1933, Am. Jour. Sci., 5th, v. 25, no. 146, p. 149.

In Littleton and Moosilauke quadrangles, Ammonoosuc River region. Village of West Bath is in Woodsville quadrangle.

**Westboro Quartzite**[1] (in Blackstone Series)

Precambrian(?): Eastern Massachusetts and northern Rhode Island.

Original reference: B. K. Emerson and J. H. Perry, 1903, Geology of Worcester, map.

Alonzo Quinn, R. G. Ray, and W. L. Seymour, 1948, *in* Alonzo Quinn and others, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 3, p. 10–11, geol. map; A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Described in Pawtucket quadrangle, Rhode Island-Massachusetts, as light-buff to white massive quartzite, locally with thin beds of quartz-mica schist. Also includes Albion schist member. Thickness 1,000 to 3,000 feet. Underlies Sneech Pond schist (new) with gradational contact; overlies Mussey

Brook schist (new). Assigned to Blackstone series of Precambrian(?) age.

Named for town of Westboro, Worcester County, Mass.

**West Branch Shale Member** (of Janesville Shale)

West Branch Shale[1] (in Admire Shale or Group)

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 74, 82, 89, 111, 113.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Reallocated to member status in Janesville shale (new). Underlies Five Point limestone member; overlies Falls City limestone. Wolfcamp series.

M. R. Mudge and H. R. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 14 (table 2), 48–49. Thickness about 27 feet in Wabaunsee County, Kans. Underlies Five Point limestone member; overlies Falls City limestone.

Named for exposures in West Branch Township, Pawnee County, Nebr.

**Westbrook Granite**[1]

Pre-Carboniferous(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, U.S. Geol. Survey Prof. Paper, 108, p. 175.

Named for exposures in Westbrook Township, Cumberland County.

West Brook Member[1] (of Tully Formation)

Middle Devonian: Central New York.

Original reference: G. A. Cooper and J. S. Williams, 1935, Geol. Soc. America Bull., v. 46, p. 790–813.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53. no. 12, pt. 1, p. 1787–1788, chart 4. Seems best to regard Tully as Middle Devonian, and to make a stage, the Taghanic, to include it and its correlates and overlying Geneseo.

R. E. Etevenson and W. S. Skinner, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 29–33. Type Tully section consists of following members: Tinkers Falls, Apulia, and West Brook.

Type locality: On West Brook, 3 miles south of Sherburne, Chenango County.

West Canyon Limestone Member (of Oquirrh Formation)

Pennsylvanian: Northern Utah.

P. W. Nygreen, 1958, Utah Geol. and Mineralog. Survey Bull. 61, p. 13–14. Proposed for basal limestone part of formation. Chiefly bioclastic limestones with some interbedded sandstone or siltstone and lesser amounts of chert. Limestones are calcarenites and calcilutites, medium blue gray, thin to thick bedded, and blocky to slabby weathering. Many limestone units cherty or silicified. Some units reflect conditions of probably cyclic sedimentation. Sandstones are quartzose, very fine grained, silty, calcareous cement, and olive brown. Thickness 1,456 feet in type section; 510 feet in Sardine Canyon section, near Logan. Conformably(?) underlies "sandy" part of formation and conformably(?) overlies Manning Canyon formation.

Type section: On divide between Threemile Canyon and Fourmile Canyon, tributaries to drainage of West Canyon. in E½ sec. 23, W½ sec. 24, T. 5 S., R. 3 W., Utah County. Named for excellent exposures along northeast side of West Canyon 6 to 9 miles north of Cedar Fort, Utah, and northwest of town along base of ridge.

West Castleton Formation or Group.

Lower Cambrian: Eastern New York and west-central Vermont.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 2. Consists largely of gray siltstone and black fissile slate, with rare beds of quartzite, pebble conglomerate, and rusty-weathering dolostone; near base of unit is black limestone, Beebe limestone, which is massive but discontinuous. Overlies Castleton member (new) of Bull formation; major unconformity probably separates West Castleton from Poultney River group (new). This conclusion is based on overlap relations as well as gaps in the stratigraphy. Thickness not determined; entire sequence has undergone intense deformation. Formation was called Hooker by Keith (1932), Schodack by Ruedemann (1914), Kaiser (1945) and Fowler (1950).

George Theokritoff, 1959, New England Intercollegiate Geol. Soc. Guidebook 51st Ann. Mtg., p. 53, 55. Described in Washington County, N.Y., where it overlies Mettawee slate member of Bull formation and locally Bomoseen grit member, and underlies Hatch Hill formation (new).

J. G. Elam, 1960, Dissert. Abs., v. 21, no. 6, p. 1523–1524. Discussion of Troy South and East Greenbush quadrangles, New York. Stratigraphic section subdivided into four groups and previously described dominant formational names have been elevated to group status. Groups are Bull (Lower Cambrian), West Castleton (upper Lower Cambrian-Upper Cambrian), Poultney (Lower Ordovician), and Normanskill (Middle Ordovician).

Westchester Gneisses and Granites[1]

Precambrian: Southeastern New York and northern New Jersey.

Original reference: F. J. H. Merrill, 1901, Geologic map of New York.

Probably named for Westchester County, N.Y.

**West Cove Member** (of Little Sitkin Dacite)

Quaternary: Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 182–183, pl. 23. Consists of two aa flows (crater flow and cove flow). Rocks of both flows are black glassy dacite containing abundant small plagioclase phenocrysts and shown by analyses to be low in silica for dacite. Flows nearly contemporaneous and were extruded about 50 years ago. Cove flow overlies Williwaw Cove formation (new); crater flow overlies low-silica dacite of Little Sitkin dacite.

Type locality: Along coast on north side of West Cove, Little Sitkin Island, in Rat Island group of Aleutian Islands. Crater flow on south slope of Little Sitkin volcano; cove flow at West cove.

West Dummerston Granite[1]

Devonian: Southeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Quarried at village of West Dummerston, Dummerston Township, Brattleboro quadrangle, Windham County.

**West Elk Breccia**[1]

Miocene(?): Western central Colorado.

Original reference: W. Cross, 1894, U.S. Geol. Survey Geol. Atlas, Folio 9.

Forms West Elk Mountains and extends south to Gunnison River, in Anthracite-Crested Butte region.

**West End Rhyolite**[1]

Tertiary: Central Nevada.

Original references: J. E. Spurr, 1911, Min. and Sci. Press, v. 102, p. 560–561; 1911, Report on geology of property of Montana-Tonopah Mining Co., Tonopah, Nev., published privately; 1915, Econ. Geology, v. 10, p. 713–769.

Well exposed in Tonopah Extension and West End mines, Tonopah district.

**Westerly Granite**[1]

Pennsylvanian or younger: Southwestern Rhode Island and southeastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 136, 152, 154.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Pre-Triassic.

G. E. Moore, Jr., 1959, U.S. Geol. Survey Geol. Quad. Map GQ–117. Described and mapped in Carolina and Quonochontaug quadrangles. Intrudes Blackstone series, Hope Valley alaskite gneiss, and Narragansett Pier granite. Lead-alpha age determinations of zircon and monazite from Westerly are 243 and 220 million years. Map bracket shows Pennsylvanian or younger.

Quarried at Westerly, R.I.

Western Cascade series

Eocene to Miocene: California and Oregon.

Eugene Callaghan, 1933, Am. Geophysical Union Trans., p. 243–249. Discussion of volcanic sequence in Cascade Range in Oregon. Cascade Range south of Mount Hood is divided into two parts, Western Cascades and High Cascades on basis of pronounced unconformity in stratigraphic sequence of lavas. Older series [Western Cascades] is divided into two groups on basis of dominant rock-type and associated structural features. One of these is characterized by black lavas with associated red agglomerates, tuffs, and rhyolites; the other of irregular flows of dominantly andesitic lavas with rhyolite and abundant andesitic and rhyolitic pyroclastic rocks in most places. The black lavas occur in two separate areas along western margin of range—one in southern Oregon in Rogue River valley area and the other along Willamette Valley. In southern Oregon, they rest upon an arkosic formation of Eocene age. Along Willamette Valley, they rest upon Oligocene. Gray andesitic series occupies remainder of Western Cascades from Rogue River north toward the Columbia. In vicinity of Rogue River, they appear to interfinger with the black lavas and farther north they are stratigraphically higher.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 20–32, pls. 1, 2. Most of Macdoel quadrangle is occupied by volcanic materials. These belong to two series, first Western Cascade series, ranging in age from Eocene to Miocene, and second, High Cascade series of Pliocene, Pleistocene, and Recent age. Older series covers most of western half of quadrangle and consists mainly of andesitic lavas, with subordinate flows of basalt and dacite, beds of rhyolite tuff, and a few domical protrusions of rhyolitic lava. At close of the Miocene, this older series was gently tilted to east and northeast and was cut by faults that border long narrow horsts trending slightly west of north. At the same time, ancestral Cascade Range was formed by regional uplift. Subsequently, a north-trending chain of volcanoes was built along crest of range; their products form High Cascade series. Width of the belt of Western Cascade series in Oregon ranges generally from 30 to 40 miles. Southward the belt becomes narrower. Along California-Oregon line, width is about 24 miles; 18 miles in southern part of Macdoel quadrangle; 3 miles south of Weed. Belt comes to end owing to overlap by lavas discharged from Mount Shasta. In Oregon, Western Cascade series corresponds with Clarno, John Day, Columbia River basalt, Mascall, and Payette formations; in northeastern California, part of series is equivalent to Cedarville beds of Warner Range. Because of overlap by flows of High Cascade volcanoes, Western Cascade series is nowhere exposed in full thickness. About 12,000 to 15,000 feet along Oregon-California boundary; about 10,000 feet in latitude of Yreka.

**Westerville Limestone Member** (of Cherryvale Formation)

Pennsylvanian: Western Maryland, western Pennsylvania, and western West Virginia.

Original reference: I. C. White, 1882, The Virginias, v. 3, p. 141–143.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 73, fig. 21. In Fayette County, Westernport sandstone lies between Upper and Lower Kittanning coals; commonly divided into two parts by Johnstown limestone and Middle Kittanning coal; in vicinity of Normalville and Whites Bridge, the parts coalesce and cut out intervening limestone and coal. Thickness 30 to 60 feet. Included in Allegheny group.

Forms cliffs along Potomac west of Westernport, Allegany County, Md.

**Westerville Limestone Member** (of Cherryvale Formation)

Westerville Limestone (in Kansas City Group)

Westerville Limestone Member (of Kansas City Formation)[1]

Westerville Limestone Member (of Sarpy Formation)

Pennsylvanian (Missouri Series): Southwestern Iowa, northeastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: H. F. Bain, 1898, Am. Jour. Sci., 4th, v. 5. p. 437–439.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 45 (fig. 8), 100–101. Westerville limestone included in Kansas City group. Underlies Quivira shale; overlies Wea shale.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2030, 2031 (fig. 4). Rank reduced to member status in Cherryvale formation. Underlies Quivira shale member; overlies Wea shale member. This is classification agreed upon by State Geological Surveys of

Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947. Clair (1943, Missouri Geol. Survey and Water Resources, 3d ser., v. 27) included the Westerville in Cherryvale shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 37–38. In Nebraska classified as uppermost member of Sarpy formation (new). Overlies Wea shale member.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 421. In section near Winterset, Iowa, Westerville member of Cherryvale is about 62 feet thick; underlies Quivira shale member; overlies Wea-Fontana shale members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Formation in Kansas City group. Thickness about 2 feet in Madison County; 10 feet in Pottawattamie County. Underlies Quivira shale; overlies Cherryvale shale.

Named for exposures at Westerville, Decatur County, Iowa.

West Fairview Member (of Martinsburg Shale)

Ordovician: South-central Pennsylvania.

Bradford Willard and A. B. Cleaves, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–8, p. 5, 6. Name proposed for principal body of massive usually weak sandstone with calcareous cement in Martinsburg shale in Harrisburg area.

Named for village of West Fairview, Cumberland County, near which unit forms prominent hill.

**West Falls Formation**

Upper Devonian: Western and west-central New York.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Map OC–55. Includes all rocks between top of Cashaqua shale and base of Pipe Creek shale member of Hanover shale. Thickness 415 feet in western Erie County and at type exposure; thickens eastward; 925 feet in Letchworth Park along western boundary of Livingston County and 1,170 feet in eastern Steuben County. Comprises (ascending) Rhinestreet shale, Hatch shale, Grimes siltstone, Gardeau shale, West Hill, and Nunda sandstone members; all members not present in every area. In Naples-Hammondsport area, underlies Wiscoy sandstone. Rocks of formation comprise thin wedge of Upper Devonian deltaic deposits of black mud, gray mud, and silt.

Wallace de Witt, Jr., 1956, U.S. Geol. Survey Geol. Quad. Map GQ–97. Described in Eden quadrangle where it is about 415 feet thick and composed of two members: Rhinestreet shale below and Angola shale above. Overlies Cashaqua shale and underlies Pipe Creek member of Hanover shale.

Wallace de Witt, Jr., 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1933, 1935 (fig. 2). Underlies Pipe Creek shale reallocated to member status in Java formation (new).

Type exposure: Along Cazenovia Creek in vicinity of West Falls and East Aurora, central Erie County.

Westfield phase (of Otis Limestone)[1]

Middle Devonian: Central eastern Iowa.

Original reference: W. H. Norton, 1921, Iowa Geol. Survey, v. 27, p. 377.

Occurs at Westfield Bridge at Fayette, Fayette County and southeast of Waverly, Bremer County.

Westfield Serpentine[1]

Ordovician: Western Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 92.

Crops out in western edge of Westfield, Hampden County.

Westfield Shale[1] (in Canadaway Group)

Westfield Shale Member (of Canadaway Formation)

Upper Devonian: Western New York.

Original reference: G. H. Chadwick, 1923, Geol. Soc. America Bull., v. 34, p. 69.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 32; 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 18. Member of Canadaway formation. Overlies Laona siltstone member; underlies Shumla siltstone member. Thickness 120 to 150 feet.

Probably named for exposures at or near Westfield, Chautauqua County.

Westford Schist

Precambrian: Northwestern Vermont.

E. C. Jacobs, [1937], Vermont State Geologist 20th Rept., p. 57, 117–118. Gray fine-grained thinly foliated schist. Interbedded with metamorphic rocks of Green Mountain series.

E. C. Jacobs, [1939], Vermont State Geologist 21st Rept., p. 33–35. Age designated. Derivation of name given; exposures described.

Named for occurrence in Westford Township, Chittenden County. Exposures include those in Lamoille River Gorge at Fairfax Falls and small gorge of Browns River in Jericho where eastern border of outcrop area is exposed.

**West Fork Formation**[1]

Upper Devonian or Mississippian: Northern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 475.

Crosses Chandalar River valley in belt 15 miles wide from below Granite Creek to above West Fork of Chandalar River, in Wiseman-Chandalar region.

**West Franklin Limestone**[1]

West Franklin Limestone Member (of Modesto Formation)

Upper Pennsylvanian: Southwestern Indiana and southern Illinois.

Original references: Leo Lesquereux, 1862, *in* Rept. of Geol. Reconn. of Indiana, p. 294, 297; J. Collett, 1884, Indiana Dept. Geology and Nat. History 13th Ann. Rept., p. 61–62.

C. A. Malott, 1947, Indiana Acad. Sci. Proc., v. 57, p. 126 (fig. 1), 128. In Dicksburg Hills area, where only upper part of formation is exposed, underlies Ditney formation.

C. E. Wier, 1951, U.S. Geol. Survey Coal Inv. Map C–9. In Greene and Sullivan Counties, underlies Shelburn formation (restricted).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1). Member of Modesto formation (new) in southeastern

Illinois. Complex member which may include Piasa limestone, DeGraff, Pond Creek, and Lake Creek coal members in part of area. Type locality noted.

Type locality: South-central part sec. 24, T. 7 S.,R. 12 W., Posey County, Ind. Named for exposures at West Franklin.

West Gull jasper facies (of Ogishke Conglomerate)

Precambrian (Knife Lake Series) : Northeastern Minnesota.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1034, 1035. Characterized (at type locality) by closely spaced red jasper pebbles and cobbles. Thickness about 1,700 feet. Underlies Zeta Lake conglomerate or granite porphyry facies; overlies Peebles granite facies.

Type locality: On West Gull Lake, a few miles northeast of Ogishkemuncie Lake, in Vermilion district.

Westheimer Member (of Hoxbar Formation)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 15.

Well exposed on property of Westheimer & Daube, in NW¼SE¼ sec. 7, T. 6 S., R. 2 E, and about 200 yards east of asphalt prospect belonging to that firm, in Carter County.

**West Hill Member** (of West Falls Formation)

West Hill Formation[1]

Upper Devonian: West-central New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 23.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Map OC–55. Name West Hill flags proposed by Clarke (1903) and applied by Clarke and Luther (1904 New York State Mus. Bull. 63) to sequence of siltstones and shales overlying the Grimes and underlying the Nunda in vicinity of West Hill. Measured sections for present report show that in Naples area rocks for 300 to 400 feet above Grimes member are similar in lithology to upper part of Gardeau member in Genesee Gorge. Therefore, these rocks in Naples area are herein included in Gardeau. West Hill member of West Falls formation (new) as used in this report applies only to those rocks higher in stratigraphic column that show noticeable increase in siltstone content. As used here, West Hill member consists of a series of rocks intermediate in lithology between Gardeau shale member and Nunda sandstone member. Consists mainly of gray siltstone and silty gray shale and at some places includes small amounts of petroliferous dark-gray shale and grayish-black slightly silty shale and a few layers of calcareous nodules; in southeastern part of mapped area, silty gray mudrock makes up much of member. Thickness 35 feet, northwestern Wyoming County; 240 feet northeastern Steuben County. Basal and upper contacts arbitrarily drawn. In western Wyoming County, West Hill intertongues with Gardeau member and uppermost siltstone bed is overlain by thin tongue of Gardeau.

Named for West Hill, Ontario County.

West Index Andesitic Series[1]

Eocene or Miocene: Central Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 7, p. 34–50.

Named for Mount West Index, Snohomish County.

West Jefferson Sandstone[1]

Middle Devonian: Central Ohio.

Original reference: E. Orton, 1888, Ohio Geol. Survey, v. 6, p. 4, 21.

Named for West Jefferson, Madison County.

West Ledge Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. Mining Jour-Press., v. 115, p. 793–799, 836–843, maps.

Occurs in Lead district, Lawrence County. Derivation of name not stated.

West Mead limestone member[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 132, table facing p. 61.

Named for West Mead Township, Crawford County, where it is well developed.

**West Minesota Conglomerate**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: S. H. Broughton, 1863, Remarks on the mining interest and details of the geology of Ontonagon County, 24 p., map, Philadelphia, 1863; p. 21, map.

Named for occurrence on property of West Minesota Mining Co., in Ontonagon County.

**West Molokai Volcanic Series**

Pliocene(?): Molokai Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 69 (table), 71; H. T. Stearns and G. A. Macdonald, 1947, Hawaii Div. Hydrography Bull. 11, p. 23–25, table facing p. 16; G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 146. Thin-bedded aa and pahoehoe basalt flows, associated cinder cones; some intercalated vitric tuff. Thickness 1,381 feet; base not exposed. Separated from overlying East Molokai volcanic series (new) by erosional unconformity.

Type locality: West Molokai Mountain (Mouna Loa). Cover an area of 120 square miles, comprising most of mountain.

Westmore Formation (in Barre Group)

Silurian or Lower Devonian: Northeastern Vermont.

C. G. Doll, 1951, Vermont Geol. Survey Bull. 3, p. 15, 33–37. Chiefly light- to medium-gray phyllites interbedded with smaller amounts of light-gray to black schists and limestone and quartzites; all are generally fine to medium grained. Thickness about 4,300 feet. Overlies Barton River formation (new).

V. R. Murthy, 1958, Jour. Geology, v. 66, no. 3, p. 276–287. Formation crops out in southeastern corner of Barre quadrangle and northwestern corner of East Barre quadrangle in belt 1¾ to 2 miles wide. These rocks have been mapped as Waits River formation (Currier and Jahns, 1941) and as Gile Mountain(?) formation by White and Jahns (1950, Jour. Geology, v. 58, no. 3). Thickness 3,700 to 5,100 feet. Overlies Barton River formation; underlies Waits River (redefined). Included in Barre group (new).

Type locality: Section exposed in whetstone quarry 1¼ miles due north of Lake Willoughby in southeastern Brownington. Other exposures directly north and south of village of Margan; in pasture one-half mile west-southwest of Echo Pond; and in cuts along State highway leading from West Charleston to Island Pond. Named from village of Westmore on Lake Willoughby in southeastern corner of Memphremagog quadrangle.

Westmoreland Member (of Clinton Formation)

Middle Silurian: New York.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 90, 93–94. Name Westmoreland (iron ore) is introduced as designation for oolitic iron ore of Smyth [1892, Am. Jour. Sci., 3d, v. 43] and Newland and Hartnagel (1908, New York State Mus. Bull. 123). Overlies Sauquoit beds; underlies Willowvale shale (new). Thickness about 18 inches at type locality.

Type locality: On tributary of Oriskany Creek about one-half mile east of hamlet of Lairdsville in town of Westmoreland, Oneida County.

Westmoreland Shale (in Chattanooga Shale)

Lower Mississippian: Central Tennessee.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 885, pl. 1.

Hard fissile black shale, indistinguishable in lithology from the Gassaway (new); contains scattered nodules at Westmoreland. Thickness 6 to 12 inches. Distinguishable as distinct bed in the Chattanooga only by its position above the Eulie shale (new). Underlies New Providence shale. Eulie and Westmoreland shales are complementary in their stratigraphic relations; absence of either would make determination of the status of the other very difficult.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 11. Westmoreland shale is grayish-black shale which locally contains phosphatic nodules. Name Westmoreland shale not used in present report [Chattanooga shale and Maury formation]; beds so named by Campbell are placed in Maury formation and not named.

Type section: Two Hundred yards north of Garritt's Creek Church, north of Westmoreland, Sumner County.

Weston Limestone[1]

Pennsylvanian: Northwestern Missouri.

Original reference: J. A. Gallaher, 1898, Missouri Bur. Geology and Mines Bienn. Rept., p. 52.

Named for exposures at Weston, Platte County.

Weston Sandstone (in Monongahela Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: D. B. Reger, 1916, West Virginia Geol. Survey Rept. Lewis and Gilmer Counties, p. 124.

Occurs along Town Run, at southeast edge of village of Weston, Lewis County.

Weston Shale (in Monongahela Formation)[1]

Pennsylvanian: Northern West Virginia.

Original reference: D. B. Reger, 1916, West Virginia Geol. Survey Rept. Lewis and Gilmer Counties, p. 128.

Exposed in vicinity of Weston, Lewis County.

**Weston Shale** (in Pedee Group)

Weston Shale or Shale Member (in Douglas Formation or Group)[1]

Weston Shale (in Lansing Group)

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and northeastern Oklahoma.

Original reference: C. R. Keyes, 1899, Am. Geologist, v. 23, p. 306.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, v. 25, 2d ser., p. 28. Included in Pedee group in Missouri.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 284 (table), 295. Weston and Iatan formations included in Lansing group. Term Pedee dropped from Iowa nomenclature.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Chart shows Weston shale in Ochelata group in Oklahoma.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 31. Thickness in Missouri and Kansas about 80 feet and 88 feet in northern Oklahoma. Missing in Nebraska due to post-Missourian erosion which extended into top of Lansing group.

Named for Weston, Platte County, Mo.

**Westphalia Limestone[1] Member** (of Stranger Formation)

Pennsylvanian (Virgil Series): Eastern Kansas.

Original reference: R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 145, 146, 150.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 73. Characterized by abundant fusulines. Thickness ranges from featheredge to about 5 feet. Underlies Vinland shale member; overlies Tonganoxie sandstone member.

Named for village in western part of Anderson County. Typical outcrops are in roadside exposures along northern part of sec. 12, T. 21 S., R. 17 E., and at NE cor. sec. 20, T. 21 S., R. 18 E., not definitely recognized in outcrops north of T. 19 S.

West Point facies (of Muldraugh Formation)

Lower Mississippian: Northern Kentucky and southern Indiana.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 75, 202–210. Northwesternmost facies of formation within Kentucky outcrop belt. It is an impure limestone phase most of which extends but a short distance in Indiana, as far as middle of T. 5 S., southeastern Harrison County, where it includes the two divisions which have been differentiated as Edwardsville and Lower Harrodsburg. Thickness as much as 95 feet. Thickness at type section 95 feet; here facies overlies Floyds Knob formation(?) and underlies Harrodsburg limestone.

Type section: At quarry, one-eighth mile southeast of Louisville and Henderson Railroad station at West Point, Hardin County, Ky.

†West Point Member[1] (of Warsaw Formation)

Mississippian: Western Kentucky.

Original reference: A. H. Sutton, 1931, Kentucky Geol. Survey, ser. 6, v. 37, p. 281.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 801. Cherty Edwardsville limestone in Jefferson and adjacent counties, Kentucky, has generally been referred to Warsaw formation and name West Point member has been proposed for it, but it has not been distinguished as a separate unit of the section farther south. Although name West Point has priority, it is abandoned in favor of Edwardsville because of the much clearer stratigraphic relations of the latter in Indiana.

Derivation of name not stated, but there is a village called West Point in Hardin County.

West Prong Lentil (in Grayson Shale)

Lower Cretaceous: Southwestern Texas.

Robert Greenwood, 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 168 (fig. 2), 169. Yellowish-brown poorly indurated argillaceous limestone with thin clay partings. Estimated thickness 50 feet. Overlies Georgetown limestone, apparent conformity.

Type locality: At intersection of West Prong Fork (a local name not shown on quadrangle map) with West Nueces River, Uvalde County.

West Prospect Basalt[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, p. 214–376, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 686. Cenozoic.

Occurs in Lassen National Park.

**West Range Limestone**[1]

Upper Devonian: Eastern Nevada.

Original references: L. G. Westgate and A. Knopf, 1927, Am. Inst. Mining Metall. Engineers Trans., no. 1647, p. 7; 1932, U.S. Geol. Survey Prof. Paper 171, p. 7, 16, map.

R. L. Langenheim, Jr., 1960, Illinois Acad. Sci. Trans., v. 53, nos. 3 and 4, p. 122–131. Discussion of Pilot shale, West Range limestone, and Devonian-Mississippian boundary in eastern Nevada. Thickness of West Range 296 feet at type section where it overlies Silverhorn dolomite and underlies 32 feet of calcareous siltstone or silty limestone assigned to lower Pilot shale.

Composes, together with underlying Silverhorn limestone, the whole of West Range, which lies west of Bristol Range, Pioche district.

West Ridge Group

Age unknown: Southern California.

K. J. Hsu, 1955, California Univ. Dept. Geol. Sci. Bull., v. 30, no. 4, p. 275–278, geol. map. Hypersthene amphibolites and almandine-diopside rocks. Occurs in narrow lenticular zone between Aurela Ridge granulites (new) and East Ridge mylonites (new); contact probably transitional. Separated from East Ridge rocks by north-dipping Marjo Canyon thrust.

Exposed in Cucamonga quadrangle, San Bernardino County.

**West River Shale Member** (of Genesee Formation)

West River Shale (in Genesee Group)[1]

Upper Devonian: Western and central New York.

Original reference: J. M. Clarke and D. D. Luther, 1904, New York State Mus. Bull. 63, p. 28.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 60–66. Formation (or shale) in Genesee group. Consists of interbedded blue-black, dark-gray, and black fissile shale with abundant spherical concretions. Proposed here to include *Styliolina* limestone facies (Genundewa limestone) in the base so that lower boundary of the West River will be lowest *Styliolina* layer. Term Genundewa abandoned. Uppermost boundary is marked by Middlesex shale. The West River continues as a clearly recognizable unit from its type area at Canadaigua Lake to Lake Erie. Interval between Geneseo shale and Middlesex shale in Keuka Lake Valley is thicker than at Canandaigua Lake. Tongue of Sherburne type rock in middle of the West River causes thickening of whole sequence to 250 feet. The West River is divided into the Penn Yan tongue (new) below and the Milo tongue (new) above by penetration of Starkey tongue (new) of Sherburne formation.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2814 (fig. 3), 2815, 2819, 2822. Name West River was proposed by Clarke and Luther (1904) for sequence of dark shaly rocks lying above their Genundewa limestone and below their Standish flags and shales. The West River is herein redefined as West River shale member of Genesee formation. Upper boundary is extended to include all rocks between base of Genundewa limestone member of the Genesee and base of Sonyea formation. Standish flags and shale of Luther and Clarke are included in the West River. At reference section, herein designated, member is about 132 feet thick, and composed largely of dark-gray shale and mudrock that contain several beds of black shale, very dark gray argillaceous limestone nodules, and a few layers of dark-gray or brown siltstone as much as 2 inches thick. In vicinity of Cayuga Lake, member is composed largely of medium-dark-gray shale and mudrock and contains many layers of siltstone ranging from laminae to beds as much as 2 feet thick near Ithaca and to beds 5 feet thick at Sheldrake Creek, 18 miles northwest of Ithaca. Thickness about 150 feet near Ithaca. Highly cross-laminated ripple-marked layer of siltstone 1 to 2 inches thick is present at base of upper third of member in most exposures between Lake Erie and Canandaigua Lake. This key bed, which is present in more than 500 square miles of western and west-central New York was traced eastward to Keuka Lake where it was found to be the 3- to 4-inch Bluff Point flagstone of Torrey (1932, Am. Petroleum Inst. Div. Production Paper 826–4A), the same bed that was named Keuka flagstone by Fox (1932).

Reference section: Exposures in Seneca Point Gully on west side of Canandaigua Lake, 9 miles north on Naples, Ontario County. Named for exposures in West River valley, Yates County.

†West Roxbury Slate[1]

Devonian or Carboniferous: Eastern Massachusetts.

Original reference: W. W. Dodge, 1881–1882, Boston Soc. Nat. History Proc., v. 21, p. 208–210.

Occurs on each side of the tract near West Roxbury Station, Boston region.

**West Rutland Marble**[1]

Middle Ordovician: West-central Vermont.

Original reference: E. J. Foyles, 1929, Vermont State Geologist 16th Rept., p. 281–288.

Named for economic occurrences around West Rutland, Rutland County.

West Spring Formation (in Salt Lake Group)

Pliocene, lower and middle: Northeastern Utah.

Neal Smith, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 73, 75 (fig. 2). Chiefly soft earthy gray tuff and occasional pebble conglomerate; thin compact stromatolitic limestone in basal part. Thickness 1,200 feet. Overlies Collingston conglomerate (new); underlies Cache Valley formation; both contacts unconformable. Name credited to J. S. Williams (unpub. ms.).

R. D. Adamson, C. T. Hardy, and J. S. Williams, 1955, Utah Geol. Soc. Guidebook 10, p. 6. Considered to be part of Cache Valley formation.

Exposed on Hyrum Bench along southwest side of Cache Valley, about 12 miles south of Logan, Cache County.

**West Spring Creek Formation**[1] (in Arbuckle Group)

Lower Ordovician: Central southern Oklahoma.

Original reference: C. E. Decker, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 12, p. 1495 (table 4).

C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55, 56. Uppermost formation in Arbuckle group. Overlies Alden limestone (new); underlies Joins formation of Simpson group. Upper Canadian.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 26–28; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1320–1321, table 1. Characterized chiefly by many zones of thin shaly limestones separated by thick resistant limestone beds. Thickness 1,611 feet at type section in Arbuckles; 250 feet in Wichitas. Gradationally overlies Kindblade formation (new) which replaces preoccupied name Alden. Lower Ordovician.

W. E. Ham, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2038–2039. Collings Ranch conglomerate (new) rests with marked angular unconformity on steeply dipping rocks of Arbuckle anticline. Exposed rocks beneath conglomerate are West Spring Creek formation of Arbuckle group, Joins, Oil Creek, McLish, Tulip Creek, and Bromide formations of Simpson group, and Viola limestone.

Type section: Along U.S. Highway 77 about 3 miles north of Springer, sec. 19, T. 2 S., R. 1. E., Carter County. Named for West Spring Creek at west end of Arbuckle Mountains (sec. 31, T. 2 S., R. 1 W.), where it flows across formation.

West Sutton Slate[1] or Formation

Precambrian(?) or Lower Cambrian: Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 225–226.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137, 143–144. Fine mud rock varying from medium and dark gray to dark blue black. Hematite characteristically present either as discrete masses or disseminated. Contains gritty beds at type locality which is cited. Thickness generally 40 to 250 feet. Underlies Gilman quartzite; overlies White Brook dolomite.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1135, 1136, 1147, 1148. Extended to Vermont where it is known as West Sutton formation because of lithologic variations.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Precambrian(?).

Type locality: One-half mile northwest of the West Sutton four corners, Sutton quadrangle, Quebec.

West Union Formation[1]

Silurian (Niagaran): Southwestern Ohio.

Original reference: E. Orton, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 271, 274, 301, fig. 1.

Alwyn Williams, 1953, Geol. Soc. America Mem. 56, p. 62. West Union formation mentioned in list of fossil localities.

Named for exposures at West Union, Adams County.

West Union Gravel

Pleistocene: Central Minnesota.

Kirk Bryan, Henry Retzek, and F. T. McCann, 1938, Texas Archeol. Paleont. Soc. Bull. 10, p. 125. Name applied to gravel in which skeleton of Sauk Valley man was discovered. Gravel is 5 to 6 feet thick and well stratified; coarse and rubbly at base and containing pebbles 2 to 4 inches in diameter; grades to finer material toward top. At south end of gravel pit, gravel rests on yellow clayey till which is more than 5 feet thick; till thins northward to featheredge and rests on slightly deformed gray gravel; the West Union rests unconformably on both of these materials. Underlies black loam about 1 foot thick.

Occurs in gravel pit on land of Daniel W. Fraser, Lot 1 of NE¼ sec. 11, T. 127 N., R. 35 W., West Union Township, Todd County.

Westville Shale[1]

Pennsylvanian: Southeastern Massachusetts.

Original reference: J. B. Woodworth, 1899, U.S. Geol. Survey Mon. 33, p. 134.

Westwater Gneisses and Schists[1]

Precambrian: Western Colorado.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 39, 281.

Exposed in bed of Grand River at Utah-Colorado line. Derivation of name not stated.

Westwater Sandstone Member (of Morrison Formation)

*See* **Westwater Canyon Sandstone Member** (of Morrison Formation).

**Westwater Canyon Sandstone Member** (of Morrison Formation)[1]

Upper Jurassic: Southeastern Utah, northeastern Arizona, southwestern Colorado, and northwestern New Mexico.

Original reference: H. E. Gregory, 1938, U.S. Geol. Survey Prof. Paper 188, p. 59, pl. 15.

J. W. Harshbarger, C. A. Repenning, and R. L. Jackson, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 98. Geographically extended into Arizona and New Mexico. About 155 feet thick at Kayenta, Ariz.; decreases in thickness to the south and not present in Hopi Buttes area; pinchout due to pre-Dakota erosion.

L. C. Craig and others, 1955, U.S. Geol. Survey Bull. 1009–E, p. 153–155. Westwater Canyon constitutes lower unit of upper part of Morrison in southern part of region of this study [Colorado Plateau]. Unit was formed as large alluvial fan. To the north, Westwater Canyon intertongues with and grades into lower part of Brushy Basin member along a limit of recognition that passes just south of Monticello, Utah. In most of northwestern New Mexico and a small part of northeastern Arizona, upper part of Brushy Basin member overlies Westwater Canyon, but to the southwest, post-Morrison erosion has removed Brushy Basin, and the Westwater Canyon is only part of upper part of Morrison preserved. Arbitrarily divided into two facies: conglomeratic sandstone facies and sandstone facies. Maximum thickness 330 feet, 30 miles northeast of Gallup.

V. L. Freeman and L. S. Hilpert, 1956, U.S. Geol. Survey Bull. 1030–J, p. 309, 314, 315 (fig. 60), 324, 326, 330, 333. In Laguna area, New Mexico, Recapture, Westwater Canyon, and most of Brushy Basin members are present in stratigraphic interval previously considered as Recapture. Sandstone, previously considered as Westwater Canyon, is at top of Brushy Basin and is informally called Jackpile ore-bearing bed. Westwater Canyon in Gallup-Albuquerque area ranges from about 50 to 190 feet in thickness; locally absent near Laguna. In general, thickens from Laguna area westward toward Gallup and northward toward San Ysidro.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 53–55, strat. sections. Gregory suggested that Westwater Canyon member might be correlative with Salt Wash member, but, in view of regional relationships presented by Stokes (1944 Geol. Soc. America Bull., v. 55, no. 8), the Salt Wash appears to be correlative with basal part of Gregory's Recapture. In this report [Navajo country], name Westwater Canyon is applied to cliff-forming sandstone of the Morrison lying below variegated shale of Brushy Basin member and above Recapture member. No positive evidence found to indicate that Westwater Canyon intertongues with Cow Springs sandstone as do underlying Recapture and Salt Wash; however, such a relationship between the Westwater Canyon and Cow Springs appears to exist in exposures between Todilto Park and Lupton. Where Brushy Basin has been removed by pre-Dakota erosion, Westwater Canyon unconformably underlies Dakota sandstone. Thicknesses: 155 feet south of Kayenta; 239 feet at Yale Point; 227 feet at Todilto Park; 127 feet at Thoreau, N. Mex.

R. T. Zitting and others, 1957, The Mines Magazine, v. 47, no. 3, p. 55, 57. In Ambrosia Lake area, McKinley County, N. Mex., includes Poison Canyon sandstone (new) at top.

Named for exposures in canyon of Westwater Creek near Blanding, San Juan County, Utah.

Wetmore conglomerate member[1] (of Knapp formational suite)

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 61, 111–112, table facing p. 61.

Occurs only in McKean, northern Forest, northern Elk, and eastern Warren Counties, Pa., and in typical Knapp area, in vicinity of Knapp Creek, N.Y. Named for exposures along face of the hills between Wetmore and Ludlow, McKean County, Pa.

**Wetumka Shale**[1] (in Marmaton Group)

Pennsylvanian (Des Moines Series) : Central Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 30–32. Described in Okfuskee County where it is 120 to 148 feet thick. Conformably overlies Calvin sandstone; conformably underlies Wewoka formation. Marmaton group.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000) : U.S. Geol. Survey. As mapped, extends northeastward from Pontotoc County through Hughes, Okfuskee, Okmulgee, and Tulsa Counties to near Arkansas River. Marmaton group.

Named for exposures at or near Wetumka, Hughes County.

**Weverton Quartzite** or **Formation** (in Chilhowee Group)

Weverton Sandstone[1]

Lower Cambrian(?) : Maryland, southeastern Pennsylvania, Virginia, and West Virginia.

Original reference: A. Keith, 1893, as reported by G. H. Williams and W. B. Clark in Maryland, its resources, industries, and institutions, chap. 3, p. 68.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties [Rept. 12], p. 34–39. Weverton quartzite described in Carroll and Frederick Counties, where it is about 500 feet thick. Overlies Loudoun formation; underlies Harpers phyllite. Lower Cambrian.

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 15 (fig. 5), 17–19, pl. 1. Formation described in Elkton area, Virginia, where it is included in Chilhowee group. Divided into three members: lower, conglomerate and coarse-grained feldspathic quartzite; middle, persistent body of argillaceous shale; upper, contains numerous beds of quartzite, many of which are dark and ferruginous, between are layers of thin-bedded siltstone and fine-grained gray sandstone. Thickness 1,000 to 1,600 feet. In some areas, Loudoun formation pinches out and Weverton lies directly in injection complex. Conformably underlies Harpers formation. Lower Cambrian.

D. M. Scotford, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 48–49. Discussion of Sugarloaf Mountain area, Maryland. Quartzites on Sugarloaf Mountain were considered Lower Cambrian and therefore Weverton by early workers such as J. P. Lesley, G. H. Williamson, and C. R. Keyes. Jonas and Stose (1938, Geologic map of Frederick County) mapped these rocks as Sugarloaf Mountain quartzites and assigned them to probable Lower Cambrian age. Writer [Scotford] believes these rocks are equivalent to Lower Cambrian Weverton quartzite because Sugarloaf Mountain is an anticline rather than a syncline as reported by Stose and Stose (1946). Stratigraphic sequence is therefore reverse of that previously described and corresponds to known Cambrian sequence in South Mountain uplift. Underlies Harpers phyllite.

A. J. Stose and G. W. Stose, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 697–699. Discussion of article by Scotford (1951) in which he interpreted Sugarloaf Mountain area as anticlinal. Arguments are presented to uphold interpretation that area is synclinal.

J. C. Whitaker, 1955, Geol. Soc. America Bull., v. 66, no. 4, p. 442–445, pl. 1. Discussion of geology of Catoctin Mountain. Results of study indicate that area is not a syncline as previously interpreted, but a tightly folded eastward-dipping sequence which forms upper and eastern limb of South Mountain anticlinorium. Strata previously mapped as Loudon along eastern border of Catoctin Mountain constitute a zone including upper Weverton quartzite and basal Harpers phyllite. Weverton as herein interpreted forms complex unit of clastic which vary along strike over limited geographic area. Rock types are: banded quartzite, thin-bedded quartzite, laminated micaceous quartzite, interbedded quartzite and phyllite, ferruginous quartzite, crossbedded quartzite, ledge-maker quartzite, and ferruginous quartz conglomerate. Overlies Loudoun formation; underlies Harpers phyllite.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 18. Formation, in Rockingham County, crops out on northwest slopes of Blue Ridge. Overlies Loudoun formation; underlies Hampton formation. Term Hampton used in preference to Harpers in this report.

Named for exposures at Weverton, Washington County, Md.

**Wewe Slate**[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 530.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1436 (table 1), 1461. Palmer gneiss, previously considered pre-Huronian, consists of metamorphic Mesnard quartzite, Kona dolomite, Wewe slate, and Ajibik quartzite. Table 1 shows lower Huronian sequence in Marquette area (ascending) Mesnard, Kona, and Wewe. Palmer gneiss is not listed on this table.

Typical development on Wewe Hills, west of Goose Lake, Marquette district.

**Wewoka Formation**[1] (in Marmaton Group)

Pennsylvanian (Des Moines Series): Central Oklahoma.

Original reference: J. A. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 32–40. Described in Okfuskee County where it is a succession of thick shales containing interstratified friable sandstones and a few local limestones. Has composite thickness ranging from 780 feet in southern part of county to 730 feet along northern boundary. Conformably overlies Wetumka formation and conformably underlies Holdenville shale. Marmaton group.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. As mapped, extends northeastward from east-central part of Pontotoc County, through Hughes, Okfuskee, Okmulgee, and Tulsa Counties to Arkansas River. Marmaton group.

Named for Wewoka Creek, Seminole and Hughes Counties.

**Weybridge Member** (of Chipman Formation)

Weybridge Member (of Beldens Formation)

Lower Ordovician: West-central Vermont.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524, 550–552. Limestone with sandy streaks which weather into raised ridges and are more granular and darker than the intervening blue limestone. Sedimentary channels, some filled with fossil fragments, and crossbedding common. Current ripple marks present. Maximum thickness about 500 feet. Underlies and overlies undifferentiated parts of Beldens formation.

Marshall Kay, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1476. Quartz-silty facies of Beldens in Middlebury synclinorium. *Goniotelus* and *Syntrophia* support late Canadian age.

W. M. Cady and E-an Zen( 1960, Am. Jour. Sci., v. 258, no. 10, p. 728–739. A real distribution and structural and stratigraphic relations of the Beldens, Burchards, and Weybridge indicate that these members are lithofacies in Chipman formation. Sequence varies; in some areas, the Weybridge is at or near the bottom of formation; in other areas, either the Beldens or the Burchards is at the bottom and they are succeeded to west and upward stratigraphically by the Weybridge; in other areas, the Weybridge is succeeded by both the Burchards and the Beldens lithofacies. Lower Ordovician.

Typically exposed at "Weybridge Upper Falls," 1 mile east-northeast of Weybridge village, now locally known as Huntington Falls, Addison County.

**Weymouth Formation**[1]

Lower Cambrian: Eastern Massachusetts.

Original reference: Laurence LaForge, 1909, Science, new ser., v. 29, p. 945–946.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart above Hoppin formation.

Exposed north and east of Mill Cove at Weymouth, Norfolk County, and at Nahant, Essex County.

**Weyquosque Formation**[1]

Pleistocene: Southeastern Massachusetts and Rhode Island.

Original reference: J. B. Woodworth and Edwards Wigglesworth, 1934, Harvard Coll. Mus. Comp. Zoology Mem., v. 52.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1715, chart 12. Pleistocene (Kansan).

Named for exposures at east end of Nashaquitsa Cliffs on south shore of Marthas Vineyard, Mass., at locality known as Weyquosque.

†Weyquosque Series[1]

Pleistocene: Southeastern Massachusetts.

Original reference: N. S. Shaler, 1888, U.S Geol. Survey 7th Ann. Rept., p. 303–363, maps.

Well exposed in western part of Chilmark or Weyquosque Cliffs, Marthas Vineyard.

Whaleback Basalts

Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 42, pl. 3. Name appears on explanation of geologic sections. Text discusses basalt flows that make up cone of Whaleback volcano.

Whaleback volcano is largest of Recent volcanoes in Macdoel quadrangle.

**Whalen Group**[1]

Precambrian: Southeastern Wyoming.

Original reference: W. S. T. Smith and N. H. Darton, 1903, U.S. Geol. Survey Geol. Atlas, Folio 91.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 32 (fig. 11), 36. In section measured in vicinity of Lake Guernsey, the Precambrian (Whalen group) is exposed in banks and bed of Platte River. Composed of schists, granite, and dolomite. Underlies Deadwood sandstone.

Typical occurrence along walls of Whalen Canyon, Hartville uplift.

Wharncliffe Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 222.

Named for town in Mingo County.

Whately Bed[1]

Pre-Triassic: Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 190, 193.

Crops out beneath the sands of the valley in Whately, Old Hampshire County.

Wheatland Formation

Eocene, upper, or Oligocene, lower: Northern California.

B. L. Clark and C. A. Anderson, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 326–327. Fossiliferous conglomerate, sandstone, and silty shales. Thickness about 300 feet. Upper Eocene.

B. L. Clark and C. A. Anderson, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 932–938, 942–945. Overlies greenstone of Sierra Nevada basement complex. Exact measurement of thickness impossible because of disconnected exposures and because dip varies both in amount and direction. Upper Eocene or lower Oligocene. Type section designated.

Type section: Six miles northeast of Wheatland at east margin of Sacramento Valley, Yuba County.

Wheatland Formation

Pleistocene, upper: Eastern New Mexico.

Sheldon Judson, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 263. Fine sand, gravel, and silt 5 to 15 feet thick. Base 1 to 5 feet above base of arroyos.

Sheldon Judson, 1953, Smithsonian Misc. Colln., v. 121, no. 1, p. 22–23, 24 (fig. 9), 30. Name proposed for terrace sediments at San Jon site. Each terrace remnant consists of fine basal gravel, mostly fragments of concretions from Ogallala sandstone, and of sand. Sand gravel layer is 1 to 3 feet thick and overlies irregular surface cut in older formations. Highest terrace has base 20 to 25 feet above grade of streams at point nearest head of canyon. Two lower terraces have bases at 8 to 10 feet and 1 to 5 feet above present grades. Each terrace records downcutting of streams through Sand Canyon and older formations with stabilization of grades and later slight alluviation. This episode was repeated three times before present stream grades were established. Highest terrace contains *Bison bison* bones.

Type locality: San Jon site approximately 10 miles south of town of San Jon, Quay County. Name derived from town of Wheatland, about 4½ miles south of site.

**Wheeler Formation**[1]

Middle Cambrian: Western Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 9, 10.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1141 (fig. 5), 1146. Wheeler (emended) consists of dull-sooty-black, fine-grained, hard, platy, and rarely, fissile calcareous shale, which weathers pale gray and contains numerous intercalated argillaceous and finely arenaceous limestones which increase slightly in amount upward; about 85 feet below top is 2- to 4-foot zone of black thin-bedded fine-grained limestone which weathers bright orange tan. Fossiliferous. Thickness 350 feet. Overlies Swasey limestone (emended); underlies Marjum limestone (emended).

Type locality: Center of Wheeler Amphitheater, southeast of Antelope Springs, House Range, Millard County. Emended section measured south of Marjum Canyon, 10 miles southwest of Wheeler Amphitheater.

Wheeler Formation (in Cabaniss Group)

Pennsylvanian (Desmoinesian): Southwestern Missouri.

W. V. Searight *in* W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. Name appears on generalized stratigraphic section. Underlies Bevier formation; overlies Verdigris formation. Contains Wheeler coal at top.

Exposed in northeastern Carroll and southeastern Livingston Counties.

Wheeler limestone

*See* **Pioche Shale.**

Wheeler Sandstone or Sandstone Member (of Juncal Formation)

Eocene, middle: Southern California.

T. L. Bailey, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1920 (fig. 3). Wheeler sandstone shown on structure section as underlying middle Eocene Sisar black shale and overlying lower Eocene beds.

W. R. Merrill, 1952, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists Mineralogists, Soc. Exploration Geophysicists, Joint Ann. Mtg. Guidebook, p. 77. Wheeler sandstone member of Juncal noted on road log from Ojai to Ozena.

Occurs in Ventura County.

Wheelerian Stage

Pliocene: Southern California.

Manley Natland, 1953, Pacific Petroleum Geologist, v. 7, no. 2, p. 2. One of four stages, based on foraminiferal assemblages, in the Pliocene and Pleistocene of southern California. Includes interval between Hallian stage above and Venturian stage. The Wheelerian includes the middle

Pico and part of the upper Pico. Division between Wheelerian and Hallian is within the upper Pico or "Mud Pit shale."

Wheeling Group[1]

Pennsylvanian: Appalachian Basin.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 178.

Named for stream which flows through western parts of Greene and Washington Counties, Pa., and Marshall and Ohio Counties, W. Va.

Wheelock Marl Member (of Cook Mountain Formation)

Wheelock Marl Member (of Crockett Formation)

Eocene, middle: Eastern Texas.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 125–134 [1939]. Basal member of Crockett formation. Commonly light gray-green, bluish-gray, or slate-gray thin-bedded to laminated marl not rich in glauconite and fossils. Calculated thickness 70 feet. Interfingers with and transitional into overlying Landrum shale member; disconformably overlies Stone City beds.

H. B. Stenzel, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 9, p. 1664. Reallocated to Cook Mountain formation. Type locality stated.

Type locality: Wheelock Prairie in Brazos and Robertson Counties.

Whetstone Branch Shale[1]

Upper Devonian and Mississippian (Kinderhook): Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 163, 166, chart 5 (column 89). Whetstone Branch formation is local designation for Chattanooga shale which contains interbedded sandstones in this area. Occurrence of *Tentaculites* seems to prove Devonian age of at least part of this formation, but middle New Albany conodonts have been recognized nearby in Tennessee, so the upper part may be younger. Shown on chart as Kinderhookian.

Type locality: In Tishomingo County in middle part of Whetstone Branch, which enters Tennessee River about 3½ miles above Tennessee State line and mouth of Yellow Creek.

**Whetstone Creek Shale Member** (of Breathitt Formation)

Middle Pennsylvanian: Southeastern Kentucky.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 64, 65, 76, 153. Proposed for dark-gray shale that contains numerous fairly regular bands of ironstone. Thickness about 71 feet. Occurs in upper part of Breathitt formation below Bacon Creek or lower Blue Gem coal.

Exposed in north bluff of Cumberland River along Kentucky Highway 92 just west of Whetstone Creek, about 9 miles east of Williamsburg, Whitley County.

Whetstone Gulf Formation[1] (in Lorraine Group)

Upper Ordovician: Northern New York, and Southern Ontario, Canada.

Original reference: Rudolf Ruedemann, 1925, New York State Mus. Bull. 258.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2, column 19. Shale is lower unit in Lorraine group.

Named for exposure in Whetstone Gulf near Martinsburg, Lewis County, N.Y.

Whetstone Hill Member (of Moretown Formation)

Age not stated: Vermont.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 51. Incidental mention of name. Refers to Thompson (unpub. thesis, 1950).

Whetstonian series

Paleozoic (Mid-Cambric): Arizona and New Mexico.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 2, p. 107 (table), 120. Comprises (ascending) Dragoon and Carrasco terranes.

Whim Hill Breccia

Upper Cretaceous or younger: Southwestern New Mexico.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 289–291, fig. 3, pl. 1. Compact mass of angular blocks firmly cemented by matrix rich in magnetite. Fragments represent a number of rock types known to occur in the stratigraphic section. Broken pieces of biotite granodiorite porphyry predominate. Angular and rounded fragments of indurated shales and quartzites, which probably came from Beartooth and Colorado formations, included.

Two areas of exposure in northern part of Santa Rita stock; larger, comprises area of over 40,000 square feet and forms elongate mass in central part of North Pit; second body found on northern edge of Central Island between North and South Pits. In Santa Rita copper mine, in southeastern corner of Santa Rita quadrangle, about 12 miles east of Silver City, Grant County.

Whipple Marble

Ordovician: West central Vermont.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 13, 32–34, pl. 1. Thin-bedded dark-blue-gray marble containing lenses of black slate and some buff-weathering dark-gray dolomite beds. Thickness from 50 to 250 feet. Underlies Hortonville slate though locally appears to be contemporaneous with it. Lenses of each occur in the other. Overlies Orwell limestone unconformably. Middle Ordovician (Trenton).

E-an Zen, 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1830. Age of at least a part is Canadian [Lower Ordovician].

Best exposed in band about 2½ miles long extending northward along east side of West Rutland Valley from point about 2 miles north of West Rutland. Northern part of West Rutland Valley is labeled "Whipple Hollow" on Proctor 7½ minute topographic map. Other exposures also in and near Castleton quadrangle.

**Whirlpool Sandstone** (in Albion Group)

Whirlpool Sandstone (in Medina Group)

Whirlpool Sandstone Member (of Albion Sandstone)[1]

Lower Silurian: Western New York, and Ontario, Canada.

Original reference: A. W. Grabau, 1909, Jour. Geology, v. 17, p. 238.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Albion group in New York and Cataract group in Ontario.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1981 (fig. 2), 1982 (fig. 3), 1985–1987. Discussion of stratigraphy of Medinan group in Ontario and New York. Whirlpool sandstone is basal formation of group. Extends from Mitchells Mills, Ontario. along, or slightly north of, base of Niagara escarpment to its easternmost exposure at Medina, N.Y., a distance of about 150 miles. Maximum thickness 25 feet. Underlies Manitoulin dolomite in vicinity of Hamilton; underlies Fish Creek shale (new) from DeCew Falls to Lockport. Overlies Queenston shale.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Underlies Rumsey Ridge, herein raised to formational rank, and preoccupied term Fish Creek abandoned.

Named for occurrence at the Whirlpool of Niagara River.

Whirlwind Breccia Member (of Pruett Formation)

Tertiary: Western Texas.

C. G. Moon, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 179. Persistent light-colored sandstone marker bed that extends from northwest corner of area [Agua Fria quadrangle] southward to about latitude of Burnt House Camp may correspond to upper Whirlwind breccia member of Pruett formation. [Goldich and Elms (1949) refer to breccia-conglomerate at Whirlwind Spring.]

Sandstone bed dips gently west and is continuous along west bank of tributary which flows from north and empties into Crystal Creek.

Whirlwind Formation

Middle Cambrian: Western Utah and eastern Nevada.

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 47, 48 (fig. 3), 50 (fig. 4), 51. Name replaces Condor member of Swasey formation (Wheeler, 1948) and Condor formation (Cohenour, 1959). Series of paleolithofacies maps of Great Basin area illustrates gross shifts in lithofacies boundaries caused by alternately transgressive and regressive Lower and Middle Cambrian sea. Major Middle Cambrian regressive movements during *Glossoplura* and *Bathyuriscus-Elrathina* times caused noncalcareous detrital sediments to be swept westward over top of older carbonate sediments. Those two regressive tongues form recognizable stratigraphic marker units in much of eastern Great Basin. Name Chisholm formation is here extended to include all occurrences of older tongue. Rocks of younger tongue have had name Condor member of Swasey applied to them. Type section of Condor member is believed to be noncorrelative with type section of Swasey limestone; hence, younger regressive tongue has no valid name and term Whirlwind is proposed. In House and Wah Wah Ranges, underlies Swasey formation and overlies Dome formation; in Pioche district, overlies Burrows formation and underlies Highland Peak formation.

Type section: Along road in Marjum Canyon, House Range, Utah. Name derived from Whirlwind Valley to east of House Range.

Whiskey Canyon Limestone (in Armendaris Group)

Pennsylvanian (Des Moines Series) : Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 43–47, 50. Term proposed for massive bluish-gray to gray cherty limestones between top of Elephant Butte formation (new) below and base of Garcia formation (new) above. Thickness at type section about 163 feet.

J. A. Young, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1247. In Sangre de Cristo Mountains, overlies Cortado formation (new).

Type locality: Westernmost box canyon of Whiskey Canyon, in southwest part of sec. 1, T. 13 S., R. 5 W., Sierra County.

Whiskey Creek Pass Limestone Member (of Madera Formation)

Pennsylvanian (Desmoinesian) : South-central Colorado and north-central New Mexico.

K. G. Brill, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 8, p. 818–819, pl. 1. Interbedded sandstone and light-gray sandy oolitic limestone, about 150 feet thick in vicinity of Whiskey Creek Pass. Persistent horizon marker in southern part of Permo-Pennsylvanian zeugogeosyncline of Colorado and New Mexico.

Typically developed at an elevation of about 13,000 feet above sea level on north side of north fork of Whiskey Creek, Las Animas County, Colo.

Whiskey Mountain Granodiorite

Mesozoic: Northeastern Washington.

A. C. Waters and Konrad Krauskopf, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1370–1371, pl. 1. Porphyritic biotite granodiorite occurring in Whiskey Mountain stock which is considered roughly contemporaneous with Colville batholith.

Exposed over about 6 square miles on Whiskey Mountain, northern Okanogan County.

Whistle Creek Limestone

Middle Ordovician: Western Virginia.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 74–75, 85 (fig. 7), 103. Name introduced for cherty limestones containing *Hesperorthis* fauna, which succeed New Market limestone (new) and underlie either coarse-grained "Holston" limestone of Lexington area or *Dinorthis atavoides* zone; at type section, underlies Lincolnshire limestone. Predominantly dark-bluish to brownish-gray cherty limestone, irregularly bedded. Thickness at type locality 82 feet. In many places, position of the Whistle Creek is indicated by blocks of fossiliferous. punky chert; where Whistle Creek is in direct contact with *Dinorthis atavoides* zone, the two can be distinguished only by fossils.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 80. Neuman named an 800-foot sequence of "Stones River" the Row Park formation. Cooper and Cooper had previously identified this sequence as Whistle Creek on basis of contained fossils. Below the New Market of Cooper and Cooper, Neuman discovered granular limestone containing abundance of *Rostricellula*. It is postulated here that both identifications of New Market are correct but that the Row Park is partial facies of the New Market and also the Whistle Creek.

Type section: Between U.S. Route 60 and Whistle Creek about 2 miles N. 40° W. of Lexington, Rockbridge County, Va.

Whistler Mountain Alaskite

Post-Mississippian: East-central Nevada.

C. W. Merriam, 1940, Geol. Soc. America Special Paper 25, p. 28, 29, 44, fig. 2. Consists of fine-grained alaskite intrusive body cutting certain shales and quartzitic deposits long regarded as entirely Diamond Peak Carboniferous but known to include beds of Ordovician age.

Constitutes central mass of Whistler Mountain, Roberts Mountain quadrangle.

**White Porphyry**[1]

Upper Cretaceous or early Tertiary: West-central Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1883, U.S. Geol. Survey Leadville Atlas; 1886, U.S. Geol. Survey Mon. 12, p. 76; 1927, U.S. Geol. Survey Prof. Paper 148.

C. H. Behre, Jr., 1953, U.S. Geol. Survey Prof. Paper 235, p. 42–46, pl. 1. Since term White porphyry is well established in local mining parlance and in literature, it is retained here for the older of two white porphyries in area [west slope of Mosquito Range].

Term first used in Leadville district.

White Beach Sandrock[1]

Miocene, lower: Central Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 114, 337.

Named for exposures at a locality known in 1892 as "White Beach," at northern and western extreme of Little Sarasota Bay, south of Tampa Bay.

White Bluff Formation

White Bluff Marl[1]

Eocene (Jacksonian): Southeastern Arkansas.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 343, table opposite p. 334.

L. J. Wilbert, Jr.. 1953, Arkansas Div. Geology Bull. 19, p. 27–80. Resurrected and emended; includes all marine Jacksonian deposits exposed in southeastern Arkansas. Includes three facies: Pastoria sand member (new) and Caney Point marl member, which are stratigraphically equivalent, and Rison clay member, which in places overlies the other members. Outcrops in northern Jefferson County lie near northern limit of Jacksonian outcrop area in this part of the embayment; formation thins northward and disappears; to the south, it dips beneath Redfield formation (new). Overlies beds of Claiborne group; where Caney Point marl member is present, contact is sharp and exhibits evidence of unconformity; where Pastoria sand member constitutes basal unit, contact is not so well expressed. Type locality designated.

Type locality: White Bluff, a prominent bluff on right bank of Arkansas River, 4 miles east of village of Redfield, in northern Jefferson County.

White Brook Dolomite[1]

Precambrian(?) or Lower Cambrian: Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1931, Geol. Soc. America Bull., v. 42, no. 1, p. 225–226.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137, 143. Commonly white dolomite mottled with pink or purple patches, though very variable in color. Weathers to buff or brown shades. Contains much vein and nodular quartz. Stratification rare; where present, rock is a dolomitic sandstone. Thickness 20 to 75 feet. Underlies West Sutton slate; overlies Pinnacle graywacke. Type locality cited.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1135, 1136, 1145–1147. Extended into Vermont.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 1. Precambrian(?).

Type locality: Exposures around headwaters of White Brook, one-half mile northeast of four corners at West Sutton, Sutton quadrangle, Quebec.

**White Caps Limestone Member** (of Gold Hill Formation)[1]

Cambrian: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

At White Caps mine, Manhattan district.

†White Cliff Limestone[1]

Upper Jurassic: Southwestern to northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 51, 152.

Caps the White Cliffs, Kane County, Utah; also occurs in vicinity of Flaming Gorge, northeast Utah.

†White Cliff Sandstone[1] or Group[1]

Jurassic(?): Southwestern to northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 51, 52, 151.

Type locality: Escarpment known as White Cliffs, in Paria, Kanab, and Rio Virgen region, Kane County.

†White Cliffs Chalk[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas and northwestern Louisiana.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72, 87–88, 188.

Named for exposures at White Cliffs of Little River, Little River County, Ark.

†White Cliffs subchalk[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 7, 88–89, 188.

At White Cliffs of Little River, Little River County, Ark.

**White Cloud Shale Member** (of Scranton Shale)[1]

White Cloud Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 41, 58.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 49 (fig. 11), 210–211. Rank raised to formation in Wabaunsee group. Term Scranton abandoned. Overlies Howard limestone; underlies Happy Hollow limestone. Thickness 30 to 80 feet.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 19. Areal extent given.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2277. Rank reduced to member of Scranton shale here reintroduced as formation with stratigraphic span as assigned to it by Haworth and Bennett (1908). Underlies Happy Hollow limestone member; overlies Howard limestone [Utopia member].

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 14, fig. 5. Thickest formation of Wabaunsee group in area. Gray and green shale; upper half commonly contains many limestone nodules; massive sandstone present at base locally. Full thickness not exposed at surface. Measured at 100 feet in coal mines in Adams County. Overlies Howard limestone; underlies Happy Hollow limestone.

Named from exposures west of White Cloud, Doniphan County, Kans.

White Cone Member (of Bidahochi Formation)

White Cone Series[1]

Pliocene: Northeastern Arizona.

Original reference: A. B. Reagan, 1932, Kansas Acad. Sci. Trans., v. 35, p. 253–258.

E. M. Shoemaker, F. S. Hensley, Jr., and R. W. Hallogen, 1957, U.S. Atomic Energy Comm. TEI Rept. 690, p. 392–394. An informal field designation for member of Bidahochi. Consists mainly of trachybasalt tuff and claystone. This member includes major part of section measured at White Cone by Gregory (1917, U.S. Geol. Survey Prof. Paper 83) which was designated White Cone series by Reagan (1932). It includes beds designated as "volcanic member" as well as beds included in lower part of "upper member" of Repenning and Irwin (1954).

Present in Hopi Volcanic Buttes field and along edge of Black Mesa west and northwest Hopi Volcanic Buttes. A typical section is at White Cone.

White Eagle Rhyolite

Tertiary: Southwestern New Mexico.

W. E. Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 36–37, pl. 1. Porphyritic rhyolite flows, sills and dikes. Rock is aphanitic, cream colored, flow banded, and flow folded. Many dikes in Precambrian granite as much as 1 mile long and 50 feet wide. Sills as thick as 56 feet in Bliss quartzite. Stratigraphic position unknown but possibly equivalent to Mimbres Peak rhyolite.

Named after White Eagle mine, in sec. 34, T. 19 S., R. 9 W. Confined to northern part of Cooks Range, Dwyer quadrangle.

White Earth Clay (in Golden Valley Formation)

Eocene: Western North Dakota.

1958, Great Northern Railway Company Mineral Research and Devel. Dept. Rept. 5, p. 2, 3, 12, 14, 15, map. Light-colored clay in lower part of Golden

Valley formation. Average thickness about 20 feet. South Ross, Lakeside, and East Tioga clays occur in same general area.

Occurs 9 miles north of town of White Earth and 7 miles southeast of Power Lake in secs. 20, 29, and 30, T. 158 N., R. 93 W., Mountrail County.

Whiteface Anorthosite[1]

Precambrian: Northern New York.

Original reference: J. F. Kemp, 1898, New York State Mus. 52d Ann. Rept., v. 1, p. 51–63.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 19–21, table 3, pl. 5. Discussion of Adirondack igneous rocks and their metamorphism. Main massif of anorthositic rocks occupies about 1,200 square miles. Two facies of anorthositic rocks have been defined, named, and differentiated on geologic maps. One facies, the Whiteface, originally described by Kemp, is almost wholly restricted to borders of anorthosite masses or to bands closely involved with Grenville layers and inclusions, characterized by medium granular texture, more dark silicates than core of massif, a milky-white or nearly white feldspar, and usually a distinct foliation. Predominant rock is gabbroic anorthosite, but rocks mapped as Whiteface facies include true anorthosite, gabbroic anorthosite, and anorthositic gabbro. Miller (1918, Geol. Soc. America Bull., v. 29, no. 3) named rock characteristic of the core of the anorthosite massif the Marcy anorthosite. Thus, terms Whiteface and Marcy have been used in sense of formation names rather than of closely defined rock types, and it is with this significance that they are used in this report. Locally there are belts of anorthositic rocks which do not fit requirements for either Marcy or Whiteface facies, and term "transitional facies" is used to cover them. "Border facies," as shown in figure 3, includes both the Whiteface and "transitional" facies and in addition, as along exposed north border of St. Regis-Marcy anorthosite, a facies which has coarse Marcy texture but is commonly gabbroic anorthosite and contains garnet.

Forms summit and southern part of Mount Whiteface, Essex County.

**Whitefield Gneiss** (in Oliverian Plutonic Series)

Middle or Upper Devonian(?): Northwestern New Hampshire.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Dark-gray medium-grained foliated biotite granodiorite gneiss. Included in Oliverian plutonic series.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 49–50, 52. Cut by pink quartz monzonite dikes of the Oliverian plutonic series. Derivation of name.

Named for town of Whitefield, Coos County, where well exposed. Lies in belt extending from Barrett to Riverton.

Whitefish Bay Limestone

Whitefish Bay member (of Alpena limestone stage)

Middle Devonian: Southern Michigan.

W. A. Kelly, 1940, Michigan Acad. Sci. Arts and Letters Sec. Geology and Mineralogy [Guidebook] 10th Ann. Field Excursion, [p. 13, columnar section]. Shown on columnar section as limestone underlying Alpena limestone and overlying Genshaw formation.

Charles Schuchert, [1943], Stratigraphy of the eastern and central United States: New York, John Wiley & Sons, p. 606 (chart 480, 613). Basal member of Alpena stage. Shown on chart as underlying Alpena limestone member and overlying Killians limestone member, Long Lake stage.

Present in Alpena area.

Whitehall Formation (in Beekmantown Group)

Lower Ordovician: New York and Vermont.

John Rodgers, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1576–1577. Beds of Calciferous Division B (Brainerd and Seely, 1890, Am. Mus. Nat. History Bull., v. 3), together with upper 35 feet of their Division A, form a stratigraphic unit. They are separated from Division C above and from Little Falls formation below by unconformities. These beds are here named Whitehall formation. According to Brainerd and Seely, Division B consists of dove-colored limestone, intermingled with light-gray dolomite in massive beds; in lower beds and just above the middle, dolomite predominates; middle and upper beds are nearly pure limestone; thickness of unit 295 feet. Base of Whitehall is made up of 35 feet of alternating sandstone and dolomite. Underlies unnamed formation (Upper Calciferous).

R. H. Wheeler, 1942, Am. Jour. Sci., v. 240, no. 7, p. 518–524. Base of Whitehall is raised to coincide with contact of Little Falls dolomite and Hoyt limestone, and the latter redefined as lower member of Whitehall. Includes Skene member (new) at top. Underlies Tribes Hill formation. Thickness about 160 feet.

John Rodgers, 1952, Geol. Soc. America Guidebook for Field Trips in New England, Nov. 10–12, p. 35 (table 2), 53 (road log). Table of Upper Cambrian and Lower Ordovician formations shows Whitehall formation (Upper Cambrian) above Dewey Bridge dolomite (new) and below Lower Ordovician Baldwin Corner formation (new). Baldwin Corner formation formerly included in original Whitehall.

C. W. Welby, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 22–23. In central Champlain Valley, formation (dolostone) is basal unit of Beekmantown group. Thickness about 300 feet. Underlies Cutting formation. As originally defined, Whitehall included beds that are now placed in underlying Ticonderoga formation (new).

Type section: On Skene Mountain, which rises out of village of Whitehall, Washington County, N.Y. Base of formation exposed not far below brow of mountain on steep west face; base of Division C is exposed in hillock to east just across first road east of mountain.

**Whitehead Granite**[1]

Precambrian: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1905, U.S. Geol. Survey Geol. Atlas, Folio 131.

Named for occurrence about mouth of Whitehead Gulch, Needle Mountain quadrangle.

**Whitehorse Sandstone[1] or Group**

Whitehorse Formation (in Custer Group)

Permian: Western and southern Oklahoma, central southern Kansas, and Texas.

Original reference: C. N. Gould, 1905, U.S. Geol. Survey Water-Supply Paper 148, p. 55.

N. H. Darton, L. W. Stephenson, and Julia Gardner, 1937, Geologic map of Texas (1:500,000): U.S. Geol. Survey. Whitehorse sandstone mapped in Double Mountain group in northwestern Texas.

Robert Roth, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 422–433. Report reviews history of problem of Whitehorse nomenclature and correlation. Term Whitehorse has been loosely applied to sediments of Custer age in Texas.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 4, p. 1526 (fig. 3), 1528. Used as group term to include Marlow, Rush Springs, and Cloud Chief formations.

R. K. DeFord, 1938, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1706. The Whitehorse-Capitan [Eddy County, N. Mex.] is subdivided from top downward into Carlsbad, Yates, Seven Rivers, and Queen. This involves redefinition of the Carlsbad. Gradation of Whitehorse into Capitan disposes of theory that Whitehorse is Triassic.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1802–1811. In Kansas, Whitehorse sandstone can be divided into four members (ascending): Marlow, Relay Creek dolomite, an even-bedded sandstone member, and an upper shale member, the latter two representing Rush Springs-Cloud Chief members of Oklahoma section. Overlies Dog Creek shale; underlies Day Creek dolomite. Cimarron series.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 44–49. Whitehorse is used as group term in Texas-New Mexico area to include (ascending) Grayburg, Queen, Seven Rivers, Yates, and Tansill formations.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Chart of revised terminology shows Whitehorse group above El Reno (San Andres group).

Robert Roth, N. D. Newell, and B. H. Burma, 1941, Jour. Paleontology, v. 15, no. 3, p. 313. Table shows Custer group comprises (ascending) Whitehorse formation, Day Creek dolomite, and Quartermaster formation.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, pl. 2. Correlation chart shows Whitehorse group in central basin platform and Midland basin comprises (ascending) Grayburg formation, Queen sandstone, Seven Rivers formation, Yates sandstone, and Tansill formation; in eastern shelf area comprises (ascending) Childress dolomite member of Marlow formation, Eskota dolomite, and Claytonville dolomite; north-central Texas, near Red River (ascending) Marlow formation, Rush Springs formation, and Cloud Chief gypsum. Name Double Mountain group abandoned in this report.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 81, p. 36 (fig. 15), 37–38. Whitehorse sandstone, in Quartermaster group, comprises (ascending) Marlow sandstone member, Relay Creek(?) dolomite and sandstone member, even-bedded sandstone and siltstone member, and upper shale member. Thickness about 270 feet. Underlies Day Creek dolomite; overlies Dog Creek shale of Nippewalla group.

L. V. Davis, 1955, Oklahoma Geol. Survey Bull. 73, p. 57–81. As used in this report, name Whitehorse is group name applied to all Permian strata above El Reno group and below Cloud Chief formation. Divided into two formations (ascending) Marlow and Rush Springs. Limited above and below by unconformities. Summary of literature.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Formation comprises Marlow sandstone, Relay Creek dolostone, and unnamed member. Underlies Day Creek dolomite; overlies Dog Creek formation of Nippewalla group. Term Quartermaster group not used in this report.

Named for exposures in vicinity of Whitehorse Springs, Woods County, Okla.

†White Iron Granite[1]

Precambrian (Laurentian): Northeastern Minnesota.

Original reference: A. Winchell, 1888, Minnesota Geol. Nat. History Survey 16th Ann. Rept.

Occurs on shores of White Iron Lake, Vermilion district.

†White Mesa Sandstone[1]

Jurassic(?): Northeastern Arizona.

Original reference: H. F. Lunt, 1904, Am. Inst. Mining Engrs. Trans., v. 34, p. 989–990.

Occurs in White Mesa.

**White Mountain Plutonic-Volcanic Series**

White Mountain Magma Series[1]

Permian: New Hampshire and southeastern Vermont.

Original reference: M. P. Billings, 1934, Science, v. 79, no. 2038, p. 55–56.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1894–1914, pl. 1. Chronology in Belknap Mountains, N.H., is (ascending) Moat volcanics, Gilford gabbro, Endicott diorite, Ames monzodiorite, Gilmanton monzodiorite, Belknap syenite, Sawyer quartz syenite, Lake quartz syenite, Albany quartz syenite, Conway granite, and Rowes vent-agglomerate. Also includes Pine Mountain complex; its age relative to other units in series unknown. Numerous leucocratic and melanocratic dikes cut the major intrusives.

Alonzo Quinn, 1937, Geol. Soc. America Bull., v. 48, no. 3, p. 379, 400. Subdivided in Red Hill area of central New Hampshire to include Garland Peak quartz syenite (new), Watson Ledge quartz syenite (new), and other syenites and a granite.

C. R. Williams and M. P. Billings, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1025–1034, 1042. Further description of extrusive and intrusive phases in Franconia quadrangle, New Hampshire. Probably Mississippian.

A. P. Smith and others, 1938, Geologic map and structure sections of the Mount Chocorua quadrangle, New Hampshire (1:62,500): New Hampshire Highway Dept. Red Hill complex and Mount Tripyramid complex assigned to series in Mount Chocorua quadrangle.

C. J. Roy and Jacob Freedman, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 908. Represented by Pawtuckaway complex in Pawtuckaway Mountains of southeastern New Hampshire.

M. P. Billings, 1945, Am. Jour. Sci., v. 243–A, p. 43–47. Geographically extended to Vermont where unit includes rocks of Mount Ascutney area. Description of ring dikes in series.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 35–37, 69–88, 105, 106–107, 129–135, 145–146, 182–183, 186. Summary discussion of plutonic-volcanic series. Rocks are massive and rarely show foliation and banding. Hypidiomorphic granular texture typical. Mineralogically characterized by amphiboles, pyroxenes, and olivines even in syenites and granitic rocks; muscovite absent. Pegmatites very rare. Mississippian(?). Derivation of name.

H. W. Jaffe, H. T. Evans, Jr., and R. W. Chapman, 1956, Am. Mineralogist, v. 41, nos. 5–6, p. 474, 485. Includes Devils Slide syenite (new) in Percy quadrangle, New Hampshire.

U.S. Geological Survey currently designates the age of the White Mountain Plutonic-Volcanic Series as Permian on the basis of a study now in progress.

Type area: North Conway quadrangle, New Hampshire. No one type locality can be designated. Named for extensive development in White Mountains of New Hampshire.

White Mountain Series[1]

Precambrian(?) and younger: Northern New Hampshire.

Original reference: C. H. Hitchcock, 1869, New Hampshire 1st Rept. on geology and mining.

White Mountain region.

White Oak Mountain Sandstone[1]

White Oak Mountain Sandstone (in Red Mountain Group)

Silurian (Albion Series): Southeastern Tennessee and northeastern Georgia.

Original reference: N. Sayler, 1866, Geologic map of Tennessee.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Red Mountain group, Albion series. Underlies Clinton formation.

Named for White Oak Mountain, James and Bradley Counties, Tenn.

†White Pine Shale[1] or Group

Mississippian: Northeastern Nevada and eastern California.

Original reference: A. Hague, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 255–267.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 8 (table 1), 43–46. Term Diamond Peak series used to apply to post-Devils Gate sedimentary rocks in Roberts Mountains region; term is used in preference to extending Hagues' White Pine shale and Diamond Peak quartzite into area.

C. W. Merriam and C. A. Anderson, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1690–1691. Because stratigraphic relations of true White Pine formation in White Pine district are not well understood, it appears undesirable to use this term for dark shale in Eureka and Roberts Mountains area. In this report, term Diamond Peak beds is used to include not only original Diamond Peak quartzite of Diamond Peak (Eureka district) but also underlying black shales and sandy interbed referred by Hague (1892, U.S. Geol. Survey Mon. 20) to White Pine shale.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2), 149. In recommended revisions of stratigraphic units in Great Basin, it is proposed that White Pine shale be subdivided to include (ascending) Pilot shale, Joana limestone, and Chainman shale members. Term White Pine shale to be used in Roberts Mountains and Lone Mountain area, Eureka district, Ely district, and Pioche districts, Nevada, and Confusion and House Ranges, and Ibex area, Utah.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 56–57. Problems of nomenclature and correlation of White Pine shale and Diamond Peak quartzite reviewed. Usage of White Pine shale as proposed by Easton and others rejected; their proposal has advantage of retaining White Pine for dominant black-shale sequence but does not provide for satisfactory treatment of the thick gradational zone between the black shales and coarser clastics characteristic of Hague's Diamond Peak. Proposed to use Diamond Peak formation for coarse clastic part of upper Mississippian sequence where it can be separated from underlying black shales and to adopt Spencer's name of Chainman for lower unit, where it can be mapped separately.

R. L. Langenheim, Jr., and Herbert Tischler, 1960, California Univ. Pubs., Geol. Sci., v. 38, no. 2, p. 108 (fig. 5), 110. Discussion of Quartz Spring area, Inyo County, Calif. For purposes of expressing regional stratigraphic relationships, many already proposed stratigraphic names are redundant. Figure 5 presents condensed set of already proposed names, as restricted and applied to units of regional significance. These names, selected on basis of priority, have been utilized for rock bodies that most nearly approach original author's concept of the formation. Names Peers Spring formation and Chainman shale are retained for formational units within White Pine group, although these names have frequently been employed in synonymous sense. Name White Pine has been retained for group because it was first applied to entire detrital sequence (Hague, 1883).

Walter Sadlick, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Field Conf., p. 81–90. Discussion of aspects of Chainman stratigraphy. Chainman is recognized as valid stratigraphic unit. White Pine shale seems to be correlative with Pilot shale, Joana limestone, and Chainman formation; if so, term White Pine should be suppressed.

R. L. Langenheim, Jr., and others, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 149 (fig. 1), 151. White Pine shale, in Ely No. 3 quadrangle, is 950 feet thick and consists of 50 feet of calcareous siltstone assigned to Peers Spring member, succeeded by 900 feet of black fissile shale belonging to Chainman member. Overlies Joana limestone, disconformity; underlies Scotty Wash quartzite with contact gradational. Assigned to Late Mississippian because of goniatite occurrences in surrounding regions.

Named for exposures in White Pine mining district (now known as Hamilton), White Pine County, Nev.

**Whiteport Dolomite Member** (of Rondout Limestone)

Whiteport Waterlime

Lower Devonian: Southeastern New York.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey, Map and Chart Ser., No. 1. Recent studies by L. V. Rickard (in press) suggest that Manlius, upper Chrysler, and Whiteport (Upper Cement of the Rondout) are Devonian, pending precise placement of the Silurian-Devonian contact in Europe and more refined intercontinental correlations.

U.S. Geological Survey currently classifies the Whiteport as a member of the Rondout Limestone and designates its age as Lower Devonian on the basis of a study now in progress.

Town of Whiteport is in Ulster County.

**White Quail Limestone Member** (of Minturn Formation)

White Quail Limestone

Pennsylvanian and Permian(?) : Northwestern Colorado.

S. F. Emmons, 1898, U..S. Geol. Survey Geol. Atlas, Folio 48, p. 4. Commonly, a single limestone bed about 20 feet thick. Occurs above Robinson limestone and below Jacque Mountain limestone.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 203–204, 208–211. Limestone which in Pando area lies 150 to 200 feet above Elk Ridge limestone member of Minturn, or about 5,000 feet above Belden shale, has been known as White Quail limestone in Kokomo district. It is here designated White Quail limestone member of Minturn. Consists of massive dark-gray oolitic limestone and small lenses of dolomite; locally black dolomite and fossiliferous dolomitic shale. Thickness 8 to 10 feet. Separated from overlying Jacque Mountain member by 950-foot interval of siltstone, grit, conglomerate, arkose, and shale. Age uncertain; more likely Pennsylvanian than Permian.

Well exposed on northeastern slope of Elk Ridge, near Kokomo, Summit County. Named derived from White Quail mines.

White Ranch Limestone (in Graham Formation)[1]

Pennsylvanian: Central Texas.

Original reference: F. M. Bullard and R. H. Cuyler, 1936, Texas Univ. Bull. 3501, p. 197, 222.

Typically exposed on White Ranch along west side of Bluff Creek, McCulloch County.

**White Raven Quartz Monzonite**[1]

Eocene: Central northern Colorado.

Original reference: P. G. Worcester, 1921, Colorado Geol. Survey Bull. 21, p. 33–34.

Named for White Raven mine, Boulder County.

White Ridge Limestone Member[1] (of Jefferson Limestone)

Upper Devonian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 42.

Charles Deiss, 1939, Geol. Soc. America Spec. Paper 18, p. 15, 49, 50. Basal Devonian.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4 (facing p. 1788). Age shown as Upper Devonian on correlation chart.

Named for White Ridge. Forms lower part of slope above saddle on south side of peak forming west end of White Ridge, in S½ sec. 16, T. 22 N., R. 11 W.

White Ridge Quartzite or Formation

Precambrian: Central New Mexico.

J. T. Stark and E. C. Dapples, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1936. Older than Sevilleta rhyolite (new); younger than Blue Springs muscovite schist (new); intruded by Los Pinos granite (new).

J. T. Stark and E. C. Dapples, 1946, Geol. Soc. America Bull., v. 57, no. 12, pt. 1, p. 1133–1134. Near base, formation composed of massive quartzite beds 2 to 7 feet thick which vary from white to light pink, tan, and red. Impure shaly beds occur throughout formation and become prominent near top, where beds vary from light pink to red. Thin beds of gray quartzite 1 to 2 feet thick alternate with schistoze zones of gray and white sericitic schist near top. Thickness ranges from 3,000 to 3,700 feet in central part of belt. Near Sierra Montosa it thins to 900 feet.

Named after White Ridge, a prominent ridge on eastern side of Precambrian section of Los Pinos Mountains. Forms high eastern ridge crests in northern half of Los Pinos Range. Outcrop maintains width of 1 mile for 5 miles south of Highway 60, then narrows to less than one-half mile and continues southward another 5 miles.

**White Rim Sandstone Member** (of Cutler Formation)[1]

Permian: Southeastern Utah.

Original reference: A. A. Baker and J. B. Reeside, Jr., 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 11, p. 1423, 1425, 1436, 1444, 1445, 1446.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 39 (table), 45, pl. 1. White Rim, as mapped in Henry Mountains, is restricted to white crossbedded sandstone at top of Cutler. Thickness as much as 250 feet. Conformably overlies Organ Rock tongue; in most places White Rim and Organ Rock are separated by sharp bedding plane, but at some places where color changes from red to white within a massive sandstone bed, boundary was mapped at next higher bedding plane. Unconformably underlies Moenkopi formation.

Exposed in escarpment between Green and Colorado Rivers, known as the White Rim.

**White River Group[1] or Formation[1]**

Oligocene: South Dakota, northeastern Colorado, eastern Montana, Nebraska, North Dakota, and Wyoming.

Original reference: F. B. Meek and F. V. Hayden, 1858, Philadelphia Acad. Sci. Proc. 1857, v. 9, p. 119, 133.

A. L. Lugn, 1938, Am. Jour. Sci., v. 36, 5th, no. 213, p. 227; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1250–1251, 1264 (table 1). Group, in

Nebraska, attains or exceeds thickness of 700 feet. Comprises Chadron and Brule formations. Underlies Arikaree group; overlies Cretaceous shale formations, the Pierre, and others.

A. R. Edwards, 1941, Wyoming Geol. Survey Bull. 32, p. 10–13. As used in this report, term White River group includes Chadron, Brule, and Arikaree formations.

F. B. Van Houten, 1950, U.S. Geol. Survey Oil and Gas Inv. Map OM–113. White River formation of Granger (1910, Am. Mus. Nat. History Bull., v. 28) in Fremont County, Wyo., includes (ascending) unnamed channel deposit, Beaver Divide conglomerate member, and unnamed upper part. Upper part is divided into three units. Lower unit is massive, light-gray, tuffaceous siltstone and fine-grained sandstone with very little clay or coarse sand. Next is a thicker unit consisting of massive pale grayish-orange siltstone and fine-grained sandstone. Uppermost unit is massive, grayish-orange, locally cross-bedded arkosic conglomerate 60 to 80 feet thick, resting on erosional unconformity that has several feet of relief. Thickness 225 to 485 feet. Overlies middle and upper Eocene rocks. Underlies Miocene(?) rocks.

P. O. McGrew, 1953, Wyoming Geol. Assoc. Guidebook 8th Ann. Field Conf., p. 61–63. In Wyoming, it is customary to use term White River as formation name recognizing that to east the unit becomes a group divisible into two distinct formations.

E. C. Galbreath, 1953, Kansas Univ. Paleont. Contr. 13, Vertebrata, art. 4, p. 12–18, 27 (fig. 8). Formation in northeastern Colorado comprises (ascending) Horsetail Creek (of Chadron age), Cedar Creek (of Orellan age), and Vista (new) members. Underlies Pawnee Creek formation; overlies Cretaceous sandstones. Late lower Oligocene to early upper Oligocene, inclusive.

F. B. Van Houten, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–140. Formation in Long Creek-Beaver Divide area, Fremont County, Wyo., includes (ascending) Sand Draw sandstone lentil (new), Beaver Divide conglomerate member, and unnamed upper part. Overlies middle and upper Eocene rocks and underlies Miocene(?) rocks.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 70–71, pls. 6, 8. Formation restricted to two small outliers on subsummit uplands of Bighorn Mountains and consists mainly of marlstone, conglomerate, and soft brown bentonitic clay. Thickness 200 to 300 feet along North Fork of Crazy Woman Creek. Formation fills pre-Oligocene valleys of high relief. Stratigraphically above Wasatch formation.

John de la Montagne and W. C. Barnes, 1957, Guidebook to the geology of the North and Middle Parks Basin, Colorado: Rocky Mountain Assoc. Geologists, p. 55–60. White River formation of this report is equivalent of Chadron. Thickness about 400 feet. Underlies North Park formation; overlies Coalmont formation.

J. C. Harksen, 1960, Geology of the Sharps Corner quadrangle (1:62,500): South Dakota Geol. Survey. Group comprises (ascending) Brule formation and Sharps formation (new). Underlies Arikaree group.

T. A. Steven, 1960, U.S. Geol. Survey Bull. 1082–F, p. 350–353, pl. 12. Formation described in Northgate district, Colorado, where it consists of grayish to white tuffaceous silt and clay beds that partly fill old valleys cut in Precambrian rocks. Underlies North Park formation.

Named for occurrence near mouth of White River, S. Dak.

†White River Limestone[1]

Lower Ordovician: Southwestern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 338–340.

Named for White River.

Whiterock Stage

Middle Ordovician (Mohawkian): North America.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 7–8, chart 1 (facing p. 130). Mohawkian series divided into five stages of which the Whiterock is lowermost. Brachiopod fauna taken from rocks deposited during this stage is characterized by numerous orthids, early strophomenids, plectambonitids, and decline of Syntrophiacea. Followed by Marmor stage (new). Discussion of unsuitability of older stage terms, such as Chazyan, Black River, Bolarian, Hatterian, and Hunterian.

Name is taken from Whiterock Canyon in Monitor Range, south center of Roberts Mountains quadrangle, Nevada. Rocks of interval well exposed in parts of Antelope, Monitor, and Toquima Ranges.

**Whiterock Bluff Shale Member** (of Santa Margarita Formation)[1]

Whiterock Bluff Shale Member (of Monterey Shale)

Miocene, upper: Southern California.

Original reference: W. A. English, 1916, U.S. Geol. Survey Bull. 621, p. 191–215.

M. L. Hill, S. A. Carlson, T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2874 (fig. 1), 2978 (fig. 3), 2990–2991. Reallocated to member status in Monterey shale. Conformably overlies Saltos shale member (new); conformably underlies Santa Margarita sand. Grades southeastward into upper part of Branch Canyon sandstone (new). Thickness in type area 1,200 feet.

Type area: Near Whiterock Bluff, sec. 25, T. 11 N., R. 28 W., north side Cuyama Valley, Caliente Mountain quadrangle. Well exposed on both flanks of Caliente Range. Traceable along northeast flank of La Panza Range into restricted Monterey shale as mapped by Bramlette and Daviess (1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. May 24).

**White Sage Formation**[1]

Eocene(?): Western Utah.

Original reference: T. B. Nolan, 1935, U.S. Geol. Survey Prof. Paper 177.

Occurs only in northwest part of Gold Hill quadrangle. Named for White Sage Flat in Gold Hill district.

Whites Bend Limestone[1]

Silurian (Niagaran): Western Tennessee.

Original reference: A. F. Foerste, 1901, Geol. Soc. America Bull., v. 12, p. 397, 402.

Named for Whites Bend, Davidson County.

**Whitesburg Limestone Member** (of Blockhouse Shale)

Whitesburg Limestone (in Blount Group)[1]

Middle Ordovician: Northeastern Tennessee and western Virginia.

Original reference: E. O. Ulrich, 1924, Tennessee Dept. Ed., Div. Geology Bull. 28, p. 34; Bull. 31, p. 16.

R. B. Neuman, 1956, U.S. Geol. Survey Prof. Paper 274–F, p. 149. Rank reduced to member status in Blockhouse shale (new). Thickness at type locality of Blockhouse 5 to 20 feet. At base of formation. Overlies Lenoir limestone.

Type locality: Two miles southeast of Whitesburg, Hamblen County, and 1½ miles southwest of Bulls Gap, Tenn.

Whites Creek Beds Member (of Shoal River Formation)

Miocene, middle: Western Florida.

H. R. Smith, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 2, p. 270 (fig. 2), 271 (table 1), 275. Proposed for member of Shoal River formation either older than, or in part equivalent to, typical Shoal River as exposed at Shell Bluff on Shoal River. At type section, about 12 feet thick; consists of blue shell marl, gray shell marl in places indurated to form hard lumps, brown and yellow sand; fossiliferous.

Type locality: In gulch about 200 feet south of road from Knoxhill to Eucheeana on east bank of Whites Creek, Walton County.

Whites Crossing Coquina Member (of Chappel Formation)

Mississippian: Central Texas.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 28. Consists of several lenticular layers of massive limestone made up of crinoidal fragments and poorly preserved fossils; occurs in limestone sinks and depressions in the Ellenburger where it has escaped post-Chappel erosion; deposits range in thickness up to 60 feet or more depending upon the depth of the sink hole. Chappel comprises [ascending] King Creek marl (new), Ives conglomerate, Espey Creek limestone (new), and Whites Crossing coquina members.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 810 (footnote). Plummer's Whites Crossing coquina referred by him to Chappel formation is echinodermal limestone facies in lower part of Barnett formation.

Well exposed on east side of Llano River and on north side of road at White's Crossing, Mason County.

**Whiteside Granite**[1]

Ordovician to Devonian: Western North Carolina and northwestern South Carolina.

Original reference: A. Keith, 1907, U.S. Geol. Survey Geol. Atlas, Folio 147, p. 4.

W. R. Griffitts and W. C. Overstreet, 1952, Am. Jour. Sci., v. 250, no. 11, p. 787. Geographically restricted to area of its type locality where it is in part medium-grained biotite-muscovite-quartz-monzonite, having composition that is common in granitic rocks through much of southeast; also includes coarse-grained pegmatitic rock dissimilar to Toluca and Cherryville quartz monzonites (both new). Both Toluca and Cherryville were included in unit assigned to Whiteside granite by Keith and Sterrett (1931, U.S. Geol. Survey Bull. 660–D, p. 130–132).

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 24; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. As mapped, Whiteside granite is essentially Whiteside granite as originally named and described by Keith. Paleozoic.

Named for exposures in cliffs of Whiteside Mountain, Jackson County, N.C.

White Spot Sandstone[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 1, p. 165, 166.

At White Spot on mountain behind Reading, Berks County.

Whitesville Formation (in Chadakoin Group or Conneaut Group)

Whitesville Member (of Chadakoin Formation)

Upper Devonian: Southwestern New York.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 17 (fig. 4), 37–47. Whitesville formation is lower 300 feet of what has been called by Chadwick (1924) the Chadakoin formation. Overlies Hinsdale formation; underlies Germania formation (new). Beds are twofold in character: those of marine deposition and those of "Catskill" type of deposition. Nearly horizontal beds with marine fossils occur near Whitesville, but beds deposited at the same time 10 to 15 miles north are thinly laminated crossbedded green sandstone, bearing few or no marine fossils.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 18. Rank reduced to member status in Chadakoin formation. Underlies Germania member; overlies Hinsdale member.

L. V. Rickard, 1957, New York State Geol. Assoc. [Guidebook] 29th Ann. Mtg., p. 17 (table 2), 19. Formation in Chadakoin group. Inasmuch as Upper Devonian strata are still not thoroughly understood, a more or less permanent classification satisfactory to majority of workers may not be obtained for some time.

Named for exposures near village of Whitesville, Wellsville quadrangle, Allegany County. [Tesmer and Rickard state type locality is near Whitesville.]

**Whitetail Conglomerate[1]**

Tertiary(?): Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

P. A. Wood, 1959, Arizona Geol. Soc. Guidebook 2, p. 60. In Globe-Ray area, consists of conglomerate up to about 1,000 feet thick that rests unconformably on eroded surfaces of older rocks and is conformably overlain by dacite flow. Near Ray, dacite is overlain by 125 feet of conglomerate referred to by Ransome (1923, U.S. Geol. Survey Geol. Atlas, Folio 217) as Gila conglomerate. Tentatively considered younger than middle Tertiary.

T. F. Stipp and H. M. Beikman, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–201. Shown on stratigraphic section as Tertiary(?).

D. W. Peterson, 1960. U.S. Geol. Survey Geol. Quad. Map GQ–128. Thickness 0 to 200 feet in Haunted Canyon quadrangle. Was deposited in low-lying areas on erosion surface of considerable relief and may overlie any of the older formations. Tertiary(?).

Named for exposures in Whitetail Gulch and Whitetail Spring, Globe quadrangle.

White Tank Monzonite

Jurassic(?): Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 493. Megascopically monzonite, light gray to light pinkish gray, medium to moderately coarse-grained, contains several percent of mafic minerals; massive with faint primary foliation. Plainly and sharply cuts other rocks—Gold Park gabbro-diorite (new) and Pinto gneiss (new). Contains roof pendants of Palms granite (new). Late Mesozoic.

J. J. W. Rogers, 1958, Geol. Soc. America Bull., v. 69, no. 4, p. 449–464. Textural and spectrochemical study.

Named because of its typical occurrence in vicinity of White Tank, 10 miles south of Twentynine Palms, Riverside County.

†White Wall Sandstone[1]

Jurassic(?): Southeastern Utah.

Original reference: B. S. Butler, 1920, U.S. Geol. Survey Prof. Paper 111, p. 619.

In Abajo (Blue) Mountains, San Juan County.

**Whitewater Formation** (in Richmond Group)[1]

Upper Ordovician: Southeastern Indiana, north-central Kentucky, and southwestern Ohio.

Original reference: J. M. Nickles, 1903, Am. Geologist, v. 32, p. 208, 218.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 110. In Ohio, Whitewater formation is shown on page 110 as including (ascending) Weisburg, Saluda, and Oxford members. Stratigraphic chart and page 114 shows Whitewater sequence (ascending) Lower Whitewater, Saluda, and Upper Whitewater members. Calcareous shales with thin-bedded limestones. Thickness 60 to 100 feet. On chart, occurs above Liberty formation and below Silurian Elkhorn formation.

E. B. Branson, M. G. Mehl, and C. C. Branson, 1951, Jour. Paleontology, v. 25, no. 1, p. 2, fig. 1. Formation geographically extended into west-central Kentucky where it includes Saluda member. Overlies Liberty formation.

James Conklin, 1952, Kansas Acad. Sci. Trans., v. 55, p. 130. In Oldham County, Kentucky, Upper Richmond, which is similar to that of Ohio, is divided into Liberty formation, Lower Whitewater, Saluda, and Upper Whitewater members of Whitewater formation.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, p. 13–15, pl. 1. Thickness of formation in Indiana 4 to 35 feet. As described at stop 4 on itinerary, it is 14 feet thick and consists of dark-gray to black finely crystalline limestone in lower part and interbedded black limestone and shale in upper part; underlies Ordovician Brassfield limestone. North of Cross Plains, Brassfield is locally missing and Silurian Osgood formation rests on the Whitewater. Stratigraphic chart shows that Whitewater overlies Saluda formation and underlies Elkhorn where it is present.

W. C. Sweet and others, 1959, Jour. Paleontology, v. 33, no. 6, p. 1030. Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn formations define Richmond stage of the Cincinnatian.

Named for Whitewater River, at Richmond, Wayne County, Ind.

**Whitewater Creek Rhyolite**[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures in steep canyons along lower reaches of Whitewater and Mineral Creeks, Mogollon district.

**Whitewood Limestone**[1] **or Dolomite**

Upper Ordovician: Western South Dakota and northeastern Wyoming.

Original reference: N. H. Darton, 1904, Geol. Soc. America Bull., v. 15, p. 383.

W. M. Furnish, E. J. Barragy, and A. K. Miller, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 10, p. 1329–1341. In northern Black Hills, Middle(?) Ordovician fossils have been found to occur throughout approximately 70 feet of shale and siltstone beds immediately below typical Whitewood dolomite. Concluded that strata involved should be included tentatively with overlying Whitewood formation (Ordovician) rather than with underlying Deadwood formation (Cambrian) as has been done heretofore.

M. R. McCoy, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 44, 45, 46. Referred to as Whitewood dolomite. Thickness 50 to 60 feet. Underlies Englewood dolomite with angular unconformity; overlies Roughlock siltstone (new).

M. R. McCoy, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 25–30. Thickness Whitewood dolomite about 50 feet at type section; underlies Englewood dolomitic shale; overlies Roughlock siltstone with gradational contact. Ordovician (Champlainian-Cincinnatian.)

Type section (McCoy): Sec. 13, T. 5 N., R. 3 E., Lawrence County, S. Dak. Named for exposures at Whitewood Canyon below Deadwood.

Whitingham Schist[1]

Upper Cambrian(?): Southeastern Vermont.

Original reference: G. D. Hubbard, 1924, Vermont State Geologist 14th Rept., p. 276–278, map.

Named for exposures in Whitingham Township, Windham County.

Whitmore Point Member (of Moenave Formation)

[Triassic]: Southwestern Utah.

R. A. Cadigan, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI-700, p. 126 (fig. 26), 127. Limy arkoses about 61 feet thick. Underlies Springdale sandstone member; overlies Dinosaur Canyon member.

Type locality and derivation of name not given. Report discusses area near St. George.

Whitmores Ferry Amphibolite[1]

Pre-Triassic: Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 190, 194.

Crops out at Whitmores Ferry, in North Sunderland, Old Hampshire County.

Whitney Member (of Brule Formation)

Oligocene, upper: Northwestern Nebraska, eastern Colorado, southwestern South Dakota, and eastern Wyoming.

C. B. Schultz and T. M. Stout, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1921; 1941, Guide for a field conference on the Tertiary and Pleistocene of Nebraska: Nebraska Univ. State Mus. Spec. Pub., p. 4 (table 1), 37, fig. 9. Proposed for massive clays of upper or *Leptauchenia* zone part of Brule formation. Thickness about 290 feet. Disconformably overlies Orella member (new).

A. L. Lugn and B. W. Brown, 1952, (abs.) Geol. Soc. America Bull., v. 63, pt. 2, p. 1384. Geographically extended into Bear Lodge Mountains, Wyo. Erosional unconformity separates Whitney from 11 to 16 feet of overlying Ogallala "mortar beds" of lower Ash Hollow formation.

C. B. Schultz and T. M. Stout, 1955, Nebraska Univ. State Mus. Bull., v. 4, no. 2, p. 42 (fig. 12), 44–46, figs. 3, 10, tables 1, 2. Three divisions of member recognized throughout much of outcrop belt in western Nebraska, eastern Wyoming, and in area southeast of Oelrichs, S. Dak. Recognition of these divisions is largely on the basis of separating beds of volcanic ash. Member consists chiefly of massive pinkish-buff silt and silty clay. Thickness in Crawford area, Nebraska, 278 feet; 460 feet in Scotts Bluff and Torrington areas, western Nebraska and eastern Wyoming. Bayard paleosol complex (new) locally caps member; elsewhere there is disconformity at contact; underlies Gering formation. Late Oligocene.

T. M. Stout, 1960, Nebraska Acad. Sci. Proc. 70th Ann. Mtg., p. 15. Proposed that classification of Oligocene sediments in Nebraska (Schultz and Stout, 1955) be extended into northeastern Colorado and eastern Wyoming. Exposures south and west of Peetz, Logan County, Colo., display the Lower ash and Upper ash beds of Whitney member of Brule. When these beds are traced westward, it is evident that the Upper ash is the "White marker bed" of Galbreath (1953, Kansas Univ. Paleont. Contr., Vertebrata, art. 4); thus basal part of Galbreath's "Vista" is equivalent to Upper Whitney (Whitney C) of Nebraska, and remainder of the "Vista" is probably Miocene (Gering and younger). Remaining Whitney as well as the Orella and Chadron units are like those in Nebraska.

Type locality: East of Toadstool Park along escarpment near Round Top, in secs. 16 and 21, T. 33 N., R. 53 W., about 16 miles west and 3 miles north of Whitney, Dawes County, Nebr.

Whitneyan Age

Oligocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 11, pl. 1. Provincial time term, based on Whitney member of Brule formation, type locality, Whitney, northwestern Nebraska. Includes old term, "*Protoceras-Leptauchenia* beds," used in the most extended sense. Covers interval between the Orellan (Oligocene) and Arikareean (Miocene) ages. Report defines 18 provincial time terms, based on mammal-bearing units, for the North American continental Tertiary. [For sequence see under Puercan.]

**Whitsett Formation** (in Jackson Group)

†Whitsett Beds[1]

Eocene, upper: South-central Texas.

Original reference: E. T. Dumble, 1924, Am. Assoc. Petroleum Geologists Bull., v. 8, p. 424–436.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2624 (fig. 1), 2626 (table 1), 2631–2634. Formation includes (ascending) Stones Switch sandstone, Dubose, Calliham sandstone, and Fashing clay members. Characterized chiefly by preponderance of sandstone near base and of carbonaceous tuffs and bentonitic clays near top. Overlies McElroy formation (redefined); overlain by Olmos sand of Ellisor (1933); this sand is apparently overlapped by the Catahoula. Additional information on type locality.

Type locality: Bluff 90 feet in height, on east bank of Atascosa River, near Whitsett's house in sec. 48, Reiffert and Forbese 109-acre tract of Juan Houligan Survey. Bluff is in Atascosa County, just northwest of Live Oak County line, and extends from 6½ to 7½ miles south of Campbellton, Atascosa County, and 1.7 miles N. 60°–70° W. of Whitsett, Live Oak County.

Whitsett Limestone Lentils (in Myrtle Formation)[1]

Upper Jurassic and Upper Cretaceous: Southwestern Oregon.

Original reference: J. S. Diller, 1898, U.S. Geol. Survey Geol. Atlas, Folio 49.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2778–2780. Some of Diller's Whitsett limestone lentils are included in Riddle formation (new). Lentils are gray to white or locally pink, range from 15 to 60 feet or more in thickness, are thin- to thick-bedded, and may be dense, coarsely crystalline, locally oolitic, or fossiliferous. Most common megafossils are fragments of pelecypods and echinoids. In one lentil exposed in Roberts Creek in secs. 14 and 15, T. 28 S., R. 5 W., James Storr collected fossils that T. W. Stanton identified as *Opis californica* Stanton and *Hoplites* cf. *H. dilleri* Stanton (Diller, 1898). The ammonite appears to be an immature specimen of Portlandian genus *Durangites*. Its presence indicates that at least one of the limestone lentils is middle Portlandian in age. Probably, some clastic beds associated with the limestone lentils likewise belong in Riddle and Days Creek (new) formations. Age problem of Diller's Whitsett lentils is complicated by fact that some lentils contain microfossils of Cenomanian or Turonian age.

Occur near J. H. Whitsett's secs. 14 and 15, T. 28 S., R. 5 W., Roseburg quadrangle.

Whitt Group

Pennsylvanian (Canyon Series): North-central Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Beds between the Millsap Lake and Graford (restricted) groups are divided into lower Lone Camp group and upper Whitt group with common boundary at disconformity between Strawn and Canyon series. Includes (ascending) Salesville, Keechi Creek, and Palo Pinto formations. Group is nearly equivalent to Brownwood shale.

M. G. Cheney and D. H. Eargle, 1951, Geologic map of Brown County, Texas (1:62,500): Texas Univ. Bur. Econ. Geology. Includes Brownwood shale at base and Adams Branch limestone at top. Overlies Lone Camp group; underlies Graford formation.

R. J. Cordell and others, 1954, *in* Abilene Geol. Soc. Guidebook Nov. 19–20, fig. 2 (strat. chart). Revision suggested since Strawn-Canyon boundary has been placed at faunal break at top of Salesville shale and base of Turkey Creek sandstone and conglomerate member of Keechi Creek shale.

Named for village of Whitt in northwest Parker County near which included formations appear from beneath Comanche overlap.

**Whitwell Shale** (in Lee Group)[1]

**Whitwell Shale Member** (of Crab Orchard Mountains Formation)

Whitwell Member (of Lee Group)

Whitwell Shale (in Crab Orchard Mountains Group)

Lower Pennsylvanian: Eastern Tennessee and northern Georgia.

Original reference: Charles Butts and W. A. Nelson, 1925, Tennessee Div. Geology Bull. 33-D, p. 7, pl. 4.

H. R. Wanless, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1941. Listed as member of Lee formation.

V. H. Johnson, 1946, Coal deposits on Sand and Lookout Mountains, Dade and Walker Counties, Georgia: U.S. Geol. Survey Prelim. Map. Geographically extended into northern Georgia where it is 6 to 50 feet thick. Underlies Bonair sandstone; overlies Sewanee member of Lookout sandstone.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 4, 19, pls. 2, 3, 4. Assigned to Crab Orchard Mountains group (new). Thickness 60 to more than 200 feet; 75 to 100 feet in type area. Includes Richland and Sewanee coal. Underlies Newton sandstone; grades conformably downward into Sewanee conglomerate. In northwestern part of Cumberland Plateau, forms part of Fentress formation. Pottsville series.

U.S. Geological Survey currently classifies the Whitwell Shale as a member of the Crab Orchard Mountains Formation on the basis of a study now in progress.

Named for exposures west of Whitwell, Marion County, Tenn.

†Wichita Conglomerate (in Clear Fork Formation)[1]

Permian: Central northern Texas.

Original reference: E. C. Case, 1907, Am. Mus. Nat. History Bull. 23, p. 662-664.

Named for Big Wichita River, near Seymour-Vernon Road, Baylor County.

**Wichita Group**[1] or **Formation**[1]

Lower Permian: Northern and central Texas and western Oklahoma.

Original reference: E. T. Dumble and W. F. Cummins, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxix, 188, pl. 3.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 42. Cheney proposes to abandon term Wichita. He places part of old Wichita group in Wolfcamp series and subdivides remaining part in Leonard series into three groups (ascending): Belle Plains, Clyde, and Lueders. These three groups are not distinguishable in subsurface of west Texas. Proposed here to continue term Wichita group (restricted) for beds of Leonard age between base of Clear Fork group and top of

Wolfcamp series. Wichita group (restricted) in Fisher County is about 800 feet thick from top of Lueders limestone to top of Fisk formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 97. Term Wichita group discarded. Terms Pueblo, Moran, Putnam, Admiral, Belle Plains, Clyde, and Lueders raised to rank of group. Pennsylvanian-Permian boundary placed at base of Pueblo group. Wolfcamp-Leonard boundary placed at top of Fisk formation (new) in Admiral group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80. Group comprises (ascending) Pueblo, Moran, Putnam, Admiral, Belle Plains, Clyde, and Lueders formations. Overlies Cisco group; underlies Clear Fork group. Permian.

G. W. Chase, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 2028–2035. In Wichita Mountains, Okla., formation includes Post Oak conglomerate member (new). Member is equivalent to Wellington formation and may be as old as upper part of Pontotoc group and as young as lowermost part of Garber sandstone.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 266–276, pl. 11. Group in north-central Texas includes rocks between base of Waldrip shale member of Pueblo formation and top of Lueders limestone. Comprises (ascending) Pueblo, Moran, Putnam, Admiral, Belle Plains, and Clyde formations, and Lueders limestone. Includes all rocks assigned to Wolfcamp series and about half of those assigned to Leonard series. Rocks of Pennsylvanian-Permian transition zone are included in lower part of Waldrip shale member of Pueblo. Overlies Pennsylvanian Cisco group; underlies Clear Fork group. Thickness ranges from about 1,650 feet in northern Callahan and northwestern Eastland Counties to 1,550 feet in central Shackelford and western Stevens Counties, and to 1,800 feet north of Clear Fork of Brazos River in Young and Throckmorton Counties. Channel deposits near base of group locally may increase thickness as much as 200 feet.

Named for Wichita River and Wichita County, Tex.

Wichitan series[1]

Carboniferous: Texas.

Original reference: C. R. Keyes, 1928, Pan-Am. Geologist, v. 49, p. 130, 133.

Wichman Formation

Pliocene, upper: Western Nevada.

D. I. Alexrod and W. S. Ting, 1960, California Univ. Pubs. Geol. Sci., v. 39, no. 1, p. 2–5. Consists of light-colored poorly indurated fluvio-lacustrine sediments and associated rhyolite ash; well-bedded pumiceous claystone, diatomaceous mudstone, sandstone, and conglomerate; rhyolitic tuff; rhyolitic breccia-agglomerate. Thickness not determined precisely; approximately 500 feet. Faults duplicate part of upper section. Lower part of section in fault contact with three formations: Excelsior, Kate Peak, and Coal Valley.

Type area: Four miles north of Wichman post office, Lyon County, and 1 mile northwest of entrance to East Walker Ranch headquarters. Exposed on east side of Pine Grove Mountains from vicinity of Wichman northward for over 15 miles; in southern part of area, crops out discontinuously under alluvial cover.

Wickcliff Sandstone (in Chester Group)[1]

Mississippian: Southern Indiana and western central Kentucky.

Original reference: C. A. Malott, 1925, Indiana Acad. Sci. Proc., v. 34, p. 108–132.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 7. Replaced by Waltersburg sandstone. Local Indiana names of upper Chester are dropped and formations given names of standard Chester column.

Named for exposures in ravines around Wickcliff, Crawford County, Ind.

†Wicker Formation[1]

Pliocene: Florida.

Original reference: H. F. Osborn, 1907, Am. Mus. Nat. History Bull., v. 23, pl. facing p. 249.

**Wicomico Formation** (in Columbia Group)[1]

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

Original reference: G. B. Shattuck, 1901, Johns Hopkins Univ. Circ., v. 20, no. 152, p. 73–75.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 75–77, pls. 2, 3. In southern Florida, the Talbot, Penholoway, and Wicomico formations comprise a conformable sequence of deposits whose differentiation is based mainly on location of their respective shore lines—42, 70, and 100 feet above present sea level. Presumably, the Penholoway everywhere merges downward into deposits of Wicomico age, and the Talbot into Penholoway and Wicomico successively. The sequence unconformably overlies Caloosahatchee marls and is likewise separated by a stratigraphic break from the Pamlico which fringes around it.

C. W. Cooke, 1952, Maryland Dept. Geology, Mines and Mineral Resources Bull. 10, p. 48–50. In Prince Georges County, Md., and District of Columbia, consists of coarse gravel bed at base and finer sand and silt above; color of silt ranges from yellow to drab to dirty white; local basal deposits of carbonaceous clay contain tree stumps and other woody debris. Thickness rarely more than 30 feet. In Potomac Valley, follows meandering course cut in crystalline bedrock and the Potomac group; along Patuxent River, lies on Cretaceous, Eocene, and Miocene beds; is sunk below base of Sunderland formation, and separated from it by a slope exposing older rocks. Deposition is believed to have begun during second (Kansan) glacial stage and completed during second (Yarmouth) interglacial stages.

Named for Wicomico River, St. Marys and Charles Counties, Md.

**Wiggins Formation**

Oligocene: Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 79–85, pl. 17. Proposed to replace preoccupied name Ramshorn volcanic series (Love, 1934). Consists of white and light-colored sequence of conglomerates, tuffs, sandstone, and shale. Thickness 1,700 feet on East Fork-South Fork of Owl Creek divide; 3,000 feet in vicinity of Brown Rock Canyon; 989 feet on east face of Steamboat Rock. Unconformably overlies Tepee Trail formation (new). Overlain by younger rocks only on Wiggins Peak.

Oligocene(?). Lithology varies from place to place; no standard section designated.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 37, pl. 1. Oligocene (Chadronian).

Name taken from Wiggins Fork River. Comprises high divides and ridges of southern and highest part of Absaroka Range.

Wigwam Formation[1]

Precambrian: Southern British Columbia, Canada, and northwestern Montana.

Original reference: R. A. Daly, 1912, Canada Geol. Survey, Dept. Mines Mem. 38, maps.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, pt. 1, p. 1892. Incidental mention in discussion of Belt series.

Named for Wigwam River, which essentially is in British Columbia.

Wilbarger Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 384.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec., [Guidebook] Spring Mtg., p. 78. Thickness 75 to 200 feet. Underlies Comanche Creek bed; overlies Buffalo Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315-D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Named for Wilbarger Creek, San Saba County.

**Wilberns Formation**[1]

Upper Cambrian: Central Texas.

Original reference: S. Paige, 1911, U.S. Geol. Survey Bull. 450, p. 23.

Frederick Romberg and V. E. Barnes, Geophysics, v. 9, no. 1, p. 88. Subdivided to include (ascending) Welge sandstone, Morgan Creek limestone, Point Peak shale, San Saba limestone, and Pedernales dolomite members.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 133, 149–151, 155–156 [1945]. Underlies Tanyard formation of Ellenburger group; overlies Riley formation (new). San Saba limestone and Pedernales dolomite are essentially equivalent facies, with limestone predominating to the west and dolomite to the east. Dolomites here termed Pedernales had formerly been considered part of Ellenburger limestone herein redefined as group and restricted to Lower Ordovician.

Josiah Bridge, V. E. Barnes, and P. E. Cloud, Jr., 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 114–123, pls. 1, 2. Through most of Llano uplift thickness ranges from 540 to 610 feet; in southeastern part of region about 360 feet due to truncation and disconformity at top.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 136, 155–157, 187–188, 192–194, 225, 253–255, 310–312, pls. [1946]. Local stratigraphy described in detail.

V. E. Barnes and W. C. Bell, 1954, San Angelo Geol. Soc. [Guidebook] March 19–20, p. 35, 36–37. Name Pedernales dropped. Formation includes four members: Welge sandstone, Morgan Creek limestone, Point Peak shale, and San Saba limestone.

Named for Wilberns Glen, Llano County.

†Wilbraham Gneiss[1]

Late Carboniferous or post-Carboniferous: Southern central Massachusetts.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 116.

**Wilbur Member** (of Rondout Limestone)

Wilbur Limestone Member (of Salina Formation)[1]

Upper Silurian: Eastern New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Bull. 69, p. 855–867.

U.S. Geological Survey currently classifies the Wilbur as a member of the Rondout Limestone on the basis of a study now in progress.

Named for exposures at Wilbur, Ulster County.

Wilbur Tuff Lentils[1]

Eocene: Southwestern Oregon.

Original reference: J. S. Diller, 1898, U.S. Geol. Survey Geol. Atlas, Folio 49.

Has been traced from 2 miles west of Wilbur to Calapooya, Lynn County, a distance of 13 miles.

Wilburton Group[1]

Pennsylvanian: Oklahoma and Kansas.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Abandoned by Oklahoma Geological Survey.

Named for town in Latimer County, Okla.

Wilcox Formation

Precambrian: West-central Vermont.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 19–20, 21–22, 29. Predominantly green, white, and black schist enclosing thin dolomite beds near base of schist. Schists are feldspathic and dolomitic, show fine banding, and contain thin buff and blue quartzite beds. Pegmatitic quartzose gneiss occurs near middle of the formation. Above the gneiss, dark schistose grits contrast with strictly argillaceous types below. Thickness about 3,000 feet. Underlies Mendon formation unconformably.

Exposed in western part of Mendon and Shrewsbury Towns, Rutland quadrangle. Best seen on slopes south of Cold River at Wilcox Hill and on northwest slopes of Mendon Peak.

**Wilcox Group[1] or Formation**

Eocene, lower: Gulf Coastal Plain from Georgia to southern Texas, inclusive, also southwestern Illinois, western Kentucky, southeastern Missouri, and western Tennessee.

Original reference: A. F. Crider and L. C. Johnson, 1906, U.S. Geol. Survey Water-Supply Paper 159, p. 5, 9.

Wythe Cooke, 1925, U.S. Geol. Survey Prof. Paper 140–E, p. 133, 134–135. Wilcox group in Alabama comprises (ascending) Nanafalia, Tuscahoma, Bashi, and Hatchetigbee formations. In Mississippi, comprises (ascending) Ackerman, Holly Springs sand, and Grenada formation. Overlies Midway group (Porters Creek clay in Mississippi and Naheola formation in Alabama). Underlies Tallahatta formation of Claiborne group.

H. V. Howe, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 6, p. 617–621. Term Wilcox group should be abandoned in favor of Sabine. Sabine has priority and better type locality.

E. N. Lowe, 1933, Mississippi Geol. Survey Bull. 25, p. 32–119. Group subdivided into (ascending) Ackerman formation, Holly Springs sand, Bashi formation, Hatchetigbee formation, and Grenada formation. Although the same number of subdivisions is recognized in Mississippi as in Alabama, it is not possible to correlate them with corresponding subdivisions of Alabama Wilcox, except the Bashi and overlying Grenada beds which, in part, at least, correspond with Hatchetigbee of Alabama. Naheola is probably traceable in State in extensive sand outcrops immediately west of Porters Creek outcrop. Overlies Midway group; underlies Claiborne group.

F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 571–606. Group, in Texas, subdivided into (ascending) Seguin, Rockdale, and Sabinetown formations. Overlies Wills Point formation of Midway group; underlies Carrizo formation of Claiborne group.

H. V. Howe and J. B. Garrett, Jr., 1934, Louisiana Dept. Conserv., Geol. Bull. 4, p. 3–9. Sabine group divided into Mansfield and Wilcox subgroups. In Sabinetown outcrop, Mansfield subgroup is equivalent of "Rockdale formation" of Plummer in Texas. Wilcox subgroup is represented in Pendleton, Marthaville, and Fort Jessup outcrops and in Sabinetown outcrops. Alabama equivalents of Wilcox subgroup are Tuscahoma and Nanafalia formations and Bashi formation. Although name Wilcox is unfortunate because of its original usage, it has gained such wide acceptance that it is retained as subgroup name when it is distinctly understood that it applies only to upper one-third(?) of Sabine group or to marine beds overlying continental Mansfield subgroup. Such usage is fair because it is giving term "Wilcox" exactly same usage in Louisiana that it has at present in Alabama—its type section—and it is preferable to use of Sabinetown.

J. M. Weller and H. S. McQueen, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 159. Group in southeastern Missouri includes Ackerman formation.

F. F. Mellen, 1939, Mississippi Geol. Survey Bull. 38, p. 29–46. Wilcox series in Winston County comprises (ascending) Fearn Springs (new), Ackerman, Holly Springs, and Hatchetigbee formations. Disconformably overlies Betheden formation (new) of Midway series; disconformably underlies Meridian formation of Claiborne series.

L. D. Toulmin, Jr., 1940, Alabama Geol. Survey Bull. 46, p. 25–36. Under heading of Wilcox group, report discusses (ascending) Ackerman formation, Nanfalia formation, Salt Mountain limestone, Tuscahoma formation, Bashi formation, and Hatchetigbee formation.

R. J. LeBlanc and J. O. Barry, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 4, p. 734–737. Basal Wilcox of Louisiana, as of Alabama, is characterized by beds containing *Ostrea thirsae* (Gabb). In Louisiana, this fossil, which characterizes Nanafalia formation, of Alabama, has been reported in abundance only from beds of Marthaville, Natchitoches Parish. Collections have been made recently from 18 additional *Ostrea thirsae* localities between Red River and Sabine River flood plains. These localities comprise zone traceable from 8 miles east of Marthaville to 5 miles east of Zwolle, Sabine Parish. Establishment of this zone affords firmer basis for correlation proposed by Veatch (1905, Louisiana Geol. Survey Bull. 5) and Howe and Garrett (1934), of beds at Marthaville with Nanafalia. Basal Wilcox of Texas is also equivalent of *Ostrea thirsae* zone of Louisiana. Writers have collected from three localities in this zone specimens of another oyster, *Ostrea multilirata* Conrad (*tasex Gardner*), a species which, according to Plummer, occurs in Caldwell Knob member of Seguin formation, the basal Wilcox formation of Texas. Extension of *Ostrea multilirata* zone into Louisiana as part of *Ostrea thirsae* zone forms connecting link between lower Wilcox of Alabama and of Texas.

J. O. Barry, 1941 (abs.) Am. Assoc. Petroleum Geologists Bull., v. 25, no. 5, p. 941. Discovery of 40 new fossil localities permits better definition of the three faunal units of Louisiana Sabine (Wilcox): Sabinetown (youngest), Pendleton, and Marthaville beds (oldest). Study of these fossils substantiates long-standing correlation of Louisiana section with marine Wilcox of Alabama. Presence of *Ostrea multilirata* Conrad, a guide fossil of basal Wilcox Seguin formation of Texas, associated with *Ostrea thirsae* (Gabb) in Marthaville beds is of importance because it establishes connecting link between basal Wilcox faunas of Alabama and Texas.

R. J. Le Blanc, 1941, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 25, no. 5, p. 941. Lower Eocene sediments below basal Sabine (Wilcox) *Ostrea thirsac* zone have surface thickness of about 800 feet in Sabine uplift region of northwestern Louisiana. Upper 300 feet of sediments contain limited fauna. Lower 500 feet carry fauna which is older than Solomon Creek fauna of Texas (basal Wilcox or upper Midway in age) and correlated with upper Midway faunas of Alabama, Naheola formation, and Kerens member of Wills Point formation of Texas. This correlation based on results of study of over 90 species from 15 previously undescribed localities in Sabine, Natchitoches, and De Soto Parishes, La.

D. P. Meagher and L. C. Aycock, 1942, Louisiana Geol. Pamph. 3, p. 12. Group in Louisiana, includes Marthaville, Pendleton, and Sabinetown units.

C. W. Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 48–53. Deposits of Wilcox age in Georgia have not been subdivided and are called Wilcox formation, though equivalents of Nanafalia, Tuscahoma, and Bashi formations are known to be represented. Thickness 150 to 200 feet. Unconformably overlies Clayton formation; unconformably underlies McBean formation or Flint River formation, both of which overlap it.

M. W. Beckwith and F. E. Turner, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 608–621. Seguin formation as originally defined straddles boundary between Midway and Wilcox groups. Members of Seguin formation, Solomon Creek clays, and Caldwell Knob sands, are redefined so that base of Wilcox group is placed at disconformity marking top of Solomon Creek clays and base of Caldwell Knob sands. Solomon Creek member, as defined herein, apparently corresponds to upper part of Hall Summit unit of Barry and LeBlanc, whereas Caldwell Knob member may be correlated with basal sand member of Marthaville unit and beds containing *Ostrea thirsae* in association with *O. multilirata.*

Lyman Toulmin, Jr., Sept. 1944, Alabama Acad. Sci. Jour., v. 16, p. 41–42. Discussion of Midway-Wilcox contact in Alabama. Contact is easily located in exposures on Chattahoochee River at Fort Gaines, Ga., where fossiliferous Wilcox (Nanafalia) beds lie on irregular surface of Midway limestone. Stratigraphic position of Midway-Wilcox contact in central and western Alabama has heretofore been indefinite. Stratigraphic interval consisting of 200 feet or more of beds of uncertain age separates uppermost fossiliferous Midway bed and lowermost fossiliferous Wilcox bed. These beds consist of laminated clay and sand, lignite, greensand, and crossbedded coarse sand. Heretofore, paleontological evidence has been insufficient for determining whether these beds should be assigned to Midway or Wilcox group. A fossiliferous greensand marl within this sequence has been discovered in Wilcox County. Microfossils, including diagnostic Midway species, occur in this bed, and it has been assigned to Midway group. Midway-Wilcox contact has been placed above sequence of greensand beds at erosional unconformity beneath crossbedded coarse sand that underlies fossiliferous Nanafalia beds of Wilcox group. The crossbedded sand is absent in places and fossiliferous Nanafalia beds lie directly on irregular surface of the Midway. Wilcox group comprises (ascending) Nanafalia formation consisting of (ascending) "Basal sand," "Nanafalia Landing (*Ostrea thirsae*) marl," and "Gullette Bluff beds," Tuscahoma formation (including beds below Bashi marl formerly assigned to Bashi formation), Bashi marl (restricted), and Hatchetigbee formation. Disconformity separates "Basal sand" of Nanafalia formation from "Coal Bluff beds" of Naheola formation of Midway group.

F. S. MacNeil, 1944, Southeastern Geol. Soc. [Guidebook] 2d Field Trip, p. 23–28. Wilcox formations were treated together as undifferentiated Wilcox formation in Georgia by Cooke (1943). Wilcox is here treated to show same units recognized in Alabama section—Nanafalia formation, Tuscahoma sand, and Hatchetigbee formation with Bashi marl member. Wilcox formations are progressively overlapped in Georgia by Claiborne and Jackson groups. Not certain that Jackson anywhere rests directly on Wilcox in present exposures. It is probable that at least a thin wedge of Claiborne overlies Wilcox as far as vicinity of Montezuma where both Midway and Wilcox pass under cover of younger beds, Claiborne and Jackson. Basal beds of Claiborne, definitely equivalent to Tallahatta formation, rest directly on upper shales and sands of Hatchetigbee formation near Fort Gaines and down Chattahoochee River to near mouth of Abbie Creek, on Alabama side about 13 miles south of Fort Gaines. Near Andersonville, in northern Sumter County, sands of either Claiborne or Jackson rest directly on Nanafalia.

W. E. Belt and others, 1945, Geologic map of Mississippi (1:500,000): Mississippi Geol. Survey. Formation, as mapped in Mississippi, includes Fearn Springs sand member at base, Bashi marl member, and fossiliferous marl bed which, in Alabama, occurs near middle of Nanafalia formation.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 45–70. Sabine uplift of northwestern Louisiana and northeastern Texas is reflected as subregional doming by presence of inlier of Midway, Wilcox, and lower Claiborne sediments. Midway and Wilcox beds are largely deltaic and barren of fossils, but lentils bearing marine faunas are found around southern flank of uplift. Wilcox age of upper part of section was established by Harris and Veatch (1899, Louisiana State Expt. Sta., Geol. Rept., pt. 5, section 2), and entire section was considered Wilcox in age by subsequent writers until recent investigations by Louisiana Geological Survey revealed presence of faunas of Midway age in lower part. Three Midway and four Wilcox formations are recognized within section exposed on Sabine uplift, and these are correlated with type formational units of Alabama section. Group, in southern half of Sabine uplift, comprises (ascending) Marthaville, Pendleton (with Bayou Lenann, Slaughter Creek, and High Bluff members), Sabinetown, and Carrizo formations. In northern half of uplift, comprises (ascending) Marthaville(?) shale, undifferentiated Wilcox, and Carrizo formation. Overlies Hall Summit formation of Midway group. Eocene. Carrizo formation considered basal Claiborne by many geologists.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 17–22, correlation chart. Discussion of beds of Wilcox age-Wilcox formation and Wilcox group. Name Wilcox is not based on a type exposure, an objection commonly voiced against employing it at all. Name was derived from either Wilcox County or now abandoned Wilcox post office in Alabama. In Alabama, Wilcox group consists of Nanafalia formation with Fearn Springs sand member at base, Tuscahoma sand, and Hatchetigbee formation with Bashi marl member at base. In Mississippi, the Wilcox is treated as a formation equivalent to whole Wilcox group in Alabama. Two members of formation are recognized: Fearn Springs sand member at base and Bashi marl member in upper part. Formation is more than 800 feet thick in southeastern Neshoba County, Miss.; thins northward along strike, largely as result of overlap by Claiborne group to less than 100 feet at Tennessee line. Recent work has revealed that type Holly Springs formation of northern Mississippi, formerly included in the Wilcox and correlated with Tuscahoma sand of Alabama, is nonmarine equivalent of Tallahatta formation to south; name Holly Springs abandoned in favor of Tallahatta for all Mississippi. Removal of beds designated as Holy Springs from Wilcox group left Ackerman formation as only unit formerly recognized by U.S. Geological Survey in Wilcox of Mississippi. Although usually correlated with Nanafalia formation of Alabama, Ackerman at its type locality in Mississippi was found to be correlated with beds well up in Tuscahoma sand of Alabama. Rather than attempt to redefine the Ackerman, it was decided to adopt Wilcox formation for all beds of Wilcox age in Mississippi.

G. E. Murray, 1948, Louisiana Dept. Conserv., Geol. Bull. 25, p. 135–140. Barry and Le Blanc have presented evidence for drawing base of Wilcox group in Louisiana at base of *Ostrea thirsae-Ostrea multilirata* zone. In present report, base of Wilcox group is drawn at base of lithologic sequence (Marthaville formation) that contains the *Ostrea thirsae-Ostrea multilirata* zone.

H. B. Stenzel, 1950, Texas Univ. Bur. Econ. Geology Pub. 5019, p. 12–18. Wilcox group described in Troup district. Only upper part exposed. Includes Henrys Chapel ball clay (new).

G. E. Murray, 1953, Mississippi Geol. Soc. [Guidebook] 10th Ann. Field Trip, p. 48–60. Controversy concerning term Wilcox, as well as term Midway, stems from usage of both terms in dual sense, as (1) rock terms and as (2) time and time-rock terms. Proposed to use Wilcox strictly as rock-unit term. Such usage permits retention of Midway as time and time-rock term for all time and rocks deposited during fluctuations of Paleocene sea in Coastal Plain province. This usage also permits application of Sabine as a time and time-rock term for all time and rocks deposited during fluctuations of early Eocene sea in Coast Plain province. Wilcox group is considered to be the mass of complexly interbedded continental to deltaic deposits of Midway and Sabine ages. It is a three-dimensional lithologic unit, limits of which are determined by discernible extent of typical Wilcox lithology. Group contains delineatable and mappable litholigic units, some of Midway age and some of Sabine age. Exposures in Wilcox County, Ala., are typical of the group.

G. E. Murray, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 5, p. 671–696. Discussion of history and development of Paleocene-lower Eocene nomenclature of central Gulf Coast region. Midway group, Wilcox group, and Sabine group, the modern geographic class nouns most commonly applied to these deposits, are used dually as major divisions (groups) of rocks and as provincial subdivisions (stages) of the Paleocene and Eocene. Initially established as names of lithologic units, stated or implied modern usage of Midway, Wilcox, and Sabine is predominantly in a time-rock sense. Dual usage of Wilcox as a rock-unit name is increasingly common. Use of (1) Midway and Sabine stages and their companion units, Midway and Sabine ages, as provincial time-rock and time units of early Tertiary of Coastal Plain, based on major fluctuations of strand line; and (2) Wilcox group for mass of lignitic, prominently arenaceous deposits of both Midway and Sabine ages can clarify nomenclatural confusion and permit conformity to standard usage of time and time-rock units elsewhere in world. Exposures of Naheola, Nanafalia, Tuscahoma, and Hatchetigbee formations in Wilcox County, Ala., are typical of Wilcox group. Exposures of Naborton, Hall Summit, Logansport, Marthaville, Pendleton, and Sabinetown formations in De Soto, Red River, Natchitoches, Sabine Parishes, La., and in Panola, Shelby, and Sabine Counties, Tex., are cited as reference sections. Wilcox group is discriminated lithologically on first occurrence of clays or silts, commonly lignitic or carbonaceous, and (or) dirty sands, below marine greensands of Claiborne stage and above dark shales or glauconitic strata of Porters Creek formation.

C. O. Durham, Jr., and C. R. Smith, 1958, Louisiana Dept. Conserv., Geol. Pamph. 5, p. 1–17. Discussion of Louisiana Midway-Wilcox correlation problems and comparison of Alabama and Louisiana sequences. Problem of determining boundary in Louisiana involves same difficulties as in Alabama but with added necessity of correlating cross-country with Alabama section. In both Louisiana and Alabama, lower beds of deltaic (Wilcox) lithology contain fauna of Midway aspect. Sequence in Alabama embraces Naheola as now restricted and in Louisiana the Mansfield subgroup of Howe and Garrett (1934) later subdivided by Murray (1941). Surface evidence in Mississippi-Alabama area indicates that Naheola is missing inland so that these problematical and somewhat transition beds only occur in thicker gulfward sections. By analogy, the same is true in Louisiana although documentation is incomplete. Evidence does not prove exact contemporaneity for base of Wilcox in Louisiana and Alabama but certainly does not indicate any great variation in time of deposition. In both Alabama and Louisiana, a wedge of gulfward thickening deltaic sediments is present. This wedge, absent inland, contains typical Wilcox lithology but fossils considered by most workers to be Midway in affinity. Various Louisiana workers have dealt differently with nomenclature problem of this wedge. The many interpretations reflect difficulty of using same names in lithologic, faunal, and time sense when geologic facts do not lend themselves to such combined usage. It is doubtful if Murray's (1955) proposal of labeling the same sequence both Midway and Wilcox will be adopted generally. Several recent papers by both paleontologists and stratigraphers have used Midway and Paleocene as well as Wilcox and lower Eocene in synonymous sense (Cushman, 1944, Cushman Lab. Foram. Research Contr., v. 20, pt. 2; Munsey, 1953, Jour. Paleontology, v. 27, no. 1; Loeblich and Tappan, 1957, Jour. Paleontology, v. 31, no. 6; Toulmin and others, 1951, Alabama Geol. Survey Spec. Rept. 21; LaMoreaux and Toulmin, 1953, Mississippi Geol. Soc. Guidebook 10th Field Trip). This usage of Midway and Wilcox is based on faunal rather than lithologic considerations reinforced perhaps in some instances by position of disconformable contact between the Naheola and Nanafalia of Alabama. In stratigraphic summary, Toulmin (1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 2) eliminated all reference to terms Midway and Wilcox using Paleocene and lower Eocene exclusively instead. This frees terms Midway and Wilcox to be used in their other lithologic sense. As first used, Wilcox was called a formation, and that usage persists in Mississippi. Inland where Wilcox is thin, of variable rapid facies changes, and mappable subdivisions cannot be made, this is permissible. Gulfward in thicker Alabama and west-central Louisiana sequences, individual formations as well as members have been delineated and mapped. In this area, Wilcox must be considered a group. In northernmost Louisiana, the Wilcox has the same characteristics that led it to be called formation in Mississippi. But, inasmuch as it is subdivided into formations only a short distance southward, it is preferable to refer to it as "undifferentiated Wilcox group" in that area. In present report, the term "Mansfield subgroup," as used by Howe and Garrett (1934), is used informally for the lower Wilcox although it embraces subdivisions of Murray (1941, 1948) that is, Naborton, Logansport, and Hall Summit formations with their members. "Mansfield" thus comprises the thicker Louisiana counterpart of Naheola formation of Alabama. Use of the several formational names of Murray is avoided because recent work in Sabine, Red River, and Caddo Parishes has indicated need for their revision. In Alabama and Louisiana, the Paleocene character of the fauna persisted during deposition of older part of deltaic sequence, the Naheola of Alabama and Mansfield of Louisiana. Thus, Paleocene-Eocene contact falls within deltaic mass. Inland, a disconformity rests on Midway clay. Lack of fossils prevents positive proof, but this hiatus probably occurred while Naheola and Mansfield were being deposited to the south during late Paleocene. Hence, Midway and Wilcox cannot be used in both lithologic sense and as time-stratigraphic terms equivalent to Paleocene and lower Eocene, but Midway and Wilcox are available for use as lithologic terms. Without this usage, no terms exist to describe the underlying lime and clay sequence of Paleocene age nor overlying deltaic sequence of late Paleocene and early Eocene age.

A lithologic boundary is drawn between Midway and Wilcox groups in Louisiana. Updip in Caddo Parish, this contact is disconformable; to the south, it is transitional. Lower deltaic Wilcox comprises partially fossiliferous sequence containing Paleocene fossils beneath beds containing *Ostrea thirsae*. This sequence is probably completely absent inland, thickens rapidly gulfward, and is divisible into formational units, locally. Upper Wilcox group of lower Eocene age includes *O. thirsae* beds (Marthaville), as well as overlying Pendleton and Sabinetown formations on south flank of Sabine uplift, but is undifferentiated in thinner nonfossiliferous sequence on north flank. This is practical nomenclature for both surface and subsurface Midway-Wilcox sequence wherever studied in Louisiana, as well as entire Gulf Coast area.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and W. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 11 (fig. 4), 38–58. Group described in Arkansas bauxite region. Divided into (ascending) Berger formation, Saline formation, and Detonti sand (all new). Thickness as much as 1,209 feet. Unconformably overlies Wills Point formation of Midway group. Overlain by variegated clay and sand and thin lignite beds similar to those assigned to Claiborne group in other parts of Arkansas; whether this represents true contact of Wilcox and Claiborne must be decided by later studies. It is possible that Wilcox in Arkansas bauxite region, on lithologic basis, probably should be restricted to Berger formation, but current Arkansas usage is being followed in this report. Lower Eocene.

H. V. Andersen, 1960, Louisiana Dept. Conserv., Geol. Bull. 34, p. 48–85, maps. Wilcox group (rock group) in Sabine Parish comprises (ascending) Converse (new), Lime Hill, and "Hall Summit" formations (all Paleocene) and Marthaville, Pendleton, Sabinetown (with lower Pierson glauconite member), and Carrizo formations (all Eocene). Naborton, Dolet Hills, and Cow Bayou formations recognized in subsurface.

C. C. Mason, 1960, Texas Board Water Engineers Bull. 6003, p. 15–25. Group, In Dimmit County, contains Indio formation. Overlies Kincaid formation of Midway group; underlies Carrizo sand of Claiborne group. Eocene.

Named for extensive development in Wilcox County, Ala.

†Wild Cat Coquinite[1]

Upper Devonian or Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 203.

Well exposed on Wild Cat Creek at Ludlow, McKean County.

Wildcat Group

Wildcat Series[1]

Miocene, upper, to Pleistocene, lower: Northern California.

Original reference: A. C. Lawson, 1894, California Univ. Pub., Dept. Geol. Bull., v. 1, p. 255–263.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 24–26, 102, pls. 1, 2. Wildcat series (Lawson 1894) has become established in literature as loose term for Tertiary sediments (in Humboldt County) of suspected Pliocene age. Term Wildcat group is used here for sediments ranging from upper Miocene to lower Pleistocene. Composed principally of slightly indurated mudstone, siltstone, claystone, sandstone, and conglomerate; minor amounts of limestone, tuff, and lignite. Thickness more than 12,000 feet. In Ferndale Hills, on south side of Cenozoic basin, subdivided into (ascending) Pullen, Eel River, Rio Dell, Scotia Bluffs, and Carlotta formations (all new). Northeast of Foruna, group is undifferentiated. Strong angular unconformity separates group from Yager formation (new) and Franciscan; Hookton formation (new) deposited on eroded surface of Wildcat group.

G. C. Gester, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 205. Generalized stratigraphic section across Tertiary formations of Eel River basin near Scotia shows that Pliocene Wildcat series, 11,000 feet thick, overlies upper Miocene Bear River formation.

Type locality for group: Along Eel River from west of Scotia, Humboldt County, north to Van Duzen River. Region occupied by terrace is commonly known to people of Humboldt County as "Wild-cat Country."

Wildcat Marble

Precambrian: Northern New Jersey.

J. M. Hague and others, 1956, Geol. Soc. America Bull., v. 67, no. 4, p. 440, 468, 469, fig. 18. Throughout most of outcrop length horizon represented by single band of marble, but in area north of Sparta it gradually changes into series of tightly folded bands of impure marble and calcareous hornblende and pyroxene gneisses. Commonly contains blocks and discontinuous bands of gneiss and pegmatite. Thickness at Franklin, 300 feet. Underlies Pochuck Mountain gneiss series (new); overlies Cork Hill gneiss (new).

Named for small creek which flows through its outcrop southwest of Franklin. Also found north, west, and southwest of Sparta.

**Wildcat Creek Shale Member** (of Admiral Formation)

Permian: North-central Texas.

R. C. Moore, 1947, *in* A. K. Miller and Walter Youngquist, Kansas Univ. Paleont. Contr. 2, Mollusca, art. 1, p. 1 (footnote). Name introduced for shale overlying Hords Creek limestone and underlying Overall limestone (new).

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Drake (1893) applied name Indian Creek bed to predominantly shaly strata occurring between Hords Creek limestone below and "Bed No. 5" (here named Overall limestone) above. Drake also used Indian Creek for beds in his Strawn division of Pennsylvanian age; Sellards (1933, Texas Univ. Bull. 3232) restricted application of name to the Strawn without renaming the Permian Indian Creek. This shale member is named Wildcat Creek shale. Thickness near Colorado River about 60 feet. Wildcat Creek shale makes up lower main part of Cheney's Fisk formation.

Named for exposures on Wildcat Creek which joins Home Creek at a point about 0.9 mile north of south line, and 1 mile east of west line of J. H. Barkey Survey No. 700, 6 miles S. 15° W. from courthouse at Coleman, Coleman County.

Wild Cat Mountain Conglomerate[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: C. J. Norwood, 1877, Kentucky Geol. Survey, 2d ser., v. 2, pt. 6, p. 201, 243.

Forms top of Wild Cat Mountain and extends to hills around London, Laurel County, which it covers.

Wildcat Peak Formation

Carboniferous: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 98 (fig. 4). Named on structure section in report on Paleozoic continental margin in central Nevada. Overlies Pinecone formation (new).

Toquima Range, Nye County.

**Wilder Formation**

Late Tertiary(?) or Pleistocene(?): West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 26–27, pl. 3. Consists of porphyritic olivine basalt flows, intrusive plug of olivine basalt, coarse pyroclastic basaltic deposits formed as cinder cones or interbeds of pyroclastics in flows, and horizontically bedded basaltic tuffaceous sediments. Aggregate thickness generally ranges from 200 to 300 feet, but west of Contreras Wash 400 feet is exposed. In Wilder and upper Boulder Canyons, intercalated throughout the Gila(?) conglomerate; on west bank of Wilder Canyon, intercalated with and underlies Sanders basalt (new).

Exposed along walls of Wilder Canyon, for which it is named. Also crops out to east of Wilder Creek, along north wall of Boulder Canyon; to the south, along west wall of Boulder Canyon, and along eastern margin of Bozarth Mesa, Bagdad area, Yavapai County.

Wilderness Stage

Middle Ordovician (Mohawkian): North America.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 8–9, chart 1 (facing p. 130). Mohawkian series divided into five stages (ascending): Whiterock, Marmor, Ashby, Porterfield, and Wilderness. Wilderness stage includes old Black River stage plus the Rockland and their equivalents. Older than Trenton stage. Name credited to G. A. Cooper and B. N. Cooper.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 94. Pre-Trentonian part constitutes upper part of type Bolarian series.

Named from Wilderness Trail (U.S. Highway 58) that parallels Cumberland Front in western Virginia. Rocks deposited during this stage well exposed for several miles east of Cumberland Gap and are revealed in their entirety along the railroad at the switch near Hagan, Rose Hill quadrangle, Virginia.

Wildhorse Dolomite Member or Bed (in Barnsdall Formation)

Wildhorse Limestone (in Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Central northern Oklahoma.

Original reference: F. C. Greene, 1918, Am. Assoc. Petroleum Geologists Bull., v. 2, p. 121–122.

M. C. Oakes, 1951, Tulsa Geol. Soc. Digest, v. 19, p. 120. Rank reduced to bed in unnamed shale member of Barnsdall formation (new).

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 19. Wildhorse dolomite member, which occurs near top of Barnsdall in southern Osage County, is not found south of Arkansas River.

First described in Osage County.

Wildhorse Formation[1]

Pleistocene: Southeastern Oregon.

Original reference: W. D. Smith, 1926, Oregon Univ. Commonwealth Rev., v. 8, p. 207–214.

Typically exposed in Kieger and Wildhorse Canyons, Harney County.

Wildhorse Member (of Muldoon Formation)

[Upper Mississippian or Pennsylvanian]: Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Overlies Iron Mine member (new); underlies Wood River formation.

Deposited in Muldoon trough, alined N. 30° W.

Wildhorse Sandstone[1]

Permian: Central southern Oklahoma.

Original reference: E. R. Brockway and H. J. Owens, 1923, Oklahoma Univ. Bull., new ser., no. 271, p. 95–96.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 108. Abandoned by Oklahoma Geological Survey. Name preoccupied.

Exposed along Wildhorse Creek, Garvin and Carter Counties.

Wildhorse Canyon Series

Precambrian: Southwestern Utah.

K. C. Condie, 1959, The Compass, v. 36, no. 3, p. 184, 185, 186, 187. Comprised of ptygmatically folded gneisses and schists. Enclosed within Mineral Range pluton. Early Precambrian in age.

Crops out on west side of Mineral Range from Ranch Canyon on the south to contact of the pluton on the north; in Beaver and Millard Counties.

Wildhorse Mountain Formation (in Jackfork Group)

Upper Mississippian: Southeastern Oklahoma.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 856–857, 878–880. Proposed for lowermost formation of group. Consists of massive basal sandstone, which is commonly succeeded by thin-bedded sandstones and intercalated shales, and massive sandstone about 60 feet thick at top. Thickness varies from east to west; approximately 3,600 feet at type locality (in Tuskahoma syncline); about 1,000 feet in Round Prairie syncline in Tps. 1 and 2 S., R. 12 E. Underlies Prairie Mountain formation (new); overlies Chickasaw Creek siliceous shale (new) of Stanley group. Pushmataha series.

L. M. Cline, 1956, Tulsa Geol. Soc. Digest, v. 24, p. 101, 102. Restudy of type sections of Jackfork formation reveals that upper part of type Wildhorse Mountain formation duplicates an equivalent interval in lower part of type Prairie Mountain formation. By definition Harlton's type Prairie Mountain includes type locality of Prairie Hollow maroon shale member but it has been found that the Prairie Hollow also occurs in midst of Wildhorse Mountain type section; stratigraphic overlap amounts to about 3,600 feet.

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 47–51. Redefined to include Prairie Hollow shale member.

Type locality: Wildhorse Mountain, north of town of Moyers, in T. 2 S., R. 16 E., Pushmataha County.

**Wildie Sandstone Member** (of Warsaw Formation)[1]

Upper Mississippian: Southeastern Kentucky.

Original reference: Charles Butts, 1922, Kentucky Geol. Survey, ser. 6, v. 7, p. 89, 102.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 215, 229. Unit termed Wildie sandstone member of Warsaw formation is here included in Wildie siltstone member (new) of Muldraugh formation (new).

Well exposed in vicinity of Wildie, Rockcastle County.

Wildie Siltstone Member (of Muldraugh Formation)

Lower Mississippian: Southeastern Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 215–216, pls. 6, 15. Name applied to rock unit bounded by two well-marked glauconitic silt horizons, irrespective of number or thickness of individual siltstone beds or relative proportions of interval filled by siltstone or silty shale. Thickness 20 to 30 feet; at type locality about 27 feet. In vicinity of type locality, consists mostly of bedded fairly resistant siltstone, with subordinate amount of shale. Included in Hummel facies (new) at base of formation; underlies unnamed silty yellow limestone; overlies Floyds Knob formation. As defined, includes unit termed Wildie sandstone member of Warsaw formation by Butts (1922).

Type locality: Sec. 36, at quarry of A. G. Carter Stone Works, Hummel post office, east of south end of abandoned tunnel of Louisville and Nashville Railroad, 1¾ miles south-southeast of Wildie, Rockcastle County. This is abandoned quarry of old Kentucky Freestone Co.

Wildrose Formation[1] (in Telescope Group)

Precambrian: Southeastern California.

Original references: F. M. Murphy, 1930, Econ. Geology, v. 25, p. 309–310, map; 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Dept. Geol. Sci., v. 30, no. 5, p. 355, 365, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible correlation of formations defined by Murphy (1930, 1932 [1933]) in Telescope Peak quadrangle with formations now commonly in use in Death Valley region. South Park member (new) of Kingston Peak formation (Precambrian) is correlative of three formations in Murphy's Telescope group: Middle Park formation, Mountain Girl conglomerate-quartzite, and Wildrose formation. None of these formations was recognized as mappable unit in Manly Peak quadrangle.

Probably named for exposures near Wildrose Canyon, Panamint Mountains, Inyo County.

Wildwood Limestone[1]

Permian: Northern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, p. 218, chart facing p. 217.

Named for Wildwood (Landis' Ranch), on Hay Fork, Trinity County.

**Wiles Limestone Member** (of Graford Formation)[1]

Wiles Limestone (in Whitt Group)

Wiles Limestone Member (of Palo Pinto Formation)

Upper Pennsylvanian: Central northern Texas.

Original reference: C. E. Dobbin, 1922, U.S. Geol. Survey Bull. 736-C, p. 60.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in Palo Pinto formation (redefined). Overlies Wynn limestone member (new); underlies Adams Branch formation.

C. E. Davis, 1956, *in* North Texas Geol. Soc. Guidebook, May 25–26, p. [6]. Shown on columnar section as uppermost formation in Whitt group. Stratigraphically above Palo Pinto limestone and below Wolf Mountain shales in Graford group.

Named for exposures near Wiles, Stephen County.

Wiley Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), 62, pl. 1. Assigned member status in Spoon formation (new). Occurs below Greenbush coal member and above Seahorne limestone member. Thickness 10 inches in type section of formation. Coal named by Wanless (1931, Illinois Geol. Survey Bull. 60). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: SW¼NW¼ sec. 16, T. 7 N., R. 2 E., Fulton County. Near Wiley School.

Wiley cyclothem (in Spoon Formation)

Wiley cyclothem[1] (in Tradewater Group)

Pennsylvanian: Western Illinois and eastern Iowa.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 188, 192.

J. M. Weller and others, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1589. Geographically extended into Iowa.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 63, 79–81. Normally thinnest cyclothem in area—about 4 inches to 4½ feet thick. Underlies Greenbush cyclothem; overlies Seahorne cyclothem. Gives type exposure.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), 56 (table 3), pl. 1. In Spoon formation (new). Above Seahorne cyclothem and below Greenbush cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type exposure south bank of ravine, near westline of SW¼SW¼ sec. 16, T. 7 N., R. 2 E., Avon quadrangle, Fulton County, Ill.

Wiley dolomite[1]

Carboniferous: Texas.

Original reference: C. R. Keyes, 1933, Pan-Am. Geologist, v. 59, no. 2, p. 136.

Wiley Mountains east of Van Horn, Culberson County.

†Wileys Landing Bed[1]

Miocene, lower: Southwestern Georgia and northern Florida.

Original reference: A. F. Foerste, 1894, Am. Jour. Sci., 3d v. 48, p. 50–51.

Named for exposures at Wiley's Landing, on Flint River, in Decatur County, Ga.

Wilgus Clay[1] (in Conemaugh Formation)

Wilgus underclay member

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

[Original reference:] Wilber Stout and R. E. Lamborn, 1924, Ohio Geol. Survey, 4th ser., Bull. 28, p. 334–335.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 65. Included in Wilgus cyclothem, Conemaugh series. Clay not present in area of this report, Perry County.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 116. Wilgus underclay member noted in discussion of Wilgus cyclothem in Athens County. Thickness about 1¾ feet.

Named for its association with Wilgus coal which is well developed near Wilgus, Lawrence County. Wilgus coal named by D. D. Condit (1912, Ohio Geol. Survey, 4th ser., Bull. 17).

Wilgus cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 11. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 65–66, table 1, geol. map. Includes (ascending) Buffalo shale, 33 feet; Wilgus clay and Wilgus coal (both absent in Perry County); and Cambridge limestone. Occurs below Anderson cyclothem and above Brush Creek cyclothem. In area of this report, Conemaugh series is described on cyclothemic basis; seven cyclothems are named. [For sequence see Mahoning cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 113–118. In Athens County, includes (ascending) Buffalo shale and (or) sandstone, Meyersdale redbed, Wilgus underclay and coal, and Cambridge limestone members. Overlies Upper Brush Creek cyclothem; underlies Anderson cyclothem. Conemaugh series.

Wilgus coal was named by Condit (1912, Ohio Geol. Survey, 4th ser., Bull. 17) for occurrence near Wilgus, Lawrence County.

**Wilhite Formation** (in Walden Creek Group)

Wilhite Slate[1]

Precambrian (Ocoee Series): Eastern Tennessee, northwestern Georgia, and western North Carolina.

Original reference: C. D. Walcott, 1894, Geol. Soc. America Bull., v. 5, p. 196–198.

A. S. Furcron, K. H. Teague, and J. L. Calver, 1947, Georgia Geol. Survey Bull. 53, p. 21–22, pl. 1. Wilhite slate mapped in Chatsworth talc district, Murray County. Wilhite of this area does not seem to correspond entirely to description of Wilhite to north; thus its age is open to question. Mapped separately from Ocoee rocks as it does not appear to belong to that series lithologically.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 29. Wilhite slate, as used by Keith (1895, U.S. Geol. Survey Geol. Atlas, Folio 16) is considered synonym of Sandsuck shale.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 962, 963. Redefined as formation in Walden Creek group (new). Near type locality, divisible into two members (ascending) Dixon Mountain and Yellow Breeches (both new). Combined thickness of members at type locality about 3,500 feet. Overlies Shields formation (new); underlies Sandsuck formation.

Type locality: Wilhite Creek, Sevier County, Tenn.

**Wilkes Formation**

Miocene, upper: Southwestern Washington.

M. H. Pease, Jr., and Linn Hoover, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM-188. Named on correlation chart. Older than Logan Hill formation. Name credited to A. E. Roberts (in press).

A. E. Roberts, 1958, U.S. Geol. Survey Bull. 1062, p. 12 (chart), 34-37, pl. 1. Name designates sequence of fluvial, lacustrine, and brackish-water deposits consisting of more than 760 feet of semiconsolidated claystone, siltstone, sandstone, and conglomerate. Contains fossil wood. Unconformably underlies Logan Hill formation; overlies middle(?) Miocene volcanic sequence and in some areas unconformably overlies Toutle formation.

Type area: Section measured from new roadcuts along State Highway 1-Q in secs. 20 and 29, T. 11 N., R. 1 E., and secs. 3 and 10, T. 10 N., R. 1 E., in Wilkes Hills, Toledo-Castle Rock district.

Wilkeson [coal] series[1]

Eocene: Western central Washington.

Original reference: B. Willis, 1886, U.S. 10th Census, v. 15, pls. 81, 84.

Puget Sound region.

**Wilkeson Formation** (in Puget Group)[1]

Eocene: Western Washington.

Original reference: Bailey Willis, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 400-436.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 55, 63, 65. Middle formation of group in Carbon River area. Lies stratigraphically below Burnett formation on South Prairie Creek and is approximately 1,000 feet thick. Overlies Carbonado formation. Formations in Carbon Canyon have been folded into anticlines and synclines with general northwesterly trend.

Typical occurrence upon the eastern dip, either in quarries along South Prairie Creek, east of Burnett or in bluffs a quarter mile east of Wilkeson, Pierce County, on north side of valley.

**Wilkins Peak Member** (of Green River Formation)

Eocene, lower and middle: Southwestern Wyoming.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1073-1074. Name applied to beds in Bridger basin formerly thought to be Laney shale member of Schultz (1920). Thickness about 900 feet at type locality. Overlies Tipton shale member along eastern side of Bridger basin; does not crop out on west side of basin. Everywhere underlies Laney shale member.

Type locality: Wilkins Peak, T. 18 N., R. 106 W., Sweetwater County.

Wilkinson Creek Member (of Fleming Formation)

Probably lapsus for Williamson Creek Member (of Fleming Formation).

Willamette Group[1]

Miocene: Northwestern Oregon.

Original reference: T. Condon, 1902, The Two Islands: Portland, Oreg., The J. K. Gill Co.

Named for Willamette region.

**Willamette Silt**

Pleistocene: Western Oregon.

R. C. Treasher, 1942, Geologic map of Portland area, Oregon (1:96,000): Oregon Dept. Geology and Mineral Resources. Referred to as Willamette terrace deposits occurring along Willamette River at elevations from 100 to 250 feet. Thickness probably as much as 150 feet.

I. S. Allison, 1953, Oregon Dept. Geology and Mineral Industries Bull. 37, p. 12–13. Name Willamette silts proposed for parallel to bedded sheets of silt and associated materials that cover the greater part of Willamette Valley lowland. At type section, silts are 9 to 13 feet thick and overlie deposits of Linn stage [Linn gravels].

E. M. Baldwin and others, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–155. In McMinnville quadrangle, Willamette silt is approximately 75 feet thick and uniform in texture; bedding is not distinct but is shown by faint color changes. Top of silt deposits reaches altitude of 160 feet throughout Willamette Valley and thinner coverings along hill slopes reach altitude of 200 feet or more; above 200 feet silt is difficult to distinguish from weathered Tertiary formations and soil.

Type locality: On right bank of Willamette River at Irish bend in southwestern Linn County.

Willamettian Stage[1] or Glacial Epoch

Pleistocene: Central northern Oregon.

Original reference: E. T. Hodge, 1930, Monthly Weather Rev., v. 58, p. 405–411.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 836, 841 (table 1). Third of five glacial epochs in area. Occurs in interval between Bull Run epoch and Jeffersonian.

Willapa Clays

Pleistocene: Southwestern Washington.

S. L. Glover, 1941, Washington Div. Mines and Geology Bull. 24, p. 52–53. Term adopted to designate surficial materials that occur throughout much of southwestern Washington and which are abundant in Willapa Hills region. As used, term includes vast amounts of clays, clayey sand, and decomposed gravel that masks bedrock throughout large part of nonglaciated western Washington. Commonly clays are alluvial; lacustrine and marine beds occur near coast.

Name derived from Willapa, Pacific County.

**Willard Shale** (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1898, Kansas Acad. Sci. Trans., v. 15, p. 31.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull. 40, no. 9, 2274 (fig. 1), 2276. Underlies Zeandale formation (new); overlies Emporia limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 12, fig. 5. Shale, gray at top, maroon near center, and black at base. Thin argillaceous limestone present about 3 feet below top. Thickness 9½ feet. Underlies Tarkio limestone; overlies Elmont limestone. Wabaunsee group.

Named for exposures south of Willard, Shawnee County, Kans.

William Henry Bay Marble

Lower Paleozoic: Southeastern Alaska.

E. C. Robertson, 1955, Geol. Soc. America Bull., v. 66, no. 10, p. 1309. White medium-grained rock. Age tentatively set as early Paleozoic.

In small inlet of same name, off Lynn Canal and about 20 miles south of Haines.

**Williams Formation**

Upper Cretaceous: Southern California.

W. P. Popenoe, 1937, Jour. Paleontology, v. 11, no. 5, p. 380. Named on generalized section of formations in Santa Ana Mountains. Thickness about 520 feet. Comprises two sandstone members (ascending) Schulz and Pleasants. Unconformably underlies Eocene Martinez(?); unconformably overlies Ladd formation (new).

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166, 168 (fig. 2), 173. Type locality and derivation of name given.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. In this report, name Schulz member has been altered to Schulz Ranch sandstone member of Williams formation. Underlies Silverado formation (new).

Type locality: Along Williams Canyon near its mouth. Formation forms summit of Cretaceous section of Santa Ana Mountains, Orange County.

Williams Member (of Deese Formation or Group)

Pennsylvanian (Des Moines Series): Central Oklahoma.

C. W. Tomlinson, 1937, Ardmore Geol. Soc. [Guidebook] Field Trip, Mar. 13, p. 1, geol. map. At type locality, includes 2 feet of impure silty fossiliferous limestone capping some 30 feet of more or less calcareous sandstones. At base of formation; underlies Natsy member (new). Name credited to Guthrey and Milner (unpub. map).

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 35. Williams member, about 900 feet from top of Deese group, southeast of Ardmore includes 2 feet of impure silty limestone which caps some 30 feet of more or less calcareous sandstones and underlies 3 or 4 feet of calcareous shale. This is basal member of Harlton's West Arm formation, which extends upward to top of Deese group. Stratigraphically above Camp Ground member. About 300 feet below Natsy member.

Type locality: On former Williams Farm, now part of Lake Murray State Park, 100 yards north of CSL SE¼ sec. 17, T. 5 S., R. 2 E., Carter County.

Williams Brook Shale (in Ithaca Shale)

Williams Brook coquinite member[1] (of Ithaca facies subgroup)

Upper Devonian: South-central New York.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 202.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4. Termed shale and included in Ithaca shale.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2824, 2827. At Williams Brook, about 1½ miles northwest of Ithaca, Williams Brook coquinite (Caster, 1933) is apparently at horizon of Crosby sandstone of Torrey (1932)—the horizon of Genundewa member of Genesee formation.

Occurs in Ithaca region.

**Williamsburg Granodiorite[1]**

Carboniferous(?): Central Massachusetts and north-central Connecticut.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, pl. 34.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Restricted. Gneissic rocks which occur extensively north of town of Amherst, Mass., and which Emerson (1917, U.S. Geol. Survey Bull. 597) mapped as Williamsburg are here included in Amherst schist and Joshua schist (new).

M. E. Willard, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–85. In Williamsburg quadrangle, only body which fits Emerson's (1917) description is that exposed east and north of Haydenville. Dikes and sills of equigranular medium-grained biotite-muscovite granodiorite are associated with pegmatite and pegmatitic alterations of country rock. All other exposures, including those in village of Williamstown, are of mixed type. Carboniferous(?).

Named for exposures at Williamsburg, Mass.

†Williamsburg Marl[1] or Pseudobuhr[1]

Eocene, lower: Eastern South Carolina.

Original reference: E. Sloan, 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 449, 451, 452.

Named for exposures in Williamsburg County, near Rhems, but more extensively as mantle covering ridge between Black River and Santee River, notably on scarp of swamp southwest of Gourdin Station and on crest of ridge, 3 miles north of Salters.

**Williams Canyon Limestone[1]**

Mississippian: Eastern Colorado.

Original reference: A. E. Brainerd, H. L. Baldwin, Jr., and I. A. Keyte, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 4, p. 381–396.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Prelim. Chart 39; 1951, World Oil, v. 133 (Oct.), 89–91. Sequence of dolomite and limestone beds overlying Ordovician rocks and underlying Pennsylvanian rocks along Front Range has been divided in earlier reports into Williams Canyon limestone, considered Devonian in age, and Madison (or Leadville) limestone considered lower Mississippian. In this report, these beds are considered Mississippian (Meramec?). Commonly, a thin-bedded sequence of lavender- to purple-mottled, gray to buff, finely granular to finely crystalline limestone, dolomitic limestone, dolomite, and sandy dolomite with a few thin layers of pink to lavendar fine- to medium-grained sandstone; thin beds of tan limy to sandy shale and gray platy limy shale present near middle of formation at several places; very thin bed of maroon fine sandy shale containing dolomite pebbles present at base in Priest Canyon; pinkish-white chert nodules present locally. Thickness 16 to 53 feet. Underlies Hardscrabble limestone (new); overlies Fremont limestone; both contacts unconformable.

Typically exposed near Cave of Winds in Williams Canyon at Manitou, El Paso County.

**Williams Fork Formation** (in Mesaverde Group)[1]

Upper Cretaceous: Northwestern Colorado and northeastern Utah.

Original references: Named by E. T. Hancock, but publication of his report was delayed, so name first appeared in U.S. Geol. Survey Press Memo. 16037, Oct. 1, 1923, on map of Hamilton and Seeping Gulch domes and vicinity, Moffat County, Colo; also used by J. D. Sears but credited to Hancock, in U.S. Geol. Survey Bull. 751, 1924, p. 290.

E. T. Hancock and J. B. Eby, 1929, U.S. Geol. Survey Bull. 812–D, p. 203–208. In Meeker quadrangle, Colorado, includes Fairfield coal group, Goff coal group, Lion Canyon sandstone member, and Lion Canyon coal group. Overlies Iles formation; unconformably underlies Wasatch formation.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 99 (table 2), 114–117. Geographically extended into Uinta Basin, Utah. Consists of buff, brown, and white sandstone, gray, pink, and brown shale, and coal beds. Includes more than type Williams Fork. Thickness as much as 2,614 feet. Overlies Rim Rock sandstone (new). Beginning at Asphalt Ridge and proceeding eastward, formation is successively overlain unconformably by Duchesne River, Green River, and Wasatch formations.

N. W. Bass, J. B. Eby, and M. R. Campbell, 1955, U.S. Geol. Survey Bull. 1027–D, p. 157–159, pl. 19. Includes all beds between top of Trout Creek limestone member of Iles formation and base of Lewis shale. Thickness 1,100 to about 2,000 feet. Includes lower unit about 1,000 feet thick, consisting chiefly of shale, thin sandstone beds, sandy shale, and several coal beds; Twentymile sandstone member, 100 to 200 feet thick; upper unit of interbedded sandstone, sandy shale, shale, sandstone, and coal beds.

Exposed on Williams Fork Mountain and along Williams Fork near its junction with Yampa River, Moffat County, Colo.

Williamson Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 84, 165.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 108. Massive sandstone in Kanawha group.

Exposed on Williamson Creek at Williamson, Mingo County.

**Williamson Shale** (in Clinton Group)

Williamson Shale Member (of Clinton Formation)[1]

Middle Silurian: Central and western New York.

Original reference: J. M. Clarke, 1906, New York State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 16 (table 1), 71–79. Formation in Clinton group. Williamson shale described in Clyde and Sodus Bay quadrangles where it is lowest member of Upper Clinton group. Directly overlies Wolcott Furnace iron ore. Lower Sodus and Williamson are in contact at Rochester, but in area of this report the two are separated by upper Sodus shale, Wolcott limestone, and Wolcott Furnace iron ore. Underlies Irondequoit limestone. In Genesee Gorge, Hartnagel used term Williamson to include both the Williamson and Lower Sodus as used in this report.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 13 (fig. 2), 15 (table 2), 79–84. Williamson shale enters Clinton section between Oak Orchard Creek in Orleans County and Genesee Gorge. In the gorge, formation is about 6 feet thick and is dark-green to black calcareous to slightly calcareous fissile graptolite-bearing shale. Upper part, which is predominantly dark green, contains a few limestones. The limestones are particularly evident near contact with Irondequoit. Unconformity at base of Williamson is of considerable magnitude; at Lakeport, the Williamson rests on the Sauquoit; overlaps westward progressively older formations, Wolcott Furnace iron ore, Wolcott limestone, and Lower Sodus shale. Williamson is westward equivalent of lower part of Willowvale shale of Oneida and Madison Counties.

Named for exposures at Williamson, Wayne County.

Williamson Creek Member (of Fleming Formation)

Miocene: Central Louisiana.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 118 (fig. 26), 161–164, geol. map. Consists of thick group of non-marine silts and silty clays, with incorporated sand lentils and local brackish-water clay tongues. Total thickness approximately 500 feet. Overlies Dough Hills member (new), and contact arbitrarily is placed in clayey-silt sequence where sand lentils begin to appear in abundance; underlies Castor Creek member (new), and contact is placed where sand lentils are replaced by silty clay sequence grading upward into calcareous clays.

Typically exposed in uplands within drainage area of Williamson Creek headwaters south of Dough Hills, Rapides Parish.

Williamsport Sandstone[1]

Upper Silurian (Cayugan): Northern West Virginia, western Maryland, and western Virginia.

Original reference: D. B. Reger, 1924, West Virginia Geol. Survey Rept. Mineral and Grant Counties, p. 395–398.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 149–153. Term Williamsport sandstone, applied by Reger (1924) to this sandstone when it was considered to be subdivision of Bloomsburg shale, is herein redefined as formational name. As thus interpreted, Williamsport sandstone is basal member of Cayugan group. Its identity in eastern Silurian outcrops is obliterated by, or absorbed in, red nonmarine Bloomsburg facies. Near Cumberland, Md., includes near middle, Cedar Cliff limestone member (reallocated). Abruptly overlies calcareous shales of McKenzie formation; transition unto overlying Wills Creek limestone is normally sharp. At some localities in Virginia, contacts are gradational and the formation is more a zone of sandstones than a distinct siliceous body. Geographically extended into Maryland and Virginia.

Named for exposure on a short branch of Patterson Creek, 0.6 mile east of Williamsport, Grant County, W. Va., at point where private road turns northeast from main Williamsport-Moorefield Highway.

†Williamsport Sandstone[1]

Mississippian: Central western Indiana.

Original references: A. Winchell, 1870, Am. Philos. Soc. Proc., v. 11, p. 414–415; S. S. Gorby, 1886, Indiana Dept. Geology and Nat. History 15th Ann. Rept., p. 86.

Probably named for Williamsport, Warren County.

Williamstown Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table facing p. 288.

Probably named for Williamstown Township, or village within the township, northwestern part of Orange County.

Williamsville Dolomite Member (of Bertie Formation)

Williamsville Waterlime (in Bertie Group)

Williamsville Waterlime and Shale[1]

Upper Silurian: Western and central New York.

Original reference: G. H. Chadwick, 1919, *in* M. Y. Williams, Canada Geol. Survey Mem. 111, p. 85, 93.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 9, fig. 1. Rank reduced to member status at top of Bertie formation. Overlies unnamed middle member; underlies Cobleskill.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7, 9. In central New York, considered upper member of Bertie formation. Overlies Forge Hollow member (new); underlies Cobleskill formation. Thickness 4 to 10 feet. Believed to be continuous with same unit in western New York. Cayugan series.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Williamsville waterlime is uppermost formation in Bertie group. Overlies Scajaquada shale or waterlime; underlies Akron dolomite. Fieldwork has not demonstrated lateral continuity of Williamsville and Oxbow dolomite (new) as shown on present chart. Thick glacial deposits conceal units in area where they may merge. For the present, distinct names are retained for western and central New York.

Probably named for exposures at Williamsville, Erie County.

**Williana Formation**

Williana member

Pleistocene: Central and southwestern Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 78 (fig. 6), 155–157. The series of Pleistocene deposits in Grant and La Salle Parishes is divided into four members, their names corresponding to the four distinct depositional terrace surfaces, Williana (oldest), Bentley, Montgomery, and Prairie. Williana member consists of three transitional phases: coarse phase with lenticular masses of sands and gravels, predominantly sandy phase with local lenses of gravels, and upper silty clay phase with local sand lenses. Thickness 50 to 95 feet. Unconformably overlies Vicksburg sediments.

H. N. Fisk, 1940, Louisiana Dept. Conserv. Geol. Bull. 18, p. 176–177, pl. 1. Rank raised to formation. Described in Rapides and Avoyelles Parishes where it overlies undifferentiated Fleming formation.

P. H. Jones *in* P. H. Jones, A. N. Turcan, Jr., and H. E. Skibitzke, 1954, Louisiana Dept. Conserv. Geol. Bull. 30, p. 57, 63–65. In southwestern Louisiana, overlies Pliocene Foley formation (new).

Well exposed along U.S. Highway 167 between Mosley Hill, 2 miles north of Williana and Bentley, Grant County.

**Willimantic Gneiss**[1]

Pre-Pennsylvanian: Eastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 140, 141, 142.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 51. Restricted; igneous part of Willimantic included in Monson gneiss.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Pre-Triassic.

U.S. Geological Survey currently designates the age of the Willimantic Gneiss as pre-Pennsylvanian on the basis of a study now in progress.

Crops out in and around Willimantic, Windham County.

Willis Coal Member (of Abbott Formation)

Pennsylvanian: Southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1), 62, pl. 1. Assigned to member status in Abbott formation (new). Occurs above Grindstaff sandstone member and below Finnie sandstone member. Thickness 2 to 4 inches at type section of Abbott. Coal named by Charles Butts (1925, Illinois Geol. Survey Bull. 47). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: SE¼SW¼ sec. 30, T. 10 S., R. 9 E., Gallatin County.

Willis Phyllite

Precambrian: Southwestern Virginia.

R. V. Dietrich, 1959, Virginia Polytech. Inst. Bull., Engineering Expt. Sta. Ser. 134, p. 74, 75, pl. 1. A highly crenulated garnet-bearing phyllite. Top of unit grades into Lynchburg formation through many hundred feet of alternating layers of phyllite like the Willis proper and layers of mica schist-gneiss indistinguishable from Lynchburg mica schist. (Lynchburg as used here may not be correlative of type locality Lynchburg). Base of Willis not recognized in Floyd County; phyllite unit may be wholly beneath the Lynchburg and may even represent a facies of Little River gneiss (new), or it may be wholly within the Lynchburg and therefore be a member of that formation. May be of same general age as some of rocks in Blue Ridge complex.

Named for the fact that it underlies Willis Ridge, Floyd County. It also is bedrock of two belts that trend east-northeast with their geographical centers on either side of Route 221 near Kings store.

**Willis Sand**[1]

Pliocene(?) : Southeastern Texas and southern Louisiana.

Original reference: J. Doering, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 5, p. 644, 656, 660.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1702–1703. Discussed with Quaternary deposits of Texas Coastal Plain. Unconformably overlies sandstone and clay beds of Pliocene and upper Miocene age. Underlies terrace deposit herein named Gay Hill. Age of Willis not determined from fossil evidence but is here considered to be Pleistocene.

J. A. Doering, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1822. Citronelle formation of south Mississippi and Alabama, which was considered to be, in part, a residual formation is now recognized to be equivalent of Willis formation of Texas and Louisiana. Name Citronelle has priority and is here used for combined Citronelle-Willis in newly proposed classification of Gulf Coast. Pleistocene.

Named for town of Willis, 10 miles north of Conroe, Montgomery County, Tex.

Williston Formation (in Ocala Group)

Williston Member (of Moodys Branch Formation)

Eocene: Western Florida.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 141–152. Upper member of formation. Overlies Inglis member (new). Two types of marine limestone predominate: cream-colored coquina of camerinids and miliolids loosely held in calcite paste, and cream to tan-colored detrital limestone composed of quantities of small foraminifers with minor percentages of echinoids, large foraminifers, Comatulid brachials, and mollusks loosely held by secondary calcite and calcite paste. Thickness 27 to 32 feet. Underlies Ocala limestone restricted.

H. S. Puri, 1953, (abs.) Jour. Sed. Petrology, v. 23, no. 2, p. 130; 1957, Florida Geol. Survey Bull. 38, p. 29–30. Rank raised to formation in Ocala group. Overlies Inglis formation; underlies Crystal River formation (new).

Type locality: Pit in SE¼NE¼ sec. 27, T. 12 S., R. 18 E., Levy County.

**Williston Limestone**[1]

Upper Cambrian: Northwestern Vermont.

Original reference: Arthur Keith, 1923, Am. Jour. Sci., 5th ser., v. 5, p. 117+.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1078. Age designated Beekmantown, Upper Canadian series [Lower Ordovician].

Named for exposures in western part of Williston Township about 5 miles southeast of Burlington.

**Williwaw Cove Formation**

Tertiary or Quaternary: Southwestern Alaska.

G. L. Snyder, 1959, U.S. Geol. Survey Bull. 1028–H, p. 173–175, pl. 23. Thick sequence of andesite and bandaite flows with minor amounts of basalt and dacite flows and major amounts of pyrocalstic material. Dikes of andesite and basalt in some areas. Pyroclastic deposits occur in beds, 1 to 40 feet thick, interbedded with the flows. Vertical sea cliff exposures, as much as 550 feet high appear to represent a single flow. Forms base upon which all later volcanic deposits accumulated. Contact with younger rocks very irregular; locally has relief of several thousand feet. Probably late Tertiary or early Quaternary. Andesite adjacent to West Cove member (new) of Little Sitkin dacite (new) has been highly altered by fumarolic activity.

Named from exposures in sea cliffs on west side of Williwaw Cove, Little Sitkin Island, in Rat Islands group of Aleutian Islands.

**Willoughby Limestone**

Upper Silurian: Southeastern Alaska.

J. F. Seitz, 1959, U.S. Geol. Survey Bull. 1058–C, p. 71–72, pl. 6. Discussion of Geikie Inlet area, Glacier Bay. Limestone of Willoughby formation forms one isolated outcrop within area; relationship to other bedded rock in area not determined. In adjacent areas, Willoughby forms large conspicuous outcrops that reveal stratigraphic thickness of more than 5,000 feet.

Type locality and derivation of name not given.

Willow limestone[1]

Lower Ordovician: Eastern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53; 1924, Pan-Am. Geologist, v. 41, p. 78.

Named for exposures on east flank of Egan Range along Willow Creek, Ely region.

†Willow Creek Beds[1]

Upper Cretaceous: Eastern Colorado.

Original reference: G. T. Eldridge, 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 86–112.

Named for Willow Creek, in southern part of field, 1 to 3 miles southeast of mouth of Platte Canyon, where it is well exposed.

Willow Creek facies (of Flagstaff Formation)

Paleocene, upper: Central Utah.

W. N. Gilliland, 1951, Nebraska Univ. Studies, new ser., no. 8, p. 29–30, pl. 5 (fig. B). Consists of light-gray to white very dense limestone and gray conglomerate with limestone and quartzite pebbles. Minor amounts of red shale and siltstone also included. Thickness nearly 750 feet. Three units generally recognized (ascending): conglomerate, limestone, and conglomerate. Overlies Twist Gulch formation.

In prominent hogback located just south of Willow Creek, northeast of Redmond, Gunniston quadrangle.

**Willow Creek Formation[1]**

Upper Cretaceous and Paleocene: Southwestern Alberta, Canada, and northwestern Montana.

Original reference: G. M. Dawson, 1883, Canada Geol. Survey Rept. 1880–1882, p. 3B–6B.

R. W. Brown, 1949, Map showing Paleocene deposits of the Rocky Mountains and Plains (1:1,000,000): U.S. Geol. Survey. Paleocene.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf. p. 108 (fig. 1), 118. Discussion of Cretaceous rocks of northwestern

Montana. Willow Creek formation overlies St. Mary River formation. Present on northwest flank of Sweetgrass arch. Little is known concerning fossil record of formation in Montana. In Alberta, according to Tozer (1953, Alberta Soc. Petroleum Geologists Guidebook 3d Ann. Field Conf.), Cretaceous-Paleocene boundary falls within Willow Creek formation.

Type section: Willow Creek, west of Granum, Alberta, Canada.

**Willow Creek Rhyolite** (in Alboroto Group)

Willow Creek Rhyolite (in Potosi Volcanic Series)[1]

Miocene: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull. 718.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 93 (table 18). Alboroto rhyolite described in San Juan district. Lower part consists of tridymite rhyolite which includes Campbell Mountain and Willow Creek rhyolites and probably Outlet Tunnel quartz latite [all included in Alboroto group] of Creede district.

Well exposed above Creede in canyons of Willow Creek.

Willow Lake Basalts[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 686. Cenozoic.

Occur in Lassen National Park.

Willow Lake Norite

Lower Cretaceous(?): Northeastern Oregon.

W. H. Taubeneck, 1957, Geol. Soc. America Bull., v. 68, no. 2, p. 191–193, 235. Medium-grained rock with banding characterized by plagioclase and mafic minerals in alternating layers in which the direction of elongation of individual crystals is essentially at right angles to the banding. Intrudes Elkhorn Ridge argillite.

Well exposed along cirque walls east of Willow Lake, in Elkhorn Mountains [Grant County]. Forms part of Bald Mountain batholith.

Willow Point Limestone (in Palo Pinto Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: J. M. Armstrong, 1929, Texas Bur. Econ. Geology, geol. map.

Named for Willow Point in southwestern part of Wise County.

†Willow River Limestone[1]

Willow River Member (of Prairie du Chien Formation)

Lower Ordovician: Central western Wisconsin.

Original reference: L. C. Wooster, 1882, Geology of Wisconsin, v. 4, p. 106, 123–129.

L. A. Thomas and C. A. Balster, 1949, Iowa Acad. Sci. Proc., v. 56, p. 236 (table 1). In discussion of micropaleontological zones in Iowa, Willow River is shown as uppermost member of Prairie du Chien. Occurs above Root Valley member and below the St. Peter.

Named for exposures on Willow River, St. Croix County.

**Willow Spring Granodiorite**

Willow Spring Granite[1]

Upper Cretaceous or lower Tertiary: Central Arizona.

Original reference: F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

E. D. Wilson, 1952, Arizona Geol. Soc. Guidebook for field trip excursions in southern Arizona, p. 8 (table 3). Name appears on table as Willow Springs granodiorite. Age given as Laramide (Late Cretaceous to early Tertiary).

N. P. Peterson, 1952, Arizona Geol. Soc. Guidebook for field trip excursions in southern Arizona, p. 122 (fig. 43), 124. Age of granite given as Late Cretaceous or early Tertiary.

Exposed in Willow Spring Gulch, Globe quadrangle.

Willow Spring Member (of Cove Mountain Formation)

Tertiary: Southwestern Utah.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1). Volcanic sediments. Thickness 0 to 50 feet. Basal member of formation. Underlies Racer Canyon tuff member (new).

Occurs in Washington County.

**Willow Tank Formation**

Upper Cretaceous: Southeastern Nevada.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, no. 5, p. 929 (table 1), 931–932, figs. 2, 3, pl. 5. Coarse conglomerate at base ranging in thickness from few feet to maximum of 30 feet. Conglomerate succeeded rather abruptly by about 300 feet of fine-grained deposits, largely gray and buff clays interspersed with layers of tuffaceous sandstone. Clays distinctly bentonitic at several horizons. Underlies Baseline sandstone (new); overlies Aztec sandstone with slight angular unconformity. Previously part of Overton fanglomerate.

Section described was measured near Willow Tank, in Muddy Mountains, about 5 miles southwest of Overton, Clark County.

Willowvale Shale (in Clinton Group)

Middle Silurian: New York.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 22 (fig. 6). Shown on cross section below Herkimer sandstone and above Sanquoit beds.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 94–96, 99. Name introduced for those rocks which occupy position between Westmoreland (oolitic iron ore) and the Kirkland (red flux iron ore). At type locality, unit is about 22 feet thick and consists of uniform dark-gray to purple thin-bedded shale which is highly fossiliferous. In vicinity of Clinton, underlies Dawes sandstone (new). Between Clinton and Lakeport, the Willowvale merges with Irondequoit and Williamson formations.

Type locality: On small tributary flowing eastward into Sauquoit Creek at village of Willowvale, Oneida County.

**Wills Creek Shale (in Cayuga Group)**[1]

Wills Creek Limestone or Formation

Upper Silurian: Western Maryland, central Pennsylvania, western Virginia, and West Virginia.

Original reference: P. R. Uhler, 1905, Maryland Acad. Sci. Trans., v. 2, p. 20–25.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 14, p. 8, 175–207, measured sections. Wills Creek limestone described in West Virginia, where it is 54 to 458 feet thick. Underlies Tonoloway limestone. Overlies Williamsport sandstone—Bloomsburg facies. Cayugan series, Upper Silurian. This is "Rondout limestone" of earlier reports.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 5, 20, 22. Thickness of formation in central Pennsylvania 400 to 650 feet. Underlies Tonoloway formation; overlies Bloomsburg formation. Silurian.

Named for exposures on Wills Creek at Cumberland, Md.

**Wills Point Formation** (in Midway Group)[1]

Paleocene: Eastern Texas and southern Arkansas.

Original reference: R. A. F. Penrose, Jr., 1890, Texas Geol. Survey 1st Ann. Rept., p. xliii, 17, 19.

C. W. Cooke and others, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Shown on correlation chart as overlying Kincaid formation. Paleocene.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 11 (fig. 2), 25–38, pls. "Basal or Wills Point clays" was name given by Penrose (1890) to lower Tertiary clay beds exposed in vicinity of Wills Point, Tex. Under this designation, Penrose included all beds above unconformity at top of Upper Cretaceous and below base of partly continental Sabine River strata (Wilcox). Harris (1896, Bulls. Am. Paleontology, v. 1, no. 4) noted that laminated blue and yellow clay beds exposed west of Wills Point are equivalent only to upper part of section that in Alabama was designed Midway series by Smith and Johnson (1887, U.S. Geol. Survey Bull. 43). Name Wills Point was dropped for sometime because it was considered synonymous with earlier name Midway. In 1930's name Wills Point was revived and redefined to apply only to upper part of Midway group that lies above top of Tehuacana member of Kincaid formation or its lateral equivalents in south-central to northeast Texas. In this part of Texas, the Kincaid is subdivided into (ascending) Mexia member and Kerens member containing Wortham aragonite lentil. Geographically extending into bauxite region, Arkansas [this report]. Formation is undifferentiated and consists of dark-bluish-gray to black silty clay with sideritic layers; a dark-gray calcareous mudstone containing marine microfossils at base. Thickness as much as 450 feet. Overlies Kincaid formation; underlies Berger formation (new). Paleocene.

Named for Wills Point, Van Zandt County, Tex.

**Willwood Formation**

Eocene, lower: Northern Wyoming.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 15, 37. Name to be proposed by Van Houten for the "Bighorn Wasatch".

F. B. Van Houten, 1944, Geol. Soc. America Bull., v. 55, no. 2, p. 178–191. Proposed for variegated shales and hornblende-bearing sandstones conformably overlying Polecat Bench formation near center of Big Horn basin, and truncating folds along western margin of area. Thickness about 2,500 feet. Oldest Willwood deposits yield mammals of Clark Fork fauna, and the youngest, Lost Cabin mammals. Underlies Tatman formation. Late Paleocene and early Eocene.

R. L. Hay, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1871 (fig. 5), 1875 (fig. 8), 1878 (fig. 9), 1886–1888. Underlies Pitchfork formation (new). Lower Eocene.

Name derived from Willwood division of Shoshone Reclamation project in Park County, located between Shoshone River and northeastern slope of McCulloch Peaks.

†Wilmington Beds[1]

Eocene, upper, and Miocene, lower: Southeastern North Carolina.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 344, chart facing p. 334.

Probably named for exposures at Wilmington, New Hanover County.

Wilmington Complex

Age not stated: Delaware, Maryland, and Pennsylvania.

R. F. Ward, 1959, Geol. Soc. America Bull., v. 70, no. 11, p. 1425–1458, pl. 1. Consists of banded gneiss comprising mafic bands of calcic plagioclase, hypersthene, augite, and commonly hornblende and thick felsic bands of quartz and andesine with minor pyroxene; in central part, gneiss has been invaded by granite [Arden] consisting of orthoclase, oligoclase-andesine, biotite, and pyroxene; to the southwest, banded gneiss grades into amphibolites. Veins of granite, apparently related to Port Deposit granodiorite, intrude southwestern part of complex; coarse-grained undeformed gabbro stock intrudes gneiss north of Wilmington; similar body of gabbro occurs as group of low hills surrounded by Coastal Plain sediments. Complex is bordered by Wissahickon formation (lower Paleozoic?) and Port Deposit granite; southern edge of complex is covered by Coastal Plain sediments.

Occupies about 100 square miles in Delaware and adjacent Pennsylvania and Maryland.

Wilmington Group[1]

Pleistocene, late: Southern California.

Original reference: R. T. Hill, 1929, Science, new ser., v. 69, p. 379–380.

Derivation of name not stated.

Wilmington Limestone[1]

Upper Ordovician (Richmond): Northeastern Illinois.

Original reference: J. R. C. Evans, 1926, Chicago Univ. Abs. Theses, Sci. ser., v. 2, p. 199–200.

Type locality not stated.

†Wilmore Limestone[1]

Middle Ordovician (Trenton): Central Kentucky.

Original reference: J. M. Nickles, 1905, Kentucky Geol. Survey Bull. 5, p. 15.

Named for exposures at Wilmore, Jessamine County.

**Wilmore Sandstone Member** (of Conemaugh Formation)[1]

Upper Pennsylvanian: Western Pennsylvania.

Original reference: C. Butts, 1905, U.S. Geol. Survey Geol. Atlas, Folio 133.

Exposed at top of first railroad cut west of Wilmore, on hillside west of Wilmore, about 3 miles southwest of Wilmore, Cambria County, and at other places.

Wilson Diorite or Quartz Diorite

*See* Mount Wilson Quartz Diorite.

†Wilson Formation[1]

Pennsylvanian: Southeastern Kansas and northeastern Oklahoma.

Original reference: F. C. Schrader and E. Haworth, 1905, U.S. Geol. Survey Bull. 260, p. 447.

U.S. Geological Survey has abandoned the term Wilson formation by the acceptance of its members or their successors as formations. Northward from Wilson County, they are included in Lansing group and upper part of Kansas City group.

Named for Wilson County, Kans.

Wilson Creek Member (of Wood River Formation)

Permian (Wolfcampian): Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert, Abs., v. 20, no. 3, p. 999. Youngest member of formation. Overlies Lake Creek member (new).

Deposited in Muldoon trough, aligned N. 30° W.

Wilson Ranch Beds[1]

Pliocene: Western California.

Original reference: V. C. Osmont, 1904, California Univ. Pub., Dept. Geol. Bull., v. 4, p. 74.

Probably named for exposures on a ranch in Sonoma County.

†Wilton Formation[1]

Precambrian(?): Southwestern Connecticut.

Original reference: J. G. Percival, 1842, Connecticut Geol. Survey Repts., p. 51–53, 63, map.

Covers large part of Wilton, Fairfield County.

Wimer Beds[1]

Miocene, upper: Northwestern California.

Original reference: J. S. Diller, 1902, U.S. Geol. Survey Bull. 196, p. 32–35, 47.

F. W. Cater, Jr., and F. G. Wells, 1953, U.S. Geol. Survey Bull. 995–C, p. 104. Described in Gasquet quadrangle as marine beds consisting of friable yellow shale and siltstone that weather red. Exposed at an altitude of 2,000 feet along Big Flat-Bear Basin Road just north of French Flat and at an altitude of 2,200 feet on Lower Coon Mountain.

Well exposed along old Wymer (Wimer) stage road, in sec. 20, about 13 miles northeast of Crescent City, Del Norte County.

Wimer School Limestone Member (of Labette Shale)

Pennsylvanian (Des Moines): Northeastern Oklahoma.

C. M. Cade 3d, 1953, Tulsa Geol. Soc. Digest, v. 21, p. 132 (fig. 2), 138–139. Persistent limestone in upper part of Labette. Compact massive lithographic limestone, very fossiliferous; dark gray to yellow brown, weathering to light yellow. Thickness 2 feet. Overlies greenish-yellow calcareous shale; separated from overlying Anna shale by shale interval of varying thickness.

Type locality: On north side of Oklahoma Highway 10, one-quarter mile west of SW cor. sec. 19, T. 28 N., R. 18 E., [Craig County]. This locality is three-quarters mile west of Wimer School.

Wimsattville Formation

Tertiary, lower: Southwestern New Mexico.

R. M. Hernon, W. R. Jones, and S. L. Moore, 1953, New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 118 (map), 120. Listed in table of formations. Basin-filling gravel and sand. Thickness about 1,000 feet. Unconformably underlies Rubio Peak formation (new); unconformably overlies unnamed andesite breccia.

Restricted to Wimsattville basin, Santa Rita quadrangle.

**Winchell Limestone** (in Canyon Group)

Winchell Formation (in Graford Group)

Winchell Member (of Graford Formation)[1]

Upper Pennsylvanian: Central northern Texas.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 97, 104–107. Name Winchell member of Graford formation is applied to group of thin limestones separated by thick shale beds and thin sandstones in Winchell area, Brown County, which to the west develop into conspicuous limestone bed, as recorded by well logs in central Coleman County. This group of limestones includes Clear Creek limestone of Drake (1893) and of Plummer and Moore (1921, Texas Univ Bull. 2132), plus some higher beds heretofore included in Placid shale member of Plummer and Moore (1921). Thickness 50 to 72 feet. Overlies Cedarton shale member.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Graford group. Overlies Cedarton shale; underlies Placid shale of Brad group.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook Apr. 17–19, p. 51; 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 65–66. Shown on composite stratigraphic section of Brown and Coleman Counties as Winchell limestone in Canyon group. Underlies Placid shale member of Brad formation; overlies Cedarton shale member of Graford formation. Consists of lower unnamed limestone, light olive gray to dark yellowish brown, containing brachiopods; shale, olive gray to greenish gray to yellowish-brown and grayish-red, that contains beds of fine sand and conglomerate-filled channels which have removed lower limestone locally; upper unnamed limestone, upper part of which is light gray, thick bedded, and contains brachiopods and crinoids, lower part of olive gray, thick bedded, fine grained, and separated from upper part by shale traceable across Brown County. Thickness about 100 feet.

Named for occurrence near Winchell, Brown County.

**Winchester Limestone**[1]

Middle and Upper Ordovician: Central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46.

Named for Winchester, Clark County.

**Windfall Formation**

Upper Cambrian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 19–20, pl. 2. Proposed for rocks of Cambrian age at Eureka between Dunderberg shale below and Pogonip group, as restricted above. Formation in Windfall Canyon is close to 650 feet thick, and this figure appears to be approximately correct for whole area of outcrop. At Eureka, divided into two limestone members (ascending) Catlin and Bullwhacker (both new).

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 161. In Ely district, includes Barton Canyon member (new).

Type locality: Windfall Canyon, just north of old Windfall mine, Eureka mining district, Eureka County.

**Windham Sand**

Pleistocene (Wisconsin): Northeastern Ohio.

G. W. White, 1960, U.S. Geol. Survey Bull. 1121–A, p. 2 (table 1), 3 (fig. 1), 7–8. Medium-grained outwash sand. Commonly 4 to 6 feet thick; in depression on pre-Windham surface, it is 30 feet or more thick as shown by well records. Unconformably overlies Kent till; underlies Hiram till. Associated with buried Lavery till.

Type section: Sand pit of Miller-Dutter Sand and Gravel Co., 2 miles northeast of village of Windham, 1 mile east of east line of Windham Township and 1½ miles south of north line of township, one-quarter mile south of Erie Railroad and 100 yards south of Garrettsville-Warren Road, Windham Township, Portage County.

Windom Member[1] (of Belvidere Formation)

Lower Cretaceous (Comanche Series): Central Kansas.

Original reference: W. H. Twenhofel, 1924, Kansas Geol. Survey Bull. 9, p. 31–32.

Named for extensive occurrence northeast of village of Windom, McPherson County.

**Windom Member** (of Moscow Shale)

Windom Shale[1]

Middle Devonian: Western New York and eastern Pennsylvania.

Original reference: A. W. Grabau, 1917, Geol. Soc. America Bull., v. 28, p. 946.

Bradford Willard, 1937, Am. Jour. Sci., 5th, v. 33, no. 196, p. 276. Table of Hamilton correlations in Maryland, Pennsylvania, and New York shows Windom member present in eastern Pennsylvania.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., nos. 5–6, p. 337–379, pl. 1. In Batavia quadrangle, underlies Leicester marcasite member (new). Overlies Kashong shale member.

Wallace de Witt, Jr., 1956, U.S. Geol. Survey Geol. Quad. Map GQ–96. Member described in Eden quadrangle where it is 11½ to 15½ feet thick. Overlies Tichenor limestone member of Ludlowville shale; underlies Genundewa limestone lentil of Geneseo shale.

Named for exposures near village of Windom, Erie County, N.Y.

Windous Butte Tuff

Tertiary: Eastern Nevada.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 139, 140 (fig. 4). Consists of lower member, 200 to 350 feet thick, of highly welded vitric-crystal ignimbrite, dark purplish gray and red brown with black glass zone near base, and upper member, 165 to 860 feet thick, of moderately welded crystal-vitric ignimbrite, pale purple to mottled pink and gray, prominent angular quartz. Occurs above Currant tuff and below Needles Range formation. Has K-A age of 34 million years.

Present in Grant Range.

**Wind River Formation**[1]

Eocene, lower: Western Wyoming.

Original reference: F. T. Hayden, 1862, Am. Philos. Soc. Trans., new ser., v. 12, p. 125–127.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 63–66, pl. 17. Meek and Hayden (1862, Philadelphia Acad. Nat. Sci. Proc. 1861) were not sure of relationships of Wind River strata to others in region so they provisionally placed formation between Fort Union and White River groups. Granger (1910, Am. Mus. Nat. History Bull., v. 28, art. 21) described rocks of Bridger(?) and Uinta ages, between top of Wind River sequence and base of White River group on Beaver Divide, thus restricting usage of term Wind River to lower Eocene rocks. Wood (1934) gave name Green Cove formation to Bridger(?) beds described by Granger in Beaver Divide section. Sinclair and Granger (1911) divided lower Eocene strata of Wind River basin into Lysite and Lost Cabin "formations" on faunal basis. In present report [southern margin of Absaroka Range], Indian Mountain formation (new) is separated from lower part of original part of Wind River on the basis of both faunal and structural breaks, thus limiting usage of term Wind River to beds of upper lower Eocene age, between Indian Meadows formation and Green Cove or other middle Eocene formations in Wind River basin. As thus defined, the Wind River is a formation including only Lysite and Lost Cabin members or faunal zones. No definite structural break noticeable between two members and they are both lithologically and paleontologically so similar that they are not mappable units.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 24, 25, pl. 1. Includes Lysite and Lost Cabin members.

W. R. Keefer, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 110 (fig. 1), 111–114. Described in northwestern part of Wind River basin where it is most widespread lithologic unit. Five sequences recognized: lower variegated sequence, greenish-gray and drab tuffaceous sequence, middle variegated sequence, conglomerate sequence, and upper variagated sequence. Lower three units are most widespread and are best exposed along east side of Bench Creek where they have composite thickness of 1,618 feet. Two upper units of Wind River as herein defined may be lateral equivalents of some parts of Aycross formation. Underlies Tepee Trail formation; overlies Indian Meadows formation.

H. A. Tourtelot, 1957, Smithsonian Misc. Colln., v. 134, pt. 1, no. 4, p. 4–5. Described in northeastern Wind River basin where it is divided into Lysite and Lost Cabin members, each of which consists of two facies. Underlies Tepee Trail formation.

Named for exposures in Wind River basin.

Windrock Sandstone[1]

Pennsylvanian: Northeastern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33B, p. 327–328.

Exposed in cross-country sections from Windrock to American Knob, Morgan County.

**Windrow Formation**[1]

Cretaceous or Tertiary: Southwestern Wisconsin, northeastern Iowa, and southeastern Minnesota.

Original references: F. T. Thwaites and W. H. Twenhofel, 1920, Geol. Soc. America Bull., v. 31, p. 133; 1921, v. 32, p. 293–311.

C. R. Stauffer and G. A. Thiel, 1931, Minnesota Geol. Survey Bull. 29, p. 103–104. Name Windrow abandoned in southeastern Minnesota and sediments named Ostrander member of Dakota formation.

G. W. Andrews, 1958, Jour. Geology, v. 66, no. 6, p. 597–624. Here defined to include known deposits of upper Mississippi Valley which are in lithologic and mineralogic conformity with type section as described by Thwaites and Twenhofel (1921) and as described in this paper. Comprises Iron Hill member below and East Bluff member (both new). Underlain by rocks as old as Precambrian and as young as Devonian. Overlain by deposits as old as Nebraskan drift and as young as recent soil. Available evidence strongly suggests Cretaceous age.

Named for exposure on top of Window Bluff, near Tomah, Monroe County, Wis. Area of occurrence includes Driftless Area of Wisconsin, north of Wisconsin River and extends northward into older glaciated region of west-central Wisconsin; a part of glaciated region of southeastern Minnesota and northeastern Iowa.

**Windy Gap Limestone Member** (of Greene Formation)[1]

Permian: Southwestern Pennsylvania and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 24, 30.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 17 (table 2). Listed in summary of stratigraphic sections of Dunkard group in Harrison County. Thickness 5 feet near top of Greene formation.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 2). Listed with members of Greene series. Occurs below Lower Proctor sandstone and above Windy Gap coal.

Named for Windy Gap, a divide separating Laurel Run branch of Fish Creek from waters of Wheeling Creek, in Springfield Township, Greene County, Pa.

**Windy Gulch Rhyolite Breccia** (in Potosi Volcanic Series)[1]

Miocene: Southwestern Colorado.

Original reference: W. H. Emmons and E. S. Larsen, 1923, U.S. Geol. Survey Bull. 718.

In drainage basin of Windy Gulch and to west in Creede district.

**Windy Point Granite**[1]

Precambrian: East-central Colorado.

Original reference: G. I. Finlay, 1916, U.S. Geol. Survey Geol. Atlas, Folio 203.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 43. Summit of Pikes Peak marks position of nearly vertical stock of coarsely porphyritic quartz monzonite of mineral belt associated with Laramide revolution. South of peak a linear series of outcrops of this granite, known as Windy Point granite, shows almost horizontal contacts with underlying and earlier Pikes Peak granite.

Forms summit of Pikes Peak, El Paso County.

Wineglass Welded Tuff

Wineglass Dacite Flow

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and A. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 37–38. Wineglass dacite flow lies in gap of Crater Lake rim southeast of Round Top. It is about 1 mile long, about 50 feet wide, and about 20 feet thick. Might be considered tuff were it not for stringers of black glass intermingled with reddish groundmass containing fragments of other material and imparting a decided fluidal structure to the mass. A small sheet of this tuffaceous dacite, 10 feet thick, occurs along western edge of Cloud Cap flow ( new) and closely resembles tuffaceous material of Redcloud Cliff. At the Wineglass slide it is immediately associated with pumiceous tuff. Hard rock of the rim is andesite, overlain by 15 feet of pumiceous tuff with 10 feet of red tuffaceous dacite. This is overlain by 30 feet of conglomerate and capped by fine layer of pumice 25 feet thick. Evident from this section that the fragmental dacite does not represent final eruption, for that finds expression in top layer of pumice. Gap west of Round Top contains small sheet of tuffaceous dacite like that on other side, but thicker. It is 50 feet thick in middle and tapers to thin edge on west. On east of Round Top it extends up slope a short distance, and is seen above glacial striae and is undoubtedly a post-Glacial flow. Mapped as tuffaceous dacite. Near Rugged Crest, overlaps Rugged Crest flow (new). [See Sun Creek Dacite Flow.]

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 60–63, pl. 15 (fig. 1). Diller's Wineglass dacite flow or "tuffaceous dacite" named Wineglass welded tuff. At time Diller wrote, manner of deposition of such material was not known. Wineglass welded tuff is regarded as product of glowing avalanche. As the tuff and underlying lump pumice, in sections northwest of the Wineglass, are traced uphill toward Roundtop, the pumice thins to about 50 feet and the tuff to 10 feet, at the same time losing its welded character and merging into yellow, orange, or brown friable pumiceous lapilli tuff. If the tuff was once continuous over entire top of Roundtop lava (new), it has since been stripped away and is exposed only in the saddle-shaped depression over the center, where it is about 8 feet thick and is overlain by bouldery drift. In descent from Roundtop to shallow depression separating it from Palisades flow (new), the tuffaceous dacite thickens and becomes compact again and within short distance it shows same firmly welded appearance as displayed in brim of the Wineglass. In center of valley, it forms 30-foot cliff underlain by about 50 feet of incoherent white lump pumice. The two layers then continue westward over top of Palisades flow.

Beyond Palisade Point, on rise toward Rugged Crest, both pumice and welded tuff rest on margin of Cleetwood dacite. They are not present over center of Cleetwood lava. They are exposed along Rim Road, and here the tuff rests directly on crest of Cleetwood lava. South from the Wineglass, the dacite tuff extends to top of Skell Head, a distance of 2 miles, where it comes to an end. Deposit varies in thickness between 4 and 6 feet, reaching maximum of 12 feet at head of the "Champagne Glass," just before it comes to an end. Talus obscures relations at north edge of Redcloud lava (new). Presumably, the steep margin or Redcloud flow prevented tuff from spreading farther.

Type section: Forms brim of the Wineglass and the brick-red layer near top of the long slide above Grotto Cove near Crater Lake. Throughout most of its length of 4 miles, tuff makes a conspicuous cliff as much as 50 feet in height.

†Winfield dolomite[1]

Lower Ordovician: Central eastern Missouri and southwestern Illinois.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59, 60.

Named for Winfield County, Mo.

**Winfield Limestone** (in Chase Group)[1]

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: C. S. Prosser, 1897, Kansas Univ. Geol. Survey, v. 2, p. 64–66.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 39, p. 82–88. Although name Winfield was applied because of exposures near Winfield in Cowley County, Prosser's original type exposure near Marion, in Marion County, should still be regarded as typical for formation. When formation was first named and when name was changed to Winfield, the formation included three members (ascending): Stovall limestone, Grant shale, and Cresswell limestone. Kansas Geological Survey now includes a fourth member, the Luta, above the Cresswell, Overlies Doyle shale; underlies Odell shale.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41–44. Winfield comprises (ascending) Stovall limestone, Grant shale, and Cresswell limestone members. "Luta" limestone included in Cresswell. Thickness about 25 feet. Individual members not identified in southern Kansas.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 116–119. Winfield limestone is uppermost Permian unit exposed in Pawnee County. In the western part of county, red sandstones and shales of the Doyle are capped by about 7 feet of thin-bedded sandstone, which contains thin lenticular beds of light-colored nonfossiliferous calcareous sandstone and sandy limestone. This section has been correlated with and mapped as Winfield limestone. Possibility exists that Pawnee correlative of the Winfield is the brown fossiliferous limestone in upper part of Doyle. Southern extent of formation not known. Wolfcamp series.

Named for exposures around Winfield, Cowley County, Kans.

Wing Conglomerate[1]

Lower Ordovician (Beekmanstown): Northwestern Vermont.

Original reference: H. M. Seely, 1906, Vermont State Geologist 5th Rept., p. 174–187.

Champlain Valley.

**Wingate Sandstone** (in Glen Canyon Group)[1]

Upper Triassic: Western New Mexico, northeastern Arizona, southwestern and western Colorado, and southeastern Utah.

Original reference: C. E. Dutton, 1885, U.S. Geol. Survey 6th Ann. Rept., p. 136, pl. 16.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U.S. Geol. Survey Prof. Paper 183, p. 4–5, pls. Summary of results of fieldwork in eastern Utah and adjacent parts of Arizona, New Mexico, and Colorado and revision of interpretations and correlations of Jurassic formations in area. Wingate is basal unit of Glen Canyon group which is classified as Jurassic(?). The Wingate occurs in full development in southeastern Utah, northeastern Arizona, northwestern New Mexico, and apparently across north-central New Mexico. Extends eastward into Colorado but reaches mountains only in attenuated form. Northern boundary not known; probably not represented in Nugget sandstone of Wasatch Mountains. As much as 470 feet thick but in most of extent is about 300 feet. Underlies Kayenta formation; overlies Chinle formation.

R. L. Heaton, 1937, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 8, p. 1153–1177. Results of study show that basal "Jurassic" of northern Colorado is probably part Entrada and partly Upper Triassic; that latter grades into redbeds southward and the former continues into New Mexico where it is identical with so-called Wingate. True Wingate of Zuni Mountains grades marginally into red beds and may be of Upper Triassic age.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1665, 1667–1668. Discussion of revised correlation of Jurassic formations in parts of Utah, Arizona, New Mexico, and Colorado and problems of stratigraphic nomenclature involved. Study indicates that Entrada sandstone extends into northeastern New Mexico, where it is the Jurassic sandstone that was designated by writers of present report and others as Wingate sandstone. Strict application of rules of priority would require that name Wingate sandstone be applied to unit heretofore called Entrada and that new name be applied to Wingate sandstone of Utah and adjacent regions. However, these names are well entrenched in literature and abandonment through principle of priority would be confusing. Therefore, name Entrada is extended to include sandstone at type locality of Wingate sandstone, and name Wingate is retained for sandstone forming lower part of Glen Canyon group, with understanding that original type locality of Wingate has been abandoned.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 49 (fig. 25), 51 (table), 76–79, pl. 2. Described in Zion Park region where it is best exposed in walls of Johnson, Hog, Kanab, Cottonwood, and Sand Canyons and in mesas and towers along southern edge of Wygaret Terrace. Forms band of massive crossbedded sandstone, gray, red, or tan, which lies between bedded red sandstones of Chinle below and Kayenta above. Thickness as much as 400 feet. Jurassic(?).

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2521, 2523. Name Lamb Point tongue (new) of Navajo sandstone is applied to rocks in Kanab area formerly classified as Wingate by Gregory (1950). Unit mapped as Wingate sandstone by Wanek and Stephens (1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–145) is here considered Springdale sandstone member of Moenave formation. Hence, name Wingate sandstone is eliminated in Kanab, Utah, area. Triassic age assigned to Wingate.

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 8–12, pl. 2. Dutton described Wingate from exposures in cliffs north of Fort Wingate, N. Mex. In his description he refers to limestone unit in the Chinle, since referred to as Chinle "B" by Gregory (1917, U.S. Geol. Survey Prof. Paper 93). Units Chinle "B" and Wingate stand out clearly in sketch included in Dutton's report. At point shown in sketch, unit described as Wingate is 658 feet thick. Of this thickness, basal 355 feet is composed of sedimentary rocks now considered to be Wingate sandstone, as recognized throughout northeastern Arizona, southeastern Utah, and Parts of western Colorado. Upper 303 feet of Dutton's type Wingate is now recognized as Entrada sandstone of San Rafael group (Baker, Dane, and Reeside, 1947). Wingate sandstone is here restricted to lower half of Dutton's type section. In Navajo country, Wingate comprises two mappable units herein named (ascending) Lukachukai and Rock Point members. At type locality underlies Entrada sandstone; in Arizona underlies Kayenta formation or Moenave formation. Upper Triassic.

Type locality: Cliffs north of Fort Wingate, N. Mex.

Winifrede Limestone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen, 1941, West Virginia Geol. Survey Rept. Kanawha County, p. xxvi, 641.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 108. Limestone in Kanawha group.

Exposed on South Hollow Branch of Fields Creek, south of Winifrede, Kanawha County.

Winifrede Sandstones (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: I. C. White, 1908, West Virginia Geol. Survey, v. 2A, p. 271, 430.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 93, 106. Lower and Upper Winifrede sandstones included in Kanawha group.

Probably named for occurrence at Winifrede, Kanawha County.

Winifrede Underclay

Pennsylvanian (Pottsville Series): Southwestern West Virginia.

W. A. Tallon and R. G. Hunter, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 17–18. Immediately underlies Winifrede coal. Where sampled in Kanawha County, clay is about 2 feet thick and is silty with small iron nodules.

Type locality and derivation of name not given.

Winkler Ford Limestone Member (of Grape Creek Formation)[1]

Permian: Central Texas.

Original reference: W. Kramer, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1581.

Crops out 0.1 mile south of northwest corner Elizabeth Aurand survey No. 1861, on road 1.2 mile southeast of that crossing on Concho River, Concho County.

Winklers Mill cyclothem

Permian: Western West Virginia.

A. T. Cross and M. P. Schemel, 1956, West Virginia Geol. Survey [Repts.], v. 22, pt. 1, p. 72 (fig. 1–61). Shown on geologic section above Washington cyclothem (new) and below unnamed cyclothem.

Present in Parkersburg quadrangle.

Winnebago Drift

Pleistocene (Wisconsinan): Northern Illinois.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 2 (fig. 1), 5. Named applied to rock-stratigraphic unit described by Shaffer (1956, Illinois Geol. Survey Rept. Inv. 198, p. 18–19) and assigned to Farmdale substage. Consists of till and outwash; occurs stratigraphically below loess below Shelbyville till and is younger than Sangamon soil. Assigned to Altonian substage (new).

Named for exposures in Winnebago County.

Winnebago Shale[1]

Winnebago Shale Member (of Burlingame Formation)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, and northeastern Kansas.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 5.

E. H. Wenberg, 1942, Iowa Acad. Sci. Proc., v. 49, p. 343 (fig. 6). Listed as Winnebago shale in insoluble residue correlations of Missouri and Virgil strata in Iowa.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 45–46. In Nebraska, Burlingame limestone includes (ascending) Taylor Branch limestone, Winnebago shale, and South Fork limestone members.

Type locality: In Missouri River bluffs south of mouth of Winnebago Creek, north of Rulo, Richardson County, Nebr.

**Winnemucca Formation**

Upper Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Consists of shales and sandstones interbedded with dolomites and limestones. In Sonoma Range, lower part is shale or slate with numerous limestones and dolomite beds; sandstone prominent near top. In East Range, slate and quartzite, some limestone in upper part. Basal contact drawn at lowest prominent clastic bed. Thickness at type locality about 2,000 feet. In East Range, about 3,000 feet thick. Overlies Dun Glen formation (new) with local unconformity.

R. R. Compton, 1960, Geol. Soc. America Bull., v. 71, no. 9, p. 1387, pl. 1. In Santa Rosa Range, overlies Grass Valley formation and conformably underlies O'Neill formation (new). Thickness 600 to 1,500 feet. No persistent unit as calcareous as the Dun Glen formation occurs in Santa Rosa Range, but local thick lenses of limestone and dolomite indicate that the Winnemucca formation of Santa Rosa Range may connect laterally with both Winnemucca and Dun Glen formations of Winnemucca quadrangle.

Type locality: Mullen Canyon, west side of Sonoma Range, 8 miles south of Winnemucca, Winnemucca quadrangle.

Winneshiek limestone[1]

Lower Ordovician: Iowa.

Original reference: C. R. Keyes, 1934, Pan-Am. Geologist, v. 61, no. 3, p. 240.

†Winnfield Limestone[1]

Upper Cretaceous(?): Northwestern Louisiana.

Original reference: G. D. Harris and A. C. Veatch, 1899, Louisiana Geol. Survey Rept. 1899, pt. 5, p. 56–59.

Named for Winnfield, Winn County.

**Winnipeg Formation**

Winnipeg Sandstone[1]

Middle Ordovician: Surface and subsurface in Manitoba, and subsurface in Saskatchewan, Canada; and subsurface in Montana, North Dakota, and South Dakota.

Original references: D. B. Dowling, 1896, Ottawa Field Nat. Club Trans. 1895–1896, v. 11, p. 67–68; 1901, Canada Geol. Survey Ann. Rept. 11, p. 39F–46F.

H. D. Erickson, 1954, South Dakota Geol. Survey Rept. Inv. 74, p. 43–44. Name Winnipeg formation has only recently been introduced into South Dakota by oil geologists to correlate with wells drilled north of South Dakota. Name St. Peter sandstone had been used for the Winnipeg.

Georgia Macauley, 1955, Alberta Soc. Petroleum Geologists Jour., v. 5, no. 4, p. 49–52, 59. Winnipeg formation is herein defined as the shale and sandstone section which underlies the limestone of Red River formation and which rests upon Precambrian basement complex in Manitoba. In Saskatchewan and the Dakotas, formation is underlain by Cambrian sediments. No type outcrop section can be established because nowhere are both upper and lower contacts exposed in any one outcrop. , Section between 5,220 and 5,359 feet in California Standard No. 15–8 well, in Lsd. 15, sec. 18, T. 10, R. 27, West 1st Mer., could be designated as type well section, although Union Aanstad Stratigraphic Test No. 1, in sec. 29, T. 158 N., R. 62 W., North Dakota, was cored through much of the shale and sandstone, and if this core is available, may be a better type well section.

R. J. Ross, Jr., 1957, U.S. Geol. Survey Bull. 1021–M, p. 446 (fig. 68), 448–449, pl. 44. Discussion of Ordovician fossils from wells in Williston basin, eastern Montana. In subsurface, Winnipeg formation overlies Deadwood formation and underlies Red River formation of Bighorn group.

Named for exposures on islands and shores of south part of Lake Winnipeg, Manitoba, Canada.

**Winnipegosis Formation** (in Elk Point Group)

Winnipegosan Formation[1]

Middle Devonian: Surface and subsurface in Manitoba, Canada, and subsurface in northeastern Montana, western North Dakota, and northwestern South Dakota.

Original reference (Winnipegosan): J. B. Tyrrell, 1893, Canada Geol. Survey, new ser., v. 5, pt. 1, p. 144E–199E.

A. D. Baillie, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 2, p. 444–447; 1953, Manitoba Dept. Mines and Nat. Resources Mines Br. Pub. 52–5, p. 19, 20–21, 22 (fig. 4), 24. Formation originally called Winnipegosan by Tyrrell (1892) [1893] but, because adjectival suffix has time connotation, term Winnipegosis is used in this paper to conform with usage recommended by Geological Survey of Canada and American Commission on Stratigraphic Nomenclature. In outcrop, overlies Elm Point formation and underlies Dawson Bay formation (new). Redefined in subsurface to include Elm Point limestone. Elk Point group.

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2299 (fig. 2), 2303 (fig. 4), 2304–2306. Report deals with Devonian system of United States part of Williston basin and adjacent parts of central Montana and northern Wyoming between which deposition was continuous. In area of this report, the Winnipegosis is redefined to include deposits previously assigned to Ashern formation of Baillie (1951, Manitoba Dept. Mines and Nat. Resources Mines Br. Pub. 49–2). In the United States, the Winnipegosis is restricted to Williston basin and northeastern Montana. Ranges in thickness from fraction of a foot to about 300 feet. Lower formation of Elk Point group. Underlies Prairie formation. In Birdbear well, Dunn County, N. Dak., lies between depths of 11,438 and 11,698 feet and rests unconformably on Silurian rocks. Middle Devonian. Subsurface nomenclature of this report is for Williston basin and Montana east of 111° meridian.

Well exposed in outcrop area along shores of Lake Manitoba and Lake Winnipegosis, Manitoba, Canada.

**Winnipesaukee Quartz Diorite** (in New Hampshire Plutonic Series)

Winnipesaukee Gneiss[1]

Upper Devonian(?): East-central New Hampshire.

Original reference: C. H. Hitchcock, 1874, Geology New Hampshire, pt. 1, p. 508–545.

Alonzo Quinn, 1937, Geol. Soc. America Bull., v. 48, no. 3, p. 377, 378, 400. Name revived and unit redescribed as light- to medium-gray medium-grained quartz diorite. Characterized by faint foliation. Streaky in places and cut by many small pegmatite veins and aplite dikes. Locally porphyritic with plagioclase phenocrysts. Assigned to New Hampshire magma series of probable Upper Devonian age. Subdivision of Chatham granite of Billings (1928).

Alonzo Quinn, David Modell, and Louise Kingsley, 1940, Geologic map and structure sections of the Winnipesaukee quadrangle, New Hampshire (1:62,500): New Hampshire State Highway Dept. Mapped extensively in Lake Winnipesaukee area. Includes granite, granodiorite, and diorite.

Named for Lake Winnipesaukee, Belknap and Carroll Counties.

**Winoka Gravel**[1]

Pliocene: Southwestern Missouri.

Original reference: E. J. Park, Mabel Hays, and E. M. Shepard, 1904, Bradley Geol. Field Sta. Drury Coll. Bull. 1, pt. 1, p. 14, 19, 41.

Named for exposures at Winoka, Greene or Christian County.

**Winona Amygdaloid**[1] (in Central Mine Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survery Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Winona mine, Houghton County.

**Winona Conglomerate**[1] (in Bohemia Range Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane, 1911, Michigan Geol. and Biol. Survey Pub. 6, geol. ser. 4, p. 547, 563, 566, 576, 982, fig. 42.

Named for occurrence in Winona mine, Houghton County.

**Winona Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Winona mine, Houghton County.

**Winona Sand** or **Formation** (in Claiborne Group)

Winona Sand Member (of Lisbon Formation)[1]

Eocene, middle: Mississippi.

Original reference: E. N. Lowe, 1919, Mississippi Geol. Survey Bull. 14, p. 73.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 28–33. Most authors have considered Winona greensand to be a member of either the Tallahatta or Lisbon formation. It is herein raised to formational rank. Overlies Neshoba sand member (new) of Tallahatta formation; underlies Zilpha shale. Thickness commonly 25 feet in general vicinity of type locality.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim, Chart 29. Correlation chart shows Winona formation in Claiborne group. Underlies Zilpha clay; overlies Tallahatta formation, either Holly Springs sand member, Basic City shale member, or Neshoba sand member.

Named for development at Winona, Montgomery County.

**Winooski Marble**[1] or **Dolomite**

Lower Cambrian: Northwestern Vermont.

Original reference: Edward Hitchcock, 1861, Rept. Geol. Vermont, v. 1, p. 329.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 525, 532, 534. Winooski dolomite restricted to dolomitic beds in Winooski Falls or Winooski village in Colchester Township. Localities near Malletts Bay, in vicinity of Ethan Allen Park in Burlington, and along lower Winooski River are in a distinctly lower stratigraphic zone. Thickness difficult to determine because faunal zone that must exist between top of formation and beds of Upper Cambrian age is not accompanied by recognized lithologic break. Top of Winooski has never been identified. For mapping purposes, top of formation is placed beneath lowest beds of typical Upper Cambrian Danby quartzite. Lower limit of formation also indistinct. Lower contact (with Monkton quartzite) is mapped through points where, passing down section, quartzite beds over 1 foot thick and separated by less than 25 feet begin to appear. Thickness: 100 to 150 feet on east slope Snake Mountain; about 600 feet at Brandon; at least

800 feet at Pittsford; about 350 feet on north slope of Snake Mountain on Buck Mountain.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 536. Discussion of St. Albans area, northwestern Vermont. Name Winooski abandoned in area. Rocks that are here assigned to Dunham dolomite have been known in this area as Winooski marble. Cady (1945) has shown that name Winooski has been applied to two distinct units and has restricted name to the younger of the two, which is above Monkton quartzite, a formation in west-central Vermont. The Winooski, as thus restricted, is not present in St. Albans area but is represented by its equivalent, Rugg Brook dolomite.

Named for exposures along Winooski River in Burlington, Chittenden County, where the marble was first quarried.

†Winslow Formation[1]

Pennsylvanian: Northwestern Arkansas and northeastern Oklahoma.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Prof. Paper 24, p. 29.

C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 78, no. 4, p. 511. Rocks mapped in Muskogee County, Okla., as Winslow formation on State geological map have been subdivided into units herein designated as Atoka, Hartshorne, McAlester, and Savannah formations, and lower part of true Boggy shale.

Named for exposures in and around Winslow, Ark.

Winslow Member (of Moenkopi Formation)

Lower Triassic: Northeastern Arizona.

E. D. McKee, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 86, 87 (fig. 1). Composed largely of light-colored (gray) siltstones and mudstones with considerable bedded gypsum. Contrasts strongly with red-colored overlying Holbrook member and underlying Wupatki member (new) and in slope-forming tendencies. Thickness over 50 feet.

In Winslow-Holbrook area.

Winslow shale[1]

Lower Triassic: Northern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 250, 339.

Exposed in Rio Chiquito Colorado Valley, at mouth of Rio Puerco, Navajo and Coconino Counties. Derivation of name not stated.

**Winsor Formation**

Winsor Formation (in San Rafael Group)

Upper Jurassic: Central Southern Utah.

H. E. Gregory, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 235; 1950, U.S. Geol. Survey Prof. Paper 220, p. 49 (fig. 25), 51 (table), 96–98, pl. 5. Consists of sandstone and very subordinate conglomerate. Bulk is unbroken series of horizontal white or yellow-white beds characterized by regularity of stratification and consistency of texture and composition. Few beds are more than 2 feet thick—most of them measured in inches—except in uppermost 50 feet where continuity is broken by inclusion of lenses of extraneous material. Thickness 180 to 300 feet in Zion Park region; 450 to 800 feet in Paria Valley. Unconformably underlies

Dakota(?) sandstone; unconformably overlies Curtis formation of San Rafael group. No fossils found. Provisionally classed as Jurassic.

C. T. Snyder, 1952, Utah Geol. Soc. Guidebook 7, p. 12. Included in San Rafael group.

R. R. Kennedy, 1960, Brigham Young Univ. Research Studies, Geology Ser., v. 7, no. 4, p. 24, 25, 26, geol. map. Unconformably underlies Tushar conglomerate (new) in Tushar Range, Piute County.

Name derived from Winsor, the original settlement at Mount Carmel, Kane County. Present in upper Virgin Valley, Orderville Gulch, Muddy Creek, Flume Canyon, and eastward along Gray Cliffs to Paria Valley at Cannonville.

Winston Dolomite[1]

Silurian (Albion Series): Northwestern Illinois and northeastern Iowa.

Original reference: T. E. Savage, 1914, Am. Jour. Sci., 4th, v. 38, p. 34–37.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on chart as underlying Waucoma limestone; placed in Albion series.

Named for Winston, Jo Daviess County, Ill.

Winterport (type) Granite

Age not stated: South-central Maine.

J. M. Trefethen, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 2020. Described as foliated granites. Biotite streaking on foliation planes occurs locally. Older than Waldo granite.

Crops out in small masses in Bucksport quadrangle.

Winters Clay (in Allegheny Formation)[1]

Winters underclay member

Pennsylvanian (Allegheny Series): Southeastern Ohio.

[Original reference:] Wilber Stout, 1927, Ohio Geol. Survey, 4th ser., Bull. 31, p. 186–187.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 42. Considered part of Winters cyclothem (Allegheny series). Not present in area of this report, Perry County.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 11), 56. Winters underclay member of Winters cyclothm in report on Athens County. Thickness about 1½ feet.

First described in Vinton County.

Winters cyclothem

Pennsylvanian (Allegheny Series): Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 40, 42. Winters clay and coal are only representatives of Winters cyclothem in area studied. Occurs above Ogan cyclothem and below Clarion cyclothem.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 56. Incomplete in Athens County [this report]. Includes Winters shale (or) sandstone members and Winters coal and underclay members. Occurs above Ogan cyclothem and below Clarion cyclothem. Allegheny series.

Named for Winters coal. Orton (1884, Ohio Geol. Survey, v. 5, Econ. geology) first used name Winters for coal in vicinity of McArthur, Vinton County.

Winters shale and (or) sandstone member

Pennsylvanian: Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 11), 56. Member of Winters cyclothem in report on Athens County. Thickness less than 2 feet. Allegheny series.

**Winterset Limestone Member** (of Dennis Limestone)

Winterset Limestone (in Kansas City Group)[1]

Winterset Limestone Member (of Hogshooter Limestone)

Winterset Limestone Member (of Kansas City Formation)

Upper Pennsylvanian (Missouri Series): Western Iowa, eastern Kansas, northern Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: J. L. Tilton, 1897, Iowa Acad. Sci. Proc., v. 4, p. 48–54.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 44–47; 1952, Oklahoma Geol. Survey Bull. 69, p. 59–64. Uppermost member of Hogshooter formation in Oklahoma. Normally overlies Stark shale member but locally overlies Lost City member. Except where Canville, Stark, or Lost City members are present, Winterset lies on Coffeyville strata; underlies Nellie Bly formation.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Uppermost member of Dennis formation. Overlies Stark shale member; underlies Fontana shale member of Cherryvale formation. In Oklahoma, member of Hogshooter limestone. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 27, fig. 5. Winterset, at type section, is composed of massive upper unit commonly containing brown chert nodules changing to thin-bedded basal section. Shalley zone 4 feet from top has abundance of fusulinid *Triticites irregularis*. Thickness about 12 feet. Overlies Stark shale member; underlies Fontana shale member of Cherryvale formation.

Named for exposures at Winterset, Madison County, Iowa.

Winthrop Phyllite

Silurian: Southwestern Maine.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 130, pl. 1, table 1 (facing p. 112). Described as quartz-biotite phyllite. Chloritoid and garnet-staurolite facies are recognized. In middle-grade metamorphic zone. Overlies Androscoggin formation.

Type locality: A quarter mile northwest of village of Winthrop, Kennebec County. Other outcrops located along railroad on west side of Lake Marancook half mile north of village.

Winthrop Sandstone[1]

Upper Cretaceous: Central northern Washington.

Original reference: I. C. Russell, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 2, p. 100–137.

J. D. Barksdale, 1948, Northwest Sci., v. 22, no. 4, p. 165, 167–169. Described in Methow quadrangle. Conformably overlies Virginian Ridge formation (new); conformably underlies Midnight Peak formation (new). Upper Cretaceous.

Well exposed on north border of Methow Valley about 5 miles northwest of Winthrop, Okanogan County.

**Winzeler Shale[1] Member** (of Howard Limestone)

Pennsylvanian (Virgil Series): Southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 20, 94, 96.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 170 (fig. 34), 174. Bluish-gray or yellowish and clayey to calcareous shale. About 3 to 8 feet thick. Underlies Utopia limestone member; overlies Church limestone member. Recognizable from Nebraska and Iowa southward to Oklahoma, but locally, where Utopia limestone disappears, the Winzeler cannot be differentiated from White Cloud shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 19. Occurrence, southeastern Nebraska, southwestern Iowa, and northwestern Missouri, and southward into Kansas.

Type locality: Winzeler Farm, sec. 4, T. 26 S., R. 11 E., Greenwood County, Kans.

**Wiota Gravels**

Pleistocene: Northwestern Montana.

R. B. Colton, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–67. Name applied by Jensen (1951, U.S. Geol. Survey Open-File Rept.) to preglacial gravels deposited later than Flaxville gravel. Consist of well-rounded fragments of very fine- to medium-grained quartzite. Large part of unit is sand; lenses of silt and clay are present locally. Vary laterally from deposits that consist entirely of sand to those that contain coarse gravel. Commonly reddish brown. Thickness 1 to 30 feet; commonly 10 to 15 feet; at Wolf Point 26 feet. Overlie rocks ranging in age from Upper Cretaceous to Miocene or Pliocene. In vicinity of Wolf Point, overlie Bearpaw shale, Fox Hills, Hell Creek, and Fort Union formations, and Flaxville gravel. Capped by till as much as 20 feet thick.

Area of this report is Wolf Point quadrangle. Jensen used name in area 25 miles to west. Town of Wiota is in Valley County.

**Wisconsin Glaciation, Drift, Till**

Wisconsinan Stage

Wisconsin stage of glaciation[1]

Pleistocene: North America.

Original reference: T. C. Chamberlain, 1894, *in* James Geikie, The Great Ice Age, 3d ed.: London, Edward Stanford, p. 754–775.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 123–140. Five substages (subages) of Wisconsinan recognized in Kansas: Iowan, Tazewellian, Bradyan, Caryan, and Mankatoan. Four of these substages are characterized by glacial advance and retreat and are based on type localities in Mississippi Valley region. The Bradyan is interglacial interval. Wisconsinan follows Sangamonian stage and is followed by Recent stage.

J. C. Frye and A. B. Leonard, 1955, Am. Jour. Sci., v. 253, no. 6, p. 358–364. Bradyan interglacial interval is most significant break in sedimentation in Midcontinent region during post-Sangamonian time. Correlation of deposits in this interval with those of Upper Mississippi Valley Wisconsin is still tenuous and debatable. Provincial classification of post-Sangamonian time into Scandian, Bradyan, and Almenan sub-ages is proposed for use in Midcontinent region.

T. N. V. Karlstrom, 1956, U.S. Geol. Survey Bull. 1021–J, p. 304–330. Proposed that the Cochrane be considered a Wisconsin event of substage rank.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 174–177. Wisconsin glaciation consisted of five successive glacial advances: Farmdale (oldest), Iowan, Tazewell, Cary, and Mankato. None of the glaciers reached area of this report although the Tazewell came within less than 2 miles of Glasford quadrangle. First and second glaciations are recorded by widespread loesses and the next three by glacio-fluvial, alluvial, or lacustrine deposits in Illinois Valley and its tributaries. Pleistocene epoch.

M. M. Leighton, 1957, Jour. Geology, v. 65, no. 1, p. 108–109. Discussion of Cary-Mankato-Valders problem. Wisconsin stage classified as follows (ascending): Farmdale, Iowan, Tazewell, Cary, Mankato, and Valders substages. Cochran[e] excluded from classification because it is considered that it represents a minor incident in final climactic adjustment to present interglacial stage, the Recent.

V. C. Shepps and others, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G–32, p. 22–46. Ice advanced into northwestern Pennsylvania five times during Wisconsin age. Advances occurred at least once during Tazewell substage and four times during Cary substage.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 1–16. Revised time-stratigraphic classification of Wisconsinan stage of Lake Michigan lobe as used by Illinois Geological Survey consists of following substages (descending): Valderan, Twocreekan, Woodfordian (new), Farmdalian, and Altonian (new). Extrapolation from presently available radiocarbon dates suggests that Wisconsinan time started 50,000 to 70,000 radiocarbon years ago and terminated about 5,000 radiocarbon years ago. More than half this time falls within Altonian substage. New rock-stratigraphic names introduced are Roxana silt, Morton loess, and Richland loess. In terms of stratigraphic sequence, stage includes all deposits above Sangamon soil and below Recent alluvium. Although this expands definition of stage to include deposits now known to be older than type Farmdale loess, these deposits had previously been included in the Wisconsinan. Former classification of stage as used by Illinois Geological Survey was (descending) Mankato, Cary, Tazewell, Iowan, and Farmdale.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 529–552. Wisconsin stage is classified on basis of stratigraphy into six glacial substages (ascending): Farmdale, Iowan, Tazewell, Cary, Mankato, and Valders. In this paper, names are proposed for the interglacial substages not previously designated, completing sequence as follows (ascending): Farmdale (glacial), Farm Creek (new), Iowan (glacial), Gardena (new), Tazewell (glacial), St. Charles (new), Cary (glacial), Bowmanville (new), Mankato (glacial), Two Creeks, and Valders (glacial). Paper also gives consideration to other classifications, including one proposed by Frye and Willman (1960). Author [Leighton] does not agree with Frye and Willman.

†Wisconsin Valley Slates[1]

Precambrian (Huronian) : Central northern Wisconsin.

Original references: C. R. Van Hise, 1892, U.S. Geol. Survey Bull. 86, pl. 3, map; 1892, U.S. Geol. Survey Mon. 19, pl. 1, map.

Upper part of Wisconsin River.

**Wiscoy Sandstone Member** (of Java Formation)

Wiscoy Member (of Chemung Formation)

Wiscoy Shale or Sandstone[1]

Upper Devonian: Western and west-central New York.

Original references: J. M. Clarke, 1897, Ann. Rept. State Engineer and Surveyor, p. 737; 1899, New York State Mus. 16th Ann. Rept., p. 31–41.

J. F. Pepper and Wallace de Witt, Jr., 1950, U.S. Geol. Survey Oil and Gas Prelim. Inv. Chart 37. Referred to as Wiscoy sandstone. At type locality, composed largely of massive greenish-gray silty mudstones and some argillaceous limestones. East of type locality, in vicinity of Arkport, Wiscoy is mainly greenish-gray siltstones and some medium-bedded sandstones. Intertongues with Hanover shale.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. From Franklin Gulf eastward, an expanding wedge of Wiscoy sediments underlies Perrysburg formation (new).

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1). Considered member of Chemung formation.

Wallace de Witt, Jr., 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1935–1936. Wiscoy sandstone redefined as member of Java formation (new). In type section of the Java, the Wiscoy is represented by several beds of medium-gray to medium-greenish-gray argillaceous siltstone and silty mudrock in upper 15 feet of Hanover shale member. Wiscoy thickens to east as gray shale and mudrock of Hanover shale member intertongue at successively older stratigraphic horizons with medium-gray and medium-greenish-gray silty mudrock, siltstone, and very fine grained sandstone. East of central Wyoming County, upper contact of Wiscoy is clearly marked at most places by black or brownish-black shale of Dunkirk member of Perrysburg formation.

Typically exposed in valley of Wiscoy Creek at Wiscoy, Hume Township, Allegany County.

**Wise Formation**

Wise Formation (in Pottsville Group)[a]

Middle Pennsylvanian: Southwestern Virginia and southeastern Kentucky.

Original reference: M. R. Campbell, 1893, U.S. Geol. Survey Bull. 111, p. 28, 34.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 72–75. In Wise County, formation includes coals from High Splint (above) at top to Dorchester; underlies Harlan sandstone; overlies Gladeville sandstone. Addington sandstone occupies interval between Clinton and Addington coals.

Named for Wise County, Va.

Wise Lake Formation (in Galena Group)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, figs. 3, 15B. Massively bedded dolomite, pure in upper part, slightly argillaceous in lower part. Thickness about 90 feet. Comprises (ascending) Stewartville and Sinsinawa members. Shown on columnar section as underlying Dubuque formation and overlying Dunleith formation (new).

Occurs in Dixon-Oregon area.

Wisenor Formation

Lower Cretaceous: West-central California.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 12 (fig. 2), 20–22, pls. 1, 2, 3, 4. Dark shale and thin hard carbonaceous sandstone. Thickness about 1,800 feet. Lies between Franciscan rocks of Ortigalita thrust and basal conglomerate of Panoche formation. Angular discordance exists between the Wisenor where strikes of the two formations differ, but everywhere the angle of dip of the formations is steep and approximately the same. Beds were originally included in Panoche formation by Anderson and Pack (1915). Taliaferro (1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 2) placed them in Shasta group on basis of lithology and stratigraphic position.

Named for exposures in Wisenor Hills. Area of report is Ortigalita Peak quadrangle, which is in the Coast Ranges bordering the San Joaquin Valley, about 5 miles south of Los Banos.

Wise Ridge Coal Member (of Spoon Formation)

Pennsylvanian: Southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33. 46 (table 1), 64, pl. 1. Proposed for coal formerly called Stonefort in order to restrict that name to Stonefort limestone. Thickness about 1 foot. Stratigraphically above Mount Rorah coal member (new) and below Stonefort limestone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼SE¼ sec. 25, T. 10 S., R. 4 E., Williamson County. Named for Wise Ridge, about 3 miles west of town of Stonefort.

**Wishbone Formation**

Eocene: South-central Alaska.

T. G. Payne, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–84. Name appears only on correlation chart. Paleocene(?). Nonmarine formation in Matanuska Valley.

F. F. Barnes and T. G. Payne, 1956, U.S. Geol. Survey Bull. 1016, p. 13, 18–19, pls. 1, 2. Predominantly conglomerate composed of pebbles, cobbles, and a few boulders in sandy matrix. Includes numerous lenticular beds of sandstone, generally crossbedded and ranging in thickness from a few inches to 40 feet, and a few small lenses of silty claystone. Maximum thickness at least 1,850 feet. Overlies Chickaloon formation with gradational contact; unconformably underlies Tsadaka formation (new). Represents lower conglomeratic beds in Wishbone Hill district, mapped as Eska conglomerate by Martin and Katz (1912). Probably Paleocene, or possibly early Eocene in age.

U.S. Geological Survey currently designates the age of the Wishbone as Eocene on the basis of a study now in progress.

Named for exposures on Wishbone Hill, Wishbone Hill district, Matanuska coal field.

Wiskanian series

Cretaceous (Cretacic): Northwestern Kansas and eastern Colorado.

C. R. Keyes, 1941, Pan-Am. Geologist, v. 75, no. 5, p. 369–371. Term proposed for great section of dark shales usually called vaguely and erroneously the Pierre formation. Thickness about 1,000 feet. Covers large but indefinite part of median portion of Assiniboine centrum shales, which itself is not really a stratigraphic unit of any rank, but a term applied to great central filling of Cordillera geosyncline.

Name derived from a way-station in Wallace County, Kans.

**Wissahickon Schist**[1] or **Formation**[1]

Wissahickon Gneiss

Lower Paleozoic(?) (Glenarm Series): Southeastern Pennsylvania, Delaware, northern Maryland, and Virginia.

Original reference: F. Bascom, 1902, Maryland Geol. Survey Cecil County Rept., p. 104–108.

R. O. Bloomer, 1939, Virginia Geol. Survey Bull. 51–F, p. 141–145. In Hanover County, Wissahickon granitized gneiss is intruded by Petersburg granite. Wissahickon underlies Triassic sediments.

A. W. Postel, 1940, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 2004–2005. Igneous rocks in Wissahickon schist in Philadelphia region owe their origin to two types of magmatic activity: definite magmatic intrusions into Wissahickon schist, and hydrothermal replacement of Wissahickon by potash and soda-rich intrusions. The metagabbro, the Springfield aplitic granodiorite (new), and Ridley Park granodiorite (new) are products of magmatic intrusion. Age of Wissahickon is in doubt.

A. J. Stose and G. W. Stose, 1944, U.S. Geol. Survey Prof. Paper 204, p. 39–42, 52, 54, pl. 1. Formation described in Martic overthrust block in Hanover-York district, Pennsylvania, where it is an oligoclase-biotite-muscovite schist. This schist lies on southeast side of Peters Creek quartzite. On northwest side of this quartzite, there is belt of albite-chlorite-muscovite schist regarded as different metamorphic facies of Wissahickon formation. This albite-chlorite schist occupies most of southeastern part of district. The Wissahickon lies southeast of Marburg schist and contains infolds of metabasalt. Precambrian(?) Glenarm series. Precambrian age of Glenarm series not proved.

Judith Weiss, 1949, Geol. Soc. America Bull., v. 60, no. 10, p. 1689–1726. Report deals with structure, petrology, and metamorphism of Wissahickon schist in and near Philadelphia. Area under consideration is 35 miles long and 8 miles wide, and extends from Morrisville, Pa., on Delaware River, west to Darby Creek in Delaware County. Paleozoic rocks and Baltimore gneiss form northern boundary and Delaware River southern boundary. Formation is called Wissahickon schist in order to avoid cumbersome phrase "schist and gneiss," and because prevalent structure is schistose. Name applies to those recrystallized dominantly pelitic rocks that are south of Cream Valley-Huntingdon Valley fault and Rosemont fault and that extend southwest into Delaware and Chester Counties. Deposits of unconsolidated clays, sand, and gravels of Cretaceous, Tertiary, and Quaternary age overlap Wissahickon schist to the southeast of area studied. Overlap extends west of Delaware River. Schist is exposed along major streams and at altitudes above 100 feet; small isolated patches of gravel cover schist up to altitudes as high as 400 feet. On the north and northwest, Cream Valley-Huntingdon Valley and Rosemont faults separate schist from Precambrian Baltimore gneiss and Paleozoic sediments. These sediments are Cambro-Ordovician limestone that underlies Huntingdon Valley, Wissahickon, and Cambrian Chickies quartzite that crops out between Somerton and Edge Hill. Baltimore gneiss is older than Wissahickon schist. However, since in this region a high-angle thrust fault separates schist from northern bordering rocks, stratigraphic relation between schist and Paleozoic sediments is not clear. Age not certain.

R. O. Bloomer, 1950, Am. Jour. Sci., v. 248, no. 11, p. 753–783. In places, there appears to be complete section between Catoctin in the Blue Ridge and Wissahickon in the Piedmont of central Virginia. No continuous faults, including Martic overthrust, have been identified. Catoctin is not everywhere separated from Wissahickon or Lynchburg from Wissahickon by faults. Wissahickon is herein interpreted as Paleozoic in age and at least partly equivalent to Lower Cambrian Chilhowee group of Appalachian geosyncline.

J. W. Frondel, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1550. Recent work suggests that Wissahickon schist at Philadelphia is higher grade metamorphic equivalent of phyllitic rocks lying to northwest. The phyllite, in normal stratigraphic sequence with other Paleozoic rocks, is Cambro-Ordovician or possibly Cambrian. Assignment of Wissahickon schist to Paleozoic does not seem valid.

W. C. Rasmussen and others, 1957, Delaware Geol. Survey Bull. 6, v. 1, p. 102–104, pl. 3. Mapped in northern Delaware. Glenarm series. Precambrian(?).

A. W. Postel and H. W. Jaffe, 1957, Pennsylvania Acad. Sci. Proc., v. 31, p. 120–123. Study indicates that lead-alpha ages of zircon of Wissahickon schist are older than those of Swarthmore granodiorite (new) and related rocks, and that all ages are younger than Precambrian. Swarthmore replaces preoccupied name Springfield granodiorite.

P. W. Choquette, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1029 (table 1). In Cockeysville area, Maryland, Wissahickon formation overlies Cockeysville formation with contact gradational. Glenarm series. Pre-Silurian.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Wissahickon formation mapped as probably Lower Paleozoic.

Named from Wissahickon Creek, in Philadelphia, Pa.

**Witnet Formation**[1]

Miocene, pre-middle: Southern California.

Original reference: J. P. Buwalda, 1934, Pan-Am. Geologist, v. 61, no. 4, p. 310.

J. P. Buwalda and G. E. Lewis, 1955, U.S. Geol. Survey Prof. Paper 264–G, p. 147. Consists mainly of alternate beds of coarse gray arkose, locally bouldery, and dark sandy shale; probably of continental origin. Thickness not more than 4,000 feet. Strata steeply tilted and partly overturned. Neither top nor base exposed; at lower contact, granitic basement rocks are thrust over formation, and youngest beds are covered by gently dipping Miocene strata that overlies upper part of Witnet with strong angular unconformity. Type section designated; derivation of name given.

Type section: Lower Oil Canyon about 1 mile above its junction with Cache Creek; NW¼ sec. 13, T. 32 S., R. 34 E., Mojave quadrangle; Tehachapi quadrangle, Kern County. Named from Witnet Ridge north of lower Oil Canyon.

Witt Coal Member (of Bond Formation)

Pennsylvanian: Central and southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), 71, pl. 1. Name applied to coal member stratigraphically above Flat Creek coal member (new) and below Coffeen limestone member (new). Mainly gray limestone with some gray shale. Thickness about 1 foot. Name credited to H. J. Gluskoter. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NW¼SE¼ sec. 7, T. 8 N., R. 2 W., Montgomery County. Exposed about 6½ miles due south of town of Witt.

Witt cyclothem (in Bond Formation)

Pennsylvanian: Southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 43, 53 (table 2), 70, pl. 1. Uppermost cyclothem in formation in area. Occurs above Flat Creek cyclothem. Name credited to H. J. Gluskoter (unpub. ms.). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: East bank of East Fork, Shoal Creek, NE¼NW¼SE¼ sec. 7, T. 8 N., R. 2 W., Montgomery County. Named from village of Witt, 6 miles north of type outcrop.

**Witten Limestone**

Middle Ordovician: Southwestern Virginia and northeastern Tennessee.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 841–843, 877–879, 884 (fig. 3), pl. 5. In Tazewell County, strata embraced by Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Witten limestone is proposed for zones 22 through 25, or upper laminated limestone, fourth calcilutite, *Cryptophragmus* beds, and *Camarocladia* beds. Average thickness 100 feet. Intertongues with underlying Bowen formation (new); northeast of Five Oaks, Marys Chapel, and Thompson, lies disconformably on Wardell or Gratton limestone (both new). Underlies Moccasin formation. Corresponds to part, and locally to all, of Lowville limestone or Lowville limestone facies of Lowville-Moccasin formation as defined by Butts (1941, Virginia Geol. Survey Bull. 52, pt. 2).

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1172–1176. Geographically extended into northeastern Tennessee. Locally, in Cumberland Plateau, calcilutite zone attains thickness of more than 500 feet.

Type section: Along State Highway 16 about one-fourth mile north of County Road 604, Tazewell County, Va. Name derived from Witten Valley Church.

Wittenberg Conglomerate[1]

Wittenberg Conglomerate Member (of Katsberg Redbeds)

Upper Devonian: Southeastern New York.

Original reference: G. H. Chadwick, 1935, Am. Jour. Sci. 5th ser., v. 29, no. 170, p. 140.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 135. Termed member of Katsberg redbeds. Described as white-looking and pebbly beds consisting of gray to "white" sandstones or flagstones with small amounts of red shale and red or reddish sandstones. Quartz pebbles common especially in "white" layers. Thickness about 1,250 feet on Hunter Mountain. Overlies Stony Clove sandstone member; underlies Slide Mountain conglomerate. Unit occurs about 800 feet stratigraphically below top of Katsberg as exposed on Slide Mountain. Beds are in Pocono facies and have been called "Pocono", but are older than Pocono beds of Pocono Mountains in northeastern Pennsylvania.

Best exposed on summit of Wittenberg in Catskill Mountains.

Wittenberg shale[1]

Middle Devonian: Southeastern Missouri.

Original reference: C. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 253.

Probably named for Wittenberg, Perry County.

Wizard Wells Limestone (in Graford Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: J. M. Armstrong and G. Scott, 1930, Texas Bur. Econ. Geology map of Wise County.

In Wise County.

**Woburn Formation**[1]

Precambrian: Eastern Massachusetts.

Original reference: L. LaForge, 1932, U.S. Geol. Survey Bull. 839.

Named for good exposures in southwestern part of Woburn, Middlesex County.

**Wolcott Limestone** (in Clinton Group)

Wolcott Limestone Member (of Clinton Formation)[1]

Middle Silurian: Central and western New York, and Ontario, Canada.

Original reference: J. M. Clarke, 1906, New York State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 63–68. Formation in Clinton group. In Clyde and Sodus Bay quadrangles, overlies Sodus shale; underlies Wolcott Furnace iron ore. Consists of limestones and interbedded shales. Thickness about 20 feet. Base taken as lowest *Pentamerus*-bearing beds.

R. E. Griswold, 1950, New York State Water Power and Control Comm. Bull. GW–29, p. 13. Referred to as member of Clinton formation. In

Wayne County 15 feet thick; overlies Sodus shale member and underlies Williamson shale member.

Named for Wolcott, Wayne County, N.Y.

Wolcott Furnace iron ore[1] (in Clinton Group)

Middle Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 13, 70–72, 93. Name used for all dominantly hematitic formations at top of lower Clinton group to avoid multiplicity of names. Includes Verona iron ore of Chadwick (1918). Dominantly fossiliferous at type locality. Has high calcareous content which varies noticeably between layers. At top is a thin dark-gray sandy layer with abundant phosphatic nodules. Total thickness about 1 foot. Traced westward from type locality to Second Creek where consists of 18 inches of hematitic limestone and shale. At center is a highly calcareous layer with relatively high concentration of iron; remainder of unit contains only scattered oolites of hematite. Upper limit sharp and well defined. In Wayne County, thin conglomeratic sandstone separates unit from Williamson shale above; contact with underlying Wolcott limestone everywhere gradational. Type locality described.

Type locality: In bed of Wolcott Creek at old Wolcott Furnace, 1 mile north of Wolcott village, Wayne County.

Wolf formation[1]

Precambrian: Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey, Dept. Mines Mem. 38, map.

Exposed from Mount Ripple north to headwaters of Wolf Creek, in Selkirk Mountains, British Columbia.

**Wolf Porphyry**[1]

Post-Cretaceous: Central northern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

F. C. Armstrong, 1957, Econ. Geology, v. 52, no. 3, p. 221. In Little Belt Mountains, both Neihart and Flathead quartzites unconformably overlie Archean rocks, and locally the Flathead has been intruded by post-Cretaceous Wolf and Barker porphyries.

Forms intrusive mass of Wolf Butte, the peak south of it, and Mixes Baldy, east of Barker, Fort Benton quadrangle.

**Wolfcamp Formation**[1] **or Series**

Lower Permian: Western Texas and New Mexico.

Original reference: J. A. Udden, 1917, Texas Univ. Bull. 1753, p. 41, pl. 3.

P. B. King, 1937, U.S. Geol. Survey Prof. Paper 187, p. 94–97. Wolfcamp is oldest formation of Glass Mountains section and crops out in scattered exposures in southern foothills of the mountains. In western part of mountains, it rests with strong unconformity on older Paleozoic rocks of Marathon basin. To the east, this unconformity is no longer evident, and formation rests with no marked difference in dip or strike upon higher members of the Pennsylvanian. Top of formation is everywhere well-marked plane of unconformity, by which it is separated from succeeding Leonard formation. Udden (1917) separated the Wolfcamp from uppermost Pennsylvanian (Gaptank) formation on the basis of fossils of Permian aspect collected at type locality. Section at Wolf Camp, as shown by Udden, includes at base shales and limestones of Pennsylvanian age, succeeded by 100 feet of shale containing ammonoids described by Böse as *Uddenites* fauna. These in turn are succeeded by a thick-bedded limestone which is here considered to be basal bed of Wolfcamp formation. Above this are several hundred feet of shales and thin limestones, which extend up to basal conglomerate of overlying Leonard formation. Since original work in the area, the Wolfcamp formation and its fossils have been studied by many geologists. Upper part of formation has been generally considered to be of Permian age, but shale containing *Uddenites* fauna has been interpreted by some paleontologists as uppermost Pennsylvanian and by others as lowermost Permian. It is here included in Gaptank formation and considered to be Pennsylvanian. Wolfcamp formation north of Wolf Camp is 583 feet thick and consists of lower gray limestone member, 49 feet thick, and upper shale member, 534 feet thick. Fossils listed at type section.

J. E. Adams and others, 1939. Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1674–1675, 1677. Permian system divided into four divisions of series rank. Wolfcamp is first and lowest of these divisions. Comprises beds that have been referred to as Wolfcamp formation (restricted), which is thus raised to series rank. In Glass Mountain, series consists of about 600 feet of limestone, limestone conglomerates, and shales. In West Texas, Wolfcamp rests with angular unconformity on rocks ranging in age from Precambrian to upper Pennsylvanian and is unconformably overlain by Leonard series. Characterized by fusulind genera *Schwagerina* s. s., *Pseudoschwagerina*, and *Paraschwagerina*. Wolfcamp equivalents include Hueco formation (restricted) of Diablo Plateau and Abo formation of New Mexico. Series in northern Oklahoma, Kansas, and Nebraska includes beds from disconformity above Brownville limestone up to horizon near top of Herington limestone. Recommended that in Oklahoma term Wanette be dropped in favor of Wolfcamp series.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 556–566, 646–650. Series is not exposed in Guadalupe Mountains but comes to surface in Sierra Diablo; here it is represented by Hueco limestone. Local representative of series is Wolfcamp formation, which is about 600 feet thick and consists of alternating thick beds of shale and thin beds of limestone. Base of formation is defined as bottom of gray limestone member about 45 feet thick, which lies directly on *Uddenites*-bearing shale member at top of Gaptank formation. At type locality and elsewhere in Glass Mountains, Wolfcamp formation is unconformably overlain by Leonard formation of Leonard series.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41. Wolfcampian series, formerly called Big Blue series, contains older Permian rocks of Kansas. Outcrop thickness in Kansas about 785 feet.

C. A. Ross, 1959, Washington Acad. Sci. Jour., v. 49, no. 9, p. 299–311. Wolfcamp series in Glass Mountains, Tex., is represented by sequence of diverse lithologies and includes regional unconformity. Detailed study reveals that two formations can be recognized in field and that both units are within "zone of *Pseudoschwagerina.*" Each formation has characteristic fusulinid fauna. Nealranch formation (new) embraces upper part of beds originally called Wolfcamp by Udden (1917) in Wolf Camp Hills and is renamed to retain this widely used name for time-stratigraphic unit, Wolfcamp series. Lenoxhills formation (new) unconformably overlies Nealranch formation and is upper formation of Wolfcamp series in Glass Mountains. It was in part included in Wolfcamp formation of King (1931, Texas Univ. Bull. 3080) where it crops out in western Glass Mountains and is now known to be present across southern escarpment of eastern Glass Mountains, and is lower 200 to 300 feet of Hess formation of Udden (1917). Exact placement of top of Pennsylvanian system in Glass Mountains has long been major controversy. Fusulinid faunas of Cisco (Virgil) age are known from strata as high as "grey limestone" of King (1931 and 1937). In Wolf Camp Hills, the Nealranch (300 to 470 feet thick unconformably) overlies the "grey limestone" and contains oldest *Schwagerina* and *Pseudoschwagerina* faunas thus far discovered in Glass Mountains. Boundary between Permian and Pennsylvanian systems is taken at this unconformity. The "grey limestone" of King (1931) contains youngest Pennsylvanian fauna in Wolf Camp Hills and includes *Triticites comptus* n. sp., *T. ventricosis* (Moller), *T. pinguis* Dunbar and Skinner, and *T. koschmanni* Skinner.

G. V. Cohee, 1960, Am. Assoc. Petroleum Geologist Bull., v. 44, no. 9, p. 1578–1579. U.S. Geological Survey recognizes two-fold subdivision of Permian system and period. The divisions (Lower and Upper series and Early and Late Epochs) coincide as nearly as possible with those recognized in type Permian and are drawn according to existing concepts of biotic correlation with type sequence. Reference sequence of United States is Permian outcrops of northwestern Trans-Pecos Texas (Delaware Mountains, Guadalupe Mountains, and Sierra Diablo Mountains) where approximate faunal boundary is taken as that between Cherry Canyon and Bell Canyon formations which are encompassed by Guadalupe provincial series. Boundary falls between Word and Capitan formations as recognized in Glass Mountains area. West Texas provincial series, Wolfcamp, Leonard, Guadalupe, and Ochoa, are retained according to current usage.

C. C. Branson, 1960, Oklahoma Geology Notes, v. 20, no. 9, p. 229–235. Name Lyon series (Lyonian epoch) proposed for American standard early Permian(?) rocks. Kansas section of rocks of Sakmarian age is complete and well exposed over wide and accessible area, including parts of Oklahoma and Nebraska. Name Wolfcamp and time term Wolfcampian should not be used in Kansas, Oklahoma, and Nebraska.

Named for Wolfcamp, site of an old dwelling place, just south of the two buttes, located 6½ miles east and 2 miles north of east of Leonard Mountain. Wolf Camp Hills are at base of south face of Glass Mountains, 12 to 14 miles northeast of Marathon, Brewster County, Tex.

Wolfcampian Series or Stage

*See* **Wolfcamp Formation or Series.**

**Wolf Creek Conglomerate Lentil** (in Cattaraugus Formation)[1]

Wolf Creek Conglomerate (in Conewango Group)

Devonian: Southwestern New York.

Original reference: C. S. Prosser, 1892, Rochester Acad. Sci. Proc., v. 2, p. 54–57, 64, 93–95.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 54–63. In Wellsville quadrangle, conglomerate which is lowest bed carrying Conewangan fauna is tentatively called Wolf Creek conglomerate member of Cattaraugus. Underlies Salamanca conglomerate member; overlies Germania formation.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Upper Devonian.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 19. Panama and Wolf Creek conglomerates and sandstones are contiguous. Panama has priority; name Wolf Creek is abandoned.

L. V. Rickard, 1957, New York Geol. Assoc. Guidebook 29th Ann. Mtg., p. 17 (table 2), 19. Referred to as Wolf Creek conglomerate in Conewango group. In Genesee Valley, overlies Germania formation and underlies Cattaraugus shales. Average thickness about 30 feet. Upper Devonian; Chautauquan series.

Named for occurrence on Wolf Creek, west of West Clarksville, Allegany County.

Wolf Creek Dolomite[1] (in Arbuckle Group)

Ordovician: Southern Oklahoma.

Original reference: C. E. Decker, 1933, Tulsa Geol. Soc. Digest, p. 55–57.

C. E. Decker, 1939, Geol. Soc. America Bull., v. 50, no. 9, p. 1313. Preoccupied name Wolf Creek dolomite replaced by Strange formation.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 108. Abandoned by Oklahoma Geological Survey. Name preoccupied. Unit named Wolf Creek by Decker is probably Butterly dolomite.

Occurs in Arbuckle and Wichita Mountains.

**Wolfe City Sand Member** (of Taylor Marl)[1]

Wolfe City Sand or Formation (in Taylor Group)

Upper Cretaceous: Northeastern Texas.

Original reference: L. W. Stephenson, 1918, U.S. Geol. Survey Prof. Paper 102–H, p. 155.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 38, 39 (fig. 4), 41–42 [1939]. Rank raised to formation in Taylor group. Gray fine calcareous argillaceous partly glauconitic sand or sandy marl. Thickness near Wolfe City 75 to 100 feet. Underlies Pecan Gap chalk; overlies unit referred to as lower Taylor marl.

J. T. Rouse, 1944, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 4, p. 524. Wolfe City sand (formation) described along belt of outcrop from Collin County eastward into Red River County. Name sand is confusing because in many localities formation is arenaceous clay, marl, or sandy chalk rather than sand; sandy facies is best developed in vicinity of Wolfe City. Thickness 200 to 300 feet. Underlies Pecan Gap chalk; correlated with Annona chalk.

H. R. Blank, N. L. Stoltenberg, and H. H. Emmerich, 1952, Texas Bur. Econ. Geology Rept. Inv. 12, p. 5, 10 (table 1), 11–12. Member described in Blacklands experimental watershed, near Waco. Consists of basal sandy marl about 100 feet thick and upper silty marl about 40 feet. Unconformably underlies Pecan Gap member. Lowest strata outcropping in area.

Named for exposures at Wolfe City, Hunt County.

Wolf Hollow Limestone Member (of Tribes Hill Formation)

Lower Ordovician (Lower Canadian): East-central New York.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 76 (fig. 2), 87–88. Name proposed for typically very massive thick-bedded white-weathering blue-black dolomitic calcilutite in upper part of formation. Spatterings of dolomite form buff-weathering raised reticulate markings; these have erroneously been called siliceous matter. A stratum of dolomite a few feet above base contains pockets of white, yellow, and pink calcite. Thickness 28 feet at type section; fairly uniform from one section to another. Underlies Fonda member (new) of formation in Mohawk Valley.

Type section: Abandoned quarry and field exposure 2 miles north of Greens Corners in Amsterdam quadrangle. Named for narrow north-south-trending trenchlike valley 3 miles southeast of type locality.

Wolf Lake Granite[1]

Precambrian (upper Huronian): Northwestern Michigan.

Original reference: R. C. Allen and L. P. Barrett, 1915, Michigan Geol. and Biol. Survey Pub. 18, geol. ser. 15, p. 131–139.

Named for occurrence in vicinity of Wolf Lake, Gogebic County.

Wolf Lake Schist[1]

Precambrian (upper Huronian): Northwestern Michigan.

Original reference: R. C. Allen and L. P. Barrett, 1915, Michigan Geol. and Biol. Survey Pub. 18, geol. ser. 15, p. 131–139.

Occurs in Wolf Lake area, Gogebic County.

Wolf Mountain Granite

[Precambrian]: Central Texas.

R. E. McAdams, 1936, Am. Mineralogist, v. 21, p. 128–135. Name used in discussion of accessory minerals of Wolf Mountain granite mass or intrusive. Apparently same age as Lone Grove granite and probably older than Bear Mountain granite (new).

Wolf Mountain intrusive, approximately 30 square miles in area, is north and west of Llano, Llano County.

Wolf Mountain Shale Member (of Graford Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer and J. Hornberger, Jr., 1936, Texas Univ. Bull. 3534, p. 48–55, map.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Correlation chart shows Graford group comprises (ascending) Adams Branch, Cedarton shale, and Ranger limestone. Wolf Mountain shale shown equivalent to Adams Branch and Cedarton.

Typically exposed below capping Merriman limestone in slopes of Wolf Mountain, 4 miles west-northwest of Palo Pinto, Palo Pinto County.

**Wolfpen Tonalite**[1]

Devonian(?): Eastern Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 170, 171, map.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 12. In type locality of Marlboro formation, oldest unit in contact with Marlboro is Wolfpen tonalite of Devonian(?) age.

Well exposed in Wolfpen Hill in Southboro, Worcester County.

**Wolf Ridge Sandstone Member** (of Pottsville Formation)[1]

Pennsylvanian: North-central Alabama.

Original reference: C. Butts, 1927, U.S. Geol. Survey Geol. Atlas, Folio 221.

Named for fact that it forms Wolf Ridge.

Wolf River Limestone[1] Member (of Topeka Formation)

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 7, 12, 16, 20, 24, 26, 30, 33, 51–52, figs. 1, 2.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 21. Condra and Reed (1937) were uncertain regarding relation of the Hartford of southern Kansas to lower member of the Topeka in northeastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa so proposed name Wolf River for basal member of the Topeka in this area. Nebraska Survey will drop name Wolf River if it proves to be correlative with the Hartford, which was loosely defined by Kirk (1896) and may have priority if it does not include beds of Du Bois, Iowa Point, and Wolf River age.

Type locality: Missouri River bluffs just east of mouth of Wolf River north of Sparks, Doniphan County, Kans.

**Wolfskill Formation**

Pliocene: Northwestern California.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 16 (table 3), 94–97, pls. 7, 8, 12. Consists of conglomerates, sandstones, and interbedded deposits of andesitic tuffs, all continental; poorly consolidated. Approximately 500 feet thick. Unconformably overlies San Pablo group, Lawlor tuff, and Neroly sandstone; east of Putah Creek overlaps on the Markley sandstone. Unconformably underlies Montezuma formation (new).

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 147. Suggests that name Wolfskill be abandoned in favor of Tehama since Wolfskill, as mapped and defined, is continuous with the Tehama and name Tehama has priority.

Named from Wolfskill Station between Vacaville and Winters in northwest Vacaville quadrangle. Formation mapped on western slope of Vacaville Hills, Potrero Hills, western border of Montezuma Hills, and north slope of Los Medanos Hills. Type section not designated, but unit typically exposed in extreme northeast corner of Mount Vaca quadrangle and northwest corner of Vacaville quadrangle along highway which follows south side of Putah Creek.

**Wolsey Shale**[1] **or Formation**

Wolsey Shale (in Gros Ventre Group)

Wolsey Shale Member (of Gros Ventre Formation)

Middle Cambrian: Western Montana and northwestern Wyoming.

Original references: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55; 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 285–286.

Charles Deiss, 1936, Geol. Soc. America Bull., v. 47, no. 8, p. 1276, 1328–1330, strat. sections. Weed's original definition emended; new type section designated as exposure referred to by Weed, near dam on Sheep Creek, is now covered. Conformably overlies Flathead sandstone (emended) wherever these formations are exposed in Montana and Yellowstone National Park; underlies Meagher limestone (emended). Deposit clearly transitional between subjacent and superjacent formations. Lower part of Wolsey is dominantly dull-green to greenish-gray shale, interbedded with thin lenses of sandstone; worm trails, *Cruziana*, and borings common. Middle part of formation is nearly pure micaceous paper-thin shale and occasional thin platy intercalated beds of rusty-weathering sandstone, which in upper part is often slightly calcareous and usually contains worm borings; several zones of chocolate-brown fissile shales interbedded with the characteristically green shales; intercalated limestone lenses. Upper third consists of fissile shales, dominantly chocolate- to maroon-brown in upper part; intercalated thin beds of gray crystalline limestone, which contain iron and glauconite; fossils present in the limestone lenses and in fissile maroon and green shales, and are largely concentrated into two zones. In type section, upper of these two zones occurs 10 to 24 feet below top of Wolsey, and lower occurs 25 to 50 feet below upper zone. Thickness at type section 174 feet; maximum thickness 363 feet, Beaver Creek. Type section of emended Wolsey is on south end of South Hill in Belt Park; best exposure is on Crowfoot Ridge, Yellowstone National Park. [See Flathead Quartzite.]

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1089. Deiss (1933, Montana Bur. Mines and Geology Mem. 6) divided Cambrian rocks of northwestern Montana into 11 formations. Second in sequence was Wolsey shale. This sequence is herein revised, and Walcott's name Gordon is used instead of Wolsey for shale which lies upon Flathead sandstone and underlies Damnation limestone (redefined).

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., Chart 2. Gros Ventre group in western Wyoming includes three mappable formations (ascending): Wolsey shale, Death Canyon limestone, and Park shale.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 12–13. In this report, the Wolsey is considered basal member of Gros Ventre formation. Underlies Meagher limestone member; overlies Flathead sandstone. Thicknesses: 86 feet, Gros Ventre Range; 134 feet, Teton Range; 607 feet, Snake River Range.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 8, pls. 1, 2, 3. Five lowest natural Cambrian map units in southern Elkhorn Mountains are lithologically similar to Flathead sandstone, Wolsey shale, Meagher limestone, Park shale, and Pilgrim dolomite of nearby areas, as redefined by Deiss (1936), and these formational names have been adopted. Wolsey shale is 368 feet thick; underlies Meagher limestone, and overlies Flathead quartzite. Upper half of unit is interbedded gray argillaceous limestone and greenish- and yellowish-gray calcareous mudstone and shale; lower half is greenish-gray and drab shale with some interbeds of sandstone and limestone; many beds micaceous, some glauconitic.

Type section (emended): South end of South Hill Belt Park. Little Belt Mountains. Keegan Butte is in central part of sec. 15, T. 14 N., R. 7 E., and isolated hill immediately to south, called South Hill (Deiss, 1936), is in central part of sec. 15, in same township and range. Keegan Butte is near southern edge of Fort Benton quadrangle. and south Hill is near northern edge of Little Belt Mountains quadrangle. Both are from 4 to 6 miles west of Belt Creek section. Field evidence indicates Weed meant South Hill to be type locality of Wolsey, but that he took name Wolsey from post office of that name at a ranch on Sheep Creek. Post office no longer in existence. Named for exposures at dam on Sheep Creek near Wolsey, Meagher County, Mont.

**Wolverine Sandstone**[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, pt. 2, p. 77, 81, 93.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

Named for outcrops near Wolverine mine, Houghton County.

**Wolverine Canyon Limestone Member** (of Preuss Sandstone)

Upper Jurassic: Southeastern Idaho.

R. W. Imlay, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1741–1743. Consists mainly of yellowish gray sandy thin- to medium-bedded limestone but including some yellowish thin-bedded sandstone and containing, a little above the middle, one prominent unit of cliff-forming oolite 14 feet or more in thickness. Upper part of oolite crumbly and less massive then lower part and bears corals and algal-like markings or, locally, numerous gastropods and pelecypods. Member is 193 feet thick at type section, where it is bounded above and below by sandstones of the Preuss.

Type section: North slope of Wolverine Canyon is west-central part of sec. 27, T. 1 S., R. 39 E., Bingham County. Main area of outcrop is in Ammon quadrangle from Wolverine Canyon northward 5 miles to headwaters of Henry Creek. Excellent exposures occur along ridges at head of Dry Fork of Henry Creek.

Womac Coal Member (of Modesto Formation)

Pennsylvanian: Southwestern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 38, 49 (table 1), 68, pl. 1. Proposed for coal formerly called Macoupin coal. Name Macoupin restricted to Macoupin limestone. Thickness 8 inches. Stratigraphically above Burroughs limestone member and below Macoupin limestone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: NE¼NW¼ sec. 2, T. 9 N., R. 7 W., Macoupin County. Named for village of Womac approximately 3 miles northeast of type exposure.

Womack Gneiss[1]

Precambrian: Eastern Colorado.

Original reference: L. C. Graton, 1906, U.S. Geol. Survey Prof. Paper 54.

Named for Womack Hill, at east edge of town of Cripple Creek, Teller County.

**Womble Shale,**[1] **Schistose Sandstone,**[1] or **Formation**

Lower and Middle Ordovician: Southwestern Arkansas and southern Oklahoma.

Original reference: H. D. Miser, 1917, U.S. Geol. Survey Bull. 600, p. 67.

August Goldstein, Jr., and T. A. Hendricks, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 424 (fig. 2). Formation consists of shale, black to green, with thin layers of limestone and argillaceous sandstone in Arkansas. Predominantly schistose, micaceous, chloritic sandstone in McCurtain County, Okla. Thickness 250 to 1,000 feet. Underlies Bigfork formation; overlies Blakely formation.

W. D. Pitt, 1955, Oklahoma Geol. Survey Circ. 34, p. 23, 24–25. Womble shale, as defined in this report (core of Ouachita Mountains), includes stratigraphic interval between Mazarn shale below and Bigfork chert above. As originally defined, Blakely sandstone lies stratigraphically above Mazarn shale and below Womble shale. A series of beds distinct lithologically from Mazarn shale below and Womble siltstone above was noted at some localities. This [unit] could be designated as separate formation, but if it were designated in this way, it is recommended that it not be called Blakely because of findings of current field work in Blakely sandstone type area in Arkansas.

Type section: Crystal Mountain, Ark. Named for town of Womble (now called Norman).

Wompats limestone[1] (in Aubreyan series)

Carbonic: Northern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, p. 251, 339.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart), 223, Underlies Kanab limestones (new). Of Carbonic age. Spelled Wombats on page 223.

Named for Wompats Spring, northeast of great Shinumo Amphitheater, Grand Canyon.

Wonder Rhyolite[1]

Tertiary: Central western Nevada.

Original reference: J. A. Burgess, 1917, Econ. Geology, v. 12, no. 7, p. 589–593.

Quarried in Nevada Wonder mine, Wonder district, Churchill County.

**Wonder Lake Glaciation**

Pleistocene: South-central Alaska.

A. T. Fernald, 1960, U.S. Geol. Survey Bull. 1071–G, p. 232 (chart). Named on correlation chart. Correlated with Farewell, Riley Creek, and Donnelly glaciations. Younger than Slow Fork glaciation (new). Name credited to J. C. Reed, Jr.

In Mount McKinley area.

**Wood Shale Tongue** (of Ankareh Formation)

Wood Shale[1]

Upper Triassic: Southeastern Idaho, central northern Utah, and central western Wyoming.

Original references: G. R. Mansfield, 1915, Washington Acad. Sci. Jour., v. 5, p. 492; 1916, Washington Acad. Sci. Jour., v. 6, p. 41.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 473, 476–477. Use of term Wood shale extended to Park City area, Utah, to replace upper part of Ankareh shale, latter being stratigraphically restricted. Upper Triassic.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 35, pl. 1. Type locality designated. Mapped in Ammon and Paradise Valley quadrangles where rock is primarily bright-red sandy shale or shaly sandstone. Locally contains purplish and green shale in addition to red beds.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 180, 181, fig. 18. Unit considered to be westward extending tongue of Ankareh formation in western Wyoming and southeastern Idaho. Thickness approximately 250 feet at Spring Canyon, 40 feet at Cokesville, and 400 feet at Hot Springs. Upper Triassic.

Type locality: On Wood Creek, from which unit takes its name, in T. 3 S., R. 38 E., less than 2 miles west of Paradise Valley quadrangle, Idaho.

**Woodbine Sand,[1] Clay,[1] or Formation**

Woodbine Group

Upper Cretaceous (Gulf Series): Texas, southwestern Arkansas, western Louisiana, and central southern and southeastern Oklahoma.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 293.

R. T. Hazzard, B. W. Blanpied, and W. C. Spooner, [1947], Shreveport Geol. Soc. 1945 Reference Rept., v. 2, p. 475, 476, 477, 480. Woodbine group comprises (ascending) Euless formation (new) with basal Dexter sand member, Lewisville formation with basal Pine Bluff tuffaceous gravelly member, and Eagle Ford formation with Tarrant member. Unconformably overlies South Tyler formation (new); unconformably underlies Austin chalk.

H. R. Bergquist, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 98. Formation crops out in belt a few miles wide to form Eastern Cross Timbers area between Black and Grand Prairies of northeastern Texas. Belt extends northward from Hill County nearly to the Red River, but from northeastern Cooke County, it trends southeast across Grayson County into northwestern part of Fannin County. Along this belt, formation consists of varied and interlensing sequence of nonmarine, brackish water, and marine beds of sand, shale, clay, and sandstone about 350 feet thick. Seemingly lies unconformably on Washita group and older beds of Comanche series. At some places, Grayson marl appears to grade upward into Woodbine and it is difficult to determine where unconformity occurs. At these places, Woodbine appears to be conformable with fossiliferous clay and shale younger than Grayson marl. Top of Woodbine of Red River area is about 40 or 50 feet below base of *Metoicoceras whitei* zone of lower Eagle Ford shale. Sequence exposed in Cooke, Grayson, and Fannin Counties is divided into (ascending) Dexter, Red Branch (new), Lewisville, and Templeton (new) members.

W. S. Adkins and F. E. Lozo *in* F. E. Lozo, 1951, Fondren Sci. Series, no. 4, p. 105–161, pls. Report is symposium on Woodbine group and adjacent strata. Relationships of Woodbine with Eagle Ford and Comanchean beds discussed in detail. Pepper shale is believed to be southward continuation of part of Woodbine group (Lewisville formation) in north-central Texas. In Dallas, McLennan, and Travis Counties, the Woodbine underlies Lake Waco formation (new).

L. W. Stephenson, 1952, U.S. Geol. Survey Prof. Paper 242, p. 1–226, pls. Woodbine formation, as originally defined, is made up of deposits laid down in fresh, brackish, and very shallow marine waters. Formation intervens between deeper marine facies of Comanche series below and Eagle Ford and younger formations above. Basal unit of Woodbine is Dexter member which consists chiefly of nonmarine sands interbedded with clays, but includes also important marine fossil-bearing zones in Tarrant and Denton Counties. Dexter is overlain in different areas by nearly contemporaneous nonmarine carbonaceous shales and tuffaceous sandstones of Red Branch member and marine shaly beds of Euless member. These in turn are overlain by marine sandy shales and sandstones of Lewisville member, and these by marine shales and minor sands of Templeton member. Hazzard, Blanpied, and Spooner's classification discussed and reasons cited for not accepting it. As used in present report, name Euless member is restricted to an upper shale unit between Dexter member and Lewisville member. So-called Pine Bluff member is part of Lewisville member and "Tarrant" unit is also considered part of Lewisville. Systematic description of larger invertebrate fossils.

L. W. Stephenson, 1953, U.S. Geol. Survey Prof. Paper 243–E, p. 57–66, pls. Includes Pepper shale member. Evidence afforded by assemblage of mulluscan fossils from Pepper shale confirms conclusion that the Pepper is southward extension of the Woodbine, and is probably extension of Lewisville member.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 39–42. Formation described in McCurtain County, where it is as much as 355 feet thick. Lower member is principally crossbedded dark tuffaceous sand, red clay, and gravel lentils. Upper member mostly gray to brown crossbedded quartz sand and sandy gravel. Unconformably underlies Tokio formation; unconformably overlies Washita group.

Named for exposures at Woodbine, Cooke County, Tex.

Woodbridge fire clay[1] (in Raritan Formation)

Cretaceous: Northeastern New Jersey.

Original reference: G. H. Cook and J. C. Smock, 1877, Map of clay district of Middlesex County. New Jersey Geol. Survey; G. H. Cook, 1878, New Jersey Geol. Survey Rept. on clays, p. 34.

H. C. Barksdale and others, 1943, The ground-water supplies of Middlesex County, New Jersey: New Jersey State Water Policy Comm. [Spec. Rept. 8], p. 66, 103–104. Overlies Farrington sand member (new); underlies Sayreville sand member (new). Thickness 50 to 90 feet.

Named for occurrence at Woodbridge, Middlesex County.

**Woodburn Limestone Member** (of Cynthiana Formation)

Woodburn Limestone

Woodburn Phosphatic Member (of Brannon Limestone)

Woodburn Phosphatic Member (of Flanagan Limestone)[1]

Middle Ordovician: North-central Kentucky.

Original reference: A. M. Miller, 1913, Kentucky Geol. Survey, 4th ser., v. 1, pt. 1, p. 326.

D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 41 (fig. 2), 42. Woodburn limestone in Lexington area is about 40 feet thick and consists of coarsely crystalline phosphatic limestone. Overlies Brannon limestone; underlies Perryville limestone.

A. C. McFarlan, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1636–1637. Referred to as phosphatic member of Brannon limestone.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 17, 18. Rank reduced to member status in Cynthiana formation.

Named for celebrated Alexander Estate in Woodford County.

**Woodbury Clay** (in Matawan Group)[1]

Woodbury Member (of Matawan Formation)

Upper Cretaceous: New Jersey.

Original reference: G. N. Knapp, as reported by R. D. Salisbury, 1899, New Jersey Geol. Survey Ann. Rept. State Geologist 1898, p. 35.

W. B. Spangler and J. J. Peterson, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 1, p. 8 (fig. 4), 24, 26–28. Member of Matawan which is here reduced to formational rank. Underlies Marshalltown member; overlies and apparently grades into Merchantville member. Thickness about 50 feet.

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184. Formation in Matawan group. Overlies Merchantville formation; underlies Englishtown formation. Average dip SE. 40 feet per mile. Thickness 50 feet.

Named for exposures in railway cut at Woodbury, Gloucester County.

Woodbury cyclothem (in McLeansboro Group)

Woodbury cyclothem (in Mattoon Formation)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 28–30; J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). Uppermost cyclothem exposed in area. Occurs above Greenup cyclothem (new) in Cumberland County and above the Gila cyclothem in Jasper County.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 53 (table 2), pl. 1. In Mattoon formation (new). Above Gila cyclothem and below Newton cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Along Webster Creek just north of Jasper County line about 2 miles southwest of Woodbury, Cumberland County.

†Woodbury Formation[1]

Upper Cretaceous: Northwestern Iowa.

Original reference: C. A. White, 1870, Iowa Geol. Survey, v. 1, p. 26. 291–293.

Named for Woodbury County.

Woodbury Granite[1]

Devonian: Northeastern Vermont.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept.

Quarried in Woodbury Township, Washington County.

†Woodbury Granite

Devonian or post-Devonian: West-central Connecticut.

R. M. Gates, 1951, Connecticut Geol. Nat. History Survey Misc. Ser. 3, p. 3, 5, 11–12. Described as intrusive into Hartland formation. Texture varies from aplitic to pegmatitic.

R. M. Gates *in* R. M. Gates and W. C. Bradley, 1952, Connecticut Geol. Nat. History Survey Misc. Ser. 5, p. 12, 14. Both granite and associated granite gneisses were formerly termed Thomaston granite. Name Woodbury restricted to intrusive granite. Age tentatively designated Devonian or younger. Type occurrence given.

R. M. Gates, 1954, Connecticut Geol. Nat. History Survey Quad. Rept. 3, p. 3 (footnote). Name abandoned to avoid confusion with Woodbury granite in Vermont. Replaced by Nonewaug granite.

Type occurrence: Northern half of Woodbury quadrangle west of Watertown.

Woodbury Limestone Member (of Mattoon Formation)

Woodbury Limestone (in McLeansboro Group)

Pennsylvanian: Southeastern Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 108. Thin marine limestone in upper part of McLeansboro, between Shumway above and Gila coals.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Correlation chart shows Woodbury limestone below Bogota cyclothem and above Gila limestone. Gives type locality same as Woodbury cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 41, 51 (table 1), 78, pl. 1. Assigned member status in Mattoon formation (new). Above Gila limestone member and below Reisner limestone member (new). Thickness about 7 inches at type outcrop. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: SE½SE¼ sec. 32, T. 9 N., R. 8 E., Cumberland County.

Woodbury Creek Member (of Esopus Formation)

Lower Devonian: Southeastern New York.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 728, 731 (fig. 2), 734. Consists of interbedded brown-weathering medium- to fine-grained sandstone, blue gray where fresh. Fossiliferous. Thickness about 50 feet. Gradationally overlies unnamed middle member of formation; contact with overlying Kanouse sandstone not exposed, but strata on either side of contact are conformable.

Type section: Thruway cut at Highland Mills, Orange County. Unit known only from this area. Name derived from Woodbury Creek which is adjacent to exposures of member in railroad cut at Highland Mills. Section is located on eastern side of Green Pond-Schunemunk Mountain outlier.

**Wood Canyon Formation**[1]

Precambrian and Lower Cambrian: Southeastern Nevada and eastern California.

Original reference: T. B. Nolan, 1928, Am. Jour. Sci., 5th, v. 17, p. 461–472.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 278 (fig. 3d), 307–312. Geographically extended into Nopah-Resting Springs area, Inyo County, Calif., where it is about 3,033 feet thick and includes Zabriskie quartzite member (new) in upper half. Overlies Stirling quartzite; underlies Cadiz formation.

R. H. Hopper, 1947, Geol. Soc. America Bull., v. 58, no. 5, p. 404 (fig. 1), 406–407. Formation, in Panamint Range, is about 2,600 feet thick and consists largely of quartzite, but with some limestone and shale in upper part. Includes Zabriskie quartzite member. Overlies Stirling(?) quartzite; underlies unnamed Cambrian and Lower Ordovician dolomite and limestone. Lower Cambrian.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 24 (fig. 3), 25–26, fig. 5. As defined in this report, includes strata above Prospect Mountain quartzite and below Zabriskie quartzite, here given formational rank. This restricts Hazzard's 1938 [1937] section both above and below. On basis of establishment of base of zone of *Olenellus* as base of Cambrian, basal 343 feet of Wood Canyon formation in Nopah Range appears to belong to latest Precambrian and upper 363 feet to Lower Cambrian. On the basis of lithology and fauna, formation is correlated with Lower Cambrian Wood Canyon formation of northwestern part of Spring Mountain, Nev. (Nolan, 1929 [1928]) although it includes more beds than were placed in formation by Nolan at type locality.

B. K. Johnston, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p. 377–380, 381 (fig. 8), figs. 1 (geol. map), 2 (columnar section). Described in Manly Peak quadrangle, southern Panamint Range, Calif., where it is mostly quartzite and quartz-rich sandstone, with large amounts of siltstone and shale and some limestone and dolomite. Comprises two sections that are not in depositional contact and do not overlap. Lower section about 1,600 feet thick; upper section, about 700 feet thick, includes Zabriskie quartzite member. In fault contact with Archean gneiss; conformably underlies Lotus formation (new). Considered both Cambrian and Precambrian in age.

U.S. Geological Survey currently designates the age of the Wood Canyon as Precambrian and Lower Cambrian on the basis of a study now in progress.

Named for exposures in Wood Canyon, about 4 miles south of Crystal Springs, on west side of Spring Mountains, Clark County, Nev.

**Woodchopper Volcanics**[1]

Middle Devonian: Northeastern Alaska.

Original reference: J. B. Mertie, Jr., 1930, U.S. Geol. Survey Bull. 816, p. 75–80, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Exposed on Woodchopper Creek at and below Woodchopper, Eagle-Circle district.

Woodcock Member (of Venango Formation)

Woodcock Sandstone[1]

Upper Devonian: Northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1925, Geol. Soc. America Bull., v. 36, no. 3, p. 457–464.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Shown on generalized succession of marine Upper Devonian as member of Venango formation above Saegerstown member and below Roystone member of Riceville formation.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Woodcock sandstone shown on correlation chart above Saegerstown [formation] and below Oswayo formation. Upper Devonian.

Named for exposures along Woodcock Creek, Woodcock Township, Crawford County.

Wood Creek Beds[1]

Upper Ordovician: Northern New York.

Original reference: R. Ruedemann, 1925, New York State Mus. Bull. 258, p. 90–95, 137, 141, 149, 154.

Well exposed along Wood Creek, between Lee's Center and Stokes, 7 miles northwest of Rome, Oneida County, and in Lorraine Gulf.

**Woodford Chert[1] or Shale**

Devonian and Mississippian: Central southern and southeastern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Upper Devonian.

S. P. Ellison, Jr., 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 1, p. 93–110. Discussion of conodonts as Paleozoic guide fossils and problem of correlation among beds containing upper Devonian conodonts and fossil wood. Woodford formation and Arkansas novaculite are part of this correlation problem. However, assignment of Devonian age to Woodford is not acceptable to many stratigraphers.

T. A. Hendricks, L. S. Gardner, and M. M. Knechtel, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 66. In western part of Ouachita Mountains in block southeast of Pine Mountain fault, Woodford chert unconformably overlies Pinetop chert. Basal 7 feet consist of white chert breccia or conglomerate containing some lenses of very fine grained crystalline limestone. Upper part consists of alternating beds of black papery shale that weather light gray, and black chert in beds 1 to 4 inches thick. Contains abundant round and discoidal phosphate nodules and conodonts. Thickness about 67 feet. Table shows Woodford chert separated from upper part of Arkansas novaculite. Upper Devonian(?). Correlated with Chattanooga shale, Woodford chert of Arbuckle Mountains, and upper part of Arkansas novaculite.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 145, chart 5 (columns 55, 56). Woodford chert shown on correlation chart as Kinderhookian. Locally contains considerable black shale of Chattanooga type, and the two formations are known to be continuous in subsurface although beds of later Kinderhookian age have not been identified and are probably not represented in Chattanooga as it is developed in Ozark region. Woodford overlies older formations with conspicuous unconformity and in subsurface locally overlaps onto Arbuckle limestone.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Woodford shale and Woodford chert mapped as Devonian and Mississippian.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 2), 48–49, fig. 3. Throughout Arbuckle region Hunton group is unconformably overlain by Woodford shale. Erosional interval separating Woodford from Hunton is considerable, so this shale may be in contact with any of Hunton formations or members, and in places Woodford rests directly on Sylvan shale.

J. D. Prestridge, 1959, *in* Petroleum geology in southern Oklahoma, v. 2: Tulsa, Am. Assoc. Petroleum Geologists, p. 158 (fig. 2), 161. Underlies Cornell Ranch member (new) of Sycamore formation. Uppermost Wooford is Kinderhookian.

Named for exposures about one-fourth mile north of Woodford, Carter County.

†Woodford Gneiss[1]

Precambrian: Southwestern Vermont.

Original reference: F. A. Burt, 1929, Vermont State Geologist 16th Rept., p. 68–69.

Probably named for Woodford village or Woodford Township, Bennington County.

Woodfordian Substage

Pleistocene (Wisconsinan): Illinois.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 1, 2 (fig. 1), 6–8. Wisconsinan stage of Lake Michigan lobe is subdivided into (ascending) Altonian, Farmdalian, Woodfordian, Twocreekan, and Valderan substages. Woodfordian is based on pre-Shelbyville Morton loess (new) that overlies Farmdale silt, and succession of progressively younger moraines extending from the Shelbyville to, but not including, the Valders. Stratigraphically terminated upward by Two Creeks forest bed of Wisconsin. From former classification Woodfordian includes Iowan substage of Illinois usage (but not of the type), the type Tazewell and Cary substages, it includes that part of the Cary that has recently been assigned to Mankato (Leighton, 1957). On the basis of numerous dates, the total time span of Woodfordian is less than 10,000 radiocarbon years. Includes Peoria loess and Richland loess (new). Also contains about 30 recognized end moraines.

Name derived from Woodford County which is just north of Shelbyville moraine and is crossed by Bloomington, Metamora, Normal, and Cropsey moraines.

Woodglen Limestone (in Washington Group)

Permian (Dunkard): Southeastern Pennsylvania.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, ser. 4, Bull. C–26, p. 147–148. Name given to gray to dark fine-grained homogeneous nonfossiliferous limestone which breaks with conchoidal fracture. Maximum thickness 10 feet, average about 7 feet. Underlies Lower Mannington sandstone; commonly overlies clay shale or sandy shale below which is Colvin Run limestone. Included in lower part of Washington group.

Well exposed in Hugh Murphy quarry just northeast of Woodglen, Fayette County.

Woodhams Formation

Miocene (Relizian?) : Northern California.

R. M. Touring, 1959, Dissert. Abs., v. 20, no. 4, p. 1325. Name given to about 500 feet of siliceous mudstone and foraminiferal shales which conformably overlie Mindego formation (new) near east edge of La Honda quadrangle.

Area of report is in Santa Cruz Mountains, 30 to 40 miles south of San Francisco.

Woodhill Member (of Franconia Formation)

Upper Cambrian: Central Wisconsin and southeastern Minnesota.

R. R. Berg, 1951, Minnesota Geologist, v. 8, no. 4, p. 1. Proposed for basal member of Franconia. At type locality, consists of lower coarse-grained, poorly sorted sandstone 13 feet thick overlain by a medium-grained well-sorted sandstone 17 feet thick; in all outcrops, base of member is characterized by coarse-grained sandstone that overlies uniformly medium-grained Galesville sandstone member of Dresbach formation. Maximum thickness 44 feet in Houston County, Minn. Underlies Birkmose member (new).

R. R. Berg, 1953, Jour. Paleontology, v. 27, no. 4, p. 553, 554, 555; 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 861–862, 871. Term Ironton member had previously been applied to basal unit of Franconia; although defined as lithic unit (Ulrich, 1924, Wisconsin Acad. Sci. Trans., Arts, and Letters, v. 21), "Ironton member" came to mean all beds containing *Elvinia* fauna, and new name that did not carry faunal connotation became advisable.

Type locality: Roadcuts on State Highway 80 at Wood Hill, SE¼ sec. 3, T. 15 N., R. 2 E., Juneau County, Wis.

Woodhouse Clay (in Ogallala Formation)[1]

Woodhouse Formation

Miocene or Pliocene: Western Kansas.

Original reference: M. K. Elias, 1931, Kansas Geol. Survey Bull. 18, p. 155.

M. K. Elias, 1937, Kansas Geol. Survey Mineral Resources Circ. 7, p. 8. Woodhouse formation in Rawlins and Decatur Counties described as local clayey formation that is wedged in between sandy Ogallala beds above and Pierre shale below. Consists of silts and fine silty sands, with coarses sand to conglomerate at base, and chocolate to maroon plastic clays in upper part. Thickness as much as 60 feet.

Type locality: One mile west of Woodhouse Ranch, Wallace County.

**Woodhurst Limestone Member** (of Lodgepole Limestone)

Woodhurst Limestone Member (of Madison Limestone)[1]

Lower Mississippian: Central northern, central southern, and southwestern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 56.

L. L. Sloss and R. H. Hamblin, 1942, Am. Assoc. Petroleum Geologists Bull, v. 26, no. 3, p. 315, 317, 319, 320, 321–322, 324. Reallocated to member status in Lodgepole limestone; overlies Paine member; underlies Mission Canyon limestone. Thickness 240 to 570 feet.

First described in vicinity of Woodhurst Mountain, northeastern part Little Belt Mountains quadrangle.

**Woodland Gneiss**

Precambrian: Central western Georgia.

D. F. Hewett and G. W. Crickmay, 1937, U.S. Geol. Survey Water-Supply Paper 819, p. 29–30, pl. 1. Largely coarse-grained biotite augen gneiss. Persistently underlies basal bed of Hollis quartzite; 100 feet or more of gneiss immediately underneath quartzite is thinly laminated, locally schistose; progressively lower or deeper in the mass, the lamination is more widely spaced, and rock assumes common gneissic texture; because gneiss is most completely metamorphosed of the igneous rocks of the region, it is assumed to be the oldest. Intruded by Cunningham granite (new).

J. W. Clarke, 1952, Georgia Geol. Survey Bull. 59, p. 6 (table), 7–11. Precambrian(?).

Named for Woodland, Talbot County. Confined to belt that lies between Pine and Oak Mountains, south of Towaliga fault; also present in Thomaston quadrangle.

Woodland Trachyte[1]

Age(?) : Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 109, 110, 164.

Forms low hills along branch of Caribou Stream, in Woodland Township, Aroostook County.

**Woodman Formation**[1]

Upper Mississippian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 30). Shown on correlation chart above Madison limestone and below Ochre Mountain limestone.

Named for the fact that it underlies Woodman Peak on south end of Dutch Mountain, Gold Hill region.

Woodmansie phase (of Bridgeton Formation)[1]

Pleistocene: New Jersey.

Original reference: R. D. Salisbury and G. N. Knapp, 1917, New Jersey Geol. Survey, v. 8, p. 11, 62.

Probably named for occurrence at or near Woodmansie, Burlington County.

**Woodmont Shale**

**Woodmont Shale Member** (of Jennings Formation)[1]

Upper Devonian: Western Maryland, southern Pennsylvania, and northern West Virginia.

Original reference: C. K. Swartz and others, 1913, Maryland Geol. Survey Lower Devonian volume, p. 26; 1913, Middle and Upper Devonian volume, p. 411, 412.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 90–91. In Washington County, Md., varies in thickness between 1,600 feet in eastern and 1,200 to 1,300 feet in western sections. Conformably overlies Genesee member or, where latter is lacking, rests on Romney shale; underlies Parkhead sandstone member.

Named from Woodmont Station, Washington County, Md., one-half mile east of which it is well exposed in cut of Western Maryland Railroad.

Woodpecker limestone[1]

Devonian: East-central Nevada.

Original references: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52; 1924, Pan-Am. Geologist, v. 41, p. 79.

Name derived from Woodpecker Peak, Eureka district.

**Woodpecker Limestone Member** (of Nevada Formation)

Middle Devonian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 41, 44–45, pl. 2. Made up of thin- to medium-bedded limestone not uncommonly sandy or argillaceous. Limestones fine grained to aphanitic or porcellaneous and light olive gray to dark gray. Weathering of shaly partings produces pinkish or yellowish colors. Thickness ranges from 220 through 450 feet. Lower boundary notably gradational with underlying Sentinel Mountain dolomite member (new) whereas contact with overlying Bay State dolomite member (new) is quite sharp being marked by varying thickness of light-gray dolomite sand at base of Bay State dolomite member. Calcareous nature of unit between the two dolomite members serves to distinguish it.

Type locality: In gulch draining south slope of Woodpeckers Peak, which is situated on north boundary of Oxyoke Canyon, in vicinity of Eureka.

**Wood River Formation**[1]

Pennsylvanian and Permian: Southern central Idaho.

Original reference: W. Lindgren, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 89–90, 193–195, pl. 8.

D. A. Bostwick, 1955, Jour. Paleontology, v. 29, no. 6, p. 941–951. Formation, with exception of several hundred feet of conglomerates and limestones near base, is succession of calcareous sandstones and arenaceous limestones of 12,000 feet maximal thickness. Near Bellevue, contains fusulinids that compare closely with those of Desmoinesian, Virgilian, and Wolfcampian ages in rocks of Midcontinent and Southwest regions.

M. R. Thomasson, 1959, Dissert, Abs., v. 20, no. 3, p. 999. Subdivided into (ascending) Hailey, Slate Creek (Desmoinesian-Missourian), Lake Creek (Virgilian), and Wilson Creek (Wolfcampian) members. Overlies Muldoon formation (new). Wood River and Muldoon are time equivalents of Lemhi formation (new).

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3). Correlation chart shows that Wood River formation in Bellevue area comprises (ascending) Hailey member, unnamed lower sandy limestones, and upper calcareous sandstones and sandy limestones. Uncomformable above Milligen formation and below Phosphoria. Morrowan-Leonardian.

C. P. Ross, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B232. Discussion of interfingering Carboniferous strata in Mackay quadrangle, Idaho. Wood River where exposed west of Mackay quadrangle is lithologically diverse, but is characterized by abundant sandy beds, and, especially near base, by abundant conglomerate, part of it coarse and in thick layers. Formation has been regarded as of Pennsylvanian age, but microfossils (Bostwick, 1955), discovered since formation was defined, have shown that large thicknesses of beds assigned to it by Bostwick are of Permian age. These beds have nowhere been mapped separately. Formation west of Mackay quadrangle is probably at least 8,000 feet thick, and may be much thicker if beds containing Permian fossils are included in it. Beds definitely assignable to Wood River are now known to occur east of western part of Mackay quadrangle, but name has been used tentatively as far east as Montana boundary.

First described in vicinity of Hailey, Blaine County.

†Woods Bluff Group[1] or Series[1]

Eocene, lower: Southern Alabama and southeastern Mississippi.

Original reference: A. Heilprin, 1882, Philadelphia Acad. Nat. Sci. Proc. 1881, p. 158–159.

Named for exposures at Woods Bluff, on Tombigbee River, in northwestern part of Clarke County, Ala.

Woods Bluff Marl (in Bashi Formation)[1]

Eocene, lower: Southwestern Alabama.

Original reference: A. Heilprin, 1882, Philadelphia Acad. Nat. Sci. Proc. 1881, p. 157.

Named for exposures at Woods Bluff, on Tombigbee River, in northwestern part of Clarke County.

Woods Corners Group

Middle Cambrian: Northwestern Vermont.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 532 (fig. 5), 533 (fig. 6), 536. Proposed for entire succession between Rugg Brook dolomite below and Gorge formation above. Includes (ascending) St. Albans slate, Mill River conglomerate, Skeels Corners slate, Rockledge conglomerate, and its northern equivalent Saxe Brook dolomite, and Hungerford slate.

Name is taken from alternate local name for Skeels Corners, 5 miles north of St. Albans, St. Albans quadrangle.

Woods Hole Shale

Probably lapsus for **Woods Hollow shale.**

**Woods Hollow Shale**[1]

Middle Ordovician: Southwestern Texas.

Original reference: P. B. King, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 9, p. 1066, 1071–1072.

W. B. N. Berry, 1960, Texas Univ. Bur. Econ. Geology Pub. 6005, p. 23–27, strat. sections. Graptolite fauna discussed. Underlies Maravillas chert; overlies Fort Pena formation.

Named for exposures in Woods Hollow Mountains between Woods Hollow and Little Woods Hollow, in anticlinal valley on former Louis Granger Ranch, Brewster County.

**Woodside Formation, Siltstone, or Redbeds**

Woodside Shale[1]

Lower Triassic: Northeastern Utah, southeastern Idaho, southwestern Montana, and southwestern Wyoming.

Original reference: J. M. Boutwell, 1907, Jour. Geology, v. 15, p. 439–458.

J. S. Williams, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 1, p. 91–93. In Uinta Mountains, overlies Phosphoria formation (Rex member); Park City not considered valid term. Concomitantly with thinning of Rex member of Phosphoria, gray and red sandstones and shales appear between the calcareous sandstones and main body of Woodside shale; they are here named Mackentire redbeds tongue of Phosphoria.

H. D. Thomas, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 8, p. 1249–1250. Discussion of Williams' paper. Proper designation should be Mackentire redbeds tongue of Woodside formation.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, pt. 1, p. 1268–1270, strat. sections. Along western part of Uinta Mountains, Woodside shale consists of 500 to 800 feet or red to maroon shales, siltstones, and very fine grained sandstones. Type Woodside rests directly above Phosphoria equivalent of Park City. Eastward along Uinta Mountains, it is impossible to separate redbeds of Park City age from true Woodside, and base of Woodside descends in section until at Skull Creek the entire upper Park City is represented by basal Woodside. Underlies Stanaker formation (new) at type section of Stanaker. Underlies Ankareh or Thaynes formations in some areas. Nomenclatural problems discussed.

N. D. Newell, 1948, Geol. Soc. America Bull., v. 59, no. 10, p. 1056 (fig. 2), 1057. Woodside formation in Confusion Range consists of several hundred feet of alternating red shales and sandy limestones. Overlies Phosphoria formation.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 170–171. In type area, consists of approximately 1,000 feet of maroon and red, shaly siltstone; overlies Phosphoria formation and underlies Thaynes formation. Extends over wide area in northern Utah, western Wyoming, and southwestern Montana; tongues out westward in southeastern Idaho and southwestern Montana into Dinwoody formation. Areas of occurrence discussed.

V. E. McKelvey and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12 p. 2837 (fig. 2), 2842–2843. In central and southern Wasatch Mountains and western Uinta Mountains, overlies Franson member (new) of Phosphoria.

W. W. Rubey, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–109. Referred to as Woodside redbeds in Bedford quadrangle, Wyoming.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2185–2189. Term Thaynes extended into Confusion Range where it replaces term Woodside as used by Newell (1948).

Named for Woodside Gulch, Park City district, Utah.

**Wood Siding Formation** (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Southeastern Nebraska and eastern Kansas.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 41, 42, 43. Name applied to include section between base of the Brownville above and base of the Nebraska City below. This was done because (1) the Nebraska City limestone, with Lorton coal below it, is persistent recognizable marker; (2) nonpersistent Gray Horse limestone, named from Oklahoma, is not good boundary marker between so-called Caneyville formation and Pony Creek as restricted by Moore (1936, Kansas Geol. Survey Bull. 22); and (3) restricted Caneyville and Pony Creek are not good formations in Nebraska. Includes (ascending) Nebraska City limestone, 9 to 10 feet of greenish-gray sandy shale, 6 to 11 feet of gray to brownish limy sandstone, and Pony Creek shale; first three units are the Caneyville formation of Kansas Geological Survey.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 13. Type locality and derivation of name stated.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273–2275. As originally defined, formation included approximately 20 feet of beds between former Nebraska City limestone and base of former Brownville limestone. As herein redefined, includes (ascending) Nebraska City limestone, Plumb shale (new), Grayhorse limestone, Pony Creek shale, and Brownville limestone members. Thickness 12 to 50 feet. Underlies Permian Onaga shale (new) ; overlies Root shale (new).

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 62–71. Uppermost formation of Pennsylvanian system in Midcontinent area. As redefined by Moore and Mudge (1956), includes (ascending) Nebraska City limestone, Plumb shale, Grayhorse limestone, Pony Creek shale, and Brownville limestone members. Branson (1956, Oklahoma Geology Notes, v. 16) extended name into Oklahoma and modified Kansas definition to suit transitional sediments of Oklahoma section. As redefined, formation extends downward from top of Brownville limestone to base of lowest recognizable member unit. As result of southward pinchout of Nebraska City limestone member in Osage County, Okla., base of formation is defined by base of "Grayhorse" limestone. South of Pawnee County where "Grayhorse" limestone cannot be recognized, Brownville limestone member constitutes entire formation. In Pawnee County, formation comprises (ascending) "Grayhorse" limestone, Pony Creek shale, and Brownville limestone members. Average thickness in Pawnee County 75 feet. Overlies Gano shale; underlies Admire group.

Type locality: Missouri River bluffs south of Wood Siding Station, Nemaha County, Nebr.

**Woodson Mountain Granodiorite**

Cretaceous: South California.

F. S. Miller, 1937, Geol. Soc. America Bull., v. 48, no. 10, p. 1399. Incidental mention. Named credited to E. S. Larsen, Jr.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 76–82, pl. 1. Light-colored rather coarse-grained granodiorite that contains biotite and a little hornblende. Intrudes Green Valley, Bonsall, and La Sierra tonalites, and Temescal Wash porphyry. Older than Roblar leucogranite (new) and Mount Hole granodiorite. Includes Steele Valley granodiorite and Cajalco quartz monzonite of Dudley (1935).

Named from its characteristic outcrops on Woodson Mountain, which is a few miles northeast of southeastern corner of San Luis Rey quadrangle and a few miles southwest of Ramona, San Diego County. Underlies area of about 220 square miles; among rocks of batholith, is exceeded in area only by Bonsall tonalite.

Woods Run Limestone (in Conemaugh Formation)[L]

Woods Run Limestone (in Conemaugh Group)

Pennsylvanian: Western Pennsylvania and western Maryland.

Original reference: P. E. Raymond, 1910, Carnegie Mus. Annals, v. 7, p. 147.

M. N. Shaffer, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 141, geol. map. This report considers Conemaugh a group.

J. J. Burke, 1958, Science, v. 128, no. 3319, p. 302. Original name Woods Run retained, without modification, for limestone described by Raymond (1910). Separated from overlying Carnahan Run shale (new) by 21½ feet of reddish-brown shale that carries plant fossils. Johnson (1929, Pennsylvania Geol. Survey Topog and Geol. Atlas 27) described a limestone which, in Pittsburgh region, occurs approximately 8 to 17 feet below the Woods Run; subsequent workers have referred to the two strata as Woods Run limestones or as Upper and Lower Woods Run limestones. Name Nadine limestone is here applied to this limestone described by Johnson.

Named for Woods Run within city of Allegheny, Pa. Allegheny is now incorporated in city of Pittsburgh.

Woods Run Shale (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania and western Maryland.

Original reference: C. K. Swartz, 1922, Maryland Geol. Survey, v. 11, pl. 6.

R. R. Dutcher and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 69 (fig. 4). Woods Run (Friendsville) shale shown on generalized columnar section for western Pennsylvania above Lower Bakerstown coal and below Ewing limestone.

Named derived from Woods Run, Pa.

**Woodstock Granite**[1] or **Granodiorite**

Carboniferous (?) : Northern Maryland.

Original reference: G. H. Williams and N. H. Darton, 1892, U.S. Geol. Survey map of Baltimore and vicinity to accompany "Guide to Baltimore," prepared for Baltimore meeting Am. Inst. Min. Engrs., Feb. 1892.

H. E. Vokes, 1957, Maryland Dept. Geology, Mines and Water Resources Bull. 19, p. 63. At least three periods of granite formation are recognized in Maryland. Granitic rocks of third period are represented by the Woodstock, Ellicott City, and at least part of the Sykesville.

Occurs in small elliptical area of less than 2 miles in diameter near Granite, close to junction of North and South Branches of Patapsco River. Woodstock is in Howard County, across river from Granite.

**Woodstock Greensand Marl Member** (of Nanjemoy Formation)[1]

Eocene, middle: Eastern Virginia and eastern Maryland.

Original reference: W. B. Clark, 1895, Johns Hopkins Univ. Circ., v. 15, no. 121, p. 3.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Uppermost member of formation. Overlies Potapaco clay member. Middle Eocene (Claiborne).

Named for Woodstock, an old estate a short distance above Mathias Point on Virginia bank of the Potomac in King George County, Va.

Woodstock Quartz Schist[1]

Woodstock quartz schist phase (of Hebron Gneiss)

Pre-Triassic: Northwestern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 114, 128, and map.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1 :253,440) : Connecticut Geol. Nat. History Survey. Refers to Woodstock (Paxton) quartz schist phase of Hebron gneiss. Occurs chiefly in northeastern part of Hebron outcrop area. Further described as including fine-grained quartz-mica schist, quartzite, and quartzose gneiss. Also contains thin layers of greenish lime-silicate rock and impure limestone. Pre-Triassic.

Crops out in eastern part of Woodstock Township, Windham County.

Woodstock Schist[1]

Ordovician: Southeastern Vermont.

Original reference: C. H. Richardson, 1927, Vermont State Geologist 15th Rept., p. 127–158.

Crops out in Woodstock, Windsor County.

Woodville Marble

Pre-Triassic: Western Connecticut.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Described as grayish-white coarsely granular marble, generally calcitic but locally dolomitic.

Named for Woodville in town of Washington, Litchfield County.

**Woodville Sandstone Member** (of Saginaw Formation)

Woodville Sandstone[1]

Woodville Sandstone (in Grand River Group)

Pennsylvanian: Southern Michigan.

Original reference: A. Winchell, 1861, Michigan Geol. Survey 1st Ann. Rept. Prog., p. 126, 138, 153, 158.

W. A. Kelley, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 206–207, 211. Included in Grand River group (new). Stratigraphic relation to Eaton sandstone (new) not determined. Not known certainly whether Woodville at type locality represents lentil of limited distribution which should be grouped with sandstones of Saginaw group or whether it is formation younger than any member of Saginaw group.

G. V. Cohee, Carol Mach, and Margery Holk, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart 41, sheet 5. Recommended that name Woodville be restricted to sandstone member in lower part of Saginaw formation.

Type locality: Exposure in cut of side track from (Woodville) mine to Central Railroad. Name has no reference to village of Woodville, in Newaygo County, but to old Woodville mine in Jackson County.

†Woodward Group[1]

Permian: Southwestern Oklahoma and Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bien. Rept., p. 42, 49.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 103. Poorly understood sequence including Dog Creek, Whitehorse, and Day Creek. Abandoned by Oklahoma Geological Survey.

Named for Woodward County, Okla.

**Woodway Limestone**

Middle Ordovician: Southwestern Virginia.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104, (two sheets). Cryptocrystalline tan and gray limestone with interbeds and zones of medium-crystalline limestone; prominent zone of *Stromatocerium rugosum* at base. Thickness 256 to 288 feet. Overlies Hurricane Bridge limestone (new); underlies Ben Hur limestone (new). Same as platy member of Lowville limestone on U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table 1), 33–34, 51–56, pl. 1. Further described and type section given. Discussion of problems of correlation and summary of nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

Type section: On north slopes of Elk Knob, 1¾ miles east of Woodway, Lee County.

Wooleys Bluff Clays[1] (in McElroy Formation)

Eocene (Jackson): Western Louisiana and eastern Texas.

Original reference: A. C. Ellisor, 1936, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1303.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2627–2628, 2629. Incidental mention in discussion of Wellborn sandstone and McElroy formation.

Named for locality in sec. 4, T. 3 N., R. 12 W., Sabine Parish, La.

**Woolsey Member** (of Bloyd Shale)

Pennsylvanian (Morrow Series): Northwestern Arkansas.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1943–1944, 1948 (fig. 2). Consists of a succession of terrestrial sediments up to 45 feet thick that intervene between Brentwood limestone member and unnamed upper division of Bloyd shale which includes Kessler limestone lentil. Member includes Baldwin or Zion Chapel coal. Disconformably overlies and (or) truncates uppermost beds of Brentwood member.

Named for its most complete and characteristic development in vicinity of Woolsey Station, Washington County.

**Woonasquatucket Formation**

Precambrian(?): North-central Rhode Island.

G. M. Richmond *in* G. M. Richmond and W. B. Allen, 1951, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 4, p. 10, 12, pl. 1. Comprises four distinct rock types: light-gray medium-grained feldspathic quartz-muscovite schist which is very weakly foliated, gray medium-grained quartz biotite schist with strong foliation, gray medium-grained feldspathic quartz biotite gneiss which is strongly foliated and thinly and irregularly layered, and conglomerate of granite and quartzite pebbles and cobbles in a quartz-muscovite schist matrix. Thickness 575 to 1,300 feet. Underlies Blackstone series; overlies Absalona formation (new); both contacts gradational.

Named from exposures on slopes northeast of Woonasquatucket Reservoir, Georgiaville quadrangle, Providence County.

†Woonsocket Conglomerate[1]

Carboniferous: Northeastern Rhode Island.

Original reference: G. R. Mansfield, 1906, Harvard Coll. Mus. Comp. Zoology Bull., v. 49, geol, ser., v. 8, p. 100.

Occurs in rather limited area around Woonsocket, Providence County.

†Woonsocket Basin Series[1]

Carboniferous: Northeastern Rhode Island.

Original reference: A. C. Hawkins, 1918, Am. Jour. Sci., 4th, v. 46, p. 437–472, map.

Occurs in Woonsocket Basin, Providence County.

Wooster Shale Member (of Cuyahoga Formation)

Lower Mississippian (Osagian): Northern Ohio.

E. J. Szmuc, 1957, Dissert. Abs., v. 18, no. 6, p. 2109. Used in place of name Black Hand shale since latter term is restricted to the pebbly sandstone. Intertongues with partly younger Black Hand sandstone, and in parts of Wayne, Medina, and Ashland Counties the sandstone is completely replaced by shale. Overlies Armstrong member.

Area investigated extends from vicinity of Meadville, Pa., to southern Ashland County, Ohio.

**Worcester Formation**

Worcester Phyllite[1]

Carboniferous: Eastern Massachusetts, northern Connecticut, and southern New Hampshire.

Original reference: B. K. Emerson, 1889, Geol. Soc. America Bull., v. 1, p. 560.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 20–31, pl. 1. Name Worcester formation proposed to include rocks of Carboniferous age formerly mapped in this area as Worcester phyllite and Brimfield schist and also a previously unmapped quartzite unit here named Vaughn Hills member. Worcester phyllite and Brimfield schist of previous reports dealing with this area are regarded as stratigraphically equivalent metamorphic facies, and terms "phyllite facies" and "mica schist facies" are suggested for use in this area. Also proposed that term "Brimfield schist" be restricted to those areas where the schist is not known to be equivalent to Worcester formation. Problematical whether or not Worcester formation of Hudson quadrangle and adjoining areas is to be correlated with Brimfield schist of Emerson's (1917) type locality; the two areas are separate and the schist is not exposed continuously between them; on the other hand, field evidence supports correlation of mica schist facies of this area with phyllite facies of Worcester formation. Includes Harvard conglomerate lentil. Mica schist facies grades upward into Nashoba formation (new).

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,400): Connecticut Geol. Nat. History Survey. Refers to Pomfret (Worcester) phyllite phase of Hebron gneiss; pre-Triassic.

Named for exposures in Worcester County, Mass.

†Worcester Quartzite[1]

Carboniferous: Eastern central Massachusetts, northern Connecticut, and central southern New Hampshire.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 17.

Exposed at Worcester, Mass., and over large area in northern part of Worcester County.

†Worcester County Gneiss[1]

Age(?): Massachusetts.

Original reference: E. Hitchcock, 1833, Rept. on geology, mineralogy, botany, and zoology of Massachusetts, p. 387–388.

Occurs along western margin of Worcester County gneiss range, in Northfield, Mass., and Winchester, N.H.

**Word Formation**[1]

Permian: Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 52.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 654–662, pl. 2. In this report, the Vidrio is restricted to that part of former member which is believed to be middle Guadalupe in age and classed as member of Word formation. Includes four unnamed limestone members. Plate shows uppermost limestone member grades laterally into Vidrio limestone member. Overlies Leonard formation; underlies Altuda formation, Capitan limestone, and Gilliam limestone.

R. L. Clifton, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1766–1768. Fauna and stratigraphic correlatives discussed. Word strata considered correlative with strata of Cherry Canyon and Brushy Canyon of Delaware Mountain group, San Andres group, and Blaine and Dog Creek formations.

E. R. Lloyd, 1947, West Texas, Geol. Soc [Guidebook] Spring Field Trip May 30–31, p. 5–6. Name Word should be restricted to local formation in Glass Mountains.

Named for Word's Ranch, Glass Mountains, Hess Canyon quadrangle, Brewster County.

Workman Hill Conglomerate

Miocene and Pliocene: Southern California.

G. J. Bellemin, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 652 (fig. 1), 653–655. Named as one of five conglomerates interbedded in Miocene and Pliocene shales of Puente Hills, Los Angeles County.

Named for occurrence adjacent to Workman Hill.

Worland Limestone[1]

Worland Limestone (in Altamont Limestone Member of Oologah Formation)

Worland Limestone Member (of Altamont Limestone)

Pennsylvanian (Des Moines Series): Western Missouri, southern Iowa, southeastern Kansas, and northeastern Oklahoma.

Original reference: F. C. Greene, 1933, Missouri Bur. Geology and Mines 57th Bien. Rept., p. 14, 18, 37, App. 2, pl. 2.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 29. Lower and upper Worland limestone of Greene (1933) have been traced across southwestern Missouri into southeastern Kansas and are equivalent to lower and upper Altamont limestones, respectively. Lower limestone of Altamont is herein named Tina, and name Worland retained for upper member of Altamont. Traced into Appanoose County, Iowa.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, p. 332–334. At type exposure, herein designated, consists of about 4½ feet of gray-brown-weathering massive limestone containing large fusulinids. Overlies Lake Neosho shale member (new).

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ., 31, p. 14–15, 16 (fig. 5). In this report, Oologah is used for sequence of beds between base of cap rock of Lexington coal and top of Altamont limestone in Nowata County and for equivalent sequence of limestone not yet subdivided in vicinity of Tulsa. In Nowata County, upper member of Oologah is Altamont limestone which is subdivided into Amoret limestone below and Worland limestone above, with shale interval between. The Worland is gray massive cherty limestone about 30 feet thick. Occurs below Nowata shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 30–31, fig. 5. Uppermost member of Altamont limestone in southwestern Iowa. Consists of thin wavy beds separated by green-gray fossiliferous shale seams and occasional pockets of green shale. Thickness 2½ feet in Madison County; 6 feet in Appanoose County. Overlies Lake Neosho shale member; underlies Nowata shale.

Type exposure: Along Kansas City Southern Railway just north of grade crossing northeast of Worland, Bates County, Mo.

Worldbeater Granite Porphyry

World Beater Porphyry[1]

Precambrian(?): Southeastern California.

Original reference: F. M. Murphy, 1933, California State Div. Mines Rept. 28 of State Min., July-Oct. 1932, p. 339, map.

J. H. Maxson, 1950, Geol. Soc. America Bull., v. 61, no. 2, p. 111. Incidental mention of Worldbeater granite porphyry in discussion of physiographic features of Panamint Range.

Occurs in southern part of Panamint Range, Inyo County, between Pleasant Canyon and Happy Canyon. Probably named for Worldbeater mine.

**Worm Creek Quartzite member** (of St. Charles Limestone)[1]

Upper Cambrian: Southeastern Idaho and northeastern Utah.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 407, 408.

J. S. Williams and G. B. Maxey, 1941, Am. Jour. Sci., v. 239, no. 4, p. 282, 283 (fig. 2); J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1135, pl. 1. Described in Logan quadrangle, Utah. Drab fine- to medium-grained medium-bedded quartzite; at base of formation. Thickness on High Creek 75 feet; at Calls Fort, west of quadrangle, 6 feet. Overlies Nounan formation. Deiss (1938, Geol. Soc. America Bull., v. 49, no. 7) erred in redefinition of St. Charles in Blacksmith Fork section, because he failed to locate Worm Creek quartzite, which is distinctly present there. Upper Cambrian.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 13. In Randolph quadrangle, Utah, is massive gray quartzite about 300 feet thick.

W. H. Coulter, 1956, Idaho Bur. Mines and Geology Pamph. 107, p. 18. Thickness, east of Willow Flat, Idaho, 170 feet.

R. H. Olson, 1956, Utah Geol. Soc. Guidebook 11, p. 48–49. Area of report is Promontory Range. A 3,800-foot sequence of dolomites, limestones, and minor interbedded shales lying between Dunderberg shale (herein geographically extended into Utah) and Ordovician Garden City formation is referred to as Upper Cambrian (undifferentiated). A 60-foot quartzite member is present 1,160 feet below base of Garden City formation. This quartzite unit may be correlative of Worm Creek quartzite member of St. Charles formation.

C. B. Bentley, 1958, Bringham Young Univ. Research Studies Geology Ser., v. 5, no. 6, p. 22. Haynie (1957, unpub. thesis) affirmed Olson's (1956) Worm Creek designation in Promontory Range. Since Worm Creek is same age as Dunderberg shale of Eureka, Nev., Olson's Dunderberg shale is misnomer.

Named for exposures on Worm Creek, Bear Lake County, Idaho.

†Wortham Aragonite Lentil (in Wills Point Formation)[1]

Paleocene: Northeastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 535, 537, 538, 559.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 25. Lentil in Kerens member of Wills Point formation.

Named for occurrence in stream valley, 1 mile east of Wortham, Freestone County.

Worthey Member (of Sycamore Formation)

Mississippian: Central southern Oklahoma.

J. D. Prestridge, 1959, *in* Petroleum geology of southern Oklahoma, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 158 (fig. 2), 161–162, 163. Comprises approximately 310 feet of compact tough blocky blue slate, silty to sandy limestone which is massive at base becoming thick bedded near middle and thin bedded near top; also member becomes more shaly toward top. Eastward from type locality upper part gives way to lower Caney shale which becomes calcareous near base; contact gradational. Overlies Cornell Ranch member (new).

Type section: SE¼SE¼NE¼ sec. 33, T. 2 S., R. 1 E., Carter County. Named for Ed Worthey Farm. Massive part of member forms prominent Sycamore hogback.

**Worthington Sandstone Member** (of Allegheny Formation)[1]

Middle Pennsylvanian: Western Pennsylvania.

Original reference: J. P. Lesley, 1880, Pennsylvania 2d Geol. Survey Rept. $H_5$, p. xxi, 319.

Worthington is in Armstrong County.

Worthville Beds[1]

Upper Ordovician: Northern New York.

Original reference: R. Ruedemann, 1925, New York State Mus. Bull. 258, p. 137, 141, 149, 154.

Exposed along Sandy Creek about Worthville, Jefferson County.

**Wrangell Lava**[1]

Tertiary to Recent: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 54, map.

F. H. Moffit, 1954, U.S. Geol. Survey Bull. 989-D, p. 165-167, pls. 6, 7. Proportion of fragmental beds, tuffs, and agglomerates much greater in western part of area (eastern part of Alaska Range and adjacent area), near the volcanic centers. The lava flows, particularly younger flows, are quite fresh and commonly black or dark gray in color; less commonly show colors of brick red, brown, and tan. Most lava is porphyritic and much is highly vesicular. Columnar structure well developed in many flows. Glassy phases of lava more numerous in upper part of section. Thickness varies with distance from vents; may be 12,000 feet or more in neighborhood of Mount Sanford, but because base of deposits is uneven surface, definite measurement applies to only one locality. Extrusion of Wrangell lava probably began in Eocene time and continued intermittently to Recent time. Mapped as Tertiary to Recent.

Forms entire western part of Wrangell group of mountains. Occupies an irregular elongated area extending from lower western slopes of Mount Drum to international boundary, a distance of about 130 miles.

Wray Channel Beds (in Ash Hollow Formation)

Pliocene: Northeastern Colorado.

M. K. Elias, 1942, Geol. Soc. America Spec. Paper 41, p. 143. Name applied to thin channel sandstone near base of Ash Hollow.

Occurs near Beecher Island Post Office about 15 miles south of Wray, Yuma County.

**Wreford Limestone** (in Chase Group)[1]

Permian: Eastern Kansas, central Oklahoma, and southeastern Nebraska.

Original reference: R. Hay, 1893, Kansas State Bd. Agr. 8th Bien. Rept., p. 104.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 165. Includes (ascending) Threemile limestone, Havensville shale, and Schroyer limestone members. Average thickness 35 feet. Underlies Matfield shale; overlies Speiser shale. Wolfcamp series.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 105-109. Described in Pawnee County where it overlies Garrison shale in Council Grove group, and underlies Matfield shale. This is essentially usage of Prosser (1902). In Kansas, Wreford is divided into three members but these divisions have not been recognized in Oklahoma. Thickness 12 to 31 feet.

Named from exposures near Wreford, Geary County, Kans.

Wrightsville Conglomerate[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: J. F. Carll, 1883, Pennsylvania 2d Geol. Survey Rept. $L_4$, p. 180, 203-208, 230.

Forms several escarpments near Wrightsville, Warren County.

**Wupatki Member** (of Moenkopi Formation)

Lower Triassic: Northeastern Arizona.

E. D. McKee, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 86, 87 (fig. 1). Red beds—shaly siltstones and structureless mudstones—alternating with resistant thick-bedded sandstones. Thickness over 50 feet. Underlies Winslow member (new); overlies Kaibab limestone.

E. D. McKee, 1954, Geol. Soc. America Mem. 61, p. 18, 19. Thickness ranges from 70 to 119 feet. Underlies Moqui member (new) in Poverty Tank-Concho area. Units here called Wupatki and Moqui were referred to as Salt Creek by Hager (1922, Mining and Oil Bull., v. 8, no. 2, p. 73).

Named in Winslow-Holbrook area.

Wurtemburg Limestone (in Pottsville Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: J. P. Lesley, 1875, Pennsylvania 2d Geol. Survey Rept. J., p. 93–100.

Well exposed just east of Wurtemburg along Slippery Rock Creek, in Lawrence County.

Wurtemburg Sandstone (in Pottsville Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: J. P. Lesley, 1875, Pennsylvania 2d Geol. Survey Rept. J, p. 93–94.

Wurtemburg, Lawrence County.

**Wyandot Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Wyandot mine, Houghton County.

**Wyandot Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Wyandot mine, Houghton County.

**Wyandot No. 8 Amygdaloid**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Occurs in interval between conglomerate No. 6 above and Superior West amygdaloid below and is eight amygdaloids back from Wyandot shaft, Houghton County.

**Wyandot No. 8 Flow**[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Wyandot mine, Houghton County.

Wyandotte Group[1]

Pennsylvanian: Eastern Kansas.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. Guidebook 5th Ann. Field Conf., correlation chart.

**Wyandotte Limestone**[1] (in Kansas City Group)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., Guidebook, p. 85, 91, 92, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4). Formation includes (ascending) Frisbie limestone, Quindaro shale, Argentine limestone, Island Creek shale, and Farley limestone members. Underlies Bonner Springs shale; overlies Lane shale. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 34. Thickness of formation about 32 feet in Cass County, Nebr.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. Thickness of formation about 22 feet in Madison County, Iowa. Five members present.

Named from Wyandotte County, Kans.

†Wyckoff Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 111.

Named for Wyckoff, Lyon County.

Wykoff Beds[1]

Wykoff Member (of Maquoketa Formation)[1]

Upper Ordovician (Cincinnatian): Southeastern Minnesota and northeastern Iowa.

Original reference: C. W. Hall and F. W. Sardeson, 1892, Geol. Soc. America Bull., v. 3, p. 349, 359, 366.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9, 92–93. Wykoff member of Maquoketa consists of about 30 to 45 feet of argillaceous gray limestone and weathered shale; fossiliferous. Occurs above Dubuque member and below Devonian Cedar Valley limestone. Name is satisfactory and should be retained in Minnesota classification.

Named for exposures at Wykoff, Fillmore County, Minn. Also well exposed 1 mile east of Spring Valley, along U.S. Highway 16.

**Wyman Formation[1]**

Precambrian(?): Southern California.

Original reference: J. H. Maxson, 1934, Pan-Am. Geologist, v. 61, no. 4, p. 311.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 280 (fig. 4). Shown on columnar section above Roberts formation and below Reed dolomite. Thickness 3,700 feet.

U.S. Geological Survey currently designates the age of the Wyman as Precambrian(?) on the basis of a study now in progress.

In Wyman Canyon, Inyo Range.

Wyman[1] (formation)

Lower Cretaceous: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46, p. 195–232.

†Wyman Sandstone[1]

Mississippian: Northern Arkansas and eastern Oklahoma.

Original reference: F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. 26, 38–41.

Named for Wyman, Washington County, Ark.

Wymanian series

Precambrian (Protozoic): Eastern California.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 4, p. 307 (chart). Listed as lowermost series in section. Consists of 3,700 feet of schists. Unconformable below Reedian series.

Occurs in Death Valley region.

Wymer Beds[1]

*See* Wimer Beds.

**Wymore Shale Member** (of Matfield Shale)

Wymore Shale (in Chase Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 37.

D. E. Hattin, 1957, Kansas Geol. Survey Bull. 124, p. 49–50, 122. Generally exhibits fourfold depositional sequence (ascending): (1) silty green shale; (2) silty red shale and red mudstone, (3) silty green shale, and (4) very silty shale, very calcareous mudstone, or hard very silty limestone. Thickness 9 to 26 feet. Underlies Kinney limestone member; overlies Schroyer limestone member of Wreford limestone. Wolfcamp series.

Type locality: Ravines on west side of creek 2½ miles east of south side of Wymore, Gage County, Nebr., in E½ sec. 27, T. 2 N., R. 4 E., about one-quarter mile north of where highway crosses Burlington and Union Pacific Railroads.

Wynn Limestone Member (of Palo Pinto Formation)

Pennsylvanian (Canyon Series): North-central Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Name applied to lower limestone member of formation. Underlies Posideon shale member (here reallocated to redefined Palo Pinto).

Named from Wynn Mountain, 2½ miles east of Palo Pinto, Palo Pinto County.

Wynona Sandstone Group[1] or Series[1]

Pennsylvanian: Central northern Oklahoma.

Original reference: H. T. Beckwith, 1928, Oklahoma Geol. Survey Bull. 40T, p. 22–24.

Occurs in vicinity of Wynona, Osage County.

**Wynona Sandstone Member** (of Vamoosa Formation)

Wynona Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Bull. 686–D, p. 17, 18.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 12 (fig. 1), 50–52, fig. 14, pl. 1. Reallocated to Vamoosa formation. Described as sequence of beds about 70 feet thick; consists of at least two sandstones, each about 25 feet thick, separated by about 20 feet of shale and sandy shale. Beds are buff, very fine to coarse grained, thin bedded to massive; sandstones become thinner northward and split into many tongues. Lies stratigraphically above Cochahee sandstone member and below Oread limestone member.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 30. Lowest member of Vamoosa identified in Pawnee County. Thickness 15 feet. Occurs at top of complex 100-foot shale-sandstone sequence which comprises lower part of Vamoosa; underlies thick sequence of dark fossiliferous shales; occurs below Kanwaka shale member.

Named from exposures near Wynona, T. 24 N., R. 9 E., Osage County.

Wyo division[1]

Upper Cambrian or Lower Ordovician: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. 295–306, pl. 3.

Named for "well-known cattle brand (YO) used in Blue Mountain region along course of James River in adjoining parts of Mason and Kimble Counties."

†Wyoming Conglomerate[1]

Miocene(?): Northwestern Colorado, northeastern Utah, and southern Wyoming.

Original reference: C. King, 1876, U.S. Geol. Expl. 40th Par. Atlas, maps 1, 2; separate sheets were issued in 1875, but atlas bears 1876 imprint.

Occurs in region of Big Thompson, eastern Colorado, and east of Laramie Hills, Wyo.

†Wyoming Formation[1] or Group[1]

Pennsylvanian, Permian, and Triassic(?): Eastern Colorado.

Original reference: G. H. Eldridge, 1896, U.S. Geol. Survey Mon. 27.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, pl. 6; R. L. Langenheim, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 550 (fig. 2). Name appears on correlation charts citing history of nomenclature applied to Pennsylvanian and Permian rocks in Colorado.

Named for widespread development in Wyoming, but application of name in literature has been restricted to eastern Colorado.

Wyoming Valley Limestone Beds[1]

Pennsylvanian: Pennsylvania.

Original reference: C. A. Ashburner, 1886, Pennsylvania 2d Geol. Survey Rept. 1885, p. 437–450, map.

Occurs in Wyoming Valley, Luzerne County.

Wyopo Formation (in Chugwater Group)

Triassic: Northwestern Wyoming.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 124 (table 1), 136. Cliff-forming series of white buff light-gray, and pink siltstone which is crossbedded in large part. In southern part of range, lower part of formation changes in short distances from light gray to light red. Thickness about 200 feet in Lander region and less than 100 feet near Dubois. Underlies Gypsum Spring formation; overlies Popo Agie formation.

Type locality: Wyopo, a loading spur on Northwestern Railway, 2 miles northeast of Lander, Fremont County.

Wyota Member (of Dunleith Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 24, figs. 3, 12. Dolomite, argillaceous and dense at top; pure, coarsely crystalline and porous below; medium- to thick-bedded. Thickness about 19 feet. Shown on columnar section as underlying Sinsinawa member (new) of Wise Lake formation and overlying Wall member (new) of Dunleith formation.

Occurs in Dixon-Oregon area.

XI Member (of Rexroad Formation)

Pliocene, upper: Southwestern Kansas.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no. 5, p. 93–94, 96–97. Consists of about 25 feet of sand, caliche, and clay beds in basal part of formation. Overlies Laverne formation with angular unconformity. Contains vertebrate fauna.

C. W. Hibbard, 1953, Michigan Acad. Sci., Arts, and Letters, Papers, v. 38, p. 389, 408. Contains Saw Rock Canyon fauna considered to be lower upper Pliocene in age.

Type locality: Near center of west line of sec. 36, T. 34 S., R. 31 W., Seward County. Name derived from XI ranch on which exposures occur.

Yaak Quartzite[1]

Precambrian: Northwestern Montana, and British Columbia, Canada.

Original reference: R. A. Daly, 1905, Canada Geol. Survey Summ. Rept. 1904, p. 96–100.

Probably named for Yaak River, Montana-British Columbia.

Yabucoa Granite[1]

Age(?): Puerto Rico.

Original reference: C. R. Fettke, 1924, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 2, p. 159.

Yaeger Greenstone (in Yavapai Group)

Precambrian: Central Arizona.

E. D. Wilson, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 112; 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1118 (table 1), 1120, pl. 10. Largely of intermediate to mafic flows and small intrusives, tuff, and agglomerate, together with some sedimentary material. Rocks show extensive alteration to greenish-black and grayish-green aggregates and fine-grained chlorite, sericite, and quartz, with local rude schistosity. Thickness appears to exceed 2,000 feet; base not exposed. Probably oldest member of Yavapai group. In fault contact with Red Rock rhyolite (new) above. Yaeger greenstone is equivalent to "greenstone complex" of earlier authors, especially Lausen (1930, Jour. Geology, v. 38, no. 2, p. 174).

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1496. In Gila County, basic volcanic rocks belong not to a single unit, the Yaeger greenstone, placed at base of stratigraphic sequence, but to at least three stratigraphically separate units—Flying W, Board Cabin, and Haigler formations (new).

Named for typical occurrence east of Yaeger mine, in southwestern part of Black Hills. Also crops out in Mazatzal Mountains and eastern Tonto Basin areas.

Yager Formation

Upper Jurassic to Lower Cretaceous: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 16–22, pls. 1, 2. Series of dark-gray indurated mudstone, shale, graywacke, and conglomerate. Thickness about 10,000 feet. In fault contact with Franciscan in northeastern part of Fortuna quadrangle and with rocks of False Cape shear zone along Russ fault in southern part of quadrangle; in southern area, unconformably underlies Pullen formation (new) and farther north undifferentiated Wildcat group; along Yager fault is faulted against Rio Dell formation (new) and Eel River formation (new). It is possible that rocks included in formation range from Upper Jurassic to Upper Cretaceous; most evidence points to Cretaceous age. Columnar section shows Upper Jurassic to Lower Cretaceous.

Exposed in Yager Creek in Fortuna quadrangle, Eel River valley area, Humboldt County.

**Yakataga Formation**[1]

Miocene and Pliocene(?): Southeastern Alaska.

Original reference: N. L. Taliaferro, 1932, Geol. Soc. America Bull., v. 43, no. 3, p. 756.

D. J. Miller, 1951, Preliminary report on the geology and oil possibilities of the Yakataga district, Alaska: U.S. Geol. Survey, p. 35, fig. 1. Horizon of Yakataga-Poul Creek contact in area between Twomile Creek and White River found to lie several hundred feet stratigraphically above sandstone cited by Taliaferro as marking base of Yakataga formation. Formation includes entire sequence of Tertiary strata overlying Poul Creek formation in Yakataga district. Upper Oligocene(?), Miocene and Pliocene(?).

D. J. Miller, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–187, sheets 1 and 2. In southeastern part of Robinson Mountains, formation comprises minimum of 10,000 feet, possibly 15,000 feet or more, of sedimentary rocks, chiefly siltstone, sandstone, and unsorted coarse ice-transported debris, called conglomeratic sandy mudstone. Lower part of Yakataga Reef section reassigned to Poul Creek formation. Considerable diversity of opinion as to age of formation. Mapped as Miocene and Pliocene(?).

Well exposed at Yakataga Reef and on both flanks of "Yakataga" anticline (Sullivan anticline in report of Miller, 1957), Yakataga district, Controller Bay region.

**Yakima Basalt**[1]

Miocene, upper, and Pliocene, lower: Eastern Washington.

Original reference: G. O. Smith, 1901, U.S. Geol. Survey Water-Supply Paper 55.

W. C. Warren, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2034–2035; 1941, Jour. Geology, v. 49, no. 8, p. 795–814. Yakima basalt is typical plateau basalt which is associated toward west in Cascade Mountains with different type of volcanic formation, the Keechelus andesitic series. Latter has commonly been regarded as younger. In Mount Aix quadrangle, upper part of Keechelus andesitic series, which has long been known to be unconformable on lower part, has been split off as separate unit and is here named Fifes Peak andesite. Marginal flows of Yakima overlap Fifes Peak andesite. In some areas, overlies Taneum andesite. Yakima commonly regarded as middle Miocene but may be upper Miocene.

J. H. Mackin, 1947, Northwest Sci., v. 21, no. 1, p. 33. In Yakima-Ellensburg area, Yakima basalt with Squaw Creek diatomite member (new) one flow below top, is overlain in ascending order by Selah tuff (new), Wenas basalt, and main body of Ellensburg formation.

A. C. Waters, 1955, Geol. Soc. America Bull., v. 66, no. 6, p. 669–672, pl. 1. Described and mapped in Yakima East quadrangle where it is exposed in four southeast-trending strips that coincide with crestal portions of four anticlinal axes. Interfingers with overlying Ellensburg formation. Thickness as much as 1,500 feet; base not exposed. Lenses of micaceous silt, sandstone, and clay, with occasional conglomerate beds, occur between flows at many localities in upper part of section. Layer of fresh-water diatomite, 6 to 10 feet thick, together with 150-foot basalt on which it rests, forms good horizon marker. Top of flow that overlies the diatomite was apparently selected by Smith as top of Yakima basalt and base of Ellensburg where he mapped Ellensburg quadrangle. Present mapping indicates that contact between any one basalt flow and an overlying sedimentary bed cannot serve as workable horizon for defining top of Yakima basalt and base of Ellensburg; in general, sedimentary parts of the section thin and pinch out between successively younger flows when traced eastward; in some areas, exact position of contact is a matter of arbitrary choice; at one locality, Ellensburg pinches out and Wenas basalt rests directly on Yakima. In a broad sense, entire lower part of Ellensburg can be considered marginal sedimentary facies of Yakima basalt flows.

Named for occurrence in Yakima area.

Yakima Group[1]

Pliocene: Central northern Oregon.

Original reference: T. Condon, 1902, The two Islands: Portland, Oreg., The J. K. Gill Co.

Yakinikak Limestone[1]

Upper Mississippian: Northwestern Montana.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 324.

L. L. Sloss, 1945, Jour. Paleontology, v. 19, no. 3, p. 309. Represents remnant of an imbricate thrust sheet that has been thrust over subjacent Pennsylvanian(?) quartzite.

Type locality: On Yakinikak Creek, 4 miles west of North Fork of Flathead River, Glacier National Park.

**Yakutat Group**[1]

Upper(?) Cretaceous: Southeastern Alaska.

Original reference: I. C. Russell, 1891, Nat. Geog. Mag., v. 3, p. 167–175.

George Plafker and D. J. Miller, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–189. Sedimentary sequence in Malaspina district assigned to Yakutat group probably thousands of feet thick. Paleontological evidence indicates Upper (?) Cretaceous age. Underlies Tertiary(?) siltstone sequence and overlies Cretaceous or older crystalline complex with unconformable contacts.

Exposed about Yakutat Bay and westward along foot of St. Elias Mountain to Icy Bay. Also forms major part of coastal mountains between Disenchantment Bay and Dry Bay.

**Yale Member** (of Ironwood Iron-Formation)[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: W. O. Hotchkiss, 1919, Eng. Mining Jour., v. 108, p. 501, 503.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 104 (table 10), 106 (table 11), 107 (fig. 6). Underlies Norrie member; overlies Plymouth member. Thicknesses (taken from drill holes) 48½ and 67½ feet.

Named for Yale mine, near Bessemer, Gogebic County, Mich.

**Yale Point Sandstone** (in Mesaverde Group)

Upper Cretaceous: Northeastern Arizona.

G. A. Kiersch, 1955 Mineral Resources Navajo-Hopi Indian Reservations, Arizona-Utah, v. 2: Tucson, Ariz., Univ. Arizona Press, p. 4 (fig. 1), 7. Prominent cliff-forming sandstone capping group along eastern margin of Black Mesa. Overlies Wepo formation (new). Name credited to Repenning and Page.

C. A. Repenning and H. G. Page, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 271, 279–281. Yellowish-gray massive sandstone, weathering grayish orange, and composed of coarse- to medium-grained subrounded to subangular clear quartz. Bedding is lenticular, individual units crossbedded. Thin silty units present at widely spaced intervals. Minor amounts of coal present. Thickness at Yale Point 204 feet, maximum of 300 feet at north end of Marsh Pass. Caps Black Mesa; no younger sediments overlie formation; and its upper limit is surface of recent erosion. Intertongues with underlying Wepo formation to south. Type section designated.

Type locality: Three-fourths mile west of Yale Point of Black Mesa, from which it is named, Apache County.

**Yamhill Formation**

Eocene, upper: Western Oregon.

E. M. Baldwin and others, 1955, U.S. Geol. Survey Oil and Gas Inv. Map OM–155. Name proposed for thick sequence of marine sedimentary rocks that overlie Siletz River volcanic series. These sedimentary rocks have been known locally as Mill Creek beds. At Mill Creek, sedimentary rocks that compose lower 500 feet of formation are predominantly dark-gray shale and siltstone with occasional beds of lime-cemented sandstone. The siltstone and shale sequence along Mill Creek is overlain by sequence of massive sandstone beds. The sandstone is medium to greenish gray, thick bedded, and fossilferous. This sandstone is about 500 feet thick and grades upward into more argillaceous rock. Greenish-gray sand beds of the Yamhill are in turn overlain along Mill Creek by approximately 4,000 feet of finely micaceous siltstone and mudstone. Unconformably overlain by Nestucca formation. Yamhill and Burpee formations occupy same general stratigraphic position and are probably equivalent in age. Eocene.

E. M. Baldwin, 1959, Geology of Oregon: Ann Arbor, Mich., Edwards Bros., Inc., p. 13–14. Formation is exposed along south slope of Yamhill Valley and southward through the Dallas area to Luckiamute River where it appears to interfinger with beds of Tyee formation. Near Dallas, limestone at base of formation is referred to as Dallas limestone member.

Type section: Exposures along Mill Creek from a point 0.6 mile south of Sheridan quadrangle to point 0.1 mile southeast of Mill Creek School. Formation best preserved within Yamhill Valley downwarp, which occupies broad area along South Yamhill River in Sheridan quadrangle.

**Yampa Limestone Lentil** (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 43, map, sections.

Named for Yampa mine, Bingham district.

†Yampa Sandstone[1]

Pennsylvanian: Northeastern Utah.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 41, 55.

Occurs along Yampa River and on Yampa Plateau.

Yampai sandstone[1]

Yampai shales (in Tusayan series)

Permian: Northwestern Arizona.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 38, no. 3, p. 251, 339.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (table). Underlies Shiwits sandstones; overlies Seligman limestones. In Tusayan series (new) of Carbonic age.

In Grand Canyon region.

**Yankee Fork Rhyolite Member** (of Challis Volcanics)[1]

Oligocene, upper, or Miocene, lower: Southern central Idaho.

Original reference: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 13. In Bayhorse region, Challis volcanics have been divided into five members: latite-andesite, Germer tuffaceous, basalt and related flows, Yankee Fork rhyolite, and travertine. Rhyolitic member has three subdivisions that have been distinguished in mapping on the basis of differences in lithology.

Type locality: Head of Yankee Fork Creek, southeast corner of Casto quadrangle.

**Yankeetown Chert**[1]

Yankeetown Chert (in New Design Group)

Upper Mississippian (Chester Series): Southwestern Illinois and eastern Missouri.

Original reference: S. Weller, 1913, Illinois Acad. Sci. Trans., v. 6, p. 120, 124.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 135; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 826. Assigned to New Design group (new).

Named for Yankeetown School, southeastern corner Monroe County, Ill.

Yanktonian series

Cretaceous: Iowa.

C. R. Keyes, 1936, Pan-Am. Geologist, v. 66, no. 2, p. 154–156. Term used for so-called Benton shales of Iowa. Comprises (ascending) Woodbury shales, Dixon chalk, Hawarden shales, and Niobrara chalk.

Yap Beds or Formation

Pre-Tertiary(?): Caroline Islands (Yap).

Risaburo Tayama, 1935, Topography, geology, and coral reefs of the Yap Islands: Tohoku Univ., Inst. Geology and Paleontology Contr. in Japanese Language, no. 19, p. 36–38 [English translation in library of U.S. Geol. Survey, p. 32–33]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 60–61, table 4 [English translation in library of U.S. Geol. Survey, p. 71–72]. Group of green rocks composed chiefly of massive amphibolite, granular amphibolite, platy amphibolite, and green schist. Dips at high angles. Unconformably underlies Map beds. Pre-Tertiary(?).

C. G. Johnson, R. J. Alvis, and R. L. Hetzler, 1960, Military geology of Yap Islands, Caroline Islands: U.S. Army Far East Command, p. 63–65. Pre-Miocene, possibly Mesozoic.

Occurs in Yap proper, Yap Island group.

Yapoah Flows, Basalt

Recent: Southwestern Oregon.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, no. 3, p. 55, 62, pl. 9. Discussion of volcanoes of Three Sisters region. Name is applied to flows from Yapoah Cone.

Yapoah Cone is north of North Sister Mountain.

Yaquian series

Cambrian (Mid-Cambric): Northern Arizona.

Charles Keyes, 1940, Pan-Am. Geologist, v. 74, no. 2, p. 154–156. Name proposed for beds of Mid-Cambric age in the Grand Canyon which were previously called Tonto group and correlated with the type Tonto series section (of Protozoic age) near Fort Apache.

In the Grand Canyon region.

**Yaquina Formation[1] or Sandstone**

Oligocene, upper: Northwestern Oregon.

Original reference: Harrison and Eaton [consulting firm], 1920, Report on investigation of oil and gas possibilities of western Oregon: Oregon Bur. Mines and Geology, Mineral Resources Oregon, v. 3, no. 1, p. 3–40.

H. E. Vokes, Hans Norbisrath, and P. D. Snavely, Jr., 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 88. Described in Newport-Waldport area as approximately 2,700 feet of shallow-water deposits, predominantly light-gray to brown tuffaceous and usually carbonaceous poorly consolidated sandstones, sandy tuffs, and interbedded or alternating tuffs and sandstones. Disconformably overlies Toledo formation; disconformably underlies Nye mudstone.

P. D. Snavely, Jr., and H. E. Vokes, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 97. Described in coastal area near Cape Foulweather as 2,500 to 3,000 feet of arenaceous sedimentary rocks, unconformably overlying Nestucca formation. Outcrop belt narrows northward as dip steepens and the Yaquina is progressively overlapped by Astoria formation.

Type locality not designated in original description. Schenck (1928) interpreted type locality to be near village of Yaquina, near Newport, Lincoln County.

**Yarmouth Interglaciation**

Yarmouth (Yarmouthian) Stage, Age

Yarmouth stage of deglaciation[1]

Pleistocene: Mississippi Valley.

Original reference: F. Leverett, 1898, Jour. Geology, v. 6, p. 176, 238–243.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 24, 31, 35, 38, 52, 55, 104, 118, 156. Discussion of Yarmouth soil, Yarmouthian age, and stage. The Yarmouthian follows the Kansan and precedes the Illinoian.

Name amended to Yarmouth Interglaciation to comply with Stratigraphic Code adopted 1961.

Name derived from Yarmouth, Des Moines County, Iowa.

**Yates Formation** (in Artesia Group)

**Yates Sandstone** (in Whitehorse Group)

Permian: Subsurface in Texas and subsurface and surface in New Mexico.

G. C. Gester and H. J. Hawley, 1929, Structure of typical American oil fields: Tulsa, Okla., Am. Assoc. Petroleum Geologists, v. 2, p. 487, 488. In Yates field, upper division of Permian is known as "Anhydrite series" and ranges in thickness from 650 to 750 feet. Yates is 50-foot sandstone that occurs 100 to 150 feet below top of Anhydrite series and from 500 to 550 feet above top of "brown lime," topmost member of "Big lime" in this field.

R. K. DeFord, G. D. Riggs, and N. H. Wills, 1938, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 22, no. 12, p. 1706. Yates sand has been traced from subsurface to surface outcrop and top of Yates mapped from Carlsbad to McKittrick Canyon. Subdivision of Whitehorse-Capitan is simplified. From top downward, it is subdivided into Carlsbad, Yates, Seven Rivers, and Queen. This involves redefinition of the Carlsbad.

P. T. Hayes, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–98. Formation included in Carlsbad group. Overlies Seven Rivers formation; underlies Tansill formation.

Term Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4) used in preference to Whitehorse Group in New Mexico.

Named from subsurface sections in Yates field in Pecos County, Tex.

Yauco Mudstone (in Mayagüez Group)

Upper Cretaceous: Southwestern Puerto Rico.

P. H. Mattson, 1958, Dissert. Abs., v. 18, no. 1, p. 197. Group comprises seven units. The Yauco is fourth in sequence [ascending]; overlies Melones limestone and underlies Maricao basalt (both new). Group ranges in age from Santonian or Campanian to early Maestrichtian.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 330 (fig. 3), 331–333, pl. 1. Mudstone, minor tuff, and rare conglomerate are herein named Yauco mudstone. These are rocks called strongly bedded shale by Mitchell (1922) who named them Río Yauco shale. Hubbard (1923, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 1) named them Río Yauco series. Río has been dropped to avoid confusion with other Puerto Rican formational names. Consists of foraminiferal tuffaceous mudstone with minor amount of tuff, wacke, conglomerate, and bedded chert. Bedded tuff forms 20 to 60 percent of Yauco mudstone; the larger tuff and flow units have been separated as Maricao basalt (new). Mudstone forms narrow belts on limbs of Hormigueros syncline; it averages 250 meters in north limb and ranges from 0 to 30 meters in south limb. Bedding in Yauco mudstone generally parallels contact with Rio Loco lava, but locally exposures show bedding truncated at contact. Relationships with Río Blanco formation not definitely known. Gradational contact with Sabana Grande andesite.

Report discusses Mayagüez area, about 250 square miles, in southwest Puerto Rico. Area contains large alluvium-filled valleys and part of the Cordillera Central in its southern foothills.

**Yavapai Series**

Yavapai Group

Yavapai Schist[1]

Precambrian: Central Arizona.

Original reference: T. A. Jaggar, Jr., and C. Palache, 1905, U.S. Geol. Survey Geol. Atlas, Folio 126.

E. D. Wilson, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 112; 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1119–1120, table 1. Precambrian schists in central Arizona, which show recrystallization only in vicinity of intrusive bodies, collectively termed Yavapai group and subdivided into (ascending) Yaeger greenstone (new), Red Rock rhyolite (new), and Adler [Alder] sedimentary series (new). Term Yavapai group preferred because Yavapai formation is only locally schistose.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 7, pl. 3. Series composed of many formations in Jerome area and divided into two groups. In Bagdad area, series comprises three formations (ascending): Bridle formation (new), Butte Falls tuff (new), and Hillside mica schist (new).

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 8–9, pl. 1. Series includes all older Precambrian volcanic and sedimentary rocks in Prescott-Jerome area. Separated into two major subdivisions: eastern Ash Creek group (new) of seven formations and western Alder group of six formations. The two groups separated by the Shylock fault. Wilson (1939) suggested that Yavapai schist be modified to Yavapai group. Yavapai series is used in this report to replace Yavapai schist.

Named for extensive development in Yavapai County.

**Yazoo Clay** (in Jackson Group)

Yazoo Clay Member (of Jackson Formation)[1]

Yazoo Group

Eocene, upper: Mississippi, southwestern Alabama, and central northern Louisiana.

Original reference: E. N. Lowe, 1915, Mississippi Geol. Survey Bull. 12, p. 79.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 98–105. Yazoo clay, as used in this report [Grant and La Salle Parishes], includes all materials between Danville Landing beds above and Moodys Branch marl below. Includes Tullus clay member (new) below and Verda member (new). Thickness 275 to 375 feet. Jackson group.

F. F. Mellen, 1940, Mississippi Geol. Survey Bull. 39, p. 12 (table), 18–22. Member of Jackson formation. Conformably overlies Moodys Branch marl member; conformably underlies Forest Hill sand member. Thickness about 500 feet.

U. B. Hughes and others, 1940, Mississippi Geol. Soc. [Guidebook 1] Field Trip Feb. 10, 11, 2d day's field trip, p. 2, columnar section. Yazoo clay in Jackson group. Massively bedded yellow to green calcareous clay. Interbedded lignitic clay in western Mississippi. Bentonitic zone near base. Thickness 90 to 600 feet. Underlies Forest Hill sand; overlies Moodys marl. Contains Cocoa sand member.

H. A. Tourtelot, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 6. Yazoo clay, in Quitman fault zone area, is divided into two tongues by Cocoa sand member. Estimated thickness 125 feet in southeastern part of area; thickens northwest to 250 feet in Jasper County, Miss. Overlies Moodys marl; underlies Red Bluff clay.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1838 (fig. 6), 1839. Yazoo clay, in Mississippi and Alabama, divided into (ascending) North Creek clay (new), Cocoa sand, Pachuta clay (new), and Shubuta clay (new) members.

Alan Cheetham, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 97 (fig. 5). Chart shows Yazoo group, consisting of North Creek clay, Cocoa sand, Pachuta marl, and Shubuta clay, as Eocene–Oligocene.

H. V. Andersen, 1960, Louisiana Geol. Survey Geol. Bull. 34, p. 96–99. Most continuous section of Yazoo formation in Sabine Parish extends from bottom of Caney Creek (SW¼SE¼ sec. 34, T. 4 N., R. 12 W.) approximately 100 yards south of bridge and thence eastward in ditches along Clare-Toro ward road. At this locality, about 65 feet of Yazoo clay is exposed. Included in this section is a 5.8–foot bed of highly fossiliferous, glauconitic, sandy marl, which is equivalent to basal sediment of Wooleys Bluff clays (member?) of Wellborn formation of Texas, and a 7-foot fossiliferous sand, which is probably equivalent to some part of sands reported overlying Wooleys Bluff clays at Sabine River in Texas. Overlies Moodys Branch marl with contact transitional; underlies Danville Landing beds. Jackson group.

Named for exposures in bluff of Yazoo River at Yazoo City, Yazoo County, Miss.

†Yeager Clay[1]

Oligocene(?): Southern Texas.

Original reference: Julia Gardner and A. C. Trowbridge, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4, p. 470.

Named from Yeager Ranch, on Cotulla-Sandiego Road, in northeast Webb County.

Yeager Greenstone

*See* Yaeger Greenstone.

Yearwood Formation

Cretaceous (Comanche Series) : Southwestern Texas.

J. P. Brand and R. K. DeFord, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 2, p. 373–376. Name proposed for lowermost Cretaceous formation in Kent quadrangle. Formation consists of up to 160 feet of limestone and a sporadically distributed basal conglomerate. Basal clastic part is restricted to vicinity of type locality where maximum section of about 55 feet is recorded; elsewhere, basal conglomerate is absent or exemplified by scattered quartz pebbles in basal few feet of the limestone. Upper member consists of up to 110 feet of light-gray to grayish-orange-pink thin bedded to massive micrograined limestone with thin light-gray calcareous shale interbeds. Yearwood rests unconformably on Permian formations; at type locality, on Permian red beds; in escarpment northeast of Kent and between Kent and Boracho Station, on Tansill (Guadalupian) limestone; underlies Cox sandstone with contact disconformable.

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Quad. Map 23. Crops out in four isolated localities in northern third of Van Horn Mountains area. Average thickness about 225 feet. At all exposures, overlies Permian limestone unconformably and slightly discordantly. Regional stratigraphy indicates the Yearwood is correlative with Bluff formation.

Type locality: West slope of prominent hill in NW¼ sec. 7, Blk. 59, Texas and Pacific Railroad Co., Kent quadrangle. Name derived from Yearwood (Drake) Ranch about 5 miles north-northeast of Kent, Culberson County.

**Yegua Formation** (in Claiborne Group)[1]

Yegua Group

Yegua Member (of Lisbon Formation)

Eocene, middle: Eastern and southern Texas, northwestern Louisiana, and western and southern Mississippi.

Original reference: E. T. Dumble, 1892, Brown coal and lignite of Texas, p. 124, 148–154.

H. B. Stenzel, 1940, Texas Univ. Bur. Econ. Geology Pub. 3945, p. 847–904. Comprehensive report on Yegua problem. Terms Lufkin, Yegua, and Cockfield have been used for beds in question in the past. All three terms have their advocates. Writer [Stenzel] would have preferred Lufkin but consensus was decidedly against it and for retention of name Yegua; hence, term Yegua is retained in this report. Type localities of Yegua as given by Dumble and other authors following him are declared invalid and are abandoned. However, new type locality is not designated. Formation is divided into an upper, partly marine member Creola (new), and lower, nonmarine member, Lufkin. Lower boundary of Yegua lies at top of Mount Tabor member of Crockett formation and at base of Bryan sand, which is local sand lentil in Yegua; upper boundary is defined by disconformity with which sediments of Jackson group begin.

F. F. Mellen, 1940, Mississippi Geol. Survey Bull. 39, p. 12 (table), 13–16. Referred to as member of Lisbon formation. In Yazoo County, consists of about 100 feet of silty lignitic clays, argillaceous lignitic silts, and fine-grained argillaceous sands of nonmarine or estuarine origin. Disconformably underlies Moodys Branch member of Jackson formation; base not exposed.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 263–266. Formation described in south Texas. In Starr and Zapata Counties, consists of two marine sandstones and three marginal shale members. Northward, in southern Webb County, these sand members wedge out and entire Yegua section becomes a series of red and green bentonitic shales with interbedded tuff and ash beds. Includes (ascending) La Perla shale member (new), Mier sandstone tongue, Jose shale member (new), Loma Blanca tongue, and Los Arrieros shale member (new). Thickness about 800 feet. Overlies Falcon sandstone member (new) of Cook Mountain formation; underlies Fayette formation.

A. A. L. Mathews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 1–4. Rank raised to group. Includes (ascending) Smetana sandstone (new), Bryan sandstone, Easterwood shales (new), and Cockfield formation. Estimated thickness about 1,700 feet. Unconformably underlies Rock Prairie sandstone (new) of Jackson group. Unconformably overlies Mount Tabor shales.

U.S. Geological Survey has restricted the term Yegua to Texas and restored the term Cockfield Formation for use in Mississippi, Louisiana, and Arkansas.

Type locality: Near mouth of Elm Creek, on [West] Yegua River [Creek], Lee County, Tex.

Yegua River Conglomerate (in Yegua Formation)[1]

Eocene: Eastern Texas.

Original reference: L. C. Reed and O. M. Longnecker, Jr., 1929, Texas Univ. Bull. 2901, p. 163–174.

A. A. L. Mathews, 1950, Texas Eng. Expt. Sta. Research Rept. 14, p. 2. Reed and Longnecker described Yegua River conglomerate with thickness of 40 feet and stated that it gouges both the Turkey and upper Turkey Creeks beds. Since its position in Yegua group is not clear or determinable, nor location of Turkey Creek definite, and since only conglomerate of Yegua age observed in Brazos County is at base of Smetana sandstone (new), name Yegua River conglomerate cannot be used.

Derivation of name not stated.

Yellian series[1]

Pennsylvanian: Western Arkansas.

Original reference: C. R. Keyes, 1928, Pan-Am. Geologist, v. 49, p. 287; 1932, Pan-Am. Geologist, v. 57, p. 344.

Named for Yell County.

Yellow Branch Member (of Poteet Formation)

Middle Ordovician (Mohawkian): Southwestern Virginia.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 99, pl. 1 (facing p. 130). Gray thick-bedded calcarenite. Thickness about 8 or 9 feet. Chart shows unit in lower part of Poteet formation. Corresponds to "9-foot limestone bed" in much discussed Yellow Branch section. Name attributed to B. N. Cooper and G. A. Cooper.

Occurs in section along Yellow Branch (so called locally, but Yellow Creek on Rose Hill quad. map), 5¼ miles south of Hagan and 2 miles north of Tennessee line, Rose Hill quadrangle, Lee County.

**Yellow Breeches Member** (of Wilhite Formation)

Precambrian (Ocoee Series): Southeastern Tennessee.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 55 (table 1), 962. Characterized by limestone and dolomite which in places form units more than 100 feet thick, many of which are sandy and conglomeratic; these are interbedded with various argillaceous, silty, and sandy rocks. Thickness about 2,000 feet. Upper member of formation; overlies Dixon Mountain member (new).

Named for Yellow Breeches Creek east of Jones Cove, Sevier County.

†Yellow Creek Beds[1]

Devonian and Lower Mississippian: Northeastern Mississippi.

Original reference: E. N. Lowe, 1915, Mississippi Geol. Survey Bull. 12, p. 51.

Named for exposures on Yellow Creek, a branch of Tennessee River in Tishomingo County.

**Yellow Creek Sandstone Member** (of Hance Formation)[1]

Middle Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 38, 119.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 65, 66, 67, 154. In Hance formation about 100 feet above Naese sandstone, the top member of Lee formation.

Named for Yellow Creek, Bell County, Ky.

**Yellow Hill Limestone**[1]

Yellow Hill Limestone (in Pogonip Group)

Lower Ordovician: Eastern Nevada.

Original reference: L. G. Westgate and A. Knopf, 1932, U.S. Geol. Survey Prof. Paper 171.

L. F. Hintze, 1952, Utah Geol. and Mineralog. Survey Bull. 48, p. 48–50, 51–52. In Ely Springs Range, Pogonip group includes Yellow Hill limestone and Tank Hill limestone (top of Ordovician sequence). Inasmuch as both upper and lower limits of Yellow Hill are fault bounded as is lower limit of Tank Hill, it is not considered advisable to carry these formations as stratigraphic units into other areas.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). Shown on correlation chart of Pioche district above Mendha limestone and below Tank Hill limestone. Pioche district as used in this report extends to Dutch John Mountain, approximately 40 miles north of Pioche.

Well exposed on Yellow Hill, near center of Ely Springs Range, Pioche region.

**Yellowjacket Formation**[1]

Precambrian (Belt Series) : Southern central Idaho.

Original reference: C. P. Ross, 1934, U.S. Geol. Survey Bull. 854.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 7. Belt series, in vicinity of middle Fork of Salmon River includes Yellowjacket formation, at least 9,000 feet thick, overlain by Hoodoo quartzite over 3,560 feet thick.

Named for exposures at town of Yellowjacket, Casto quadrangle.

**Yellow Leaf Quartz Schist**[1]

Devonian (possibly post-Lower Devonian) : Eastern Alabama.

Original reference: C. Butts, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 57, 147–148, map.

Named for exposures on headwaters of Yellow Leaf Creek, 1½ miles east of Jemison, Chilton County.

**Yellowpine Limestone Member** (of Monte Cristo Limestone)

Upper Mississippian: Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 9, 18.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 23). Age shown on correlation chart as Mississippian (Meramecian).

J. C. Hazzard, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1503; 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 5, p. 881, 883 (fig. 2), Geographically extended into Nopah Range, Inyo County, Calif., where it is 100 feet thick, and overlies Bullion limestone member (Arrowhead limestone member not recognized in area). Underlies Bird Springs formation.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 42. Described in Ivanpah quadrangle (California-Nevada). About 120 feet thick in Goodsprings quadrangle, generally thinner westward and southward. Overlies Arrowhead limestone member; underlies Bird Spring formation.

Contains productive ore bodies of Yellow Pine, Potosi, Ingomar, and other mines, Good Springs region, Nevada.

†Yellowstone Formation[1]

Jurassic(?) and Lower and Upper Cretaceous: Central southern Montana.

Original reference: G. D. Harris, 1845, Philadelphia Acad. Nat. Sci. Proc., v. 2, p. 235–237.

Occurs on east flank of Little Belt Mountains, in southwestern part of Little Belt quadrangle, Little Belt Mountains region.

†Yellowstone Lake Group[1]

Pliocene: Northwestern Wyoming.

Original reference: T. B. Comstock, 1874, Rept. of reconn. of northwestern Wyoming made in 1873 by Wm. A. Jones, table facing p. 103.

†Yellville Limestone[1]

Lower Ordovician: Northern Arkansas and southern Missouri.

Original reference: G. I. Adams and E. O. Ulrich, 1904, U.S. Geol. Survey Prof. Paper 24, p. 18, 32 (fig. 1), 90, 93.

Named for exposures at Yellville, Marion County, Ark.

†Yentna Beds[1]

Tertiary: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 172, 183.

Crops out opposite Sushitna trading post, on Sushitna River, below mouth of the Yentna.

Yeoman Beds

Ordovician: Subsurface in north-central North Dakota, and southern Saskatchewan, Canada.

Saskatchewan Geological Society, 1958, Report of the Lower Palaeozoic names and correlations committee: Saskatchewan Geol. Soc., p. 4, 5, charts A and B [p. 18, 19]. Largely composed of mottled fossiliferous-fragmental brown dolomitic limestone; dense brown dolomites abundant in outlying areas of the Williston Basin. Thin but very widespread argillaceous section marks top of unit. Reach maximum known thickness of 600 feet in north-central North Dakota. Underlies Herald beds (new) and overlies Winnipeg formation with conformable contacts.

Type locality: Shell Yeoman No. 6–32 (Lsd. 6, sec. 32, T. 8, R. 16, W. 2nd Mer., Saskatchewan) between 8,008 and 8,281 feet; Williston Basin.

**Yeso Formation**

Yeso Member (of Chupadero Formation)[1]

Permian: Northern, central, and southern New Mexico.

Original reference: W. T. Lee, 1909, U.S. Geol. Survey Bull. 389.

C. E. Needham and R. L. Bates, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1655 (fig. 1), 1657–1661. Lee (1909) named the Yeso as middle formation of Manzano group. Name is derived from Mesa del Yeso, a small tableland 12 miles northeast of Socorro. Lee stated that Yeso beds were typically exposed on this mesa. However section he described in text, columnar section, and faunal list lies 2 miles southeast of this Mesa del Yeso. Section given in present report was measured in immediate vicinity of Lee's section and some parts are no doubt identical with his. Lee's description of Yeso is unsatisfactory because: (1) type locality is not completely designated; (2) section is measured in such general terms that it is not suitable for present stratigraphic needs; (3) at top of Lee's section, and included by him in Yeso, is a 75-foot limestone, top of which is an exposed erosion surface. This limestone is now known to be basal San Andres; (4) below this bed, Lee also included in Yeso 200 feet of sandstone, part of which is now separated as Glorieta sandstone; and (5) a limestone layer at base of Yeso is described as highly fossiliferous and 50 feet thick. Such a layer is not believed to occur at or near base of formation. In present report, base of Yeso is placed at base of a limestone bed, this bed is only 7 to 10 feet thick and is barren of fossils. Prominent exposure of San Andres limestone is present three-eighths mile west of base of Yeso type section as herein described, the position of which is result of faulting. Because this stratum is about 50 feet thick and contains many fossils, it is thought that Lee may have mistakenly included it in basal Yeso. As redescribed herein, Yeso consists of at least four units. Lowest is general zone of clastic material, characterized by pink and orange sandstone; middle evaporites; Canas member (new); Joyita member (new) Thickness 592.7 feet at type section; thickens toward both northwest and southeast from type section. Overlies Abo formation; underlies Glorieta sandstone. Darton (1922, U.S. Geol. Survey Bull. 726) reduced Yeso to member status in Chupadero formation, a term he introduced to include beds of Yeso and San Andres age. Term Chupadero has been abandoned by U.S. Geological Survey, and Yeso is now considered formation in Manzano group.

G. H. Wood and S. A. Northrop, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 57. In Sandoval and Rio Arriba Counties, subdivided into Meseta Blanca member at base and San Ysidro member above (both new). Overlies Abo formation; underlies Glorieta sandstone member of San Andres.

V. C. Kelley and G. H. Wood, 1946, U. S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. Formation, in Lucero uplift, Valencia, Socorro, and Bernalillo Counties, subdivided into (ascending) Meseta Blanca member, 0 to 20 feet, and Los Vallos member (new), 820 to 1,020 feet. Overlies Abo formation; underlies San Andres formation.

R. H. Wilpolt and others, 1946, U.S. Geol. Survey Oil and Gas Prelim. Map 61. In La Joya area, Los Pinos Mountains, and northern Chupadera Mesa, subdivided into (ascending) Meseta Blanca, Torres (new), Canas gypsum, and Joyita sandstone members. Thickness as much as 1,015 feet.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 696 (fig. 4), 697. In Otero County, includes Otero Mesa member (new). Overlies Lee Ranch tongue (new) of Abo sandstone; west of Otero Mesa overlies Hueco limestone.

Type section (Needham and Bates): Base of section is 11.2 miles N. 46° E. of Socorro at point on Socorro quadrangle where its eastern edge is intersected by the 34° 10′ parallel. Section measured northeast from this point, in canyons and cuesta escarpments in secs. 4 and 5, T. 2 S., R. 2 E., and in sec. 33, T. 1 S., R. 2 E., Socorro County. Top of section is 2¼ miles southeast of Mesa del Yeso on high isolated butte. Named for exposures on Mesa del Yeso, small tableland, 12 miles northeast of Socorro.

Ynezian Stage

Paleocene: California.

V. S. Mallory, 1953, (abs.) Jour. Paleontology, v. 27, no. 6, p. 903. Named as lowermost of six stages, based on foraminiferal assemblages, in lower Tertiary of California. Occurs below Bulitan [Bulitian] stage.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 22–27, 74, 91, fig. 7, tables. Lowest of Tertiary stages. Divisible into two zones, *Silicosigmoilina californica* below and *Bulimina excavata* above. Stage is generally correlative with Laiming's (1939, 6th Pacific Cong. Proc., v. 2) "E-Zone." Base of chronologic-biostratigraphic classification presented is taken as being horizon at which "Martinez" megafossils or associated Foraminifera first occur as distinguished from those horizons generally understood to be Upper Cretaceous. Base of Paleocene, as established here, would be at horizons immediately superjacent to European Danian stage; base of Ynezian may not represent lowest Tertiary in California region. Type section of stage in lower Anita formation rests conformably on strata referred to Jalama formation by Dibblee (1950).

Type area: Canada el Bulito, Santa Barbara County.

Yoakum Dolomite Member (of Queen Formation)

Permian: Subsurface in Texas and New Mexico.

W. C. Fritz and James Fitzgerald, Jr., 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 24–25. Name applied to brown dolomite in Queen formation. Occurs between depths of 4,180 feet and 4,215 feet in type well.

Type well: Well No. 30, formerly Davidson, now Honolulu-Cascade, Bennett No. 1, center NE¼ sec. 678, Block D, John H. Gibson Survey, Yoakum County, Tex.

Yoder Formation[1]

Oligocene, lower: Southwestern Wyoming.

Original reference: E. M. Schlaikjer, 1935, Harvard Coll. Mus. Comp. Zool., v. 76, no. 3, p. 71–75.

C. B. Schultz and T. M. Stout, 1955, Nebraska Univ. State Mus. Bull., v. 4, no. 2, p. 31, 34, table 1. Lower Chadron, or Chadron A of this report, is essentially the Yoder of Schlaikjer (1935) and the Ahearn of Clark (1954), which may prove to be a synonym of the former.

Type locality: SE¼ sec. 29, T. 23 N., R. 62 W., Goshen County. Named for town of Yoder, 1½ miles southeast of type locality.

**Yogo Limestone**[1]

Upper Cambrian: Central northern and central southern Montana.

Original references: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55; 1899, Folio 56; 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 3, p. 285–286.

Charles Deiss, 1936, Geol. Soc. America Bull., v. 47, no. 8, p. 1272, 1282, 1285, 1336, 1337. Original description of Yogo limestone has no meaning because Cambrian rocks could not be found in any section in Montana or Yellowstone Park between Dry Creek shale and overlying Devonian limestone or dolomites. Name Yogo has no basis in observable fact and must be discarded.

L. L. Sloss and W. M. Laird, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 8, p. 1413–1415. In work on Little Belt Mountains, Weed (1900) described thin-bedded limestones interbedded with gray or greenish shale and grading into rather pure thick-bedded limestone. To these beds, he gave name Yogo limestone and assigned them to Cambrian. It is evident that Weed considered Yogo limestone equivalent to Peale's (1893, U.S. Geol. Survey Bull. 110) pebbly limestones of Three Forks area. It now seems clear that Weed's Yogo limestone is equivalent to basal Devonian of this paper, plus a variable part of the base of limestone member of Jefferson formation. If the basal Devonian unit is proved to be a cartographic unit, Yogo, suitably revised, would have priority as formational name. Deiss (1936) found no Cambrian fossils above Dry Creek shale in Belt Creek section; hence, no Yogo in the section. He believed that name Yogo should be discarded. Present authors agree that there may be no Cambrian above Dry Creek shale in central Montana, but this fact does not invalidate term Yogo. If formation is a lithologic unit, its identity is not destroyed because it was first assigned to wrong geologic age.

Christina Lochman,. 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 11, p. 2212. Yogo limestone, if used as originally defined by Weed does not exist. Even if used in restricted sense as indicated by Sloss and Laird, Yogo can only be lithologic and stratigraphic equivalent of beds in upper part of their basal Devonian unit—beds which because of their transitional character are more difficult to separate from overlying Jefferson than the prominent red and yellow dolomites and mudstones of lower part of basal Devonian unit.

Derivation of name not stated. Unit was mapped by Weed in vicinity of village of Yogo and along Yogo Creek, Little Belt Mountains quadrangle.

Yokohl Amphibolite (in Kaweah Series)

Triassic(?): Southern California.

Cordell Durrell, 1940, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 1, p. 13–14, 116, fig. 29, geol. map. Oldest in sequence (ascending) of four units in series. Most important original lithologic types are basic volcanic rocks, both flows and tuffs; bedded cherts of radiolarian type; acid volcanic rocks; argillaceous sediments; and limestone. Approximate thickness in Woodlake Mountain 8,000 feet, base not exposed; older than Lemon Cove schist (new).

Occurs in the southern Sierra Nevada in north-central Tulare County.

Yokut Sandstone

Eocene: East-central California.

R. T. White, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 10, p. 1726–1727 (fig. 1), 1744 (fig. 5), 1745–1747. Massive sandstone, fine-grained, white, brown, and gray. Thickness varies from 0 to 305 feet; at type locality 45 feet. Underlies Domengine formation (as restricted by Clark, 1926, California Univ. Pub. Bull., Geology Dept., v. 16, no. 5); overlapped by Domengine at axis of Coalinga anticline on south, and approximately 1 mile northwest of Tumey Gulch on north; overlies Arroyo Hondo member of Lodo formation with contact gradational. This unit was lower part of "Tejon" of Anderson and Pack (1915, U.S. Geol. Survey Bull. 603); referred to "Meganos" group by some authors. Incorrectly included in Domengine by White (1938, Geol. Soc. America Proc. 1937) and erroneously included in Arroyo Hondo by Vokes (1939).

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 208–209. Described in San Benito quadrangle where it is exposed along southwest flank of Butts Ranch syncline. Thickness varied between 800 to 1,200 feet. Overlies Lodo formation; unconformably overlain by Domengine sandstone.

M. B. Payne, 1951, California Div. Mines Spec. Rept. 9, p. 15. North of Cantua Creek in Panoche Hills [Fresno County], Yokut sand underlies basal Kreyenhagen glauconitic sand, Domengine formation missing.

Type locality: Near west boundary of SE¼ sec. 29, T. 18 S., R. 15 E., in Domengine Creek. No geographic names were available. Yokut was named after Yokut Indians who inhabited San Joaquin Valley.

**Yolo Formation**

Upper Cretaceous (Chico Series) : Northern California.

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 282, 285–287, 291, 293. Consists of well-bedded greenish-gray or light drab siltstones with numerous thin layers of fine flaggy sandstone. Thickness 500 to 1,100 feet. Underlies Sites formation; overlies Venado formation (new). Replaces preoccupied name Mills formation (Kirby, 1942).

Named because of widespread distribution along west side of Sacramento Valley in Yolo County. Well exposed at Cache Creek, immediately downstream from concrete bridge on Rumsey-Lake County highway.

**Yonkers Granite**[1]

Precambrian : Southeastern New York.

Original reference: F. J. H. Merrill, 1890, Am. Jour. Sci., 3d ser., v. 39, p. 388.

T. W. Fluhr, 1948, Rocks and Minerals Mag., v. 23, no. 8, p. 699. Age shown in map legend as probable Upper Ordovician.

Occurs in hills in Yonkers, Westchester County.

**Yonna Formation**

Pliocene: Southwestern Oregon.

R. C. Newcomb, 1958, Northwest Sci., v. 32, no. 2, p. 41–48. In type area, consists of (1) a lower sedimentary (lacustrine) section consisting of ashy diatomite, stratified sandstone, laminated siltstone, waterlaid volcanic ash, pumice, and semiconsolidated gravel, and (2) a rather thick upper unit of basaltic lapilli tuff, part of which was deposited in water. Outside type area, there is much diatomite, waterlaid volcanic ash, and other sedimentary material in upper part of formation, and relation of a sedimentary lower unit and a tuffaceous upper unit is not clearly established. As much as 2,000 feet thick. Formation is cut by dikes and sills of generally basaltic composition and is broken by an intricate system of block faulting; breakage and displacement are greatest in the Klamath and Langell grabens, here strata of the Yonna have dips as high as 30° or 40°. Overlies unnamed lava rocks; underlies with minor erosional unconformity, lava rocks (Pliocene?), Quaternary lava or alluvium.

Type locality: Along west side of Yonna Valley in T. 38 S., R. 11½ E., Willamette meridian and baseline, Klamath County. Crops out in large areas in Yonna, Swan Lake, Sprague River, Williamson River, Poe and Klamath Valleys, and adjacent Lost River basin.

**Yorba Member** (of Puente Formation)

Miocene, upper: Southern California.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–154. Thin-bedded gray siltstone with lesser amounts of thin-bedded fine-grained sandstone. Maximum exposed thickness about 2,500 feet. Underlies Sycamore Canyon member, contact gradational; overlies Soquel member (new), contact gradational.

Named for Yorba Bridge across Santa Ana River, 2½ miles east of Atwood, Orange County. Exposed in Puente Hills north of Yorba Bridge and in northwestern Santa Ana Mountains to south of bridge.

†York Limestone[1]

Cambrian and Ordovician: Southeastern Pennsylvania.

Original reference: P. Frazer, Jr., 1876, Pennsylvania 2d Geol. Survey Rept. C, p. 130.

In York County.

†York Schist[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: P. Frazer, Jr., 1876, Pennsylvania 2d Geol. Survey Rept. C, p. 130–143.

Composes greater part of Chikis Ridge and Chestnut Hill in York County.

†York Shale[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: C. D. Walcott, 1896, U.S. Geol. Survey Bull. 134, p. 14–15, 26, 36–37.

Well exposed in York County.

†York County Hydromica Slates[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 1, p. 203.

Composes greater part of Chikis Ridge and Chestnut Hill in York County.

York Harbor Biotite Granite[1]

Devonian(?): Southwestern Maine.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 148, 149.

Exposed along south side of York Harbor, York County.

Yorkian[1] or Yorkic period[1]

Silurian and Devonian: New York.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 37, p. 234, 243–244.

York-Petro Limestone[1]

Pennsylvanian: Utah.

Original reference: R. N. Hunt and O. P. Peterson, 1924, Am. Inst. Mining Metall. Engineers Trans., v. 70, p. 859–883, 908–926.

Occurs in Bingham district.

†Yorktown Epoch[1]

Miocene: Atlantic coast.

Original reference: J. D. Dana, 1863, Manuel geology, p. 506, 510, 521, 522.

Occurs at Gay Head on Martha's Yineyard; in New Jersey; in Maryland, on both sides of the Chesapeake Bay for a great distance; and in Virginia, at Yorktown, Suffolk, Smithfield, and through larger part of Tertiary region.

**Yorktown Formation** (in Chesapeake Group)[1]

Miocene, upper: Eastern Virginia, eastern Maryland, and North Carolina.

Original reference: W. B. Clark and B. L. Miller, 1906, Virginia Geol. Survey Bull. 2, pt. 1, p. 19.

L. W. Stephenson and F. S. MacNeil, 1954, Geol. Soc. America Bull., v. 65, no. 8, p. 733–738. Geographically extended into eastern Maryland where it reaches Chesapeake Bay in the Calvert Cliffs. Overlies St. Marys formation.

H. E. LeGrand and P. M. Brown, 1955, Carolina Geol. Soc. Guidebook of Excursion in Coastal Plain of North Carolina, Oct. 8–9, p. 11–12. Formation, as extended into North Carolina, may include elements of St. Marys formation as mapped elsewhere. In this report, Duplin marl is considered to be a shallow-water facies of the Yorktown; Waccamaw formation, considered as contemporaneous with Duplin, is also included in Yorktown.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 45; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. As mapped, includes Duplin marl.

First described at Yorktown on James River, Va.

Yorktownian Substage

Miocene, upper: Maryland, New Jersey, and Virginia.

D. S. Malkin, 1953, Jour. Paleontology, v. 27, no. 6, p. 767, 768. A substage based on microfaunal assemblages; includes all sediments deposited in central Atlantic Coastal Plain province during time of accumulation of Yorktown formation, type exposure of which is considered exemplary of the substage. In sequence, the Yorktownian succeeds St. Marysan substage.

**Yorkville Quartz Monzonite**

Yorkville Granite[1]

Permian: Northwestern South Carolina and southern North Carolina.

Original reference: A. Keith, 1931, U.S. Geol. Survey Geol. Atlas, Folio 222.

L. L. Smith and Roy Newcome, Jr., 1951, Econ. Geology, v. 46, no. 7, p. 759–760. Granite exposed over large area south and southeast of Henry Knob, which is 3 miles west of Clover, S. C.

Named for exposures at Yorkville (also called York), York County, S.C.

Yosemite Glacial Epoch[1]

Pleistocene: California.

Original reference: E. Blackwelder, 1930, Geol. Soc. America Bull., v. 41, p. 91–92.

Youghall Formation

Youghall Member (of Morgan Formation)

Pennsylvanian: Northwestern Colorado and northeastern Utah.

M. L. Thompson, 1945, Kansas Geol. Survey Bull. 60, pt. 2, p. 29, 30, 34–39, geol. sections. Proposed for the fossiliferous limestones, thin shales, and thick interbedded highly crossbedded sandstones stratigraphically between Hells Canyon formation (new) and Weber sandstone (redefined). Type section, approximately 625 feet thick, composed of crossbedded to massive buff to reddish-brown sandstone and interbedded highly fossiliferous limestone. Thickness at Juniper Mountain 650 feet, contact with overlying Weber not observed; 500 feet at Split Mountain; 600 feet at White Rock Canyon; 530 feet at Sheep Mountain Canyon. Overlies Hells Canyon formation on south and southeast margins of Uinta Mountains; on southwest margin, overlies Morgan formation (as defined by Williams); on north margin, overlies Belden formation.

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Redefined as upper member of Morgan formation and restricted to upper tan and buff sandstones and interbedded limestones; balance of formation which is red sandstone and interbedded limestone is designated "Red Morgan" member.

Type locality: Exposures on west side of Hells Canyon in sec. 31, T. 6 N., R. 102 W., and along east side of head of Hells Canyon in W½ sec. 7, T. 5 N., R. 102 W., Moffat County, Colo. Name derived from old stage station of Youghall, east of Hells Canyon.

Youghiogheny Sandstone

Upper Devonian (Conewango): Southwestern Pennsylvania.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Progress Rept. 126, p. 9–11. Name will probably be used. following more definitive study of area, for unit here termed Sandstone B and described as alternating red sandstone and brick-red shales interbedded with some massive green sandstones and green shales. Red beds show rapid lateral change to green. A tongue like expression of Catskill magnifacies into a marine magnafacies represented by Shale C above (Watering Trough shale) and Sandstone A below (Maple Summit sandstone). Thickness 422 feet in Youghiogheny Gorge through Laurel Hill. Conformable contacts with overlying and underlying units.

Type exposure along tracks of Western Maryland Railroad on south bank of Youghiogheny River opposite settlement of Victoria, Fayette County.

Youngman Formation (in Maquam Group)

Middle Ordovician (Chazyan): Northwestern Vermont, and southeastern Quebec, Canada.

Marshall Kay, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1172. Typically argillaceous limestone grading up into dark slate having limestone interbeds. Thickness 300 feet at type locality. Underlies Isle la Motte limestone disconformably; overlies Carman quartzite.

Marshall Kay and W. M. Cady, 1947, Science, v. 105, no. 2736, p. 601. Upper formation of Maquam group (new).

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 81–82, 83–85. Type Youngman contains some fossils known in the Chazy limestones to west along Lake Champlain, but others that are unknown there and have been thought diagnostic of later age. Stratigraphic relations of Carman and Youngman seem to preclude their being other than Chazyan. It is concluded that the Carman-Youngman is Chazyan of facies different from typical Chazyan group and from St. Dominique [in Quebec] and that presence of *Christiania*, *Sowerbyella*, and *Platymena* and other forms in formation must be accepted as showing that ranges of these genera are somewhat greater than had been recognized, and that their sensitivity in correlation is reduced.

Type locality: Mississquoi Park, Highgate Springs, Franklin County, Vt.

**Young Peak Dolomite**[1]

Middle Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). Listed on correlation chart of recommended revision of stratigraphic units in Great Basin. Above Abercrombie formation and below Trippe limestone.

Well exposed on Young Peak, on south side of Dry Canyon, Gold Hill district.

Youngs Bluff Bed[1]

Eocene (Jackson): Northwestern Louisiana.

Original reference: T. L. Casey, 1902, Science, new ser., v. 15, p. 716.

Named for outcrops on estate of John Young, south of Montgomery, Grant County.

Ysidro shale[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 12.

Well exposed in sharp truncated arch in Tijeras Canyon between Sandia and Manzano Ranges. Derivation of name not given.

**Yucca Formation**

Yucca Bed[1]

Lower Cretaceous: Western Texas.

Original reference: J. A. Taff, 1891, Texas Geol. Survey 2d Ann. Rept., p. 725, 736.

R. M. Huffington, 1943, Geol. Soc. America Bull., v. 54, no. 7, p. 992 (fig. 2), 997–1000. Formation, in northern Quitman Mountains, is predominantly gray, buff, and red limestone, arenaceous limestone, maroon shale, sandstone, and limestone-, chert-, and quartz-pebble conglomerate. Thickness 1,117 to 5,518 feet. Overlies Torcer formation (emended) with contact not exposed; underlies Bluff formation with contact arbitrarily chosen. Beds correlative with parts or all of Yucca formation have previously been mapped or designated by other names in parts of Quitman area. Baker (1927, Texas Univ. Bull. 2745) erroneously mapped Yucca as Cox. Las Vigas(?) in Malone Mountains is evidently same as the Yucca. Recommended that earlier and diverse terminology for all, or parts, of the same formation be abandoned in favor of name Yucca.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 12 (table 1), 15–16, pl. 1. In Eagle Mountains, formation consists chiefly of red shales and limestones; brown limestones, red and brown sandstones, and limestone pebble conglomerate. Thickness as much as 330 feet. Overlies Wolfcamp(?); underlies Bluff Mesa formation (name replaces preoccupied Bluff formation).

D. L. Amsbury, 1958, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 22. In Presidio County, overlies Pinto Canyon formation (new); underlies Bluff formation.

R. K. DeFord and L. W. Bridges, 1959, Texas Jour. Sci., v. 11, no. 3, p. 291. In northern Rim Rock country, locally underlies Tarantula gravel (new).

Named for Yucca Mesa, El Paso County.

†Yucca Flat Formation

Middle to Upper Cambrian: Southern Nevada.

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 340–342, pls. 32, 33. Consists of two parts: lower part of generally light- to medium-gray massive calcitic limestone which weathers a mottled buff to gray, thickness 395 feet; upper part contains four recognizable units, (ascending) A through D, and consists of dark- and light-colored, well-bedded, and generally thin-bedded limestone and dolomite; thickness more than 2,420 feet. Underlies Dunderberg shale and overlies Jangle limestone (new) with contacts conformable.

Named for exposures on east side of Yucca Flat in the Atomic Energy Commission Nevada proving grounds area, Nye County. Occupies hills and valleys of great relief. Banded Mountain obtains its name from alternating bands of dark- and light-colored limestone and dolomite characteristic of parts of formation. Mose complete section exposed from Jangle Ridge to Banded Mountain but section incomplete due to faulting.

Yukon Group[1]

Precambrian: Northeastern Alaska, and northwestern Yukon, Canada.

Original references: D. D. Cairnes, 1914, Geol. Soc. America Bull., v. 25, p. 184; 1914, Canada Geol. Survey Summ. Rept. 1912, p. 11; 1914, Canada Geol. Survey Mem. 67, p. 40.

Yukon Silts[1]

Pleistocene: Northeastern Alaska.

Original reference: J. E. Spurr, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 200–220.

A. J. Eardley, 1938, Geol. Soc. America Bull., v. 49, no. 2, p. 317–336. Divided into six groups of unconsolidated deposits.

Form lower terraces of Yukon River.

†Yule Limestone[1]

Ordovician: Western and central Colorado.

Original reference: G. H. Eldridge, 1894. U.S. Geol. Survey Geol. Atlas, Folio 9.

J. H. Johnson, 1955, Geol. Soc. America Bull., v. 55, no. 3, p. 315, 320, 322. Mentioned in report on Paleozoic stratigraphy of Sawatch Range. Yule limestone of various authors is now included in Manitou dolomite, Harding sandstone, and Fremont limestone of this report.

Named for development at head of Yule Creek, Anthracite-Crested Butte area.

†Yulean series[1]

Cambrian to Upper Devonian: Western Colorado.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 281, 289.

Yuma Sandstone Member[1] (of Manning Formation)

Eocene, upper: Southeastern Texas.

Original reference: B. C. Renick, 1936, Texas Univ. Bull. 3619, p. 36–39, table opp. p. 17.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2630. Tentatively considered equivalent to Stones Switch sandstone member of Whitsett formation.

Exposed in vicinity of Yuma.

**Zabriskie Quartzite**

Zabriskie Formation

Zabriskie Quartzite Member (of Wood Canyon Formation)

Lower Cambrian: Southeastern California and western Nevada.

J. C. Hazzard, 1937, California Jour. Mines and Geology, v. 33, no. 4, p. 278 (fig. 3d), 309–310. Discussion of Paleozoic section in Nopah and Resting Springs Mountains, Inyo County. Zabriskie quartzite member is 160-foot unit, upper 100 feet of which consists of massive indistinctly crossbedded fine- to medium-grained fairly well-sorted pinkish to light-gray quartzite in beds 1 to 6 feet thick; weathered surface is characteristically salmon pink to rusty brown; below 100-foot massive part unit grades into reddish-brown sandy shale and medium- to coarse-grained shaly quartzite and sandstone, locally conglomeratic. Basal 10 feet is light-gray to nearly white reddish-brown weathering massive quartzite. Basal part contains vertical tubelike structures assumed to be sand-filled burrows of forms like *Scolithus;* these are characteristics of base of Zabriskie both in the Nopah and Resting Springs Ranges; in Emigrant Pass, upper beds of Zabriskie show horizontal worm(?) castings and ripple marks. Top of Zabriskie is 630 feet below top of Wood Canyon formation; overlies unnamed micaceous shale interval of Wood Canyon; upper 630 feet of Wood Canyon unnamed.

R. H. Hooper, 1947, Geol. Soc. America Bull., v. 58, no. 5, p. 404 (fig. 1), 406. Member, in Panamint Range, is about 70 feet thick and consists of light-pink cross-laminated saccharoidal quartzite.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 24 (fig. 3), 26–27, fig. 5 facing p. 32. Rank raised to formation. Underlies Tecopa formation (new); overlies Wood Canyon formation. Thins to about 20 feet at Spring Mountain and apparently grades out completely toward the east. By inference, the Zabriskie is a tongue extending northwestward from the time-transgressing top surface of Prospect Mountain quartzite and thus should become part of the Prospect Mountain as the Wood Canyon thins out on border of geosyncline. Geographically extended into southwestern Nevada.

Name derived from Zabriskie Station on Tonopah and Tidewater Railroad in Amargosa Valley west of Resting Springs Range, Inyo County, Calif.

Zadoc Member (of McNairy Formation)

Cretaceous (Gulf Series): Southeastern Missouri.

H. S. McQueen and others, 1939, *in* Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 70 (fig. 25), 71. Light-gray to dark-brown sandy, ferruginous clay about 29 feet thick. Occurs about 10 feet above base of formation and 22 feet below top.

Present in Ardeola Hill section, center NW¼ sec. 10, T. 27 N., R. 11 E., Ardeola, Stoddard County. This is stop 33 on road log.

Zaleski Flint (in Allegheny Formation)[1]

Zaleski marine member

Pennsylvanian (Allegheny Series): Southeastern Ohio.

Original reference: Wilber Stout, 1927, Ohio Geol. Survey, 4th ser., Bull. 31, p. 181.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 55–56. Member of Ogan cyclothem in report on Athens County. In its type area, this bed is normally a flint but locally in type area is also represented by calcareous flint, siliceous limestone, calcareous shale, and iron ore. Nodular fossiliferous marine limestone and shale has been observed in Sandy Township, Tuscarawas County, at horizon of Zaleski member. Thickness about 8 inches. Overlies Ogan coal and underclay members; underlies members of Winters(?) cyclothem. Allegheny series.

Exposed near Zaleski, Vinton County.

**Zanzibar Limestone**[1]

Ordovician(?): Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 148. Listed with names not included on chart of recommended revision of stratigraphic units in Great Basin. Reasons for omission usually are that names are incapable of being interpreted or are rejected synonyms. [Toquima formation and Mayflower schist, noted by Ferguson, 1924, as overlying and underlying Zanzibar are also omitted from chart.]

Prominently developed on Zanzibar claim, about 1½ miles east of Manhattan, Nye County.

Zarah Subgroup (of Kansas City Group)

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, western Missouri, and southeastern Nebraska.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2033. Name applied to upper part of Kansas City group. Includes beds between top of Iola formation and base of Plattsburg formation of Lansing group. As thus defined, subgroup comprises (ascending) Lane shale, Wyandotte formation, and Bonner Springs shale. Thickness of subdivisions varies from place to place. Occurs above Linn subgroup (new).

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 81. Thickness in Kansas about 100 feet.

Named for village of Zarah on Kansas Highway 10 at Santa Fe Railway crossing in western Johnson County, Kans.

**Zeandale Limestone** (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Northeastern Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., 40, no. 9, p. 2274 (fig. 1), 2276. Defined to include strata between Pillsbury shale (new) above and Willard shale below. Thickness ranges from 19 to 53 feet and averages about 25 feet. Comprises (ascending) Tarkio limestone, Wamego shale, and Maple Hill limestone members.

Type section: In SE¼NE¼NE¼ sec. 28, T. 10 S., R. 9 E., along north-south farm access road south of Deep Creek, about 1 mile east and one-quarter mile south of Zeandale, Riley County. Name derived from town of Zeandale on south side of Kansas River.

Zell Limestone Member (of Macy Formation)

Middle Ordovician: Southeastern Missouri.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists, v. 35, no. 9, p. 2061–2064. Name applied to upper member of formation. Consists of fine-textured well-bedded calcitite with green shale partings and thin layers of intraformational conglomerate and shell beds; contains thin bed of metabentonite near top. Thickness at type locality 32 feet; thickens southward to 69 feet in southeastern Perry County. Overlies Hook member (new); underlies Decorah formation.

Type exposure: At type exposure of Macy formation, along Missouri Highway 25 in SE¼ NW¼ sec. 27, T. 38 N., R. 8 E., 1 mile north of Zell, Ste. Genevieve County.

Zemorrian Stage[1]

Miocene, lower: California.

Original reference: R. M. Kleinpell, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 3, p. 376–378.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 103–113, figs. 4, 14 (correlation chart). Superjacent to Refugian stage; subjacent to Saucesion stage. Includes two zones: *Uvigerina gallowayi* and *Uvigerinella sparsicostata*. Systematic catalogue.

Type locality: Zemorra Creek, head of which is in SW¼ sec. 17, T. 29 S., R. 20 E., western Kern County. Creek runs northeast cutting the northwestern tip of sec. 16 and thence across SW¼ sec. 9, turns east-northeast and joins Chico Martinez Creek near center NW¼ sec. 10.

Zenoria Lentil (in Verda Member of Yazoo Clay)

Eocene (Jackson): Central Louisiana.

H. N. Fisk, 1938, Louisiana Dept. Conserv. Geol. Bull. 10, p. 101 (fig. 9), 104–105. Consists of series of fossiliferous blue-gray clays and sands; clays are fine, very plastic, contain considerable glauconite and lack lignitic particles of the typical Verda. Occurs in upper part of member at about the same stratigraphic position as the Mossy Ridge lentil (new). Thickness in wells about 50 feet.

Named from exposure along a creek bank 1 mile northeast of Zenoria, La Salle Parish.

†Zesch Formation

Upper(?) Devonian: Central Texas.

V. E. Barnes, P. E. Cloud, Jr., and L. E. Warren, 1947, Geol. Soc. America Bull., v. 58, no. 2, p. 128 (fig. 2), 137 (fig. 7), 138–139. Thin highly siliceous limestone and leached silica rock containing a few species of brachiopods; brownish to yellowish and contains angular fragments of chert. About 18 to 24 inches thick; thins to feather edge. Rests on older Devonian strata (Bear Spring formation) and is collapsed into middle Ellenburger strata (Gorman formation); appears to grade upward into chert breccia here assigned to Ives breccia.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 811. Term abandoned. Partial synonym for Ives breccia member of Houy formation (new).

Type locality: On Ray Zesch Ranch, Mason County.

Zeta Lake granite porphyry facies (of Ogishke Conglomerate)

Precambrian (Knife Lake Series): Northeastern Minnesota.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1034, 1035. Black granite porphyry pebble conglomerate at top of Ogishke conglomerate. Thickness 1,000 feet. Conformably underlies and interbeds with Knife Lake slates; overlies West Gull jasper facies of Ogishke conglomerate.

Occurs in vicinity of Zeta Lake in Vermilion district.

**Zeto Point Basalt Porphyry**

Tertiary: Southwestern Alaska.

R. R. Coats, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 5, p. 77, pl. 6. Constitues five domical masses of basalt porphyry. Largest of the masses, about 230 feet thick, lies north of entrance to Sweeper Cove. All rocks have abundant calcic plagioclase phenocrysts, as much as 1 centimeter long, in medium- to light-gray groundmass. Basalt porphyry is younger than Finger Bay volcanics (new) which it intrudes; older than Andrew Bay volcanics (new).

Five domical masses which crop out on and near shore line of Kuluk Bay from Zeto Point northward (two of the domes mapped along Kuluk Bay south of Zeto Point), northern Adak Island, in central part of Aleutian Islands.

Zia Marl[1]

Eocene(?): Central northern New Mexico.

Original reference: A. B. Reagan, 1903, Am. Geologist, v. 31, p. 67–111.

Probably named for village of Zia, near Jemez, Sandoval County.

Zilhlejini Formation[1]

Upper Cretaceous: Northeastern Arizona.

Original reference: A. B. Reagan, 1925, Pan-Am. Geologist, v. 44, p. 287, 291.

Probably named for exposures on Ziltahjina Peak [as spelled on 1924 geologic map of Arizona], in Black Mesa.

**Zilpha Clay** (in Claiborne Group)

Zilpha Clay Member (of Lisbon Formation)

Eocene, middle: Western Mississippi.

U. B. Hughes and others, 1940, Mississippi Geol. Soc. [Guidebook 2] Field Trip, Mar. 9–10, p. 3, 11–12, column section. Gray-white to chocolate-brown clay; sandy at top and glauconitic at base. Thickness about 60 feet in Lisbon formation; underlies Kosciusko sand member; overlies Winona sand member. Name credited to Raymond Moore.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 33–40, fig. 1, pls. 1, 2, profiles A, B, C. Rank raised to formation in Claiborne group. Thickness at designated type locality 54 feet; upper contact not exposed. Overlies Winona greensand and underlies Kosciusko formation.

Type locality: Along county road at Bucksnort Hill 1½ miles north of Zilpha Creek and near center sec. 8, T. 16 N., R. 6 E., northwestern Attala County.

**Zion Hill Member (of Bull Formation)**

**Zion Hill Quartzite**[1]

**Zion Hill Quartzite Member (of Schodack Formation)**

Lower Cambrian: Southwestern Vermont and eastern New York.

Original reference: R. Ruedemann, 1914, New York State Mus. Bull. 169, p. 69–70.

D. M. Larrabee, 1939, Eng. Mining Jour., v. 140, no. 12, p. 47–48, 49 (fig. 3), 51. In area studied [near Rutland, Vt.], Cambrian grits, quartzites, slates, limestone, and shales are separated from overlying Ordovician quartzites, graywackes, slates, and cherts by angular unconformity, exposed in road cut at Hampton, N.Y., where at a near contact, Cambrian Schodack shales dip 78° E., and Ordovician Zion Hill quartzite dips 48° E. Thickness about 70 feet. Underlies Normanskill.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland, 1942, New York State Mus. Bull. 331, p. 65–67. Member of Schodack formation. Exposed as deep iron-red quartzitic sandstone in many localities in Catskill quadrangle. At top of formation.

E. P. Kaiser, 1945, Geol. Soc. America Bull., v. 56, no. 12, pt. 1, p. 1084 (table 1), 1089, 1090, 1091, pl. 1. Discussion of Taconic thrust sheet in Vermont. Zion Hill formation is chiefly massive gray medium- or coarse-grained quartzite. Thickness at Zion Hill and Wallace Ledge about 80 feet. Formation varies in details of lithology and thickness. In Zion Hill district, composed of two massive beds of quartzite separated by thin layer of sandy shale. In slate belt, overlies Schodack slate; in Zion Hill district, overlies Wallace Ledge formation (new); underlies Normanskill formation. Keith's (1932, Washington Acad. Sci. Jour., v. 22; 1933, 16th Internat. Geol. Cong. Guidebook 1 [eastern New York and western New England]) sequence and the sequence used in this report are incompatible. Keith's Barker quartzite (which must be that exposed on Barker Hill) is Zion Hill quartzite. Bird Mountain grit is thick facies of Zion Hill formation.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 53–54. Zion Hill quartzite described in Castleton area. Lower Cambrian, not Ordovician as believed by Larrabee (1939). Cambro-Ordovician boundary is placed between Zion Hill quartzite and overlying banded slate which is arbitrarily mapped as Normanskill. Kaiser (1945) suggested that Bird Mountain grit was phase of Zion Hill. This is not unlikely as long as Berkshire schist surrounding Bird Mountain was considered to be metamorphosed Mettawee and Schodack. Inasmuch as bulk of Berkshire is here assigned to Nassau formation, Bird Mountain grit cannot be facies of Zion Hill quartzite. Overlies Schodack formation.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 116 (fig. 16). Correlation chart for Taconic sequence, Vermont, shows Zion Hill quartzite above Wallace Ledge slate and below Schaghticoke shale.

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 1. Member of Bull formation. Massive greywacke or subgreywacke, ranging in thickness from 0 to 100 feet. Rapid variation in thickness suggests that it may be a shoestring sand and it occurs as discontinuous beds in general in middle part of formation. Base of rock may be pebble conglomerate, with load-casting features, whereas top may be mudstone. Overlies Bomoseen graywacke member; underlies Mudd Pond member (new).

George Theokritoff, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 54. In Washington County, N.Y., a fine greenish to brownish quartzite weathering whitish to light gray occurs in Bull formation. It is correlated with Zion Hill quartzite in Vermont on basis of lithological similarity and stratigraphical position. Dale (1899, U.S. Geol. Survey Ann. Rept. 19, pt. 3) correlated quartzite of Zion Hill with quartzites "between Cambrian black shales (Horizon D) and the Ordovician black shales (Horizon G)." He named this unit "Ferruginous quartzite" and included in it the quartzite at Zion Hill as well as quartzites developed at higher horizons. Ruedemann (1914) named Dale's Ferruginous quartzite "Zion Hill quartzite," but quartzites included in this unit which occur at higher horizons are here referred to higher unit assigned to Upper Cambrian and named Hatch Hill formation.

Named for Zion Hill, Hubbardtown, Castleton quadrangle, Vt.

Zoar Limestone (in Pottsville Formation)[1]

Pennsylvanian: Eastern Ohio.

Original reference: J. S. Newberry, 1874, Ohio Geol. Survey, v. 2, p. 133, 134, pl. facing p. 31.

Named for Zoar, Tuscarawas County.

Zopilote Breccia (in Garren Group)

Tertiary: Western Texas:

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology, Geol. Quad. Map 21. Named proposed for alkali-feldspar trachyte flow-breccia that forms larger part of Zopilote Hills. Type section, measured from base, includes 148 feet of hard grayish-red massive lithic breccia. Unit is evidently the basal flow breccia of thick sequence, which crops out in hills south of area and is overlain by vesicular andesite correlative with Bell Valley andesite; thus the Zopilote is homotaxially equivalent to Means trachyte. Overlies Moon trachyte.

Type section: Zopilote Hills, Wylie Mountain area, Jeff Davis County.

Zoroaster Granite

Precambrian (Archean): Northern Arizona.

Ian Campbell and J. H. Maxson, 1936, Carnegie Inst. Washington Year Book 35, p. 330, 331. Granite cuts across, at steep angle, the nearly vertical schistosity of the country rocks. Contact best exposed on south side of Colorado gorge.

Well exposed by narrow canyon of Zoroaster Creek, Grand Canyon region.

Zuckerman Limestone Member (of Hoxbar Formation)[1]

Zuckerman (Zuckermann) Sandstone or Beds (in Hoxbar Group)

Pennsylvanian (Virgil Series): South-central Oklahoma.

Original reference: C. W. Tomlinson, 1928, Oklahoma Geol. Survey Bull. 40Z, p. 16.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 697. Upper Hoxbar deposits, including Zuckerman sandstone, may be Virgilian in age.

C. W. Tomlinson and William McBee, Jr., 1959 *in* Ardmore Geol. Soc. Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 43–44. Zuckermann beds or member (of Hoxbar group) lies about 500 feet above Daube limestone member. Includes 30 feet or more of strata, chiefly white to buff coarsely crystalline calcareous sandstone, with finer grained layer at top and local development (intraformational?) conglomerate of gray limestone pebbles calcareous matrix. Crops out only in northern part of Lake Murray State Park and around north end of Criner Hills. Elsewhere (if present) it is hidden beneath unconformably overlying sediments.

Named for occurrence at abandoned coal mine of Daube, Westheimer, Munzeheimer, and Zuckerman, SE¼ sec. 8, T. 5 S., R. 2 E., Carter County.

Zuni pebble zone

Tertiary [Oligocene or Miocene]: Northeastern Arizona and northwestern New Mexico.

P. W. Howell, 1959, Dissert. Abs., v. 20, no. 2, p. 641. Younger than Zuni erosion surface, which may extend back to Oligocene time; older than late Miocene-early Pliocene Chetoh formation (new).

In Cheton country, a section of Colorado Plateau north of Little Colorado River, extending from Zuni Uplift west to Painted Desert.

**Zuni Sandstone**[1]

Upper Jurassic: Northwestern New Mexico and northeastern Arizona.

Original reference: C. E. Dutton, 1885, U.S. Geol. Survey 6th Ann. Rept., p. 137, pl. 16.

U.S. Geological Survey has restored the term Zuni Sandstone for use in Gallup-Zuni and Ackomas Basins.

Named for occurrence in Zuni Plateau, N. Mex.

†Zuni shale[1]

Upper Jurassic: Western New Mexico.

Original reference: C. R. Keyes, 1905, Am. Jour. Sci., 4th, v. 20, p. 424.

Derivation of name not stated.

†Zunian series[1]

Triassic(?) and Jurassic: Northeastern Arizona and northwestern New Mexico.

Original references: C. R. Keyes, 1906, Science, new ser., v. 23, p. 921; 1906, Am. Jour, Sci., 4th, v. 21, p. 298–300.
